In this project, composite cathodes of Sulfur/CQD/SWCNT and Sulfur/CQD/SWCNT/BFO were fabricated adopting a melt diffusion strategy; sintering a high-press pellet. Carbon quantum dots (CQD) and single-wall carbon nanotubes (SWCNT) were synthesized using a pyrolysis process. We tested the electrochemical performances Li-Sulfur (Li-S) battery. X-ray diffraction (XRD), Raman spectroscopy & Scanning electron microscopy (SEM) measurements of prepared composites were executed to study structural and morphological properties. Elemental analysis was carried out using EDS and XRF techniques.
Charge/discharge profiles at various C-rate were carried out and achieved a high discharge capacity of ~1000 $mAhg^{-1}$ at C-rate of C/16. The exciting results of ferroelectric nanoparticles; bismuth ferrites (BFO) injected cathode composites towards stable electrochemical performances and long-term cycle stability which attributes to that process and design architecture of electrode fabrication in this work. The culminated data could address the challenges of commercialization of Li-S batteries due to polysulfide formation. The detailed results of this study will be presented in the meeting.

Relationship between Time-Dependent Schottky Parameters and Doping Concentration during Resistance Relaxation in Pt/Nb:$SrTiO_3$ Junctions HayatoNakamura, YumengZheng and KentaroKinoshita; Tokyo University of Science, Japan

Resistive switching (RS) devices of Pt/Nb-doped $SrTiO_3$ (STO) Schottky junctions have been the subject of considerable interest in terms of both non-volatile and volatile resistance relaxation nature. When used as general non-volatile memory, the continuously tunable write/erase characteristics are advantageous for multibit application. In this sense, resistance state retention characteristics are important and improving resistance volatility is crucial. On the other hand, when used in new computational paradigm for the breakthrough of von Neumann-type computing, controllability of resistance relaxation phenomenon (RRP) is critically important. It has been reported that the RRP after RS in Pt/Nb(0.5 wt%):STO can be used to mimic synaptic plasticity for AI applications [1]. The development of nanoscale devices with this neuromorphic function is the basis for hardware implementation of artificial neural networks. For practical application, details of the resistive relaxation phenomenon is required to be understood. Schottky parameters (SPs) such as barrier height (SBH) and depletion width (W_D) can be determined by combining *I-V* and *C-V* measurements. SPs had been estimated only for two extreme states, high-resistance states (HRS) and low-resistance states (LRS) [2], and we reported on the time dependence of SPs during the resistance relaxation last year [3].Since carrier concentration (*n)* strongly influences SPs, it is important to clarify the time dependence of SPs as a function of *n*. In this study, we revealed the time dependence of SPs of Nb:STO as a function of Nb doping concentration, for the first time.
Therefore, in this study, we conducted a comparative analysis using devices with varying doping concentrations (0.1, 0.5, 1.0 wt%) to investigate the control of volatility in Pt/Nb:STO junctions. Sequential *I-V* and *C-V* measurements were performed on the same junction to extract the time evolution of SPs during the relaxation. Additionally, we investigated the location of electronic traps using the conductance method. "*I-V* measurement" and "*C-V* measurement and conductance method" were performed by the two-terminal method using a semiconductor parameter analyzer and impedance analyzer, respectively. Since the resistance value changes logarithmically after RS, the switching unit was employed to quickly switch from the circuit for I-V measurements, which set the junction to HRS or LRS, to the circuit for AC measurements.
We measured the relaxation phenomenon up to 1000 s after RS. After setting the Nb 1.0 wt% device to LRS, SBH was estimated to increase by 0.12 eV from 0.54 to 0.66 eV by *I-V* measurement and from 0.76 to 0.90 eV by *C-V* measurement. At the same time, the donor concentration (N_D) decreased from 5.8×10^{19} to 4.2×10^{19} cm^{-3}, and the W_D increased from 20.8 to 26.6 nm. It was observed that all SPs exhibited a linear dependence on the logarithm of time during the resistance relaxation. Furthermore, these trends of temporal changes in SPs were confirmed to be consistent regardless of doping concentrations.
On the other hand, from the results obtained by the conductance method, it was discerned that traps tend to be positioned at deeper locations as the doping concentration decreases. This observation aligned with the 0.2 eV difference in SBH between 0.5 and 1.0 wt% cases. Furthermore, it was found that their respective time dependencies also shift in a direction indicative of traps becoming deeper with time. This result is consistent with the 0.12 eV increase in SBH. Consequently, it is suggested that this effect is attributed to interface-layer traps that become deeper as SBH increases. Therefore, RRP is suggested to occur due to the re-trapping of electrons by defects after they were de-trapped by applying forward bias to set to LRS.

Perovskite Oxide $SrCo_{0.5}Ir_{0.5}O_3$ as an Efferent Anodic Catalyst for Proton Exchange Membrane Water Electrolysis SaowalukSoonthornkit, DongqiYang and ZhenxingFeng; Oregon State University, United States

Hydrogen, as an energy carrier, holds great promise for addressing the increasing demand for clean and sustainable energy sources. Proton exchange membrane water electrolysis (PEMWE) has standout as a promising technology for hydrogen production through the oxygen evolution reaction (OER). However, the sluggish kinetics of the OER posed a challenge to achieving high energy conversion efficiency and the commercialization of water electrolysis systems. In this study, we investigated the application of the promising $SrCo_{0.5}Ir_{0.5}O_3$ (SCIO) perovskite as an electrocatalyst in PEMWE and evaluated the electrochemical performance and durability. The SCIO perovskite catalyst is synthesized and characterized to assess its performance as an anode

electrocatalyst for lab-scale PEM water splitting. This study reveals the potential of perovskite as an anode electrocatalyst for PEM water splitting. Further research and optimization are required to explore the full potential of SCIO perovskite catalysts and their scalability for commercial-scale PEMWE systems.

Surface Restructuring and Stability of Perovskite Oxide Electrocatalysts Studied by Surface X-Ray Diffraction and Grazing Incidence X-Ray Absorption Spectroscopy AlvinChang, RajkumarJana, KelseyStoerzinger and ZhenxingFeng; Oregon State University, United States

In recent years, the trend towards clean and renewable energy sources has led to an increased interest in water-based electrocatalysis (i.e., producing green hydrogen from water as fuels and chemicals) for energy conversion and storage, but a key barrier for efficient water splitting is the high overpotential of the sluggish oxygen evolution reaction (OER).[1-3] To overcome this, earth-abundant perovskite oxides of chemical formula AMO_3 with compositional substitutions have shown drastically improved OER activities and are particularly attractive due to their high activity, low cost, high tunability of composition, and controllable electronic structures.[2,3] For many metal oxides it was discovered that the surface can reconstruct under the oxidative conditions imposed by OER, forming (hydr)oxides prior to the onset of the reaction, and resulting in a different surface termination than that expected from the bulk. This restructuring is varied among materials and plays a critical role in determining the stability and activity of an electrocatalyst material during and after electrochemical cycling. Thus, understanding the drivers of transformation at electrocatalyst interfaces towards the development of materials design is a key research direction in many fields.[1] In this work we examine the impact of electrochemical cycling on surface reconstruction of Lanthanum Nickel Iron Oxide ($LaNi_{1-x}Fe_xO_3$: x=0-0.375) and Lanthanum Strontium Nickel Iron Oxide ($La_{0.5}Sr_{0.5}Ni_{1-x}Fe_xO_3$: x=0-0.625) epitaxial thin films. Surface X-ray diffraction (SXRD) is employed to investigate the relationship between complex oxide bulk composition and terminal surface OER activity and stability. X-ray reflectivity (XRR) is used to probe the electron density of surface layers and crystal truncation rod (CTR) is used to study atomic reconstruction at the surface. In select compositions, in-situ XRR and CTR illuminate the reconstruction and amorphization process during cycling under OER conditions. Furthermore, grazing incidence X-ray absorption spectroscopy (GIXAS) is performed to capture the evolution of local coordination environments with increasing compositional substitutions and soft XAS is used to explore local electronic structures. Our findings uncover the role of underlying bulk descriptors in modulating OER performance through cycling-induced restructuring and unearth the fundamental driving forces behind surface transformations in perovskite oxide materials which will provide invaluable understanding to aid in the development of electrocatalytic surfaces under OER conditions for effective materials design towards high-performance electrolyzers and batteries for renewable energy storage and conversion.

8:00 AM *EN10.02.01
Coupled Ion-Electron Transfer Reactions: Dynamically-Evolving Electrodes William C.Chueh; Stanford University, United States

Most non-metallic electrocatalysts and battery electrodes change composition during operation. This change in the composition directly modifies the kinetics of heterogeneous reactions at the electrode/electrolyte interface, whether it is the lithium intercalation reaction in Li_XFePO_4, oxygen evolution reaction in CoO_XH_Y, or oxygen incorporation in CeO_{2-X}. While it is possible to infer the composition of the electrode via electrochemical measurements, knowing the composition at or near the active site is challenging. In this talk, I will present on the development of operando nanoscale microscopy (specifically, X-ray and scanning probe) and spectroscopy to track the dynamic evolution of electrocatalysts and battery electrodes during operation, and how the composition of the active site modifies reaction kinetics.

8:30 AM *EN10.05.01
Transition Metal K Edge Spectra under OER Working Conditions Frankde Groot; Utrecht University, Netherlands

Transition metal K edges are related to excitations of the transition metal 1s core electron to empty states. The K edges can be divided into the excitonic 3d pre-edges and the main edge that describes the excitations to the empty metal p-states.Using High-Energy-Resolution-Fluorescence-Detection (HERFD), one can sharpen the pre-edge structures revealing their multiplet nature. They can be calculated from the transition from the $3d^N$ ground state to the $1s^13d^{N+1}$ final state [1]. The main edge is usually interpreted from the calculation of the transitions to empty states, using DFT theory, for example multiple scattering (FEFF). The 1s XPS spectra of transition metal oxides show multiple peaks, implying that one photon energy gives rise to electrons with multiple kinetic energies. This implies that the 1s XAS spectral shape must be described as the convolution of the empty states with the 1s XPS spectral shape [2].
We measured the iron, cobalt and nickel K edges of thin film perovskite-based electrodes at the solid-liquid interface to probe the oxygen evolution reaction (OER). The 3 nm thin perovskite films are measured in fluorescence yield through the backside of the membrane electrodes.

***In-Situ* XAS Studies of Cu-S Complex Catalysts for Electrochemical CO2 Reduction Reaction**Chun-WaiChang[1], XinyuWang[2], ZhenxingFeng[1] and ZheWeng[2]; [1]Oregon State University, United States; [2]Tianjin University, China

The increasing level of carbon dioxide (CO_2) was known to be one of the reasons causing global warming by greenhouse effects. Therefore, it is crucial to reduce the CO_2 level. The application of restructuring-induced catalytic activity has shown a remarkable effectiveness in reducing carbon dioxide electrochemically to value-added products, such as methane (CH_4), ethylene (C_2H_4), etc. This research examined the *in-situ* electrochemical CO_2 reduction process of a Cu-S centered metal organic complex. The Cu-S complex exhibited a high Faradaic efficiency for CO_2 reduction and selectivity of 52% CO_2-to-CH_4 and 16% CO_2-to-C_2H_4. Combining cyclic voltammetry (CV) and in-situ X-ray absorption spectroscopy (XAS) results, we found the high performance of Cu-S complex catalysts is attributed to the reversibly reconstructed Cu nanoparticles formed during electrochemical reaction, rather than the molecule itself. In addition, the formed Cu nanoparticles, which are identified as the reaction active sites, are allowed to reverse back into the complex structure after the reaction. The relative intensities of interfacial H_2O/*CO obtained from operando infrared spectroscopy suggests that a higher amount of H_2O molecules is accumulated on the surface of catalysts. Moreover, time-of-flight mass spectrometry (TOFMS) demonstrates that the structure of catalyst can be maintained after CO_2 reduction reaction (CO_2RR) at -1.6V vs Ag/AgCl for 10 hr. Our study provides deeper understanding toward designing metal-complex molecular structures for controllably generating active species under reaction conditions to catalyze desirable chemistry.

Operando EXAFS to Determine the Mechanism of Bi Dopant at Low Concentration in Rechargeable MnO_2 Cathodes EricK. Zimmerer, DominickGuida and JoshuaW. Gallaway; Northeastern University, United States

The rechargeable Zn-MnO_2 battery system is one few systems in development capable of meeting the extreme cost requirements needed for global integration of battery storage in the power grid. Doping the MnO_2 cathode with Bi allows it to cycle reversibly between layered Mn oxides δ-MnO_2 and $Mn(OH)_2$, without detrimental formation of Mn_3O_4. This provides a cathode capacity of 617 mAh/g, which modeling has shown to enable costs below $50/kWh. However, to achieve commercial adoption, cycling stability must be improved. The mechanism through which the Bi dopant improves rechargeability remains largely unknown, and this must be clarified to rationally improve the system. Our previous work has established that the mechanism involves structurally disordered intermediates, and thus characterization techniques based on short-range order need to be used. This talk will demonstrate rapidly collected, operando extended x-ray absorption fine-structure (EXAFS) data collected on MnO_2 cathodes with and without Bi dopant. Operando techniques are scientifically powerful as they reduce experimental uncertainty resulting from destructive preparation of samples for ex-situ analysis. In addition, rapid EXAFS collection allows for analysis of the kinetics of Mn coordination changes.

The Bi-modified alkaline MnO_2 cathode has been of much interest in literature as only a small amount of Bi_2O_3 additive (Bi:Mn molar ratio 0.075) incorporated by high-energy ball-milling

enables rechargeable behavior. Previously, a disordered δ-MnO_2 phase with no diffraction signal was identified during the first charge of Bi-modified MnO_2 cathodes.[1] In this work, operando X-Ray Absorption Spectroscopy (XAS) was employed to further compare Mn coordination environments in standard and Bi-modified cathodes throughout cycling. Specifically, EXAFS analysis was used to visualize the dynamic first shell (Mn-O) and second shell (Mn-Mn) interatomic distances during the first cycle. Comparison with theoretical EXAFS modeled from CIF allows for "fingerprinting" of the charge/discharge products, while rapid EXAFS collection time allows for identification of intermediates and precise analysis of the potentials and states of charge at which materials deform. In the first discharge an earlier conversion to $Mn(OH)_2$ is observed in the Bi-modified MnO_2 cathode. Upon charge, deformation of $Mn(OH)_2$ is observed at the same potential energy in both cases, demonstrating that the thermodynamic stability of $Mn(OH)_2$ is not affect by Bi-modification. Finally, the formation of Mn_3O_4 is identified in the standard MnO_2 cathode during the conversion reaction that occurs upon charge. These findings suggest that Bi dopant blocks the pathway leading to the formation of Mn_3O_4 through interfacial effects rather than bulk incorporation.

Probing the Distribution of Alkali Cations at the Au/Electrolyte Interface with Vibrational Spectroscopy Yu ShenS. Hsu and MatthiasWaegele; Boston College, Department of Chemistry, United States

The electrode/electrolyte contact represents a material interface whose catalytic properties are determined by the interaction of the solid and liquid sides. This interaction gives rise to the electrochemical double layer (EDL), which forms the reaction environment of electrocatalytic processes. Therefore, understanding how the structure of the EDL emerges from the coupling between the solid and liquid phases is central to the development of efficient energy storage and conversion devices. Of particular interest is the distribution of cations of the supporting electrolyte in the EDL; it has been found that cations of the supporting electrolyte influence numerous electrocatalytic processes. However, our understanding of the distribution of these cations at the electrode/electrolyte interface is still poorly understood due to numerous experimental challenges in probing (alkali) metal cations at electrocatalytic interfaces. In this study, we use operando surface-enhanced infrared absorption spectroscopy (SEIRAS) to probe the distribution of alkali cations in the EDL. We demonstrate that the asymmetric CH_3 deformation mode of tetramethylammonium ($methyl_4N^+$) is a powerful probe of the distribution of alkali cations in the EDL. The vibrational probe simultaneously characterizes the populations of alkali cations in the inner and outer Helmholtz planes. We found that Cs^+ has a higher
tendency to accumulate in the inner and outer Helmholtz planes of the EDL compared with Li^+ under CO_2 -to-CO conversion conditions. We rationalize these findings in terms of the hydration free energies of the cations and electrostatic interactions with the electrode. These observations contribute to a deeper understanding of the electrode/electrolyte material interface and how interfacial properties can be
tailored for energy storage and conversion.

10:15 AM *EN10.05.05
Surface Dynamics under Reaction Conditions EdvinLundgren; Lund University, Sweden

During recent years, 2D Surface Optical Reflectance (2D-SOR) [1,2] microscopy [3] has emerged as a valuable surface characterization tool for model catalysts or electrodes [4] when performing operando investigations in harsh environments. In particular, 2D-SOR microscopy is favorably used as a complementary technique to other photon-in-photon-out techniques which do not carry direct information on the surface 2D morphology. In this presentation we will present the development and examples of 2D-SOR instrumentation and investigations from single and poly-crystalline samples in combination with Planar Laser Induced Fluorescence (PLIF) [2, 3], High Energy Surface X-Ray Diffraction (HESXRD) [5,6,7] and Polarization Modulation-Infrared Reflection Absorption Spectroscopy (PM-IRRAS) [8] coupled to Mass Spectrometry (MS) and Cyclic Voltammetry (CV) in thermal catalysis, electrocatalysis and corrosion. Illustrating examples of the versatility of the technique will be shown including reflectance changes during the thermal CO oxidation over Pd(100) and Pd polycrystalline surfaces. We show that reflectance changes during the reaction can be associated with the formation of thin Pd oxides by the combination of 2D-SOR and Surface X-Ray Diffraction (SXRD). The combined measurements demonstrate a sensitivity of 2D-SOR to the formation of a 2-3 Å thin Pd oxide film.
During Cyclic Voltammetry (CV) in an acidic electrolyte using a Au(111) surface as an electrode, we show that the differential of the change in 2D-SOR reflectance correlate to various current features in the CV curve. This observation can be used to differentiate current features in the CV curve from a polycrystalline Au surface, demonstrating that the different grains contribute to the current at different potentials due to the different surface orientations.
Finally, we show that 2D-SOR is a cheap and useful technique to investigate the corrosion of applied materials such as duplex stainless steels and Ni alloys.

Atomic Probing Surface Restructuring of Epitaxial IrO2 Thin Films Towards Extreme Oxygen Evolution Reaction Conditions HuaZhou[1], MaoyuWang[1], PerrinGodbold[2], SreejithNair[3] and BharatJalan[3]; [1]Argonne National Laboratory, United States; [2]University of Virginia, United States; [3]University of Minnesota Twin Cities, United States

Electrochemical water splitting offers efficient energy conversion potential, but it faces hurdles in the form of slow oxygen evolution reaction (OER) kinetics and harsh acidic conditions. Acidic OER electrocatalysis directly impacts making the proton exchange membrane viable on an industrial scale. IrO2 is widely recognized as a benchmark electrocatalyst for OER which dictates the overall performace on electrochemical water splitting, in particular in regard with its superior catalytic stability under long term operations. Investigating the interaction between IrO2 and aqueous solutions is crucial for understanding the intriguing properties and active sites of this catalyst in operation. Recently, many groups have used epitaxial single crystal films as model surfaces to address these fundamental questions. These developments enable for the first time the ability to assess the activities on different facets, which has significantly improved the understanding of the OER and degradation mechanism. However, there is no deep understanding of IrO2 atomic level surface structure during electrocatalytic reactions due to the extreme challenge of synthesizing epitaxial IrO2 thin film. Very recently, our collaborators have demonstrated the successful growth of atomically smooth epitaxial IrO2 films on TiO2 single crytal substrates by the unique hybrid oxide MBE growth method, which allows us to utilize in-situ surface scattering techniques, including crystal truncation rod (CTR) analysis and X-ray reflectivity (XRR), to examine epitaxial IrO2 thin films with various crystallographic orientations and their relationship with OER performance. By employing coherent Bragg rod analysis during in-situ electrochemical reactions, the interfacial structure, specifically the presence of oxygenated adsorbed species, can be resolved as a function of potential. Our study endeavors to uncover the surface chemistry of IrO2, shedding light on its activity, stability, and degradation mechanisms under extreme electrochemical conditions.

In the talk, we will present our investigation of epitaxial IrO2 films with three distinct crystallographic orientations (e.g., 001, 101, and 110 orientations) using in-situ CTR and XRR techniques, which could comprehend the influence of orientation or facet dependence on surface structuring when exposed to controlled OER conditions. Additionally, we will demonstrate surface modifications induced by different electrolytes (KOH, H2SO4, and HClO4) that lead to diverse catalytic performance and stability. Preliminary synchrotron in-situ grazing incident X-ray absorption spectroscopy (GIXAS) measurements have revealed surface structure modifications, which will be further elucidated using CTR/XRR analysis. By employing energy-modulated measurements at the element-specific Ir L-edge, taking advantage of the resonant anomalous effect, we can gather detailed information on the concentration of Ir cations at each monolayer, providing direct experimental evidence on surface composition. The resulting quantitative structural and compositional information from CTR measurements will be correlated with electrochemical properties, enabling profound mechanistic insights into the activity and stability of IrO2 toward extreme OER conditions. Our experimental results offer a comprehensive understanding of the surface properties and electrochemical behavior of IrO2, contributing to the rational design and development of efficient catalysts for the oxygen evolution reaction.

11:00 AM EN10.05.07
***In-Situ* XAS Studies of the Reconstruction of Nickel Selenide OER Electrocatalysts**FelixHiege[1], Chun-WaiChang[2], AlvinChang[2], MaoyuWang[3], Seyed PouyaHosseini Yazdeli[4], JuliaLinnemann[1], ZhenxingFeng[2] and KristinaTshculik[1]; [1]Ruhr-Universität Bochum, Germany; [2]Oregon State University, United States; [3]Argonne National Laboratory, United States; [4]Max Planck Institute for Iron Research, Germany

Nickel selenides are one of the state-of-the-art electrocatalysts for full water splitting and are especially efficient for catalyzing the oxygen evolution part reaction (OER) in alkaline media. They are cost-effective due to the consistency of earth-abundant elements. [1] Under OER conditions, nickel selenides are converted to the real catalytically active species nickel (oxy)hydroxides. [1,2]
In this work, we investigated the OER performance of in-situ generated nickel (oxy)hydroxides from nickel selenides using in-situ X-ray absorption spectroscopy (XAS). Nickel selenides

were electrodeposited on a gold-coated carbon paper and fluorescence XAS spectra were recorded using a home-designed cell [3] at different OER overpotentials. The as-deposited nickel selenides were first transformed via cyclic voltammetry (CV) under OER conditions to a nickel (oxy)hydroxide species. Afterward, the catalyst behavior was monitored during a series of chronoamperometry experiments at different OER overpotentials. In-situ X-ray near-edge spectroscopy (XANES) on the nickel edge was used to extract the oxidation states and electronic structure of the catalyst at each overpotential. [4] Furthermore, information about the local atomic structure of the active nickel centers (e.g., bond distances and coordination numbers) were extracted from the extended X-ray absorption fine structure (EXAFS) regions of the in-situ XAS spectra. [5] Additionally, we gained information about transformational and pseudo-capacitive processes of the catalyst from electrochemical impedance spectroscopy (EIS) [6] and related them to those extracted from XANES and EXAFS analyses. EIS spectra were recorded at each investigated OER overpotential before and after the CA experiments. With this combined approach, we have a better understanding of transformation processes in highly active nickel-selenides-based OER electrocatalysts under working conditions.

Application of Dark Field X-Ray Microscopy in Epitaxial Thin Film ZhanZhang[1], SeohyoungChang[2] and HuaZhou[1]; [1]Argonne National Laboratory, United States; [2]Chung-Ang University, Korea (the Republic of)

While the atomic structure is fundamental to the understanding of the static and dynamic properties of functional materials, it was realized that some phenomena emerge because of the collective behavior of a large number of atoms. One of such collection of atoms is domains in the material, whose formation, interaction, and evolution under external stimuli would dictate success or failure of the material. Studying domains would require tools with good spatial-resolution as well as large enough sampling area/volume. A diffraction based, dark field X-ray microscopy method, the X-ray reflection interface microscopy (XRIM), can be very useful in studying domains at the surfaces, buried interfaces, and inside of thin film material systems, with sub-nanometer sensitivity in the surface normal direction and better than 100 nm lateral resolution.

With the penetrating power of hard X-rays, XRIM can emphasize the features at different depth from the top surface by selecting proper scattering conditions, making it an excellent candidate to study the films in-operando in real time. Combined with the reciprocal space mapping (RSM), the spatially resolved structure evolution can be identified. A couple examples will be discussed to demonstrate the capability of XRIM method and its potential applications in a broader field.

11:30 AM *EN10.10.02
Electrochemistry in the Light of *In Situ* Bragg Coherent Diffraction ImagingClémentAtlan[1], CorentinChatelier[1], KyleOlson[1], ArnaudViola[2], FrédéricMaillard[2] and Marie-IngridRichard[1]; [1]CEA, France; [2]Centre National de la Recherche Scientifique, France

The advent of the new 4th generation x-ray light sources represents an unprecedented opportunity to conduct *in situ* and *operando* studies on the structure of nanoparticles in reactive liquid environments.
Here, we will illustrate how Bragg coherent x-ray imaging [1] allows to image in three dimensions (3D) and at the nanoscale the strain and defect dynamics inside nanoparticles during an electrochemical reaction. First, we successfully imaged the lattice displacement and the strain inside a single Pt nanoparticle in electrochemical environment. The new Extremely Brilliant Source at the European synchrotron, with unmatched brilliance and coherence, allowed monitoring the changes in structure and morphology of nanocatalysts during *in situ* conditions. Our results reveal that the strain is heterogeneously distributed between highly- and weakly-coordinated surface atoms, and propagates from the surface to the bulk of the Pt nanoparticle under polarisation [2]. Secondly, we will show how *in situ* and *operando* Bragg coherent x-ray imaging allows to study the structural evolution of single Pd nanocrystals at various electrode potentials typical of H adsorption, H absorption, and H_2 evolution. Open questions remain regarding the maximal quantity of H that can be inserted into a Pd nanocrystallite, the mechanism and kinetics of hydride (PdH_x) nucleation (preferential sites for nucleation or homogeneous nucleation at the whole particle surface) and growth (α/β sharp transition or two-phase coexistence).

Correlating Charge and Ion Kinetics in Defective Metal Chalcogenide Systems under Solid-State Confinement EdwinJ. Miller and LuisaL. Whittaker-Brooks; University of Utah, United States

Realizing fast ion kinetics in solid-state materials is of critical interest for the development of technologies including energy storage, neuromorphic computing, water desalination, and selective ion extraction. Development in these areas hinges on one fundamental challenge: facilitating ion transport through a host material. Layered van der Waals (vdW) structures stand out as a promising class of materials for reversible ion insertion, as ion intercalation can occur in the interstitial layers without permanent structural alterations. Of these vdW materials, titanium disulfide (TiS_2) is an attractive candidate for study due to its wide inter-lamellar spacing, continuous single-phase solid-solution lithiation, and material stability. While Li^+ ion kinetics in TiS_2 itself have been well-characterized, our group seeks to further advance its development by studying the effect of selenium (Se) doping on Li^+ ion kinetics in TiS_2 nanobelts. To pursue this goal, a synthesis of $TiS_{1.8}Se_{0.2}$ nanobelts has been developed. Since both TiS_2 and $TiS_{1.8}Se_{0.2}$ share the same nanobelt morphology, differences in ion kinetics between the two materials can purely be ascribed to the doping process. Compositional changes to nanostructured materials become important as it become increasingly apparent that nanostructured materials improve ion kinetics; thus, by realizing the need for nanoscaling *and* altering composition, we are including factors that will allow this study to remain relevant in the fast-paced development of ion kinetics.
Our synthesis of $TiS_{1.8}Se_{0.2}$ nanobelts predictably increases the interlayer spacing and electronic conductivity of the doped material versus pure TiS_2; both properties are expected to improve ion kinetics in these doped systems. Rate-dependent cyclic voltammetry (CV) and electrochemical impedance spectroscopy (EIS) are both used to investigate the effect of Se doping on ion kinetics in layered TiS_2 nanobelt systems. Analysis via these methods indicates that $TiS_{1.8}Se_{0.2}$ nanobelts do indeed display a charge storage process that is less diffusion-limited than their TiS_2 analogues. Lower electrochemical impedance across faster frequency ranges for $TiS_{1.8}Se_{0.2}$ also indicates a decrease in resistances across the cell for the doped material. This insight into the effects of chalcogen doping on the charge storage process of TiS_2 nanobelts informs future development of layered vdW materials.

Engineering Surface Dipoles on Mixed Conducting Oxides with Ultra-Thin Oxide Decoration Layers MatthäusSiebenhofer[1,2], AndreasNenning[1], MarkusKubicek[1], PeterBlaha[1] and JürgenFleig[1]; [1]TU Wien, Austria; [2]Massachusetts Institute of Technology, United States

The surfaces of mixed ionic and electronic conducting (MIEC) materials play a crucial role in a wide range of applications within energy and sensing technologies, including solid oxide cells, catalysts, and oxygen permeation membranes. Consequently, the optimization of these surfaces and interfaces has become a focal point for research efforts aimed at advancing energy materials and devices. Recent studies have unveiled the significant impact that even small amounts of surface modifications, in sub-monolayer quantities, can have on the electrochemical properties of MIEC oxide surfaces. These modifications can alter the work function and the catalytic activity, demonstrating promising potential for targeted material and device optimization [1,2,3].

In this contribution, we conducted a comprehensive investigation into the effects of ultra-thin oxide layers on the electronic and ionic properties of different MIEC oxide surfaces, combining experimental and computational approaches. We employed in-situ impedance spectroscopy during pulsed laser deposition (i-PLD) and near ambient pressure X-ray photoelectron spectroscopy

(NAP-XPS) to assess the impact of surface decorations on the properties of uncontaminated, pristine surfaces of epitaxial thin films of MIEC oxides such as $La_{0.6}Sr_{0.4}CoO_{3-\delta}$ or $Pr_{0.1}Ce_{0.9}O_{2-\delta}$. Building on these results, we employed density functional theory (DFT) to elucidate the atomic scale processes responsible for these effects.

Our study demonstrates that the electrochemical properties of MIEC oxide surfaces can be tailored systematically by decorating them with oxides of different ionic potential or acidity. Basic oxides with low ionic potential, such as SrO, lead to a reduction in the work function, while acidic oxides with high ionic potential, such as SnO_2, lead to an increase in the work function. As the fundamental underlying mechanism we could identify charge redistribution and dipole formation processes at the heterojunction between host material and decoration. To illustrate the potential of this surface modification method, we explored its impact on the oxygen exchange reaction kinetics on various solid oxide fuel cell (SOFC) cathode materials, highlighting the broad applicability of ultra-thin oxide layers in tuning reaction rates on MIEC surfaces.

***In-Situ* Vibrational Spectroscopic Analysis of Solid Layer Formation at a Superconcentrated Electrolyte/Electrode Interface**KentaMotobayashi, MasanoriNagasaka and KatsuyoshiIkeda; Nagoya Institute of Technology, Japan

Superconcentrated electrolytes have been attracted considerable attention for battery applications for their useful properties such as low flammability, high oxidation stability, etc. Reversible charge/discharge processes were reported, suggesting the successful formation of appropriate solid electrolyte interphases (SEI) in superconcentrated electrolytes, which prevents co-intercalation of solvent molecules. The origin of SEI was reported to be anion species,[1] while that for conventional dilute electrolytes consist of decomposition products of the organic solvents. This feature leads to wide variety of applicable solvents for superconcentrated electrolytes. However, details of the origin of SEI in superconcentrated electrolytes are still under debate. Therefore, we performed in-situ chemical and mechanical analysis of the superconcentrated electrolyte/electrode interface by using surface-enhanced infrared absorption spectroscopy (SEIRAS) to elucidate the origin and formation process of SEI.
We employed 4.2 M LiTFSA/acetonitrile (AN) solution on an Au electrode as a model system for interface analysis. For a negative-going potential scan, SEIRA spectra showed that both TFSA anions and Li^+ coordinated by AN move toward the electrode when the surface charge of the electrode is switched from positive to negative. It means increased density of the solution on the surface, which can be explained as follows; Li^+ is drawn to the negatively charged electrode, and then AN and TFSA anions directly interacting with Li^+ are drawn to the electrode together. Thus, characteristic coordination structure in superconcentrated electrolytes (anion-Li^+ bond which is absent in dilute concentration) is responsible for such a phenomenon.
At more negative potentials (< 2.0 V), the local concentration of AN decreased and instead that of TFSA forming aggregated network structure with Li^+ started to increase. Such a structure appears at oversaturated concentration in the bulk. It means that local ionic concentration increased at this potential range, and finally LiTFSA was deposited on the electrode together with small amount of AN by exceeding the saturation concentration. This model is supported by our in-situ AFM analysis of the viscoelasticity of the deposits.

Uncovering Photoinduced Charge Transfer Dynamics in Thin Films and Devices of the Extremely-Thin Absorbing Material Sb_2S_3ElizabethR. Young[1], JulienBachmann[2] and RobertHamburger[1]; [1]Lehigh University, United States; [2]Friedrich Alexander University Erlangen-Nürnberg, Germany

Widespread energy conversion from sunlight requires solar cells fabricated using stable, sustainable, non-toxic semiconductors based on earth-abundant elements. The continually shrinking feature sizes in nanoelectronics and the drive for inexpensive solar energy conversion systems make fundamental understanding of charge transfer processes at interfaces and within actual devices essential to next generation photo and photoelectrochemical systems. Such devices are comprised of stacks of light-absorbing layers and hole and electron transporting materials forming thin film p-i-n structures. Necessarily, they must operate under both electrochemical applied potentials (in situ) and constant steady-state irradiation (operando) conditions. However, when measuring the photophysics and photo-induced chemical processes of these materials, experiments have thus far primarily been carried under *ex situ* conditions – with either the material alone or in partly formed semi-conductor stacks. More real-life conditions are needed to fully understand how charge carriers are generated, how they flow through materials and how material interfaces mediate charge transfer across multiple layers in these photophysical mechanisms. I will discuss our initial efforts at designing and developing experimental probes and data analysis tools capable of characterizing photochemical reactions under more realistic operating conditions. Using transient absorption spectroscopy (TAS), we *directly* observe carrier diffusion, electron transfer, hole transfer and charge recombination through uniform ultra-thin (< 3 nm) layers of insulating or transport materials deposited by atomic layer deposition (ALD) that are coupled to photoactive materials. Our work focuses on stibnite (Sb_2S_3) as the photo-active layer, which is of particular interest due to the suitable band gap of 1.7 eV and high absorption coefficient (1.8×10^5 cm^{-1} at 450 nm). We quantify the dynamics that can be observed in thin transparent films through the use of *in situ* and *operando* TAS. Use of *in situ* and *operando* TAS affords the opportunity to study these materials in operating conditions and gain a quantitative understanding of the electron transfer dynamics at play in thin films.

Epitaxial Growth of Defect-Free Yttrium-Doped Barium Zirconate Films by Co-Sputtering for Improved Protonic Conductivity in Protonic Ceramic Fuel Cells JaewonHwang, SuhyukKo and Suk WonCha; Seoul National University, Korea (the Republic of)

Protonic ceramic fuel cells (PCFCs) have emerged as a promising technology for the generation of clean energy for their low operating temperature (< 600°C) and high efficiency. Among the various proton-conducting materials, yttrium-doped barium zirconate (BZY) is commonly utilized as an electrolyte material due to its high bulk conductivity and high chemical stability in H_2O and CO_2 environments. However, owing to the poor sinterability of protonic ceramic materials, conventional slurry-based fabrication methods require high-temperature sintering above 1500°C, resulting in detrimental effects such as the evaporation of constituent elements and the formation of secondary phases. To mitigate these issues, we investigated a novel approach for fabricating yttrium-doped barium zirconate (BZY) through the co-sputtering of $BaCO_3$ and yttrium-stabilized zirconia (YSZ) targets at a significantly lower temperature than that required for conventional wet processes. We explored various sputtering parameters and substrates to fabricate BZY films with different microstructures and compositions.
The incorporation of carbon from the $BaCO_3$ target and undesirable carbonate formation in the film was prevented by investigating different sputtering parameters related to the thermodynamics and kinetics of carbonate deposition, including radio frequency (RF) power applied to the targets and oxygen partial pressure. Sputtering parameters that influence the growth kinetics, including deposition rate, deposition pressure, and substrate temperature, were controlled to minimize the structural defects that reduce the film's proton conductivity. Successful deposition of stoichiometric, defect-free epitaxial BZY film on a MgO substrate was confirmed by advanced characterization techniques, including transmission electron microscopy (TEM), depth-profile X-ray photoelectron spectroscopy (DP-XPS), X-ray energy dispersive spectroscopy (EDS), X-ray diffraction (XRD), and field emission scanning electron microscopy (FE-SEM). The epitaxial BZY film had no grain boundaries, thereby minimizing the negative contribution of the grain boundaries to proton conductivity. Consequently, the in-plane proton conductivity of the epitaxial BZY film measured via the AC impedance method was significantly higher than that of wet-processed polycrystalline BZY. Our results demonstrate the potential of co-sputtering as a low-temperature fabrication approach for producing high-quality BZY electrolytes with improved protonic conductivity and reduced thickness for PCFC applications.

Electronic and Ionic Effects of Acidic Adsorbates on Solid Oxide Fuel Cell Cathode Surfaces MatthäusSiebenhofer[1,2], AndreasNenning[1], MarkusKubicek[1], JürgenFleig[1] and PeterBlaha[1]; [1]TU Wien, Austria; [2]Massachusetts Institute of Technology, United States

The oxygen exchange reaction is an important reaction for various applications in energy- and environment-related technologies. For example, during operation of low and intermediate temperature solid oxide fuel cells (SOFCs), the kinetics of this fundamental reaction is often regarded as the bottleneck for the overall performance. To tackle this issue, research and development of new SOFC cathode materials are focused on high intrinsic catalytic activity and high degradation stability. For promising cathode materials, this degradation is commonly attributed to poisoning effects due to different elements in the environment, such as S, Si or Cr, as well as to cation segregation, for example Sr segregation for perovskites like $La_{0.6}Sr_{0.4}CoO_{3-\delta}$ (LSC) and $SrTi_{0.3}Fe_{0.7}O_{3-\delta}$ (STF). In particular, it was recently shown that acidic adsorbates, such as SO_4^{2-}, originating from trace impurities, which are omnipresent in nominally pure measurement atmospheres, readily adsorb on the surfaces of different SOFC cathode materials and cause a sudden and strong degradation [1]. However, the underlying mechanism of these effects has so far been unclear.

In this contribution, the effects of adsorbed SO_2 and other typical solid oxide fuel cell (SOFC) poisons, such as CO_2 and CrO_3, on the electronic and ionic properties of an SrO-terminated (La,Sr)$CoO_{3-\delta}$ (LSC) surface and on its oxygen exchange kinetics have been investigated experimentally with near ambient pressure X-ray photoelectron spectroscopy (NAP-XPS), low energy ion scattering (LEIS) and impedance spectroscopy, as well as computationally with density functional theory (DFT) [2]. The investigations revealed that acidic adsorbates induce the formation of a surface dipole and extract charge from the LSC surface. As a result, they strongly increase the surface work function and alter the energetics of molecular oxygen adsorbates and oxygen vacancies in LSC.

Interestingly, the total work function changes as well as the redistributed charge for different acidic adsorbates scale quantitatively with the Smith acidity of the adsorbed oxide, which has recently been identified as a descriptor for the effect of binary oxide infiltrations on the oxygen exchange kinetics of $Pr_{0.1}Ce_{0.9}O_{2-\delta}$ [3]. We suspect that the here presented concept of charge redistribution and its impact on the oxygen exchange reaction is highly relevant for multiple phenomena on mixed conducting surfaces and that it is a further step on the way to a detailed understanding of the oxygen exchange reaction on these surfaces.

Enhanced Electrokinetic Streaming Potential Generation Through Surface Modulation on Microfluidic LiCheng[1], BeiFan[2] and PrabBandaru[1]; [1]University of California, San Diego, United States; [2]Michigan State University, United States

The generation of electrical voltages and currents through aqueous electrolyte flow on charged surfaces is of significant interest for insights into surface-fluid interactions as well as for the development of new energy sources. The related phenomena broadly involve the attraction of counterions in the electrolyte to a charged surface forming an electric double layer (EDL). An electrical charge separation in the EDL may be obtained through a pressure difference (*DP*) applied to the electrolyte along the channel length, and results in a streaming potential (V_s). It has been determined that both the surface electrical potential, *i.e.,* the zeta potential (*z*), as well as the electrolyte slip length (*b*) contribute to the V_s.
We investigate through detailed experiments and subsequent theoretical analysis, the influence of various patterned surfaces, comprised of grooves, meshes, and pillars, in modulating the electrolyte flow for obtaining large V_s. We have obtained fascinating insights into how such *patchy* surfaces may be utilized in further increasing the figure of merit (related to the V_s/DP ratio) to a record 0.1271 mV/Pa - three-fold larger compared to what was previously obtained, through such investigations. We have probed flow on the patterned surfaces with *both* impregnated air and electrolyte immiscible oil, *i.e.,* an air-filled surface (*AFS*) as well as a liquid filled surfaces (*LFS*), respectively. We note that crucial to obtaining a large V_s is the optimization of the product of the effective slip length (b_{eff}) and the zeta potential (*z*). While a larger b_{eff} may be obtained from the *AFS*, the effective *z* is shown to be larger through the use of the *LFS.* Consequently, the interplay of the *z* and b_{eff}, with respect to the underlying patterned surface was considered in detail. On this basis, we posit a modified *effective* zeta potential which may be of significant use for modeling flow over patterned or non-homogeneous surfaces.
While the use of hydrophobic surfaces was advocated to increase the *b*, related surfaces are difficult to fabricate and maintain. Much less attention has been paid to methods for enhancing *z*. We then proposed the use of plasma processing of surfaces to modulate *both* the *b* as well as the *z* over silicon surfaces. Such methodology is shown to result in a larger V_s and a record figure of merit (FOM) of 0.1 mV/Pa – a factor of two larger compared to what was previously obtained. In our work we deployed CF_4 based plasmas for the possibility of creating of a thin fluorocarbon film over the surface, which may increase the hydrophobicity. Moreover, the ions in the plasma would also have a role in increasing the surface charge density and the resultant *z*. It was then determined experimentally that the latter effect predominates. In contrast, Ar-based plasmas are often preferred for their relatively simple constitution (with only Ar^+ ions and absence of chemical reactions). However, it was seen that such plasmas were more influential in only roughening the surface with minimal influence on the *z* or *b*. Generally, with the estimated *b* at less than 2 nm, the contribution to the increased V_s is typically small. Consequently, the major contributor to the record V_s values obtained in our study was due to the enlarged *z*. Our results have major implications in enhancing the understanding of electrokinetic phenomena with respect to the variation of the electrical and mechanical attributes of surfaces. Further development through deploying hydrophobic surfaces *coupled* with plasma processing, and related principles outlined in our work, could yield much larger V_s and pave the way for large scale voltage sources. Our two articles, entitled *The influence of surface texture on the variation of electrokinetic streaming potentials* and *The Modulation of Electrokinetic Streaming Potentials of Silicon-Based Surfaces through Plasma-Based Surface Processing*, were published at ***Langmuir***.

Finding Infinities in Nanoconfined Geothermal Electrolyte Dielectric Properties, and Implications on Ion Adsorption/Pairing KevinLeung; Sandia National Laboratories, United States

Infinities should naturally occur in the dielectric responses of ionic solutions relevant to many geochemical, energy storage, and electrochemical applications at strictly zero frequency. Using molecular dynamics simulations cross-referenced with coarse-grained Monte Carlo models, nano-slit pore models at hydrothermal conditions, and treating confined mobile charges as polarization, we demonstrate the far-reaching consequences. The dielectric permittivity profile perpendicular to the slit epsilon_perp (z) increases, not decreases, with ionic concentration, unlike in the more widely studied megahertz-to-gigahertz frequency range. In confined electrolytes the divergences in epsilon_perp(z) correctly describe cross-overs between bulk- and surface-dominated dielectric behavior. Nanoconfinement at low ionic concentrations changes monovalent ion energetics by 1-2 kJ/mol, but no dielectric property studied so far is universally correlated to ion adsorption or ion-ion interactions. We caution that infinities signal violation of the “electrical insulator” dielectric assumption.

High Voltage Electrolytes Development for High-Ni Cathodes LaisuoSu; The University of Texas at Dallas, United States

Electrolytes connect the two electrodes in a lithium battery by providing Li^+ transport channels between them. Recently, ether-based localized high-concentration electrolytes have been developed for lithium-metal batteries and show a great success. Despite their high Coulombic efficiency (~ 99.5%) with lithium metal, the relatively high highest occupied molecular orbital (HOMO) of ethers limits their application at high voltages (> 4.4 V). To tackle this issue, we proposed a new concept of electrolyte, namely localized saturated electrolyte (LSE), based on carbonate solvents that have lower HOMO levels than ether solvents. The formation of a special Li^+ solvation structure can further reduce the HOMO level of the electrolyte, increasing its oxidative stability. We demonstrate that the developed LSE can stabilize various types of cathodes at high voltages up to 4.85 V. Materials characterizations were further conducted to uncover the mechanisms. And we found that advanced electrolytes help form close-packed homogeneous Li morphology on the anode, generate thin and inorganic-rich interphase layers on both electrodes, and reduce surface degradation into spinel and rock-salt phases of high-Ni cathodes, leading to superior cycling performance of lithium batteries. Our work highlights the importance of developing advanced electrolytes for stabilizing cathodes at high voltages in next-generation batteries.

Enhancing the Durability of Silicon Anodes by Anchoring Carbon-Coated Active Particles to Reduced Graphene Oxide NawrajSapkota[1], NancyChen[1], MortezaSabet[1], MihirParekh[1],

YiDing[2], SrikanthPilla[1] and ApparaoM. Rao[1]; [1]Clemson University, United States; [2]U.S. Army DEVCOM GVSC, United States

Conventional graphitic anodes are quickly approaching their theoretical capacity limits. Among potential candidates, silicon (Si) is recognized as an alternative active material for next-generation lithium-ion batteries (LIBs) owing to its high theoretical capacity and earth abundance. However, the practical implication of Si in LIBs has been hindered by its low electrical conductivity, large volume change during charge/discharge processes, and rapid capacity fading during cycling. In the current study, we modified the Si/electrolyte interface by developing a low-cost, scalable, dual-carbon protection technique to mitigate these issues. After introducing a thin polydopamine coating on commercial Si nanoparticles (SiNPs, solid spherical, 100-nm dia.), the coated particles were combined with graphene oxide, subjected to sudden freezing and freeze drying, and finally annealed in an environment of argon and hydrogen. Microstructural studies confirmed the formation of micron-sized composite particles in which a thin nitrogen (N)-doped carbon layer was formed on individual SiNPs, denoted here by SiNP@NC, and the SiNP@NC particles were wrapped/anchored by a reduced graphene oxide sheet, denoted by SiNP@NC@rGO. Pristine SiNPs and SiNP@NC@rGO were utilized as active materials to prepare identical anodes with water-based formulation and SiNP mass loading of ~1.0 mg cm^{-2}. Electrochemical impedance spectroscopy showed a reduction in the internal impedance by applying our dual-carbon protection technique. While the SiNP anode exhibited a reversible capacity of 500 mAh g^{-1} at a current density of 2100 mA g^{-1}, the SiNP@NC@rGO anode displayed a reversible capacity of 1400 mAh g^{-1}. After 200 cycles at 420 mA g^{-1}, the capacity retention of SiNP and SiNP@NC@rGO anodes were 54% (from 1300 to 700 mAh g^{-1}) and 72% (from 2370 to 1700 mAh g^{-1}), respectively. The enhanced initial capacity and superior capacity retention of SiNP@NC@rGO indicate the effective protection of SiNPs by applying our synthesis method. The post-mortem characterizations of cycled electrodes also confirmed the effectiveness of our protection strategy.

Understanding Lithium-Solid Electrolyte Interfaces from a Single-Atom Level YifeiMo; University of Maryland, United States

The interfaces between lithium metal and solid electrolytes are critically important for enabling solid-state lithium batteries but remain less understood, especially at the atomistic level. Atomistic modeling allows for the direct observation of atomic dynamics, which can be challenging to assess directly in experiments. In this talk, I will discuss how we have addressed the following key questions using large-scale atomistic modeling:
1) What are the atomistic structures of the lithium interfaces with solid electrolytes?
2) How do these interface structures affect the atomistic-level mechanisms of Li stripping and plating under electrochemical cycling?
3) How do electrochemically deposited Li-ions transition into crystalline Li metal, and what are the corresponding kinetic processes and energy barriers?
By using large-scale atomistic modeling, we aim to offer insights into these questions and propose strategies to address some of the key limitations or failure mechanisms.

10:30 AM EN10.08.05
Challenging the Assumptions of Lithium Dendritic Shorting Safety Consequences in Lithium Cobalt Oxide Lithium-Ion Batteries BretSchumacher, JonSullivan, LaurenMarbella and DanSteingart; Columbia University, United States

As the steady push for electrification continues, there is a growing need for more energy-dense storage devices. Lithium-ion batteries have dominated the market, in part, because of their high energy density and cycleability. An unfortunate consequence of the increased introduction of lithium-ion batteries in personal mobility devices is the sharp uptick in catastrophic safety events such as fires and explosions, especially in densely populated urban areas. One possible mechanism attributed to these events is attributed to dendritic lithium shorting the electrodes causing thermal runaway.
This work challenges the assumption that lithium dendritic shorting will cause catastrophic events. Using isothermal microcalorimetry (ITMC), differential scanning calorimetry (DSC), and a custom-built cell design for a controlled lithium-ion soft short, the total energy release of a soft short is quantified *in operando.* Then, via first-principles calculations and thermal reduction experiments, the total local temperature change during the shorting events were determined to be significantly lower than the temperature needed for thermal reduction and eventual thermal runaway in this system.

10:45 AM EN10.08.07
Electrode Coating and Electrolyte Dependent Intercalation Rates and Activation Energies of Lithium-Ion Battery Electrodes SravaniR. Duggirala[1], YiruiZhang[2], CristinaGrosu[1] and ArmandoNeto[1]; [1]Massachusetts Institute of Technology, United States; [2]Stanford University, United States

Lithium-ion batteries continue to be an attractive choice for electronics and larger sustainability applications, however the reaction kinetics of various chemistries are poorly understood. The intercalation rates determine the power densities of Li-ion batteries, but the energy barriers and microscopic interfacial processes are not known. Here we understand and model the electrochemical intercalation kinetics of various electrode-electrolyte interfaces through systematically tested experiments on a list of thin oxide electrodes (LiCoO2, LiNixMnyCozO2 materials) with controlled surface coatings and different organic electrolytes. Through temperature-dependent measurements, we extract the activation energy for moving an ion near the intercalation material interface and intercalating the ion, where LiCoO2 electrodes shows higher activation energy than LiFePO4 and LiNixMnyCozO2 electrodes, and LiCoO2 in LiPF6-containing electrolytes gives similar action energy compared to LiClO4-containing electrolytes. The coupled-ion electron transfer theory is used to extract the reorganization energy and reaction rates which can be used to predict materials with optimal kinetic properties for electrified interfaces. These results provide a fundamental understanding of ion intercalation kinetics and new directions for interfacial engineering of Li-ion batteries to boost power density.

11:00 AM EN10.08.08
Binder-Free Silicon-Impregnated Carbon Paper Electrodes PeshalKarki[1], MortezaSabet[1], MihirParekh[1], YiDing[2], SrikanthPilla[1] and ApparaoM. Rao[1]; [1]Clemson University, United States; [2]U.S. Army DEVCOM GVSC, United States

During cycling, the Si-based electrodes suffer from a large volume change, which leads to electrode pulverization and an unstable solid-electrolyte interphase (SEI) growth. Silicon-carbon (Si@C) materials have proved meritorious in mitigating the detrimental effects of large volume change of Si-based electrodes during cycling. The use of C-rich biorenewable materials for producing sustainable Si@C materials is continuously expanding. Aligned with this approach, we developed a simple, environmentally friendly technology based on low-cost biorenewable resources to create a Si@C material in which Si particles are uniformly dispersed in a matrix of porous C (i.e., embedded in a carbon cloud). In this method, commercial Si nanoparticles (solid spherical, 100-nm dia.) and lignin were dispersed in epoxidized soybean oil and subjected to oil-in-water emulsion polymerization, followed by low-temperature (500 °C) carbonization. The scanning transmission electron microscopy studies confirmed the production of micron-sized hybrid particles with Si nanoparticles embedded in a porous carbon cloud. Thermogravimetric analysis showed the presence of 40 wt.% Si in the Si@C material, which showed a reversible capacity that was two to three times higher than conventional Si nanoparticles-based electrodes. Although Si@C material increased the specific capacity of the anode, the presence of high-density metallic foil and inactive materials (such as binder and conductive carbon) would adversely affect the electrode-level specific capacity. As a next step we produced binder-free, flexible, and robust anodes by directly incorporating Si@C or pristine Si in separate porous Bucky Papers (BP, 60 gsm) made out of carbon nanotubes. Eliminating the copper foil, binder, and conductive carbon resulted in a 30% weight reduction of the electrode when Si mass loading was set to 1 mg cm^{-2}. These BP-based electrodes impregnated with Si nanoparticles or Si@C active material (and Si loading of 1 mg cm^{-2}) exhibited an initial electrode-level capacity of 320 or 280 mAh g^{-1}, respectively, at a current density of 0.42 mA cm^{-2}. At this Si mass loading level, electrodes with Si nanoparticles cast on copper foil exhibited an initial electrode-level capacity of 155 mAh g^{-1} at a current density of 0.42 mA cm^{-2}. These results indicate that the electrode-level capacity doubled when Si-based active materials were impregnated into porous BP. After 150 cycles, the Si@C-impregnated BP electrode showed 84% capacity retention, while the pristine Si nanoparticle-impregnated BP electrode retained only 54% of its initial capacity. The superior capacity retention of the Si@C electrode is due to the carbon-cloud protection during cycling.

11:15 AM EN10.08.09
Filament Growth and Related Instabilites during Adsorbate Suppressed Electrodepositon TrevorBraun, WilliamOsborn and ThomasMoffat; NIST, United States

Anisotropic electrochemical deposition and whisker growth is shown to be a consequence of operating a bistable active-passive critical system under galvanostatic control. Specifically, whisker growth is examined during galvanostatic Cu electrodeposition from an electrolyte containing suppressor additives. Disruption of the passivating polyether-halide bilayer triggered by metal deposition leads to positive feedback and highly localized deposition. On macroscale electrodes active-passive Turing patterns develop while on micrometer-sized electrodes the bifurcation is frustrated and proceeds as a single active zone reinforced by hemispherical transport fields. Extended electrodeposition leads to symmetry breaking and lateral propagation of a single whisker. An increasing fraction of the applied current supports expansion of the passive sidewall area and eventually results in termination of anisotropic deposition. The dynamic range between passive versus active growth determines the shape and extent of whisker formation. Similar critical behavior may account for reports of whisker growth in certain metal/metal ion battery systems.

11:30 AM EN10.08.10
On the Mechanism of Mossy Zn Deposition ZhibinYi, KevinChan and QingChen; Hong Kong University of Science and Technology, Hong Kong

Electrochemical deposition of Zn metal from a zincate electrolyte can lead to a peculiar mossy morphology comprising numerous slim kinky filaments. Like mossy Li in Li metal batteries, mossy Zn is considered detrimental to the stability of rechargeable Zn batteries. Yet unlike Li, the cleaner interface and the easier characterizations of Zn metal offer us an opportunity to dig deeper into the mechanism of mossy deposition. With well-polished and annealed polycrystalline Zn foil as an electrode, we show that the mossy deposition, occurring at a low overpotential, is localized at the surface intersects of defects such as grain boundaries. Through the measurements of cross-sectional microstructures, stress, and surface composition, we gain insights into the formation sites, the driving force, and the kinetics, drawing a close comparison to both mossy Li and metal whiskers.

Core/Shell Nanocrystals with Ordered Intermetallic Single-Atom Alloy Layers for Efficient Ammonia Synthesis HuiyuanZhu; University of Virginia, United States

Single-atom alloys (SAAs) in which precious metal single atoms are embedded into a host metal, are an emerging class of catalytic structural motifs. Benefitting from the free-atom-like *d*-states, SAAs have been proved in theory to have the potential to break the linear scaling relations inherent to metal catalysts and improve the selectivity toward desired products. In this talk, we will discuss our recent efforts in developing a facile, direct solution-phase synthesis of Cu/CuAu core/shell NCs with tunable single-atom alloy (SAA) layers. This synthesis can be extended to other Cu/CuM (M = Pt, Pd) systems, in which M atoms are isolated in the Cu host and can be considered the highest density of single-atom sites. The density of single-sites and the number of atomic layers can be synthetically controlled. The ligand and strain effects of Cu/CuAu for electrocatalytic ammonia synthesis will also be discussed in this talk.

Ultrarapid Photothermal Annealing Synthesis of Single-Atom Catalysts-Stabilized Carbon Nano-Onion DogyeongJeon, HaminShin, Jun-HweCha and Il-DooKim; Korea Advanced Institute of Science and Technology, Korea (the Republic of)

Carbon nano-onions (CNO) with nanometer-scale surface curvature and versatile functionalization have attracted attention in energy and environmental applications. However, conventional methods for synthesizing CNOs, and post-synthesis treatments for functionalization are extremely time consuming and energy intensive. Here, we present an ultrarapid photothermal annealing (UPA) platform for millisecond-scale synthesis of CNO and simultaneous surface functionalization with single-atom catalysts (SACs). The UPA platform reaches up to 3030 K within 1.4 ms (2.2×10^6 K s^{-1}), achieving full conversion from nanodiamond to CNO within 20 ms, significantly improving energy consumption efficiency. Moreover, we demonstrate the universal applicability of SACs functionalization on the outer surface of CNOs with eight different transition metal elements. In a case study, Pt SACs-functionalized CNO exhibit outstanding catalytic performances in hydrogen evolution reaction (HER), with an overpotential of 13.9 mV at 10 mA cm^{-2} and a Tafel slope of 52 mV dec^{-1}.

2:30 PM EN10.09.04
Design and Optimized Fabrication of Highly Dispersed Single-Atom Catalysts for Efficient Electrochemical Nitrogen-to-Ammonia Conversion NagehK. Allam; American University in Cairo, Egypt

Electrochemical nitrogen reduction reaction (NRR) has been established as a promising and sustainable alternative to the Haber–Bosch process, which requires intensive energy to produce ammonia. Unfortunately, NRR is constrained by the high adsorption/activation of the N_2 energy barrier and the competing hydrogen evolution reaction (HER), resulting in low faradic efficiency. Herein, a well-dispersed iron single-atom catalyst was successfully immobilized on nitrogen-doped carbon sheets (Fe_{SAC}-N-C) synthesized from pre-hydrothermally derived Fe-doped carbon quantum dots (CQDs) and used for efficient electrochemical N_2 fixation at ambient conditions. The as-synthesized Fe_{SAC}-N-C catalyst records an onset potential of 0.12 V_{RHE}, exhibiting a considerable faradic efficiency of 23.7% and a NH_3 yield rate of 3.47 μg $h^{-1}cm^{-2}$ in aqueous 0.1 M KOH electrolyte at a potential of -0.1 V_{RHE} under continuous N_2 feeding conditions. The control experiment asserts that the produced NH_3 molecules only emerge from the dissolved N_2-gas, reflecting the remarkable stability of the nitrogen–carbon framework during electrolysis. The DFT calculations showed the Fe_{SAC}-N-C catalyst to demonstrate a lower energy barrier during the rate-limiting step of the NRR process, consistent with the observed high activity of the catalyst. This study highlights the exceptional potential of single-atom catalysts for electrochemical NRR and offers a comprehensive understanding of the catalytic mechanisms involved. Ultimately, this work provides a facile synthesis strategy of sheet-like Fe_{SAC}-N-C with high atomic dispersion, creating a new design avenue of Fe_{SAC}-N-C that can vividly have a potential applicability in large spectrum of electrocatalytic applications.

Computational Modeling of Atomically Dispersed Iron/Nitrogen Carbon Electrocatalysts for Proton Exchange Membrane Fuel Cells GuofengWang; University of Pittsburgh, United States

Proton exchange membrane fuel cells (PEMFCs) can covert chemical energy stored in hydrogen fuels to electricity and produce environmentally benign product water. However, the emergent application of PEMFCs is hindered by the requirement of expensive Pt group metals as their electrocatalysts. To advance PEMFC technology, it is of great interest to develop earth-abundant, non-precious metal-based catalysts in replacement of Pt, especially for oxygen reduction reaction (ORR) occurring at the cathode of PEMFCs. In this regard, atomically dispersed iron/nitrogen carbon catalysts (denoted as Fe-N-C) have drawn wide attention since they exhibited promising ORR activity close to Pt and improved stability than macrocyclic molecules. However, the structure of the active sites in these Fe-N-C catalysts and their catalytic mechanism for ORR have not been fully understood. Recent study reveals that there exist two distinct types of FeN_4 sites, namely porphyrin-like S1 FeN_4 sites and S2 FeN_4 sites containing four pyridinic nitrogen, in Fe-N-C catalysts active for ORR. In this study, we have performed density functional theory (DFT) calculations to predict the reaction energetics of ORR on both S1 and S2 FeN_4 sites. We calculated the adsorption energies of all the possible chemical species and the activation energies for O-O bond dissociation reactions involved in ORR on the FeN_4 sites. Our DFT calculations predicted that the ORR could happen through $4e^-$ associative pathway on the FeN_4 sites and with higher kinetic rate on S1 FeN_4 sites than S2 FeN_4 sites. The theoretical results are in agreement with experimental observations. Furthermore, we predicted the Gibbs free energy change for demetallation of Fe from both S1 and S2 FeN_4 sites. We assume that the demetallation of Fe from FeN_4 sites consists of two steps. At the first step, the Fe atom moves away from the N_4-coordinated state to an inactive N_2-coordinated state, with two N atoms passivated by H from the acidic environment. At the second step, the Fe atom with ORR adsorbates will be desorbed from the catalytic surface. Our computational results show that the tendency of demetallation is much higher for S1 FeN_4 sites than that for S2 FeN_4 sites. Consequently, computational modeling provides in-depth atomistic understanding of the chemical nature of active sites in Fe-N-C catalysts for PEMFCs.

3:30 PM EN10.09.06
Mechanistic Insight into Dual-Metal-Site Catalysts for the Oxygen Reduction Reaction GuoxiangHu; Georgia Institute of Technology, United States

Incorporating a second transition metal to iron–nitrogen–carbon single-atom catalysts (Fe–N–C SACs) to design dual-metal-site catalysts (DMSCs) was demonstrated to offer a promising opportunity to enhance the oxygen reduction reaction (ORR). However, due to the many possible structural configurations and the dynamic structure evolution of metal centers under reaction conditions, it is challenging to clearly elucidate the structure–property relationship at the atomic level. Here, we develop a computational workflow integrating configuration generations, phase diagram constructions, and reaction free energy calculations to provide an insightful understanding of the active site structures and catalytic mechanisms of ORR on DMSCs. Using Fe–Cu as an example, we generate 31 configurations by tiling the hexagonal lattice of graphene and investigate their atomic structures under reaction conditions. We find that for a wide range of electrode potentials, the Fe site is covered by an *OH intermediate, while the Cu site is not covered by any intermediate. With the OH-ligated structures, we identify the configurations which possess higher catalytic activity than Fe–N–C and Pt(111). We demonstrate that ORR on Fe–Cu DMSCs proceeds *via* the associative pathway, and the desorption of *OH is the rate-determining step. Further analysis reveals a linear correlation between the limiting potential and the magnetic moment on Fe and suggests a closer distance between the two metal sites benefits the catalytic activity. These mechanistic insights pave the way for the rational design of efficient platinum group metal-free DMSCs for ORR.

Computational Quest for High-Performance Single-Atom Electrocatalysts and Beyond ZhongfangChen; University of Puerto Rico at Río Piedras, United States

Nanocatalysis holds immense promise for achieving significant breakthroughs in various fields. Among the most remarkable advancements are single-atom catalysts (SACs), renowned for their exceptional activity, selectivity, and stability. However, catalysts beyond SACs, such as dual-atom catalysts (DACs), have the potential to outperform SACs in specific reactions. In this talk, we will unveil our recent computational advancements in designing SACs and DACs based on two-dimensional nanosheets, specifically focusing on their application in crucial electrochemical reactions. Moreover, we will underscore the significance of emerging big-data techniques for the computational screening and design of such catalysts.

Calculations of the Voltage Dependent Mechanisms and Rates of HER, ORR and CO2RR under Electrochemical Conditions HannesJonsson; University of Iceland, Iceland

Theoretical calculations of electrocatalytic reactions such as the hydrogen evolution reaction (HER), oxygen reduction reaction (ORR) and CO2 reduction reaction (CO2RR) in order to determine the mechanism and estimate the rate of the various elementary steps can be carried out various levels of theory. At the simplest level, only the free energy of intermediates is estimated from calculations in the absence of applied voltage and dielectric solution and corrections later made to account for the electrochemical environment, the so-called thermochemical model. More detailed and reliable calculations involve estimates of the activation energy barrier as well as chemical interaction with solvent molecules, and going beyond the usual generalised gradient approximation for the functional. Such calculations can give significantly different results as has been shown for HER [1], ORR [2] and CO2RR [3,4]. Still, the effect of the dielectric solution and the role of dissolved ions remains elusive [5] and calls for methodology that can be used for larger systems and longer time scale, such as hybrid simulations where the central part of the system is described using electronic structure theory while the rest is described with a potential energy function that includes polarisation [6]. Several results of ORR and CO2RR calculations will be presented and the various levels of theory compared in order to identify what is required to obtain reliable results of electrocatalysis by electronic structure calculations and rate theory.

A Stable Lithium Metal Anode Interface via a Gelatin-Based Separator YaqinHuang; Beijing University of Chemical Technology, China

Lithium metal is regarded as one of the most promising anode materials, owing to its high theoretical specific capacity and ultra-low redox potential. However, non-uniform charge distribution at the electrode-electrolyte interface induces the growth of metallic lithium dendrites, leading to low coulombic efficiency and poor cycle stability of the lithium metal anode. Herein, with gelatin as a structural material, a fibrous separator was prepared and based on which a stable interface was constructed. The gelatin-based separator shows outstanding adhesion to the lithium anode and tolerance to stress. Besides, the evenly distributed charged groups on the gelatin chain facilitated the uniform distribution of charge/current on the electrode-electrolyte interface, which further inhibited the growth of lithium dendrite. The Li||Li cell with gelatin-based separator shows much-enhanced cycling stability with minimal overpotential. These results provide a new strategy for high-performance lithium metal anode and open a new opportunity for the application of lithium metal batteries.

8:30 AM *EN10.10.03
Tuning the Bio/Electrode Interface for Direct Bioelectrocatalysis Shelley DMinteer; Missouri University of Science and Technology, United States

Oxidoreductase enzymes are of interest in the electrochemical energy conversion field, because they catalyze important transformations (oxygen reduction, hydrogen oxidation, hydrogen evolution, nitrogen reduction, carbon dioxide reduction, etc.) at low overpotentials. However, there are challenges interfacing oxidoreductase enzymes with electrode surfaces to promote electron transfer between the enzyme catalyst and the electrode. Therefore, mediators or mediated electron transfer is typically utilized, but it results in substantial potential inefficiencies. In this paper, we will discuss polymer design for providing an ideal interface for maintaining the activity and preventing denatures of oxidoreductase enzymes at the electrode interface. We will discuss the use of biocompatible linear polyethyleneimine hydrogels and hydrophobic modifications to tailor the interface for direct bioelectrocatalysis.

9:00 AM EN10.10.04
Revealing of Effects of Surface on Nickel-Rich Layered Cathodes Enabling High-Performance Lithium Rechargeable Batteries by Preventing Irreversible Phase Transition MerryLee[1], Hyung MoJeong[1] and Ji HoonLee[2]; [1]Sungkyunkwan University, Korea (the Republic of); [2]Kyungpook National University, Korea (the Republic of)

With the increasing demand for high-performance lithium (Li) rechargeable batteries, nickel (Ni)-rich layered cathodes which have chemical formula of $LiNi_xCo_yMn_zO_2$ (x>0.8, x+y+z=1) have attracted attentions; however, the capacity fade is their main obstacle for commercializing high-quality cathodes as a trade-off of high-capacity as increased amount of Ni which has a high redox capability. One of the main reasons is caused by that Ni can easily diffuse into vacant site of Li during charging process because of similar ionic radius each other. This makes Ni-rich layered cathodes undergo irreversible phase transition resulted from Li-moving blockage when they naturally change their phase into hexagonal H1, H2, and H3 sequentially as a level of Li-extraction during charge and H3, H2, and H1 as a level of Li-insertion again during discharge. To suppress this culprit in degradation of Ni-rich layered cathodes, previous studies have tried to solve this issue through a lattice doping with other elements; incompletely, this strategy cannot solve much important surface-triggered Li-moving blockage. Moreover, since the surface is more susceptible to unwanted side reactions by directly contacting with electrolytes, the surface can seriously influence on degradation of Ni-rich layered cathodes. In this study, we created selectively functionable surface on Ni-rich layered cathodes by utilizing unconventional materials, enabling Li-ion to move easily and smoothly in and out through the Ni-rich layered cathode. This newly created surface on the Ni-rich layered cathode was investigated through various analysis for understanding its effects on electrochemical performances when the cathode was composed in Li rechargeable batteries. Notably, in situ synchrotron X-ray diffraction (in situ synchrotron XRD) spectroscopy and ex situ X-ray absorption fine structure (ex situ XAFS) spectroscopy revealed that the new surface induced the Ni-rich layered cathode not to undergo irreversible phase transition during charging and discharging process. In addition, spherical aberration-corrected scanning transmission electron microscopy (Cs-corrected STEM) and further electrochemical analysis techniques also supported the abovementioned findings. With the aid of these affirmative effects, our cathode showed increased capacity of 218.42 mAh g^{-1}, improved rate capability of having capacity of 128.65 mAh g^{-1} at 5C, and superior cycle performance of having capacity of 177.65 mAh g^{-1} after 300 cycles with the capacity retention of 91.7%. This remarkable electrochemical performance was obviously contrasting results of that of pristine cathode, which was capacity of 192.51 mAh g^{-1}, rate capability of having 72.21 mAh g^{-1}, and cycle performance having capacity of 127.03 mAh g^{-1} after 300 cycles with the capacity retention of 77.2%. This research shines on the complex surface-triggered degradation phenomena on Ni-rich layered cathodes with the concrete interpretation, suggesting a solution of creating a new functionable surface.

Exploring Catalytic Active Sites in Covalent Organic Frameworks for Oxygen Evolution Reactions Seyed PouyaHosseini Yazdeli[1], AndrésRodríguez-Camargo[2], LiangYao[2], BettinaV.

Lotsch[2] and KristinaTschulik[3]; [1]Max-Planck-Institut für Eisenforschung, Germany; [2]Max Planck Institute for Institution Solid State Research Institution, Germany; [3]Ruhr-Universität Bochum, Germany

Enhancing the efficiency and stability of catalysts for the oxygen evolution reaction (OER) is crucial for the advancement of renewable electrochemical energy conversion and storage technologies. The OER process, which plays a pivotal role in emerging technologies like water splitting, suffers from slow kinetics, leading to decreased overall device efficiency [1]. Addressing global energy and environmental challenges necessitates substantial research efforts in improving OER catalysts.

Covalent organic frameworks (COFs) offer great promise as a versatile class of materials with applications spanning multiple domains. These frameworks are constructed from light elements using reversible covalent bonds, resulting in crystalline structures characterized by high surface area, low density, and well-defined channels. Such properties render COFs suitable for a broad range of applications, including gas adsorption, chemical sensing, and heterogeneous catalysis. Furthermore, the facile functionalization of COFs grants them exceptional adaptability and versatility to cater to diverse requirements. [2]

In this study, we assessed the performance of a cobalt-modified bipyridine-based covalent organic framework (Co-TpBpy) as a heterogeneous catalyst for OER under alkaline conditions. To evaluate its effectiveness, we employed techniques such as voltammetry and differential electrochemical mass spectrometry (DEMS). Additionally, operando EC-SEIRAS experiments and post-mortem analyses involving TEM, XPS, XRD, and SEM-EDX were conducted to investigate the structural and compositional changes occurring during OER. The observations revealed the formation of cobalt oxide nanoparticles, serving as active sites for OER catalysis, embedded within the organic framework of Co-TpBpy. This phenomenon led to improved stability and catalytic performance. Our findings suggest that COFs can be utilized as templates to facilitate the uniform distribution of highly active cobalt oxide nanoparticles, thus enhancing the OER process.

Engineering Single Photon Emission and Collective Phenomena with Lead Halide Perovskite Nanocrystals MaksymV. Kovalenko[1,2]; [1]ETH Zurich, Switzerland; [2]Empa–Swiss Federal Laboratories for Materials Science and Technology, Switzerland

Colloidal lead halide perovskite (LHP) nanocrystals (NCs), with bright and spectrally narrow photoluminescence (PL) tunable over the entire visible spectral range, are of immense interest as classical and quantum light sources. Attaining pure single-photon emission is key for many quantum technologies, from optical quantum computing to quantum key distribution and quantum imaging. Across single $CsPbX_3$ NCs (X: Br and I) of different sizes and compositions, we find that increasing quantum confinement is an effective strategy for maximizing single-photon purity due to the suppressed biexciton quantum yield. We achieve 98% single-photon purity (g(2) (0) as low as 2%) from a cavity-free, nonresonantly excited single 6.6 nm $CsPbI_3$ NCs, showcasing the great potential of $CsPbX_3$ NCs as room-temperature highly pure single-photon sources for quantum technologies [1]. In another study, we address the linewidth of the single-photon emission from perovskite NCs at room temperature. By using ab-initio molecular dynamics for simulating exciton-surface-phonon interactions in structurally dynamic $CsPbBr_3$ NCs, followed by single quantum dot optical spectroscopy, we demonstrate that emission line-broadening in these quantum dots is primarily governed by the coupling of excitons to low-energy surface phonons. Mild adjustments of the surface chemical composition allow for attaining much smaller emission linewidths of 35−65 meV (vs. initial values of 70–120 meV), which are on par with the best values known for structurally rigid, colloidal II-VI quantum dots (20−60 meV) [2]. Many-body interactions and exciton complexes are of essential role, for example, for stimulated emission, LED efficiencies, or the single-photon purity in quantum light sources. We studied the size-dependent trion and biexciton binding energies in CsPbX3 NCs of 9-30 nm in size [3]. NC self-assembly is a versatile platform for materials engineering, particularly for attaining collective phenomena with perovskite NCs, such as superfluorescence [4, 5, 6]. The NC shape anisotropy leads to structures not observed with spherical NCs. We present a broad structural diversity in multicomponent, long-range ordered superlattices (SLs) comprising highly luminescent cubic $CsPbBr_3$ NCs (and $FAPbBr_3$ NCs) co-assembled with the spherical, truncated cuboid, and disk-shaped NC building blocks. We also discuss a critical role of the ligand-deformability on the outcome of co-crystallization, or even for the formation of single-component SLs [7]. Perovskite SLs exhibit superfluorescence, characterized, at high excitation density, by emission pulses with ultrafast (22 ps) radiative decay and Burnham-Chiao ringing behavior with a strongly accelerated build-up time.

Excitonic Coupling in Gradually Fluorinated β-Phase Zinc Phthalocyanine LisaSchraut-May[1], KilianStrauß[1], SebastianHammer[2], Luca NilsPhilipp[1], KrzysztofRadacki[1], HolgerBraunschweig[1], RolandMitric[1] and JensPflaum[1]; [1]Julius-Maximilians-Universität Würzburg, Germany; [2]McGill University, Canada

Understanding how the crystallographic structure influences the excitonic properties of novel organic semiconductors plays a crucial role in fundamental research on this material class as well as for its implementation in devices with new functionalities. The class of phthalocyanines provides a perfect model system to study this relationship, as it offers a wide range of different crystallographic phases and the possibility to reliably steer the structural and electronic parameters by gradual fluorination of the molecular ligands [1]. The shift of the respective frontier orbital energies caused by fluorination while, simultaneously, leaving the optical properties almost unchanged has already led to phthalocyanine based devices with advanced functionalities, such as dual emitting organic LEDs or color-switchable subwavelength plasmonic organic light emitting antennas [2,3].

In this contribution, we report on a comprehensive study on the interplay between molecular spacing and excitonic coupling in β-phase zinc phthalocyanine (ZnPc) single crystals. Temperature dependent photoluminescence measurements were performed on non-fluorinated ZnPc, partially fluorinated F_4-ZnPc crystals as well as their co-crystals, all of which grown by horizontal vapor deposition. Our measurements yield clear evidence for a change in the emission characteristics as function of temperature and polarization. For neat ZnPc crystals, a narrow emission of only 20 meV linewidth occurs below about 100 K, which we attribute to a superradiant enhancement caused by the coherent excitation of next neighboring molecules within the crystal lattice perpendicular to the crystallographic b-direction. In contrast, this phenomenon is absent in pure F_4-ZnPc as well as mixed ZnPc:F_4-ZnPc crystals, where already at small admixtures of the fluorinated counterparts, the intermolecular arrangement and coupling is changed in such a way that a coherently coupled state between adjacent molecules is strongly suppressed or energetically less favorable than a coexisting charge-transfer state as in case of the co-crystals. This hypothesis is corroborated by temperature dependent x-ray structural analyses on the investigated crystals in combination with extended theoretical simulations by means of time-dependent DFT, which highlight the role of the anisotropic coupling of the excitonic states and its spatial variation with temperature.

Our results demonstrate the potential inherent to this material class and the possible strategy of tuning the excitonic properties of molecular semiconductors by controlling their crystalline packing via gradual chemical substitution.

Novel Excitons in $MoSe_2$ from Proximitized Charge Density Waves JaydeepJoshi[1,1], BenediktScharf[2], IgorMazin[1,1], SergiyKrylyuk[3], DanielJ. Campbell[4,4], JohnpierrePaglione[4,4,5], AlbertV. Davydov[3,1,4], IgorZutic[6] and PatrickVora[1,1]; [1]George Mason University, United States; [2]University of Wurzburg, Germany; [3]National Institute of Standards and Technology, United States; [4]University of Maryland, United States; [5]Canadian Institute for Advanced Research, Canada; [6]University at Buffalo, The State University of New York, United States

Two-dimensional (2D) materials allow for the construction of heterostructures without the constraint of lattice matching. This increased flexibility enables novel proximity effects through the stacking of strongly correlated 2D materials on 2D semiconductors. Here we use temperature-dependent photoluminescence (PL) microscopy to reveal a new proximity effect where excitons in monolayer $MoSe_2$ interact with the commensurate charge density wave (CDW) in bulk $TiSe_2$ [1]. Below the CDW ordering temperature we observe a new PL emission line (H1) on the $TiSe_2$-$MoSe_2$ interface that is 30 meV higher in energy than the neutral exciton. This observation is unique compared to other examinations of 2D heterostructures where additional spectral features appear at lower energies compared to the neutral exciton. Power and temperature-dependent measurements show that H1 behaves as a free exciton, therefore excluding interface trapping or localization as an explanation. Most interestingly, we find that H1 disappears above the $TiSe_2$ CDW ordering temperature, which suggests that the CDW plays a vital role in activating this previously unobserved exciton. We discuss possible CDW-based origins of H1 and outline future opportunities for using proximity effects to engineer novel excitonic states.

Overcoming the Size Cap of InAs Colloidal Quantum Dots for SWIR Applications TariqSheikh and OsmanM. Bakr; King Abdullah University of Science and Technology, Saudi Arabia

InAs colloidal quantum dots (CQDs) have emerged as potential candidates for infrared (IR) technology due to their exciting optoelectronic and charge transport properties. However, the InAs CQD synthesis demands highly reactive As precursors, which are hard to find commercially. Moreover, these As precursors are highly pyrophoric and also toxic. The lack of suitable As precursors and methodology has also limited the InAs quantum dots to smaller sizes (<7 nm), thus absorbing below 1200 nm only. Here we present a novel synthesis methodology utilizing less reactive and easily available precursors to achieve InAs CQD deep short wave infrared (SWIR) absorbers. The synthesized CQDs easily cross the size barrier, as faced by the InAs CQDs synthesized by conventional methods. The CQDs have a tunable bandgap from 1200 to 1800 nm, thus crossing deep into the SWIR region. These CQDs show high monodispersity and have high crystallinity, which is reflected in their superior excited state properties like sharp excitonic feature and efficient carrier multiplication at low pump fluences and energies. Our synthesis methodology opens up the InAs CQDs for a wide range of SWIR applications.

11:45 AM QT01.01.05
Interfacing Colloidal Er-Doped SiO_2 Thin-Film with p-Type Cz-Silicon For Enhanced Emission via Exitonic-Correlated e-h Recombination SufianAbedrabbo[1], AnthonyT. Fiory[2] and NuggehalliM. Ravindra[3]; [1]Khalifa University, United Arab Emirates; [2]Integron Solutions LLC., United States; [3]New Jersey Institute of Technology, United States

Czochralski silicon (Cz-Si) indirect bandgap has been a hampering point in realizing efficient bandgap emission. In this work, we report our studies of interfacing Cz-Si with Er-doped SiO_2 thin films prepared by sol-gel processes. Colloidal interfacial reactions with Cz-Si surface results in significant improvements in Si bandgap emission. Model fitting the room-temperature photoluminescence spectra indicates correlated carrier recombination interactions; and the random strain fields are theorized to be the cause. Given that the optically active region is estimated to be of similar thickness to the coating thickness, it is anticipated that interfacial excitons are playing a role in shielding the e-h pairs from Auger recombination, thereby increasing the radiative recombination activities. The presentation will include comparative study of the bandgap emission of thermally oxidized Cz-Si with the colloidal prepared spin-coated silica on Cz-Si.

The Surface Chemistry of Halide Perovskite and Perovskite-Related Nanocrystals LiberatoManna; Instituto Italiano di Tecnologia, Italy

Halide perovskite semiconductors can merge the highly efficient operational principles of conventional inorganic semiconductors with the low temperature solution processability of emerging organic and hybrid materials, offering a promising route towards cheaply generating electricity as well as light. Following a surge of interest in this class of materials, research on halide perovskite nanocrystals (NCs) has gathered momentum in the last years. While most of the emphasis has been put on led-based perovskite NCs, more recently the so-called double perovskite NCs, having chemical formula $A^+_2B^+B^{3+}X_6$, have been identified as possible alternative materials, together with various other metal halide structures and compositions, often doped with different elements. This talk will discuss the synthesis efforts of our group towards all these materials and our current understanding of their surface chemistry. I will highlight how for example halide double perovskite NCs are less surface tolerant than the corresponding Pb-based perovskites. Other topics that will be covered are the role of ligands, exogenous cations and

acid-base equilibria on stabilizing the NCs and controlling their size and shape evolution.

2D Perovskite: Exciting Playground for Exciton and Polaron Studies PaulinaPlochocka; CNRS, France

High environmental stability and surprisingly high efficiency of solar cells based on 2D perovskites have renewed interest in these materials. These natural quantum wells consist of planes of metal-halide octahedra, separated by organic spacers. The unique synergy of soft lattice and opto-electronic properties are often invoked to explain superior characteristic of perovskites materials in applications. At the same time such unique synergy creates fascinating playground for exciton physics which challenges our understanding of this elementary excitation. I will demonstrate that even after decade of intense investigation the notation" unique" so often used in case of perovskites deserves serious scrutiny.
First, I will show that in 2D perovskites, the distortion imposed by the organic spacers governs the effective mass of the carriers. As a result, and unlike in any other semiconductor, the effective mass of the carriers in 2D perovskites can be easily tailored. Secondly, I will highlight controversy related to exciton fine structure in different perovskite compounds and demonstrate that the soft lattice can suppress relaxation of excitons to dark state making 2D perovskites great light emitters. I will further demonstrate the optical evidences of the polaron formation.
In the end I will present excitonic properties in novel type heterostructures: a combination of the monolayer transition metal dichalcogenides with layered organic inorganic perovskites, where spin injection into 2D perovskites has been acheived.

Origin of Broadband Emission in Low Dimensional Halide Perovskites DineshKabra; Indian Institute of Technology Bombay, India

In this talk, I will provide an overview on research activities of our research group with emphasis on electroluminescent devices. Majority of this work is focused on molecular semiconductor and halide perovskites. In this talk I would show results of single junction OLEDs, single color tandem OLEDs and color tuneable vertically stacked tandem OLEDs. Further, triplet excitons are key aspects to enhance the efficiency and hence understanding triplet excitons is key for the success of these devices. Which will be further extended to halide perovskites too.
Here in this talk, we will discuss the origin of broadband illumination and other emission peaks using temperature-dependent time-resolved photoluminescence (PL) spectra of 2D layered halide perovskites semiconductors. For temperatures below 100 K, $(PEA)_2PbBr_4$ film gives broad PL emission, stoke shifted by 750 meV from narrow exciton emission peaks, whereas $(PEA)_2PbI_4$ film does not show any broad emission. Kinetics of various peaks could provide useful insight to propose a consistent energy level scheme associated with a barrier (PEA) and well (PbX_6^{4-}) material system's electronic states. This broad emission in $(PEA)_2PbBr_4$ perovskite is observed due to coupling of electronic states in inorganic well part and organic barrier part, which is in contrast to a proposed model based on self-trapped-exciton.

Excitons in the Layered Magnetic Semiconductor CrSBr JulianKlein; Massachusetts Institute of Technology, United States

Materials with a correlated degree of spin, lattice, and charge are attractive platforms for the study of fundamental magneto-correlated phenomena and for realizing spin-based devices for spintronic applications. Such physics was initially explored in dilute magnetic semiconductors; however, their structural inhomogeneity limited their study. Fortunately, such ideas transfer to the emerging class of layered magnetic semiconductors with chromium sulfide bromide (CrSBr) as a prime candidate for such explorations. Unlike dilute systems, materials such as CrSBr are structurally homogenous and benefit from the well-known property enhancements that layered materials exhibit. In this unique combination, new opportunities arise for the study of a breadth of quasiparticle excitations immersed in magnetic environments.
In my talk, I will elaborate on the rich excitonic physics of CrSBr and showcase new opportunities for its control. I will start by showing that CrSBr is a quasi-1D material. The extreme anisotropy is manifested in its excitons, electronic band structure, a Peierls-like structural instability, and strong exciton-phonon and electron-phonon interactions. [1] As such, CrSBr is best rationalized as a stack of weakly coupled monolayers, each hosting tightly bound quasi-1D excitons. Second, I will discuss the crystal defects in CrSBr and provide a link to their optical emission properties. In particular, I will discuss the correlation of defects with a defect-magnetic order. [2] Lastly, I will demonstrate that CrSBr is an exceptional material for the controlled generation of crystal defects using a focused electron beam. [3] I will provide an outlook and motivate this as a key ingredient for controlling quasiparticle excitations and magneto-correlated phenomena one atom at a time.

Strongly Bound Excitonic States and the Exciton Dispersion of the Layered Semiconductor BiI_3AlejandroMolina-Sanchez and JorgeCervantes-Villanueva; University of Valencia, Spain

BiI_3 is a layered semiconductor with extraordinary excitonic effects in the visible range of the optical spectra, both in the case of bulk and monolayer systems. The excitonic binding energy of bulk is to that of the paradigmatic monolayer MoS_2 and the BiI_3 monolayer has even a higher excitonic binding energy, of more than 0.5 eV. The lower dielectric screening of this trihalide material explains in part these extraordinary exciton binding energy. Therefore, this layered material has a great potential for the design of optoelectronic devices and the realization of the experiments looking for exciton physics. In addition to the interesting excitonic properties, BiI_3 is also remarkable for the strong spin-orbit interaction, which makes the material suitable to have a strong Rashba effect under electric field or to tune the spin properties using magnetic proximity effects.
In this work we present a theoretical study of the electronic and optical properties of BiI_3 bulk and monolayer, within the framework of ab initio many-body perturbation theory, using the GW method and the Bethe-Salpeter Equation. We analyze the excitonic states, the influence on the spin properties of magnetic proximity effect and the possibilities to generate Rashba effect on BiI_3 monolayers. We analize also the exciton dispersion of BiI_3 bulk and monolayer, of importance to understand the exciton dynamics. Our results are very promising for experiments like time-resolved angle-resolved photoemission and other time-resolve spectroscopies.

High-Lying Excitons and Excitonic Quantum Interference in 2D Semiconductors KaiqiangLin; Xiamen University, China

Two-dimensional transition-metal dichalcogenides (TMDCs) show a wealth of exciton physics. We present the existence of a new excitonic species, the high-lying exciton (HX), in transition metal dichalcogenide monolayers with almost twice the band-edge A-exciton energy and with a linewidth as narrow as that of band-edge excitons [1]. The HX is populated through momentum-selective optical excitation in the K-valleys, and is identified experimentally in upconverted photoluminescence (UPL) and theoretically in *ab initio GW*-BSE calculations. These calculations suggest that the HX is comprised of electrons of negative effective mass. The coincidence of such high-lying excitonic species at around twice the energy of band-edge excitons rationalize the efficient exciton-exciton annihilation in TMDC monolayers, and enables the excitonic quantum-interference phenomenon revealed in optical second-harmonic generation (SHG) [2]. We probe the excitonic temporal dynamics in such three-level system through time-resolved sum-frequency generation (SFG) and four-wave mixing (FWM) [3]. High-lying

excitons in bilayer WSe_2 can be largely tuned by twisting [4], electrical gate [5] and Stark effect, which gives control over the excitonic quantum interference and the corresponding optical nonlinearity.

Spatially Indirect Interfacial Excitons in c-Oriented n-ZnO/p-GaN Heterostructures SubhabrataDhar, SimranArora and AmandeepKaur; Indian Institute of Technology Bombay, India

Zinc oxide (ZnO) with wide direct band gap (3.37 eV) and large excitonic binding energy (~60 meV) has significant prospects in UV optoelectronics. However, stable p-type doping is a big challenge. Recently, there are efforts to study ZnO/GaN np-heterojunctions as GaN, which is a semiconductor with a direct band gap of ~3.5 eV, has a very close lattice matching with ZnO and can be controllably doped p-type. A type-II band alignment at the interface is expected between the two materials. Moreover, the difference in spontaneous polarizations along the c-direction for the two semiconductors can result in a net positive polarization charge at the interface. We have shown theoretically that the combination of the two effects can lead to the formation of a unique type of spatially indirect excitons (SIDXs) at the n-ZnO/p-GaN interface. While the electron part of such excitons is quantum confined along c-direction in the ZnO side, the hole part stays at the GaN side of the junction[1]. Like interlayer excitons reported in homo-/hetero-bilayers of transition metal dichalcogenides (TMDs), these excitons have planer nature with finite dipole moment along c-direction. Unlike conventional direct excitons, SIDXs can interact repulsively with each other through dipole-dipole coupling, which should favour Bose-Einstein condensation (BEC). Though, BEC of the excitons has long been anticipated theoretically, its experimental demonstration remains to be elusive until now. Moreover, due to the spatial separation between the electrons and holes, SIDXs are expected to have lifetime much longer than that of the conventional direct excitons. Long lifetime means that the excitons can travel long distances before annihilation. The added advantage of the present system is that the lifetime of the SIDXs is expected to be controlled by applying bias across the junction. Note that the longer is the survival of the excitons, better would be the scope for controlling their spins. Long lifetime of the excitons as well as a control over their lifespan are essential for the development of exciton-based logic circuits, which are supposed to be better than the electronic devices in terms of the energy efficiency and compatibility with the optical communication. Experimentally, we investigate the behaviour of electroluminescence (EL) as a function of applied bias at different temperatures in pn-heterojunctions consisting of c-oriented n-ZnO layer grown epitaxially on p-type c-GaN/sapphire templates [1]. In certain samples, where the acceptor concentration in GaN is more than a critical value, an EL peak is found at low temperatures, which shows a redshift with increasing forward bias. Our study assigns this peak to the SIDXs. Binding energy of these excitons can be significantly increased by changing the applied bias and can even be made larger than that of ZnO bulk. We also study the time dynamics of electroluminescence (EL) in these heterostructures. EL is found to have an extremely slow rise (decay) time (hundreds of milliseconds). Our study finds a strong connection between the existence of SIDXs and the extraordinarily slow EL rise(decay) property observed in these structures. The effect can thus be attributed to the SIDXs, meaning that the lifetime of SIDXs in this system must be hundreds of milliseconds and the lifespan can be controlled by external bias. All these features make ZnO/GaN pn-heterojunction system a unique platform not only to study the physics of excitonic Bose-Einstein condensation but also to investigate the transport of the excitonic spin and its manipulation via electrical means towards the realization of exciton-based electronics.

Self-Hybridized Polaritons in a Van der Waals Magnet Pratap ChandraAdak, BiswajitDatta, SichaoYu and VinodMenon; City College of New York, United States

Recent discoveries of van der Waals magnetic materials have opened up new possibilities for exploring magnetic order in reduced dimensions, with implications for quantum phenomena and device applications. Among these materials, CrSBr stands out as a promising candidate. It consists of monolayer ferromagnets stacked into an A-type antiferromagnetic structure and exhibits a high Neel temperature. Furthermore, as a semiconductor with strong coupling between excitons and magnetism, CrSBr provides a novel platform for optical manipulation of its magnetic properties. With tightly-bound excitons and large oscillator strength, CrSBr supports strong light-matter coupling, leading to the formation of polaritons—hybrid quasi-particles formed by the coupling of excitons and photons. Our study focuses on self-hybridized polaritons in CrSBr samples, capitalizing on the material's high refractive index to achieve strong light confinement without external mirrors. In particular, we utilize polarization-resolved photoluminescence excitation (PLE) spectroscopy to comprehensively investigate the anisotropic properties of CrSBr. Our work sheds light on the light-matter coupling in CrSBr, offering insights for optically accessible device applications in spintronics and magnonics.

Exciton Evolution by Singlet Fission and Excimer Formation in DNA-Semiconductor π-Stacks JeffreyGorman[1,2], SarahOrsborne[1], FlorianAuras[1] and RichardH. Friend[1]; [1]University of Cambridge, United Kingdom; [2]MIT, United States

Natural photosystems control sub-nm interchromophore coupling using a protein scaffold to evolve remote singlet excitons into free charges at the reaction centre. Nature must achieve this with a limited set of pigments, necessitating exquisite control over excitonic coupling. In contrast, traditional organic electronic devices lack such nano-structural fidelity. This has limited our understanding over electronic coupling and our ability to optimize condense-phase organic semiconducting aggregates. To address this disparity, we have developed efficient methods for the insertion of perylene diimides or pentacenes into DNA.[1,2] DNA's selective self-assembly yields size-defined aggregates of pseudo-1D π-stacked organic semiconductors. We selectively program size and exciton delocalization to vary from isolated monomers up to strongly coupled pentamers.

We characterize excited evolution using transient absorption and spin resonance spectroscopy, we track the evolution of singlet excited states in our aggregates, showing results are well-matched to traditional—but disordered—thin films. In size-controlled pentacene monomers, the excited singlet state remains localized to single chromophore. In larger pentacene assembly size we observe singlet exciton evolution <0.5 ps triplet formation by singlet fission. We interrogate this process further using cryogenic transient electron spin resonance spectroscopy. This reveals the initial singlet exciton evolves into a bound triplet pair quintet state (ca. 0.5 μs), which subsequently converts into free triplets. Interestingly, we can tune the rate of singlet fission through DNA programmed assembly alone. In the case of perylene diimides, we can controllably tune the extent of excimer formation as a function of DNA-directed aggregate size. These results point towards a more rational design process for organic semiconductor clusters, where kinetics can be tuned through extrinsic assembly rather than chemical change to the semiconductor skeleton. Our modular DNA-based assembly offers real opportunities for the rapid development of bespoke semiconductor architectures with molecule-by-molecule precision, a material 'toolbox' for spectroscopic study.

Tuning the Interlayer Exciton in Bilayer MoS_2 by Means of Self-Assembled Monolayers MostafaShagar[1], ChristianImperiale[2], FelixThouin[2], LucaRazzari[1], StephaneKena-Cohen[2] and EmanueleOrgiu[1]; [1]Institut National de la Recherche Scientifique, Canada; [2]Polytechnique Montréal, Canada

The field of study surrounding Transition Metal Dichalcogenides (TMDs), a class of two dimensional materials that can be exfoliated down to a single molecular level, has recently seen large improvements and advancements. Whether in the of study of monolayer properties or in the various possibilities that stacking different materials as heterostructures allow for. However, one interesting application of these materials is in their natural homobilayer form. For example, in molybdenum disulfide (MoS_2), there exists an interlayer exciton that emerges purely out of the interlayer interaction inside the natural homobilayer.

This exciton is unique in its ability to couple to its environment due to having both strong in-plane and out-of-plane dipole sensitivity. This project attempts to leverage this sensitivity by utilizing self-assembled organic monolayers (SAMs), a method of dielectric tuning that is not commonly used for two dimensional materials. Our SAM is formed by a monolayer of non-conjugated organic molecules that spontaneously assemble and are covalently tethered to a substrate. By using SAMs with a strongly dipolar functional group, it is possible to create an effective electric field across the homobilayer to couple with the interlayer exciton without external electrical bias [1] or optical pumping.

In this project, we use SAMs with different dipole moments and sign. These molecules will form SAMs with a very strong electrostatic dipole (of opposite signs) in the vertical direction which makes them prime candidates for exerting a local electric field to the bilayer MoS_2. We then perform optical reflectance measurements in order to directly probe the interlayer exciton and the effects of the SAM interface.

We observed a clear reorganization of the excitonic properties of the MoS_2 and a splitting of the interlayer exciton due to the existence of an external electric field causing Stark splitting. We also observed a very strong dependence on annealing on our structures, where the existence of randomly oriented water dipoles completely screens the effect of the SAM dipole on the

MoS_2 exciton.

Additionally, Angle Resolved Photoemission Spectroscopy (ARPES) is being performed in order to better understand the band structure of the coupled system. This method of interfacing organic molecules to TMDs is vastly unexplored and opens a new range of possibilities for materials by using two classes of materials both known for theirversatility. The development of bias free local tuning of TMDs that is easily deposited on a wide array of substrates offers a unique set of advantages compared to typical coupling methods such as depositing contacts, doping or coupling to optical cavities.

Plexcitons for Solar Energy Harvesting and Sensing Devices KarthikShankar; University of Alberta, Canada

Excitons and plasmons are both quantum quasiparticles. While excitons are bound electron-hole pairs, plasmons are the collective and coherent oscillations of conduction band electrons (typically in coinage metals) at metal-dielectric interfaces. Plasmons can interact with excitons in several different ways. When plasmonic and excitonic resonances are spatially and energetically close to one another, the two resonators can be strongly coupled. The strong coupling regime is characterized by a significant Rabi splitting and anti-crossing behavior. Strongly coupled plexcitonic states are entangled quantum systems which can be used to construct quantum sensors. Plasmons and excitons can also be weakly coupled to each other. The weak coupling regime is characterized by an anomalously broadened absorption band, and is particularly beneficial in light harvesting devices such as solar cells, photodetectors and photocatalysts. The Shankar Lab has found that strongly coupled plexcitons in gold nanoparticle (NP)-cyanine dye J-aggregate assemblies are excellent platforms for chemical sensing due to their sensitivity to the dielectric permittivity. The Rabi splitting (as large as 217 meV) decreases upon exposure to humidity and eventually disappears as the plexcitonic interaction moves into the weak coupling regime. Once humidity is expelled, the large Rabi splitting is recovered. Plasmons and excitons also interact through the PIRET effect, which stands for plasmon-induced resonance energy transfer, a plasmonic analog of the more well-known Förster resonance energy transfer. The PIRET effect involving Au NP plasmons and excitons in n-type carbon nitride NPs enabled a huge improvement in photoelectrochemical water-splitting performance, achieving a photocurrent density as high as 3 $mAcm^{-2}$.

10:45 AM *QT01.04.02
Design of Dimer, Oligomer and Polymer Acceptors for Efficient and Stable Organic Solar Cells BumjoonKim; Korea Advanced Institute of Science and Technology, Korea (the Republic of)

High power conversion efficiency (PCE) and long-term stability are important requirements for commercialization of organic solar cells (OSCs). Small-molecule acceptors (SMAs) are the core materials that have led to remarkable advances in the PCEs of the OSCs, but the resulting OSCs typically have poor long-term stability. The low glass transition temperatures (T_gs) and rapid diffusion of SMAs owing to their small molecular sizes are recognized as the main causes of the poor stability of OSCs. In addition, the PCEs of OSCs are still lower than those of other types of photovoltaic devices, such as perovskite solar cells, mainly because of their relatively low open-circuit voltage (V_{oc} < 0.90 V). In this talk, we present the development of different dimer and oligomer acceptors for improving the V_{oc} and PCE values of the OSCs. Interestingly, dimer and oligomer acceptors have significantly higher T_g and lower diffusion coefficient compared to SMAs, which enhances the photo and thermal stabilities of the OSCs. Finally, by adding the examples of polymer acceptors, we discuss the impact of molecular sizes of acceptors in the device stabilities and mechanical properties of the OSCs.

11:15 AM QT01.04.03
Photon Upconversion in 'FuLEDs' and in Hybrid Materials LeYang[1,2]; [1]Institute of Materials Research and Engineering A*STAR, Singapore; [2]National University of Singapore, Singapore

Triplet-triplet annihilation (TTA) enables photon or energy upconversion in organic semiconductors – advantageous in that they are more efficient in the upconversion process and that they are more versatile in the visible light range. The same photophysical process of TTA, when occurring in a electronic device (an OLED), also known as triplet fusion, is one strategy to enhance the device efficiency from typical fluorescent emitters by utilising all the triplet "dark" states. In this talk, we will explore 2 main ideas, exploring the process of TTA across optically-excited systems (in photon upconversion) to electrically-excited systems (in triplet fusion enhanced 'FuLEDs').
Firstly, for functionally viable single-colour organic light emitting diodes (OLEDs), we believe they must satisfy three criteria: efficiency, lifetime, and colour (sharpness, gamut). However, for the significant advances in device efficiencies achieved in new classes of emitters (phosphorescence, TADF), they often tend to have less decent stability and colour sharpness. We have demonstrated strategies in lifting the device efficiencies of simple fluorescent systems.[1,2] This includes single-dopant triplet fusion enhanced OLEDs ('FuLEDs').[3,4] We also advocate that all (blue) TTA upconverters will make suitable (blue) FuLED emitters. This is because we are utilising the same photophysical process in both cases, and that TTA/triplet fusion is a naturally energetically uphill process, encouraging high-energy emission, and thus suitable for blue or deep-blue higher efficiency OLEDs.[4]
Lastly, we turn our attention to a new system of TTA-upconversion, using perovskite nanocrystals as triplet sensitizer and a nested, Russian-doll-like system of two TTA upconverters, to achieve a much enhanced photon upconversion.[5] We provide available experimental data to speculate on possible pathway for this enhancement.

11:30 AM QT01.04.04
Monolayer WS_2 Electro- and Photo-Luminescence Enhancement by TFSI Treatment AlissonR. Cadore; Brazilian Nanotechnology National Laboratory, Brazil

Light-emitting diodes (LEDs) based on layered material heterostructures (LMHs) allow the fabrication of electroluminescent (EL) devices operating in the visible spectral region. A major advantage of LMH-LEDs is that the EL emission wavelength can be tuned among different types of exciton complexes by controlling the charge density. However, these devices display EL quantum efficiency, i.e. the ratio between emitted photons and injected electrons, as low as ~10^{-4}%, and mostly limited by non-radiative recombination processes. Here, we perform EL measurements before and after chemical treatment with superacid TFSI in monolayer WS_2-LEDs. We demonstrate that TFSI boosts the EL emission by over one order of magnitude at room temperature. Moreover, we observe that non-treated devices emit light mainly from negatively charged trions, while the emission in TFSI-treated WS_2-LEDs predominantly involves radiative recombination of neutral excitons due to activation of trapping states in WS_2. We then present simulations and modeling of the integration of LMH-LEDs with photonic cavities for further enhancement of EQE. Our observation opens up a route to obtain more efficient and tunable LMH-LEDs, unveiling additional insights into the nature and behavior of the exciton dynamics in the TFSI-treated TMDs, as well as suggesting an additional route towards LEDs engineering [1].

Improving Substrate Mode Outcoupling in Organic Light-Emitting Diodes on Polymer Microlens Arrays with Very Low Index Coatings ClaireArneson, HafizK. Sheriff and StephenR. Forrest; University of Michigan, United States

Increasing the external efficiency of organic light-emitting diodes (OLEDs) is essential for their use in mobile applications where battery life is a primary concern. However, an even more

important consideration is that the device reliability is improved by increased efficiency since the OLED can be operated at a lower current to achieve the same luminance. [1] OLEDs can achieve internal quantum efficiencies as high as 100% using either phosphorescence or thermally activated delayed fluorescence. However, the external quantum efficiency for OLEDs are ~ 20% for devices grown on planar glass substrates, as the majority of photons are coupled to modes trapped within the device. Approximately 40% of photons, which are emitted from a high-index organic layer with n~1.7, are trapped within waveguide and substrate modes because of the index mismatch between these layers and the substrate, and between the substrate and air. In this work, we introduce a new, and potentially inexpensive and scalable method to improve on existing sub-electrode and conventional external microlens-array (MLA) technology by incorporating optically designed low-index coatings on the MLA surface to achieve substrate mode outcoupling efficiencies approaching 100%. We use porous thin organic and ALD films on the polymer MLA surface to achieve refractive indexes from 1.5, matching with glass, to 1.1, approaching that of air. Through the use of outcoupling structures external to the organic device stack, and that exhibit no wavelength or viewing angle dependence, we demonstrate a method for achieving high-efficiency devices with applicability in both lighting and display applications.

SESSION QT01.05: Device Applications of Excitons II
Session Chairs: Sudeshna Chattopadhyay and Karthik Shankar
Tuesday Afternoon, November28, 2023
Sheraton, Fifth Floor, Public Garden

2:00 PM *QT01.05.01
Photophysics, Photochemistry and Optoelectronics of Singlet Fission Organic Materials in Microcavities WinstonGoldthwaite[1], RoshellLamug[1], GinaMayonado[1], AhasanUllah[1], JohnAnthony[2], L.-J.Cheng[1], MattW. Graham[1] and OksanaOstroverkhova[1]; [1]Oregon State University, United States; [2]University of Kentucky, United States

Organic (opto)electronic materials have been explored in a variety of applications in electronics and photonics, driven by several advantages over traditional silicon technology, including low-cost processing, fabrication of large-area flexible devices, and widely tunable properties through functionalization of the molecules. Over the past decade, remarkable progress has been achieved in understanding physical mechanisms and in developing guidelines for the material design, which boosted the performance of organic devices that rely on photophysics and/or (photo)conductive properties of the material. However, further improvements in device performance are desirable, and challenges related to (photo)stability of organic devices need addressing.
One of the major thrusts in developing new organic materials and device concepts has focused on materials exhibiting singlet fission, which is a carrier multiplication process which would enable, for example, enhanced power conversion efficiencies in solar cells. Nevertheless, fundamental questions pertaining to exciton physics in singlet fission materials, and how it can be manipulated by material design and external parameters, remain. Some of these questions will be addressed in this presentation using model singlet fission organic materials, exemplified by functionalized acene and anthradithiophene derivatives, and combinations of photoluminescence and ultrafast transient absorption time-resolved spectroscopy carried out in a broad range of temperatures and magnetic fields.
Strong exciton-photon coupling that occurs when an organic film is placed in a microcavity, enabling formation of a light-matter hybrid state (polariton), presents a largely unexplored opportunity to control photophysics, photochemistry, and optoelectronic characteristics in existing singlet fission materials and devices by using polaritons. This presentation will summarize our efforts aiming to understand and tune exciton polariton properties in model singlet fission organic materials, towards exploiting these properties in optoelectronic devices and controlling photochemical reactions directly relevant to photostability.

Exciton-Polaritons Facilitated Photogeneration and Charge Carrier Transport in Solution-Processed Cavity Organic Solar Cells YahuiTang[1,2], AlexandraStuart[1], Timothyvan der Laan[2] and GirishLakhwani[1]; [1]The University of Sydney, Australia; [2]Commonwealth Scientific and Industrial Research Organisation, Australia

Strong light-matter coupling in organic solar cells (OSCs) has recently shown great potential in increasing the power conversion efficiencies of light. [1–4] Strong light-matter coupling creates new hybrid states termed exciton-polaritons, and the formation of polaritons in OSCs can significantly influence device performance. It has been shown in thermally evaporated planar heterojunction OSCs that exciton-polaritons can reliably exist at room temperature and leads to more efficient energy transfer.[1] Yet, it has not been demonstrated for solution-processed bulk-heterojunction OSC devices, whereas the latter is more scalable for practical applications. Here, we report that exciton-polaritons can reliably exist in solution-processed bulk-heterojunction OSCs and their influence on device properties. Combining time-resolved spectroscopic measurements for thin films and transient photocurrent/photovoltage decay measurements for devices, we investigated the photo- and device physics of cavity OSCs. We find that the benefits of strong coupling to OSCs are two-fold. Firstly, the charge photogeneration through the new pathway facilitated by the exciton-polaritons is enhanced compared to the reference OSC devices. Secondly, we find that the energy of the charge transfer state is blue-shifted, accompanied by the longer charge carrier lifetime observed in the transient photovoltage decay measurements. Our work demonstrates that strong coupling is a promising avenue for further improving the device properties of OSCs.

Analysis of Interfacial Charges by Spontaneous Orientation Polarization in the Co-Host EML Organic Light-Emitting Diodes with Impedance Spectroscopy So-YoungBoo, AkeemRaji, Jae-YongPark, SomiPark, Eun-JeongJang, JongheeLee and Jae-HyunLee; Hanbat National University, Korea (the Republic of)

Organic light-emitting diodes (OLED) consist of a multi-layer such as hole injection layer (HIL), hole transport layer (HTL), emission layer (EML), electron transport layer (ETL), and electron injection layer (EIL) between two electrodes. By applying an external voltage, electrons and holes are injected and transported from the respective electrodes, resulting in light emission in the EML. In OLED, the presence of interfacial charges at the organic interface allows charge injection before applying voltage to the device. This property can be originated from the permanent dipole moment (PDM) of organic molecules. Most organic molecules used as electron transport layer, such as 2,2',2"-(1,3,5-Benzinetriyl)-tris(1-phenyl-1-H-benzimidazole) (TPBi) and tris-(8-hydroxyquinoline)aluminum (Alq_3), and 4,6-Bis(3,5-di(pyridin-3-yl)phenyl)-2-methylpyrimidine (B3PyMPM) possess PDM, aligned spontaneously during the vacuum deposition process. The non-vanishing net aligned PDM, known as spontaneous orientation polarization (SOP), induces interfacial charges and affects charge injection properties. When the electron transport material of ETL forms a positive SOP against the cathode, the ETL shows negative interfacial charge (NIC) at the EML/ETL interface, influencing hole injection. Consequently, holes are injected and accumulated before the applying voltage to the device, and it can be shown in the capacitance-voltage (C-V) characteristics as the transition voltage (V_t). However, holes injected by NIC can lead to exciton-polaron quenching (EPQ) within the emissive layer. Therefore, it is important to understand the interface characteristics where holes accumulated by NIC. In this presentation, we investigated the difference in charge accumulation property caused by SOP at the ETL/EML interface in co-host EML OLED using impedance spectroscopy (IS). IS was employed to analyze the accumulation and transportation of charges in the co-host EML OLED.

External Radiative Efficiency of Organic Semiconductor Materials Doped with Organometallic Phosphors JinyuChong; Rutgers, The State University of New Jersey, United States

Organic photovoltaics (OPVs) can have certain desirable properties, such as, lightweight, adjustable bandgap, semitransparency, low toxicity, and solution processability, that differentiate them from inorganic and perovskite solar cells. However, the current record efficiency of OPVs (~19%) is still less than for many other solar cell technologies, which limits their application. Shockley-Queisser theory helps to elucidate the efficiency limit of a solar cell, and it assumes that the highest efficiency can be achieved when the external radiative efficiency (ERE) of the solar cell is equal to unity. ERE quantifies the radiative recombination of excitons under total dark current recombination. For the power conversion efficiency (PCE) of solar cells, the best performing solar cells display high EREs due to low nonradiative recombination. One major nonradiative loss pathway in OPVs that suppresses ERE, and hence PCE, is non-emissive triplet states in organic semiconductors.
In this work, we introduce organometallic phosphors into organic semiconducting donor:acceptor OPV films with the goal of converting non-emissive triplet states into emissive

phosphorescence and, thereby, increasing ERE. An iridium-based organometallic phosphor with a low triplet energy level, tris(1-phenylisoquinoline) iridium, $Ir(piq)_3$, is incorporated into bilayer OPV films composed of polyfluorene polymers - poly(9,9-di-n-octylfluorenyl-2,7-diyl), PFO, as the electron donor, and poly(9,9-dioctylfluorene-alt-benzothiadiazole), F8BT, as the electron acceptor. The photophysical properties of PFO, F8BT and PFO/F8BT donor:acceptor bilayer films with $Ir(piq)_3$ phosphor doping are studied. Additionally, both OPV and photodetector devices are fabricated and tested with and without $Ir(piq)_3$.
Photoluminescence (PL) spectroscopy confirms that photoexcitation of PFO/$Ir(piq)_3$ films results in efficient triplet exciton transfer from PFO to the triplet state of the $Ir(piq)_3$ phosphor. In addition, when the phosphor doping concentration is increased, there is an increase in PL quantum yield (PLQY), from 38% to 56%, attributed to reduced nonradiative recombination from the PFO triplet state. In contrast, the PLQY of PFO/F8BT and [PFO/$Ir(piq)_3$]/ F8BT bilayer films decreases with increasing doping concentration, which indicates that the photogenerated triplet state of $Ir(piq)_3$ is quenched by the presence of the F8BT acceptor. In addition, time-resolved PL measurements show that the average lifetime of PFO decreases from 964 ps to 219 ps in the presence of phosphor, which further indicates efficient energy transfer. We also perform PL lifetime measurements of PFO/F8BT and [PFO/$Ir(piq)_3$]/F8BT bilayer films and the lifetime changes from 930 ps to 770 ps in the presence of phosphor, which show that efficient energy transfer occurs from the donor to the acceptor. Transient absorption spectrum of PFO and PFO(Ir) films shows that there is singlet exciton absorption peak at a wavelength of 826 nm, around 1.5 eV.
OPV devices are fabricated with the following configuration, indium-tin oxide (ITO)/PEDOT: PSS/PFO/F8BT/Ca/Al, with and without phosphor doping in the PFO layer. The OPV devices are tested under one sun illumination. Due to the bilayer structure of PFO/F8BT, the PCE is extremely low, which is ~0.02%; however, the open-circuit voltage is improved by 0.1 V in the presence of the phosphor, suggesting reduced nonradiative recombination. The devices are also tested as organic photodetectors (OPD). PFO(Ir)/F8BT has a responsivity of 0.64 mA/W, the detectivity of 3.25E10 Jones. As for PFO/F8BT devices, their responsivity is 0.48 mA/W, and the detectivity is 3.28E10 Jones. The OPD test indicates that their responsivity is comparable with other photodetector devices.

Acridine-Based TADF Molecules in Organic Light-Emitting Transistors (OLETs) CaterinaSoldano, OrnellaLaouadi, VladimirKornienko and KatherineGallegos-Rosas; Aalto University, Finland

Organic light-emitting transistors are photonic devices combining the function of an electrical switch with the capability of generating light under appropriate bias conditions. Achieving high-performance light-emitting transistors requires high mobility organic semiconductors, optimized device structures and highly efficient emissive layers. Thermally-activated delayed-fluorescence (TADF) has enabled the possibility to achieve heavy-metal-free phosphorescent emitter-based devices with high brightness and state-of-the-art color coordinates, with efficiency exceeding 30%. Since the first report on delayed fluorescence in 2012, TADF molecules have been successfully exploited mainly in OLEDs emissive layers, where host(s)-guest configurations are commonly adopted, mainly to suppress concentration quenching arising from the long-lived triplet excitons.
Here, we present our recent results on the use of an acridine-based TADF molecule (DMAC-DPS) in a host-guest configuration and its optoelectronic behavior in the limit of *field-effect* devices. First, we studied the optical response of these blends by tuning the doping concentration to optimize light generation, for which we observed a quenching of the photoluminescence signal for increasing dye concentration. These blends are then implemented in multilayer organic light-emitting transistors; by engineering the structure (*i.e.*, organic stack), we achieved a large improvement in the light output (~ 4 times). We analyzed our results in terms of balanced charge transport in the emissive layer as well as the device, which, in the limit of horizontal charge transport, leads to an improved exciton formation and decay process.
While the efficiency of our devices is yet to achieve state-of-the-art diode counterpart, this work demonstrates that using TADF molecule while engineering the emissive layer is a promising approach to enhance the light emission in field-effect devices. This opens the way for a broader exploitation of organic light-emitting transistors as alternative photonic devices in fields ranging from display technology to flexible and wearable electronics.

Study of Interface Effect on InP/ZnSe QDs' Non-Linear Properties LucaGiordano, PieterSchiettecatte and ZegerHens; Ghent University, Belgium

QDs show size-tunable opto-electronic properties and are highly suitable for solution-based processing. In this field, Cd-based QDs are the materials with most promising results, but the use of Cd in electronic appliances is restricted by the European Commission's ROHS directive. Considering this, sustainable alternatives are strictly needed, and InP-based QDs are the most promising ones thanks to their high level performance, showing, for example, a near-unity photoluminescence quantum yield across the full visible spectrum. However, opposite from such a linear optical property related to the formation of single electron-hole pairs in InP-based QDs, the characteristics of multiple electron-hole pairs within a single InP-based QDs remain poorly understood. For Cd-based QDs, multiple electron-hole phenomena, such as optical gain, stimulated emission and lasing, have been mostly demonstrated using CdSe QDs, for which the growth of core/shell CdSe/CdS architectures with an alloyed interface was decisive to slow down biexciton Auger recombination and attain stimulated emission under continuous wave optical or electrical pumping.
In this work, we analyze the Auger recombination rate of biexcitons in InP/ZnSe core/shell QDs, where the synthesis protocol was adapted to obtain 4 different interfacial compositions. A first set of two InP/ZnSe samples was formed by purifying or not the InP reaction mixture prior to ZnSe formation. Here, the one-pot approach without intermediate purification may lead to the incorporation of In within the ZnSe shell, while a neat ZnSe shell will grow when starting from purified InP core QDs. A second set of two samples was formed by adding gallium as a second group III precursor at the end of the InP core formation, where again cores were either purified or not before ZnSe shell growth. We found that in particular the addition of $GaCl_3$ leads to the incorporation of Ga at the InP core QD surface. Interestingly, we observed a systematically higher photoluminescence quantum yield for the samples formed through a one-pot procedure, i.e., without intermediate purification. In addition, a well-defined biexciton Auger recombination rate was only observed for the InP/ZnSe core/shell QDs formed by the one-pot approach. For all other samples, a significantly faster and muti-exponential Auger decay of multi-excitons was observed. The relation between these observations and the elemental and structural characteristics of the core/shell interface will be discussed. We conclude that, not unlike the seminal example of CdSe/CdS, the interfacial composition strongly affects the properties of multi-excitons of InP/ZnSe core/shell QDs.

Influence of Y6 Aggregation on Energetics and Charge Generation in High Performance OPV Blends JohnB. Asbury; Pennsylvania State University, United States

We investigated the origin of the high ratio of open circuit voltage to charge transfer state energy (eV_{OC}/E_{CT}) of OPV polymer blends consisting of the electron donating polymer PM6 and the non-fullerene electron acceptor Y6. PM6-Y6 and related donor-acceptor OPV blends exhibit remarkable optoelectronic properties and record power conversion efficiencies in part because of their unusually high eV_{OC}/E_{CT} ratios, which is believed to be related to the small energetic offset of the HOMO levels of PM6 and Y6. In this study, we varied the amount of Y6 in PM6 blends as a means to control the aggregation of Y6 molecules. We examined the corresponding influence that Y6 aggregation has on the energetic offsets and the charge generation efficiency of the materials by probing the appearance of polaron absorption signals in the mid-infrared using time-resolved infrared spectroscopy. Furthermore, we examined the optical absorption and emission spectra of the PM6-Y6 blends over the range of compositions to correlate the efficiency of charge generation with the signatures of Y6 aggregation in the optical spectra. We observed an abrupt transition around 30 mass% Y6 content at which polarons were efficiently generated by charge separation from PM6 to Y6. Comparison to composition dependent GIWAXS studies of PM6-Y6 blends revealed the formation of Y6 aggregates around the same 30 mass% threshold. These observations demonstrate that aggregation of Y6 molecules is required for charge separation to occur from PM6 to Y6 as measured through the mid-infrared absorption of polarons in the TRIR spectra. Although charges were efficiently generated in blends with only 30 mass% Y6 content, OPV device studies revealed that 50-60 mass% Y6 was needed to reach optimized short-circuit current and OPV device efficiency because these measurements convolve charge generation with charge transport. These findings clarify the optoelectronic properties of the novel class of Y6 acceptors and emphasize the importance of molecular aggregation for tuning the energetics of high performance systems that minimize energy offsets for maximum OPV power conversion efficiencies.

Enhancing Structural Integrity and Emission Efficiency of Two-Dimensional Supramolecular Structures Through Silica Encapsulation DimuthuH. Thanippuli Arachchi, UlugbekBarotov, AlexanderE. Kaplan, TaraSverko, CollinF. Perkinson and MoungiG. Bawendi; Massachusetts Institute of Technology, United States

The optical properties of J-aggregates are closely linked to their structural integrity, making them susceptible to chemical environments and mechanical stresses. We explore the use of silica encapsulation to enhance the structural rigidity and light emission efficiency of 5,5′,6,6′-tetrachloro-1,1′-diethyl-3,3′-di(4–sulfobutyl)-benzimidazolocarbocyanine (TDBC) two-dimensional sheet-like J-aggregates. Silica as an encapsulating matrix provides optical transparency, chemical inertness, and ease of functionalization while rigidifying the J-aggregate structure. Our novel

in-situ encapsulation process results in silica-encapsulated J-aggregates whose light absorption and emission properties show no significant change from those of bare J-aggregates, indicating that encapsulation preserves the excitonic structure in TDBC J-aggregates. Microscopic analysis confirms successful and homogeneous silica coating on J-aggregate sheets through cryogenic-TEM images and Scanning Transmission Electron Microscopy with Energy Dispersive X-Ray Analysis (STEM-EDX). Dynamic Light Scattering (DLS) reveals smaller sizes for silica-coated J-aggregates compared to uncoated ones. Stability studies involving dilution demonstrate that silica coating enhances structural integrity, enabling extensive dilutions without a breakdown of J-aggregates into monomers. Silica-coated TDBC J-aggregates achieve a quantum yield of ~95%, the highest recorded for such aggregates, and an ultrafast emissive lifetime of ~200 ps. The absorbance and emission line widths, already quite narrow at room temperature, exhibit further narrowing upon cooling to 79 K. The silica shell allows attaching functional groups on the shell surface or embedding them in the silica shell, permitting hybrid systems without disturbing the assembly of J-aggregates. Encapsulated J-aggregates provide (1) a platform for further manipulation of J-aggregates as building blocks for integration with other optical materials and structures, and (2) a platform for fundamental studies of exciton delocalization, transport, and emission dynamics within a rigid matrix.

Keywords: J-aggregates, silica-encapsulation, quantum yield, cyanine dyes

Intramolecular Locking-Induced Triplet Exciton-Harvesting Emitters with Aggregation-Induced Emission Effect for Non-Doped OLEDs TaehyunKim, Dae HwanLee and TaihoPark; Pohang University of Science and Technology, Korea (the Republic of)

Conventional triplet exciton-harvesting organic emitters can attain high internal quantum efficiency (IQE). Despite their advantages, these emitters suffer from the need to introduce heavy atoms and elongated skeleton structures leading to concentration quenching problems. Therefore, heavy-atom-free (HAF) triplet exciton-harvesting emitters have been promising due to unique photophysical characteristics and high photoluminescence quantum yield (PLQY). However, their device application to organic light emitting diodes (OLEDs) has been rarely explored since the performance of non-doped devices is inferior to that of doped devices because of the lack of suitable molecular design strategies. Therefore, the exploration of structural design is essential for decreasing reorganization energy of molecular structures to achieve high PLQY by utilizing triplet-excitons and aggregation-induced emission (AIE) characteristics in a non-doped system. Herein, we synthesized three asymmetric HAF triplet-harvesting emitters. The effect of non-covalent interaction for intramolecular hydrogen bonding between the N atoms and adjacent H atoms of emitters were detected in single-crystal XRD. Hydrogen bonding channel induced intramolecular locking reduced reorganization energy effectively, that increased the intersystem crossing (ISC; k_{ISC}), reverse intersystem crossing (RISC; k_{RISC}) rate and enhanced radiative decay (k_r) process. As a result, intramolecular hydrogen bonding assisted Qx-Py-2DMAC exhibited fast k_{ISC} (3.52×10^7 s^{-1}), k_{RISC} (2.54×10^6 s^{-1}), k_r (3.47×10^7 s^{-1}), and high PLQY (0.94). Besides, hydrogen bonding produced conformation-locked crystal structures were deeply investigated by two-dimensional grazing-incidence wide-angle X-ray diffraction (2D-GIWAXD). H-bond based emitters formed enhanced dense packing modes with a large coherence length (L_c) and preferred horizontal orientations, and exhibited the AIE property that can be applied to non-doped OLEDs. Moreover, molecular locking effect triggered spin-forbidden triplet excitonic emission known as room-temperature phosphorescence (RTP) with a lifetime of milliseconds in the neat film. By utilizing Qx-Py-2DMAC as the emitter, a un-optimized non-doped device, exhibiting a high current efficiency of 33.6%, a power efficiency of 30.1%, and an external quantum efficiency of 11.1% representing relatively high efficiency among RTP emissive and AIE featuring non-doped OLEDs.

8:00 PM QT01.06.06
Near-Field Coupling with a Nanoimprinted Probe for Dark Exciton Nanoimaging in Monolayer WSe_2JunzeZhou[1], JohnC. Thomas[1], ElyseBarre[1], EdwardBarnard[1], ArchanaRaja[1], KeikoMunechika[2], AdamSchwartzberg[1] and AlexanderWeber-Bargioni[1]; [1]Lawrence Berkeley National Laboratory, United States; [2]HighRI Optics, United States

The spin-dark dark excitons (X_D) in WSe_2 monolayer have long radiative lifetimes and are the excitonic ground state, making them attractive for quantum information applications. However, these states exhibit out-of-plane radiation patterns that are typically challenging to observe locally with objective lenses. This work presents a novel Tip-enhanced photoluminescence (TRPL) approach for spectrally and spatially resolving these dark states. The near-field measurement configuration provides an ~3 orders of magnitude out-of-plane Purcell enhancement, diffraction-limited excitation spot, and subdiffraction hyperspectral imaging resolution (below 50 nm) of X_D emission. The effectiveness of this high spatial X_D mapping technique was then demonstrated through reproducible hyperspectral mapping of oxidized sites and nanobubble areas.

8:00 PM QT01.06.07
Probing the 2D Momentum Space of an Excitonic Bose-Einstein Condensate using a Modified Michelson InterferometerS.V.U.Vedhanth and ShouvikDatta; IISER Pune, India

Excitons as bound electron-hole pairs can undergo interesting phase transitions such as Bose-Einstein Condensation (BEC). This is marked by a spontaneous, long range spatial order below a critical temperature. Physics of such phase transitions can be probed by measuring the 1st order, transverse, spatial correlation/coherence $|g^{(1)}(x,y)|$ with optical interferometry assuming that the BEC ground state of these excitons is 'bright'. We know that the Wiener-Khintchine Theorem in statistical physics relates any 2D mapping of $|g^{(1)}(x,y)|$ with the 2D momentum space (k-space) distribution of the emitted light. Consequently, we demonstrated [1] a modified Michelson Interferometer, which can first measure the 2D map of $|g^{(1)}(x,y)|$ of the excitonic light emission and then subsequently determine its 2D k-space.

Usually k-space measurements are often done by scanning the Back Focal Plane (BFP) image of a 'Bertrand lens' for excitonic samples which are kept inside a low temperature cryostat. One requires a high numerical aperture lens very close to these low temperature samples for BFP imaging. Alternatively, performing Young's double slit experiment with varying slit widths and adjustable slit separations kept within such low-temperature cryostat to measure $|g^{(1)}(x,y)|$ is also a challenging task in terms of instrumentations. These methods can, however, substantially introduce additional heat loads to the sample due to its proximity to various optical elements which are at room temperature. Moreover, the setup doesn't suffer from problems associated with the use of Cat-Eye retroreflector (CER), Dove prisms which were used in past studies of 2D mapping of $|g^{(1)}(x,y)|$. So we first collimate the light coming out from the sample and then measure its $|g^{(1)}(x,y)|$ over a selected area using our setup [1]. This method is certainly simpler and advantageous - specifically in cases where the sample under study is kept at a low temperature, so that k-space distributions of excitonic light emission can still be measured using optical instrumentations placed totally outside the low temperature cryostat at a distance away from the sample itself. This areal mapping of the $|g^{(1)}(x,y)|$ is obtained from the visibility factor from observed interference fringes using the required temporal filtering method [2]. Unlike earlier [2], this time our instrumentations for imaging 2D k-space, involved non-coplanar retroreflectors. So we had introduced additional mirrors to compensate for the displacements of the reflected beams. As a result, we can now monitor and control the fringe width by simply tilting only one such additional mirror(s). This actually enabled us to study even smaller emission patterns. There were reports [3] of k-space studies with spatial coherence measurements but only in 1D. Whereas, here we obtain the full 2D in-plane k-space distribution of light. Moreover, if we want to increase the resolution of the 2D k-space map, then the range over which the $|g^{(1)}(x,y)|$ is measured has to be increased.

Therefore, we have used this setup to measure the $|g^{(1)}(x,y)|$ and study the evolution of 2D k-space distribution before and after the onset of lasing. Most importantly, this experimental design is helpful in probing not only Bose-Einstein Condensate of excitons, but also it can be used to study BEC of polaritons, photons etc. by observing the narrowing of k-space of light emission as an evidence for the presence of the off-diagonal long-range order.

8:00 PM QT01.06.08
Enhancing Near-infrared (NIR) Multi-Exciton Dynamics Through Quantum Shell Architecture DulanjanHarankahage; Bowling Green State University, United States

Semiconductor quantum dots (QDs) have faced significant limitations in their photonic applications due to ultrafast Auger decay of multiple excitons, leading to non-radiative processes that impede the performance of high-brightness light-emitting diodes and lasing devices. However, the introduction of colloidal quantum shell (QS) architecture, featuring a semiconductor quantum shell with an inverted QD geometry, has successfully suppressed Auger recombination. The QW morphology, characterized by a quantum confined HgS layer sandwiched between two large CdS domains, offers an extended biexciton lifetime and substantial biexciton quantum yields due to the increased exciton volume. Furthermore, the architecture-induced exciton-exciton repulsions have led to the separation of exciton and biexciton optical transitions, resulting in broad optical gain bandwidths. The remarkable longevity of single and biexciton states, along with extended single exciton gain lifetime, positions this geometry as a promising candidate for the development of optically and electrically pumped gain media.

8:00 PM QT01.06.09
Quantum Shell in a Shell: Engineering Colloidal Nanocrystals for a High-Intensity Excitation Regime JiaminHuang; Bowling Green State University, United States

The efficiency of many optoelectronic processes in colloidal semiconductor nanocrystals (NCs) tends to decline when subjected to high-intensity excitation. This decline is primarily attributed to Auger recombination, where multiple excitons result in the conversion of NC energy into excess heat. As a consequence, the efficiency and life span of NC-based devices such as photodetectors, X-ray scintillators, lasers, and high-brightness light-emitting diodes (LEDs) are negatively impacted. Although semiconductor quantum shells (QSs) have recently emerged as

a promising approach to address Auger decay, their optoelectronic performance has been impeded by surface-related carrier losses. To deal with this issue, we propose the implementation of quantum shells with a CdS–CdSe–CdS–ZnS core–shell–shell–shell multilayer structure. The presence of a ZnS barrier effectively inhibits surface carrier decay, resulting in a significant increase in the photoluminescence (PL) quantum yield (QY) to 90%, while maintaining a high biexciton emission QY of 79%. Furthermore, the enhanced morphology of the quantum shells allows for one of the longest Auger lifetimes observed in colloidal NCs to date. The reduction of nonradiative losses in QSs also leads to diminished blinking in single nanoparticles and low-threshold amplified spontaneous emission. We expect that the ZnS-encapsulated quantum shells will be widespread across various applications in high-power optical or electrical excitation regimes.

8:00 PM QT01.06.10
Energy Transfer in Organic Exciton Polariton Condensate Regime RishabhKaurav[1], Ravindra KumarYadav[2], AmarFlood[3], Bo W.Laursen[4] and VinodMenon[2]; [1]The Graduate Center of the City University of New York, United States; [2]Center for Discovery and Innovation, The City College of New York, United States; [3]Indiana University, United States; [4]University of Copenhagen, Denmark

Here we report the study of energy transfer between organic molecules where the excitons in the donor molecules are strongly coupled to cavity photons and in the polariton condensate phase. We use a host-guest system where the dye is incorporated into a small-molecule ionic isolation lattices (SMILES). This system exhibits significantly enhanced photoluminescence (PL) in the solid state overcoming the limitation of aggregation induced quenching and has allowed us to realize polariton condensation [1].
Here we study energy transfer between donor, Rhodamine (R3B) and acceptor, Nile Blue (NB) embedded in host Cyanostar to form the SMILES complex. In the mixed R3B-SMILES with NB-SMILES system, we observe significant energy transfer between the donor and the acceptor surpassing what is seen in the bare mixed dye system thus indicating the advantage of the SMILES system in molecular energy transfer. Going further, we investigate the role of the donor being in a condensate phase where coherent emission is observed on the energy transfer process. We use a combination of steady state, time resolved, and momentum resolved spectroscopy to investigate the energy transfer process. The role of the host matrix and the coherence of the donor molecule on energy transfer will be discussed.

Observing and Modeling Exciton-Polaritons in Tunable Nanofluidic Microcavities RyanPinard, SumanGunasekaran and AndrewJ. Musser; Cornell University, United States

When two mirrors are placed very close together, and a strongly absorbing substance is inserted between them, new states known as exciton-polaritons can be formed. These special light-matter hybrid states have the potential to alter the rate of energy transfer and charge transfer, among other applications. Strong coupling of light with electronic excitations is typically measured in the solid phase; thus, creating polaritons in solution is one vital next step the field could take. However, few have attempted to observe exciton-polaritons in the liquid state — in part due to the difficulty of constructing microcavity devices on the nanometer scale that are capable of receiving liquid, and in part due to the difficulty of dissolving highly-absorbing molecules at high concentration. Here, to tackle these challenges, we have fabricated microcavities into which solutions can be deposited or cycled through continuously. Moreover, these devices are highly tunable in real time on the order of the wavelength of visible light. We are also working toward fabricating aluminum mirrors that are highly reflective in the UV region. These mirrors may have the potential to house a cooperative coupling regime between solvent and solute, which could lower the concentration of dye required for strong coupling. Alongside this progress, we have developed an interactive application in MATLAB that can fully describe the optical properties of our devices. The program can also model the refractive index of a material from inputted absorption data using the Kramers-Kronig relations. Comparison of measured K-space images with the model can provide valuable insight into the nature of solution-phase strong coupling.

8:00 PM QT01.06.12
Luminescent Mechanisms of Crystalline and Amorphous Carbon Dots YongqiYang and DeirdreO'Carroll; Rutgers, The State University of New Jersey, United States

Luminescent carbon dots (CDs), as an emerging material class, have been actively investigated for applications in bioimaging, photocatalysis, and optoelectronic devices. However, standard synthesis procedures have not been established for carbon dots and the mechanism for the luminescence is still unclear, especially the effect of the crystallinity. In this work, we study and compare the optical properties of both crystalline and amorphous CDs in the bulk solution, as well as in thin films. We report on the microwave synthesis method to prepare both crystalline and amorphous CDs. Starting from citric acid and urea as precursors, and phosphoric acid as an additional reagent, we synthesize CDs with different crystallinity by controlling the amount of phosphoric acid during the microwave treatment. The crystallinity and structure of the nanoparticles are characterized by powder X-ray diffraction (XRD) techniques. No peaks are observed in the XRD patterns of CDs synthesized without phosphoric acid, while several peaks are observed in the CDs synthesized with the acid, which indicates the crystallinity in the structure. The size and morphology of the CDs are studied by transmission electron microscopy (TEM) and dynamic light scattering. The sizes of the two types of CDs (with and without phosphoric acid) are both around 20-30 nm, while fast-Fourier-transforms of the TEM images indicate crystallinity at the single particle level for the CDs synthesized with phosphoric acid. The structure and composition of the CDs are also analyzed by high-resolution TEM. The luminescence spectra of amorphous and crystalline CDs are similar in emission wavelength and intensity, while the quantum yield of amorphous CDs is higher than crystalline CDs, with values of 33 % and 24 %, respectively. We will also present single-particle photoluminescence spectroscopy studies of CDs with different crystallinity to assess their size and composition-dependent luminescence. This study sheds new light on the role of crystallinity in the luminescence properties of CDs and the performance of CDs for use as emissive nanomaterials.

Effect of Systematic Variation of Light-Matter Coupling Strength on Polariton Condensation Threshold BeatricePence, ThomasM. Khazanov and AndrewJ. Musser; Cornell University, United States

Exciton-polaritons, bosonic quasiparticles arising from strong coupling between an exciton and the electromagnetic field, are a promising platform for quantum information science. They may undergo condensation above a certain particle density to form a non-equilibrium polariton condensate analogous to classic Bose-Einstein condensates. While most studies have focused on inorganic materials, which undergo condensation at cryogenic temperatures, the higher binding energy of excitons in organic materials allows polariton condensates to form even at room temperature. However, the dependence of key condensation properties, such as condensation threshold and linewidth, on the light-matter coupling strength and other factors related to device structure are not well understood.
Poly-(9,9)-dioctylfluorene (PFO), a highly disordered semiconducting polymer, is known to support polariton condensation in Fabry-Perot microcavities. This study investigates the effect of light-matter coupling strength on condensation threshold experimentally by combining active and spacer layers such that only the PFO concentration inside the cavity is varied, while maintaining other parameters such as total cavity length constant.

Identity of T* Matters! Improved k_{rISC} by Modulating Locally Excited Triplet State in TADF EmittersMadalasaMondal and RatheeshK. Vijayaraghavan; IISER Kolkata, India

Effective triplet exciton utilization efficiency is an essential factor for constructing low-power operational OLED devices with high luminescence efficiency and durability. Thermally activated delayed fluorescence assists this 100% triplet harvesting by converting dark triplet excitons into radiative singlet excitons via a reverse intersystem crossing process. The enhancement of this rISC rate (k_{rISC}) is primarily realized by the low energy offset between lowest S & T states; to pursue an extremely large $k_{rISC,}$ the involvement of high energy locally excited triplet states has become a hot topic in TADF-OLED research in present days. However, the regulation of the ^{3}LE states to match precisely with the ^{1}CT energy level by suitable molecular design is still under progress.
Here, we demonstrated an effective electronic coupling between ^{1}CT & ^{3}LE or hybridized triplet state in a series of newly designed and synthesized TADF emitters with strongly twisted D-A structure. The detailed theoretical and experimental investigation reveals that the addition of peripheral donor units to the core D-A backbone incorporates multiple triplet excited states of locally excited or hybridized nature between S_1 and T_1 states, and the close alignment of ^{1}CT & ^{3}LE states accelerates the spin-flip process and the sizeable radiative rate results in suppressed efficiency roll off with short (ns) delayed lifetime. On the contrary, the isoenergetic alignment of ^{1}CT and ^{3}CT states realized due to the near orthogonal structure promotes the rISC mechanism. Our work highlights the pivotal role of the electronic nature of the intermediate triplet states in controlling the $k_{rISC,}$ a thorough photophysical investigation was also performed by manipulating ^{3}LE states by introducing variable donor units to the D-A backbone.

Improved Device Performance of Quantum Dot Light Emitting Diodes by an Insertion of Thermal Activated Delayed Fluorescent Layer for Utilizing the Excess Exciton Jeong-YeolYoo, Yoon-JeongChoi, Chil WonLee and Byung DooChin; Dankook University, Korea (the Republic of)

Quantum dots (QDs) are promising light emitters for the next-generation display, especially in the form of QD light-emitting diodes (QLED). Recently, PL-type QD display was successfully implemented in commercial products, including recent QD-OLED with superior properties. In spite of the great success of PL-type QD display, however, self-emissive electroluminescence (EL) type QD display is still under development.[1,2]

Recent issues on EL-type QLED studies the imbalance between the holes and electrons causes over-injection of electrons compared to holes, electron leakage from the QD emission layer (EML), and accumulation of charges at the EML/hole transporting layer (HTL) interfaces. As a result, the efficiency and lifetime of the device were reduced. Therefore, controlling the charge balance is essential for realizing highly efficient QLED.[3]
Several studies have been focused on charge balance by improving the hole injection and suppressing the electron injection. Nevertheless, in most of the QLEDs reported so far, electron injection was always too efficient. In addition, the incorporation of phosphorescent sensitizer into QLED devices enhanced energy transfer and promoted to harvest the energy of the excitons to the QD EML, which were regarded as an effective method to enhance the efficiency of QLEDs. However, it is expected that Dexter energy transfer occurs by T_1 excitons, which has a too short transfer distance (<1 nm).[4,5]
In this study, a blue thermally activated delayed fluorescence (TADF) material layer between EML and HTL was employed for utilizing the leaked electron and promote exciton harvesting. In the TADF layer, the leaked and accumulated electrons can form exciton with holes injected from HTL, energies by S_1 exciton were transferred from TADF layer into QDs and emission of QDs via Förster resonance energy transfer mechanism (FRET).[5] The critical radius of FRET (R_{FRET}) can be calculated from the spectral overlap of TADF materials and QDs. As a result, maximized efficiency R_{FRET} is calculated to be about 4.25 nm. Compared with the control QLED device without TADF layer, the QLED with TADF layer showed about 2-fold increment for external quantum efficiency and current efficiency and 4-fold improvement for maximum luminance. Moreover, significant improvements in device lifetime. The EL properties indicate that the devices exhibit a symmetric EL peak emission. These results clearly reveal that TADF materials can be successfully applied to utilize excessive electrons, generally improving the overall performance of QLED. The proposed approaches are expected to provide a possible realization of highly efficient QLEDs where the analysis of detailed mechanism is studied.

Control of the Exciton and Spin/Valley Properties in Atomically Thin Transition Metal Dichalcogenides MarieXavier; Institut National des Sciences Appliquées - LPCNO, France

Encapsulation of TMD monolayers in hexagonal boron nitride (hBN) yields narrow optical transitions approaching the homogeneous exciton linewidth[1,2,3]. We have demonstrated that the exciton radiative rate in these van der Waals heterostructures can be tailored by a simple change of the hBN encapsulation layer thickness as a consequence of the Purcell effect [4].
We also measured the exciton fine structure by magneto-photoluminescence spectroscopy in magnetic fields up to 30 T [5,6]. I will show that the bright-dark exciton splitting can be tuned by a few meV, as a result of a significant Lamb shift of the optically active exciton which arises from emission and absorption of virtual photons triggered by the vacuum fluctuations of the electromagnetic field[7] .
Finally I will present recent experimental results on spin/valley pumping of resident electrons in WSe_2 and WS_2monolayers[8]. Using a spatially-resolved optical pump-probe experiment, we measure the lateral transport of spin/valley polarized electrons over very long distances (tens of micrometers)[9]. These results highlight the key role played by the spin-valley locking effect in TMD monolayers on the pumping efficiency and the polarized electron transport.

High-Performance Broadband Faraday Rotation Spectroscopy of Excitons in Atomically Thin Semiconductors AshishArora[1,2]; [1]Indian Institute of Science Education and Research, Pune, India; [2]University of Muenster, Germany

Faraday rotation is a fundamental effect in the magneto-optical response of solids, liquids and gases. However, due to many speed limiting components such as polarization modulators combined with lock-in amplifiers, each spectrum could take several hours to measure. Therefore, Faraday rotation spectroscopy measurements with micrometer spatial resolution become extremely challenging, if high spatial stabilities of the samples over the measurement time scales are required.

In this talk, first I will describe a newly developed high-performance broadband Faraday rotation spectroscopy technique for measurements on the micron scale [1]. Spectral acquisition speeds of two-to-three orders of magnitude faster than state-of-the-art modulation spectroscopy setups are demonstrated. The experimental method is based on charge-coupled-device detection, avoiding speed-limiting components used in the modulation spectroscopy, such as a photoelastic modulator and a lock-in amplifier. At the same time, Faraday rotation spectra are obtained with a sensitivity of 20μrad (0.001º) over a broad spectral range (525 nm – 800 nm), which is on par with polarization-modulation techniques [1]. The new measurement technique also automatically cancels unwanted Faraday rotation backgrounds.

Using the setup, we perform Faraday rotation spectroscopy of excitons in an hBN-encapsulated atomically thin semiconductor WS_2 under magnetic fields of up to 1.4 T. We resolve extremely small exciton Zeeman splittings such as 50 μeV at B = 0.2 T, and tiny valley polarizations such as 0.05 % at B = 0.4 T. I will discuss the prospects of creating ultrathin optical isolators based on excitonic transitions in 2D materials, for optical integrated circuits.

Our work presents a dramatic improvement in measurement speeds over the state-of-the-art modulation techniques. It enables us to perform spatially-resolved high-performance Faraday rotation spectroscopy of excitons in 2D semiconductors.

Quantum Shells Versus Quantum Dots—Suppressing Auger Recombination in Colloidal Semiconductors MikhailZamkov; Bowling Green State University, United States

The quantum efficiency of many optoelectronic processes in colloidal semiconductor nanocrystals (NCs) declines with increasing optical or electrical excitation intensity. This issue is caused by Auger recombination of multiple excitons, which converts the NC energy into excess heat, whereby reducing the efficiency and lifespan of NC-based devices, including lasers, photodetectors, X-ray scintillators, and high-brightness LEDs. Recently, semiconductor quantum shells (QSs) have emerged as a viable nanoscale architecture for the suppression of Auger decay. The spherical-shell geometry of these nanostructures leads to a significant reduction of Auger decay rates, while exhibiting a near unity photoluminescence quantum yield. In this talk, I will compare the optoelectronic properties of quantum shells against other low-dimensional semiconductors and discuss their emerging opportunities in solid-state lighting and energy-harvesting applications.

Flattening Conduction and Valence Bands for Interlayer Excitons in Twisted Van der Waals Bilayers AndreyChaves[1,2], SaraConti[2], TribhuwanPandey[2], LucianCovaci[2], FrancoisPeeters[2], DavidNeilson[2] and M. V.Milosevic[2]; [1]Universidade Federal do Ceara, Brazil; [2]University of Antwerp, Belgium

Recent advances in fabrication and manipulation of two-dimensional (2D) materials have enabled the control over stacking and twisting between layers of transition metal dichalcogenides (TMDs) in van der Waals (vdW) heterostructures. In these systems, the moiré pattern created by the lattice mismatch between the layers plays an important role: it produces a periodic potential profile along the plane for electrons and holes, with potential minima in regions with specific stacking orders. Such moiré superlattice potential leads to a band structure for the bilayer that is tunable e.g. by inter-layer twisting. The recent observation of Mott insulator and superconducting phases in twisted bilayer graphene [1,2], due to the band flattening induced by interlayer twist, has brought even further excitement into this field, towards controlling transport and opto-electronic properties of TMDs vdW heterostructures by similar moiré pattern effects. [3]
In this work, we explore the flatness of conduction and valence bands of interlayer excitons in MoS_2/WSe_2 van der Waals heterobilayers, tuned by interlayer twist angle, pressure, and external electric field. We employ an efficient continuum model [4] where the moiré pattern from lattice mismatch and/or twisting is represented by an equivalent mesoscopic periodic potential. We demonstrate that the mismatch moiré potential is too weak to produce significant flattening. Moreover, we draw attention to the fact that the quasi-particle effective masses around the Γ-point and the band flattening are *reduced* with twisting. As an alternative approach, we show (i) that reducing the interlayer distance by uniform vertical pressure can significantly increase the effective mass of the moiré hole, and (ii) that the moiré depth and its band flattening effects are strongly enhanced by accessible electric gating fields perpendicular to the heterobilayer, with resulting electron and hole effective masses increased by more than an order of magnitude leading to record-flat bands. These findings impose boundaries on the commonly generalized benefits of moiré twistronics, while also revealing alternate feasible routes to achieve truly flat electron and hole bands to carry us to strongly correlated excitonic phenomena on demand.

Strong and Tunable Light-Matter Interactions in Excitonic Semiconductors DeepM. Jariwala; University of Pennsylvania, United States

The isolation of stable atomically thin two-dimensional (2D) materials on arbitrary substrates has led to a revolution in solid state physics and semiconductor device research over the past decade. A variety of other 2D materials (including semiconductors) with varying properties have been isolated raising the prospects for devices assembled by van der Waals forces.[1] Particularly, these van der Waals bonded semiconductors exhibit strong excitonic resonances[2] and large optical dielectric constants as compared to bulk 3D semiconductors. .
First, I will focus on the subject of strong light-matter coupling in excitonic 2D semiconductors, namely chalcogenides of Mo and W. Visible spectrum band-gaps with strong excitonic absorption makes transition metal dichalcogenides (TMDCs) of molybdenum and tungsten as attractive candidates for investigating strong light-matter interaction formation of hybrid states.[3-5] We will present our recent work on the fundamental physics of light trapping in multi-layer TMDCs when coupled to plasmonic substrates.[6]
Next, we will show the extension of these results to halide perovskites[7, 8] and superlattices of excitonic chalcogenides.[9] These hybrid multilayers offer a unique opportunity to tailor the light-dispersion in the strong-coupling regime.[9] We will discuss the physics of strong light-matter coupling and applications of these structures. If time permits, I will also present our recent work on van der Waals semimetals,[10] control of light in magnetic semiconductors[11] and extending some of these concepts to 1D carbon-nanotubes.[12]
Our results highlight the vast opportunities available to tailor light-matter interactions[11] and building practical devices with 2D semiconductors. I will conclude with a broad vision and prospects for 2D materials in the future of semiconductor opto-electronics and photonics.

Trion Photoluminescence and Trion Stability in Atomically Thin Semiconductors RaulPerea-Causin[1], SamuelBrem[2], OleSchmidt[2] and ErminMalic[2]; [1]Chalmers University of Technology, Sweden; [2]Philipps University of Marburg, Germany

The optical response of doped monolayer semiconductors is governed by trions [1], i.e. three-particle complexes consisting of a photoexcited electron-hole pair bound to a doping charge. While photoluminescence (PL) signatures of trions have been identified in experiments [2], the microscopic description of trion recombination and trion stability is still incomplete.

In this work, we derive a generalized trion PL formula on a fully quantum-mechanical footing, considering both direct and phonon-assisted recombination mechanisms [3]. Considering WSe_2 as exemplary material, we access the trion energy landscape by solving the trion Schrödinger equation with a variational approach [4] and reveal the important impact of the mass imbalance between equal charges on the trion stability. Finally, we compute the temperature-dependent PL spectra for n- and p-doped monolayers and find a good agreement with experimental data. Moreover, we predict additional signatures originating from trions with an electron located at the Λ point, which, interestingly, exhibit a higher three-body energy than their K-point counterpart but a lower recombination resonance. Although these signatures have not been clearly observed in experiments yet, we expect that Λ-point trions play a relevant role in the dynamics and can be experimentally accessed via strain engineering [5] or in time-resolved PL spectra [6]. Our work presents an important step towards a microscopic understanding of the quantum nature of trions, which determines their stability and optical fingerprint.

Modulating Optical Properties of Monolayer WS2 by Dielectric and Substrate Engineering TamaghnaChowdhury, GokulM. A and AtikurRahman; IISER Pune, India

The optical properties of monolayers of transition metal dichalcogenides (TMDs) are profoundly influenced by the surrounding dielectric environment. Defect states within the substrate introduce uncontrolled doping in the TMD monolayer, thereby altering the photoluminescence (PL) spectra. In this study, we systematically investigated the influence of surface defects by gradually increasing the separation between the WS2 monolayer and the substrate. This allowed for precise modulation of the exciton and trion contributions in the PL spectra of WS2. By performing excitation power-dependent measurements on dielectric-engineered and patterned substrates, we gained insight into the mechanism behind the PL modulation in monolayer WS2. Furthermore, we examined the impact of the charged nature of substrate defects on the PL spectra. These findings present a novel pathway for modulating and obtaining desired PL spectra of TMDs through substrate engineering.

Tunable Localized Charge Transfer Exciton in a Mixed Dimensional Van der Waals Heterostructure MahfujurRahaman[1], EmanueleMarino[1], Alan GJoly[2], SeungukSong[1], ZhiqiaoJiang[1], Brian T.O'Callahan[2], DanielJ. Rosen[1], KiyoungJo[1], GwangwooKim[1], Patrick Z.El-Khoury[2], Christopher B.Murray[1] and DeepM. Jariwala[1]; [1]University of Pennsylvania, United States; [2]Pacific Northwest National Laboratory, United States

The observation of interlayer excitons (ILX) in van der Waals heterostructures (vdWHs) based on 2D-2D systems makes them a very promising candidate for next generation photonic and valleytronic devices. However, the true potential of ILXs depends on spatially confining and isolating them below their de Broglie wavelength[1,2]. One approach that has garnered significant attention in this regard, is the formation of moiré superlattices in twisted van der Waals 2D homo/hetero stacks[3]. Though the material modulation through moiré superlattices faces challenges, including limited control over the energy and position of the trapping potential due to the delicate alignment required between 2D sheets, crystal imperfections over large areas, and repulsive interactions among the trapped ILXs[4,5]. In this contribution[6], we demonstrate the formation of highly localized ILX analogous charge transfer (CT) excitons in a 2D/quasi-2D system comprising $MoSe_2$ monolayers and CdSe/CdS based core/shell nanoplates (NPLs). We employ room temperature nano-PL to resolve the spectral signature of CT excitons in our MDHs, which are spatially confined within the dimension of single NPL (~ 10 x 10 nm^2). Moreover, we are able to tune the energy of the CT excitons up to 120 meV via tuning the NPL thickness and achieve an electrostatic gating tunabilty of 0.8 eV/(V/nm), which surpasses the ILX tunability in 2D-2D systems[7,8]. Our finding is a significant step towards the realization of highly tunable MDH-based next generation photonic devices.

SESSION QT01.08: Excitonic Phenomena II
Session Chairs: Ashish Arora and Stefan Zollner
Wednesday Afternoon, November29, 2023
Sheraton, Fifth Floor, Public Garden

1:30 PM *QT01.08.01
Excitonic Absorption in Semiconductors with Low and High Carrier Densities StefanZollner[1], CarolaEmminger[2,3] and JoseMenendez[4]; [1]New Mexico State University, United States; [2]Universität Leipzig, Germany; [3]Humboldt-Universität zu Berlin, Germany; [4]Arizona State University, United States

Spectroscopic ellipsometry is an optical reflection technique with polarized light. Most commonly, it is used to measure the thicknesses of thin-film layers, such as SiO_2 on Si. But it can also be used to study the energies and broadenings of elementary excitations in solids, such as free carriers (electrons and holes, band gaps, transport), excitons, infrared active phonons, and their interactions. We previously reported precision measurements of the complex refractive index of germanium due to the absorption of photons by excitons near the direct band gap. These results were compared quantitatively with theoretical predictions from Fermi's Golden Rule, based on k.p theory and including the excitonic interaction between electrons and holes (Sommerfeld enhancement). Going further, we can investigate how many-body effects impact the excitonic absorption of photons in highly excited semiconductors. Large carrier concentrations can be achieved through doping, thermal excitation of electron-hole pairs in small band-gap semiconductors, or optical excitation with ultrafast lasers. In this talk, we will report recent ellipsometry results for the temperature-dependent dielectric function of InSb near the direct band gap and the transient dielectric function of Ge near the E_1 and $E_1+\Delta_1$ transitions from femtosecond pump-probe ellipsometry. We will also point out the theoretical approach needed to explain these data sets, especially the Fermi-Dirac distribution functions of carriers (Burstein-Moss shift) and the screening of the excitonic effects at high carrier densities.

Exciton Transport in a Van der Waals Antiferromagnet FlorianDirnberger[1], SophiaTerres[1], MikhailGlazov[2] and AlexeyChernikov[1]; [1]TU Dresden, Germany; [2]Ioffe Institute, Russian Federation

Optical spectroscopy of van der Waals magnets recently unveiled *magnetic excitons* – a rare type of optical excitation emerging from spin-polarized electronic states in magnets. With properties that have no analogue amongst excitons in conventional band semiconductors, these optical quasiparticles not only inherit tremendous potential for optoelectronic devices with new functionalities, they provide insight into elementary interactions between electron-hole pairs, magnons, and light. A strongly bound example of such *magnetic excitons* was recently discovered in the prototypical layered antiferromagnetic semiconductor CrSBr. In this contribution, we will present its fundamental optical properties and discuss our latest experimental results on the spatio-temporal transport of excitons in the presence of large structural anisotropy and magnon coupling.

2:30 PMBREAK

3:30 PM QT01.08.03
Impact of Excitons on the Non-Linear Optical Properties of 2D Materials Su YingQuek; National University of Singapore, Singapore

Non-linear optical phenomena are at the core of many important technologies and spectroscopic techniques. The second-order optical susceptibility is responsible for spontaneous parametric down conversion (SPDC) which generates entangled photon pairs, shift currents which give rise to bulk photovoltaic effects, and second harmonic generation that is useful for spectroscopy. In recent years, there has been increasing interest in studying non-linear optical phenomena in the 2D limit, where phase-matching conditions are eliminated while allowing for more facile integration with hybrid quantum photonic platforms. Reduced electronic screening in 2D leads to enhanced excitonic effects, and it is therefore critical to elucidate the impact of excitons on non-linear optical properties. We develop a theory for the second-order optical susceptibility that takes into account excitonic effects with a first principles GW-Bethe-Salpeter-Equation (GW-BSE) approach. We apply the theory to niobium oxydihalides ($NbOX_2$, X = Cl, Br, I) [1], a material of significant current interest in non-linear optics [2]. We predict that excitonic effects greatly enhance the probability for SPDC [3] and increase the magnitude of the shift currents in this material. We further benchmark our approach by comparison with experiment for the shift current in bulk $BaTiO_3$ and the SHG spectra for layered $NbOI_2$, where we clearly demonstrate the important role of excitons in non-linear optics. Our work provides a fundamental understanding of non-linear optical phenomena in excitonic materials and paves the way for 2D non-linear quantum photonics.

Exciton-Plasmon Interactions in Binary Superlattices of Infrared Colloidal Nanocrystals SarahBrittman, PatrickYee, VeronicaPolicht, PaulCunningham and JaniceBoercker; U.S. Naval Research Laboratory, United States

Semiconductor colloidal nanocrystals have immense potential to contribute to efficient and inexpensive infrared optoelectronics. State-of-the-art devices made from colloidal nanocrystals contain films of randomly arranged nanocrystals that do not exhibit long-range order. Controlling the ordering of these nanocrystals into superlattices has the potential to generate engineered metamaterials that exhibit properties not achievable in natural semiconductors or in films of disordered nanocrystals. The current size of individual ordered domains in these materials

(analogous to grain size in polycrystalline materials), however, is typically microscopic, so the field lacks detailed structure-property relationships. Expanding on our previous work [1, 2], we have engineered the surface chemistry of our nanocrystals to create enlarged (>1 micron) domains of binary nanocrystal ordered solids of infrared plasmonic Cu2-xS/PbS core/shell and excitonic PbS nanocrystals. We then directly correlate photoluminescence microscopy performed in an air-free environment on single ordered domains with transmission electron microscopy of the binary PbS and Cu2-xS nanocrystal solids. Initial results from our correlative microscopy indicate that energy transfer does occur between the excitonic emitters and plasmonic nanocrystals and suggest that fine-tuning the geometry and energetics of the binary system will optimize this composite material's properties. We envision that combining single-domain measurements and optical modeling will generate well-defined structure-property relationships that will further our understanding of multicomponent ordered nanocrystal solids and allow us to design solids with desired properties.

Linear and Non-linear Optical Properties of Semiconductor Quantum Dots ChandlerMartin[1], AnairaJalan[2] and ArindamChakraborty[1]; [1]Syracuse University, United States; [2]Westminster School, United Kingdom

This computational work presents a systematic investigation of linear and non-linear optical response properties of CdSe, CdS, PbSe, and PbS quantum dots in the size range of 1-10 nm. First-principles quantum mechanical calculations were performed using the frequency-dependent geminal screened electron-hole interaction kernel (FD-GSIK) method, and the polarizability and hyper-polarizability were evaluated from the time-dependent correlated electron-hole reduced density matrix. The FD-GSIK is a real-space method that uses an explicitly-correlated operator to include many-body quasiparticle correlation effect. The results from the real-time propagation approach will be compared with the sum-over-states approach, and analysis of the key differences will be presented. The scaling law for the polarizability and hyper-polarizability as a function of dot size will be presented, and the impact of material type and surface defects will be discussed.

Exciton Transport and Dissociation in Molecular Photocells ChuminWang, FernandoSanchez and VicentaSanchez; Universidad Nacional Autonoma de Mexico, Mexico

Sunlight is the most plentiful source of clean energy providing to the earth in one hour enough energy for current human needs of one year [1]. In addition, photovoltaic devices based on organic semiconductors possess many remarkable advantages in comparison with the inorganic technology, such as flexibility, transparency, low weight and inexpensive manufacture. Hence, understanding the kinetics of light-generated excitons around the organic donor-acceptor heterojunction may significantly improve the performance of solar cells. In this work, we present a quantum model of molecular photocells based on a coarse-grained attractive Hubbard Hamiltonian, where the transport and dissociation of excitons are analyzed on an excitonic state lattice containing impurity sites originated from the attractive electron-hole interaction [2]. The presence of these impurity sites prevents the use of reciprocal space and then, the numerical calculation was carried out by means of an independent channel plus real-space renormalization method, where the competition between the driving force from heterojunction and the Coulomb attraction leading to an electron-hole recombination has been explicitly addressed [3]. The results reveal an optimal distance between molecular photocells to achieve the maximum quantum efficiency, in accordance with various experimental reports about the optimal concentration of donor molecules [4]. Moreover, the calculated quantum efficiency has a good agreement with those obtained from diverse organic photovoltaic devices, such as bilayer, perovskite and inverted solar cells [5].

This work has been partially supported by projects UNAM-IN112522, UNAM-IN110823 and CF-2023-I-830. Computations were performed at Miztli of DGTIC-UNAM.

Emergent Optical Properties of 2D Materials XiaolongZou[1], NannanLuo[2] and DanWang[1]; [1]Tsinghua University, China; [2]Hunan University, China

Two-dimensional (2D) materials are ideal platforms for exploring emerging optical behaviors, at unprecedentedly high temperature and feasible control. Here, we report our systematic study on the effects of different band topologies on the optical properties of 2D systems and their control by twisting and proximity. Different 2D materials with characteristic band topologies can be adopted to achieve various long-sought high-temperature excitonic quantum behaviors, including electron-hole liquid in a new-phase (γ-phase) group IV monochalcogenides, excitonic Bose-Einstein Condensation in TiS_3, and saddle excitons in β-phase group IV monochalcogenides. While twist can introduce remarkably strong moiré optical resonances in trilayer black phosphorous even at a large twist angle of 19°, its combination with pressure or electric field leads to controllable tuning of bandgap, bandwidth, and dimension of moiré bands. Further, by turning the interlayer orbital hybridization in stacked heterobilayer, large valley band splitting and valley exciton splitting can be achieved in VSe_2/MSe_2 (M = Mo or W) at room temperature. These results show great potential of 2D materials in future opto-electronic applications.

8:30 AM *QT01.09.02
Bose Polaron Interactions in a Cavity-Coupled Monolayer Semiconductor MartinKroner; ETH Zurich, Switzerland

The interaction between a mobile quantum impurity and a bosonic bath leads to the formation of quasiparticles, termed Bose polarons. The elementary properties of Bose polarons, such as their mutual interactions, can differ drastically from those of the bare impurities. Here, we explore Bose polaron physics in a two-dimensional nonequilibrium setting by injecting left hand circular polarised exciton-polariton impurities into a bath of coherent right hand circular polarised polaritons generated by resonant laser excitation of monolayer MoSe2 embedded in an optical cavity. By exploiting a biexciton Feshbach resonance between the impurity and the bath polaritons, we tune the interacting system to the strong-coupling regime and demonstrate the coexistence of two new quasiparticle branches. Using time-resolved pump-probe measurements we observe how polaron dressing modifies the interaction between impurity polaritons. Remarkably, we find that the interactions between high-energy polaron quasiparticles, that are repulsive for small bath occupancy, can become attractive in the strong impurity-bath coupling regime.

9:00 AM *QT01.09.03
Proximity Effects and Excitons in Van der Waals Heterostructures JaroslavFabian; University of Regensburg, Germany

Excitonic spectra of 2D semiconductors are known to be very sensitive to the dielectric surroundings. But they can also be tailored by weak van der Waals hybridizations across the layers---the so called proximity effects. Placing a transition metal dichalcogenide, such as WSe2, in contact with a ferromagnetci CrI3, results in exchange induced valley-resolved single-particle spectral shifts which can be probed by excitonic absorption. I will present our theoretical efforts in ab initio modeling of the proximity effects and the Bethe-Salpeter equation simulation of the excitonic spectra affected by the proximity. I will also argue that in addition to pure dielectric screening effects, there are also hybridization signitures in the g-factor of excitons in transition metal dichalcogenides in contact with graphene. Finally, I will present an analysis of the excitonic g-factors in strained TMDCs in which a hybridization between inter and intraband transistions can be tuned by strain.
Support from DFG SFB 1277, SPP2244, and FLAG-ERA is acknoweldged.

Anisotropic Excitons and Polaritons HuiDeng; University of Michigan, United States

Anisotropy is a fundamental property of materials widely exploited in science and engineering. However, the interplay between the material and engineered photonic anisotropies has been difficult to access. Van der Waals materials open the opportunity to explore a wide range of anisotropic materials and to integrate them with photonic structures. We show here a matter-light hybrid system, exciton-polaritons in a 2D antiferromagnet, CrSBr, coupled with an anisotropic photonic crystal cavity, where the spin, atomic lattice, and photonic lattices anisotropies intertwine and give rise to unusual properties of the hybrid system. We measure strong coupling between engineered anisotropic optical modes and anisotropic excitons in CrSBr, which is stable against excitation densities a few orders of magnitude higher than polaritons in isotropic materials. Moreover, the polaritons feature a highly anisotropic polarization tunable by tens of degrees by controlling the matter-light coupling via, for instance, spatial alignment between the material and photonic lattices, magnetic field, temperature, cavity detuning and cavity quality-factors.

Efficient Light Collection from Single-Photon Emitters in 2D Materials RudolfBratschitsch; University of Muenster, Germany

Single-photon sources are crucial components for quantum networks and communications. Recently, single-photon sources in 2D materials have emerged as robust solid-state light emitters. For collecting and making use of single photons emitted from 2D materials, different strategies can be envisioned, whether the photons are needed on-chip or in free space.
We present waveguide-coupled single-photon emitters in the layered semiconductor GaSe as promising on-chip sources [1]. GaSe crystals are placed on Si_3N_4 waveguides, resulting in a modified mode structure efficient for light coupling. Using optical excitation from within the waveguide, we find nonclassicality of the generated photons routed on a photonic chip. Thus, our work provides an easy-to-implement and robust platform for integrated photonic quantum technology.
For far-field collection, we present polymer microlenses, which are 3D-printed directly on single-photon emitters in commercially available hBN nanocrystals. First, a regular array of hBN nanocrystals is created using capillary assembly [2]. Subsequently, we 3D-print elliptical polymer microlenses onto the nanocrystals. The light emission is efficiently collimated to angles below 5° [3]. The small angle of emission of the new single-photon source allows for using collection lenses with very low numerical apertures > 0.06, including optical fibers.
In summary, we have demonstrated two methods to efficiently harvest single photons from 2D materials, rendering these single-photon sources highly promising for quantum optics and photonic quantum technologies.

Excitonic Tuning Through Dynamic Modulation of Moiré Potential KausikMajumdar[1], MedhaDandu[2], PushkarDasika[1], GarimaGupta[1], MayankChhaperwal[1], RabindraBiswas[1], KenjiWatanabe[3], TakashiTaniguchi[3], VarunRaghunathan[1] and SumanChatterjee[1]; [1]Indian Institute of Science, India; [2]Lawrence Berkeley National Laboratory, United States; [3]National Institute for Materials Science, Japan

Moiré superlattice created by stacking two monolayers of transition metal dichalcogenides at different twist angles is an excellent testbed for exciton physics. In this work, we explore dynamic tuning of the moiré excitons through external stimulus in different moiré configurations, including homo-bilayer, hetero-bilayer, and hetero-bilayer on a nanopillar-induced strain well. We specifically show a large tunability of the confinement potential, spectral position, lifetime, and polarization characteristics of the exciton in these different types of moiré-superlattices under the influence of a gate voltage and excitation power. The experimental results corroborate well with a tunable two-dimensional quasi-harmonic oscillator model for the moiré-trapped exciton. Such strong tunability of moiré exciton has intriguing implications towards moiré-inspired device applications.

Quantum Melting Phase Diagram of a Two-Dimensional Electron Wigner Crystal JihoSung[1], JueWang[1], IlyaEsterlis[1], PavelA. Volkov[1], GiovanniScuri[1], YouZhou[2], EliseBrutschea[1], TakashiTaniguchi[3], KenjiWatanabe[3], YuboYang[4], MiguelMorales[4], ShiweiZhang[4], AndrewMillis[4], MikhailD. Lukin[1], PhilipKim[1], EugeneDemler[5] and HongkunPark[1,1]; [1]Harvard University, United States; [2]University of Maryland, United States; [3]National Institute for Materials Science, Japan; [4]Flatiron Institute, United States; [5]ETH Zürich, Switzerland

Strongly interacting electrons can form novel quantum states of matter, exhibiting rich phase diagrams and exotic physical phenomena. The two-dimensional (2D) electron gas provides a paradigmatic example, where competition between Coulomb repulsion and kinetic energy leads to quantum melting of an electron Wigner crystal on increasing electron density. Despite nearly a century of intensive research, however, the detailed nature of this transition is not fully understood. Here, using cryogenic reflectance and magneto-optic spectroscopy, we provide clear experimental evidence for long-standing theoretical predictions that the density-driven quantum melting of a Wigner crystal proceeds through an electronic mixture phase characterized by a microscopic coexistence of crystal and liquid states. At densities below ~3×10^{11} cm^{-2}, electrons in a $MoSe_2$ monolayer form a two-dimensional Wigner crystal. As the electron density increases, we observe abrupt changes in the spin susceptibility, excitonic reflection spectrum, and charge-order-induced exciton scattering. These anomalies mark clear phase boundaries separating a Wigner crystal, intermediate quantum melting phase(s), and a Fermi liquid state. The experimentally determined phase diagram reveals the prominent Pomeranchuk effect arising from the enhanced stability of the crystalline phase upon heating due to its large spin entropy. Our study reveals the interplay between distinct electronic states and establishes the multi-staged nature of the quantum melting in a 2D correlated electron system. Atomically thin semiconductors thus provide a unique experimental platform to study the universal properties of quantum phase transitions in correlated electron systems in two dimensions.

SESSION QT01.10: Time Resolved Studies of Excitons

2:00 PM *QT01.10.01
Imaging Excitons in Momentum Space KeshavM. Dani; Okinawa Institute of Science and Technology, Japan

Optical techniques have provided us with rich information about the exciton – a two-particle photoexcited state in semiconductors and insulators. Yet, they have left a fundamental degree of freedom of the exciton inaccessible – it's *momentum*!
In this talk, I will discuss the application of time-resolved photoemission techniques to access the momentum coordinate of excitons in 2D semiconductors, thereby providing us with the formation pathways of momentum-forbidden dark excitons [*Science* **370**, 1199 (2020)], an image of the electron around the hole in the exciton, the observation of the long-predicted anomalous dispersion of the exciton-bound electron [*Science Advances* **7**, eabg0192 (2021)], the momentum distribution of the exciton-bound hole, and the confinement of the interlayer exciton in a moiré cell [*Nature* **603,** 247 (2022)].

2:30 PM *QT01.10.02
Ultrafast Nonlinear Spectroscopy of 2D Excitons: Local Field Effects and a New Destructive Photon Echo DanielWigger; Trinity College Dublin, Ireland

Over the last several years, two-dimensional semiconductors, especially in the form of transition metal dichalcogenides, have gained considerable attention in several areas of physics. One of the reasons for this is their strong excitonic optical response, which makes them attractive for future optoelectronic or quantum applications. Their remarkable brightness allows to efficiently study them with ultrafast nonlinear spectroscopy to learn about their fundamental excitonic properties and the excitons' coupling to other quasi-particles. We have recently studied how the spectral dynamics of pump-probe [1] and four-wave mixing signals [2,3] can be interpreted by an exactly solvable model that extends the basic optical Bloch equations by a local field effect [4]. This local field coupling takes into account the exciton-exciton interaction between the optically generated excitons in the 2D systems on a mean field level and leads to spectral shifts depending on the excitonic occupations.
We then went a step further and studied six-wave mixing (SWM) signal dynamics and discovered a peculiar temporary signal depression, depending on the considered delay between the two applied laser pulses [5]. In this contribution, we will report on this experimental finding and demonstrate that the observed signal dynamics can be understood as a new destructive photon echo. With our local field model we are able to attribute this effect to the interaction between the excitons. We show that the two main contributions to the SWM signal interfere destructively for certain times. Already in his first report of the spin echo effect in 1950, E. Hahn has used the Bloch vector description to illustrate his newly discovered phenomenon [6]. Inspired by this, we developed a similar Bloch vector description for the destructive photon echo. Interestingly, we found that the Bloch vectors contributing to the SWM signal form Lissajous figures that get distorted with progressing time [5]. The new destructive photon echo effect allows to efficiently and systematically study the exciton-exciton interaction across 2D semiconductor samples with a spatial resolution which is only restricted by the diffraction limit of the applied laser pulses. Thereby we will be able to learn more about the potential interplay between exciton-exciton interaction and for example local strain distributions.

3:00 PMBREAK

3:30 PM QT01.10.03
Nanoplatelet-Like Ultrafast Dephasing Behavior of CdS/CdSe/CdS Spherical Quantum Wells TomasA. Ferreira[1], AlbertLiu[2], Guk JeongByeong[3], Wan KiBae[4], StevenCundiff[5], DiogoB. Almeida[6] and LazaroPadilha[1]; [1]Unicamp, Brazil; [2]Max Planck Institute for the Structure and Dynamics of Matter, Germany; [3]Pusan National University, Korea (the Republic of); [4]Sungkyunkwan University Advanced Institute of NanoTechnology, Korea (the Republic of); [5]University of Michigan, United States; [6]Universidade Federal do ABC, Brazil

Carrier dynamics in colloidal nanostructures has been the subject of scrutiny for several decades, given the possibility of tuning these materials' optical and electronic properties by the proper choice of size, shape, and composition. The ever-growing possibilities regarding architecture and composition still translate into a great demand for a comprehensive understanding of the dynamics of the many-body phenomena involved in nanomaterial systems, especially coherent exciton dynamics, with potential applications to emerging quantum systems.

In this work we perform optical multidimensional coherent spectroscopy (MDCS) on different samples of CdS/CdSe/CdS colloidal spherical quantum wells (SQWs), probing their exciton dephasing times and population dynamics, at a series of cryogenic temperatures.
Colloidal nanostructures, in general, have inherently large inhomogeneous spectral broadening due to the size distribution of the probed ensemble, hindering the characterization of the system's homogeneous responses. In addition to the temporal resolution, common on nonlinear optical spectroscopies, MDCS allow the probing of homogeneous responses even in the presence of large size inhomogeneity. Additionally, by spectrally resolving the signal, one can measure coupling strengths between quantum states.

Spherical quantum wells are nanoparticles consisting of a nucleus, enveloped by a layer of different composition that, in turn, is covered by another layer of distinct composition. The middle layer (well) material (CdSe) has an optical gap smaller than the nucleus and the outer shell (CdS) subjecting the excitons to confinement in the middle layer, effectively creating a quantum well with spherical symmetry.
The SQW architecture results in higher quantum-yields and absorption cross-sections when compared to their CdSe/CdS quantum dots counterparts. Additionally, our results indicate that the strong quantum confinement of the hole wave-function in the CdSe well indeed renders to excitons in such structures dephasing times comparable to those of CdSe nanoplates (NPLs).

Our results show that excitons confined in SQWs can become spatially separated along the spherical surface of the well analogous to the spatial separation of excitons across the lateral dimensions of CdSe NPLs, reducing the Auger recombination rates. The SQWs examined in this work differ in the width of the outer CdS shell, which translates in different strengths of the electron wave-function confinement, giving extra insight to the role of electron confinement on the exciton dephasing times.

We measured sub-ps dephasing times, at 6K, for our samples. These values are, at least, one order of magnitude shorter than those for spherical CdSe/CdS core/shell quantum dots. Additionally, we observe a decrease in dephasing time with increasing the electronic wavefunction delocalization by increasing the outer shell thickness, the opposite of what is reported on core/shell systems. Finally, our temperature series measurements corroborate with acoustic phonon population increase and coupling behaviors similar to core/shell quantum dots, indicating a similar (additional) dephasing route.

3:45 PM QT01.10.04
Emission Dynamics of Hexagonal-Boron Nitride (hBN) Single Photon Emitters (SPEs) Pumped by High Power Density Laser Excitation KristinaL. Malinowski, HamidrezaAkbari and HarryA. Atwater; California Institute of Technology, United States

Color centers in thin hBN crystals are promising candidate single photon emitters (SPEs), as they exhibit bright single photon emission at room temperature. We find that at high pump power densities (~70 kW/cm^2 at 532 nm wavelength), single photon emitting defects in hBN exhibit unstable emission around 600 nm wavelength under pulsed or continuous wave lasers. We observe both blinking (switching between a state of radiative emission and no radiative emission on long time scales), and long-term irreversible degradation of the SPE character of individual defects. To characterize the SPE at a given power, we scanned over the area containing the color center (~ 9 μm^2) with a confocal luminescence microscope to measure the emission of the color center at each wavelength. This measurement produces both a visible emission spectrum for each scan point, as well as the emission integrated over wavelength for each point, which can be arranged in a photoluminescence (PL) map indicating how total emission changes spatially. We found, the full width half maximum (FWHM) at the zero-phonon line (ZPL) increases from 27 nm to over 88 nm when the power is increased from 25 kW/cm^2 to 165 kW/cm^2 at 532 nm. This broadening coincides with a transition from photon anti-bunching to bunching, quantified with second-order correlation (g^2) measurements. The PL maps also show that under increased pump powers the radius of strong emission increases over 3-fold from 0.4 μm to 1.25 μm. This implies that at high pump powers, the color centers evolve from localized SPEs to classically emissive defects, capable of transporting the excited charge on the order of microns prior to radiative emission. Further, increasing the power causes a blue shift in the emission wavelength of the photons, indicating modification of the radiative emission pathway. We also observe a self-recovery of radiative emission over extended (336 hour) times. Fast, self-recovery of emitters, suggests there may be a relation between the blinking and apparent irreversible degradation, with blinking occurring over minutes or hours and degradation occurring over days or weeks. The observed self-recovery phenomenon points to the dynamics of photoexcited trapped charges in emission. This hypothesis will be further addressed by Kelvin probe force microscopy to reveal the spatial profile and role of trapped charges on hBN single photon emitter electrostatic charging and discharging.

4:00 PM QT01.10.05
Exciton Dynamics and Anisotropy in 2D Silver Phenylchalcogenolates Woo SeokLee, YeongsuCho, PeterMüller, RuomengWan, EricPowers, WatcharapholParitmongkol, TomoakiSakurada, NicholasSamulewicz, HeatherJ. Kulik and WilliamTisdale; Massachusetts Institute of Technology, United States

Silver phenylselenolate (AgSePh) and silver phenyltelluroate (AgTePh) are novel two-dimensional (2D) van der Waals semiconductors. However, despite having a similar crystal structure and composition, AgSePh and AgTePh exhibit strikingly different excitonic properties. While the three distinct excitonic absorption resonances of AgSePh are close in energy, AgTePh exhibits a large energetic separation between the two lowest excitonic absorption resonances. More strikingly, whereas AgSePh exhibits narrow, fast luminescence with a minimal Stokes shift, AgTePh exhibits comparatively slow, significantly red-shifted and broadened luminescence. In this presentation, we will present the synthesis, structural and optical properties of single crystals and thin films of AgSePh and AgTePh. Using time-resolved and temperature-dependent optical spectroscopy, combined with sub-gap photoexcitation studies, we will show that exciton dynamics in AgTePh films are dominated by intrinsic exciton self-trapping behavior, whereas dynamics in AgTePh films are dominated by the interaction of free-excitons with extrinsic defect states. Furthermore, using polarization-dependent optical spectroscopic studies on single crystals of AgSePh and AgTePh, we will show the strikingly different exciton anisotropy in these materials. Whereas the lowest and the second lowest free-excitons in AgSePh are polarized along [010] and [100] direction, respectively, the two lowest free-excitons and self-trapped excitons in AgTePh are all polarized along [010] direction. Finally, we will discuss GW plus Bethe-Salpeter equation calculations to understand anisotropic excitons in these materials. Overall, this work highlights the properties of a novel class of 2D excitonic semiconductors and lays the foundation for understanding exciton dynamics and anisotropy in these

materials.

Engineering Qubits in Silicon with Atomic Precision MichelleY. Simmons; University of New South Wales, Australia

The realisation of a large-scale error corrected quantum computer relies on our ability to reproducibly manufacture qubits that are fast, highly coherent, controllable and stable. The promise of achieving this in a highly manufacturable platform such as silicon requires a deep understanding of the materials issues that impact device operation. In this talk I will demonstrate our progress to engineer every aspect of device behaviour in atomic qubits in silicon. This will cover the use of atomic precision lithography to achieve fast, controllable exchange coupling [1], fast, high fidelity qubit initialisation and read-out [2]; low noise all epitaxial gates allowing for highly stable qubits [3]; and qubit control [4] that provide a deep understanding of the impact of the solid-state environment [5] on qubit designs and operation. I will also discuss our latest results in [6] analogue quantum simulation.

Bose-Einstein Condensation of Excitons in a Bulk Semiconductor at Sub-Kelvin Temperatures KosukeYoshioka, YusukeMorita and MakotoKuwata-Gonokami; University of Tokyo, Japan

It has long been a major problem in solid state physics and quantum statistical physics to experimentally clarify whether excitons, which are bound pairs of electrons and holes in bulk semiconductors, can spontaneously form Bose-Einstein condensates or not. The 1s para exciton of cuprous oxide has been studied for many years from both theoretical and experimental aspects as the most promising candidate for the realization of BEC, because it has an extremely long lifetime and behaves as a pure matter-like quasiparticle with finite mass. In this talk, we will present a study that demonstrates for the first time by real-space imaging that 1s para excitons form condensates in the temperature range of a few hundred mK [1].
BEC in this system was expected to be possible at superfluid helium temperatures by the production of high-density excitons by relatively intense laser irradiation. However, experimental evidence of BEC has not been observed. It has turned out that exciton loss processes resulting from two-body collisions between excitons occur with orders of magnitude higher efficiency than expected [2]. In such a case, the excitons cannot have a long enough lifetime for cooling, which was the reason why BECs did not appear. Therefore, during the last decade or so, the transition temperature setting has been lowered to sub-Kelvin temperatures, and the search for BEC at lower BEC transition densities has been conducted [3].
In recent years, we have realized an experimental setup in which a semiconductor crystal is cooled using a cryogen-free dilution refrigerator and laser beams in the visible and mid-infrared wavelength regions are introduced. Through exciton accumulation in an inhomogeneous strain-induced harmonic trap potential and activation of cooling channels effective for slow excitons through exciton-phonon interactions in the strain field, we have achieved exciton ensembles at approximately 100 mK [4], which is the lowest temperature in exciton systems. By evaluating the induced absorption associated with the 1s-2p transition located in the mid-infrared wavelength range, we can quantitatively evaluate the density of the exciton system [5], which is a key quantity for BEC. We have extended this measurement method to absorption imaging [6] and have utilized it in low temperature experiments in a dilution refrigerator. This was essentially important for the observation of the real image of the condensate.
The exciton condensate is a brand-new quantum many-body physical system. When the BEC criteria are satisfied, a localized density distribution appears at the bottom of the trap potential. As the exciton number is increased, the spatial broadening of the condensate increases, and this behavior can be interpreted in the same way as BEC of real particles, from which the elastic scattering length of the repulsive interaction between excitons can be derived. While those phenomena are within the framework of conventional BEC theory, the observed small fraction of condensates cannot be understood by conventional theory. This may be characteristic of quantum statistical phenomena in non-equilibrium and open systems of quasiparticles.

Enhancing the Light Emission of 2D-TMDs and MXene Quantum Dots JeongyongKim; Sungkyunkwan University, Korea (the Republic of)

Quantum-confined semiconductors with light-emitting properties offer tremendous opportunities in photonic devices with the advantages of high efficiency, tunability and flexibility. Photoluminescence quantum yield (PL QY) is one of fundamental performance parameters of these quantum optical semiconductors. In this presentation, I will discuss some of the strategies we developed to enhance the PL QY of two-dimensional (2D) transition metal dichalcogenides (TMDs) and MXene quantum dots (MQDs).

While the structural defects are the main cause that degrades the PL QY of monolayer (1L) TMDs, Auger process represented by exciton-exciton annihilation (EEA) is the major non-radiative decay channel of excitons of 1L-TMDs in high exciton density regime [1,2]. We demonstrate that combined use of proximal Au plate and negative electric gate bias for 1L-WS_2 provides the dramatic enhancement of QY and exciton lifetime at high exciton densities [3]. QY was enhanced by 30 times and the EEA rate constant decreased by 80 times. Suppression of EEA by negative electric bias is attributed to the reduction of defect-assisted EEA process, which was then explained by the theoretical model. Our results provide a synergetic solution to cope with EEA to realize the high-intensity 2D light emitters using TMDs.

MQDs, obtained by fragmenting MXene into quantum dimension, provide the light emission properites with the advantages of the low cost and the biocompatibility [4,5]. However, because of active surface trap sites of MQDs, PL QY of MQDs is low in their pristine states. We show that a dramatic enhancement of PL QY of MQDs can be achieved by removing the F-termination during the synthesis, resulting in 25% PLQY in UV emission [6]. We also observed the degradation of PL QY with the increasing excitation intensity, of which details will be discussed. This work was supported by National Research Foundation of Korea (2021R1A6A1A03039696; 2022R1A2C2009412; 2022K2A9A1A06093582)

Excitonic Behavior in Perovskite Nanoplatelets—The Role of Defects and Achieving Linearly Polarized Electroluminescence RobertHoye; University of Oxford, United Kingdom

Linearly polarized light is important for a wide range of applications, such as 3D displays and optical communications. However, linear polarization is typically achieved by filtering unpolarized light, which leads to significant losses in energy. This talk examines the use of nanostructured lead-halide perovskites to directly achieve polarized light emission.

Although nanostructured halide perovskites have important advantages in terms of color purity and tunability, they are strongly affected by surface defects. Thus, the first half of this talk examines how the surface chemistry of $CsPb(Br_xI_{3-x})$ nanocrystals can be controlled through the polarity of the antisolvent used during purification. Through detailed nuclear magnetic resonance, Fourier transform infrared spectroscopy and X-ray photoemission spectroscopy measurements, we show that higher polarity antisolvents lead to increased selective etching of the iodide species due to the removal of the long-chain organic ligands through condensation reactions [1].

The second half of the talk discusses the use of self-assembled $CsPbI_3$ perovskite nanoplatelets to achieve polarized light emission. We show that the high dielectric and quantum confinement in these nanoplatelets leads to a large splitting in the exciton fine structure. In the edge-up perovskite nanoplatelet superlattices, we achieve strong emission from the out-of-plane dipole for the optically bright excitons. In light-emitting diodes, this led to a high degree of polarization in electroluminescence of 74.4% without requiring the use of any photonic structures [2].

Exciton-Exciton Interactions - A Comparative Study of Complimentary Phenomenological Models PradeepKumar, BhaskarDe, RishabhTripathi and RohanSingh; Indian Institute of Science Education and Research, Bhopal, India

The optical response of semiconductor nanostructures is significantly influenced by many-body interactions (MBIs), such as exciton-exciton interactions. Excitation density-dependent optical experiments have previously shown the existence of these MBIs effect in 2D nanomaterials like quantum wells, transition metal dichalcogenides (TMDCs), perovskite nanoplatelets. The effects of the MBIs can be seen in the coherence - decay dynamics of the excitonic transition. To investigate the coherence dynamics of these nanomaterials' optical response, nonlinear techniques such as four-wave mixing (FWM) and two-dimensional coherent spectroscopy (2DCS) are usually used.

Theoretical models have been developed to explain the microscopic origins of these MBIs. The semiconductor Bloch equation (SBE) formalism based on microscopic model is the most robust approach, comprises a complete many-body treatment. How ever these microscopic calculations can be computationally challenging and also have limited physical insight. To overcome these limitations, phenomenological models were developed as a reasonable substitute. Phenomenologically, MBI effect can be described in terms of excitation induced dephasing (EID), and excitation induced shift (EIS). The EIS and EID effects were measured as a change in the exciton resonance energy and dephasing rate, respectively, with an increase in the excitation density.

One way to understand these interactions is through the Modified optical Bloch equations (MOBEs). The excitons are primarily treated as a two-level system (fermions) and the OBEs are used to describe their interaction with light. The MOBEs incorporate EID and EIS through a linear dependence of dephasing rate and resonance frequency with excitation density to comprehend the physical nature of MBIs. Here MOBEs need to be numerically solved, which limits their application to quantitative data analysis.

Another, less computationally intense approach to understand these MBIs is through the anharmonic oscillator model. In this formalism interacting excitons are treated as composite bosons or pure harmonic system. MBIs between interacting excitons produces anharmonicity in the system. This anharmonicity leads to nonlinear optical response in the interacting excitonic system. The nonlinear signal obtained here by analytically solving OBEs for a three-level anharmonic ladder system using a perturbative approach.

The phenomenological models outlined above have each been used to comprehend the nonlinear optical response of excitons separately. To the best of our knowledge, a direct correspondence between the two models is yet to be studied. It is still undetermined whether these models' coherence decay dynamics are equivalent. It also needs to be determined whether the parameters utilized in the two models to quantify MBIs are equivalent. Since MBI affects 2D spectra peak shape and its phase which is usually apparent in 2DCS. In this work, we show the empirical equivalence between these two complimentary MBI models through 2DCS simulations. Interestingly, we find that both the complimentary approaches are consistent with each other. We also perform a quantitative comparison of these MBI models with experiments, which highlights the usefulness of these phenomenological models in interpreting experimental results. The formalisms used here can also be used to compare and quantify the relative strength of MBIs in various excitonic systems, such as quantum wells, layered semiconductors and perovskite nanomaterials. These new finding might be crucial in directing the substantial work being done to construct flexible semiconductor quantum dot lasers and TMDCs-based valleytronics devices.

X-Ray Spectroscopy for 2D Quantum Materials RiccardoComin; Massachusetts Institute of Technology, United States

Over the past two decades, Resonant Inelastic X-ray Scattering (RIXS) has become an essential tool for investigating the microscopic interactions and low energy dynamics in various quantum materials. RIXS possesses a unique capability to probe the spin, charge, and orbital degrees of freedom with a shallow probing depth in the range of 50-100 nm. Consequently, RIXS has gained prominence as a fundamental spectroscopic technique for investigating a broad spectrum of materials, including bulk, thin films, and more recently, few-layer 2D materials.
In this presentation, I will focus on recent advancements that have facilitated RIXS studies of two-dimensional quantum materials exhibiting emergent properties in the ultrathin limit. Specifically, I will discuss two recent investigations involving unconventional superconductor FeSe and type-II van der Waals multiferroic NiI2. In the case of FeSe, I will present RIXS data

that elucidate the evolution of spin excitations from bulk FeSe to its monolayer form. For NiI2, I will discuss the progression of low-energy orbital and spin excitations as the material is thinned down from bulk crystals to few-layer flakes.

11:00 AM QT02.01.02
Noise Magnetometry of Topological BKT Transition in Two-Dimensional Superconductors JonathanCurtis[1], NicholasPoniatowski[2], PavelDolgirev[2], IlyaEsterlis[3], BertrandHalperin[2], AmirYacoby[2], EugeneDemler[4] and PrinehaNarang[1]; [1]University of California, Los Angeles, United States; [2]Harvard University, United States; [3]University of Wisconsin–Madison, United States; [4]ETH Zürich, Switzerland

The Berezinskii-Kosterlitz-Thouless (BKT) transition is an exotic type of phase transition present in two-dimensional systems that spontaneously break a U(1) type of symmetry. This transition is characterized by the proliferation of topological defects (vortices) above the transition temperature T_{BKT}, which then destroy the quasi-long-range order (QLRO) present below T_{BKT}. While superconductors in the extreme two-dimensional limit should in principle show such a transition, it is often hard to conclusively demonstrate the presence of BKT physics and even more difficult to fully characterize beyond DC transport.

Here we will show how, using diamond nitrogen-vacancy center (NV) noise magnetometry, the BKT transition can be carefully studied across different length scales and dynamical regimes, offering new insight and more detail into the nature of the transition. NV noise magnetometry is a new non-invasive technique for the quantum sensing of magnetic fields, where highly coherent spin-qubits, hosted by nitrogen-vacancy point defects in lattice of diamond, can be used to precisely measure dynamical magnetic field fluctuations as a function of frequency and length scale. Since the BKT transition is characterized by the proliferation of vortices, which each carry magnetic flux, NV noise magnetometry is in fact perfectly suited for studying how these vortices unbind and proliferate beyond simple DC transport considerations. We show how using this technique, new insights in to the dynamics and scaling of two-dimensional superconductors near the transition can be studied in the atomically-thin limit.

11:15 AM QT02.01.03
Highly Tunable Electronic Structures in Kagome Magnet Fe_xSn_y Thin Films ZhengRen[1,2], IlijaZeljkovic[2] and MingYi[1]; [1]Rice University, United States; [2]Boston College, United States

The kagome lattice is a corner-sharing triangular lattice that hosts flat bands, van Hove singularities and Dirac crossings. Recent experimental discoveries in kagome metals have showcased that they are an excellent platform for studying emergent charge, magnetic, superconducting orders as well as topological electronic structures. Fe_xSn_y (Fe_3Sn_2 and FeSn) has been shown to exhibit (massive) Dirac fermions, anomalous Hall effect, flat bands and more. Here, we selectively synthesize Fe_3Sn_2 and FeSn thin films using molecular beam epitaxy. In Fe_3Sn_2, using spectroscopic-imaging scanning tunneling microscopy, we discover a number of dI/dV spectral peaks. These peaks show a prominent magnetic-field-tunability. The features point to the theoretically-predicted tunable Weyl points near the Fermi level. In FeSn, we use angle-resolved photoemission spectroscopy to resolve the band structure, which is significantly tunable as we change the temperature of the sample. Our findings suggest highly tunable electronic structures in the kagome magnet Fe_xSn_y thin films.

11:30 AM QT02.01.04
Sharp Band Renormalizations in Superconducting $LiTi_2O_4$ Thin Films Observed by Angle-Resolved Photoemission Spectroscopy (ARPES) ZubiaHasan[1], GracePan[1], MatthewBarone[2], Albertode La Torre Duran[3], AustinKaczmarek[2], ShekharSharma[4], KatjaNowack[2], AntiaBotana[4], BrendanFaeth[2] and JuliaMundy[1]; [1]Harvard University, United States; [2]Cornell University, United States; [3]Brown University, United States; [4]Arizona State University, United States

The mechanisms behind unconventional superconductivity have been intensely studied over the past few decades. Leading this thrust has been the high T_c cuprates, whose pairing 'glue' has been widely debated. $LiTi_2O_4$, a spinel oxide material, is an unconventional superconductor that preceded the cuprates [1]. However, despite having one of the highest T_c (~13.7 K) for a non-cuprate oxide, little is known about its' superconducting mechanism, with reports of both unconventional pairing [2] and traditional phonon-mediated BCS-like behavior [3]. There have also been signs of orbital and spin fluctuations persisting up to ~100 K, based on angle-dependent transport data [4]. Nevertheless, it remains unclear which mechanisms—spin fluctuations, electron-phonon coupling or mixed valency—are essential for superconductivity in $LiTi_2O_4$. Here, we use angle-resolved photoemission spectroscopy (ARPES) with molecular beam epitaxy (MBE) to interrogate the electronic band structure of $LiTi_2O_4$ thin films on $MgAl_2O_4$ (111) substrates. Our work shows the first-ever experimentally-determined band structure of $LiTi_2O_4$. The bands intriguingly show kinks resembling cuprate-like band renormalizations. Our data indicates the presence of strong correlations: the band centered at Γ shows a 'kink' at around E_B~40 meV and a quasi-particle peak and incoherent tail suggestive of coupling to a bosonic mode. We see that this mode is present at all values of k_F and k_Z and persists above T_c. We discuss the origin of the kinks in $LiTi_2O_4$, providing broader insight into the pairing symmetry present in this superconducting system.

11:45 AM QT02.01.05
Individual Ultrabright Fluorescent Nanoparticles as Nanothermometers MahshidIraniparast; Tufts University, United States

Temperature measurement at the nanoscale is important in various scientific and engineering studies, from assessing temperature distribution in the cellular medium to conducting thermal imaging of integrated circuit devices. A serious challenge in nanoscale temperature measurement lies in achieving high spatial resolution, which can be overcome by utilizing individual nanoparticles.
For this purpose, we selected fluorescent silica nanoparticles with mesoporous structure, which have encapsulated fluorescent dyes. As has been shown, such particles demonstrate ultrahigh fluorescent brightness, which is sufficient to image single nanoparticles. To be used as thermometers, two different types of dye molecules, reference molecules, and temperature-sensitive ones, were used. The measured sensitivity, reversibility, and reproducibility of measurements of temperature using these individual nanoparticles have shown the superiority of the reported particles compared to the previously reported ones. For example, the obtained individual nanothermometers exhibited a temperature fluctuation of ~0.5 K at the measurement time of 0.69 msec and excitation power density of (temperature resolution of 0.22 $K.Hz^{-1/2}$), showing a relative sensitivity of 8% within the physiologically relevant range of 25-50ºC. This sensitivity is ~4 times beter and the temperature resolution (at an excitation power of 0.26 μW) is ~2 times better than the previously reported best temperature measuring fluorescent particles.
These superior properties are presumably the result of the fluorescence resonance energy transfer (FRET) between the encapsulated dye molecules, which act as donors and acceptors. The enhanced brightness of these nanosensors offers numerous benefits, including the improved signal-to-noise ratio and the ability to locate the particles with high spatial precision. This work was supported by NSF grants CBET 1911253 and 2110757 (IS).

SESSION QT02.02: Characterization of Low-Dimensional Quantum Systems II

1:30 PM *QT02.02.01
Emergent Topological and Magnetic Phases in 2D Van der Waals Materials MingYi; Rice University, United States

The recent discoveries of long-range magnetic order in van der Waals materials have established a new platform for probing emergent orders in correlated quantum materials. In this talk I will present our recent studies on the Fe_xGeTe_2 (x=3,5) family of 2D ferromagnets. In particular, I will report the observation of a quantum phase switching between a Weyl nodal line phase and a topological flat band phase in Fe_5GeTe_2 via a thermal annealing process. We further demonstrate that the switching of the electronic properties is associated with a crystal symmetry change driven by a Fe site ordering that is modulated by the thermal annealing process. The presence or absence of the ordering modifies the global crystal symmetry and gives rise to either magnetic nodal lines in one case or geometrically frustrated flat bands in the other. The modified crystal and electronic structures subsequently affect the magnetism of the two phases. We further demonstrate that this phase switching is reversibly controlled via the thermal annealing and quenching method. Our work not only reveals a rich range of quantum phases emergent in 2D van der Waals ferromagnets, but also uncovers the potential of utilizing site occupancy as a novel degree of freedom for tuning symmetry and therefore topology in quantum materials for the realization of exotic emergent phases.

2:00 PM QT02.02.02
Spectroscopic Signature of 3D Magnetism in a Van der Waals Ferromagnet Fe_5GeTe_2VivekBhartiya[1], JieminLi[1], TaehunKim[1], JonathanPelliciari[1], XiadongXu[2], DimitriBasov[3], AndrewMay[4] and ValentinaBisogni[1]; [1]Brookhaven National Laboratory, United States; [2]University of Washington, United States; [3]Columbia University, United States; [4]Oak Ridge National Laboratory, United States

The recently discovered family of van der Waals itinerant ferromagnets $Fe_{5-x}GeTe_2$ ($0<x<2$) are strongly correlated electronic systems and realize intriguing ground states i.e. heavy fermions and charge density wave [1-3]. Moreover, the *cleavable* Fe_5GeTe_2 displays the highest $T_c \sim 315$ K and has the potential for miniaturized spintronic devices operating at room temperature [4-5]. However, it is not yet known if the magnons in Fe_5GeTe_2 are confined in 2D or propagate in 3D. To date, investigation of magnons via inelastic neutron scattering is not feasible due to the small size of the available single crystals. In this study, we overcome this issue by employing a high-resolution resonant inelastic X-ray scattering (RIXS) on a mm-size single crystal of Fe_5GeTe_2 [5]. A broad magnetic continuum stretching up to 150 meV and displaying a strong intensity modulation along (0 0 *L*) is observed [6]. We show that this intensity modulation is compatible with a dominant inter-slab magnetic interaction enabling 3D propagation of magnons in the room-temperature ferromagnet Fe_5GeTe_2 [6].

2:15 PM QT02.02.03
Combined Nano-Optical/Scanning Tunneling Microscopy of Localized Excitons in 1L-WSe_2ThomasP. Darlington, XuehaoWu, MadisenHolbrook, KevinW. Kwock, DimitriBasov, P. JamesSchuck and Abhay NarayanPasupathy; Columbia University, United States

The transition metal dichalcogenides (TMDs) are among the most studied low dimensional material classes largely due to their tightly bound exciton states which strongly interact with light. Extensive experimental and theoretical work has shown that monolayer TMDs host a rich variety of exciton complexes, from dark excitons, biexcitons, to moiré excitons. Because of this strong light-matter coupling, optical probes are often the tool of choice, however for a full understanding combined electronic, optical, and structural probes are needed to disentangle the many degrees of freedom. Combining these probes is however experimentally challenging because of the large scale mismatch of light, ~500 nm, and high resolution electronic/structural techniques such as scanning tunneling microscopy (STM), ~1 nm.

In this presentation, I will show results from a newly constructed scanning tunneling microscope integrated with a nano-optical probe that allows for co-localized near-field light delivery, at high excitation intensities, with tunneling current measurements. I will show the application of this tool to strain-localized excitons in nanobubbles of monolayer WSe_2. We observe strong modification of the density of states in scanning tunneling spectroscopy as a function of pump fluence. Further, by hole tunneling we are able to map the STM-luminescence, revealing a localized exciton edge state with a resolution <10 nm. Our work represents a novel demonstration of the effect of optical pumping on the single particle electronic structure in TMDs at the exciton's native length scale.

New Features in Phonon Spectra from Highly Anharmonic Crystals Found by Inelastic Neutron Scattering BrentFultz, VladimirLadygin, ClaireN. Saunders and Camille MarieBernal-Choban; California Institute of Technology, United States

Textbook phonons are bosonic quasiparticles that populate vibrational modes of a crystal. Classical dynamics is often used to find the vibrational modes, which are then quantized in units of hv, where v is frequency and h is Planck's constant. This approach is extended to "quasiharmonic" theory, where v is a function of volume, and to "anharmonic" theory, where a phonon self-energy depends on interactions with other phonons through cubic or quartic perturbations to the potential. Larger deviations of the potential from harmonic can be accommodated by molecular dynamics simulations. Combining these simulations with inelastic neutron scattering (INS) experiments revealed two new types of nonlinear vibrational behavior. Both are interpreted with the quantum Langevin equation.
A phonon potential with forces that depart from linearity produces spectral features found in other nonlinear media, such as crystals for nonlinear optics. Our INS measurements on rocksalt NaBr found intermodulation phonon sidebands (IPS) at frequencies approximately equal to the sum and difference of strongly-interacting TA and TO phonon modes [1]. The "input-output theory" of quantum optics [2] was successful for predicting the intensities and shapes of the intermodulation sidebands, although the wavevector dependence of phonons adds complexity. Very recent measurements on NaBr show frequency doubling at elevated temperatures.
A second nonlinear phenomenon was found in cuprite, Cu2O. At temperatures above room temperature, a diffuse inelastic intensity (DII) replaced the optical modes. Again, the Schrödinger-Langevin equation could predict the general appearance and perhaps the shape of the DII. It originates with phase shifts in the oscillations of oxygen atoms caused by slower movements of neighboring Cu atoms. The DII requires both anharmonicity and some temporal randomness in the nonlinear forces between neighboring atoms.
Experiments to isolate the IPS and DII were performed with single crystals on a direct-geometry Fermi chopper spectrometer, ARCS, at the Spallation Neutron Source. Background removal was a challenge, but the experiments could not have been done without the low background, high flux, and detector efficiency of the ARCS spectrometer. Advances in experimental capabilities will allow other studies of nonlinear phenomena in phonon physics, and new insights into phonon anharmonicity.

PRX: What Quantum-Materials Papers are suitable?YimingXu; American Physical Society, United States

PRX is published by the American Physical Society, a nonprofit membership society of scientists. Its mission goal is to select around 250 *landmark* papers a year from all fields of physics and showcase them to a broad and multidisciplinary readership. Quantum Materials is undoubtedly a field of high interest to PRX, and also to the Physical Review journal family.

Is your paper a good match for PRX? Or asked differently, what papers qualify as *landmark* papers, especially in the field of quantum materials?

How do the PRX editors actually select such papers? Are such selections always accurate?
How can you, as an author, navigate PRX's editorial and peer-review process effectively and get the most out of your interactions with the editors and referees?
Many of these questions do not have a black-and-white answer in the case of a single paper. Open-minded, reasoned, and constructive dialogues amongst the authors, the editors, and the referees are key to making each concrete process a meaningful and productive experience, and sometimes even a pleasure, for everyone. I will use the talk to discuss with you how to answer these questions.

4:00 PM *QT02.03.03
Observation of Pines' Demon in Sr_2RuO_4PeterAbbamonte; University of Illinois at Urbana-Champaign, United States

The characteristic excitation of a metal is its plasmon, which is a quantized collective oscillation of its electron density. In 1956, David Pines predicted that a distinct type of plasmon, dubbed a "demon," could exist in three-dimensional metals containing more than one species of charge carrier. Consisting of out-of-phase movement of electrons in different bands, demons are acoustic, electrically neutral, and do not couple to light, so have never been detected in an equilibrium, three-dimensional metal. Nevertheless, demons are believed to be critical for diverse phenomena including phase transitions in mixed-valence semimetals, optical properties of metal nanoparticles, soundarons in Weyl semimetals, and high temperature superconductivity in, for example, metal hydrides. Here, we present evidence for a demon in Sr_2RuO_4 from momentum-resolved electron energy-loss spectroscopy (M-EELS). Formed of electrons in the β and γ bands, the demon is gapless with critical momentum $q_c = 0.08$ reciprocal lattice units and room temperature velocity $v = (1.065 \pm 0.12) \times 10^5$ m/s, which undergoes a 14% renormalization upon cooling to 20 K due to coupling to the particle-hole continuum. The momentum dependence of the intensity of the demon confirms its neutral character. Our study confirms a 66-year old prediction and suggests that demons may be a pervasive feature of multiband metals.

Magnetic Structure of Hexagonal Mn3Ga Thin Film by Neutron Scattering QuanzhengTao[1,2], JohannaRosen[1] and AndrewBoothroyd[2]; [1]Linkoping University, Sweden; [2]University of Oxford, United Kingdom

Hexagonal Mn_3X compounds (where X=Sn, Ge, Ga) have recently gained substantial attention due to their large anomalous Hall effect, even with a negligible magnetic moment. Compared to Mn_3Sn and Mn_3Ge, Mn_3Ga has been less studied owing to the unavailability of single crystals. In this research, we demonstrate that high-quality epitaxial thin films can effectively substitute for single crystals, thus enabling advanced neutron scattering techniques. Utilizing unpolarized neutron diffraction and spherical polarized neutron scattering methods, we successfully delineated the magnetic structure of Mn_3Ga. Furthermore, through magnetotransport measurements, we identify Mn_3Ga thin film as a promising candidate for spintronics applications. This abstract presents a breakthrough for both the study and application of Mn_3Ga, demonstrating its potential for revolutionizing spintronics.

Deciphering the Nature of Cation Disordering via Vibrational Structure Characterizations DongchangChen, YouWang, BasiratRaji-Adefila and AlexandraOutka; The University of New Mexico, United States

Cation disordering, a fascinating phenomenon that represents random cation distribution in a long range, has brought about numerous novel materials for battery applications. As a key to the performance of a cation-disordered battery material, how the cations are arranged in a shorter range is an intriguing question. In this talk, we will present our study in understanding the nature of cation disordering for a series of cation-disordered electrode materials via analyzing their vibrational structures. Owing to the unique working principle of vibrational spectroscopy, it generates critical information of cation arrangement, which cannot be feasibly obtained via diffraction analyses. Furthermore, the spectroscopic information allows to locate a few hidden key factors that control the electrochemical performance and help us build models to better understand the role of these factors.

Synthesis and X-Ray Absorption Spectroscopy of $Nd_{2-x}Sr_xNio_4$ Thin Films ($0 \leq x \leq 1.4$) NicoleK. Taylor, DanFerenc Segedin, GracePan, SpencerDoyle, AriTurkiewicz, CharlesBrooks and JuliaMundy; Harvard University, United States

Ruddlesden-Popper nickelates have been studied extensively over the last three decades due to their structural similarities to the high T_c superconductivity cuprates. In particular, the layered nickelate $La_{2-x}Sr_xNiO_4$ is analogous to the high T_c superconductor, $La_{2-x}Sr_xCuO_4$. Using reactive oxide molecular beam epitaxy (MBE), we synthesis $Nd_{2-x}Sr_xNiO_4$, thin films for x = 0, 0.50, 1, 1.2, and 1.4. We observe metallic conductivity for x=1.2 and 1.4 thin films whereas the lower doping shows semiconducting transport over the full temperature range. We present polarization-dependent O-K and Ni-$L_{2,3}$ XAS spectra for our Sr-doped Nd_2NiO_4 thin films. We track the evolution of the oxygen-nickel hybridization, distribution of holes between O 2p and Ni 3d states and the nickel oxidation state across the series. Our results are consistent with previous work on bulk layered nickelates [1].

Towards Floquet Engineering of Ferroelectric Semiconductors via Coherent Multidimensional Spectroscopy RyanP. McDonnell, DanielD. Kohler, YueaiLin, WillaMihalyi-Koch, SongJin and JohnC. Wright; University of Wisconsin–Madison, United States

Bismuth telluroiodide (BiTeI) is a prototypical, ferroelectric Rashba semiconductor (FERSC) which possesses a myriad of interesting electronic and optical properties.[1, 2] Multiple optical transitions throughout the infrared and visible in BiTeI make it a promising material for understanding spin states in Rashba materials. However, the most promising methods for Floquet engineering of spin states in FERSCs are $\chi^{(2)}$ and $\chi^{(3)}$ dependent spectroscopies, e.g., sum frequency generation (SFG), pump-probe spectroscopy.[3, 4] The electronic structure of BiTeI is well studied, making it an ideal candidate for understanding its nonlinear response. Previous experiments reported the relative prevalence of second harmonic (SHG) over third harmonic generation (THG) output from BiTeI with an input fundamental of 0.80 eV. [5, 6] To our knowledge, there are no reports regarding frequency dependent SHG and THG output of BiTeI. Here, we use coherent multidimensional spectroscopy to probe the frequency dependence of SHG and THG output of BiTeI and perovskite FERSCs throughout the visible.[7] Since the Rashba splitting in BiTeI varies as a function of temperature,[8] multidimensional harmonic generation experiments on these materials are performed at cryogenic (*ca.* 90 K) and room temperatures (*ca.* 293 K) to probe the effect of temperature on SHG and THG output. These results will have implications on identifying spectroscopies for understanding and controlling the electronic structure of FERSCs.

Second Harmonic Generation Spectroscopic Study of Weyl Semimetal Mn_3Sn with Broken Time-Reversal Symmetry ZiyadThekkayil[1], SomaiyehDadashi[1], PrajwalLaxmeesha[2], StevenMay[2] and EricBorguet[1]; [1]Temple University, United States; [2]Drexel University, United States

Topological Weyl semimetals constitute an important class of quantum materials, characterized by a chiral band structure resulting from the breaking of inversion and/or time-reversal symmetries. However, their experimental identification typically relies on techniques such as angle-resolved photoelectron spectroscopy or ultrahigh vacuum scanning tunnelling microscopy which require demanding conditions including low temperatures and ultrahigh vacuum environments. Consequently, there is a growing need for experimental techniques capable of identifying signatures of topological states under ambient conditions. Second-order nonlinear optical processes, such as second harmonic generation (SHG), have emerged as promising tools for studying Weyl semimetals and other topologically nontrivial systems due to their sensitivity to symmetry-breaking effects. However, most previous SHG studies on Weyl semimetals have been limited to systems with broken inversion symmetry or a combination of broken inversion and time reversal symmetries. There has been a scarcity of investigations focusing solely on Weyl

semimetals with broken time-reversal symmetry. In this study, we employ reflection SHG measurements to investigate the surface of thin films of the Weyl semimetal Mn_3Sn, which exhibits broken time-reversal symmetry. Our findings demonstrate that the surface SHG response of this system exhibits significant dependence on the excitation wavelength and polarization geometry. These observations provide valuable insights into the understanding of surface electronic properties and spin chirality in these materials. By employing these experimental techniques under ambient conditions, our research contributes to the broader goal of developing efficient methods for characterizing topological states in Weyl semimetals, paving the way for potential applications in electronic and spintronic devices.

8:00 PM QT02.04.04
Probing the Triplet Exciton in Singlet Fission Tetracene with Inelastic Neutron Scattering from First Principles FarahnazMaleki[1], DanielVong[1], EricNovak[2], LukeDaemen[2] and AdamJ. Moule[1]; [1]University of California, Davis, United States; [2]Oak Ridge National Laboratory, United States

Singlet fission (SF) is the process of converting an excited singlet into a pair of excited triplets. Harvesting two charges from a single photon has the potential to increase photovoltaic device efficiencies. In this study, we have used Inelastic Neutron Scattering (INS) spectroscopy to investigate the phonon density of states (pDOS) of photoexcited tetracene, in order to study its singlet fission mechanism. For the first time, our group has reported in-situ excited state INS measurements on organic chromophores using a recently developed sample environment on the indirect geometry VISION neutron spectrometer at Oak Ridge National Laboratory. We employed a DFT based open source Davis computational spectroscopy (DCS) workflow to simulate INS data in the ground state of tetracene. To model the excited state of INS spectra, we performed spin-polarized calculations with triplet spin multiplet setting. It is also the first simulation of the exited state of INS data. The modeled INS spectra show the effect of the triplets on the pDOS and verifying the validity of the periodic exciton structure. The structure is used in TD-DFT to calculate the electronic states. Analysis of the results suggests that the deformations from the excited state and neighboring molecules may induce local electronic shifting, allowing E(2T1) to lower until the SF barrier reduces to be more easily overcome.

SESSION QT02.05: Foundation of Quantum Materials Characterization

8:15 AM QT02.05.01
ARPES Characterization of the Insulator-Metal Transition in Sr-Doped Nd_2NiO_4 Thin Films DanFerenc Segedin[1], NicoleK. Taylor[1], AriTurkiewicz[1], GracePan[1], CharlesBrooks[1], LucaMoreschini[2,3] and JuliaMundy[1,1]; [1]Harvard University, United States; [2]University of California, Berkeley, United States; [3]Lawrence Berkeley National Laboratory, United States

The layered nickelates, $R_{2-x}Sr_xNiO_4$ (R = trivalent rare-earth cation), and high-T_c cuprate superconductor, $La_{2-x}Sr_xCuO_4$, are isostructural and both exhibit the suppression of antiferromagnetism, charge/spin strip order, and an insulator-metal transition upon hole-doping. However, no superconductivity has been observed in $R_{2-x}Sr_xNiO_4$ to date. Differences in the electronic structure between the layered nickelates and cuprates may shed light on the key ingredients for high-temperature superconductivity. Here, we present the ARPES characterization of $Nd_{2-x}Sr_xNiO_4$ (x = 0.8, 1.0, 1.2, and 1.4) thin films grown on $LaAlO_3$ (100). We observe a large hole pocket of x^2-y^2 character at the M-point and an electron pocket of z^2 character at the Γ-point, consistent with previous work [1]. We track the volume of the electron and hole pockets upon hole-doping and characterize the quasi-particle peak across the insulator-metal transition at x = 1.0. Finally, we observe no k_z-dispersion in either the hole or electron pockets, in contrast to $Eu_{0.9}Sr_{1.1}NiO_4$ [1, 2] and the three-dimensional electronic structure of $NdNiO_3$.

8:30 AM QT02.05.02
Electric-Field Driven Domain Reconfiguration in The Charge Density Wave 1T-TaS_2YueCao; Argonne National Laboratory, United States

Charge density wave (CDW) is ubiquitous in quantum materials. Under a minor electric field, CDWs fluctuate giving rise to increased electric conductivity long believed to arise from the depinning and sliding of CDWs. In real space, sliding of CDW will lead to the reconfiguration of CDW domains on the nano and mesoscale. Direct observation of sliding CDW is challenging. The nature of such reconfigurations, e.g., whether they are stochastic, as well as the relevant timescales, remains elusive.

We used X-ray Photon Correlation Spectroscopy (XPCS) for revealing E-field-driven domain reconfigurations in the canonical CDW material 1T-TaS_2. Combining in-situ XPCS studies with few-seconds counting time at the Advanced Photon Source (APS) and the 100 fs X-ray pulses at the MID endstation of the European XFEL, we show the CDW domain reconfigure above few microseconds and reaches ergodicity in domain configuration by seconds. These results shed light on the nature of the CDW fluctuation in 1T-TaS_2 as a stochastic process. Our results also provide quantitative measure of the depinning energy landscape in the material, which is critical to the macroscopic transport material property.

Beyond Perturbation Theory: Multi-Photon and Non-Radiative Recombination Effects in Spectroscopies AdrianE. Feiguin; Northeastern University, United States

The conventional calculation of scattering cross sections relies on a treatment based on time-dependent perturbation theory that provides formulation in terms of Green's functions in the frequency domain. In equilibrium, it boils down to evaluating a simple spectral function equivalent to Fermi's golden rule, which can be solved efficiently by a number of numerical methods. However, away from equilibrium, the resulting expressions require a full knowledge of the excitation spectrum and eigenvectors to account for all the possible allowed transitions and intermediate states, a seemingly unsurmountable complication. We have recently presented a new paradigm to overcome these hurdles[1-4]: we explicitly introduce the scattering particles (neutron, electron, photon, positron) and simulate the full scattering event by solving the time-dependent Schrödinger equation. The spectrum is recovered by measuring the momentum and energy lost by the scattered particles, akin an actual energy-loss experiment. I here show how these ideas can be generalized to study multi-photon processes such as coincidence ARPES, and the interplay between radiative and non-radiative recombination channels in X-ray spectroscopies.

Prediction of the Optical Properties of Spin Defects in Semiconductors and Insulators using Time-Dependent Density Functional Theory YuJin[1], MarcoGovoni[2,1,3], Victor WenzheYu[3], AndrewC. Xu[1] and GiuliaGalli[1,3]; [1]University of Chicago, United States; [2]University of Modena and Reggio Emilia, Italy; [3]Argonne National Laboratory, United States

Optically active point defects in semiconductors and insulators hold great potential for quantum technology applications. First-principles investigations of excited state properties of point defects are instrumental in characterizing the defects through the interpretation of spectroscopic experimental results [1-3] and in predicting spin defects with tailored optical properties [4]. Time-dependent density functional theory (TDDFT) allows for exploring not only excited-state energies and wavefunctions of localized defect states but also potential energy surfaces by performing geometry optimizations [1]. Here, I will present the study of the properties of several spin-defects using TDDFT, including the absorption spectra of the negatively charged nitrogen-vacancy center in diamond [1], the neutral silicon-vacancy center in diamond, and the neutral oxygen-vacancy center in magnesium oxide. Our calculations were made possible by our recent implementation of TDDFT with analytical forces in the West code [5,6], which enables TDDFT calculations with hybrid functionals for systems containing thousands of atoms and detailed investigations of excited-state geometries and finite-size effects.

Open Shell Molecular Platforms MatthewKaminow and JasonAzoulay; Georgia Institute of Technology, United States

The diradical behavior of open shell polymers opens many doors for emerging areas of materials research. Donor acceptor (DA) conjugated polymers (CP) can have intermediate and strong electronic correlations which allows for narrow bandgaps and diradical behavior in the ground state. In addition to the intrinsic conductivity that ground state radicals mixed with conjugation provide the polymer systems, the diradical behavior allows for high spin states that provide emergent properties in quantum information and optoelectronics. When the bandgap becomes narrow enough, the diradical behavior forms a triplet at ground state. This high spin conformation has ferromagnetic, and electron paramagnetic resonance (EPR) has been useful in confirming that the spins are spatially localized. This high spin conformation has been found using EPR to have coherence times rivalling that of diamond NV defect qubits allowing for inexpensive and novel forms of quantum computing and sensing. The long coherence times and spatial resolution also allows for the chains to be spin addressable, aiding in quantum information efforts. This narrow bandgap is also tunable, as using different donor and acceptor monomers to traverse from an aromatic structure, to a quinoidal one, to diradicals of singlet and triplet states as described in the figure. This tunability and ability to narrow the bandgap to such an extent has allowed for novel optoelectronic materials in ranges as low energy as LWIR, areas which have recently been though of as unattainable for organic materials.

Absolute Superconducting Spin Valve Effects in Superconductors with a Spin-Splitting Field and Spin-Orbit Coupling HisakazuMatsuki[1], AlbertoHijano[2,3], Miguel AguedaVelasco[4], Grzegorz P.Mazur[5], StefanIlic[2], BeilunWu[4], EdwinHerrera Vasco[4], HermannSuderow[4], GuangYang[6], SebastianBergeret[2] and JasonW. Robinson[1]; [1]University of Cambridge, United Kingdom; [2]Centro de Física de Materiales (CFM-MPC) Centro Mixto CSIC-UPV/EHU, Spain; [3]University of the Basque Country UPV/EHU, Spain; [4]Universidad Autónoma de Madrid, Spain; [5]Delft University of Technology, Netherlands; [6]Beihang University, China

At a thin-film superconductor (S) interface with a ferromagnetic insulator (FI), the magnetic proximity effect (MPE) can spin-split the superconducting density of states and suppress the critical temperature (T_c) of S. For S metals with weak spin-orbit coupling (SOC), the spin splitting can translate to several Tesla [1, 2] and the T_c suppression can reach tens of mK [3]. For a FI/S/FI spin switch, the T_c suppression is reduced for antiparallel (AP) FI magnetizations due to a net cancellation effect of the MPE in S; conversely, for parallel (P) magnetizations, the exchange fields add, enhancing the suppression of T_c with the spin switch efficiency defined as $\Delta T_c = T_c(\mathrm{AP}) - T_c(\mathrm{P}) > 0$ [4].

In the presence of SOC, the spin-splitting in S should smear out, reducing ΔT_c. Here, however, we show that in optimized EuS/Nb/EuS (FI/S/FI) structures, ΔT_c can reach 1 K and achieve an absolute spin-valve effect with $\Delta T_c/T_c$ close to 1 by inserting a thin layer of Au at a single interface - i.e., EuS/Nb/Au/EuS. Scanning tunneling spectroscopy on Au in Au/Nb and Au/Nb/EuS structures show evidence for a modification of the superconducting state due to the presence of EuS. These results demonstrate new physics in which ΔT_c is boosted by SOC.

Indications of Broken Symmetry States from Raman Measurements at High Temperature near the Putative QCP Point in the Phase Diagram of Doped $BaFe_2As_2$DebasmitaSwain[1], SoumyadeepGhosh[2], KousikBera[3], SvenFriedemann[4], HaranathGhosh[5], AnushreeRoy[1] and SitikanthaD. Das[1]; [1]Indian Institute of Technology, Kharagpur, India; [2]Lawrence Berkeley National Laboratory, United States; [3]Indian Institute of Technology Kharagpur, India; [4]University of Bristol, United Kingdom; [5]RRCAT, Indore, India

The concept of nematicity is still not well settled in case of Fe based Superconductors. Signatures of nematic ordering exist well above the structural transition temperature i.e. the presence of orthorhombic distortion in the tetragonal symmetry broken phase. Tetragonal symmetry dictates that both Fe d_{xz} and d_{yz} orbitals should be degenerate, whereas studies like ARPES, X-ray pair distribution function etc. show the unequal occupation of Fe d_{xz} and d_{yz} orbitals in the symmetry broken orthorhombic phase. By using Raman spectroscopy, we have studied P doped $BaFe_2As_2$ for x~0.23, whose doping composition lies near quantum criticality and enhanced nematic fluctuation in the doping temperature phase diagram. From transport measurement it is observed that P doped $BaFe_2As_2$ exhibits a tetragonal to orthorhombic phase transition around 60K followed by a superconducting transition below ~16K. A room temperature micro-Raman spectrum of the studied compound shows a phonon mode around ~211cm^{-1} with two broad high frequency modes around 515 cm^{-1} and 635cm^{-1}. The separation between these two modes remains around 15 mev at room temperature. Temperature dependent Raman measurement shows that the B_{1g} mode (phonon mode around ~211cm^{-1}) follows standard anharmonicity behavior within a temperature range from 80 to 300K, whereas with varying temperature these broad modes show a drop in intensity which is typically observed for electronic Raman modes. In the non-superconducting state, strong anisotropic behavior is observed for these BMs in polarization dependent Raman scattering. Electronic structure calculations for P doped and undoped $BaFe_2As_2$ show that while Fe d_{xz} and d_{yz} orbitals do not split in the tetragonal phase, the splitting energy is 13.5 meV in the orthorhombic phase of the doped system, which is reasonably close to the experimentally observed value of the energy separation of the BMs. Hence, we believe that these reported broad modes bear signatures of crystal field splitting of Fe d orbitals due to local breaking of tetragonal C_4 symmetry in the doped system.

10:45 AM QT02.05.08
Advances in Zinc Oxide Materials for Quantum Applications VishalSaravade[1,2], ChuanleZhou[3], Zhe ChuanFeng[2], BenjaminKlein[2] and IanT. Ferguson[2]; [1]Pennsylvania State University, United States; [2]Kennesaw State University, United States; [3]Missouri University of Science and Technology, United States

Advanced characterizations of zinc oxide-based materials for spintronic and quantum applications are investigated. Zinc oxide (ZnO) based materials have been explored for various applications in electronics, nanotechnology, biomedicine, power devices, and so on. Zinc oxide doped with transition metals (ZnTMO) has a potential for spintronic and quantum applications. However, its properties in this area are not well understood. In this work, characterizations of transition metal-doped zinc oxide are systematically performed and investigated to gain insights into their spin-related properties. Sets of Mn-doped ZnO and Ni-doped ZnO were epitaxially grown on sapphire substrates using metal-organic chemical vapor deposition (MOCVD). X-ray diffraction showed a nearly monocrystalline structure in the (002) direction, along with appearances of low intensity secondary phases related to the transition metal materials and host ZnO. A systematic reducing trend in the bandgap was observed in both Ni-doped and Mn-doped ZnO with increased transition metal dopant concentration. This could be due to the energy states that are introduced with the transition metals, and this shows a potential controllability in spin-inducing energy states by transition metal-doping. As per photoluminescence measurement, transition-metal doping attenuated the ultraviolet narrow band and increased emissions in the yellow-green regions. This could be due to secondary phases of TM-oxides that were formed during the MOCVD growth. Advanced Hall Effect characterizations were done to understand the inherent spin-related properties of ZnTMO. ZnTMO exhibited Anomalous Hall Effect (AHE). The transverse Hall resistivity overlapped with the longitudinal resistivity, and both these resistivity were not linear. This indicates spin-polarization in ZnTMO that is not induced by intrinsic carriers. The spin polarization in ZnTMO could be the result of TM-TM clusters, secondary phases, defects, and extrinsic carrier scattering. Annealing reversed the AHE response and indicated the influence of annealing on spin-polarizations of the AHE-causing components of ZnTMO. The mechanism for spin in ZnTMO is based on extrinsic scattering by TM centers/clusters or secondary phases. Understanding of spin mechanism in ZnTMO can help in the investigation of ZnO for quantum and other spintronic applications.

Recreating the Physics of a Doped Mott Insulator on a Silicon Surface StevenJohnston; The University of Tennessee, Knoxville, United States

Sn adatoms on a Si(111) substrate with 1/3 monolayer coverage form a two-dimensional triangular lattice with one unpaired electron per site and an antiferromagnetic Mott insulating state. The Sn layers can be modulation hole-doped and metalized using heavily-doped p-type Si(111) substrates and become superconducting at low temperatures, recreating cuprate-like physics on a Si template. Here, the combination of repulsive interactions and frustration inherent to the triangular adatom lattice opens up the possibility for a chiral order parameter. In this talk, I will discuss recent theoretical and experimental studies leveraging scanning tunneling microscopy/spectroscopy and quasi-particle interference imaging to study this novel system. We find

evidence for a doping-dependent Tc with a fully gapped order parameter, time-reversal symmetry breaking, and a substantial enhancement of the zero-bias conductance near the edges of the superconducting domains. While each piece of evidence could have a more mundane interpretation, our combined results suggest the tantalizing possibility that Sn/Si(111) is an unconventional chiral d-wave superconductor, consistent with theoretical models.

Synchrotron Spectroscopy of Epitaxial Rare Earth Nickelates CharlesAhn; Yale University, United States

The rare-earth nickelates display a broad range of phenomena, including functional behavior such as antiferromagnetism and superconductivity. The ability to synthesize heterogeneous epitaxial thin film structures out of nickelates enables one to control and modify these functional properties via the creation of atomically abrupt interfaces. Advanced synchrotron characterization can then be used to measure the resulting electronic and magnetic properties of these atomically engineered systems. For example, the antiferromagnetic order parameter of nickelate superlattices can be imaged using resonant soft x-ray diffraction, and information about the dynamics can be accessed by x-ray photon correlation spectroscopy (XPCS) measurements using coherent soft x-rays. In this talk, we focus on synchrotron characterization of the square-planar nickelates, which are a novel class of superconductors. We use in situ aluminum reduction of the perovskite nickelates to achieve superconducting Nd1-xEuxNiO2 (NENO) thin films grown by molecular beam epitaxy (MBE). Atomic structure is characterized using crystal truncation rod (CTR) analysis, and electronic structure is characterized using diffraction-based X-ray absorption near edge structure (dXANES). We also report on the superconducting transport properties of NENO films.

U.S. National Academies Report Identifies Measurements and Infrastructure Needs for QIS Research LindaNhon; NASEM, United States

Scientific progress in the field of Quantum Information Science (QIS) will pioneer the development of cutting-edge technologies in computing, sensing, and communications. These efforts will strengthen key sectors of the United States economy and workforce. To achieve this innovation landscape, a robust QIS research enterprise needs to be established. This ecosystem includes state-of-the-art instrumentation and tools that are required for in-depth characterization of quantum molecular materials. A 2023 U.S. National Academies of Sciences, Engineering, and Medicine report, *Advancing Chemistry and Quantum Information Science*, identifies fundamental research priorities that should be targeted to enhance the measurement and control of quantum systems. The study provided recommendations for advancing these fields to federal agencies such as the U.S. Department of Energy and the National Science Foundation, U.S. Congress, the research community, and other stakeholders. Spearheaded by a committee of chemists and physicists, the study assessed a wide range of techniques, chemical approaches, and tools that would offer more precise measurements of molecular-scale quantum devices in different environments (e.g., on surfaces or at complex interfaces). Addressing facility maintenance concerns and broadening access to laboratory- and mid-scale instrumentation were also discussed. Here, the research opportunities, infrastructure and facility needs, and workforce development strategies identified in the National Academies report will be presented.

Electronic Structure, Magnetic Interactions and Charge Order in Low Valence Nickelates Probed by Resonant Inelastic X-Ray Scattering MarkP. Dean; Brookhaven National Laboratory, United States

After a 30-year quest, researchers recently succeeded in realizing superconductivity in low-valence nickelates [1]. This ignited a vigorous debate regarding the essential electronic properties of these materials and their similarity to cuprates. Some important questions include: Do these materials have appreciable oxygen charge-transfer character and superexchange akin to the cuprates or are they in a distinct Mott-Hubbard regime where oxygen plays a minimal role and superexchange is negligible? Given that cuprates have a propensity to host proximate competing phases such as charge and spin order, one might ask whether the nickelate's phase diagrams also host competing orders and to what extent they are similar to those in cuprates? In this talk, I will describe our use of resonant inelastic x-ray scattering to solve these questions [2-4].

Resolving Emergent Structure States in Quantum Materials by Total X-Ray Scattering ValeriPetkov; Central Michigan University, United States

Materials with properties rooted in the quantum world exhibit coupled electronic, magnetic and lattice degrees of freedom leading to fascinating properties. However, the lattice degrees of freedom often appear as lattice distortions which are not necessarily amenable to crystallographic description, hampering the understanding of the underlaying physics. In the talk, we will show that the problem may be solved by total x-ray scattering and show examples from our recent studies on dual heavy fermion liquid UPt_2Si_2, which exhibits antiferromagnetism consistent with localized 5f-electron states and transport properties characteristic to Kondo lattice systems (1), layered transition metal dichalcogenide 1T-TaS_2, which is a putative Mott insulator (2), and $NbTe_4$ topological superconductor, where double Dirac points emerge thanks to the emergence of charge density wave order (3).

Case Studies of Quantum Materials via RIXS Wei-ShengLee; SLAC National Accelerator Laboratory, United States

Quantum materials exhibit extraordinary properties stemming from the interplay of different degrees of freedom, encompassing quantum topology, orbital, spin, lattice, and charge interactions. However, comprehending and manipulating these underlying degrees of freedom presents a substantial challenge. Resonant inelastic X-ray scattering (RIXS) has emerged as a powerful technique for studying elementary excitations associated with these fundamental degrees of freedom, including orbital, magnon, phonon, and charge excitations, in the energy-momentum domain. This capability offers great opportunities to unravel the intricate phenomena exhibited by quantum materials.

In particular, the recent advancements in X-ray free-electron laser have heralded a new era of time-resolved RIXS, enabling the measurement of elementary excitations when they are driven out of equilibrium. In this presentation, I will showcase our latest investigations employing RIXS and time-resolved RIXS on unconventional superconductors and related compounds. Our

findings highlight how RIXS can illuminate the microscopic behaviors, thereby contributing to a broader understanding and potential control of quantum materials.

Next-Nearest-Neighbor Hopping and Charge-Ordering Tendencies in a Cuprate Ladder HariPadma[1], JinuThomas[2], SophiaTenHuisen[1], WeiHe[3], ZiqiangGuan[1], JieminLi[3], YuWang[4], ZhiqiangMao[4], ValentinaBisogni[3], JonathanPelliciari[3], MarkP. Dean[3], StevenJohnston[2] and MatteoMitrano[1]; [1]Harvard University, United States; [2]The University of Tennessee, Knoxville, United States; [3]Brookhaven National Laboratory, United States; [4]The Pennsylvania State University, United States

The competing nature of charge-order and superconductivity in the cuprates is an open experimental and theoretical problem in condensed matter physics. Recent theoretical studies on the Hubbard model have revealed that the next-nearest neighbor hopping *t'* is a key tuning parameter that destabilizes charge-ordered phases in favor of superconductivity[1]. However, the influence of *t'* remains relatively unexplored experimentally. Quasi-1D systems are an ideal platform to study the microscopic physics of the cuprates, owing to the availability of reliable theory that may be rigorously compared to experimental results. Here we consider the quasi-1D cuprate ladder system $Sr_{14-x}Ca_xCu_{24}O_{41}$, which exhibits a gapped spin singlet ground state[2] that is charge ordered at ambient pressure[3] and superconducting at high pressure[4] ($x > 11$, $T_C = 9$ K at 3.5 GPa). Focusing on the hole self-doped parent compound ($x = 0$), we map the spectrum of dispersive two-triplon spin fluctuations as a function of temperature across the CO phase transition using high-resolution resonant inelastic X-ray scattering at the Cu *L*-edge. We identify a substantial downturn in the two-triplon dispersion near the zone boundary, a feature that is at odds with predictions of the Hubbard model with only nearest-neighbor hopping. Furthermore, we observe a dramatic reshaping of the two-triplon spectrum across the CO transition temperature. We fit the experimental two-triplon dispersion measured in the CO ground state using DMRG calculations and unbiased Bayesian optimization to extract the Hubbard model parameters including the exchange anisotropy and *t'*. We examine the role of *t'* in the reshaping of the spin fluctuations across the CO transition, in particular identifying signatures of hole pairing and hole-triplon bound states, which have been hypothesized to be precursors to superconductivity in spin ladders[5,6]. Our work provides a rigorous experimental quantification of *t'* in cuprates and clarifies its influence over spin fluctuations and electronic ordering.

Lead-Reduced Halide Perovskite Solar Cells with Photo-Assisted Kelvin Probe Force Microscopy Ming-ChungWu; Chang Gung University, Taiwan

With the intensification of the global energy crisis, characterized by increasing demand and diminishing fossil fuel reserves, it has become imperative to explore sustainable and efficient energy-harvesting technologies. Perovskite solar cells (PSCs) have rapidly gained prominence as a promising photovoltaic device, boasting power conversion efficiencies (PCE) exceeding 26%. However, the widespread use of lead (Pb) in PSCs introduces environmental and health hazards that pose challenges to their broad commercialization. In this presentation, I will introduce the strategic research roadmap of our group in advancing perovskite solar cell technology. Our discussion will be divided into four key areas: (1) high-efficiency perovskite solar cells employing metal-doped TiO_2 as the electron transport layer (ETL); (2) the design of side-chain modulated, carbazole-based bifunctional hole-shuttle interlayers; (3) the development of lead-reduced perovskite solar cells; and (4) the exploration of lead-free Ag_3BiI_6 rudorffite solar cells. Predicting the quality of photovoltaic (PV) materials necessitates a thorough understanding of the material properties, manufacturing processes, and the long-term performance of solar cells or modules. To this end, we utilize various methods and techniques. Photoluminescence (PL) and time-resolved photoluminescence (TRPL) is utilized to determine charge carrier lifetimes, recombination mechanisms, and assess the impact of defects on material quality. Generally, higher-quality PV materials are indicated by lower recombination rates, which can lead to potentially higher efficiencies in solar cell applications. The photo-assisted Kelvin Probe Force Microscopy (photo-assisted KPFM), an adaptation of traditional KPFM that includes sample illumination during measurement, proves especially beneficial for PV materials. It allows for the investigation of surface electron accumulation under conditions that closely replicate the operational environment of the solar cells. Our research group is committed to spearheading innovative solutions in PSCs that prioritize both high efficiency and environmental stewardship.

Light-Induced Floquet Effects in Graphene under Continuous-Wave Mid-Infrared Irradiation YijingLiu[1], GabrielGaertner[2], JohnHuckabee[2], AlexeySuslov[3], Luis E.F.Foa Torres[4], PaolaBarbara[1] and NikolaiKalugin[2]; [1]Georgetown University, United States; [2]New Mexico Tech, United States; [3]National High Magnetic Field Laboratory, United States; [4]University of Chile, Chile

Light-matter interaction in 2D materials is predicted to induce Floquet-Bloch states with non-trivial topology [1,2,3]. We report on the experimental observation of photoinduced transverse voltage and photoinduced current in graphene Hall bars irradiated with high-power linearly and circularly-polarized mid-Infrared radiation at cryogenic temperatures. The radiation wavelength is 10.6 μm and the power density is larger than 1 $mW/\mu m^2$. We investigate the dependence of the photoresponse on the temperature, position of Fermi level, and light polarization. The observation of Floquet signatures at lower power densities and in the CW regime lifts substantial experimental restrictions, helping to unlock potential applications for light-induced manipulation of material properties [4].
We acknowledge support from NSF (projects DMR CMP #2104755 and DMR CMP #2104770). The National High Magnetic Field Laboratory is supported by the National Science Foundation through NSF/DMR-2128556 and the State of Florida.

Spin Dynamics in a Photoexcited Mott Insulator on a Square Lattice TakamiTohyama; Tokyo University of Science, Japan

The recent development of time-resolved resonant inelastic x-ray scattering (trRIXS) opens a new avenue for probing collective two-particle excitations, from which one can investigate novel photoinduced nonequilibrium phenomena in the wide range of momentum and energy spaces. RIXS can probe not only charge excitation but also single-magnetic excitation if one uses incident x rays tuned for L edge in transition metals. Therefore, trRIXS is a good tool to investigate single-magnon excitation in photoexcited Mott insulators. On the other hand, time-resolved two-magnon Raman scattering (trTMRS) is suitable for investigating two-magnon excitation in photoexcited Mott insulators. In order to give theoretical predictions to trRIXS, we investigate momentum dependent single-magnon excitation that evolves after pumping within a femtosecond timescale in an antiferromagnetic Mott insulator on a square lattice [1]. Using a numerically exact-diagonalization technique based on the time-dependent Lanczos method for a half-filled Hubbard model on a square lattice, we find a characteristic temporal oscillation for the intensity of the dynamical spin correlation function describing single-magnon excitation. This oscillation shows an antiphase behavior for two orthogonal directions that are parallel and perpendicular to the electric field of a pump pulse. The same behavior is also seen in the static spin structure factor. Their oscillation period in time is determined by two-magnon excitation in the Mott insulator. This theoretical prediction will be confirmed for Mott insulating cuprates and iridates once TRRIXS is ready for a femtosecond timescale. The photoexcitation of the Mott insulator

on a square lattice weakens the intensity of two- magnon excitation as observed in trTMRS [2]. However, the spectral changes in the low-energy region below the two-magnon excitation have not yet been clearly understood. After turning off a pump pulse tuned for an absorption edge, we find that a new magnetic signal clearly emerges well below the two-magnon energy [3]. We find that low-energy excitation is predominantly created via an excitonic state at the absorption edge. This exciton-assisted magnetic excitation may provide a possible explanation for the low-energy spectral weight in the recent trTMRS experiment [2].

11:45 AM QT02.08.04
Ultrafast Nonsymmorphic Symmetry Breaking by Strong Light-Matter Interaction ChanghuaBao[1], ShaohuaZhou[1], BenshuFan[1], PeizheTang[2], WenhuiDuan[1] and ShuyunZhou[1]; [1]Tsinghua University, China; [2]Beihang University, China

In condensed matter physics, symmetry breaking lays the cornerstone of the formation of rich phases of matter, such as charge density waves and magnetism. Symmetry breaking can be on-demand controlled in equilibrium states by external fields, including electric/magnetic field and strain, leading to intriguing phase transitions and collective modes, such as tailoring topological Dirac nodal line, Mobius, and hourglass fermions by breaking nonsymmorphic symmetry. Beyond equilibrium states, strong light-matter interaction potentially provides unprecedented opportunities for breaking symmetry on an ultrafast timescale and even realizing exotic quantum states which have no counterpart in equilibrium states.

Here, by utilizing time- and angle-resolved photoemission spectroscopy (TrARPES), we demonstrate the realization of ultrafast symmetry breaking by strong light-matter interaction in a two-dimensional semiconductor. Driven by a strong mid-infrared light field, an emerged band crossing nodal ring is observed, which is gapped by the interactions and leaves nonsymmorphic symmetry-protected Dirac nodes. Interestingly, when the driving light field is tuned to polarize along the direction which breaks the nonsymmorphic symmetry, Dirac nodes are further gapped to form a fully gaped nodal ring, indicating a light-induced nonsymmorphic symmetry breaking. Moreover, the Dirac nodes are gapped only in the presence of the light field and recover gapless almost instantaneously (<<100 fs) when the light field is turned off, suggesting an ultrafast nonsymmorphic symmetry breaking. This work not only demonstrates light-matter interaction as an effective way to manipulate symmetry in quantum materials but also paves an important step for the long-sought Floquet topological insulator.

Exploring Novel Quantum Materials under High Pressure and High Temperature WeiweiXie; Michigan State University, United States

Pressure, an intensive variable, is a virtually unexplored pathway to new quantum materials. The application of high pressure can yield dramatic new examples of quantum materials. In this presentation, I will discuss how high pressure can be used to tune unexpected physical properties in magnetic topological materials and low dimensional materials. The use of high pressure and high temperature synthesis can stabilize the exotic quantum phenomena detected by high pressure X-ray and neutron scattering. I will also introduce our new lab-based in-situ high pressure and high temperature single crystal X-ray diffraction technique, which can guide us to synthesize materials rationally under high pressure and high temperature. High pressure synthesis techniques will be the focus of the discussion, novel iridates (Sr2IrO4, SrIrO3), and tetragonal BaCoO3.

Photoemission Studies of Ferroelectric Rashba Semiconductors—From Static to Transient Properties ClaudeF. Monney[1], FredericChassot[1], GeoffroyKremer[2], AkiPulkkinen[3], ChristopherNicholson[4], HugoDil[5,6], JurajKrempasky[6], JanMinar[3], GuntherSpringholz[7], JulianMaklar[8], RalphErnstorfer[8], LaurenzRettig[8], ChangmingYue[1] and PhilippWerner[1]; [1]University of Fribourg, Switzerland; [2]Université de Lorraine, France; [3]University of West Bohemia, Czechia; [4]Specs, Germany; [5]EPFL, Switzerland; [6]Paul Scherrer Institute, Switzerland; [7]Johannes Kepler Universität, Austria; [8]Fritz-Haber Institute, Germany

Ferroelectric Rashba semiconductor are bulk materials with noncentrosymmetric atomic structures in their ferroelectric phase combined with a significant spin-orbit interaction, leading to a strong coupling between spins, electrons and the underlying lattice. These properties are directly imprinted on their electronic structure through the occurrence of a giant Rashba splitting in their valence band. This gives the possibility of studying their paraelectric-to-ferroelectric phase transition in the momentum space with angle-resolved photoemission spectroscopy (ARPES). α-GeTe and α-SnTe are two prime examples of such a class of materials. Moreover, it has been recently demonstrated that it is possible to reversibly manipulate the spin polarization in GeTe by an external electric field, a promising behavior for spintronics applications.
A stimulating direction of research is now to investigate how it is possible to modify the ferroelectric properties of these materials with temperature or light pulses.

In this talk, I will start with the case of SnTe and will show high-energy-resolution ARPES data acquired as a function temperature across its ferroelectric phase transition. Our excellent experimental resolution and unprecedented thin film quality allow us to follow the evolution of the Rashba splitting induced by the ferroelectric distortion in the bulk bands and to reveal drastic deviations from a mean-field-like transition. I will discuss how the persistence of a splitting at room temperature supports an order-disorder type of transition and will elaborate on the implications for the topological nature of surface states in SnTe.

In a second part, I will move to the case of GeTe. Upon photoexcitation, we have driven GeTe out-of-equilibrium and probed its transient low-energy electronic structure with time-resolved ARPES. As a consequence, the Rashba splitting of its bulk states is enhanced after 200 fs, a very surprising result, especially given that bulk-sensitive time-resolved experiments have only led to a suppression of ferroelectric upon photoexcitation. In addition, our data show a coherent modulation of the Rashba splitting with a frequency that corresponds to the amplitude mode of the ferroelectric distortion. I will explain what is the physical mechanism behind this unexpected behavior.

4:00 PM *QT02.09.04
Resolving States of Matter in Space and Time by Coherent Soft X-Ray Scattering ClaudioMazzoli; Brookhaven National Laboratory, United States

Recently we succeeded in showing how states of matter - magnetic domain configurations in the specific - can be recognized and accessedby the novel Coherent Soft X-ray Scattering full field imaging, or other more traditional techniques when special analysis is added. Building on our experience in dynamics and time domain analysis, we proved the ability to disentangle intertwined details in space and time, thus accessing microscopic information in a completely new way. In my talk, I will show the proof of principle of the above approach, and conclude by surfing across some long standing problems in condensed matter physics which could naturally benefit from this new approach.

4:30 PM *QT02.09.05
Nonlinear Coupled Magnonics EdoardoBaldini; The University of Texas at Austin, United States

Tailored light excita=on and nonlinear control of la?ce vibra=ons have emerged as powerful strategies to manipulate the proper=es of quantum materials out of equilibrium. Generalizing the use of coherent phonon-phonon interac=ons to nonlinear couplings among other types of collec=ve modes would open unprecedented opportuni=es in the design of novel dynamic

func=onali=es in solids. For example, the collec=ve excita=ons of magne=c order – magnons – can carry informa=on with liIle energy dissipa=on, and their coherent and nonlinear control would provide an aIrac=ve route to achieve collec=ve-mode-based informa=on processing and storage in forthcoming spintronics and magnonics. In this talk, I will show that intense terahertz (THz) fields can ini=ate processes of magnon up-conversion mediated by an intermediate magne=c resonance. By using a suite of advanced spectroscopic tools, including a newly demonstrated two-dimensional THz polarimetry technique enabled by single-shot detec=on, we unveil the unidirec=onal nature of coupling between dis=nct magnon modes of a canted an=ferromagnet. These results demonstrate a route to inducing desirable energy transfer pathways between coherent magnons in solids and pave the way for a new era in the development of ultrafast control of magne=sm.

Phase Transitions and Spin Dynamics of the Quasi-One Dimensional Ising-Like Antiferromagnet BaCo2V2O8 in a Longitudinal Magnetic Field VirginieSimonet[1], QuentinFaure[2], ShintaroTakayoshi[3], SylvainPetit[2], BéatriceGrenier[4] and ThierryGiamarchi[5]; [1]Institut Néel, France; [2]Laboratoire Léon Brillouin, France; [3]Konan University, Japan; [4]Grenoble Alpes University, France; [5]University of Geneva, Switzerland

Combining inelastic neutron scattering and numerical simulations, we study the quasi-one-dimensional Ising anisotropic quantum antiferromagnet BaCo2V2O8 in a longitudinal magnetic field. This remarkable material shows a quantum phase transition from a Néel ordered phase at zero field to a longitudinal incommensurate spin density wave at a critical magnetic field of 3.8 T. Concomitantly, the excitation gap almost closes and a fundamental reconfiguration of the spin dynamics occurs. These experimental results are well described by the universal Tomonaga-Luttinger liquid theory developed for interacting spinless fermions in one dimension. We especially observe the rise of mainly longitudinal excitations, a hallmark of the unconventional low-field quantum regime in Ising-like quantum antiferromagnetic chains.
If the field is increased further, another transition into a transverse antiferromagnetic phase takes place at 9 T. In contrast to this abrupt change of magnetic ordering, the spectrum is not much altered at the transition at 9 T. The spin dynamics indeed reflects the 1D character of the system well accounted by Tomonaga-Luttinger liquid excitations. At the same time, the succession of magnetic phases reflects the competition between longitudinal and transverse correlations expected in the model, which can be experimentally investigated for the first time. Such an apparent disconnection of the static and dynamical properties is another nice property of the rich physics observed in the low-dimensional quantum antiferromagnet BaCo2V2O8, which is proved to be a precious material to test universal behaviors described by the Tomonaga-Luttinger liquid theory.

8:30 AM *QT02.10.02
Probing Quantum Entanglement with Neutron Scattering AlanTennant; The University of Tennessee, Knoxville, United States

The ability to pinpoint materials with highly entangled states, like quantum spin liquids, is hindered by the absence of methods that can experimentally identify and measure entanglement in quantum substances. To address this, we explore the potential of inelastic neutron scattering (INS) as a tool for a universal measurement approach to entanglement. This is done through three markers: one-tangle, two-tangle, and quantum Fisher information (QFI). Using INS, we take detailed measurements on system for S=1/2 transverse-field XXZ spin chain. This allows us to modulate entanglement with the influence of a magnetic field, and we subsequently cross-check our findings with density-matrix renormalization group analyses.

9:00 AM *QT02.10.03
Inelastic Spectroscopies of The Physics of Quantum Spin Liquid Materials YoungLee[1,2]; [1]Stanford University, United States; [2]SLAC National Accelerator Laboratory, United States

Quantum spin liquids (QSL's) are novel states of matter possessing long range quantum entanglement. Inelastic spectroscopies are the preeminent tool for exploring their rich physics. An important experimental signature of such novel phases is the presence of spin excitations characterized by fractionalized quantum numbers. For the kagome quantum spin liquid candidate materials Zn-barlowite and herbertsmithite, our inelastic scattering measurements (using both neutron and x-ray probes) provide evidence for fractionalized spinon excitations. Furthermore, experiments on closely related materials with competing states allow us to determine the most important magnetic interactions and to identify signatures of broken symmetry states. In addition, our high energy resolution studies shed light on the role that impurities play in the QSL ground state physics. We discuss the implications our recent experimental investigations of the spin excitations which span low energies (~J/100) to high energies (~10J) on our powder and single crystal samples of QSL and related materials.

9:30 AM *QT02.10.04
Machine Learning-Enabled Real Time Analysis in Ultrafast X-Ray Scatterings ZhantaoChen[1,2]; [1]Stanford University, United States; [2]SLAC National Accelerator Laboratory, United States

The X-ray free-electron laser (XFEL) has opened up numerous unique scientific opportunities for ultrafast dynamics and particle imaging studies. However, obtaining meaningful experimental signals for complex samples remains a significant challenge. In this talk, we present two recent works to help address this issue by integrating machine learning techniques into data collection and analysis. Firstly, we combine neural network (NN) models with Bayesian experimental design algorithms for real-time experiment steering. The NN facilitates uncertainty quantifications in experimental settings and provides immediate parameter estimations, leading to physics-informed experimental decisions and more meaningful experimental measurements, as demonstrated through simulated X-ray Photon Fluctuation Spectroscopy (XPFS) measurements on magnetic excitations. In the second topic, we present an NN-based reconstruction algorithm for X-ray single particle imaging (SPI), capable of simultaneously estimating particle orientations and recovering the complete reciprocal space information. Our method remains robust under challenging experimental conditions, including strong shot-to-shot photon count fluctuations. It enables successful reconstructions from datasets with limited and highly-noisy diffraction patterns, surpassing limitations of the conventional algorithm.

10:30 AM *QT02.11.01
Time-Domain Free-Electron-Laser Spectroscopies for Nonzero-Wavevector Excitations PaulEvans; University of Wisconsin–Madison, United States

Complex oxide thin film heterostructures and nanomaterials have a fascinating range of excitations including lattice vibrations, the coupling of lattice vibrations with electric polarization and magnetic degrees of freedom, and novel vibrational modes that arise due to nanoscale confinement. These excitations and their dynamics underpin the transport of heat, magnetic dynamics, coupled lattice/magnetic phenomena such as the spin-Seebeck effect, and the potential to probe predictions of predicted high-wavevector coupled excitations. We describe experimental free-electron-laser x-ray diffraction studies from two systems in which ferroic degrees of freedom are coupled to lattice vibrations: a weakly coupled ferroelectric/dielectric $PbTiO_3/SrTiO_3$ superlattice [1] and the coupled acoustic/magnetic excitations of a $Pt/Gd_3Fe_5O_{12}$ heterostructure [2]. In both cases, the transient excitation generated by ultrafast laser absorption generates a nearly impulsive perturbation with frequency and wavevector spectrum spanning ranges of THz and a large fraction of the Brillouin zone, respectively. Experimental results reveal the dispersion of acoustic excitations across the complete mini-Brillouin zone of the $PbTiO_3/SrTiO_3$ superlattice and the coupling of photoinduced expansion to the nanoscale polarization distribution. A combined experimental and Boltzmann transport equation study revealed the propagation and interface reflection of phonons in the Pt layer of the $Pt/Gd_3Fe_5O_{12}$ heterostructure. The integration of x-ray resonant scattering mechanisms with magnetic contrast can allow simultaneous probes of acoustic and magnetic excitations and the magnetoacoustic coupling.

Plastic Deformation of Quantum Materials MartinGreven; University of Minnesota, United States

Plastic deformation is the permanent distortion that occurs when a material is subjected to stresses that exceed its yield strength. While plastic deformation has been used by blacksmiths and engineers for thousands of years, its effects on the electronic properties of quantum materials have been largely unexplored. In this talk, I will review our recent [1,2] and ongoing efforts to understand the effects of compressive plastic deformation in complex oxides. For example, we have uncovered that the classic perovskite $SrTiO_3$ exhibits enhanced, low-dimensional superconductivity and ferroelectric quantum criticality correlated with the appearance of self-organized dislocation structures, as revealed by diffuse neutron and X-ray scattering [2,3]. These results as well as unpublished work for related oxides demonstrate the potential of plastic deformation and dislocation engineering for the manipulation of electronic properties of quantum materials.

Work funded by the US Department of Energy through the University of Minnesota Center for Quantum Materials, under grant number DE-SC-0016371.

Atomic and Electronic Structure Determination with Advanced X-Ray Spectroscopy GeorgeSterbinsky; Argonne National Laboratory, United States

X-ray absorption, anomalous absorption, and emission spectroscopies can reveal the atomic structures of materials, such as bond lengths and coordination environments. Insight into electronic structure, such as valence and hybridization, is also provided by these techniques. Instruments for these spectroscopic methods are available at the Advanced Photon Source, including those at beamlines 25-ID and 9-BM, which will be described. Several examples of the use of x-ray spectroscopy to gain insights into materials will be presented. These include examination of the relationship between ferromagnetism and electric polarization in multiferroic strained europium titanate films, investigation of the relationship between structure and ferromagnetism in lanthanum cobaltite films and chromium telluride crystals, and characterization of the local environments of dopants in potassium doped nickel oxide and erbium doped yttrium oxide.

Polar Textures in Ferroelectrics RamamoorthyRamesh[1] and PeterMeisenheimer[2]; [1]Rice University, United States; [2]University of California, Berkeley, United States

Complex topological configurations are a fertile playground to explore novel emergent phenomena and exotic phases in condensed-matter physics. I will describe the discovery of polar skyrmions in a lead-titanate layer confined by strontium-titanate layers by atomic-resolution scanning transmission electron microscopy (STEM). Phase-field modeling and second-principles calculations reveal that the polar skyrmions have a skyrmion number of +1 and resonant soft X-ray diffraction experiments show circular dichroism confirming chirality. Such nanometer-scale polar skyrmions exhibit a strong signature of negative permittivity at the surface of the skyrmion, which is furthermore highly tunable with an electric field. They are a new state of matter and electric analogs of magnetic skyrmions. In this talk, we will describe results of our on going work on controlling the long range order in the skyrmions and vortices as well as rigorously understanding the origins of chirality (and its electric field manipulation) in the vortex structures.

11:00 AM *QT03.01.02
Ferroelectric Incommensurate Spin Crystal DorinRusu[1,2], AnaM. Sanchez[1], ThomasHase[1], RichardBeanland[1] and MarinAlexe[1]; [1]University of Warwick, United Kingdom; [2]University College London, United Kingdom

Ferroics can form complex topological spin structures such as vortices and skyrmions, especially when subjected to particular boundary conditions. In ferroelectrics vortex-like electric dipole-based topological structures have been observed in dedicated ferroelectric systems, especially PbTiO3/SrTiO3 ferroelectric/insulator superlattices, which have proven to be an ideal model system due to their high depolarising field. The large electrostatic energy is minimised by local rotations of surface dipoles, similar to ferromagnetic Kittel domains, in the which local dipoles rotate in such a way to reduce both the depolarization and stray fields, avoiding the suppression of the ferroelectricity in the thin films.
In single PbTiO3 epitaxial layers sandwiched between SrRuO3 electrodes we observe a more complex domain structure analogue of the double- magnetic spin crystal phase. This comprises of periodic clockwise and anti-clockwise ferroelectric vortices which are modulated by a second cycloidal ordering along their toroidal core. Thus, one vector determines the periodicity of vortices and a second vector breaks the uniformity of the domains in the perpendicular direction, leading to a state described by a double- modulation. The interplay of only two orthogonal periodic modulations results in the so-called incommensurate spin crystal. [1]

The presence of such a double- structure, mediated by incommensurate interactions, would require an electric counterpart of the magnetic Dzyaloshinskii-Moriya interaction (DMi). Such an electric DMi could provide the phenomenological explanation of the emergence of magnetic-like phases in ferroelectric systems.

11:30 AM *QT03.01.03
Antiferroelectric-Like Behaviour in Ferroelectric Superlattices ChunhaiYin[1], YaqiLi[1], EdoardoZatterin[2], EvgeniosStylianidis[1], MariosHadjimichael[1,3], HugoAramberri[4], JorgeIniguez[4,5], Shelly MicheleConroy[6] and PavloZubko[1]; [1]University College London, United Kingdom; [2]European Synchrotron Radiation Facility, France; [3]University of Geneva, Switzerland; [4]Luxembourg Institute of Science and Technology, Luxembourg; [5]University of Luxembourg, Luxembourg; [6]Imperial College London, United Kingdom

Ferroelectric superlattices have proven to be an exciting platform for exploring nanoscale ferroelectricity, complex polarisation patterns, and unusual functional properties such as negative capacitance. This talk will focus on how electrostatic and mechanical boundary conditions can be exploited to realise antiferroelectric-like behaviour in ferroelectric-dielectric superlattices. Using a combination of laboratory and synchrotron X-ray diffraction, scanning probe microscopy, transmission electron microscopy, electrical measurements and simulations, we investigate the structure of these artificially layered materials and the origin of the antiferroelectric-like switching.

SESSION QT03.02: Higher-Order Topological Structures I

Polarization Dynamics during Ferroic Oxide Thin Film Growth MorganTrassin; ETH Zurich, Switzerland

Ferroelectric oxide films with a thickness of just a few atoms can now be grown with a precision matching that of semiconductors. This opens a whole world of functional device concepts and fascinating phenomena that would not occur in the expanded bulk crystal. The successful integration of ferroelectrics into nanoscale devices relies however on our ability to engineer deterministically polarization states in the application relevant ultrathin regime. Here I will show how nonlinear optics enables the in-situ investigation of the ferroelectric polarization during the thin film epitaxial growth. Beyond the unprecedented access to the emergence of ferroelectricity and domain formation during the epitaxial deposition, we investigate transient polarization states originating from the evolving charge-screening environment of the oxide thin film growth process. We show the impact of lattice chemistry, depolarizing field-related effects in-situ and identify routes towards the establishment of robust polarization states in the ultrathin regime. Our work provides new insights dealing with the physics of ultrathin ferroelectrics and further control of ferroelectric-based heterostructure.

Functional Topological Defects: Materials at the Edge of Order JanSeidel; University of New South Wales, Australia

Topological structures in ferroic functional materials such as domain walls and skyrmions attract attention due to their intriguing properties and application potential in nanoelectronics. I will discuss our recent work on various ferroelectric and multiferroic materials systems using scanning probe microscopy as the main investigative tool, which is combined with insight from electron microscopy and ab-initio theory, and discuss future prospects of this evolving research field.

2:30 PM *QT03.02.03
Modeling Spin-Control by Ferroelectric Switching KatherineInzani; University of Nottingham, United Kingdom

A key advantage of spin-defect based quantum technologies is the potential to engineer the defect properties by modifying the atomic environment. Systems which exhibit coupling between magnetic and electric degrees of freedom provide a route to manipulate spins by applying an electric-field, suggesting the prospect of localized spin-control via electrostatic gating.

We have elucidated the fundamental limit of magnetoelectric coupling by electric-field control of magnetic dopants in ferroelectric hosts, demonstrating through combined first principles calculations and electron-paramagnetic resonance measurements that the spin directionality evolves following a switching path coupled to polarization switching.[1]

We further leverage the versatility of the ferroelectric oxide platform by modifying the crystal field environment of the defect through epitaxial strain, low symmetry hosts and emergent topological polarization textures.[2,3] Results demonstrating spin-control in these systems provide an enhanced understanding of spin-charge coupling in defect systems and offer novel routes to tailored spin-control in ferroelectric crystals.

3:30 PM *QT03.02.04
Translational Boundaries of Antiferroelectrics as Topologically-Protected Polar Domains GustauCatalan[1,2] and YingLiu[3]; [1]Institut Catala de Nanociencia i Nanotecnologia, Spain; [2]ICREA, Spain; [3]The University of Sydney, Australia

Antiferroelectric materials are characterized by their antipolar dipole arrangement. Such antipolar arrangements can be disrupted by so-called translational boundaries, which separate antiferroelectric domains where the dipolar ordering is the same, but shifted by an integer number of sub-lattice units. The simplest manifestation of such translational boundaries are antiphase boundaries, where two adjacent domains are separated by half a unit cell. The antiferroelectric archetype, PbZrO3, has an unit cell that contains four dipoles, and in theory it can therefore have up to three types of translational boundaries, whereby the dipolar arrangement across the boundary is shifted by pi/2, pi or 3pi/2. Experimentally, however, we have observed “translational boundaries” with an arbitrary number of unit cells, resulting in phase shifts bigger than 2pi. These are de-facto polar domains with their own internally symmetry, polarization and electric field response. But, while they are domains, they are also, still, translational boundaries topologically constrained by their adjacent antiferroelectric domains. The dual nature of these ultra-wide translational boundaries and their functional consequences will be discussed in the talk, together with experimental evidence for their existence.

4:00 PM QT03.02.05
Crystallography of Ferroelectric Superdomain Boundaries EdoardoZatterin[1], MariosHadjimichael[2,3], StevenJ. Leake[1] and PavloZubko[3]; [1]ESRF, France; [2]University of Geneva, Switzerland; [3]University College London, United Kingdom

Due to novel functionalities recently discovered at domain walls, thin-film ferroelectrics with dense ferroelastic domain structures represent promising candidates for a new generation of nanoelectronic devices [1]. Ferroelastic domain structures form to minimize epitaxial strain in the film, which can be tailored by selecting an appropriate combination of thin film and substrate material [2]. Certain combinations give rise to peculiar hierarchical organizations, whereby ferroelastic domains arrange in distinct “superdomain” bundles [3,4]. Recent studies have demonstrated that interconversion between superdomain states can be induced by the application of an external electric field [5] or stress [6], making these systems attractive for potential applications in reconfigurable electronics. However, little is still known about the superdomain crystallography on a local scale.

Here, we use a combination of synchrotron-based scanning X-ray diffraction microscopy [7] and piezoresponse force microscopy to investigate the nature of the interfaces where superdomains composed by in-plane (a_1/a_2) and out-of-plane (a/c) polytwins come into contact. We use $PbTiO_3$ thin films deposited on $KTaO_3$ substrates as a prototype system for this study

due to the large variation in the relative fraction of a_1/a_2 and a/c superdomains that it displays as a function of film thickness. We show how such superdomain boundaries possess a characteristic distribution of polarisation, tilt, and tetragonality gradients, and discuss how these are consistent with a minimisation of local electrostatic and elastic boundary conditions.

Intertwined Dislocation Grids and Nematic Domains in an Iron-Based Superconductor Thin Film ZhengRen, HongLi, HeZhao, SharmaShrinkhala, ZiqiangWang and IlijaZeljkovic; Boston College, United States

A dislocation is a topological defect in a crystal lattice and can be associated with many functional properties. Dislocations can spontaneously form in epitaxial thin films as a strain relief mechanism. Here, we synthesize an iron-based superconductor thin film FeSe epitaxially on the $SrTiO_3$ substrate. Using scanning tunneling microscopy, we discover a structural modulation network, corresponding to a grid of edge dislocations at the film/substrate interface. We observe a striking change of the orientation of the dislocation lines as a function of the film thickness. Interestingly, since the edge dislocation grid gives rise to a spacially-varying uniaxial strain field, the formation of the nematic domains in FeSe is intimately intertwined with the dislocation grid. We further analyze their relationship by extracting the strain maps from the atomically-resolved topographs. Our finding provides an unexpected example of the formation and evolution of a dislocation grid in an epitaxial film, which is closely tied to the emergent nematic order of the iron-based superconductor FeSe.

4:30 PM QT03.02.07
Multiphoton Spectroscopy of a Dynamical Axion Insulator OliviaLiebman, JonathanCurtis, IoannisPetrides and PrinehaNarang; UCLA, United States

The unusual magnetoelectric transport present in Weyl semimetals can be compactly understood as manifestations of an underlying axion field, which itself is determined by the microscopic band structure. The axion couples nonlinearly to electric and magnetic fields and possesses a signature topological magnetoelectric response, leading to a modified form of Maxwell's equations known as axion electrodynamics. Axions are naturally present in Weyl semimetals relating to the separation of the Weyl nodes in energy and in crystal momentum. In the presence of strong interactions, charge density-wave (CDW) order may develop which serves to gap the Weyl nodes and introduces corresponding collective excitations. When the inherent chiral symmetry of Weyl semimetals is spontaneously broken by the formation of CDW order, the resultant chiral condensate is endowed with intrinsic dynamics which yields a dynamical contribution to the axion field. However, unambiguous identification of this dynamical axion mode is challenging due to its inherent nonlinear coupling to electromagnetic fields. Therefore, we propose an all-optical protocol for verifying and characterizing dynamical axion collective modes in Weyl semimetals with CDW order. First, we show that axion collective mode can be excited using two-photon excitation schemes. Following excitation, the collective axion oscillations are then diagnosed by measuring the time-resolved Kerr rotation. Our results demonstrate a pathway towards utilizing multi-photon and entangled pair spectroscopies to identify new correlated phases in quantum matter.

4:45 PM QT03.02.08
Controlling Magnetotactic Bacteria, Their Topological Properties and Generating Skyrmions in Their Polar and Non-Polar Velocity Vector Fields NoahKent[1,2], ColinGates[2], BohdanSenyuk[2], Jan BartTen-Hove[2], JefferyCameron[2] and IvanSmalyukh[2,2]; [1]Massachusetts Institute of Technology, United States; [2]University of Colorado Boulder, United States

Magnetotactic bacteria are microorganisms containing magnetite magnetic nanoparticle (MNP) bacteria organelles called magnetosomes. Magnetosomes are often arrayed in a specific pattern for a given strain of magnetotactic bacteria (i.e. a line along the long axis of the bacterium) and are made via biomineralization of ferromagnetic elements [1]. Previous work on the behavior of magneto-tactic bacteria in magnetic fields has assumed that the magnetic structure is a rigid dipole fixed along the bacteria's long axis – the direction of bacterial propulsion [1,2]. Such models have successfully elucidated the bacteria's behavior in rotating external fields, and magnetic field gradients. However, such models fail to explain the bacteria's behavior in a uniform magnetic field, do not allow for direct directional control over a set of bacteria, and do not address the inherent energetic degeneracy present in uniaxial magnetic systems [1,2].

Additionally, in recent years there has been significant research on topological structures, such as skyrmions and hopfions, in both magnetic [3] and soft matter liquid crystal systems [4] due to their stability and technological potential. Magnetic systems and soft matter systems typically differ in the nature of their order parameter: Magnetic systems have a polar order parameter and soft matter systems have a non-polar (axial) order parameter. No topological structures have been observed in magnetotactic bacteria despite both their magnetic and soft matter properties.

In this work we combine nanomagnetic simulations of magnetosome arrays distributions with transmission electron microscopy to simulate the magnetic behavior of the magnetotactic bacteria. Combining this with experiments using phase contrast optical microscopy and in-situ magnetic fields allowed us to understand the magnetic field response of bacteria based on how their magnetosomes are arranged. This allows us to explain previously anomalous behavior in the bacteria, control large, in phase groups of bacteria directly with external uniform magnetic fields, selectively change the topological parameter space from polar to non-polar, and generate topological structures in both the polar and the non-polar velocity vector fields of the bacteria. Being able to directly control these bacteria with external magnetic fields opens up the possibility of using them as guided microrobots in biomedicine (e.g. magnetic hyperthermia, drug delivery) and bio-spintronics.

Modified Landau-Lifshitz-Gilbert Dynamics Elucidating Asymmetric Spin Transport in NM/FM System ChanhoPark and SangkwonLee; Chung- Ang University, Korea (the Republic of)

Spin pumping, usually referred as the injection of the spin current pumped by thermal agitation of non-equilibrium magnetization in ferromagnetic (FM) or ferromagnetic insulator (FMI) materials,[1] has been granted trivial without any further discussion on the pumped direction (FM to NM / NM to FM, where NM refers to normal metal). The pumped spin current from FM to NM results from temperature gradient ranged between FM and NM. Over the decade, spin pumping has been investigated thoroughly armed with theories such as linear response theory,[1] and considered consistent with conducted experiments on spin-to-charge conversion. Theoretically, reversing the direction of the temperature gradient should invert the sign of the spin current signal, but its intensity is identical between the two configurations.
On the other hand, repeated experiments on Pt/YIG bilayer structure with temperature gradient up to 20 K (-20 K for opposite direction) shows inconsistency between the experiment and theory, where the experiment kept showing nonlinearities between FM → NM , NM → FM pumped spin current. Herein, we assumed there exists corrections on some parameters when changing the injected direction of the pumped spin current, and carefully suggest modified LLG approach where different magnon lifetime contributes to the asymmetric spin transport across NM/FM interface. However, these kind of minor rectification cannot be solely explained with modified LLG, as additional experimental factors also contributes to the nonlinearities of the spin current signal, such as the change in the average temperature at the Pt/YIG interface depending on the direction of thermal gradient and resultant temperature-dependent spin voltage

originated from the temperature dependence of the spin-Seebeck coefficient S(T),[2] and turned out to be sometimes more dominant than purely rectified spin current originated from interface-dependent magnon lifetime in our model. Nevertheless, the model suggested would provide meaningful applications for pure spin accompanied transport aided by material selection, configuration of spin voltage detecting device.

8:00 PM QT03.03.02
Nonreciprocal Edge Transport in Superconducting Devices with Magnetic Control JunyiZhao[1], KieranBozier[1], AnnaChesca[1], HisakazuMatsuki[1], AdrianIonescu[1], LeylaC. Arslan[2], NadiaStelmashenko[1], FrancescaChiodi[3] and JasonW. Robinson[1]; [1]University of Cambridge, United Kingdom; [2]Gebze Technical University, Turkey; [3]Université Paris-Saclay, France

The proximity effect at a superconductor interface with a ferromagnet layer (S/F) can lead to unconventional electron pairing [1-3] and nonreciprocal edge transport (i.e., a superconducting diode effect (SDE)) [4,5]. The underlying mechanism of the SDE can have mixed origins related to spin-orbit coupling (SOC) or vortex flow with a geometrically asymmetric pinning potential in S and at S/F interfaces in mesoscopic wires [6-8]. Here we report an experimental investigation of the SDE and edge transport in superconducting (Nb, V and RhS) wires interfacial magnetism and/or Rashba SOC versus layer thickness, wire width, temperature and microstructure. The F layer in conjunction with interfacial SOC should affect the pinning potential along the edge regions of an S/F wire and modulate vortex dynamics, driving a nonreciprocal supercurrent [9,10]. Our experiments form a framework for understanding and optimizing the SDE in superconducting wires with the aim of achieving full magnetic control of charge and potentially spin for superconducting quantum devices.

Martin[1,2,9]; [1]University of California, Berkeley, United States; [2]Lawrence Berkeley National Laboratory, United States; [3]The Pennsylvania State University, United States; [4]Cornell University, United States; [5]Westlake University, China; [6]Westlake Institute for Advanced Study, China; [7]Indian Institute of Science, India; [8]University of Southern California, United States; [9]Rice University, United States

Emergent topological polar textures, including vortices, dipolar waves, skyrmions, merons, hopfions, and more, have generated considerable interest in ferroelectrics and wider condensed-matter physics communities. The delicate balance of electric, elastic, and gradient energies of ferroelectrics can be tailored in low-dimensional forms and nanostructures to manipulate the order parameters. Exotic functional properties (*e.g.*, the coexistence of phases, chirality, negative capacitance, and emergent ultrafast dynamical responses) make them interesting candidates for devices. Ferroelectric-dielectric superlattices such as $(PbTiO_3)_n/(SrTiO_3)_n$ have been widely studied as a model system in part due to the high depolarizing field boundary condition provided by the $SrTiO_3$ layer. Such layers, however, limit the incorporation of such heterostructures into devices that could use the electronic characteristics of these polar topologies.

Looking to expand upon this rich design space, we ask a simple question: can similar emergent dipolar textures be produced in all-ferroelectric heterostructures while providing additional tunability based on the susceptibilities of the constituent layers? Here, we demonstrate the formation of polar vortices in all-ferroelectric $Pb_{1-x}Sr_xTiO_3/PbTiO_3/Pb_{1-x}Sr_xTiO_3$ trilayer and $(Pb_{1-x}Sr_xTiO_3)_n/(PbTiO_3)_n$ superlattice structures wherein $0.5 < x < 1$ grown on $DyScO_3$ (110) substrates. Unlike their counterparts with $SrTiO_3$, the $Pb_{1-x}Sr_xTiO_3$ layers exhibit robust, in-plane ferroelectric polarization and domain structures, but still provide the appropriate boundary condition for the formation of polar vortices in the $PbTiO_3$ layers. We describe the manifestation of complex polar order in these structures that combines traditional ferroelectric order with emergent dipolar textures. Reciprocal space mapping studies reveal that the strontium content in the $Pb_{1-x}Sr_xTiO_3$ provides a fine control knob over the vortex periodicity; as supported by molecular-dynamics simulations. Furthermore, while recent studies on in-plane ferroelectric switching of polar vortices showed classical bi-stable switching, here, the in-plane polarization component of the vortices in the $PbTiO_3$ layers and the ferroelectric domains in the $Pb_{1-x}Sr_xTiO_3$ layers exhibit strong elastic and dipolar coupling, leading to a coercivity enhancement of the trilayer stack upon decreasing the strontium content of the $Pb_{1-x}Sr_xTiO_3$. Phase-field simulations further explain the polarization arrangement in the trilayer and the system's subsequent collective switching pathway of the two order parameters. Formation of such in-plane domains in the $Pb_{1-x}Sr_xTiO_3$ leads to the formation of a labyrinthine vortex arrangement, unlike the highly unidirectional vortices observed in $(PbTiO_3)_n/(SrTiO_3)_n$ superlattices. Further, we have explored the coupling between different emergent dipolar heterostructures of the from $Pb_{1-x}Sr_xTiO_3/PbTiO_3/Pb_{1-x}Sr_xTiO_3/SrTiO_3/PbTiO_3/SrTiO_3$. Therein, the thickness of the $SrTiO_3$ layer separating the two vortex structures controls the strength of the elastic and electric fields that extend between layers, affecting the sequence in which each trilayer would switch and the number of switching events. The result is an ability to produce low-field multi-state, four-step switching with robust retention and fatigue performance. Finally, in $(Pb_{1-x}Sr_xTiO_3)_n/(PbTiO_3)_n$ superlattices, we have explored the dielectric tunability, ac electric-field-induced surface displacement, and out-of-plane switching and found improved tunability as a function of the chemistry of the $Pb_{1-x}Sr_xTiO_3$ layer, antiferroelectric-like switching due to an unraveling of the vortex phase upon application of the electric-field, and strong back switching on releasing the same leading to improvements in the low-field energy storage as compared to $(PbTiO_3)_n/(SrTiO_3)_n$.

Electric Bubble Quasiparticles JorgeIniguez[1,2]; [1]Luxembourg Institute of Science and Technology, Luxembourg; [2]University of Luxembourg, Luxembourg

My group is interested in the behavior of ferroelectric materials that present non-trivial polar orders and properties in situations of reduced dimensionality (ultra-thin layers or films) or subject to suitable electric and mechanical boundary conditions. Such intriguing phenomena include vortices [1], skyrmions [2], chirality [3] and negative capacitance [4,5], to name a few. In this talk I will review our most recent theoretical results for one of the model systems in the field, the PbTiO3/SrTiO3 ferroelectric/dielectric superlattices where many of the above effects were first demonstated. In particular, I will discuss the dynamical behavior of the polarization in these nano-ferroelectrics, paying especial attention to the state we call "domain liquid" [4], which is characterized by a spontaneous stochastic motion of the domains. I will further show that, under the action of an external electric field, the domains break into electric bubbles (e-bubbles) that can be very long-lived and display (fast) Brownian dynamics. I will show quantitative resuls for e-bubble stochastic diffusion, compare with the behavior of Brownian skyrmions [6], and briefly discuss potential applications in unconventional computing.

Work done in collaboration with Hugo Aramberri (Luxembourg Institute of Science and Technolgoy), F. Gómez-Ortiz and J. Junquera (University of Cantabria, Spain). My work is funded by the Luxembourg National Research Fund through Grants C18/MS/12705883/REFOX and C21/MS/15799044/FERRODYNAMICS.

Probing Structure, Properties and Dynamic Behaviors of Topological Polar States by Advanced Electron Microscopy and Spectroscopy XiaoqingPan; University of California, United States

Topological polar solitons, such as domain walls, polar vortices, and skyrmions, have garnered significant attention due to their unique functionalities and potential applications in electronic devices. The recent advancements in transmission electron microscopy (TEM) and electron energy-loss spectroscopy (EELS) have provided powerful tools for studying the structure, chemical bonding, functional properties, and dynamic behaviors of materials with atomic resolution. In this presentation, we will discuss the atomic scale structure, electric field and charge, and dynamic behaviors of nanoscale ferroelectric domains, vortices, and other topological structures such as polar skymions using TEM.

Through quantitative TEM techniques, we are able to map the electric polarization of nanodomains and a variety of polar structures at the atomic scale. Recently, we have developed a novel four-dimensional scanning transmission electron microscopy (4D STEM) method that allows for the direct mapping of local electric fields, charge densities, valence states of elements, and other properties of nanoscale materials in real space with sub-angstrom resolution. By utilizing this technique, we demonstrated the creation of skyrmion-like polar nanodomains in lead titanate/strontium titanate bilayers transferred onto silicon. These polar nanodomains can be switched from one type to another by an applied electric field, leading to substantial modifications in their resistive behaviors. This modulation in resistance is attributed to the distinct band bending and charge carrier distribution within the core of the two types of polar textures. The integration of high-density, switchable skyrmion-like polar nanodomains on silicon opens up possibilities for non-volatile memory applications utilizing topological polar structures in oxides. The investigation of topological polar states using advanced microscopy techniques offers valuable insights into their fundamental properties and dynamic characteristics. By combining the atomic-scale resolution of TEM and the real-space mapping capabilities of 4D STEM, we gain a deeper understanding of the behavior and manipulation of topological polar solitons. These findings pave the way for the development of innovative electronic devices harnessing the unique features of higher-order topological structures.

Imaging Atomic Scale Phonons in Ferroelectric Materials SandhyaSusarla; Arizona State University, United States

The advancement in thin film growth, and strain engineering has resulted in a variety of polarization domains and domain wall (DWs) formation in thin film ferroelectrics. State-of-art electron microscopy techniques such as High angle annular dark field (HAADF)- scanning transmission electron microscopy (STEM) have been used to probe the polarization magnitude and direction across domains and DWs in ferroelectric materials. However, a bewildering aspect that has not been well understood is what happens to phonons whenever there are nanoscale polarization heterogeneities. Proper ferroelectrics have a strong coupling between lattice and strain. Hence, the relationship between phonons and polarization can directly affect ferroelectric switching properties as coercive fields, switching energies and reminant polarization. Imaging phonons at atomic- to nano scale is challenging to poor spatial resolution of the current state-of-the-art techniques (Raman spectroscopy, IR spectroscopy, and thermoreflectance measurments). The combination of STEM and vibrational electron energy loss spectroscopy (EELS) provides a new paradigm to probe atomic- to nano- scale properties. In my talk, I will talk our progress behind probing atomic scale phononic properties at domains and DWs using prototypical thin-film PbTiO3 as our model system.

11:00 AM QT03.04.05
Mapping Local Topology, Defects and Emergent Order of Picometer-Scale Periodic Lattice Modulations BenjaminH. Savitzky; Lawrence Berkeley Laboratory, United States

In complex condensed matter systems, patchworks of order and disorder can form in competing order parameters, with localized pockets of emergent symmetry breaking which may be mere nanometers across. Measuring the real space variation of emergent order and its defects is therefore essential. By combining in-situ cryogenic (77K) high-angle annular dark-field scanning transmission electron microscopy, fast-acquisition low-SNR referenceless image registration with lattice-hop-error correction, picometer precision atomic column gaussian fitting, and isolation and reconstruction of both the underlying and symmetry broken lattices in Fourier space, it becomes possible to map modulations of the lattice parameter at each atomic site with picometer precision. Alternatively, real space measurement of periodic lattice modulations is possible using phase lock-in methods popular in scanning tunneling microscopy, geometric phase analysis more common in transmission electron microscopy, pairwise atomic distance histograms in one or two dimensions, and other methods. The advantages and drawbacks of these various approaches to uncovering the structure and topology of lattice symmetry breaking in real space will be discussed and compared, with examples drawn from complex oxides and transition metal dichalcogenides.

Imaging Topological Textures from the Pico to Micro Scale with Electron Ptychography DavidA. Muller; Cornell University, United States

The discovery of non-trivial topological textures, including flux-closure, vortices, skyrmions, merons and hopfion in both ferromagnetic and ferroelectric systems have required electron microscopy to resolve their internal structures. Here, enabled by a new design of electron detector [1] that is capable of measuring the complete distribution of momentum transfers at every probe position, we construct a 4-dimensional phase space from which we solve the inverse multiple scattering problem and retrieve the underlying 3-dimensional potential of the sample. The lateral resolution of less than 20 pm is now limited not by the instrument, but by the thermal vibrations of the atoms themselves, and the precision is improved to well below 1 pm [2]. The resulting ptychographic reconstructions have allowed us to image the internal structures of both magnetic and ferroelectric vortices, skyrmions and merons, including their singular points that are critical for accurately describing the topological properties of these field textures. Emergent Picosecond-Scale Dynamics of Nanoscale Ferroelectric Polarization Configurations PaulG. Evans; University of Wisconsin, United States

Ferroelectric thin films and superlattices with nanoscale dimensions exhibit a competition of energetic phenomena that produce configurations of the polarization that are distinct from bulk materials. These configurations have a profound effect on the equilibrium and driven dynamics of the nanoscale material. These dynamics are coupled to the structure of these layers and can be observed in synchrotron radiation or free-electron-laser structural studies. For example, the nanoscale polarization configuration of $PbTiO_3/SrTiO_3$ (PTO/STO) superlattices, for example, exhibits equilibrium fluctuations that arise from the existence of many configurations with nearly identical free energy. The optically driven dynamics of the PTO/STO superlattice include a picosecond-scale distortion of the polarization in response to the optically induced acoustic pulse and a change in the magnitude of the polarization of the PTO due to polarization screening. The effect of polarization screening is comparatively larger in a strongly $BaTiO_3/CaTiO_3$ (BTO/CTO) superlattice. In BTO/CTO superlattice screening effects following above-bandgap excitation lead to a reduction in the polarization of the $CaTiO_3$ layer, evident as a contraction of the out-of-plane lattice parameter of the $CaTiO_3$ component. The characteristic timescale for the development of these effects is on the scale of several picoseconds to tens of picoseconds, set by the propagation of acoustic pulses through the system. Further picosecond-scale diffraction studies reveal that the nanoscale structure affects the longitudinal acoustic sound velocity. There are prospects to employ these effects to affect structural parameters such as the oxygen octahedral tilt that affect other properties of ferroelectrics as well as the magnetism of multiferroics.

2:00 PM *QT03.05.02
Transferring Orbital Angular Momentum to an Electron Beam Reveals Toroidal and Chiral Order KaylaX. Nguyen[1,2]; [1]University of Illinois at Urbana-Champaign, United

States; [2]University of Oregon, United States

Orbital angular momentum and torque transfer play central roles in a wide range of magnetic textures and devices including skyrmions and spin-torque electronics. Unlike magnetic toroidal order, electric toroidal order, found in analogous topological structures in ferroelectrics, do not couple directly to linear external fields. Instead, we show that the presence of an electric toroidal moment in a ferro-rotational phase transfers a measurable torque and orbital angular momentum to a localized electron beam in the ballistic limit. We record these torque transfers from a high-energy electron beam using a momentum-resolved detector. This approach provides a high-sensitivity method to detect polarization fields and their more complex order parameters and topologies. In addition to toroidal order, we also demonstrate high-precision measurements of vorticity and chirality for polar vortex-like phases[1].

Phase Transformations in 2D Van der Waals Trichlorides: Insights from Cryogenic Scanning Transmitting Electron Microscopy MiaofangChi; Oak Ridge National Laboratory, United States

Two-dimensional (2D) van der Waals (vdW) materials and their heterostructures offer an exceptional platform for investigating intriguing physical phenomena and implementing diverse applications. While it is widely acknowledged that lattice structural transformations often coincide with changes in electronic and spin structures, leading to the emergence of exotic quantum phenomena, it remains uncertain whether the same structural transformations observed in bulk materials also occur in thin flake samples. As a result, a comprehensive understanding of the structure-property relationship in multi-layered 2D vdW materials is often lacking. In our recent studies, we aim to unveil the thickness-dependent phase transformations and changes in exciton states in several model 2D vdW trichlorides. To achieve this, we employ state-of-the-art techniques such as cryogenic atomic-resolution scanning transmission electron microscopy (STEM) and monochromated electron energy loss spectroscopy (EELS). By analyzing these materials with different numbers of layers at the atomic level, our findings provide insights into the layer-number-dependency that are crucial for harnessing the unique quantum characteristics of thin-layer 2D vdW materials in various device applications.

3:30 PM *QT03.05.04
Differential Phase Contrast STEM Imaging of Topological Structures NaoyaShibata; The University of Tokyo, Japan

Differential phase contrast scanning transmission electron microscopy (DPC STEM) is a powerful technique for directly characterizing local electromagnetic field distribution inside materials and devices. In recent years, new magnetic objective lens system that realizes a magnetic field free environment at the sample position has been developed [1]. The novel electron microscope with this new objective lens system (Magnetic-field-free Atomic Resolution STEM: MARS) combined with DPC imaging is very useful for charactering many important topological structures. In this talk, some resent applications using MARS will be presented. The topics include atomic-scale grain boundary structure analysis in Fe-Si soft magnet [2], domain wall width measurements in magnets [3], magnetic field imaging of spin devices [4], domain imaging in magnetic quasicrystals, imaging of magnetic skyrmions, imaging of ferroelectric domain walls and so on.

The Dynamics of Magnetic Helices in an Amorphous Material with Coherent X-Rays SophieMorley[1], ArnabSingh[1], RyanTumbleson[1,2], EmilyHollingworth[3], Ahmad UsSaleheen[1], MargaretMcCarter[1], PeterFischer[1,2], FrancesHellman[3], StephenKevan[1] and SujoyRoy[1,2]; [1]Lawrence Berkeley National Laboratory, United States; [2]University of California, United States; [3]University of California, Berkeley, United States

Synchrotron x-rays are a powerful element-specific probe for the electronic and magnetic ordering of a material. Here we measure the diffraction from a magnetic helix of pitch ~ 80 nm in a structurally amorphous FeGe thin film through its magnetic phase transition. We select the coherent part of the x-ray beam to produce an interference pattern known as speckle. The speckle pattern acts as a fingerprint of the specific microscopic configuration of the helical domains and their disorder. Taking speckle patterns as a function of time gives us a way to characterise the dynamics over ~ 10-micron field of view but with nanoscale spatial sensitivity and ms to hour time sensitivity. We identify static and dynamic parts of the speckle throughout the transition which follow a universal behavior over several compositions [1]. We extract faster dynamics at temperatures much lower than the transition temperature which we attribute to the motion of topological defects and on increasing temperature we observe on average slower fluctuations but from a larger volume of the sample. We have also performed micromagnetic simulations to model these disordered helical spin structures in support of our experimental findings.

Magnetoelectric Classification of Skyrmions BhowalSayantika and NicolaSpaldin; ETH Zürich, Switzerland

Magnetic skyrmions are nanometer-sized, topologically protected swirling spin structures with the potential for applications as data bits in future high-density data storage devices. In my presentation, I will discuss our recent development of a comprehensive theory for classifying magnetic skyrmions and related spin textures based on their magnetoelectric multipoles. These multipoles characterize the first-order asymmetry in magnetization density, which has proven highly effective in describing the magnetoelectric response of materials. Since magnetic skyrmions are now established in insulating materials, where magnetoelectric multipoles govern the linear magnetoelectric response, our classification framework offers insights into manipulating the magnetic properties of skyrmions through applied electric fields. We apply this formalism to skyrmions and anti-skyrmions of different helicities, as well as magnetic bimerons, which share the same topology but not the geometry of skyrmions. Our study reveals that the non-zero components of the magnetoelectric multipole and the magnetoelectric response tensors are uniquely determined by the topology, helicity, and geometry of the spin texture. As a result, we propose straightforward linear magnetoelectric response measurements as an alternative to Lorentz microscopy for characterizing insulating skyrmionic spin textures. 8:30 AM *QT03.06.01
Behavior of Magnetic Skyrmions Lattices at the Nanoscale Observed using *In Situ* Lorentz Transmission Electron MicroscopyAmandaK. Petford-Long[1,2], YueLi[1], ArthurMcCray[2,1] and CharudattaPhatak[1,2]; [1]Argonne National Laboratory, United States; [2]Northwestern University, United States

Understanding the behavior of nanoscale magnetic structures relies on being able to understand the complex interplay of the energy terms that control this behavior at a local scale. The relative contribution of these energy terms can be modified by parameters such as geometric confinement and interactions between adjacent magnetic nanostructures. In addition, it is important to be able to explore how a magnetic nanostructure responds to an external driving force, such as temperature, and electric or magnetic fields. We use Lorentz transmission electron microscopy (LTEM) combined with in-situ magnetizing and cooling experiments to elucidate the micromagnetic behavior at the sub-micron scale in nanomagnetic structures. By comparing

the experimental and simulated results we gain a detailed understanding of the way in which the various energy terms contribute to the behavior that we observe.

THe focus of this presentation will be on thin films of van der Waals materials that host magnetic skyrmions and other topological spin structures in which we make use of cryoEM to explore the way in which order in the skyrmions lattices evolves, the origin of this behavior, and the energy terms that control the behavior as a function of temperature and applied field.

9:00 AM QT03.06.02
Observation of Magnetic Resonance Modes in Polar Skyrmion Material $VOSe_2O_5$Araki Tomonao[1], TakashiKurumaji[1], MasahitoMochizuki[2], YoshinoriTokura[1,1,3], RinaTakagi[1,4] and ShinichiroSeki[1,4]; [1]The University of Tokyo, Japan; [2]Waseda University, Japan; [3]Japan Science and Technology Agency (JST), Japan; [4]RIKEN, Japan

The magnetic skyrmion is a vortex structure of electron spins that behaves as a stable particle protected by topology. $VOSe_2O_5$ is a magnetic insulator with a polar crystal structure (space group *P*4*cc*) and is one of a few materials that have been confirmed to exhibit a Néel-type magnetic skyrmion lattice[1, 2]. In this study, we experimentally investigate the microwave response of $VOSe_2O_5$ to clarify the magnetic resonance dynamics. As a function of temperature and magnetic field, this compound hosts a rich variety of magnetic phases, including the triangular skyrmion lattice (tri. SkL) and cycloidal spin states. In the tri. SkL phase, clockwise mode (CW), counterclockwise mode (CCW), and breathing mode (BR) have been identified. We also identified three distinctive magnetic resonance modes in the cycloid spin state, which corresponds to the rotational oscillation of local magnetic moment around the *x*, *y*, and *z* axes, respectively. The observed magnetic resonance spectra are well reproduced by theoretical calculations based on the magnetic Hamiltonian considering the Dzyaloshinskii-Moriya interaction and uniaxial anisotropy. The present results will contribute to the general understanding of the coherent dynamics of skyrmion and helical spin states in polar magnetic systems.

9:15 AM QT03.06.03
Effects of Dirac Band Tilting on Thermomagnetic Properties in Weyl Semimetals EleanorScott[1], PoulomiChakraborty[2], SatyaGuin[3,4], BrianSkinner[2] and Sarah J.Watzman[1]; [1]University of Cincinnati, United States; [2]The Ohio State University, United States; [3]Max Planck Institute for Chemcial Physics of Solids, Germany; [4]Birla Institute of Technology anf Science, India

The topological and semimetallic effects of Weyl semimetals make them excellent candidates for magneto-thermoelectric transport. Previous work in the thermoelectric properties of Type I Weyl semimetals (WSMs) has found that this class of materials possess both a large magneto-Seebeck effect and Nernst effect simultaneously, is very sensitive to doping, and that magneto-thermoelectric effects are maximized when the temperature is comparable to the Fermi energy. [1, 2]. Here, we shift our focus to Type II WSMs, which possesses asymmetric Dirac bands, unlike the band symmetry assumed in Type I WSMs. Our candidate material is WTe_2, and previous single-crystalline data observed an extremely large Nernst thermopower, exceeding 7,000 uV K^{-1} at 11.3 K and 9 T [3]. However, literature does not include full magneto-thermoelectric transport data over a broad temperature range, which we present here in polycrystalline WTe_2. Experimental results indicate that unlike the behavior observed in the Type I WSM [1], the magneto-Seebeck effect is significantly reduced and is not maximized in the same temperature range as the Nernst effect. Additionally, the Nernst thermopower of this Type II WSM did not exhibit an anomalous Nernst effect beyond cryogenic temperatures, while NbP, a Type I WSM, exhibited anomalous behavior over a broad temperature range.
Our experimental work is complemented by theoretical models of the thermoelectric transport behavior. Previous theoretical models created for the NbP work matched well with the transport behavior seen in the experimental results. This model is then altered to account for the tilted band structure and transport properties specific to WTe_2. By comparing both the experimental and theoretical results of thermoelectric transport in NbP and WTe_2, we can determine how the tilting of Dirac bands effects magneto-thermoelectric transport behavior in WSMs.

Thin-Film Realization of an Improper Ferroelectric Quantum Spin Liquid Candidate JohannaNordlander[1,2]; [1]Harvard University, United States; [2]Paul Drude Institute for Solid State Electronics, Germany

Magnetically frustrated materials offer a playground for realizing exotic magnetic ground states such as quantum spin ices and spin liquids that have been proposed as building blocks in quantum computing and as potential hosts for unconventional superconductivity. The ability to synthesize such materials in thin-film form is necessary for their integration into the proposed device architectures and also allows further tuning of the magnetic ground state with dimensionality and epitaxial strain. However, thin-film realizations of quantum spin liquid candidate materials remain scarce. Here, we use reactive oxide molecular beam epitaxy to synthesize the first thin films of hexagonal $TbInO_3$, a magnetically frustrated rare-earth system that was recently proposed as a spin liquid candidate. In bulk, $TbInO_3$ exhibits geometrically driven improper ferroelectricity similar to the multiferroic hexagonal manganites, and displays the same topologically protected vortex domain pattern. The underlying lattice distortion causing this domain pattern imposes a stuffed honeycomb geometry on the quasi-two-dimensional Tb^{3+} sublattice which harbors the magnetic frustration in $TbInO_3$. Here, we investigate the ferroelectric distortion in our epitaxial $TbInO_3$ thin films using in-situ RHEED and post-deposition HAADF-STEM. We furthermore use SQUID magnetometry and X-ray spectroscopy to investigate the low-temperature magnetic behavior. Our work constitutes one of the few thin-film realizations of a quantum spin liquid candidate, and opens up for the use of epitaxy to further manipulate the unusual coexistence of ferroelectricity and spin liquid physics in this thin-film system.

10:30 AM QT03.06.05
Large Anomalous Frequency Shift in Perpendicular Standing Spin Wave Modes in BiYIG Films Induced by Thin Metallic Overlayers ByunghunLee, TakianFakhrul, CarolineA. Ross and GeoffreyBeach; Massachusetts Institute of Technology, United States

Interface-driven phenomena in magnetic insulators is gaining attention owing to the possibility to control magnetization dynamics and magnetic textures in low-dissipation materials. Pure spin signals can be transported in magnetic insulators through magnon excitations, and controlling the nature of these excitations may lead to new insights into magnetization dynamics and novel spin wave devices. [1]
In this work, the influence of metallic overlayers on the spin wave dynamics of thin Bi-substituted yttrium iron garnet films is studied using Brillouin light scattering spectroscopy. [2] It is found that the magneto-static Damon-Eschbach modes exhibit a significant frequency shift when Pt, Au, or Cu films are deposited upon them, which arises from an interfacial contribution to the effective magnetic anisotropy. In addition, there is an unexpectedly large shift in the perpendicular standing spin wave mode frequencies that cannot be explained by anisotropy-induced surface spin pinning. Rather, the experimental observations are consistent with an interface-induced decrease in the effective thickness within with the standing waves are confined, increasing the exchange contribution to the mode frequency. It is suggested that this additional confinement may result from spin pumping at the insulator/metal interfaces, which results in a locally-overdamped interface region. We propose a phenomenological model that can describe the observation in terms of an interfacial region where the spin-orbit coupling plays a crucial role and the local effective damping associated with spin-pumping torque is relatively large, which would qualitatively explain the anomalously-large metal-induced frequency shifts. [3] These results uncover a previously-unidentified interface-driven change in magnetization dynamics that may be exploited to locally control and modulate magnonic properties in extended films.

10:45 AM QT03.06.06
The Effects of Doping on the Magnetic Transition Regions of the Skyrmion Hosting Material, Cu_2OSeO_3MarcoVas[1,2], AlexanderFerguson[1,2], JosephVella[1,2], ClemensUlrich[3], SamuelYick[1,2], TiloSoehnel[1,2] and ElliotGilbert[4]; [1]The University of Auckland, New Zealand; [2]MacDiarmid Institute of Advanced Materials & Nanotechnology, New Zealand; [3]University of New South Wales, Australia; [4]Australian Nuclear Science and Technology Organisation, Australia

The Cu_2OSeO_3 material system has gained a lot of interest over the last 10-15 years because it is the only multiferroic insulator known to host magnetic skyrmions. This material falls into a B20 class which has a non-centrosymmetric cubic crystal lattice and crystallises in a $P2_13$ space group. Most materials in this class, such as MnSi, FeGe, and $Fe_{1-x}Co_xSi$, despite having different compositions, have been observed to host magnetic skyrmions.[1] This suggests that the role of the crystal structure might influence the capability of the material to host skyrmions. The skyrmion formation is a result of the four different Cu^{2+} sites, which have a 3-down 1-up spin arrangement with Ferromagnetic (FM) and Antiferromagnetic (AFM) super-exchange interactions being present.[2] The lack of inversion symmetry in the corner shared O-Cu_4 tetrahedra result in an appreciable Dzyaloshinskii–Moriya interaction (DMI) between Cu^{2+} sites; this competes with the super-exchange interactions leading to spin canting that underpins the formation of helical/conical spin textures (depending on temperature and applied magnetic field strength).[3] However, due to these systems' complex spin and charge interactions, the underlying quantum-mechanical processes behind these phenomena are still not fully understood. Further

experiments are required; as such, this project aims to provide details on the roles played by the crystal structure that may enable the magnetic structures observed in different conditions.

For this project, the focus is on the relationship between the crystal structure and the magnetic structures observed in the Cu_2OSeO_3 material system. By manipulating the magnetic Cu sites and non-magnetic Se sites, the spin interactions between the magnetic sites will change, resulting in changes to the interacting Heisenberg and Dzyaloshinskii-Moriya interactions that are known to form skyrmions. These interactions are highly localised between magnetic ions, which makes them sensitive to spatial changes. Non-magnetic doping of substituting Te into the Se sites results in chemical pressure and expansion of the unit cell, which changes the spacing between atoms and the subtle crystal distortions should have an impact on these interactions. While magnetic doping by substituting Co^{2+} into the Cu^{2+} sites should have a large impact on these magnetic interactions due to the Co^{2+} ion having a stronger moment than Cu^{2+}. This, in turn, should change the nature of the formation of magnetic skyrmions in this material. Understanding the role that subtle distortion to the magnetic network plays on the formation and stability of topological spin structures will be vital in designing materials for spintronics. This might, in fact, provide a guide in developing ambient condition spintronics materials, in which their absences have hindered the technological application of these topological spin structures.

We will present data from high-resolution synchrotron powder XRD and neutron powder diffraction to present the effects of magnetic and non-magnetic doping on both the crystal and magnetic structure of the material. Along with small-angle neutron scattering to confirm the presence of the helical and skyrmion phases. While in-depth SQUID magnetometry measurements were carried out to see the effects of doping on magnetisation. This collection of data aims to build an understanding of how the crystal structure plays a more important in the formation of skyrmions than is currently believed in literature.

Characterization of the Anisotropic Anomalous Nernst Effect in Canted Antiferromagnetic $YbMnBi_2$ and $YbMnSb_2$KatherineA. Schlaak[1], ShuouLiu[2], ChenguangFu[2] and Sarah J.Watzman[1]; [1]University of Cincinnati, United States; [2]Zhejiang University of Technology, China

Recent research in the field of thermoelectrics (TEs) has been focused on transverse TE devices which surpass their traditional longitudinal counterparts in a few facets, including their elimination of complex n- and p-type legs in exchange for one material whose TE output scales with device size. However, transverse TE materials require a magnetic field for operation, which can increase the complexity of device design. Though ferromagnetic materials have been shown to exhibit anomalous thermoelectric transport in the absence of magnetic field, these materials often have a large magnetization which can negatively impact electronic components in device applications. Canted antiferromagnetic topological semimetals, such as $YbMnBi_2$ and $YbMnSb_2$, have been shown to exhibit these large anomalous effects with low magnetization and high mobility, thus making them reasonable candidates for transverse TE applications. Previous research on single crystalline $YbMnBi_2$, a Weyl semimetal, reported a notably large anomalous Nernst conductivity of ~10 A m^{-1} K^{-1} near 80 K, owing to the contribution of Mn to a non-zero Berry curvature and the strong spin-orbit coupling associated with Bi [1]. In addition to this large anomalous Nernst conductivity, $YbMnBi_2$ is highly anisotropic, which is beneficial in device applications as it allows for simultaneously low electrical resistivity and thermal conductivity in different crystallographic directions. While these results are intriguing, polycrystalline materials are more applicable to TE devices as single crystals can be challenging to synthesize. In this work, polycrystalline samples of YbMnBi2 are synthesized, and their magneto-thermoelectric transport is characterized as a function of temperature and externally applied magnetic field. Transport data is analyzed with an emphasis on the anisotropy present in single-crystalline samples being removed in polycrystalline samples.
$YbMnSb_2$ is a similarly anisotropic, canted antiferromagnetic Weyl semimetal. Previous work has reported a large, longitudinal thermopower of ~160 mV/K near 300 K [2]. However, transverse thermoelectric transport has yet to characterized. In this work, the anomalous Nernst and magneto-Seebeck effects of $YbMnSb_2$ are characterized as functions of temperature and magnetic field. Special attention is given to crystallographic orientation as well, as Dirac bands are expected to dominate transport in the ab-plane while parabolic bands dominate parallel to the c-axis.

Dy-Doping of Zn/Al Substituted Nickel Ferrite for Non-Collinear Magnetic Order VerenaNey[1], CelinaParzer[1], FabriceWilhelm[2], AndreiRogalev[2] and AndreasNey[1]; [1]Johannes Kepler University, Austria; [2]European Synchrotron Radiation Facility, France

Zn/Al substituted nickel ferrite (NiZAF) has been reported to be a very promising ferrimagnetic insulator with a Curie temperature well above room-temperature which exhibits a very low intrinsic magnetic damping [1]. Thin films of this magnetic spinel can be prepared using pulsed laser ablation [1] or reactive magnetron sputtering from single targets [2] as well as co-sputtering to vary the individual constituents independently [3]. Element selective characterization allows to determine the incorporation of the cationic species [1,2] and correlate them with the desired magnetic properties [3]. Besides an intrinsic low magnetic damping also non-collinear spin textures such as skyrmions are of potential interest for spintronic or magnonic applications [4]. For magnetic spinel such non-collinear magnetic textures have been reported to be generated either by structural effects in nanoparticles or ultrathin films, e.g. [5] or by doping with trivalent rare earth ions such as Dy [6]. In this work we will report on a systematic growth series of NiZAF films which were doped with Dy by means of co-sputtering. Due to its large ionic radius Dy distorts the crystal structure of the hosting spinel and the low coercive field as well as the low magnetic damping significantly increase. Nonetheless, the Curie temperature well-above room-temperature remains and the spinel structure is maintained on a local scale as evidenced by x-ray linear dichroism studies. Upon Dy doping a local minimum in the zero-field cooled M(T) curves develops which can be taken as a first indication for a non-collinear spin-arrangement which will be subject to further investigations and the latest results for the magnetic texture will be presented.

Additional Heat Channel in Chiral-Commensurate-Ferrimagnetic Weyl Semimetal NdAlSi PardeepK. Tanwar[1], AshutoshS. Wadge[1], XiaohanYao[2], FazelTafti[2] and MarcinMatusiak[1,3]; [1]International Research Centre MagTop, Institute of Physics, Polish Academy of Sciences, Aleja Lotnikow, Poland; [2]Boston College, Chestnut Hill, United States; [3]Institute of Low Temperature and Structure Research, Polish Academy of Sciences, Poland

Magnetic Weyl semimetals with broken lattice inversion and time reversal symmetries host numerous quasiparticles, including Weyl fermions, unconventional fermions with large Chern number, magnons and phonons with non-trivial bands. That makes them a potential playground for the search of novel type quantum excitations such as chiral magnon-polaron, which emerges from the coupling of topological magnon and chiral phonon via magneto-elastic coupling and Dzyaloshinkii-Moriya interaction. Chiral magnon-polaron is expected to carry heat in the presence of the magnetic field. Here, a substantial increase of magneto-thermal conductivity was reported when a magnetic field is oriented perpendicular to the temperature gradient in non-centrosymmetric magnetic Weyl semimetal of type–Ⅱ, NdAlSi. After a thorough analysis, we concluded that the phenomenon is inadequate to electronic, phononic, and magnonic contributions at low temperatures in high magnetic field. This additional contribution might be related to the chiral magnon-polaron/coupling of topological magnon and phonon in a magnetic field. In foreseeable future, such charge-neutral excitations can find applications in topological quantum computing technology.

Formation and Structural Transition of Magnetic Skyrmion Lattices in a Centrosymmetric Metallic Magnet RinaTakagi[1,2]; [1]The Univserity of Tokyo, Japan; [2]JST PRESTO, Japan

Topological objects in condensed matters have attracted attention as the source of rich electromagnetic phenomena. Magnetic skyrmions are topologically protected particle-like objects appearing as swirling spin texture in magnets and intensively studied as the potential candidate of high-density information carrier in magnetic memory [Y. Tokura and N, Kanazawa, Chem. Rev. 121, 2857 (2021).]. Magnetic skyrmions were originally observed in noncentrosymmetric magnets, in which a competition between the ferromagnetic exchange and Dzyaloshinskii-Moriya interactions stabilizes a triangular skyrmion lattice (SkL) state. Recently, on the other hand, SkL states are also found for centrosymmetric rare-earth intermetallic compounds, which commonly host nanoscale skyrmions, leading to relatively large topological Hall effect. In the latter systems, so far, the SkL always reflects the symmetry of underlying crystal lattice, and a different mechanism of skyrmion formation via itinerant electrons has been proposed.

Here we report the discovery of multiple topological magnetic phases in a centrosymmetric metallic magnet $EuAl_4$ [R. Takagi *et al.*, Nat. Commun. 13, 1472 (2022).]. By means of neutron and resonant X-ray scattering experiments, $EuAl_4$ turns out to show multiple-step reorientation of the fundamental magnetic modulation vector as a function of external magnetic field, which leads to the appearance of two distinctive SkL states, i.e., square and rhombic lattices of skyrmions with a diameter of 3.5 nm. We also found several other double-*Q* states in this compound, one of which corresponds to the superposition of four sinusoidal magnetic orders, suggesting the topological magnetic state with the skyrmion number of 2.

The appearance of such multiple SkL states is distinctive from the previously reported centrosymmetric rare-earth intermetallic compounds, where the magnetic modulation vector is always fixed along the one specific direction and the symmetry of the SkL reflects that of underlying crystal lattice. The present results demonstrate that various skyrmion orders can be realized even in simple centrosymmetric magnets, which highlights rare-earth intermetallic compounds as a promising platform to control the competition of multiple topological magnetic phases in a single material.

Real-Space Control of Topological Skyrmions and Antiskyrmions LicongPeng; Peking University, China

Magnetic skyrmions, characterized as topological "particles", and antiskyrmions, their corresponding "antiparticles", which host opposing topological numbers, have become the focus of significant interest within the realms of fundamental physics and spintronics. The potential for driving and controlling their movements will open the door for a new generation of skyrmion/antiskyrmion-centric spintronic devices.
Here I will introduce the in-situ Lorentz TEM imaging of topological spin textures and their dynamical behaviors. First, I will show the manipulation of a single skyrmion at room temperature in the chiral-lattice magnet $Co_9Zn_9Mn_2$-based microdevice using nanosecond current pulses. We have directly observed the skyrmion translation and transverse Hall motion and a dynamic transition from the static pinned state to the linear flow motion via a creep event using Lorentz TEM. Furthermore, we have evaluated the intrinsic skyrmion Hall angle and the skyrmion velocity. Our experimental observations of skyrmion flow motion qualitatively coincide with numerical calculations, suggesting the pinning effect on the skyrmion dynamics [1]. In addition to skyrmions, I will also discuss the real-space control of room-temperature antiskyrmions in magnets exhibiting D_{2d} [2] and S_4 [3-4] symmetries. By adjusting the external magnetic field, temperature, thickness, and sample geometries, we have induced topological transformations among the antiskyrmions, elliptical skyrmions, and non-topological bubbles. This was achieved through the creation, propagation, and annihilation of Bloch line pairs, accompanied by changes in their helicity, lattice form, and topological number.

Ferroelectric Hafnia Superlattices for Bio-Inspired Computing LauraBégon-Lours[1], ElisabettaMorabito[1], RubenHamming-Green[2,3], DonatoF. Falcone[1] and Bert JanOffrein[1]; [1]IBM Research Zurich, Switzerland; [2]Zernike Institute for Advanced Materials, University of Groningen, Netherlands; [3]CogniGron - Groningen Cognitive Systems and Materials Center, University of Groningen, Netherlands

Artificial Intelligence excels at learning and predicting: from the diagnosis an anomaly in an electrocardiogram to the detection of a collision risk by a car, many applications require always faster reactions. However, deploying AI in our society without compromising our greenhouse gas emissions goals requires the adoption of disruptive, energy-efficient solutions. In this context, neuromorphic systems aim at mimicking the brain in the way it processes information.
At IBM Research Zurich, ferroelectric materials are investigated for the fabrication of synaptic weights for in-memory deep neural networks and as well as synapses for spiking neural networks. We developed a CMOS-compatible process for the fabrication of passive crossbar arrays[1], combining ferroelectric $HfZrO_4$ “solid solution” (HZO) with WO_x. In the two-terminals configuration, the current flows through the ferroelectric material, which makes the synaptic weights’ electrical operation challenging. First, switching the ferroelectric polarization might require relatively large voltages, making their circuit integration difficult and increasing the required power. Second, the small conductivity of the devices requires them to occupy a large footprint in order to achieve measurable currents. By stabilizing ferroelectricity in ultra-thin HZO films below 3 nm[2], we achieved sub-volt programming and reduced by 4 orders of magnitude the footprint compared to 5 nm thick films[3]. However, such scaled devices required a high crystallization temperature (500°C) and exhibited a limited On/Off ratio (<2).
With the objective of controlling topological features such as non-trivial domain walls to add novel functionalities, we explored the combination of ferroelectric HfO_2 and anti-ferroelectric ZrO_2 in (HZO-SL) superlattices by Atomic Layer Deposition. In this talk, we provide recent advances on the electrical characterization of devices based on such thin films. The HZO-SL require a reduced thermal budget for crystallization, and a reduced footprint compared to HZO, while demonstrating a larger On/Off ratio of 16. Thanks to these properties, we demonstrate the CMOS co-integration of the HZO-SL devices in the Back-End-Of-Line.

Topological Phase Transitions in Chiral Magnets YukakoFujishiro; RIKEN Center for Emergent Matter Science, Japan

Topological chiral crystals give rise to unique spin texture as well as multi-fold Weyl Fermions where unique electromagnetic responses are expected. In this talk, I will discuss the exotic phase transitions realized in these systems, such as transition between skymion and emergent magnetic monopole in MnSi1-xGex as well as unique transport properties in MnGe which is associated with the nontrivial unwinding process of emergent magnetic monopole by magnetic field. Furthermore, I will introduce our recent work on high-pressure control of multi-fold Weyl Fermion in a B20-type magnet, which results in metal-to-insulator transition and magnetic quantum criticality with unusual magneto-transport properties.

Topology and Hidden Honeycomb Physics in a Triangular Atom Lattice: Indenene on SiC(0001) RalphClaessen[1,2]; [1]Julius-Maximilians-Universität Würzburg, Germany; [2]Würzburg-Dresden Cluster of Excellence ct.qmat, Germany

Following the seminal work of Kane and Mele on graphene, atomic monolayers arranged in a honeycomb lattice have been a major target in the search for quantum spin Hall insulators (QSHI), with bismuthene currently the record holder in terms of topological bandgap size [1]. Here I will demonstrate that QSHIs can also be realized in 2D *triangular* lattices, with the system In/SiC(0001) ("indenene") as case in point. ARPES band mapping confirms that the electronic structure is indeed that of a Dirac semimetal in which spin-orbit coupling (SOC) opens an inverted gap [2]. In fact, a detailed theoretical analysis reveals that the system is close to a topological phase transition between a QSHI and a higher order topological insulator (HOTI), controlled by the competition of SOC with substrate-induced inversion symmetry breaking [3]. Utilizing the fact that the gap-defining In 5p states form orbital angular momentum (OAM) eigenstates directly linked to the local Berry curvature, the topological character of indenene can experimentally be probed by two independent methods: by circular dichroism in ARPES as well as by STM/STS, because the OAM character of the valence orbitals leads to a specific energy-dependent spatial charge localization [2]. Both methods consistently find indenene on SiC(0001) to be a QSHI, representing the first such experimental identification from *bulk* states rather than from topological edge states. Finally, it is demonstrated that indenene intercalation into epitaxial graphene offers effective protection against ambient conditions (i.e., exposure to air or even water) while leaving the topological character fully intact [4].

11:00 AM *QT04.01.02
Spin-Orbit Torques Induced by Topological Insulators of the Bi_2Te_3 Family of Materials ThomasGuillet[1], ReginaGalceran[1], J.F.Sierra[1], MariusCostache[1], MatthieuJamet[2], FredericBonell[2] and SergioO. Valenzuela[3,1]; [1]Catalan Institute of Nanoscience and Nanotechnology, Spain; [2]Université Grenoble Alpes, France; [3]ICREA, Spain

Van der Waals (vdW) heterostructures, including those comprising topological insulators (TIs) of the Bi_2Te_3 family of materials, have disruptive potential for magnetic random-access memory applications [1]. The boundary states of a TI can generate a non-equilibrium spin density to control the magnetization of a ferromagnet (FM) by means of the spin-orbit torques (SOTs). Recent reports have demonstrated large SOT efficiencies with TIs, however, to identify the microscopic mechanisms at play, as well as to maximize the SOT, a deep understanding and control of the properties of the TI/FM interface is needed. In this talk, I will first introduce the potential advantages of vdW heterostructures and of TIs for non-volatile spintronics memories. I will then describe the relevance of their boundary states and of preserving the quality of the TI/FM interface. I will show that the introduction of a (non-magnetic) metallic [2] or graphene [3] interlayer between the TI and the FM, when FM is a transition metal, can notably suppress Te diffusion into the FM and change the nature of the SOT and its efficiency [2]. Finally, I will argue that the discovery of vdW FMs, which can be grown as high-quality thin films [4,5], can further improve the TI/FM interface, as the weak vdW interaction between the TI and the vdW FM can limit chemical reactions, intermixing and electronic hybridization. Our recent results using Fe_3GeTe_2 demonstrate large SOTs and magnetization switching with currents densities of about 10^{10} A/m^2 [6].

11:30 AM QT04.01.03
Topological Properties of Superconducting $Pd_3Bi_2Se_2$RamakantaChapai[1], GordonPeterson[1], MatthewSmylie[1,2], XinglongChen[1], Jidong SamuelJiang[1], DavidGraf[3], Wai-KwongKwok[1], JohnF. Mitchell[1] and UlrichWelp[1]; [1]Argonne National Laboratory, United States; [2]Hofstra University, United States; [3]National High Magnetic Field Laboratory, United States

The Parkerite-type transition-metal chalcogenides $Pd_3Bi_2Se_2$ is a superconductor with $T_c \sim 0.8$ K. Recently, a non-zero Z_2 topological index has been predicted in $Pd_3Bi_2Se_2$, and subsequently unusual magneto-transport attributed to two-dimensional fermions is reported. By measuring the field dependence of magnetic torque in bulk single crystalline $Pd_3Bi_2Se_2$ we observe de Haas-van Alphen (dHvA) oscillations. Through the analysis of the dHvA oscillations with $H \parallel c$, three frequencies are identified: $F_\alpha = 150$ T, $F_\beta = 471$ T and $F\gamma = 979$ T with the low frequency dominating the spectrum. The Lifshitz-Kosevich analysis yields a small effective mass ($0.11m_0$) and nontrivial Berry phase ($\sim\pi$) for the dominant orbit, indicating nontrivial topology. The presence of nontrivial topology in a superconducting system makes $Pd_3Bi_2Se_2$ a promising candidate to explore topological superconductivity.

11:45 AM QT04.01.04
Artificial Graphene Nanoribbons with Tailored Topological States NathanGuisinger, PierreT. Darancet and SawHla; Argonne National Laboratory, United States

Low-dimensional materials functioning at the nanoscale are a critical component for a variety of current and future technologies. From the optimization of light harvesting solar technologies to novel electronic and magnetic device architectures, key physical phenomena are occurring at the nanometer and atomic length-scales and predominately at interfaces. In this presentation, I will discuss low-dimensional material research occurring in the Quantum and Energy Materials (QEM) group at the Center for Nanoscale Materials. Specifically, the synthesis of artificial graphene nanoribbons by positioning carbon monoxide molecules on a copper surface to confine its surface state electrons into artificial atoms positioned to emulate the low-energy electronic structure of graphene derivatives. We demonstrate that the dimensionality of artificial graphene can be reduced to one dimension with proper “edge” passivation, with the emergence of an effectively-gapped one-dimensional nanoribbon structure. Remarkably, these one-dimensional structures show evidence of topological effects analogous to graphene nanoribbons. Guided by first-principles calculations, we spatially explore robust, zero-dimensional topological states by altering the topological invariants of quasi-one-dimensional artificial graphene nanostructures. The robustness and flexibility of our platform allows us to toggle the topological invariants between trivial and non-trivial on the same nanostructure. Our atomic synthesis gives access to nanoribbon geometries beyond the current reach of synthetic chemistry, and thus provides an ideal platform for the design and study of novel topological and quantum states of matter.

SESSION QT04.02: Growth and Synthesis of 2D Topological Materials

Germanium, a Unique Template for 2D Materials Growth: From Germanene to Antimony Telluride Synthesis MarcoMinissale[1], EricSalomon[2], ThierryAngot[2] and GuyLe Lay[2]; [1]CNRS, PIIM Laboratory, France; [2]Aix-Marseille Université, France

Germanene is an artificial two-dimensional graphene-like germanium allotrope predicted to be a near room temperature topological insulator, belonging to the class of so-called Xenes. It was synthesized in 2014, exactly ten years after the isolation of graphene, and just two years after the archetype growth of silicene, the first Xene ever produced. The canonical germanene paper, described its top-down synthesis by Ge deposition onto a Au(111) crystal, but revealed multi-phases [1]. Instead, we will show that a single germanene phase, as evidenced in Scanning Tunneling Microscopy in situ imaging, is obtained by Ge segregation on top of a thin Au(111) film epitaxially grown under ultra-high vacuum on a Ge(111) template through a bottom-up approach. [2] A comparison with studies performed on thin gold film epitaxially grown on a Ge(110) template will be presented.
Eventually, we will describe the growth of antimony telluride films on Ge(111) surface using a single evaporator cell. Moreover, we will discuss the structural and electronic characterization of such films, studied using standard surface science techniques (LEED, STM, PES).

Towards the Higher Curie Temperature in the $Mn_{1+x}Sb_{2-x}Te_4$ Material's System EkaterinaKochetkova[1,2], ManaswiniSahoo[1], LauraT. Corredor[1], JorgeFacio[3], VladimirHinkov[4] and AnnaIsaeva[2,1]; [1]Leibniz Institute for Solid State and Materials Research Dresden, Germany; [2]University of Amsterdam, Netherlands; [3]CNEA-CONICET, Argentina; [4]University of Würzburg, Germany

Magnetic topological materials are a hotbed for exotic quantum phenomena such as the quantum anomalous Hall effect (QAHE), the topological magneto-electric effect, new topological states like axion insulators and magnetic Weyl semimetals. In reply to the high demand for optimized material systems, magnetic topological insulators made a decade-long journey [1] from extrinsically doped Bi_2Te_3 and $(Cr,V)Bi_2(Se,Te)_3$ heterostructures [2] to the intrinsically magnetic van der Waals material $MnBi_2Te_4$ [3]. The QAHE was observed in $MnBi_2Te_4$ thin films at notably higher temperatures of 1–6 K [4] than in [2], pointing at a perspective pathway of materials optimization towards more robust quantum effects. Since the bulk $MnBi_2Te_4$ is an A-type antiferromagnet with $T_N = 25$ K, the task of fabricating structurally similar ferri- or ferromagnets with an increasing T_C is very pertinent.
$MnBi_2Te_4$ is the progenitor of a family of van der Waals materials $(MnX_2Te_4)(X_2Te_3)_n$, X = Sb or Bi, n = 0–4. Their crystal lattices are ordered stacking variants of septuple (MnX_2Te_4) layers hosting an ordered magnetic sublattice of Mn(II) atoms and of n quintuple (X_2Te_3) spacers. Varying intralayer and interlayer magnetic exchange couplings foster a rich palette of possible magnetic ground states, including ferri- and ferromagnetic. Besides the stacking order, a more subtle factor – Mn/X site intermixing [5] – influences the long-range magnetic order greatly. This phenomenon is particularly prominent in $Mn_{1+x}Sb_2Te_4$ where it raises the Curie temperature of a ferrimagnetic-to-paramagnetic transition from 27 to 46 K, while x varies in the range of 0.1–0.2 only [6-9]. We elucidate the Mn/X intermixing by single-crystal X-ray and neutron powder diffraction and link these results to the bulk magnetometry and surface XMCD data. Accumulated insights into an over-arching connection between crystal growth protocols, Mn/Sb patterns and magnetic ground states enable us to push the ordering temperature even further: I will present the recently obtained $Mn_{1.4}Sb_{1.6}Te_2$ with $T_C = 55$ K and $Mn_{1.9}Sb_{1.3}Te_4$ with $T_C = 73$ K that bring this family of magnetic topological materials close to the liquid nitrogen limit.

Synthesis of Transition Metal Ditellurides (TMTs) Nanosheets: $MoTe_2$ and $PtTe_2$ Through Simulation-Guided Tellurization Pinaka PaniTummala[1,2,3], SaraGhomi[1,4], AlessandroMolle[1], ChristianMartella[1] and AlessioLamperti[1]; [1]Consiglio Nazionale delle Ricerche, Italy; [2]KU Leuven, Belgium; [3]Università Cattolica del Sacro Cuore, Italy; [4]Politecnico di Milano, Italy

In the classification of Transition metal ditellurides (TMTs), Molybdenum ditelluride ($MoTe_2$) received significant emphasis due to its multiple polymorphic states including semiconducting, metallic, and topological semimetal phases.[1] Specifically, $MoTe_2$ is an ideal candidate for creating 2D hetero phase homojunctions due to its minimal energy barrier between the 2H and 1T' phases, as well as the negligible difference between their moduli, making it effortless to switch between the two phases. The 1T’ phase, with an orthorhombic structure, is significant for accessing topological properties and has potential as a host for the quantum spin hall effect and type-II Weyl semi-metallic state while the 2H-phase is useful as a 2D layered material in nanotechnologies due to its semiconducting properties. As the thickness decreases, $MoTe_2$ exhibits an indirect-to-direct bandgap transition with a relatively lower bandgap than other transition metal dichalcogenides (TMDs).[2][3] So far, countless efforts have been undertaken for developing $MoTe_2$ which are essential for the fabrication of devices to be integrated in different applications from nano-electronics to thermoelectric and energy sectors. Among the proposed methods, chemical vapor deposition (CVD) is considered as one of the reliable deposition methods.[4] In this context, here we report on the simulation guided CVD synthesis for obtaining $MoTe_2$ nanosheets with pure 1T' and 2H phases on SiO_2/Si substrates with extensive

coverage of 4 cm × 1 cm. The CVD based tellurization process involves a vapor-solid reaction between the pre-deposited molybdenum film and tellurium vapor, and we have optimized this process to improve the quality and scalability of the $MoTe_2$ nanosheets. We found that the $MoTe_2$ growth and its phase are primarily determined by the growth kinetics, tellurium concentration, and the configuration of the CVD furnace.[5] Further, by precisely controlling the temperature, we have extended our simulation-based tellurization approach to produce other TMTs, including $PtTe_2$ and $NiTe_2$. In particular, we were able to produce $PtTe_2$ with a sharp 1T phase from the tellurization of a pre-deposited Pt of varying thickness. The so-grown $PtTe_2$ recasts as a topological type-II Dirac semimetal and as such, it is expected to be optically tunable in the THz spectral range [6]. In this respect, we reduced the flat $PtTe_2$ film to an array of microscale stripes so as to fabricate $PtTe_2$-based plasmonic gratings where to measure optical resonances in the THz regime.

We believe this work may represent a substantial advance in facilitating the direct integration of TMTs in electronic and photonic applications where to test the intrinsic topological features.

Surface-Guided Growth of Bi_2Se_3 Nanowires TamirForsht, NogaLevinson, LotharHouben, KatyaRechav, OlgaBrontvein and ErnestoJoselevich; Weizmann Institute of Science, Israel

Topological materials exhibit exotic electronic properties, which make them promising for non-conventional electronics and spintronics. For instance, integrating nanowires of topological insulators into devices could be used for dissipationless electronics, quantum switches, generating and braiding Majorana fermions and quantum computing. However, the assembly of nanowires with controlled orientation on surface remains one challenge preventing their integration into practical devices. A possible solution that was demonstrated in our group in the past few years is the guided growth of horizontal nanowires by epitaxy or graphoepitaxy on crystal surfaces.
In this work, we demonstrate the guided growth of Bi_2Se_3 nanowires on flat and faceted sapphire surfaces. Bi_2Se_3 is a layered material with weak VdW interaction between its layers. It is also a topological insulator with narrow band gap in the bulk and topologically protected conducting states on its surface, as well as a thermoelectric material. The growth direction of these nanowires and their crystallographic orientation are controlled by the relations with the sapphire substrate, allowing the growth of ordered nanowires without the need for post-growth processes. To the best of our knowledge, this is the first example of guided growth of nanowires made of layered materials, which demonstrates the generality of the guided growth approach.

Synthetic Tuneability of the 1T' -1T Phases in TMDs CeciliaMattevi; Imperial College London, United Kingdom

In this talk, I will present our recent work on the precise synthesis of different metastable 2D Transition Metal Dichalcogenides and their use in spintronics, electrocatalysis and energy storage. I will provide an overview of the tuneability between magnetic and topologically insulating phases (1T' and 1T) and their corresponding 2H phases at the synthesis level, which we have demonstrated for different TMD materials.
The synthesis precision is scalable and based on the kinetic versus the thermodynamic control of the nucleation process, which enable the determination of the crystal structure preferentially leading to either the thermodynamically stable 2H phase or the metastable 1T' and 1T phases. The possible mechanisms of crystallization of metastable polymorphs will be discussed and liquid phase synthesis versus chemically vapour deposited materials approaches will be compared in the light of phase control. Ultimately, the functional properties of the 1T' and 1T phases, such as magnetism and electrocatalysis will be discussed.

Epitaxy of Bi2Se3 Thin Film by Chemical Vapor Deposition SkyeWilliams, EdwinFohtung and JianShi; Rensselaer Polytechnic Institute, United States

Spin-momentum locking materials present large prospects to the design of spintronic devices. One of the figures of merit of spintronic materials is the spin-charge conversion efficiency. Bi2Se3 is a topological insulator with an impressive spin-charge conversion efficiency on its conductive surface states. Epitaxial Bi2Se3 is highly demanded for optimized conversion efficiency. In this work we present a chemical vapor deposition approach to grow Bi2Se3 epitaxially that have grain sizes exceeding 200 micrometers. We identify the existence of sub-unit cell layers in the epitaxial crystal. We apply the spin pumping approach to characterize the spin-charge conversion efficiency and compare it with reported values of Bi2Se3 synthesized by approaches such as sputtering. The work suggests chemical vapor deposition is a viable approach for producing high-quality large-scale topological Bi2Se3.

Tuning Topology in 2D Materials ZeilaZanolli; Utrecht University, Netherlands

In a few years, the energy consumption for information processing will constitute more than 25% of the total electrical energy consumption. Topological materials allow for symmetry-protected dissipationless electron transport along the edges of 2D materials, which offers a possible solution to the sustainability issue of electronics. However, controlling the topological properties of a material is an open research question.

We use first-principles Density Functional Theory simulations to predict pathways to control topological properties in 2D materials and, possibly, induce or strengthen the topological phase transition. The different strategies include proximity interaction with a magnetic substrate [1, 2], van der Waals interaction with the substrate [3, 4], twisting 2D heterostructures [5], and using an external electric field to manipulate spins in a Quantum Spin Hall insulator [6]. Going further, I will discuss the role of dimensionality in going from a 3D topological insulator to the 2D limit [7].

Efficient Quantum Transduction using Magnetic Topological Insulators HaoweiXu, PaolaCappellaro and JuLi; Massachusetts Institute of Technology, United States

Transduction of quantum information between distinct quantum systems is an essential step in various applications, including quantum networks and quantum computing. Efficient quantum transduction necessitates transducers that can strongly interact with photons with vastly different frequencies. In this work, we propose that solid-state magnetic topological insulators can potentially serve as highly effective transducers, thanks to their topologically enhanced optical responses, robust spin-orbit coupling, as well as substantial spin density. Using $MnBi_2Te_4$ as an example, we showcase that unit transduction fidelity can be achieved with modest experimental requirements, while the transduction bandwidth can reach the GHz range.

Super Flat Graphene Grown on Substrate Selected by using Molecular Dynamics Calculation SatoruKaneko[1,2], TakashiTokumasu[3], ManabuYasui[1], MasahitoKurouchi[1], DaishiShiojiri[1], ChihiroKato[1], SatomiTanaka[1], ShigeoYasuhara[4], MusaCan[5], Ruei-SungYu[6], SumantaSahoo[7], KripasindhuSardar[8], MasahiroYoshimura[8], AkifumiMatsuda[2] and MamoruYoshimoto[2]; [1]KISTEC, Japan; [2]Tokyo Institute of Technology, Japan; [3]Tohoku University, Japan; [4]Japan Advanced Chemicals, Japan; [5]Istanbul University, Turkey; [6]Asia University, Taiwan; [7]Radhakrishna Institute of Technology and Engineering, India; [8]National Cheng Kung University, Taiwan

Choice of substrate is one of most important factors for thin film growth. An extensive interdiffusion or chemical reaction might happen between substrate and target materials. For oxide materials, Schlom et. al. comprehensively investigate the thermodynamic stability of binary oxides for epitaxial growth on silicon (Si) substrates[1]. However, the thermodynamic stability does not include any crystal information such as lattice constants, orientation of crystal growth. In order to predict the orientation of crystal growth, molecular dynamics (MD) is empolyed to evaluate the stability of oxide cluster on Si substrates[2].

In this study, MD was used to select suitable substrates for graphene growth with flat surface. Supercell was consisted of carbon clusters placed on variety of substrates with vacuum slab. As carbon clusters, (1) C atom, (2) six-membered ring (6-ring) and (3) seven six-membered rings (nanographene) were placed on SrTiO, silicon and sapphire substrates. On the surface of sapphire substrate, carbon clusters were placed on either aluminum or oxygen atoms, and the absorption energy was estimated by using the density functional theory (DFT) with a semi-core pseudopotential. The generalized gradient approximation (GGA) method was used to obtain the electron density. Materials Studio and DMol3 were used for preparing and optimizing supercells, respectively[3].

The surface of substrate was optimized, and then the carbon clusters were placed on the candidate substrates. Although the absorption energies showed not large differences on various surfaces, 6-ring, for an example, stood vertically up on Si(001) substrate and covered flatly on SrTiO substrate. Only SrTiO surface was flatly covered by both 6-ring and nanographene after optimization by MD simulation. The SrTiO substrate was the first choice for flat graphene.

Super flat graphene is prepared by chemical vapor deposition (CVD) with post annexing in carbon dioxide atmosphere. Amorphous carbon is selectively etched in carbon dioxide atmosphere[4]. In this study, carbon films were experimentally deposited on target substrates in carbon dioxide atmosphere by pulsed laser deposition (PLD), and super flat surface (~60 pm) was observed on only SrTiO substrate, which agreed with the results of MD simulation. Since CVD graphene usually grows with intrinsic contamination on graphene surface during film growth, a post annealing is required to obtain a flat surface. However PLD prepared as-grown flat surface in carbon dioxide atmosphere.

This study was supported in part by Amada Foundation under contract AF-2020227-B3, Tokyo Ohka Foundation for Promotion of Science and Technology 22117 and the Collaborative Research Project of the Institute of Fluid Science, Tohoku University. Topological Textures in Artificial Van der Waals Multiferroics with Twisted Two-Dimensional Materials JoseLado; Aalto University, Finland

Twisted van der Waals materials have risen as a powerful platform to engineer artificial quantum matter. Artificial moire heterostructures, in general, display two length scales, the original lattice constant and the emergent moire length. Here we reveal a microscopic mechanism to engineer van der Waals multiferroics from the interplay of non-collinear magnetism and spin–orbit coupling, both in van der Waals monolayers [1] and twisted multilayers [2]. First, focusing on the recently isolated NiI2 multiferroic monolayer, we reveal the origin of the helimagnetic order and the critical role of halide spin-orbit coupling in driving a ferroelectric distortion. We demonstrate that the electronic reconstruction accounting for the ferroelectric order emerges from the interplay of such a non-collinear magnetism and spin-orbit coupling. Second, we show the emergence of multiferroic order in twisted chromium trihalide bilayers, an order fully driven by the moiré pattern and absent in aligned multilayers. We show that a spin texture is generated in the moiré supercell of the twisted system as a consequence of the competition between stacking-dependent interlayer magnetic exchange and magnetic anisotropy. An electric polarization arises associated with such a non-collinear magnetic state due to the spin-orbit coupling, leading to the emergence of a local ferroelectric order following the moiré. Among the stochiometric trihalides, our results show that twisted CrBr3 bilayers give rise to the strongest multiferroic order. We further show the emergence of a strong magnetoelectric coupling, which allows the electric generation and control of magnetic skyrmions. Our results put forward van der Waals materials as a powerful platform to engineer artificial multiferroic order and electrically control exotic magnetic textures.

First-Principles Transport Including Magnetic and Spin-Orbit Effects MatthieuJ. Verstraete[1,2]; [1]University of Liege, Belgium; [2]University of Utrecht, Netherlands

Topology is the next frontier in materials science, opening possibilities for ultra low power devices, exquisite sensing capabilities, and synergies with quantum computing through the protection of state coherence.

We will showcase recent advances in the theory and applications of first-principles transport calculations, to include magnetism and spin-orbit interactions, and what will be needed to tackle the most complex topological materials, which contain both effects. Using spinor wave functions and SOI naturally incorporates spin-flip processes in electron-phonon scattering. Comparisons to experiments on "simple" 3d ferromagnetic metals require the inclusion of electron-magnon scattering, both in resistivity and in magnon drag.

As a next step into topology, we showcase the first-principles conductivity of Weyl semi-metals, in particular TaAs for which our calculations are in very good agreement with available experiments. Finally, magnetoelectrically-active 2D Nickel Iodide (NiI2) can host topological magnetic states, and we find that it shows strong sensitivity to pressure. Combining experimental characterization with first and second principles simulations, we determine the pressure dependency (up to 20 GPa) of the electronic band structure, magnetic phase transition, and spinwave dispersion.

11:00 AM QT04.03.06
Logic Gate Analysis for Quantum Phase Differences in Systems with Multiple Degenerate Points TatsukiTojo and KyozaburoTakeda; Waseda University, Japan

The field of quantum information has been extensively researched, and an important concept here is the phase difference between the two basis states (|0> and |1>) in a qubit, which is an important concept used to distinguish quantum logic from classical logic. Hence, manipulating this phase difference is a prerequisite for quantum arithmetic. Consequently, various methods for quantum (phase) operations have been proposed, and one such method uses the non-Abelian Berry phase [1]. Because the non-Abelian Berry phase has a characteristic structure, particularly at *quasi*-degenerate points (QDPs) in the parameter space, combining QDPs with quantum operations becomes important. However, a QDP exists alone in the parameter space, complicating its combination with quantum operations. Nevertheless, heavy-mass holes (HHs) in SiGe two-dimensional quantum wells, where Rashba and Dresselhaus spin–orbit interactions (SOIs) coexist, feature multiple spin QDPs near point Γ in the Brillouin zone (BZ) [2]. In the vicinity of these QDPs, a characteristic structure is observed in the non-Abelian Berry phase when

the wave vectors are chosen as parameters. Because these QDPs lie close to each other, they can realize novel quantum operations.

Here, we focus on the HH with multiple QDPs in the BZ and discuss the features of quantum operations based on the non-Abelian Berry phase near these QDPs. We choose the |0> and |1> states as the SOI-stabilized (+) and -destabilized (-) HH (HH+/-) states, respectively, including the dynamical phases, and discuss the change in hybridization and phase difference between the |0/1> states. A Bloch sphere is used to visualize the hybridization ratio and phase difference. Further, we construct a time-evolution operator that reproduces the motion on the Bloch sphere and decompose it into quantum logic gates to interpret changes in the state vector as quantum operations. We assume that the wave vector moves under the energy conservation law and recreate this motion as “cyclotron motion” under a perpendicular weak magnetic field. The time evolution of the state and wave vectors is determined by the simultaneous rate equation and semi-classical equation of motion.

In addition to point Γ, an HH has the following QDPs: M_1 and M_2 (16 meV) along the [1-10] and [-110] directions and D_1 and D_2 (24 meV) along the [-1-10] and [110] directions, respectively. To discuss such QDP-induced modulation, we consider the lower-energy region away from M and D (10 meV), and just above M (16 meV) and D (24 meV). We set the initial states of the wave vector along the [100] direction and the state vector to the |0> state (HH+).

At 10 meV, the state barely moves from the |0> state (+z direction on the Bloch sphere), and no operation is apparently performed. However, the rate-equation-based time-evolution operator is equivalent to the R_z gate, and its rotation angle is 2π. This rotation angle corresponds to the (Abelian) Berry phase difference of HH+/- at 10 meV (+/-π). This Berry phase can be attributed to the QDP at point Γ. This implies that even in the region away from the QDP, the state vector is operated by R_z corresponding to the Berry phase of the QDP surrounded by the parameter (wave vector) trajectory. By contrast, at 16 meV (point M), the state flip-flops during the passage of M, and the states |0> and |1> change completely to |1> and |0>, respectively. Through logic gate decomposition, we obtain the R_y gate corresponding to M, whose rotation angle is π. At 24 meV, the R_y gate corresponding to D is also obtained. However, the rotation angle is less than π, and the state transition is incomplete. Therefore, the state is operated by the R_y gate when it passes just above the QDP, and the rotation angle depends on the QDP.

Designing Quantum States in Two Dimensional Heterostructures OrlandoJ. Silveira[1], MohammadAmini[1], LiweiJing[2], ViliamVano[1], YanLinghao[3], OndrejKrejci[1], SomeshGanguli[1], ShawulienuKezilebieke[2], JoseLado[1], AdamFoster[1,4] and PeterLijeroth[1]; [1]Aalto University, Finland; [2]University of Jyväskylä, Finland; [3]Soochow University, Taiwan; [4]Kanazawa Univsersity, Japan

Vertical heterostructures have emerged as a promising route for designing quantum materials with extraordinary properties. In particular, the interplay between magnetism and superconductivity has garnered significant attention, driven by the potential realisation of topological superconductivity [1]. This research presents notable progress in the synthesis and characterization of two-dimensional materials in ultra-high vacuum environments. By employing scanning tunnelling microscopy (STM) and spectroscopy (STS), along with tight-binding (TB) and density functional theory (DFT) calculations, a comprehensive understanding of these materials has been achieved.

We propose a novel approach utilizing a heterostructure composed of a supramolecular complex (SMC) on a van der Waals (vdW) superconductor. Through our investigations, we demonstrate that the combination of a magnetic SMC with a quasi-2D superconductor, specifically NbSe2, leads to the emergence of Yu-Shiba-Rusinov (YSR) bands—a crucial element for realizing topological superconductivity. The presence of these bands, together with the exotic magnetic ground state of the SMC, is thoroughly examined using scanning tunneling microscopy (STM) and X-ray magnetic circular dichroism (XMCD), complemented by density-functional theory (DFT) calculations. Notably, our approach offers the advantage of employing diverse molecules, atoms, and substrates, enabling highly tunable YSR bands.

Furthermore, we investigate the electronic structure of a ferroelectric 001 SnTe grown on NbSe2. Our DFT calculations reveal a strong binding between Sn and Se atoms within the substrate, resulting in significant modifications to the overall electronic structure and its dependence on the number of atomic layers of SnTe. We also extend the study to SnTe deposited on other vdW layered materials such as TMDs by means of DFT calculations.

Overall, this research contributes to the understanding and advancement of quantum materials, demonstrating the synthesis and characterization of versatile heterostructures and providing insights into their unique properties.

Spin Transport Proximity Phenomena in Van der Waals HeterostructuresJ.F.Sierra, Luis AntonioBenítez, JosefSvetlik, WilliamsSavero Torres, LorenzoCamosi, MariusCostache and SergioO. Valenzuela; Catalan Institute of Nanoscience and Nanotechnology, Spain

The vast collection of two-dimensional materials and their co-integration in van der Waals heterostructures enable innovative device engineering. Their atomically thin nature promotes the design of artificial quantum and topological materials by proximity-induced effects with physical properties not readily found in their single material forms [1]. Such a flexible design approach is especially compelling for the development of spintronic devices, which usually harness functionalities from thin layers of magnetic and non-magnetic materials and their interfaces. In this talk, I will summarize recent experimental progress toward investigating proximity-induced phenomena in hybrid graphene-transition metal dichalcogenides systems through spin transport dynamics [2,3] and charge-spin interconversion experiments [4]. I will focus on the relevance of crystal symmetries in the emergence of unconventional charge-spin conversion components and anisotropic spin dynamics [5], [6].

Kramers Nodal Lines, Weyl Fermions and Large AHE in SmAlSi EmiliaMorosan and MingYi; Rice University, United States

Kramers nodal lines (KNLs) are special type of Weyl line degeneracy that connects time reversal invariant momenta. KNLs are robust to spin orbit coupling (SOC), and are inherent to all non-centrosymmetric achiral crystal structures. In this talk I will present magneto-transport and ARPES experimental data together with DFT calculation, pointing to the existence of novel KNLs in SmAlSi. SmAlSi is a non-centrosymmetric metal that develops incommensurate spin density wave AFM order at low temperatures. I will show evidence for the symmetry-protected KNLs, as well as Weyl fermions under the broken inversion symmetry in the paramagnetic phase of SmAlSi. In the AFM state, angle-dependent quantum oscillations (AQOs) provide evidence for the Weyl points, while large AHE is observed in both the AFM and the PM states. We propose a new mechanism to explain AHE in non-FM materials, based on magnetic field-induced Weyl-nodes evolution in non-centrosymmetric Weyl semimetals. The proposed mechanism qualitatively explains the temperature dependence of the anomalous Hall conductivity (AHC) in SmAlSi.

On-Surface Synthesis of Silicon Nanoribbons MariaE. Davila; ICMM-CSIC, Spain

Abstract

In recent years, the scientific community has put a lot of efforts into trying to artificially grow new functional materials by reducing their dimensionality from 2D to 1D or even 0D. However, it is not a simple task, which includes synthetic methods that could go in both possible top-down or bottom-up approaches.
Our group, working on the bottom-up approach through on-surface synthesis has been able to develop unprecedented new 0D, 1D or 2D silicon nanoshapes[1,2]. Here, we demonstrate the on-surface synthesis of atomically precise silicon nanoribbons by utilizing the Ag(110) surface and also we have unmasked the unique 1D pentagonal silicon structures formed on it, which had been elusive for over 10 years. Further, we will see how the different single crystals substrates greatly affects the growth of silicon and the new structures that can be formed on it[3].
Promising applications of new silicon nanoforms range from nanoelectronics to transistors or embedded sensors; however, one of the important challenges that we have to overcome is the isolation, through the separation of the substrates, of these interesting nanoforms.

Keywords: Silicon nanoribbons, 1D-Silicon.

Magnetic and Charge Order in Transition Metal Dichalcogenide Heterostructures DanielK. Bediako; University of California, Berkeley, United States

Next-generation electronic devices will exploit correlated electronic phenomena in quantum materials to encode information for ultra-fast, ultralow-power, and non-volatile storage and retrieval. Spin–spin correlations in exotic magnetic materials are one basis for this new paradigm of compact, energy-efficient electronic systems, but these will require a nanoscale control over long-range magnetic ordering. Conceptually, this may be realized by designing materials that are inherently two-dimensional in their atomic connectivity, or by harnessing nanoscale, non-collinear spin textures in three-dimensional crystals. Likewise, electronic correlations that produce complex charge order can be manipulated to exhibit multi-state resistance phenomena, analogous to phase change materials, but without fatigue.
This talk will describe how transition metal dichalcogenides (TMDs) intercalated with open-shell transition metals represent a family of materials allowing fine control over the chemical and electronic structure of a magnetic material to tailor the interplay between (anti)ferromagnetic exchange, magnetocrystalline anisotropy, and anisotropic exchange (Dzyaloshinskii–Moriya interactions) to bring about exotic magnetic orders in two-dimensional (2D) materials or bulk crystals. The talk will show how soft-chemical methods can be used to prepare the highly coercive 2D ferromagnetic intercalation compound, Fe_xTaS_2, and the use of angle-resolved photoemission spectroscopy to understand differences in chiral helimagnetic order in related 3D compounds, $Cr_{1/3}NbS_2$ and $Cr_{1/3}TaS_2$. The role of intercalant disorder on magnetic order will be explored in these chiral helimagnets as well as the intrinsically disordered $Fe_{0.17}ZrSe_2$. Finally, the talk will show how endotaxial polytype heterostructures of TaS_2 enable multistate resistivity and chirality switching of charge density wave phases.

Interplay between Magnetism and Topology: Large Topological Hall Effect in an Antiferromagnetic Topological Insulator, EuCuAs SubhajitRoychowdhury[1], KartikSamanta[1], PremakumarYanda[1], BernardMalaman[2], MengyuYao[1], WalterSchnelle[1], EmmanuelGuilmeau[3], ProcopiosConstantinou[4], SushmitaChandra[1], HorstBorrmann[1], MaiaG. Vergniory[1], VladimirStrocov[4], ChandraShekhar[1] and ClaudiaFelser[1]; [1]Max-Planck-Institute for Chemical Physics of Solids, Germany; [2]Institut Jean Lamour-Universite de Lorraine, Centre National de la Recherche Scientifique, France; [3]CRISMAT, CNRS, Normandie University, ENSICAEN, UNICAEN, France; [4]Paul Scherrer Institute, Switzerland

Magnetic interactions in combination with nontrivial band structures can give rise to several exotic physical properties such as a large anomalous Hall effect, the anomalous Nernst effect and the topological Hall effect (THE). Antiferromagnetic (AFM) materials exhibit THE due to the presence of nontrivial spin structures. EuCuAs crystallizes in a hexagonal structure with an AFM ground state (Néel temperature ~16 K). In this work, we observe a large topological Hall resistivity of ~7.4 μΩ-cm at 13 K which is significantly higher than the *giant topological Hall effect* of Gd_2PdSi_3 (~3 μΩ-cm). Neutron diffraction experiments reveal that the spins form a transverse conical structure during the metamagnetic transition, resulting in the large topological Hall effect. In addition, by controlling the magnetic ordering structure of EuCuAs with an external magnetic field, several fascinating topological states such as Dirac and Weyl semimetals have been revealed. These results suggest the possibility of spintronic devices based on antiferromagnets with tailored noncoplanar spin configurations.[1]

Combining Topological Properties in Reciprocal and Real Space AthanasiosDimoulas[1], PolychronisTsipas[1], SotirisFragkos[1], PanagiotisPappas[1], ElliGeorgopoulou-Kotsaki[1,2], AkylasLintzeris[1,2], NicholasFigueiredo-Prestes[3], Henri-YvesJaffres[3], Jean-MarieGeorge[3], Marie-BlandineMartin[3] and PaoloBortolloti[3]; [1]National Center for Scientific Research DEMOKRITOS, Greece; [2]National Kapodistrian University of Athens, Greece; [3]Unité Mixte de Physique, CNRS, Thales, Université Paris-Saclay, France

Nearly 30% of stoichiometric, non-magnetic materials are predicted to have non-trivial topology which stems from their electronic band structure and they can be coarsely classified as topological insulators and topological Weyl and Dirac semimetals [1]
We will focus on MBE-grown layered and 2D topological materials which have better prospects to be grown in thin film form down to the ultimate 2D limit of one monolayer. We will provide theoretical and experimental evidence that 1T $HfTe_2$ [2] and $ZrTe_2$ [3] are Dirac semimetals of type I and type II, respectively, while the $Hf_xZr_{1-x}Te_2$ (x ~ 0.2) alloy is a new type III Dirac semimetal [4] with a flat band and a line-like Fermi surface that can undergo an electronic Lifshitz transition under the influence of strain.
We will also show that using MBE, it is possible to stabilize at room temperature the non-centrosymmetric orthorhombic $1T_d$ $MoTe_2$ Weyl semimetal phase against the more stable 1T' $MoTe_2$ monoclinic and topologically trivial phase [5].
Non-colinear magnetization configurations in magnetic materials known as skyrmions possess a topological charge which makes them robust against perturbations. We will provide experimental evidence for the existence of skyrmions in the 2D van der Waals ferromagnet $Cr_{1+\delta}Te_2$ [6], [7] made by MBE by probing the topological Hall effect at low temperature. Using MOKE and micromagneic calculations, we will also provide evidence for circular double wall magnetic configurations in the 2D van der Waals ferromagnet Fe_3GeTe_2 which organize in a quasi-periodic hexagonal lattice and transform to skyrmions by increasing magnetic field.
In the last part of the presentation, we will study the spin Hall effect and the Rashba Edelstein effect to show that efficient spin to charge interconversion occurs at the interface between topological materials and skyrmion hosting magnetic materials, which makes it possible to control the magnetization by an electrical current through the topological material. The latter could be very useful in new spintronics applications.

Nonlinear Transport Effects in Chiral Elemental Tellurium AlbertFert[1], ManuelSuárez-Rodríguez[2], F.Calavalle[2], BeatrizMartín-García[2], A.Johansson[3], DiogoC. Vaz[2], F.de Juan[4], I.Sousa[5], AndreyChuvilin[2], I.Mertig[6], M.Gobbi[2], F.Casanova[2] and L. E.Hueso[2]; [1]Université Paris-Saclay, France; [2]CIC nanoGUNE, Spain; [3]Max Planck Institute of Microstructure Physics, Germany; [4]Donostia International Physics Center, Spain; [5]University of the Basque Country, Spain; [6]Martin Luther University Halle-Wittenberg, Germany

Chiral materials are an ideal playground for exploring the relation between symmetry, relativistic effects, and electronic transport [1]. Indeed, the role of low symmetry on electronic transport has been studied on chiral organic molecules, but their poor electronic conductivity limits their potential for applications. Conversely, chiral inorganic crystals, such as elemental Tellurium (Te), present excellent electrical conductivity and strong spin-orbit coupling [2]. Therefore, Te become a perfect material for studying the connection between nonlinear transport phenomena, such as unidirectional magnetoresistance (UMR) [3] or nonlinear Hall effect (NLHE) [4], and chirality. Here, we synthesized single crystalline Te nanowires (NWs) and flakes with both handedness. On one hand, we report a chirality-dependent and gate-tuneable Edelstein effect in the naturally hole-doped Te NWs [5]. By recording a UMR dependent on the relative orientation of the electrical current and the external applied magnetic field, we link the direction of the spin polarization to the handedness of the crystal. The measured UMR is explained on the basis of a chirality-dependent Edelstein effect arising from the radial spin texture at the H-point of the valence band of Te, which dominates the transport in our hole-doped Te NWs. In addition, an electrostatic gating enables the tuning of the Edelstein effect, leading to a modulation of the UMR amplitude by a factor of 6. On the other hand, we explore the NLHE in Te flakes. The symmetry of the measured second harmonic voltage under zero field, which is a consequence of the inversion symmetry breaking in Te, follows strictly the constrains for Te point group and is different from any material reported before. Moreover, by measuring flakes with opposite handedness, we were able to explore experimentally the effect of an inversion symmetry operation [6]. The all-electrical generation, control, and detection of spin polarization and second-order voltage in chiral Te NWs open the path to exploit chirality in the design of solid-state spintronic and energy harvesting devices.

2D Materials Prospects for Magnetic Tunnel Junctions PierreSeneor[1], JulianPeiro[1], VictorZatko[1], HaoWei[1], FredericBrunnett[1], SimonDubois[1], MartaGalbiati[2], ReginaGalceran[3], MaëlisPiquemal-Banci[1], FlorianGodel[1], Jean-ChristopheCharlier[4], Piran RavichandranKidambi[5], RobertWeatherup[6], StephanHofmann[7], JohnRobertson[7], MauroOch[8], CeciliaMattevi[8], AymericVecchiola[1], KarimBouzehouane[1], SophieCollin[1], AlbertFert[1], FrédéricPetroff[1], Marie-BlandineMartin[1] and BrunoDlubak[1]; [1]Université Paris-Saclay, France; [2]Universitat de València, Spain; [3]Institute de Ciencia de Materials, Spain; [4]Université Catholique de Louvain, Belgium; [5]Vanderbilt University, United States; [6]University of Oxford, United Kingdom; [7]University of Cambridge, United Kingdom; [8]Imperial College London, United Kingdom

Spin-based electronics, recently highlighted as a leading candidate for highly efficient and ultrafast embedded memories (such as MRAMs) and post-CMOS unconventional electronics strategies (including spin logics, stochastic, neuromorphic and quantum computing), have enjoyed considerable growth. Beyond the fundamental spin transport properties of graphene, 2D materials have unleashed a multitude of previously untapped possibilities for spintronic devices in terms of functionality and performance, ranging from gate control to topology.

Indeed, 2D materials offer the unlimited possibility of exposing their electronic structure to manipulation by proximity effects. We will demonstrate that this could be harnessed to shape the properties of 2Ds and van der Waals heterostructures in quantum devices[1] and materials. We will more specifically focus on how this can be leveraged in devices such as 2D based Magnetic Tunnel Junctions (2D-MTJs)[2,3].

Relying mostly on large scale 2D materials, we will give examples of spin manipulation and new mechanisms ranging from almost perfect 2D spin-filtering with -98% spin polarization in graphene [4] and up to 500% MR in black-phosphorous, to 2D material proximity hybridization leading to insulator-to-metal transition (spinterface) [5]. We will finally focus on 2D-magnets, and moreover show how this proximity effect can also be pushed further to create an artificial 2D magnet [6] relying on proximity interaction of graphene with a ferromagnetic insulator, towards a fully gateable 2D-MTJ for spin logics.

Towards a Topology-Based Compact Neuromorphic Component Marie-BlandineMartin[1], Tristanda Câmara Santa Clara Gomes[2], YanisSassi[1], SachinKrishnia[1], DedaloSanz-Hernandez[1], TanviBhatnagar-Schöffmann[3], DafinéRavelosona[3], DamienQuerlioz[3], LizaHerrera-Diez[3], BrunoDlubak[1], NicolasReyren[1], PierreSeneor[1], JulieGrollier[1] and VincentCros[1]; [1]Unite Mixte Physique CNRS/Thales, France; [2]The Université catholique de Louvain, Belgium; [3]University of Paris-Saclay, France

Thanks to their original properties, magnetic skyrmions have many promising applications, from sensors through data storage to non-conventional computing [1-3]. Among the main advantages of magnetic skyrmions are their sub-micronic size, their particle-like behavior, their stability and non-volatility at room temperature and the low energy requirement for their motion. It has been shown, most often separately, that magnetic skyrmions can be experimentally nucleated [4-7], moved [4,7], annihilated [6] and detected electrically using Anomalous Hall effect [8] in metallic multilayers.

In this talk, we will propose a neuromorphic device design using full-electrical manipulation and detection of skyrmions to perform basic operations required for neuromorphic computing. Indeed, the operating principle of an artificial neuromorphic component is to work by performing a simple operation: it multiplies various input signals with corresponding synaptic weights and sums them up [9]. Mathematically, this can be represented as $y = \Sigma(wixi)$, where xi are the inputs and wi are the synaptic weights. All the building blocks necessary to achieve the demonstration of a weighted sum of skyrmions will be presented, from the nucleation and motion of a controlled number of magnetic skyrmions in multilayer tracks using electrical current pulse parameters to the electrical detection of a sum of skyrmions through anomalous hall effect.

The demonstrated skyrmion-based neuromorphic device paves the way to skyrmionic low-energy devices contributing to a global reduction of the environmental impact of AI applications.

Collidial Synthesis of III-V Quantum Dots and Their Optical Properties CanLi; Los Alamos National Laboratory, United States

Collodial synthesis of III-V quantum dots (QDs) and their photonic properties have garnered significant attention in the field of nanotechnology and optoelectronics. III-V semiconductors, such as InAs, InP QDs, exhibit excellent tunable optical properties, strong quantum confinements effects, and are widely used in various photonic devices. Collodial synthesizing III-V QDs can indeed be a challenging process. In our case, by developing innovation synthesis strategies, exploring alternative precursors, and optimizing reaction conditions, III-V QDs (such as InSb) with uniform size distribution can be achieved. Additionally, a controlled CdS shell can be grown eptaxially onto the InSb cores, resulting into tunable optical properties.

2D Topological Insulators for New Generation Thermoelectrics: Technological Development PaoloBondavalli[1], PierreLegagneux[1], EvaDesgue[1], OlivierBourgeois[2], DominiqueCarisetti[1] and YannickFagot-Revurat[3]; [1]Thales Research and Technology, France; [2]Institut néel, France; [3]Université de Lorraine, France

The implementation of 2D topological materials is a potential revolution in this domain. During the NEXTOP project, funded by French Research Agency, we are working on a new generation of 2D topological insulators to demonstrate a ZT larger than 7. Two major issues are to be overwhelmed: the growth of 2D topological insulators on different kinds of substrates (insulating and conducting ones) and their implementation for thermoelectric tests. We are developing a new technique for growing WTe2 using sort of steps with different widths that will allow controlling its crystallinity and number of layers. Thanks to that, we will be able to perform thermoelectric measurements on this topological insulator which is up to now the only 2D material whose topological features have been demonstrated. This will be the first time that measurements will be performed. Techniques for stanene growth will be also presented during the meeting. Bottlenecks for in-situ tests to identify band structures will be also presented.

We report the possibility of obtaining Majorana zero modes (MZMs) in straight, highly perfect, and massively aligned atom-thin penta-silicene nanoribbons (p-SiNRs) with a very high aspect ratio, purely composed of silicon pentagonal building blocks, and grown by molecular beam epitaxy on the (110) surface a silver crystal template2,3. They could constitute the experimental realization of the generic Kitaev toy model3,4. The spinless and full spin p-SiNRs with p-wave superconducting pairing reveal the emergence of topologically protected MZMs at opposite ends of the p-SiNRs. Besides the first nearest neighbor hopping term and p-wave superconducting pairing we consider an external magnetic field perpendicularly applied to the nanoribbon plane and an intrinsic Rashba spin-orbit coupling. The dispersion relation profiles show the closing and reopening of the superconducting gap for only one spin component, suggesting a spin-polarized topological phase transition (TPT). Along with this TPT, the energy spectrum as a function of the p-SiNR chemical potential exhibits zero-energy states and preferential spin direction. It is associated with nonoverlapping wave functions well-localized at the opposite extremities of the superconducting p-SiNRs. Hence, we show theoretically that the p-SiNRs could constitute a tantalizing new platform for MZMs5.

Band-Gap Landscape Engineering in Large-Scale 2D Semiconductor Van der Waals Heterostructures for Spintronics BrunoDlubak[1], VictorZatko[1], HaoWei[1], FredericBrunnett[1], SimonDubois[1,2], JulianPeiro[1], MartaGalbiati[1,3], FlorianGodel[1], Jean-ChristopheCharlier[2], MauroOch[4], CeciliaMattevi[4], AymericVecchiola[1], KarimBouzehouane[1], SophieCollin[1], FrédéricPetroff[1], Marie-BlandineMartin[1] and PierreSeneor[1]; [1]Université Paris-Saclay, France; [2]Université Catholique de Louvain, Belgium; [3]Universidad de Valencia, Spain; [4]Imperial College London, United Kingdom

The discovery of graphene has opened novel exciting opportunities in terms of functionalities and performances for spintronics devices. This started a wide exploration of a large variety of 2D crystals for spintronics with the hope to exploit some of their unique topological properties. We will present here experimental results concerning integration of 2D materials in vertical Magnetic Tunnel Junctions (MTJ). We will in particular focus the discussion on a novel pulsed laser deposition (PLD) approach for the definition of complex van der Waals heterostructures of 2D materials in magnetic tunnel junctions.[1][2] This PLD growth approach unlocks the association in heterostructure of wide families of multifunctional 2D materials, including the most delicate ones. The direct growth of the 2D layers prevents the oxidation of the ferromagnet, enabling the use of these van der Waals materials for spintronics devices. Overall, the presented experiments unveil promising approaches for the quantum engineering of multifunctional 2D materials heterostructures for spintronics.

Pseudomagnetic Fields in Graphene Strain Superlattices NadyaMason[1], IvaSrut Rakic[2], PreethaSarkar[1], YingjieZhang[1], MatthewGilbert[1] and VidyaMadhavan[1]; [1]University of Illinois at Urbana-Champaign, United States; [2]Institute of Physics, Serbia

Straining graphene can modify the electronic band structure and lead to the formation of giant pseudomagnetic fields. Recently it was shown that addition of superlattice periodicity to strain leads to global electronic band flattening and signatures of correlated states. Here we show an engineered approach to producing a strained graphene superlattice system. Using scanning tunnelling spectroscopy and transport measurements, together with numerical simulations, we demonstrate that a graphene monolayer placed on a SiO_2 nanosphere superlattice undergoes a band structure change with observable pseudo-Landau level formation, not only integer ones but also with fractional indices. The results are consistent with significant flattening of the electronic bands, making it ideal playground for exploring other related interaction phenomena and possibly the emergence of correlated states.

Two-Dimensional Easy-Plane Magnets Grown by MBE: A Fertile Platform for Unconventional Topological Spin Textures AmilcarBedoya-Pinto; Universitat de València, Spain

In this talk, I will focus on the van-der-Waals epitaxy of a nearly-ideal two-dimensional magnet, a $CrCl_3$ monolayer grown on Graphene/6H-SiC(0001). *In-situ* X-ray magnetic circular dichroism reveals intrinsic ferromagnetic order with easy-plane anisotropy and a 2DXY universality class [1], indicating the realization of a Berezinskii-Kosterlitz-Thouless (BKT) phase

transition in a quasi-freestanding monolayer magnet. The important role of the van der Waals substrate interaction and the underlying crystal symmetry will be discussed, thereby highlighting routes on how to control the anisotropy of 2D magnets via growth engineering. Moreover, the crucial role of a robust easy-plane anisotropy for the emergence of in-plane topological spin textures -merons and anti-merons- will be showcased for monolayer CrCl3, both from a theoretical and experimental perspective.

2:30 PM QT04.06.03
Effect of Molecular Beam Epitaxy (MBE) Growth Conditions on the Structural and Magnetic Properties of High Curie Temperature $(MnSb_2Te_4)_x(Sb_2Te_3)_{1-x}$ Magnetic Topological Insulators CandiceForrester[1,2], ChristopheTestelin[3], KaushiniWickramasinghe[4], IdoLevy[5], XiaxinDing[4], LiaKrusin-Elbaum[4,1], GustavoLopez[1,2] and MariaTamargo[1,4]; [1]The Graduate Center, CUNY, United States; [2]Lehman College, CUNY, United States; [3]Sorbonne Université, CNRS, Institut des NanoSciences de Paris, France; [4]The City College of New York, United States; [5]New York University, United States

Recently it has been shown that structural disorder in 3D Topological Insulators (TIs) has considerable effects on the properties of the materials. The addition of magnetic ions like Mn breaks time reversal symmetry and opens a gap in the Dirac point.[1] This addition also changes the crystal structure from the typical quintuple layer (QLs) structure of non-magnetic TIs to a septuple layer (SLs) structure.[2] Furthermore, addition of a Mn flux during MBE growth results in self-assembled structures of mixed QLs and SLs.[2]
Previously we reported the MBE growth of self-assembled structures of $(MnSb_2Te_4)_x(Sb_2Te_3)_{1-x}$ magnetic topological materials,[3] and showed that their Curie temperature (T_C) is dependent on the composition x (or %SL).[4] Samples with $0.7 < x < 0.85$ exhibit very high T_C values. Additionally, it was observed that as the Mn beam equivalent pressure (BEP) ratio used was increased, there was a corresponding increase in T_C. Decreasing the growth rate further increased T_C to >100 K, the highest values reported for this material system. An understanding of how the changes in growth conditions lead to the T_C enhancement is not well-established.
Here we investigate the structural properties of the materials as they relate to the growth conditions, specifically Mn flux ratio during growth and reduced growth rate (GR). Samples grown at slow GRs (0.4 – 0.6 nm/min) were compared to samples grown at fast GRs (0.8 – 1.0 nm/min). Samples were investigated using several characterization techniques including X-ray diffraction, Energy Dispersion X-Ray Spectroscopy (EDS), Hall effect and scanning transmission electron microscopy (STEM).
We found that for the same Mn BEP ratio, low GR yields similar composition, x, as fast GRs. On the other hand, EDS showed that for $x > 0.7$, there was increased intermixing between Sb and Mn in both the fast and the slow GR samples. Furthermore, the samples grown with slow GR showed much greater Mn and Sb intermixing, as well as Mn and Te intermixing, suggesting increased Mn incorporation at the slow GR, as well as more disorder. Cross sectional EDS studies reveal a high Mn content in the QLs, consistent with $(Sb_{1-y}Mn_y)_2Te_3$ alloy formation. Hall effect measurements show that GR does not significantly affect the electrical doping in $(MnSb_2Te_4)_x(Sb_2Te_3)_{1-x}$ supporting the proposal that a super-exchange magnetic mechanism is likely at play. Other techniques, such as magnetic force microscopy (MFM) are being explored to better understand the magnetic mechanisms leading to high T_C values and Raman spectroscopy is being explored to understand the disorder in these materials. Our results provide insight as to how to achieve on-demand magnetic TIs with enhanced properties.

Discovery of Novel Kagome and Related Topological Quantum MaterialsM. ZahidHasan; Princeton University, United States

In a 2D kagome lattice, the Dirac fermions encode topology, flat bands favour correlated phenomena such as magnetism, and van Hove singularities can lead to instabilities towards long-range many-body orders, altogether allowing for the realization and discovery of a series of topological kagome magnets and superconductors with exotic properties. Recent progress in exploring kagome materials has revealed rich emergent phenomena resulting from the quantum interactions between geometry, topology, spin and correlation. I plan to present some of the key developments we made in this field covering the realizations of Chern and Weyl-like topological magnetism, to various flat-band many-body correlations, and then to the puzzles of unconventional charge-density waves and superconductivity. I plan to highlight the connection between theoretical ideas and experimental observations, and the bond between quantum interactions within kagome magnets and kagome superconductors, as well as their relation to the concepts in topological insulators, topological superconductors, Weyl semimetals and high-temperature superconductors. These developments broadly bridge topological quantum physics and correlated many-body physics in a wide range of bulk materials and substantially advance the frontier of topological quantum matter as detailed in our most recent review article (J. Yin, B. Lian & M. Z. Hasan, NATURE 612, 647–657 (2022))

SESSION QT04.07: Poster Spotlight Talk

4:00 PM QT04.07.01
Poster Spotlight: π Quantization in the Berry Phase by the Multiple Degenerate Points FukaWatanabe, KeijiroHirata, TatsukiTojo and KyozaburoTakeda; Waseda University, Japan

Physicomathematics can create new frontiers in condensed-matter physics. The application of *topology* proposes a novel concept, topological materials, that can deepen our understanding regarding quantum phenomena, particularly those related to spin and spin–orbit interactions (SOIs), such as the spin current, spin Hall effects, and spin-Zeeman effect [1]. In these topological materials, the SOI around the degenerate point is key in inducing a characteristic effective magnetic field (EMF). The degenerate state determines its own orthogonal eigenvectors but is not unique because of the “phase” indefiniteness. The Dirac corn is a prime example and results in a topological singularity originating from degeneracy. Spatial asymmetry can generate singularities in the EMF distribution, such as vortices, sources, and sinks, via the SOI around the degenerate point; subsequently, the spin is polarized characteristically therein, particularly when the system exhibits bulk inversion asymmetry (BIA) and/or structure inversion asymmetry (SIA).
In this study, we investigate the manner by which multiple degenerate points in the Brillouin zone (BZ) modify the topological features. We focus on a semiconductor system with a two-dimensional quantum well structure and investigate topological modifications via numerical calculations of the EMF, Berry connection, and curvature. Next, we reveal the energy dependence of the Berry phase modulated by the interaction between the degenerate points. We employ the Hamiltonian, in which the spatial asymmetry of the SIA and/or BIA is considered [1]. The effect of the competition between the SIA and BIA is investigated using tunable parameters a and b. To provide multiple degenerate points in the BZ, we locate the degenerate state at point Γ and then transfer it to a peculiar direction by $\pm k_i$. We vary the locations of the degenerate points by appropriately substituting a value for k_i and examine the directional dependence of the synthesized EMF distribution. We further introduce anisotropy by changing the directional effective mass.
In the SIA system, each degenerate point presents a SIA-like singularity and the concentric EMF distribution results. The synthesis of these two concentric distributions generates a source and a sink at the middle position between the two prepared degenerate points when the points ($\pm k_i$) are located in the <110> direction. Accordingly, the EMF is distributed hyperbolically, and the BIA-like singularity newly results. By contrast, the topological singularity in the BIA system distributes the EMF hyperbolically around each degenerate point. The synthesis of these two hyperbolic distributions results in a new concentric EMF distribution at the middle position. These newborn singularities in the EMF distribution results in accidental degeneracy at the middle position. The sign of the Berry curvature around the newly generated point is opposite to that at the prepared degenerate points.
Finally, we discuss the energy dependence of the Berry phase based on the calculated Berry connection and curvature. Since each degenerate point results in the Berry phase of $\pm\pi$, the multiple degenerate points quantize the Berry phase by π and result in a plateau profile against energy. We further demonstrate that this π quantization can be understood by counting the number of degenerate points in the BZ in addition to identifying the sign of the Berry curvature [2].

Poster Spotlight: Spin Transport Through Superconductor / Weyl Semimetal Heterodevices XiaodongHu, JasonW. Robinson, AdrianIonescu, NadiaStelmashenko, LeylaC. Arslan, FrancescaChiodi, HisakazuMatsuki, SijieWang and JiahuiXu; Cambridge University, United Kingdom

Transport of spin information over large distances is key for many applications in spintronics. Achieving spin transmission within superconducting devices should lead to reductions in Joule

heating and massive improvements in device efficiency and performance. The Weyl semimetal Mn_3Ge [1, 2, 3, 4] with an antiferromagnetic or ferrimagnetic phase has recently emerged as a promising material for spin transmission studies in the superconducting [1] and normal [3, 4] states. In this poster, we report the fabrication of magnetron-sputtered thin-films of Mn_3Ge and superconducting heterostructures with sub-nanometer-thickness-control in order to investigate the interplay between superconductivity and spin transport in Mn_3Ge. The results build a framework for spin-transport control in the superconducting state.

Poster Spotlight: Orientation Control of MBE Grown SnTe Layers on GaAs Substrates MasakazuKobayashi[1,2] and SuNan[1]; [1]Waseda University, Japan; [2]Material Research Technology Institution, Japan

SnTe is one of the attractive material for a topological crystalline insulator (TCI). SnTe films have been grown directly on GaAs (100) substrates by molecular beam epitaxy, and single domain SnTe layers preferentially oriented to (100) were achieved by now. The (111) oriented SnTe domains and Te were easily included in the film. The crystallographic orientation control and surface smoothness improvement was mainly performed in this study.
SnTe layers were grown on (100) and (111)B oriented GaAs substrates by molecular beam epitaxy (MBE). Most of structures were formed on (100) GaAs substrates with (100) oriented ZnTe buffer layers. Elemental sources were used and the molecular beam intensity ratio (J_{Te}/J_{Sn}) was varied between 0.6~2.9. The beam intensity ratio was tuned by changing the beam intensity of Te. The substrate temperature was calibrated using the oxide desorption temperature of chemically etched GaAs substrates prior to the film growth, and it was varied from 200 ºC to 300 ºC. The film thickness of SnTe was about 100 nm.
The introduction of the ZnTe buffer layer was effective to improve the crystallographic properties of SnTe layers. Atomic force microscopy observation revealed that plateaus with atomically smooth surfaces were obtained for SnTe layers prepared on ZnTe buffer layers. On the other hand, samples prepared without ZnTe buffer layers haven't exhibited the atomically smooth surfaces. The size of the plateau was increased by increasing the molecular beam intensity ratio up to 1.0.
Since the growth temperature was relatively low, the inclusion of the excess material was not negligible. According to the result of X-ray diffraction (XRD) measurement, a diffraction peaks originated from hexagonal Te was observed with SnTe peaks when samples were grown with Te rich (J_{Te}/J_{Sn} was between 2.9 and 1.5) conditions. In the secondary electron microscopy measurements, featureless surface was confirmed when the XRD of the sample exhibited no Te peak while dotted materials were clearly observed on the surface when the hexagonal Te peak was observed. The distribution density of the dot was high when the Te diffraction peak signal intensity was strong. Those dotted materials are presumed to be the residual of Te.
The orientation of the material was affected by the growth temperature. When the substrate temperature was raised, (111) SnTe domains were started to appear. The XRD peak intensities of (100) and (111) domains were comparable when the substrate temperature was 250 ºC. In order to eliminate the (111) domain inclusion, the substrate temperature needed to be maintained below 240 °C.
In order to enhance the (111) domain formation, (111)B oriented GaAs substrates were employed. (100) domains could be mostly eliminated when the substrate temperature was raised to 270 ºC.
A standard van der Pauw Hall measurement was performed to characterize the electrical property at room temperature. The (100) sample that didn't include the Te residual exhibited the resistivity of about ohm*cm. The resistivity has increased as the presence of Te residual became noticeable. Based on the literatures, the room temperature resistivity of SnTe and Te were about ohm*cm [1] and 0.3 ohm*cm [2], respectively. The higher resistivity obtained for the grown film might be originated from the mixing of Te residual. Although the surface morphology was improved by the introduction of the ZnTe buffer layer, the electrical properties were not improved. Boundaries of plateau probably became the center of carrier scatterings.

Poster Spotlight: Near-Absolute Spin-Valve Effect at f-Orbital Magnet/Superconductor Interfaces with Controlled Orbital-To-Spin Moments SijieWang[1], KarineDumesnil[2], HarryBradshaw[1], NadiaStelmashenko[1] and JasonW. Robinson[1]; [1]University of Cambridge, United Kingdom; [2]Institut Jean Lamour, France

The proximity effect between a thin-film superconductor (S) and a ferromagnet (F) can lead to a spin-splitting of the quasiparticle density of states and suppression of the superconducting critical temperature (T_C) (1). At an S/F interface, the average magnitude of the spin-splitting in S can be tuned via the micromagnetic state of F with shifts in T_C between magnetized ($T_{c,m}$) and de-magnetized ($T_{c,dm}$) ferromagnet states being dependent [1-3] on the ratio of the superconducting coherence length (ξ) to the domain wall width (d_w) ¾ i.e., $(T_{c,m}- T_{c,dm})/T_{c,dm} = \Delta T_C/T_{c,dm}$ µ ξ/d_w can theoretically be infinite for an appropriate combination of S and F thin films in which S is thinner than ξ. Experimentally, however, such an absolute spin-valve effect is hard to achieve with $\Delta T_C/T_{c,dm}$ ratios tending to be a small fraction of $T_{c,dm}$, indicating physics beyond the standard picture of the S/F proximity effect. Here we report S/F bilayers and F/S/F spin-valves in which F is an f-orbital ferromagnet (HoGd) with a controlled composition to tune the ratio of the orbital to spin components of the magnetization. The results demonstrate that $\Delta T_C/T_{c,dm}$ can approach infinity for a large ratio of the orbital moment to spin moment, which enables a near-absolute spin-valve effect. Our results demonstrate that the band structure of the ferromagnet in conjunction with the ξ/d_w can be tuned to enable high-performance superconducting memory for energy efficiency electronics. A first principle theory is required in order to understand the relationship between ΔT_C / $T_{c,dm}$ and the ratio of the orbital to spin moment of the F metal.

Poster Spotlight: Towards Quantum Transport in Metal and Ferromagnetic Semiconductor Thin Films Structures with Absorbed Chiral Molecules JiahuiXu[1], JasonW. Robinson[1], HisakazuMatsuki[1], NadiaStelmashenko[1], ShiraYochelis[2] and YossiPaltiel[2]; [1]University of Cambridge, United Kingdom; [2]The Hebrew University of Jerusalem, Israel

Chiral molecules (CMs), such as alpha-helix polyalanine, exhibit chiral-induced spin-selectivity (CISS) characteristics, which means that a flow of electron charge across a layer of CMs can result in a spin-filtering effect and phase coherent transport (1, 2). Recently, for example, we have demonstrated low temperature phase-coherent transport through thin-film wires of Au and Cu with absorbed CMs (2). For Au, we also observed evidence for induced ferromagnetism associated with the thiol-Au bonding and for Au and Cu, we detected an enhancement of spin-orbit coupling. Here, we systematically study charge transport and magnetic anisotropy in thin films and wires of Au and Au/EuS where EuS is a ferromagnetic semiconductor. The thickness of Au is varied in the 1-10 nm range in order to optimise magnetic hysteresis in Au and magnetic anisotropy modification in Au/EuS structures. The results provide a platform for detailed studies of quantum behaviour including magnetic control of phase coherence transport and potentially a quantum anomalous Hall effect.

Poster Spotlight: π Quantization in the Berry Phase by the Multiple Degenerate Points FukaWatanabe, KeijiroHirata, TatsukiTojo and KyozaburoTakeda; Waseda University, Japan

Physicomathematics can create new frontiers in condensed-matter physics. The application of *topology* proposes a novel concept, topological materials, that can deepen our understanding regarding quantum phenomena, particularly those related to spin and spin–orbit interactions (SOIs), such as the spin current, spin Hall effects, and spin-Zeeman effect [1]. In these topological materials, the SOI around the degenerate point is key in inducing a characteristic effective magnetic field (EMF). The degenerate state determines its own orthogonal eigenvectors but is not unique because of the "phase" indefiniteness. The Dirac corn is a prime example and results in a topological singularity originating from degeneracy. Spatial asymmetry can generate singularities in the EMF distribution, such as vortices, sources, and sinks, via the SOI around the degenerate point; subsequently, the spin is polarized characteristically therein, particularly when the system exhibits bulk inversion asymmetry (BIA) and/or structure inversion asymmetry (SIA).
In this study, we investigate the manner by which multiple degenerate points in the Brillouin zone (BZ) modify the topological features. We focus on a semiconductor system with a two-dimensional quantum well structure and investigate topological modifications via numerical calculations of the EMF, Berry connection, and curvature. Next, we reveal the energy dependence of the Berry phase modulated by the interaction between the degenerate points. We employ the Hamiltonian, in which the spatial asymmetry of the SIA and/or BIA is considered [1]. The effect of the competition between the SIA and BIA is investigated using tunable parameters a and b. To provide multiple degenerate points in the BZ, we locate the degenerate state at point Γ and then transfer it to a peculiar direction by $\pm k_i$. We vary the locations of the degenerate points by appropriately substituting a value for k_i and examine the directional dependence of the synthesized EMF distribution. We further introduce anisotropy by changing the directional effective mass.
In the SIA system, each degenerate point presents a SIA-like singularity and the concentric EMF distribution results. The synthesis of these two concentric distributions generates a source and a sink at the middle position between the two prepared degenerate points when the points ($\pm k_i$) are located in the <110> direction. Accordingly, the EMF is distributed hyperbolically, and the BIA-like singularity newly results. By contrast, the topological singularity in the BIA system distributes the EMF hyperbolically around each degenerate point. The synthesis of these two hyperbolic distributions results in a new concentric EMF distribution at the middle position. These newborn singularities in the EMF distribution results in accidental degeneracy at the middle position. The sign of the Berry curvature around the newly generated point is opposite to that at the prepared degenerate points.
Finally, we discuss the energy dependence of the Berry phase based on the calculated Berry connection and curvature. Since each degenerate point results in the Berry phase of $\pm\pi$, the multiple degenerate points quantize the Berry phase by π and result in a plateau profile against energy. We further demonstrate that this π quantization can be understood by counting the number of degenerate points in the BZ in addition to identifying the sign of the Berry curvature [2].

Poster Spotlight: Near-Absolute Spin-Valve Effect at f-Orbital Magnet/Superconductor Interfaces with Controlled Orbital-To-Spin Moments SijieWang[1], KarineDumesnil[2], HarryBradshaw[1], NadiaStelmashenko[1] and JasonW. Robinson[1]; [1]University of Cambridge, United Kingdom; [2]Institut Jean Lamour, France

The proximity effect between a thin-film superconductor (S) and a ferromagnet (F) can lead to a spin-splitting of the quasiparticle density of states and suppression of the superconducting critical temperature (T_C) (1). At an S/F interface, the average magnitude of the spin-splitting in S can be tuned via the micromagnetic state of F with shifts in T_C between magnetized ($T_{c,m}$) and de-magnetized ($T_{c,dm}$) ferromagnet states being dependent [1-3] on the ratio of the superconducting coherence length (ξ) to the domain wall width (d_w) ¾ i.e., $(T_{c,m}- T_{c,dm})/T_{c,dm}$ =

$\Delta T_C/T_{c,dm}$ μ ξ/d_w can theoretically be infinite for an appropriate combination of S and F thin films in which S is thinner than ξ. Experimentally, however, such an absolute spin-valve effect is hard to achieve with $\Delta T_C/T_{c,dm}$ ratios tending to be a small fraction of $T_{c,dm}$, indicating physics beyond the standard picture of the S/F proximity effect. Here we report S/F bilayers and F/S/F spin-valves in which F is an f-orbital ferromagnet (HoGd) with a controlled composition to tune the ratio of the orbital to spin components of the magnetization. The results demonstrate that $\Delta T_C/T_{c,dm}$ can approach infinity for a large ratio of the orbital moment to spin moment, which enables a near-absolute spin-valve effect. Our results demonstrate that the band structure of the ferromagnet in conjunction with the ξ/d_w can be tuned to enable high-performance superconducting memory for energy efficiency electronics. A first principle theory is required in order to understand the relationship between ΔT_C / $T_{c,dm}$ and the ratio of the orbital to spin moment of the F metal.

Robinson[1], HisakazuMatsuki[1], NadiaStelmashenko[1], ShiraYochelis[2] and YossiPaltiel[2]; [1]University of Cambridge, United Kingdom; [2]The Hebrew University of Jerusalem, Israel

Chiral molecules (CMs), such as alpha-helix polyalanine, exhibit chiral-induced spin-selectivity (CISS) characteristics, which means that a flow of electron charge across a layer of CMs can result in a spin-filtering effect and phase coherent transport (1, 2). Recently, for example, we have demonstrated low temperature phase-coherent transport through thin-film wires of Au and Cu with absorbed CMs (2). For Au, we also observed evidence for induced ferromagnetism associated with the thiol-Au bonding and for Au and Cu, we detected an enhancement of spin-orbit coupling. Here, we systematically study charge transport and magnetic anisotropy in thin films and wires of Au and Au/EuS where EuS is a ferromagnetic semiconductor. The thickness of Au is varied in the 1-10 nm range in order to optimise magnetic hysteresis in Au and magnetic anisotropy modification in Au/EuS structures. The results provide a platform for detailed studies of quantum behaviour including magnetic control of phase coherence transport and potentially a quantum anomalous Hall effect.

8:00 PM QT04.08.07
WTe2 Topological Insulator: Synthesis, Characterizations and Applications DimitreDimitrov[1,2], VeraM. Gospodinova[2], J.F.Sierra[3] and SergioValenzuela[3]; [1]Institute of Solid State Physics, Bulgarian Academy of Sciences, Bulgaria; [2]Institute of Optical Materials and Technologies (IOMT), Bulgarian Academy of Sciences, Bulgaria; [3]Catalan Institute of Nanoscience and Nanotechnology (ICN2), Spain

Since the discovery of a new material phase, topological quantum materials (TQMs), [1] tremendous effort has been made to explore a wide variety of novel and abundant physics appearing in topological insulators (TIs), topological superconductors (TSCs), and Weyl semimetals for creating novel electric and spintronics devices. WTe2 belongs to the family of transition-metal dichalcogenides (TMDs) and crystallizes naturally in a non-centrosymmetric orthorhombic structure (also known as the Td or distorted 1T phase, in which the tungsten atoms are octahedrally coordinated by the tellurium atoms) with polar space group Pmn21. The polar axis in WTe2 is oriented along the stacking direction of layers. Unlike other TMDs, WTe2 is a Weyl semimetal in its native crystal phase [2]. Among Weyl semimetals, Td-type WTe2 is a new class, a type-II Weyl semimetal, where the Weyl points appear at the crossing of the oblique conduction and valence bands due to the broken inversion symmetry and non-saturating giant positive magnetoresistance is a manifestation of the type-II Weyl character [3]. In this presentation the current status of the research and emerging applications of WTe2 are reviewed.

Low Secondary Electron Emission 2D Surfaces IsabelMontero; CSIC. Insituto de Ciencia de Materiales de Madrid, Spain

The secondary electron emission is the feedback mechanism of the resonant avalanche of electrons or Multipactor discharge in high- power RF devices onboard satellites. The multipactor discharge is a severe problem which limits the maximum power of RF instrumentation in space missions, it can cause RF signal loss and distortion and it can increase the noise figure or bit-error-rater even total mission failure. The search for surfaces with a low secondary electron emission yield (SEY) is considered one of the main research areas to reduce the multipactor effect in high-power RF devices used in spacecraft and other important technological fields such as high-energy particle accelerators. In this study, RF devices were made using aluminum alloy AA6061. The RF insertion losses of the devices were improved, meaning they were reduced, when AA was silver-coated. However, the SEY of silver, although lower than that of AA, still needs to be reduced to prevent multipactor. The SEY of silver exposed to air is greater than 2. The aim of this study was to deposit a 2D MoS2 layer on silver coatings that are suitable for reducing SEY and preventing multipactor discharge. Prior to the deposition of the silver coating, the aluminum alloy of the RF devices was zincated, followed by the deposition of intermediary layers of Ni and Cu. We used deep eutectic ionic liquids (2:1 ethylene glycol-choline chloride) instead of water to deposit these coatings. Finally, the MoS_2 was deposited on the external silver coating using an optimized electroless process. As a result, we have developed an electroless plating process for growing 2D nanostructures with a high aspect ratio. The characterization was performed in an ultra-high vacuum (UHV) system composed of three interconnected chambers at a pressure of less than 10-9 hPa, while the fast entry chamber remained at 2x10-7hPa. SEY is defined as the number of emitted electrons per incident electron, that is, SEY = Ie/Ip, where Ie is the emitted current and Ip is the primary or incident current. SEY was measured in the primary electron energy range from 0 to 1000 eV. The samples were also analyzed by x-ray photoemission spectroscopy (XPS) and field-emission scanning electron microscopy (FESEM).
In this study, we report an extremely low SEY of this multi-layer coating. The SEY as a function of primary electron energy curves show a maximum value close to 0.8. Furthermore, a linear translation of the SEY curve towards the region where SEY >1 for oxygen content >0.3% is observed. The energy distribution curves (EDC) or energy spectra of secondary electrons also exhibit a significant decrease in the signal for kinetic energies <50eV, which is consistent with the SEY results.

Low-Temperature Microwave Impedance Microscopy of Topological Materials MonicaAllen; University of California, San Diego, United States

Quantum-relativistic materials often host electronic phenomena with exotic spatial distributions. We employ microwave impedance microscopy (MIM), which characterizes the local complex conductivity of a material, to directly visualize chiral edge modes and phase transitions in a quantum anomalous Hall insulator. This near-field imaging technique detects the unique fingerprint of topological edge modes in the GHz regime and spatially disentangles them from trivial states in the bulk of the material. Motivated by these experimental findings, we model the microwave response of topological edge states in a Chern insulator and demonstrate an enhanced MIM response can appear at the crystal boundaries due to collective edge magnetoplasmon excitations. The resonance frequency of these plasmonic modes should depend quantitatively on the topological invariant of the Chern insulator state and on the sample’s circumference, which highlights their non-local, topological nature. Looking forward, we will also discuss progress on the construction of a new milliKelvin MIM, which will support spatially-resolved detection of topological states at low temperatures.

Zeeman Field-Induced Two-Dimensional Weyl Semimetal Phase in Cadmium Arsenide BinghaoGuo[1], WangqianMiao[1], VictorHuang[1], AlexanderLygo[1], XiDai[1,2] and SusanneStemmer[1]; [1]University of California, Santa Barbara, United States; [2]The Hong Kong University of Science and Technology, China

We report a topological phase transition in quantum-confined cadmium arsenide (Cd_3As_2) thin films under an in-plane Zeeman field when the Fermi level is tuned into the topological gap via an electric field. Symmetry considerations in this case predict the appearance of a two dimensional Weyl semimetal (2D WSM), with a pair of Weyl nodes of opposite chirality at charge neutrality that are protected by space-time inversion (C_2T) symmetry. We show that the 2D WSM phase displays unique transport signatures, including saturated resistivities on the order of h/e^2 that persist over a range of in-plane magnetic fields. Moreover, applying a small out-of-plane magnetic field, while keeping the in-plane field within the stability range of the 2D WSM phase, gives rise to a well-developed odd integer quantum Hall effect, characteristic of degenerate, massive Weyl fermions. A minimal four-band k-p model of Cd_3As_2 which incorporates first-principles effective g factors qualitatively explains our findings.

9:45 AM QT04.09.04
Van der Waals Epitaxy and Electronic Properties of Weyl-Semimetal 1Td-WTe_2AlexandreLlopez[1], FrédéricLeroy[1], CalvinTagne Kaegom[2], BorisCroes[3], AdrienMichon[4], StefanoCuriotto[1], AndrésSaùl[1], BertrandKierren[2], PatrickLefevre[5], FrançoisBertran[5], YannickFagot-Revurat[2] and FabienCheynis[1]; [1]CINaM, France; [2]IJL, France; [3]IPCMS, France; [4]CRHEA, France; [5]SOLEIL Synchrotron, France

Transition metal dichalcogenides (TMDCs) have created huge research interest due to their unique properties and potential for various applications in electronics, photonics and energy. TMDCs are mainly obtained through mechanical or chemical exfoliation of bulk crystals into thin atomic layers. Despite challenging, molecular beam epitaxy of these materials offers significant advantages, including the production of high-quality films, possible long range in-plane ordering and precise control over layer thicknesses, making it more suitable for applications. Among TMDCs, WTe_2 is the only one for which the Td phase is the most energetically favored at room temperature. This Weyl semimetal has been predicted to be a quantum spin Hall insulator [1]. It has been demonstrated to be ferroelectric down to 2 ML [2] and shows an unconventional charge–spin conversion [3]. In this study [4], 1Td-WTe_2 thin films have been elaborated by molecular beam epitaxy on ML-graphene [5] reaching a mean flake size of ≈110nm, which is up to one order of magnitude larger than results reported in the literature for epitaxial WTe_2 [6-8]. Using STM, we rationalized growth conditions and proposed a model to estimate the mean flake size as a function of growth parameters based on nucleation theory [9] and Kolmogorov-Johnson-Meh-Avrami (KJMA) equation [10]. Band structure characterizations by angle-resolved photoemission spectroscopy (ARPES) show electron-pockets at the Fermi level, in agreement with DFT calculations performed on free-standing 1Td-WTe_2 and previous reports [10]. This confirms the crystalline quality of the films. In particular, the occurrence of electron-pockets deeper than on BL-graphene [11] suggests a reinforced charge transfer on ML-graphene and allows to determine a high electron density of $n = 2.0 \pm 0.5 \times 10^{12} cm^{-2}$ for each electron pocket. Fermi surface measurements evidence three equivalent domains rotated by 120° with respect to each other that correspond to different orientations of the WTe_2 orthorhombic unit cell on ML-graphene.

Emergence of Dynamic Memory and Perturbation Effect in $Dy_{2-x}Fe_xTi_2O_7$ Pyrochlore Oxides PramodYadav[1], ChandanUpadhyay[2] and PavanNukala[1]; [1]Indian Institute of Science, Bangalore, India, India; [2]Indian Institute of Technology Banaras Hindu University, India

The investigation of topological materials and their exotic properties, along with understanding crucial exponents, holds great interest for the advancement of next-generation devices. A particular focus lies in the study of out-of-equilibrium properties observed in $Dy_2Ti_2O_7$ spin ice, which presents unique opportunities to comprehend the intricate magnetic behavior found in disordered magnetic materials. Through our experimental analysis, we have discovered the magnetic field-induced anomalous thermomagnetic hysteresis, a phenomenon exclusively observed in temperature- and magnetic field-dependent AC susceptibility measurements. Notably, this observed memory effect exhibits a strong dependence on both thermal and non-thermal driving variables. We have identified that even a minor substitution of the Heisenberg Fe-spins within the Ising matrix, formed by Dy ions, significantly alters the memory effect. Our results clearly demonstrate that defects play a crucial role in the dynamic magnetic properties, which are particularly pronounced in the out-of-equilibrium state. This phenomenon is believed to arise from the combined influences of geometric frustration, disorder, and the cooperative nature of spin dynamics exhibited by these materials. The emergence and controllability of the memory effect with thermomagnetic variables and substitution present a promising foundation for future applications of quantum-based devices.

High-Mobility Two-Dimensional Carriers from Surface Fermi Arcs in Ferromagnetic Weyl Semimetal $SrRuO_3$ Films YukiK. Wakabayashi[1], ShingoKaneta-Takada[2], YoshiharuKrockenberger[1], ToshihiroNomura[2], YoshimitsuKohama[2], HiroshiIrie[1], KosukeTakiguchi[1], ShinobuOhya[2], MasaakiTanaka[2], YoshitakaTaniyasu[1] and HidekiYamamoto[1]; [1]NTT Basic Research Laboratories, Japan; [2]The University of Tokyo, Japan

Leveraging two-dimensional quantum transport phenomena and exploiting them in topological and spin electronics require thorough investigation into magnetic Weyl semimetals. Two-dimensional charge/spin carriers arising from pairs of Weyl nodes are realized in the presence of surface Fermi arcs in topological semimetals. To demonstrate such topological quantum transport phenomena, high-quality epitaxial films of Weyl semimetals are vital. Prior to the present study, we recently demonstrated that ultrahigh-quality thin films of $SrRuO_3$ exhibit quantum transport phenomena specific to bulk three-dimensional Weyl fermions [1,2], implying that they serve as a promising platform also for investigating novel two-dimensional transport in a topological state.
Here we present our findings on the thickness- and angle-dependent magnetotransport properties of $SrRuO_3$, a magnetic Weyl semimetal. Utilizing machine-learning-assisted molecular beam epitaxy [3], we grew $SrRuO_3$ films with 10 nm and 63 nm thicknesses. Quantum oscillations in the 10-nm film demonstrate a high quantum mobility of $3.5\times10^3 cm^2/Vs$, a light cyclotron mass of $0.25m_0$ (m_0: the free electron mass in a vacuum), and two-dimensional angular dependence. The two-dimensional, angular transport dependence might be regarded within two scenarios: (1) the surface Fermi arcs, or (2) the quantum confinement of the three-dimensional Weyl fermions. The former is plausible as the identical angular dependence is also observed in the 63-nm film, which is too thick to observe the quantum confinement effect in it. In addition, the linear thickness dependence of the phase shift provides evidence of the non-trivial nature of the quantum oscillations mediated by the surface Fermi arcs. Furthermore, magnetoresistance (MR) measurements while applying magnetic field parallel to the film surface up to 52 T confirmed the saturation of negative MR in the quantum limit (chiral anomaly), assuring that the carriers arise from a pair of Weyl nodes. These results endorse $SrRuO_3$ as a promising material for topological oxide electronics and for physics investigation of two-dimensional quantum transport phenomena in magnetic Weyl semimetals [4].

8:15 AM QT04.10 .02
Strain-Induced Topological Phase Transitions in Kagome Lattices MiguelA. Mojarro and SergioUlloa; Ohio University, United States

We study the effects of a uniform strain on the electronic and topological properties of the 2D kagome lattice using a tight-binding formalism that includes intrinsic and Rashba spin-orbit coupling (SOC). The degeneracy at the Γ point, where a flat-band-parabolic-band touching occurs, evolves into a pair of (tilted) type-I Dirac cones owing to a uniform strain, as shown by effective Hamiltonians, where the anisotropy and tilting of the bands depend in a nontrivial way on the magnitude and direction of the strain field. Interestingly, we find that the Dirac cones become type-III (including flat dispersions) when the strain is applied along the bonds of the lattice. As expected, the inclusion of intrinsic SOC opens a gap at the emergent Dirac points, making the strained flat band to become topological, as characterized by a nontrivial Z_2 index. We show that the strain drives the systems into a trivial or topological phase for strains of a few percent, allowing topological transitions via uniform deformations. Additionally, when the Rashba interaction is included, semimetallic phases appear in the topological phase diagrams. These findings suggest an alternative way of engineering anisotropic tilted Dirac bands with tunable topological properties in strained kagome lattices.

8:30 AM QT04.10 .03
Optical Nonlinearities in Hexagonal and Triangular Graphene Quantum Dots SureshGnawali and VadymApalkov; Georgia State University, United States

Graphene quantum dots (GQDs), the graphene nanoparticles of a few nanometers excited by an ultrafast optical pulse of a few femtoseconds, exhibit several optical nonlinearities, including residual population and high harmonic generation (HHG). By introducing dephasing, we addressed nonlinearity, namely HHG in GQDs placed in a short linearly polarized optical pulse. At short finite dephasing times, the ultrafast electron dynamics show significant irreversibility with a large residual population of the excited quantum dot levels. When dephasing time increases, intensities correspond to a low-frequency boost, while the cutoff energy decreases regarding the high harmonic spectra. The cutoff energy's dependence on the optical pulse's amplitude is also sensitive to the frequency of the pulse. This dependence in hexagonal GQDs is almost linear when the optical pulse frequency is much less than the quantum dot band gap. However, when the pulse frequency is comparable to the band gap, the cutoff energy shows saturation behavior at a large field amplitude, >0.4 V/Å. In triangular graphene quantum dots with zigzag edges, the intensities of high harmonics show a strong dependence on the initial electron population of the edge states of the quantum dot. If a zigzag triangular quantum dot possesses an even number of edge states, then even high harmonics are strongly suppressed when half of the edge states of the quantum dots are populated before the pulse. For any other populations of the edge states, the odd and even harmonics are of comparable intensities.

8:45 AM QT04.10 .04
Probing the Quality of Bi_2Se_3 Films Grown by Molecular Beam Epitaxy *In-Situ* with Spectroscopic EllipsometryAofengBai[1], MariaHilse[2], PrasannaPatil[3], RomanEngel-Herbert[4] and FrankPeiris[1]; [1]Kenyon College, United States; [2]The Pennsylvania State University, United States; [3]Southern Illinois University Carbondale, United States; [4]Paul-Drude-Instit für Festkörperelektronik, Germany

Quantum materials such as topological insulators (TI) like Bi_2Se_3 feature massless Dirac-like states due to their spin-momentum coupling and time reversal invariance. Those massless topological surface states (TSS) enable the study of new quantum physics and with that allow access to a plethora of technological advancements and the realization of applications with new functionalities for more energy efficient and faster computation schemes. The key to exploiting the unique properties of TIs lies in high-quality materials synthesis. However, Bi_2Se_3 synthesis is plagued with a large number of unintentional carriers, shifting the Fermi level up into the conduction band and masking the TSS. Methods like compensation doping, or cation/anion mixing are being pursuit successfully to prevent the Fermi level drift out of the band gap, but the price paid is a substantial carrier mobility reduction in the film limiting TSS observation to very low temperatures. To date, best results for achieving low bulk carrier concentrations and high mobilities are reported for a meticulously designed buffer layer (BL) growth approach consisting of Bi_2Se_3, In_2Se_3, and $(Bi_xIn_{1-x})_2Se_3$ layers. This approach, on the other hand, is slow and thus expensive due to the complexity of the BL-Bi_2Se_3 synthesis engineering and subsequent TSS probing iteration. Developing a fast, ideally *in-situ* feedback loop between growth and electronic properties is highly advantageous to speed up this approach and realize meaningful progress towards highest-quality Bi_2Se_3 thin film fabrication.
In this talk, we elucidate how *in-situ* spectroscopic ellipsometry (SE) can be employed as a non-invasive, non-contact, real-time, ultra-fast probe of the electronic properties of Bi_2Se_3 during growth. Evaluating the *in-situ* SE data obtained before and after growth of each layer from differently designed Bi_2Se_3, In_2Se_3, and $(Bi_xIn_{1-x})_2Se_3$ heterostructures, we found that the observed SE measurables for Bi_2Se_3 depend sensitively on the sample heterostructure design. To gain deeper insights about the observed differences, we developed oscillator models for the dielectric functions of Bi_2Se_3, In_2Se_3, and $(Bi_xIn_{1-x})_2Se_3$, and compared the weighted average of the broadening parameter of the oscillators that make-up the dielectric function. As a result, we found that the weighted average broadening parameters for the Bi_2Se_3 oscillators of films grown on a In_2Se_3, and $(Bi_{0.7}In_{0.3})_2Se_3$ heterostructure were 20 % smaller than those of films grown directly on Al_2O_3. Smaller broadening parameters are generally associated with the degree of momentum-conservation between electronic transitions due to less pronounced electron scattering. Our finding thus indicates that the Bi_2Se_3 grown on the In_2Se_3, $(Bi_{0.7}In_{0.3})_2Se_3$ heterostructure has superior quality compared to films grown on bare Al_2O_3. This conclusion was corroborated by Hall mobility measurements conducted at room-temperature, which ranged highest for Bi_2Se_3 films grown on In_2Se_3, $(Bi_{0.7}In_{0.3})_2Se_3$ heterostructures. Based on the presented data, *in-situ* SE has the potential to serve as an ultra-fast, real-time probe of the electronic properties of Bi_2Se_3, and is thus highly advantageous for speeding up the engineering process of high-quality TIs growth.

Analysis of the Moving Boundary Problem for Spinodal Transformations in Thin Films RahulBasu[1,2]; [1]VTU, India; [2]Jawaharlal Nehru Technological University, India

The equations of Spinodal Decomposition as postulated by Cahn and Hilliard involve a fourth order pde which to date has not been solved analytically. In this article these equations are examined in their various versions, and solutions obtained for the steady state and transient forms using various methods.Then the moving boundary associated with transformation is examined using a heat transfer approach and a solution attempted using a series and a similarity transformation approach. The equation is postulated to have two contributions one from the usual Laplacian and Fickian contribution part for which Stefan solutions are known, and one with a Double Laplacian which has not been examined. The thin film approximation is applied to simplify some parts of the analysis and to try to get a numerical solution.

ARPES Study of Berry Curvature and Spin Polarization in Ultrathin Ferroelectric Films of GeTe with Giant Rashba Effect YannickFagot-Revurat[1], FabienCheynis[2], CalvinTagne Kaegom[1], BorisCroes[2], AlexandreLlopez[2], GeoffroyKremer[1], BertrandKierren[1], StefanoCuriotto[2], FrédéricLeroy[2], FrançoisBertran[3], PatrickLefevre[3] and Daniel-. Malterre[1]; [1]Institut Jean Lamour- UMR 7198, CNRS/Université de Lorraine, France; [2]Aix Marseille University, CNRS, CINAM, AMUTECH,, France; [3]Synchrotron Soleil, France

GeTe is a ferroelectric material with a giant Rashba constant in such a way bulk ferroelectricity is supposed to drive its spin polarization [1,2]. Recently, a non-volatile ferroelectric control of spin-to-charge conversion at room-temperature, has been demonstrated in epitaxial GeTe films [3]. In addition, a multiple non-trivial topology of its electronic band structure due to the existence of triple-point and type-II Weyl fermions has been reported [4]. The question of persistence of singular electronic properties of GeTe in ultrathin films at nanoscale has been recently adressed so that a cancellation of Rashba constant at a critical thickness of 2.3 nm is proposed [5]. In our work we investigated the evolution of Berry curvature, Rashba constant and spin-polarization of GeTe ultrathin films grown on Si(111) wafers [6] as function of thickness by using ARPES, CD-ARPES and spin-resolved ARPES. As a striking point we demonstrate the persistence of spin-polarized Rashba bands down to 3 nm. All the results will be discussed in the light of trivial/non trivial topological properties of GeTe.

Silk-Based Technology to Boost Food Security BenedettoMarelli; Massachusetts Institute of Technology, United States

The infrastructure of agro-food systems is responsible for more than 25% of anthropogenic greenhouse gas emissions while facing pressure to support an increasing world population. For the first time in history, the availability of arable land has plateaued, and crop yields are threatened by stressors such as soil salinity and drought that are further exacerbated by climate change. Food security and food waste are twin crises; more than 800 million people are undernourished, and 30% of food is lost or wasted from farm to fork. As new technologies that are economically sustainable, scalable, and rapidly deployable to market are needed to address these challenges, an opportunity lies for biomaterials to lead innovation in the agro-food industry. Our laboratory strives to reinvent silk proteins as advanced materials for boosting food security. Here, we will highlight recent developments in the nanomanufacturing of silk to design: (i) physical unclonable functions for food traceability, (ii) packaging that is biodegradable yet possess good membrane proprieties, sense spoilage and mitigate biotic decay, (iii) microenvironments that boost seed germination in marginal land, and (iv) different solutions to precisely deliver payloads in planta. These examples will provide an opportunity to discuss how the establishment of a prolonged biointerface between biomaterials and plants tissues requires the development of basic scientific knowledge on material-plant host response, mechanics of disorder-to-order transitions in proteinaceous materials during condensation phenomena, fluid mechanics, and transport phenomena in plants vasculature, and swelling of porous materials exposed to plant fluids.

9:15 AM SB01.01.02
From Idea to Product—Leveraging Materials to Reduce Food Waste LouisPerez; Apeel Sciences, United States

According to the United Nations - Food Agricultural Organization (UN-FAO), we will need 56% more food to feed the growing global population by 2050. In addition, with more than 800 million people who are affected by hunger today, we need solutions that can address food production and supply challenges in short order. One way to address these challenges is to reduce food waste and loss which is reported between 30 and 50% based on geography and product category by the UN-FAO. Beyond the challenge of continuing to feed a growing population, the environmental and economic impacts of food waste are staggering: 8% of greenhouse gas emissions globally and a total cost of $2.6 trillion dollars annually are due to food waste.

In this talk, we will address how Apeel Sciences, a start-up based in Santa Barbara, CA, is approaching tackling food waste and loss by developing new plant based technologies and products that 'work with nature'. The talk will review the process and the journey of an ‘idea’ to a product via a multidisciplinary approach inspired by Materials Science and Engineering principles to develop a plant based edible coating and other technologies utilizing data science and computer vision to make quantitative produce quality tools and shelf life prediction models to address food lo

9:30 AM SB01.01.03
Metabolomics in a Circular Bioeconomy: A Case for Fruit/Vegetable Waste Material Residuals NancyA. Elnaker[1], Michael A.Ochsenkühn[2], Shady A.Amin[2], MatteoChiesa[1,3] and LinaF. Yousef[4]; [1]Khalifa University of Science and Technology, United Arab Emirates; [2]New York University Abu Dhabi, United Arab Emirates; [3]UiT The Arctic University of Norway, Norway; [4]DeL'Arta-Outdoor Living Laboratory, United Arab Emirates

Research is accelerating towards establishing a circular bioeconomy to achieve the United Nations Sustainable Development Goals (SDGs) and drive sustainable development. Here, we applied untargeted metabolomics as an assessment tool for homogeneous food waste residuals, providing an assessment of their marketability in the circular bioeconomy. The circular bioeconomy involves the comprehensive conversion of biological resources into renewable biobased products, which contributes to climate action and environmental well-being. One strategy for embracing a circular bioeconomy is the discovery of vertical conversions of food and agricultural waste residues, transforming them into value-added commodities. This article applies an untargeted metabolomics approach to gain insights into the phytochemical profile of fruit and vegetable residual wastes (FVRs). Through this analysis, 472 known and 542 unknown compounds were identified, with their relative abundances determined. Among the most prevalent 50 annotated metabolites in FVRs, a significant proportion consisted of natural products or bioactive compounds (64–86%), functional foods (7–12%), fragrances (0–8%), pesticides (0–6%), and intriguingly, environmental contaminants (7–23%). Homogenous waste residuals resulting from fruit and vegetable processing emerge as a promising source of bioactive nutraceuticals, functional food derivatives, and biomaterials. This study proposes using untargeted metabolomics as a rapid method to evaluate extracts obtained from homogenous food waste residuals. This approach provides a pre-assessment of their potential market value within the context of the circular bioeconomy.

Near-Infrared Optical Gas Sensor for Intelligent Food Packaging NiloufarSharif and ArdemisBoghossian; École Polytechnique Fédérale de Lausanne (EPFL), Switzerland

Aim:
This project focuses on the design and fabrication of an intelligent packaging system based on a gas-phase optical sensor. The optical sensor emits near-infrared light that is able to penetrate through visibly opaque materials, including plastics, paper, and cardboard. The sensor will provide real-time monitoring of the quality of packaged food products using a specialized, near-infrared camera.
Method:
The near-infrared signal from the optical sensor is based on the fluorescence emissions of carbon nanotubes (CNTs). The CNTs are wrapped with single-stranded DNA that is able to spontaneously assemble onto the nanotubes following sonication. This wrapping not only solubilizes the CNTs in aqueous solutions but also controls the optical responsivity of the CNTs towards different gases. The resulting solutions are then incorporated into an agar hydrogel. We subsequently investigate the response of the sensor in the presence of ammonia, a gas associated with food spoilage. Finally, we investigate the selectivity of the sensor in the presence of other gases.
Results:
Our results show that the fluorescence intensity of the $AT_{(15)}$-wrapped CNTs increases upon exposure to ammonia. Interestingly, we observe distinct responses from different CNT chiralities. We also observe a concentration-dependent and selective response of the $AT_{(15)}$-wrapped CNT sensor to the target gas, with no significant response to the other gases used in this study.
Conclusion:
Here, we developed an optical sensor based on the fluorescence of CNTs for intelligent food packaging applications. The sensor can be used to monitor food quality in real-time, notifying the user on onset of food spoilage. This sensor thus offers both consumers and manufacturers a quick and accessible means of ensuring food quality and safety.

10:30 AM SB01.01.05
Highly Moisture Resistant Super Gas Barrier Polyelectrolyte Thin Films EthanT. Iverson, Hsu-ChengChiang, KendraSchmieg, HudsonLegendre and JaimeGrunlan; Texas A&M University, United States

Flexible, thin coatings with high barrier to oxygen are widely used for improving the lifespan and shelf life of flexible organic electronics and perishable food products, respectively. While metalized plastic and metal oxide thin films exhibit excellent barrier, they also have unique drawbacks. The lack of transparency and recyclability of metalized plastic, and the rigidity and poor adhesion of metal oxide films (e.g., SiOx and AlxOy), severely limit their benefit, especially in food packaging. The utilization of polyelectrolytes to develop high gas barriers with exceptional transparency, adhesion, and flexibility has long been realized. These barriers can be deposited utilizing layer-by-layer (LbL) assembly, providing nanoscale control over film structure and a high degree of tunability in barrier performance. Another approach utilizes a one-pot polyelectrolyte complex deposited via rod or dip coating in a single step. This film is then buffer cured, which generates ionic crosslinks between the polyelectrolytes and therefore minimizes oxygen diffusion through the film. While polyelectrolyte-based barriers typically lose their efficacy in high humidity, a LbL generated barrier, which is only 132 nm thick, provides a 99x reduction of the oxygen transmission rate of PET at 0% and 90% relative humidity (RH). This barrier retains nearly 81% of its performance at high humidity, a feat that is typically only possible with chemical crosslinking. Another impressive barrier was prepared via a simple dip-coating process of polyethyleneimine (PEI) and poly(acrylic acid) (PAA), which was then cured with a citric acid buffer solution. Through simple ionic crosslinking, undetectable oxygen transmission rate (OTR < 0.005 cc/m^2*day), at both 0% and 90% RH, can be achieved with a PEI:PAA molar ratio of 1:1. The strong complexation from ionic crosslinking creates an unusually dense thin film that is promising for various packaging applications (food, electronics, etc.). These thin film exhibit some of the best-ever polymer-based oxygen barriers at high humidity.

10:45 AM SB01.01.06
FODMAP: Food and Agriculture-Friendly, Organic Compound-Based, Degradable Nanozymes Integrated with an Optical Sensing Platform for Toxic Molecules Detection on The Food Samples Dong HoonLee and MohammedKamruzzaman; University of Illinois at Urbana-Champaign, United States

Nanozyme has recently expanded applications in the field of food and agricultural science, offering the potential to enhance food safety by detecting toxic molecules. However, most of the nanozymes are derived from conventional chemistry and material science such as MOF/metal-based NP. These nanozymes encounter challenges related to their intrinsic toxicity and low-cost effectiveness when applied in food and agriculture. Thus, novel nanozymes that are highly suitable for food and agriculture for future applications are desired.

To address this need, we have introduced a novel type of nanozyme, called OC nanozymes, which are food and agriculture friendly. These nanozymes are composed of polymer and organic compounds and exhibit decent peroxidase-like catalytic activity. The customized, chelation-driven self-assembled particle generation process was contrived to provide spherical-shaped nanozymes containing partially mimicked cofactor sites (e.g., Fe-N or Fe-O) of the natural enzyme without using the conventional engineering process, including pyrolysis, organic solvent, and ionic gelation. In contrast to conventional nanozymes, OC nanozymes exhibit decent eco-compatibility, and cost effectiveness with satisfactory catalytic performance (e.g., Km = at least $0.074 mM/H_2O_2$). These nanozymes, when integrated with colorimetric sensing platforms, enable rapid and selective detection of antioxidant (LOD = at least 7.27 μM), and toxic herbicide detection(LOD =10 pg mL^{-1}) within 7 minutes. Additionally, some OC nanozymes are designed to degrade at a moderate temperature (around 45 Celsius) after use, which provides benefits for further waste management issues. We envision that OC nanozymes can be utilized in further practical food applications.

11:00 AM *SB01.01.07
Business Collaborative Research on Novel Strategies in Functional and Active Packaging for the Food Industry ConchaBosch-Navarro, EncarnaGómez and BegoñaRuiz; AINIA, Spain

Microbial contamination supposes an issue of major concern in the food industry that affects both industrial processes and food products. Consequently, food industry is seeking for novel strategies that prevent surface contamination and microorganism proliferation during fabrication, and also innovative packaging materials that contributes to increase shelf-life of packaged food while being more environmentally friendly.

The development of functional and/or active coatings that could be applied over industrial equipment to prevent microbial growth or over packaging materials to incorporate advanced functionalities appears out as outstanding strategies that different companies in the food and packaging industry are exploring and implementing. A functional coating refers to a formulation that incorporates, for example, antimicrobial activity. To this end, different active substances can be considered. Traditionally, different preservatives and plant extracts have been used. Currently, novel strategies include the use of pro/prebiotics, peptides, endolysins or nanobodies, amongst others. Besides, a functional coating in packaging refers to a specialized type of coating applied to the surface of packaging materials to provide additional functionalities and benefits, such as gas barrier, water resistance or oil repellency. Different strategies are being followed, including the formulation of coatings based on natural ingredients such as proteins, fatty acids or lignocellulosic materials in order provide with functionality while contributing to create a circular economy model.

Several developments in the field of novel functional coatings carried out by AINIA together with different companies in the food and packaging sectors, will be presented. These developments are the result of R&D projects in which synergies between different knowledge fields have been exploited, such as biotechnology, hygienic surfaces, material's science, and packaging. The common point being the agrifood industry focus and the need to fight against food waste while guiding sustainability to the highest standards that current regulations are demanding.

Biomaterials and Food-Opportunities and Challenges FiorenzoOmenetto; Tufts University, United States

Natural materials offer new avenues for innovation across fields, bringing together, like never before, natural sciences and high technology.

Significant opportunity exists in reinventing naturally-derived materials, such as structural proteins, and applying advanced material processing, prototyping, and manufacturing techniques to these ubiquitously present substances. This approach help us imagine and realize sustainable, carbon-neutral strategies that operate seamlessly at the interface between the biological and the technological worlds.

Some of these attributes make these materials ideally suited for interfaces with food from multiple perspectives, ranging from the aesthetic, to flavors, to therapeutics to name a few. These applications leverage functional aspects that include biomaterials-based applications in edible and implantable electronics, food preservation, energy harvesting, wearable sensors, compostable technology, distributed environmental sensing. These opportunities will be outlined in this talk presenting a survey of the possibilities that lie ahead.

Food via Tissue Engineering – Challenges and Opportunities DavidL. Kaplan; Tufts University, United States

The need for future foods for the ever-growing population requires consideration of alternative approaches toward food sustainability, nutrition and security. To address this need, we pursue a cell-based, tissue engineering approach, eliminating animals from the process. Our central hypothesis is that sustainable, cost-effective, and scalable cultivated-meat and alternative proteins will provide new food availability options and healthier food alternatives, while decreasing environmental impact. Towards this goal there is much progress, with cell and tissue biomanufacturing central to the approaches. Further, there remain many challenges and opportunities ahead, from cells, media, safety and scale up, to tuning nutrition, composition and overall food quality and health. These topics will be discussed in the context of this emerging food frontier, where the impact is potentially transformative.

2:00 PM *SB01.02.02
The Development of High Protein Plant-Based Cheese AlejandroG. Marangoni and StacieDobson; University of Guelph, Canada

Animal proteins and animal by-products, such as milk and cheese, generate the greatest amounts of greenhouse gas emissions in the food sector. This, coupled with the demonstrably worsening climate crisis, means that there needs to be a shift to more sustainable alternatives in the form of plant-based foods. In particular, the plant-based cheese industry is relevant, as the products lack critical functionalities and nutrition compared to their dairy-based counterparts. Waxy starch, plant-protein isolate, and coconut oil were combined to create a novel high-protein (18w/w) plant-based cheese. We determined that by using native waxy starch, we can enhance its existing viscoelastic properties by modulating gelatinization through the addition of plant protein and fat. Texture profile analysis indicated that the cheese analogues could reach hardness levels of 15-90N, which allowed samples to be tailored to a wider range of dairy products. We determined that plant proteins and fat can behave as particulate fillers and enhance network strength but also create strategic junction zones during starch retrogradation. The degree of melt and stretch of the high protein plant-based analogues were 2-3times greater than those observed for commercial plant-based cheeses and significantly more similar to dairy cheese. The rheological melting kinetics saw that the high protein plant-based cheese displayed more viscous properties with increasing temperature. Tan (G”/G’) at 80^{o}C was used as an indicator for sample meltability where, values indicate better melt and more viscous systems. The high protein plant-based cheese reached tan values upwards to 0.8, whereas commercial plant-based cheese only reached tan values around 0.1. Synchrotron micro-CT as well as synchrotron mid-IR imaging was utilized to characterize structure and interactions between components.

2:30 PM SB01.02.03
Generating Animal-Free Protein Scaffolds using Antisolvent Precipitation under Couette Flow PatrickA. Sullivan, YingWang, LasanthiSumathirathne and LeilaDeravi; Northeastern University, United States

A common feature of animal-based proteins is their ability to self-assemble into continuous protein fibers, as seen in muscle and connective tissues. Their fibrous nature has inspired research and development in the tissue engineering, textile, and synthetic meat industries, to find methods of replicating this aligned fiber structure in nonanimal-based proteins. Zein is a nitrogen storage protein that is primarily found in corn, that has become popular due to its status of Generally Regarded As Safe (GRAS), its biocompatibility, its fabrication flexibility and its unique solubility, solvating in 60-90% mixtures of ethanol and water. This makes it a prime candidate for antisolvent precipitation and extrusion methods to produce zein fibers for food industry applications. However, extrusions methods produce a rapid but random generation of fibers in terms of diameter and alignment when utilizing this antisolvent precipitation, and the conclusion has been drawn that further antisolvent zein fiber formation should focus on fiber orientation as a next step in development. In this work we aimed to produce aligned fibrous microstructures on zein scaffolds like those found in animal-based proteins. We investigate how salt concentration and identity influence the aggregation patterns of zein as it precipitates into nanoparticles through its addition to an aqueous antisolvent. We then use the conclusions drawn from these findings in combination with a custom-built device to induce anti-solvent precipitation under Couette-flow to produce continuous fibrous scaffolds, demonstrating their use as scaffolds for future tissue engineering applications.

2:45 PM SB01.02.04
Cephalopod-Inspired Material Design for Potential Food Applications BiancaC. Datta; Ronin Institute for Independent Scholarship, United States

As the global population rises alongside a worsening climate outlook, alternative proteins such as plant and cell-based meat provide exciting avenues for meeting the increasing demand for meat sourced from animals and have implications for planetary and human health. While food science is a well-established field with a rich history, inclusion of methods and research paradigms from the materials community can accelerate the development of promising food technologies. In this work, we review the complex and interesting structure and functionality of cephalopods, the landscape of existing materials advances towards replicating these creatures, and extensions towards food and edible materials. In doing so, we bridge the rich culinary traditions around cuttlefish, octopus, and squid[7] with advancements in tissue engineering and bio-inspired design.

Few creatures generate as much wonder and curiosity as cephalopods. Renowned for their protective and communicative capabilities (camouflage, texture and shape change), they also demonstrate fascinating behavioral and cognitive abilities[6].Researchers have looked to cephalopods for inspiration in designing systems as varied as displays1, programmable coloration[2], self-healing coatings3, mechanochromic windows[4], and bioelectronics[5]. We now look to their unique structure and properties to inspire a new domain of compelling alternative food materials.

Understanding Structure in Methylcellulose Solutions using Machine Learning Enhanced Scattering Analysis (CREASE), Coarse-Grained, and Atomistic Molecular Dynamics Simulations AudreyCollins, ZijieWu and ArthiJayaraman; University of Delaware, United States

Methylcellulose (MC) iscellulose derivative in which some of the hydroxyl groups are replaced by methoxy(-OCH3) groups. Aqueous solutions of MC exhibit unique phase behavior wherein at low temperatures MC chains are soluble in water and at high temperatures MC chains assemble into semi-flexible fibrils and fibrillar networks.Fibrillar networks exhibit mechanical and rheological properties that make them useful as food and pharmaceutical ingredients. Structural characterization of MC aqueous solutions through small angle X-ray scattering (SAXS) experiments show that MC fibrils exhibit a consistent fibril diameter with varying MC concentration and molecular weights; however, the molecular underpinnings of this observation are unclear. Our work aims to elucidate these molecular underpinnings using computational techniques from top-down (machine learning enhanced computational reverse engineering analysis of scattering experiments: CREASE) and bottom-up (molecular dynamics simulations). In the top-down approach, (Macromolecules 202255(24), 11076-11091), Wu and Jayaraman found consistent MC fibril diameter distributions using CREASE and analytical model fits, confirming the results by Lodge, Bates, and co-workers (Macromolecules, 2018, 51, 7767−7775) that MC forms fibrils with consistent average diameters of∼15–20 nm regardless of the chain length and concentration of MC chains. In the bottom-up approach,which is the focus of this talk, we use both coarse-grained(CG) and atomistic(AA) molecular dynamics (MD) simulations to capture macromolecular-scale fibril assembly and the molecular-level interactions between MC chains that drive that assembly, respectively. In the CG MD simulations, we observe MC chains assemble in parallel fashion toform fibrils with consistent diameter for varying MC chain length and concentration. Guided by those CG MD chain configurations where solvent is implicit, we use atomistic MD simulations with explicit water, anduncover a potential explanation for the consistent fibril diameter: inter-MC chain twisting. We find that acombination of favorable hydrogen bonds and hydrophobic interactions drives the twisting of MC chains during fibril formation.Our work provides a holistic understanding of MC chains assembly in water and aids material development for application of MC in various industries.

3:45 PM SB01.02.06
Whey Protein Isolate Composites as Tunable Scaffolds for Cultured Meat ChristopherFoley, IrfanTahir, PatrickCharron and RachaelFloreani; The University of Vermont, United States

INTRODUCTION The rising global population and increasing prevalence of food insecurity highlights the need for alternative food sources. New developments in biotechnology have given rise to many alternative food and protein options, including the research and development of cultivated meat. Cultivated meat is produced via *in vitro* animal cell culture and their incorporation into manufactured scaffolds. Plant-based, alginate scaffolds are a common material used during manufacturing, due to the tunability of their mechanical properties through modification of molecular weight, chemical composition, and structure; however, alginate does not have the necessary cell adhesion ligands. Whey protein isolate (WPI) is a biproduct of the dairy processing industry, is a food additive, and has recently been shown in the literature to encourage cell adhesion in bone and cartilage tissue engineering. The objective of our study was to investigate the effect of WPI-based scaffolds on muscle cell adhesion and viability for the production of scaffolding for cultured meat. **METHODS** The AlgMA was synthesized by dissolving sodium alginate in deionized (DI) water at a 1% (w/v) and a 20-molar excess of methacrylic anhydride. WPI was dissolved in 1x phosphate buffered saline (PBS) at 5.25% (w/v). After 24 hours, the solutions were dialyzed (MWCO = 6-8 kDa) against chilled DI water for three days to remove any residual reactants. Polymer solutions were then frozen and lyophilized. With these dry polymers, 3% (w/v) AlgMA solutions were prepared in DI water at room temperature, to which WPI or WPI-MA, was added to bring the protein concentration to 10% (w/v). One mM eosin Y, 125 mM triethanolamine, and 20 mM 1-vinyl-2-pyrrolidinone were mixed with the control (AlgMA) and experimental samples (WPI/AlgMA, WPI-MA/AlgMA). These solutions were then cast into circular molds and exposed to the green light (525 nm) for 10 minutes for crosslinking to occur. The crosslinked polymer solutions were characterized through proton nuclear magnetic resonance (^{1}H-NMR), scanning electron microscopy (SEM), rheological & compression testing, swell/weight-loss studies, and immunofluorescent staining of C2C12 myoblast cells. **RESULTS AND DISCUSSION** A 3D interconnected porous network was created, showing differences compared to an AlgMA control. WPI-based scaffolds exhibited more ordered structures compared to that of the AlgMA control. Pore sizes ranged between 50-200 µm. While moderate weight loss was experienced by the non-modified WPI, the WPI-MA and AlgMA hydrogels displayed minimal weight loss after a period of seven days. Under a compressive load, the WPI-MA/AlgMA scaffolds were more compliant compared to the AlgMa control, and the WPI-based scaffolds exhibited moduli that closely resembled the mechanical properties of native muscle tissue. WPI-based scaffolds were non-toxic to C2C12 cells, and increased cell density over the course of seven days compared to controls. WPI/AlgMA and WPI-MA/AlgMA materials were found to be non-toxic to murine C2C12 myoblast cells and promoted increased adhesion and proliferation compared to the AlgMA control. The incorporation of non-modified and chemically modified WPI in alginate scaffolds shows encouraging data that supports the use of WPI-based scaffolds for engineering muscle tissue *in vitro*. Also, the tunability of composition and mechanical properties will allow these materials to be fine-tuned for other properties such as texture and flavor. **CONCLUSION** Scaffolds were formulated using methacrylated alginate (AlgMA), WPI, and methacrylated WPI (WPI-MA). The resultant scaffold product was a photo-crosslinked, porous network that displayed marked differences compared to the AlgMA control scaffold. In summary, our study provides compelling evidence supporting the use of WPI-based scaffolds in 3D cultivated meat production, highlighting its substantial prospects and benefits.

4:00 PM *SB01.02.07
Biomaterials and Bioprinting of Skeletal Muscle Spheroids for use as Building Blocks for Engineered Muscle Tissue KentLeach, NicholasJohnson, AndreaFiller and AlexKermani; University of California-Davis, United States

Skeletal muscle tissue engineering has the potential to address key clinical and societal challenges such as traumatic muscle injury, our fundamental understanding of skeletal muscle development and disease, and the future of meat production *via* cell cultured meat. Preclinical animal models and monolayer culture have driven our understanding of skeletal muscle biology and differentiation. However, two-dimensional (2D) cell cultures lack complex cell-cell and cell-extracellular matrix (ECM) interactions that provide essential biochemical and biomechanical signals directing cell function *in vivo*. Engineered tissue must sufficiently model the complexity of native muscle, which has led to the innovation of advanced fabrication methods such as 3D bioprinting.

Bioprinting is a promising biofabrication technique for generating structured tissue due to the potential to precisely pattern multicellular constructs of relevant cell types. The most common bioprinting applications use monodisperse cells, which requires disruption of essential cell-cell and cell-matrix interactions. A growing body of research confirms the benefits of retaining the endogenous ECM to mimic the native extracellular environment and support cell function, hence exposing a key current limitation of bioprinting.

Spheroids are dense cellular aggregates that exhibit promise as building blocks for tissue engineering due to their retention of endogenous ECM, upregulated cytokine production, and increased cell-cell interactions. Spheroids are advantageous for use in tissue engineering due to their enhanced differentiation, angiogenic potential, and cell survival *in vitro* and *in vivo* compared with monodisperse cells. Spheroids have been fabricated from a wide variety of cell types yet literature on skeletal muscle spheroids, sometimes referred to as myospheres, is sparse. The study of myospheres has primarily been focused on understanding cell behavior of primary muscle cells, but their application in tissue engineering lags behind other tissues types such as bone, heart, and adipose, among others. While work utilizing muscle spheroids from immortalized cell lines has been limited, initial studies have shown promising results in regard to cell survival and differentiation. For example, C2C12 spheroids, once dissociated, exhibited higher proliferation, upregulated MyoD expression, and enhanced myogenic potential in both 2D and 3D culture. Furthermore, C2C12 spheroids have upregulated myogenic factors compared to monodisperse cells and can differentiate into aligned myotubes on electrospun substrates. However, little is known about how muscle cell spheroids function in contiguous matrices such as bioinks, representing a key information gap in the field.

We hypothesized that skeletal muscle cell spheroids will function as potent building blocks of muscle tissue when embedded in 3D microenvironments. We bioprinted skeletal muscle spheroids to assess cell function and tissue forming potential compared to monodisperse cells. We utilized 3D bioprinting as a proof-of-concept to determine whether bioprinting may adversely affect cell viability. Experiments were first performed using C2C12 spheroids before translating to more clinically and culinarily relevant primary bovine satellite cells. Both C2C12 and primary bovine SCs formed spheroids of similar sizes, remained viable after bioprinting, and exhibited similar spreading characteristics within an alginate matrix. When bioprinted with alginate as a bioink, spheroids of both cell types fused into larger tissue constructs over time and exhibited tissue formation potential similar to monodisperse cells. These data demonstrate that skeletal muscle spheroids are promising building blocks for muscle tissue and validate 3D bioprinting as a compatible fabrication technique. I will also highlight other studies illustrating the synergy of engineered biomaterials and muscle cell response.

SESSION SB01.03: Poster Session
Session Chairs: Bianca Datta and Varsha Rao

8:00 PM SB01.03.01
Electrohydrodynamics for Efficient Droplet Coalescence in Food-Grade Non-Aqueous Pickering Emulsions BrunoTelli Ceccato[1,2], NamrahAzmi[1,3], AndrewN. Akanno[1], PaulG. Dommersnes[1], RosianeLopes da Cunha[2], LucimaraGaziola de la Torre[2] and Jon OttoFossum[1]; [1]NTNU, Norway; [2]University of Campinas, Brazil; [3]Stayfit Nutrisupplies, Tanzania, United Republic of

Coalescence is a fundamental process in emulsion synthesis. It can have positive effects depending on the approach. The emulsion stabilization can be reached when emulsifiers occupy all the droplet surface, and when low quantities of solid particles (Pickering emulsions) are used, stabilization can be reached under controlled arrested coalescence [1].
The application of electro hydrodynamics on non-aqueous emulsion systems can produce emulsion droplets with controlled size distribution and coverage, and also induce coalescence. In the latter case, when an electric field is applied, dipolar emulsion droplets can be generated and short-range dipolar droplet-droplet interactions can take place. Positive surface charges on a droplet can attract negative charges on a neighboring droplet, eventually leading to so-called electro coalescence [2], [3].
Here, we explore the electro-coalescence of food-grade droplets [4] of a non-aqueous system. Non-aqueous food-grade systems are scarcely investigated due to the miscibility of most edible oils, and the limitations of suitable polar protic solvents [5]. In this work, the electro-induced coalescence is shown for a non-aqueous Pickering emulsion with rapeseed or moringa oleifera oils as continuous phase, glycerol or lactic acid in ethanol as dispersed phase, and ethyl-cellulose or moringa oleifera leaf-based stabilizer particles.
Our preliminary results provide insights into the application of electro hydrodynamics in the emulsification processing of food-grade Pickering systems.

Reaction Kinetics and Physical Properties of Carboxymethyl Cellulose-Based Hydrogel Blends for Food Packaging SamudraGupta and JavenWeston; University of Tulsa, United States

Carboxymethyl cellulose (CMC) is a commonly studied polymer made by chemically modifying cellulose to increase water dispersability. CMC is widely used in hydrogel applications because of its biocompatibility and biodegradability. CMC hydrogels are used as absorbents, for food packaging, as additives in pharmaceutical formulations, and for other applications. CMC hydrogels can be synthesized using a variety of chemical and physical crosslinking agents. Here, ethylene glycol diglycidyl ether (EGDE) is used as a chemical crosslinker. The optimal cross-linking temperature and EGDE concentration were determined using *in-situ* oscillatory shear rheology, and other properties, such as the water vapor permeability, swelling ratio, tensile strength, and % elongation at break of the hydrogels were also measured to assess their usefulness for food packaging applications. These hydrogels were found to have unsatisfactory bulk and mechanical properties for food packaging materials, so blends of CMC with various polysaccharides have been investigated to search for synergy between the different biopolymers. In particular, κ-Carrageenan and Xanthan gum were chosen for this study; both are common anionic polysaccharides with excellent gelling, stabilizing ability, emulsifying, and thickening properties. These blends were chosen due to CMC being easy to use, readily available, and cheap. Additionally, this study focuses on finding a correlation between rheology, and bulk properties, such as tensile strength, water vapor permeability, and % elongation at break.

Magnetic Field-Made Capsules to Fight Food Waste ArneT. Skjeltorp; Instiute For Energy Technology, Norway

The European Union (EU) funded PICKFOOD project [1] addresses the 80 million tonnes of food waste generated in the EU annually. It focuses on combating quality deterioration caused by lipid oxidation and other factors. The project aims to enhance the stability and affordability of Pickering emulsions, a promising alternative. Through collaboration with the food industry, PICKFOOD will develop frameworks and methodologies to assess Pickering emulsion applications in safe, healthy, and functional foods.
In this project, magnetic fields are envisioned to make capsules, but this requires very forceful magnets. Many permanent magnets on the market have large magnetic fields, but weak field gradients. The GIAMAG magnets have unique and patented designs that produces both very large magnetic fields and high field gradients, resulting in the most forceful magnets available on the market [2].

Surface Functionalization of Pickering Emulsion Stabilized by Silk Fibroin Microparticles and Enhanced Adhesion for Foliar Spray YueHu and BenedettoMarelli; MIT, United States

Pickering emulsion is a category of emulsion that is stabilized by solid particles. Compared to emulsions stabilized by molecular emulsifiers, Pickering emulsion has high stability, low cytotoxicity, and good biocompatibility. Solid particle emulsifiers could also be modified by functional groups or antibodies to achieve different demands. Thus Pickering emulsion is widely used in the food, pharmaceutical, and cosmetic industries. Silk-fibroin regenerated from silk cocoons is a natural protein. This fibrosis protein has been widely investigated and applied in the fields of biomedicine, cosmetics, and food coating. In our study, we developed biocompatible protein particles synthesized from silk fibroin to stabilize oleic acid oil-in-water Pickering emulsion. Those Pickering emulsions could be applied to agricultural and food industries.

Specifically, water-insoluble silk fibroin microparticles (SFMPs) with a diameter of approximately 2 μm were synthesized through the salting-out method. These microparticles can act as emulsifiers, stabilizing alkane-in-water Pickering emulsion. In addition, polar oil oleic acid with payloads possessing a p*K*a below 5 can be stabilized by SFMPs to generate a Pickering emulsion. The research also delves into the mechanism and ability of SFMPs to stabilize both nonpolar and polar oil-in-water Pickering emulsion, as evidenced by the measurement of three-phase contact angles. To functionalize Pickering emulsion, we synthesized antibody-labeled SFMPs, which can partially replace the emulsifier on the surface of Pickering emulsion droplets and improve the droplets' affinity to antibody binding sites. In this work, anti-pectic polysaccharide antibody-labeled Pickering emulsion loaded with plant hormone jasmonic acid exhibited strong binding to the waxy layer weaker part of the leaf even after the wash and effectively boosted the trichome number of *Arabidopsis* new leaf.

8:00 PM SB01.03.05
Harnessing Satellite Imagery and Geospatial Analysis for Sustainable Nutrient Management in Agricultural Systems OlatundeD. Akanbi, DeepaBhuvanagiri, ErikaI. Barcelos, BrianGonzalez Hernandez, ArafathNihar, LauraBruckman, YinghuiWu, JeffreyYarus and RogerH. French; Case Western Reserve University, United States

The excessive use of fertilizers in agricultural practices poses significant challenges to environmental sustainability and food security. A substantial portion of applied fertilizers from farms , and concentrated animal feeding operations (CAFOs) and urban activities, more specifically in wastewater treatment plants, are lost through runoff, leading to water pollution, ecosystem degradation, and economical loss. To address these critical issues, this research aims to develop an innovative approach utilizing satellite imagery and geospatial analysis to enable efficient and sustainable nutrient management in agricultural systems. The study leverages the Normalized Difference Vegetation Index (NDVI) derived from satellite imagery to monitor crop growth on a daily basis and optimize fertilizer application. By regularly assessing the NDVI metrics, farmers can precisely determine the timing and location for fertilizer application, ensuring optimal nutrient uptake by crops and minimizing wastage. This approach allows for large-scale monitoring, offering a valuable tool to farmers for daily decision-making in fertilizer management. Furthermore, the research incorporates geospatial analysis and spatiotemporal modeling to monitor nutrient flow from farms and CAFOs to nearby water bodies. Utilizing and integrating data (different resolutions and types) from MODIS satellite imagery, Aster GDEM on elevation, USGS Stream Water, USDA Historical Crop, and Soil, a spatial model is developed to track and quantify nutrient runoff. By understanding the movement and accumulation of nutrients, effective mitigation strategies can be formulated to prevent pollution and minimize water contamination. The outcomes of this research contribute to the overarching goal of enhancing food production while minimizing the environmental footprint of agricultural practices. By implementing satellite-based monitoring and geospatial analysis techniques, we can empower farmers and stakeholders to make informed decisions about nutrient management. This approach not only helps reduce fertilizer usage and associated costs but also protects water quality, mitigates algae blooms, and preserves aquatic ecosystems.This provides a practical and scalable solution for addressing the fertilizer application problem, ensuring long-term agricultural sustainability, and meeting the increasing global food demand.

8:00 PM SB01.03.06
Biopolymeric Microneedles for Underwater Fish Vaccination MengLi, YuntengCao, ColleenWolfe and BenedettoMarelli; Massachusetts Institute of Technology, United States

Over the next 30 years, with the world population continues to grow, food supplies will have to increase by 70%. Addressing challenges in food security by promoting healthy and sustainable protein sources is crucial. Aquaculture plays a vital role in meeting these requirements, and fish vaccination is integral to preventing disease spread in densely populated farming environments. However, traditional methods involving intramuscular or intraperitoneal injections require fish sedation, administration outside of water, and poses safety concerns for workers due to accidental needlestick injuries.
In this work, we aim to develop an automatic system capable of precise vaccine delivery in aquaculture settings. We adapted microneedle design and fabrication for plants and mammals to meet the requirements for underwater applications.
To ensure successful fish skin penetration, we have employed proteinaceous silk fibroin microneedles encapsulated with a water-proofing coating layer of food-grade natural resin. This coating layer preserves the mechanical strength of the silk fibroin microneedles in water for hours. The water-proofing coating layer prevents water absorption and swelling of silk fibroin microneedles, which could otherwise weaken their mechanical strength. The coating layer preserves the mechanical strength of silk fibroin microneedles in water for hours.
Additionally, the coating layer prevents the loaded substance from prematurely releasing into the aquatic environment, ensuring controlled release after fish skin penetration. Our results demonstrate that once the microneedles pierce the fish skin, the cargo is released within hours primarily through diffusion.
Our study presents a novel microneedle strategy designed specifically for precise injection and substance delivery in aquaculture, offering a promising solution for enhancing fish health, productivity, and sustainability.

8:00 PM SB01.03.07
Supporting Hydroponic Crop Growth using UV-C Light DouglasX. Shattuck[1,2], SophiaSalinas[3,2], GraceGunning[3,2], EmilyParker[3,2] and SamanAbbas[3,2]; [1]St Joseph School Wakefield,

United States; [2]National STEM Honor Society, United States; [3]Malden Catholic High School, United States

Preliminary results indicate that intermittent exposure to UV-C radiation can enhance the hydroponic production of food crops by stimulating plant growth and inhibiting the growth of pathogenic organisms. However, in addition to its benefits, prolonged exposure to UV-C has been known to be harmful to plants (1, 2, 3). Watercress, a specie of aquatic flowering plant in the mustard family, was selected for this investigation. It is fast growing, can be eaten raw or cooked, and is rich in vitamins K, A, C, riboflavin, B_6, Ca, and Mn(4). It is closely related to the Arabidopsis sp. being studied for germination in lunar regolith(5).
We designed and constructed a hydroponic system that exposed Watercress to commercially available grow lights and UV-C radiation lamps. By exposing the plants to UV-C in monitored 5 or 15 minute intervals we hoped to maximize its growing process and kill any pathogens while minimizing the damage done by the radiation.
The watercress seeds were placed in net pots with moist growing medium and placed in a water-filled box and then exposed to grow lights. The plants were then exposed to five-minute of UV-C radiation followed by long periods of darkness. After each exposure to the UV-C, plants were observed and the growth and general characteristics of the plant recorded. After two days, the plants were exposed to fifteen-minute radiation intervals, following the same schedule. Each of the six boxes of plants underwent the same testing procedures for four days. The UV-C plants appeared equally as healthy as the control group but grew taller and tilted towards the lights more—exaggerated phototropism.
At the end of the test, we observed mold growing in both the control and UV-C groups. Initially, we observed much more mold in the control group. After being untreated for a week, the group exposed to UV-C light had a considerable amount of mold compared to the control group. This difference suggests that during UV-C light treatment, the mold's growth was curtailed. In conclusion, we believe
the UV-C radiation did have a positive effect on the plants as we hypothesized.

***In-Situ* Corona Discharge Non-Thermal-Plasma based Modification of Bio-Ingredients in an Integrated Food Printer: Towards Developing Novel Methodologies for Characterization of Engineered Food Materials**DerekXiong[1], PrakhyatGautam[1], DavidRyman[1], EdberthoLeal-Quiros[2], SaquibAhmed[3] and SankhaBanerjee[1,4]; [1]California State University, Fresno, United States; [2]University of California, Merced, United States; [3]Buffalo State College, United States; [4]University of California, Davis, United States

The current work involves the development of novel in-situ non-thermal plasma treatment methodologies of 3D printed starch-based bio-ingredients towards tailoring the properties of starch granule-surface proteins (SGSP). This work also includes the evaluation of continuous and discontinuous gluten networks through the surface interaction of SGSPs with quasi-static corona discharge plasma regimes. The work further studies the binding characteristics of starch-based bio-ingredients based on the plasma current-voltage characteristics. The cured starch-based sample surface will be characterized using profilometry. The binding characteristics, gluten networks, and porosity characteristics will be analyzed using microstructure evaluation through electron microscopy. Advanced hybrid machine learning models will also be developed in combination with analytical methods and empirical data sets to develop strategies for tailoring the surface and bulk properties of these materials.

8:00 PM SB01.03.09
The Impact of Titanium Dioxide Nanoparticles on Keratinocyte Proliferation and Differentiation DerekZhang[1], AshleyHuang[2], ShiFu[3], MarciaSimon[3], MiriamRafailovich[3], DinaMcGinley[4] and AliceShih[3]; [1]The Wheatley School, United States; [2]Syosset High School, United States; [3]Stony Brook University, The State University of New York, United States; [4]State University of New York at Farmingdale, United States

TiO_2 nanoparticles are still widely used as food additives in the United States for their whitening properties, UV absorption capabilities, and their potential usage as antibacterial reagents. In fact, these particles are considered valid organic additives and can be incorporated at concentrations as high as 1%. When ingested these particles can circulate in the body coming in contact with viable cells and the long term impacts of TiO_2 build up is currently of concern for the European Food Safety Authority [1]. Additionally, even though nanoparticles may not penetrate the stratum corneum and hence do not come into direct contact with viable keratinocytes, if they are used in wound care treatments, they can come into direct contact with viable epidermal and dermal cells and influence cell function and tissue healing. In early experiments producing skin equivalents with keratinocytes exposed to 0.8 mg/mL rutile TiO_2 nanoparticles, we observed nanoparticle aggregation with premature stratum corneum formation and aberrant expression of filaggrin, a late stage multifunctional differentiation marker.
Keratinocytes were grown with lethally irradiated 3T3 cells [2] with media modifications previously described [3]. At 70% confluence feeder cells were removed and cultures were treated with rutile TiO_2 (0.4 mg/mL); no TiO_2 cultures served as control. After 24 hours cultures were rinsed twice with Ca and Mg free phosphate buffered saline, resuspended in buffered saline with BSA and cells sorted at the Stony Brook University Flow Cytometry Core Facility using a FACS Aria IIIU cell sorter.
Cells associated with TiO_2 were separated from TiO_2-free cells based on side scatter using flow cytometry; cells showing low and high side scatter were collected. In these cultures, 90% of the cells exhibited low side scatter, consistent with the absence of nanoparticles. This compares with a low and high scatter population of 57.2% and 42.8%, respectively, in the TiO_2 treated cultures.
The impact of 0.4 mg/mL TiO_2 on keratinocyte proliferative capacity was also explored as a function of colony forming efficiency (CFE), and the colony forming efficiency of keratinocytes with low and high side scatter was determined; TiO_2-free keratinocyte cultures served as control [4]. 12 culture dishes containing 1000 cells each were plated: 4 control plates (low side scatter), 4 plates of TiO_2 treated high side scatter, and 4 plates of TiO_2 treated low side scatter. Following 12 days of incubation, each culture dish was rinsed with Ca and Mg free phosphate buffered saline and stained with Rhodamine B. Colonies $\geq$ 1 mm were counted. In these cultures, CFEs are about three-fold lower in the high side scatter population suggesting NP inhibition of plating efficiency or proliferation. To assess the full impact of these NPs in this system and in skin equivalents, ongoing work includes SEM analyses to determine NP location within the cell and differentiation assessment by RT-PCR to determine overall skin development.

Microfluidic Tools to Monitor Dynamic Processes Occurring during Emulsion and Foam Formation KarinSchroen[1,2] and BoxinDeng[1]; [1]Wageningen University, Netherlands; [2]University of Twente, Netherlands

Humanity faces the huge challenge to supply a growing world population with sufficient and healthy food. To make this a reality we need to rethink how we produce food at large scale. This implies rethinking production 'on the land/in the greenhouse', fractionating raw materials, understanding their functionality during processes used in food production, as well as under digestive conditions to make the connection to health effects that can be created by smart food design.
A big challenge that needs to be addressed to make smarter food design a reality is the investigation of processes that take place at micrometre scale, and even smaller scales, and often within very short times. These dynamic processes underly the food structure that we get, but the dynamics thereof are very difficult to capture due to time and size challenges, and the inaccessibility of food production line for analysis of these processes.
Microfluidics allow visualisation of very fast processes occurring during the production of for example, two phase systems such as emulsions and foams. Various tools have been developed within our lab that allow to focus on interface formation and stabilisation at very short time scales. These tools also allow distinction of interfacial tension effects from coalescence effects in

relation to the size of the structures that are formed, which is a classical dilemma that until now has not been addressed at this level of detail.
These new techniques will contribute to more flexible use of ingredients, allowing product design based on the actual functionality of components. For example, replacement of animal-based products with their plant-based counterparts, and also the use of biomass (e.g., leaves and stems) that are currently considered waist can truly contribute to more sustainable food production practice, but only if the functionality of these components is such that they lead to stable products. I could imagine that the techniques developed are ultimately used to do fast screening, comparison of ingredients, and even to establish a connection with more classic processing technologies, such as high pressure homogenization and foaming techniques given the similarity in conditions.

9:30 AM SB01.04.02
Thermoplastic Molding of Silk-Curcumin Composites to Enhance Biological Properties ArjakBhattacharjee, SaraRudolph, YingChen and DavidL. Kaplan; Tufts University, United States

Silk fibroin protein is a natural protein biopolymer generated from the cocoons of *Bombyx mori* silkworms and a useful biomaterial for many different tissue engineering applications. Flexible process engineering, versatile chemistry, and aqueous processing allow morphological and structural modifications that tailor the physical, chemical, biological, and mechanical properties of this biomaterial. However, conventional solution-based processing methods can impose limitations in terms of solubility, stability as well as scalability. Recently, we reported a thermal processing technique to fabricate dense, regenerated silk fibroin-based structures (plastics) using solid-state thermoplastic molding to address these limitations. The present work expands the utilization of thermoplastic molding of silk-fibroin to enhance the biological properties of plant-derived compounds like curcumin, the active compound of turmeric (*Curcuma longa*). Curcumin is widely used in traditional medicines. The objective of this study was to study the feasibility of fabricating silk-curcumin composite thermoplastics with enhanced biological properties. The hypothesis was that protective silk thermoplastic formation after curcumin incorporation would enhance the biological properties of curcumin, via the protective features of silk combined with the sustained slow release of the compound to reduce toxicity without affecting anti-bacterial properties. The results show that significantly higher levels of curcumin (~25-fold) can be incorporated into thermoplastic molded silk compared with solution formulations, attributed to the hydrophobic nature and low solubility of curcumin in solution-based processing. The fabricated curcumin incorporated thermoplastics show excellent stability in harsh acidic conditions (e.g., gut-like environment) and low curcumin (~ 3% over 14 days) release. The protective silk–curcumin formation led to enhanced cytocompatibility of the curcumin with immortalized human colorectal adenocarcinoma (Caco 2) cells even at higher doses when compared to curcumin without silk. The intestinal epithelial barrier integrity based on zonula occluden 1 (ZO-1) assessments indicated that higher doses of curcumin in the thermoplastic molded silk did not result in detrimental effects to the intestinal barrier. Further work is ongoing to assess additional biological outcomes as well as potential areas of utility for these systems.

Coupling Waste Feedstocks to Microbial Protein for a Circular Food System TaylorUekert, AlissaBleem, ChristopherJohnson and GreggBeckham; National Renewable Energy Laboratory, United States

The global food system is responsible for approximately 34% of annual greenhouse gas (GHG) emissions and up to 85% of water consumption. This critical sector suffers from intensive and inefficient land and water use, the generation of multiple (solid, liquid, and gaseous) waste streams, and high fuel, fertilizer, and pesticide consumption. The production of waste-derived microbial protein (MP) represents a promising alternative for reducing the environmental impacts of protein production relative to conventional agriculture. MP can be mass-produced in volumetrically scalable cultivation processes on short timescales, enabling facile up-scaling with lower greenhouse gas emissions, land use, and water impacts than animal and, in some cases, plant protein production. MP can also be produced from waste feedstocks, diverting waste from landfills or the natural environment. Here, we present the availability and suitability of waste feedstocks for MP production, as well as the fermentation and downstream processes required to convert MP into human food products. We discuss the challenges and opportunities facing waste-derived bacterial MP and highlight key areas for innovation in both the microbiology and process design space for a more sustainable and circular food system.

10:30 AM SB01.04.04
Design of Biodegradable, Climate-Specific Packaging Materials that Sense Food Spoilage and Extend Shelf-Life YangyangHan[1], SongWang[1], MichaelS. Strano[2] and BenedettoMarelli[2]; [1]Singapore-MIT Alliance for Research and Technology (SMART) Centre, Singapore; [2]Massachusetts Institute of Technology, United States

The AgriFood systems in tropical climates are under strain due to a rapid increase in human population and extreme environmental conditions that limit the efficacy of packaging technologies to extend food shelf-life and guarantee food safety. To address these challenges, we rationally designed biodegradable packaging materials that sense spoilage and prevent moulding. We nanofabricated the interface of 2D covalent organic frameworks (COF) to reinforce silk fibroin (SF) and obtain biodegradable membranes with augmented mechanical properties and that displayed an immediate colorimetric response (within 1 second) to food spoilage, using packaged poultry as an example. Loading COF with antimicrobial hexanal also mitigated biotic spoilage in high temperature and humidity conditions, resulting in a four-order of magnitude decrease in the total amount of mould growth in soybeans packaged in silk-COF, when compared to cling film (i.e., polyethylene). Together, the integration of sensing, structural reinforcement, and antimicrobial agent delivery within a biodegradable nanocomposite framework defines climate-specific packaging materials that can decrease food waste and enhance food safety.

10:45 AM SB01.04.05
Microneedles Carrying Nanosensors for Real-Time Detection of Abiotic Stress in Planta RajuCheerlavancha[1], BennySng Jian Rong[2], KhongDuc Thinh[1], YuntengCao[3], YangyangHan[1], MervinAng Chunyi[1], SongWang[1], GajendraPratap Singha[1], MichaelS Strano[3], In-CheolJang[2,1] and BenedettoMarelli[3,1]; [1]Singapore-MIT Alliance of Research and Technology, Singapore; [2]Temasek Life Sciences Laboratory, Singapore; [3]Massachusetts Institute of Technology, United States

Abiotic stress refers to adverse environmental conditions that negatively impact plant growth, development, and productivity. These stressors include extreme temperatures, drought, salinity, heavy metals, and radiation. Understanding plant responses and adaptation to abiotic stress is crucial, especially with the increasing severity and frequency of such stressors due to climate change. However, conventional methods for studying plant responses have limitations such as indirect measurements, low spatial resolution, and the inability to visualize real-time changes.

To overcome these limitations, we developed a delivery system using microneedles (MNs) to carry nanosensors. These MNs can be inserted into both soft and hard plant tissues without leaving any residues. By incorporating the nanosensor into the MNs, we successfully demonstrated real-time sensing of abiotic stress in Bok Choy and Nicotiana benthamiana. The embedded nanosensor, designed specifically for abiotic stress, enables rapid and sensitive detection of near-infrared (nIR) fluorescence signals. This allows for accurate measurement and visualization of abiotic stress levels. Furthermore, we confirmed the compatibility of the MNs with the abiotic stress nanosensors.
In summary, the integration of nanosensors with non-invasive delivery systems like MNs presents exciting opportunities for studying abiotic stress in plants. These innovative approaches help us gain a deeper understanding of how plants perceive and respond to environmental challenges. Ultimately, this knowledge can inform the development of stress-tolerant crops, sustainable agricultural practices, and strategies to mitigate the impacts of climate change on plant productivity and food security.

11:00 AM SB01.04.06
Time-Resolved Roasting-Induced Microstructural Evolution of Arabica Coffee Beans using X-Ray Computed Micro-Tomography EshanGanju[1], KunalChawla[2], SamuelYang[1] and NikhileshChawla[1]; [1]Purdue University, United States; [2]Carmel High School, United States

The aroma of coffee is deeply connected to the roasting process, which leads to notable changes in the bean's structure and chemistry. While many research studies have explored the chemical alterations occurring in the coffee bean during roasting, the structural changes have typically only been observed broadly, quantified by changes in size, density, fracture strength, or basic sectional views of the coffee bean. Traditional microscopy techniques are insufficient in providing an in-depth understanding of the coffee beans' microstructure, primarily due to their resolution, two-dimensional (2D) limitations, and the destructive nature of the analyses. These limitations are further exacerbated by the fact that the coffee bean undergoes significant three-dimensional (3D) structural changes during the roasting process. These changes are impacted by the coffee bean variety's properties, the bean's initial microstructure (which is affected by the local environment, including altitude, humidity, etc.), and the roasting process. As a result of the limited information about the initial 3D microstructure of the bean, its impact on the evolution of the emergent microstructure during roasting has been largely unexplored. Furthermore, while global measurements in porosity or pore volume at different roast levels have been reported, the heterogeneity in the evolution of porosity in different regions of the bean, which impacts the uniformity of the ground beans, has not been described. In this study, we conducted a time-resolved study of the roasting-induced microstructural evolution of Arabica coffee beans using X-ray computed micro-tomography (XCT). We combined high-resolution XCT data with computational image analysis techniques to examine the evolution of the microstructure of Coffea arabica beans during roasting. Beans sourced from Brazil, Colombia, and Ethiopia were tracked individually throughout the roasting process going from the green bean to the dark roast stage. The individual beans were tracked and scanned at multiple stages of roasting to capture the 3D tomography data of the entire bean. The XCT data, captured at different roasting levels, revealed detailed, time-resolved information about porosity, pore size distribution, and cracking within different regions of the beans. Results showed a significant increase in porosity and pore size from green-bean to dark-roast state, but the rate of increase wasn't linearly dependent on roasting time. Furthermore, beans from different regions showed markedly difference spatial heterogeneity in porosity and cracking. The effects of the initial green bean microstructure, as influenced by the growth environment, on the subsequent structural evolution will be discussed. The data and analyses presented in this study can assist in advancing research in the realm of food engineering by enabling a deeper understanding of the structural characteristics of coffee beans from various regions of the world and by clarifying the link between the processing and

microstructure of the bean at different roasting levels. Furthermore, the 3D characterization and analysis presented here can be applied as a framework to study a diverse class of food materials.

11:15 AM SB01.04.07
Living Filters for Sustainable and Selective Treatment of Drinking Water and Beverages VickiL. Colvin; Brown University, United States

Many communities in the U.S. and globally suffer because of a lack of access to safe drinking water. Cleaning water, however, using conventional technology is a dirty business that is expensive as well as material and energy intensive. There is a need to broaden access as well as provide more sustainable solutions that can improve people's water and their health. Living filters are cultures of living microbes that are engineered to both sense and treat contaminants at the very low concentrations relevant for drinking water. Here we demonstrate a system that targets the removal of arsenic from drinking water and beverages such as fruit juice and wine. Conventional remediation based on chemical sorption is challenging because of interferences from phosphates, silicates, flavor compounds, and organic matter; membrane-based separations also can be impacted by these species and more critically will remove all compounds including those that should be preserved for flavor in the case of beverages. Here, we exploit the extraordinary selectivity of biological recognition to solve this problem. Microbial engineering is applied to generate *E. Coli* that contain multiple copies of arsenic-binding proteins that are highly selective for arsenic and effectively no binding to smaller anions. When protein expression is induced, bacteria remain healthy and produce thousands of copies of Ars-R and when exposed to arsenic, the organisms within 30 minutes will reduce arsenic to sub-ppb levels. Sorption isotherms reveal at low concentrations (<50 ppb) sorption is defined by cellular transport while at higher concentrations the intracellular protein-arsenic interaction is limiting. The sorption behavior of these bacteria is insensitive to millimolar concentrations of phosphates, silicates, and many salts and is unaffected by the components of wines or fruit juices. Conventional microfiltration systems can be applied to remove all microbes down to levels suitable for meeting stringent EPA standards for drinking water. The integration of magnetic separation allows the capture of arsenic-laden microbes attached to magnetic nanoparticles which can be reused for future separations. Flavor compounds as measured by mass spectrometry in beverages remain unaffected by these treatment processes. Most recently we have incorporated bioluminescent reporters into the living filters which permit the detection of arsenic to optimize the treatment system. These engineered materials can be freeze-dried with modest impact on performance. Dry powders can be shipped easily under ambient conditions and then cultivated at the site prior to their integration into the treatment system. An important benefit of these materials is that the sorbent is in effect living, allowing for sustainable and low-cost manufacturing.

Home Composting Doesn't Work as an Environmentally Beneficial Method for Managing Biodegradable and Compostable Packaging DaniellePurkiss, AyseAllison, FabianaLorencatto, SusanMichie and MarkA. Miodownik; University College London, United Kingdom

Compostable and biodegradable plastics are growing in popularity but their environmental credentials need to be more fully assessed to determine how they can be a part of the solution to the plastic waste crisis. We present results and analysis on home compostable packaging. This type of packaging requires the citizen to able to correctly identify the packaging as 'home compostable', to have composting facilities at home, and to successfully compost the plastic. Using a citizen science approach, we engaged with 9701 UK citizens geographically spread across the UK to examine their capability, opportunity, and motivation to do this. Of this cohort 1648 citizens performed home compost experiments to test the environmental performance of compostable plastics. We report on the type of plastics they tested and their disintegration under real home composting conditions. The results show that the public are confused about the meaning of the labels of compostable and biodegradable plastics. 14% of sampled plastic packaging items tested were certified 'industrial compostable' only and 46% had no compostable certification. Of the biodegradable and compostable plastics tested under different home composting conditions, the majority did not fully disintegrate, including 60% of those that were certified 'home compostable'. We conclude that for both of these reasons, home composting is not an effective or environmentally beneficial waste processing method for biodegradable or compostable packaging in the UK. This talk also outlines the requirements to make industrial composting a viable and sustainable method for managing compostable packaging.

8:30 AM SB01/SB02/SB04/SB10.02
Advancing Food Safety and Security with Biodegradable Antimicrobial Food Coating YagmurYegin and BenedettoMarelli; Massachusetts Institute of Technology, United States

The global population, projected to reach 10 billion by 2050, presents a significant challenge in ensuring an adequate food supply with finite resources. One-third of food produced for human consumption is wasted annually due to food safety and quality concerns. This extensive food waste harms the environment, contributing to energy consumption and greenhouse gas emissions. Remarkably, the discarded food could feed 1.6 billion people, yet it is responsible for a quarter of global freshwater use and ranks as the third-largest greenhouse gas emitter, after China and the United States, making up about 10% of total global greenhouse gas emissions. Redirecting this wasted food to alleviate hunger and reduce environmental harm is imperative.
To enhance food safety and quality, we have developed an innovative solution: an antimicrobial-embedded biodegradable silk coating. Our approach combines multiple functions into one material, enabling the effective incorporation of food sanitizers to improve food safety and extend shelf life. We aim to repurpose discarded silkworm cocoon waste, often overlooked by the textile industry, into valuable silk fibroin. This natural protein polymer, derived from *Bombyx mori* cocoons, forms the foundation of an intelligent, sustainable, and cost-effective antimicrobial food packaging solution. This innovative coating effectively prevents the growth and spread of foodborne bacteria, extending the freshness of perishable foods. We encapsulated antimicrobial essential oils within silk nanoparticles using ultrasonication, eliminating the need for solvents and surfactants. Evaluation of the silk nanoparticles' properties, followed by testing of their antimicrobial efficacy against various foodborne pathogens, ensures their effectiveness. The silk nanoparticles, loaded with food sanitizers, are seamlessly integrated into the silk coating, providing a long-lasting sanitizing effect and ensuring protection for extended periods. The resulting edible silk coatings act as robust barriers against gases and moisture, preserving the freshness of cherry tomatoes. These coatings are transparent, offering excellent coverage without leaving visible residue on cherry tomatoes. Moreover, they are easily washable, providing convenience for consumers. Our transparent, sanitizer-infused silk food packaging offers a superior alternative for preserving the freshness of cherry tomatoes.
The biodegradable antimicrobial food coating acts as a formidable barrier, sealing in moisture while effectively excluding oxygen. In doing so, it efficiently inhibits the proliferation of foodborne pathogens. A crucial feature of our advanced food packaging is its delivery as dried films, simplifying transportation compared to conventional liquid solutions. These solid films exhibit prolonged stability, ensuring consistent performance over time. This innovation enables on-site preparation of dipping or spray solutions, simplifying application onto food surfaces. Consequently, it enhances food quality and safety without the need for refrigeration or single-use plastic packaging.
In summary, our research focuses on harnessing biodegradable polymers to develop functional agri-food materials through large-scale manufacturing. Our overarching goal is to create biopolymers with circular life cycles, capable of outperforming synthetic counterparts while preserving crucial performance attributes. The silk coating serves as a robust shield on perishable food surfaces, effectively preventing the entry of unwanted gases while retaining moisture. Additionally, it functions as an antimicrobial carrier, hindering the proliferation and survival of foodborne pathogens, thereby extending the shelf life of perishable foods. Our coating material represents an innovative, scalable, and sustainable solution to combat food insecurity, food waste, and climate change, all while contributing to the betterment of our planet.

8:45 AM SB01/SB02/SB04/SB10.03
Moringa Oleifera Proteins as Pickering Stabilizers: From Nanostructures to Rheology NamrahAzmi[1,2], AndrewN. Akanno[1], MattiKnaapila[1], AdrianRennie[3], LeonardRweyemamu[2,4] and Jon OttoFossum[1]; [1]Norwegian University of Science and Technology, Norway; [2]Stayfit Nutrisupplies Co. Ltd, Tanzania, United Republic of; [3]Uppsala University, Sweden; [4]University of Dar Es Salaam, Tanzania, United Republic of

Substantial food waste as a result of chemical decay of food enormously impacts the environment, henceforth the need for stabilization by surfactants but the associated carbon footprints possess a threat to the industry. Thus, Pickering emulsions, stabilized by solid- particles, residing at droplet interfaces come into the picture, providing more stable systems than surfactants. In terms of resistance against fusion (coalescence) and coarsening (Ostwald ripening) Pickering emulsions are thermodynamically stable systems with good biocompatibility and can be utilized as carriers for delivery of bioactive compounds, thus applied in food to control and enhance texture and taste and improve stability[1].
Plant proteins attract great interest and the stability of Pickering emulsions is governed by protein properties, protein concentration, and environmental factors. The Moringa protein has been chosen because it is inexpensive, with great nutritional benefits and wide availability, and has been scientifically proven to have excellent anti-oxidant, anti-hypertensive, and anti-diabetic properties[2].
Protein particle interactions are very much dependent on pH. Such protein-based nanoparticles have proven to be advantageous as they are biodegradable, non-toxic, and provide the large possibility for surface modification[3].
All this motivates our study to investigate the Moringa protein as Pickering particles for emulsions fabricated at different pH and ionic strengths. The rheology and corresponding macroscopic gel properties of such emulsions can be designed by arrested coalescence for producing food spreads with desired rheological properties[4]. During this, aggregates are formed with the

interaction between denatured non-absorbed proteins and absorbed ones at the emulsion droplet interfaces which can be impact from lipid oxidation, which influences emulsion particle interactions. Proteins can form gels after aggregation at different pH or ionic concentrations. It is difficult to separate the association mechanism of gelation and emulsification through protein aggregation[5] which is another motivation for our studies.
We have undertaken a program to distinguish the "good" and "not so good" Moringa-based protein stabilizers by utilizing microscopic observations and rheometry and using Small- Angle -X-ray-Scattering (SAXS) to examine structural stability and aggregations of the same stabilizing proteins, thus gathering information on protein[6], and how this is connected to the rheological properties. Further works include formulating food spread using this emulsion and studying its smell and mouthfeel quantification.

8:50 AM SB01/SB02/SB04/SB10.04

Asymmetric Polymersomes with Photothermal Responsiveness JingxinShao[1], YingtongLuo[1], HanglongWu[2], JianhongWang[1], ShoupengCao[3], LoaiK. Abdelmohsen[1] and JanVan Hest[1]; [1]Technische Universiteit Eindhoven, Netherlands; [2]Massachusetts Institute of Technology, United States; [3]Max Planck Institute for Polymer Research, Germany

Photo-mediated micro/nanorobots have found widespread interest over the past decade because of their application potential in many areas, especially in nanomedicine. By converting light energy into mechanical work, micro/nanorobots can be propelled to achieve active cargo transportation into cells with enhanced therapeutic effect. Most of the current micro/nanorobots are either based on inorganic particles or hybrid particles, such as Janus nanoparticles with a hemispherical Au shell.[1-5] The construction of fully organic-based micro/nanorobots is still underexplored. Here, a new type of light propelled nanorobots is created based on biodegradable polymersomes. Photothermal agents (PA) were co-assembled with polymer building blocks to form polymersomes with an asymmetric morphology, resembling a hot-air-balloon structure. With cryogenic transmission electron microscopy (Cryo-TEM) and cryo-electron tomography (Cryo-ET), this structure was confirmed. The formation mechanism of these asymmetric polymersomes was thereafter investigated by in situ observation of the dynamic assembly process with liquid phase transmission electron microscopy (LP-TEM). In combination with the cryo-TEM data, the LP-TEM results revealed that liquid-liquid phase separation was the main leading force for the formation of asymmetric polymersomes. Upon infrared laser irradiation (808 nm), the PA nano-assemblies in the polymersome structure provided photothermal heating and propelled the polymersomes in a controllable way regarding both direction and speed. This study demonstrates the formation of a new nanomotor topology which is driven by the photothermal effect and fully composed of organic building blocks. This nanomotor is further investigated for its application in active drug delivery.

9:05 AM SB01/SB02/SB04/SB10.05

Encapsulation and Delivery of Biomolecules with Cell-Mimicking Nanolipogel BertrandCzarny[1,1], Wen Jie MelvinLiew[1], AbdullahAlkaff[1], AtulParikh[2,3] and SubramanianVenkatraman[4,5]; [1]Nanyang Technological University, NTU, Singapore; [2]University of California, Davis, United States; [3]Nanyang Technological University, Singapore; [4]National University of Singapore, Singapore; [5]University of California, San Diego, United States

High initial burst release of biomolecules is just one of the many challenges faced by lipid based nanoparticulate formulations, even though it is widely used for drug encapsulation and delivery studies. One of the emerging potential strategies is the use of nanolipogels (NLG) to encapsulate biomolecules, which can suppress the initial burst release. This gives a level of control and sustain to the release of hydrophilic drugs. However, current works are short on characterisation of the release mechanistic. Therefore, varying molecular weight of Poly (ethylene glycol) Diacrylate (PEGDA) were used for the fabrication of PEGDA NLG, to study the mechanism for release of Dextran-Fluorescein Isothiocyanate (DFITC). Fluorescence Recovery after Photobleaching (FRAP), were performed on cell derived microlipogels (MLG), a novel system developed as a solution to limitations of FRAP with NLG. Results from the studies has shown that the NLGs' mesh sizes are controllable via the use of different Mw of PEGDA, where a lower Mw used resulted in a smaller mesh size of the nanogel core, by having a higher crosslinking density. This in turn gave higher suppression of the initial burst release of DFITC, up to a 10-fold difference. FRAP results then gave further validation by showing that the smaller mesh size restricted the diffusion of DFITC, consequential of a lower mobile fraction. These gave clear insight into the possibility of controlling the encapsulation and release of biomolecules, by targeting the fabrication of nanogel core. From this, Chitosan Methacrylate (CMA) NLGs was then studied to expand into other ways in manipulating the nanogel core for greater control, such as a differently charged core. Results was shown that CMA NLGs are also able to suppress the initial burst release of DFITC and it can be controlled by using a different concentration of CMA. This increases the possible strategies for consideration during the design of NLG systems and especially CMA NLGs opens up the possibility of encapsulation of negatively charge biomolecules, such as siRNA. As the NLG system involves two critical components, namely the nanogel core and the bilayer coating, the membrane properties are essential for the designing of NLGs. Herein, cell membrane coating for NLG was studied, with the development of a novel Chitosan Methacrylate-Tripolyphosphate (CMATPP) nanoparticle systems, which allows for the co-extrusion with cell membrane vesicles. The coating of CMATPP nanoparticles can possibly confer the membrane properties, such as prolonged *in-vivo* circulation and improved cellular uptake, to CMATPP nanoparticles. Coating was validated through flow cytometry with characteristic membrane proteins of cell derived nanovesicles (CDN), namely CD9, CD81, TSG101, or with RBC membrane vesicles, CD47. RBC CMATPP NLGs were also shown that it can further suppress the initial burst release and sustained release compared to Liposome CMATPP NLGs. All in all, it was shown that cell mimicking NLG system was able to provide a controlled release of hydrophilic biomolecule, and the release mechanism was studied and characterized using FRAP. Relationships with changes to the nanogel core as well as membrane coatings were also explored and proven to be viable and plausible expansions to other membrane origins were discovered. This study has provided a guide on the design of NLGs for a multitude of needs with regards to encapsulation and delivery, as well as for future *in vivo* performance

Spiky Silica Nanoparticles Embedded with ZIF-90: A Promising Approach for Intracellular Drug Delivery Manoj KumarSharma[1,2], DanChang[2], JingjingQu[2], HaoSong[2], ChengzhongYu[2], Ashok KumarGanguli[1] and JieTang[2]; [1]IIT Delhi, India; [2]The University of Queensland, Australia

Nanotechnology has emerged as a promising field in treating various diseases, offering significant advancements in drug delivery systems (DDS).[1] These systems offer advantages such as improved drug bioavailability, controlled release kinetics, and prolonged circulation time, leading to increased safety and efficacy. Mesoporous Silica (MSN)-based carriers exhibit desirable properties, including high porosity, biocompatibility, and tunable particle size. The introduction of spiky nanotopography on silica nanoparticles has garnered significant scientific interest due to its unique capabilities, including enhanced bacterial adhesion, intracellular drug delivery, and protection of genetic material.[2] Nonetheless, challenges persist in MSN-based DDS, encompassing limitations such as low drug loading capacity and premature release of anticancer agents.[3] To address these challenges, promising strategies have been explored, such as functionalizing silanol groups on mesoporous silica nanoparticles (MSN) with amine moieties or integrating organic compounds and metal-organic frameworks (MOFs). The literature provides limited information on silica-Zn-MOF composites. Previous studies have predominantly focused on ZIF-8 formation on silica nanoparticles.[4]
This study successfully synthesized a novel nanocomposite consisting of nature-inspired spiky silica nanoparticles (SNP) embedded with zeolitic imidazolate framework-90 (ZIF-90). The resulting SNP-ZIF-90 composites retained their spiky morphology and demonstrated enhanced drug-loading capacity for doxorubicin (Dox) compared to bare SNP. Furthermore, the modified SNP-ZIF-90 composites exhibited improved cellular uptake and pH-responsive drug release, highlighting their potential as an efficient drug delivery system.

High-Performance Tactile Pressure Sensor Based on Ionically Conducting Elastomer for Physiological Monitoring ZhiyongWang, MingGao, WeiWei, Kian PingLoh, Yung C.Liang and ChunxiangZhu; National University of Singapore, Singapore

Tactile pressure sensors can convert contact pressure into detectable and readable electrical signals (resistance, current, capacitance, or voltage), so they exhibit considerable potential in fields of real-time health monitoring, electronic skin, intelligent prosthesis, and human-machine interfaces. Recently, ionic pressure sensors, mainly consisting of ionically conducting filler and soft elastomer, have gained increasing attention for their good biocompatibility and conformability, well-tailored capability, and excellent sensing performance. Despite this, these ionic pressure sensors tend to suffer from limitations in mechanical strength, conductivity, and long-term instability. In order to overcome these challenges, we propose a novel approach. First, we utilize a sugar template method to create a porous silicon elastomer, which serves as the foundation and will be further coated with an ionically conducting polymer called poly(3,4-ethylene dioxythiophene) polystyrene sulfonate (PEDOT: PSS) to form our high-performance tactile pressure sensor. Moreover, mechanical and electrical properties, as well as the structure-

performance relationship, have been specifically investigated by means of different characterization tools. As a proof of concept, we have demonstrated the use of the ionic pressure sensor for continuously monitoring physiological activities such as respiratory and pulse signals.

Ink based Large Quantity Preparation of Graphene Incorporated Contact Lenses for Multi-Application Muhammed ShebeebCherum Kuzhi, MuhammedHisham, LiyamolJacob, YarjanAbdul Samad and HaiderButt; Khalifa University, United Arab Emirates

Along vision correction, incorporation of nanomaterials and other additives for multi-functionality is becoming popular in studies on contact lenses, especially hydrogel based contact lenses. There have been few investigations on the capability of graphene as an additive for added functionality such as transparent electrode, dehydration protection and EMI shielding. However, the current works involve graphene prepared through chemical vapor deposition, which makes it difficult for affordable and faster production. In this work, we investigate the preparation of graphene - hydroxy ethyl methacrylate composite based hydrogel contact lenses and graphene incorporation in commercial hydrogel based soft contact lenses without losing the optical transparency within the visible range. The incorporation of graphene onto commercial contact lenses were done using dipping lenses for certain period of time as well as breathe in breathe out technique, two common technique used to incorporate nanomaterials to hydrogels. We further investigate how the water retention and the wetting behavior have been affected by the graphene presence and its capability for EMI shielding within the range 8.2-12.4 GHz.

Ultrathin Hydrogel Biosensor with Controllable Self-Adhesion Properties for Electrophysiology Measurement ShuyunZhuo, AlexandreTessier and Shideh KabiriAmeri; Queen's University, Canada

Hydrogel has recently been utilized to develop health monitoring sensors and devices such as bioelectrodes. Owing to their good electrical conductivity, ultra-softness, and self-adhesion, current hydrogel sensors have found their application in electroencephalogram (EEG), electromyogram (EMG), and electrocardiogram (ECG) recording. However, the highly adhesive hydrogels are hard to peel off from the surface of the skin after laminating it and they are susceptible to losing the water content and unfavorable changes in the electrical conductivity and mechanical softness. Here we report an ultrathin hydrogel-based sensor with controllable self-adhesion properties that can fully conform to the skin and perform reliably for an extended period. An ultrathin, conformable biosensor with a thickness of less than 10 μm is fabricated based on gelatin-acrylamide-polypyrrole hydrogel, where the sol-gel transition of the gelatin is utilized to control the modulus and adhesion force. The ultralow thickness and good stretchability of the gelatin-acrylamide-polypyrrole hydrogel contribute to a seamless interface between the biosensor and human skin, which is desired in wearable devices for high-quality bio-signal acquisitions such as electrocardiography (ECG) and electromyography (EMG).

Viscoelastic Response of Commercial Mucin to HIV Psuedotyped Virus GabrielleTorain, AlexanderBoakye, AyobamiI. Ogundiran, Tzu-LanChang, SergeiNekhai and PreethiChandran; Howard University, United States

Mucin is a heavily glycosylated protein that makes up the mucus gel which serves as a protective barrier against pathogens like viruses. Mucins are prone to self-aggregation which imparts a viscoelastic (fluid-like and solid-like) characteristic to the mucus gel. However little is known about how the presence of viruses change the flow properties of mucin. Replication-deficient HIV viruses pseudotyped with either gp120 or vesicular stomatitis virus (VSV-G) envelope proteins were used as model viruses. Commercially available Porcine gastric mucin-type II (PGM-II) and porcine gastric mucin type III (PGM-III) in the filtered (free mucin) and unfiltered (having mucin-mucin interactions) states were used as model mucins. DLS was used to determine the landscape of the sizes of the diffusing species (mucin, virus, or virus-mucin species). Rheology was used to determine change in the inter-mucin interaction and friction. Axisymmetric drop shape analysis was used to determine the changes to the mucin surface tension. Preliminary results suggest that the average intensity of PGM-II and PGM-III, in the filtered state, are lowered and the hydrodynamic diameter decreases with both pseudotyped viruses. Subsequent rheology studies show a lowered elastic and frictional character when either VSV-G or gp120 pseudotyped viruses are present. The unfiltered state of mucin shows no significant changes in DLS measurements but increased elastic and frictional characteristics are observed at lower oscillatory frequencies in rheology studies. Our data demonstrates that viruses change solution behavior of mucin both in the singular and aggregated states and thus may alter the viscoelastic characteristics of the mucus gel.

10:05 AM *SB01/SB02/SB04/SB10.10
From Sub-Micron Resolution Towards 3D-Printing at the Speed of Light: Pushing the Boundaries to Serve Health QuintenThijssen[1], LaurensParmentier[1], HaydenTaylor[2], StevenBallet[3] and SandraVan Vlierberghe[1]; [1]Ghent University, Belgium; [2]University of California, Berkeley, United States Minor Outlying Islands; [3]Vrije Universiteit Brussel, Belgium

Current thoroughly described biodegradable and cross-linkable polymers mainly rely on acrylate cross-linking. However, despite the swift cross-linking kinetics of acrylates, the concomitant brittleness of the resulting materials limits their applicability. Here, photo-cross-linkable poly(ε-caprolactone) (PCL) networks through orthogonal thiol-ene chemistry are introduced. The step-growth polymerized networks are tunable, predictable by means of the rubber elasticity theory and it is shown that their mechanical properties are significantly improved over their acrylate cross-linked counterparts. Tunability is introduced to the materials, by altering M_c (or the molar mass between cross-links), and its effect on the thermal properties, mechanical strength and degradability of the materials is evaluated. Moreover, excellent volumetric printability is illustrated and the smallest features obtained via volumetric 3D-printing to date are reported, for thiol-ene systems. Finally, by means of in vitro and in vivo characterization of 3D-printed constructs, it is illustrated that the volumetrically 3D-printed materials are biocompatible.
In an attempt to mimic nature's ability to adhere cells, PCL is often coated with nature-derived polymers or its surface is functionalized with a cell-binding motif. However, said surface modifications are limited to the material's surface, include multiple steps, and are mediated by harsh conditions. In a second part, we introduce a single-step strategy toward cell-adhesive polymer networks where thiol-ene chemistry serves a dual purpose. First, alkene-functionalized PCL was crosslinked by means of a multifunctional thiol (*vide supra*). Second, by means of a cysteine coupling site, the cell-binding motif C(-linker-)RGD was covalently bound throughout the PCL networks during crosslinking. Moreover, the influence of various linkers (type and length), between the cysteine coupling site and the cell-binding motif RGD, was investigated and the functionalization was assessed by means of static contact angle measurements and X-ray photoelectron spectroscopy. Finally, successful introduction of cell adhesiveness was illustrated for the networks by seeding fibroblasts onto the functionalized PCL networks.
This combination of mechanical stability, tunability, biocompatibility, no post-processing functionalization required and rapid fabrication by volumetric 3D-printing charts a new path toward bedside manufacturing of biodegradable cell-interactive, patient-specific implants.
In addition to photo-crosslinkable polyesters, also progress in the field of high resolution two-photon polymerization and volumetric additive manufacturing of gelatin-based hydrogels will be addressed. Hence, our material platform can serve both hard and soft tissue engineering applications.

Smart and Programmable Crystalline Sponges for Protection OmarK. Farha; Northwestern University, United States

This talk will focus on metal–organic frameworks (MOFs) from basic research to implementation and commercialization. MOFs are a class of porous, crystalline materials composed of metal-based nodes and organic ligands that self-assemble into multi-dimensional lattices. In contrast to conventional porous materials such as zeolites and activated carbon, an abundantly diverse set of molecular building blocks allows for the realization of MOFs with a broad range of properties. We have developed an extensive understanding of how the physical architecture and chemical properties of MOFs affect material performance in applications such as catalytic activity for chemical warfare agent detoxification.

11:00 AM *SB02.01.02
Supramolecular Design of Mesoporous 2D Covalent Organic Frameworks for the Encapsulation of Large and Small Guests RonaldA. Smaldone; The University of Texas at Dallas, United States

Interlayer interactions in 2D covalent organic frameworks (COFs) have been shown to be important factors in both their formation and bulk properties. There are many previous examples of controlling interlayer interactions in COFs by tuning the monomer or geometry. However, the use of hydrogen bonding is much rarer. The highly directional nature of a hydrogen bonding interaction makes it difficult orient properly in a COF structure. To accomplish this, we have designed monomers with a non-planar structure that arises from steric crowding, forcing the amide side groups out of plane with the COF sheets orienting the hydrogen bonds between the layers. The presence of these hydrogen bonds provides significant structural stabilization as demonstrated by comparison to control structures that lack hydrogen bonding capability, resulting in lower surface area and crystallinity. We have characterized both azine and imine-linked versions of these COFs for their surface areas, pore sizes and crystallinity. The rigidified structure that results from these supramolecular interactions can enable the production of COFs with mesopores capable of hosting large protein guests. In addition to more conventional COF characterization methods (such as powder X-ray diffraction and porosity analysis), we also used variable temperature infrared spectroscopy (VT-IR) methods and van der Waals density functional calculations to directly observe the presence and character of the hydrogen bonding interactions. This talk will also discuss the importance of mesopore design in COFs for the adosorption of different guests in aquous solutions, ranging from proteins, to small molecule pollutants.

11:30 AM *SB02.01.03
Insights into MOF Chemical Biology—Biocatalysts Encapsulated within MOFs Fa-KuenShieh[1], Lien-YangChou[2] and Chia-KuangTsung[3]; [1]National Central University, Taiwan; [2]Shanghai Tech University, China; [3]Boston College, United States

Metal-organic frameworks (MOFs) have found diverse applications in bio-sensing, biomass utilization, and catalysis. This study introduces a novel concept in material biology known as MOF Chemical Biology. It focuses on investigating the impact of containing biomolecules, such as protein enzymes, within synthetic MOF biocomposites, referred to as enzyme@MOFs. These biocomposites are prepared using a *de novo* biomineralization synthesis route, conducted under mild and aqueous conditions. The framework of these biocomposites possesses apertures that enable the free movement of substrates, while the encapsulated enzymes or bacteria remain confined within the structure, thereby shielding them against most structural changes. Furthermore, we present the first successful demonstration of encapsulating enzymes into robust Zirconium-based MOFs, specifically UiO-66, using a solid-state mechanochemical process. The enzymes encapsulated through this method retain their desired functionality and exhibit resistance to proteases, even under acidic conditions. These innovative approaches provide an alternative system, exploiting the structural confinement effect, for expanding the application of MOFs in studying the biochemical functionalities of prokaryotes, eukaryotes, mammalian cells, and more.

Biocompatible Robust MOFs for New Wound Healing Solutions ChristianSerre; CNRS, ENS, ESPCI Paris, PSL University, France

The development of new wound healing solutions is still a critical issue in order to treat infectious diseases. Biocompatible metal organic frameworks (MOFs) have long term been considered mainly against cancer. We will show in this presentation two new strategies to take benefit from their open metal sites and/or ordered porosity to propose new solutions out of traditional antibiotics treatments.
A first strategy relies on the controlled delivery of Nitric oxide (NO), a powerful gaseous therapeutic agent of interest to treat a wide variety of disease states. As it can overcome the bacterial resistance to antibiotics, it is an appealing alternative to conventional drugs, and the development of efficient NO-donating drugs is being demanded. However traditional NO carriers are often toxic which precludes their practical use. It is crucial to find biocompatible carriers with prolonged biological half-life. MOFs have been previously proposed as antibacterial or anti-thrombogenic carriers but only in gas phase mainly through a coordination on their unsaturated metal sites. However once in contact with body fluids, the release of NO occurs within minutes compromising their practical use. [1] We have therefore selected a robust biocompatible Ti-MOF such as MIP-177[2] that is enable to release NO within 2 hours in phosphate buffer, due to an unprecedented NO adsorption/release mechanism. Very recently, we also designed a new ultra-narrow pores iron bisphosphonate MOF, denoted MIP-210[3], that is stable in PBS while adsorbing NO on its metal sites. Due to the combination of a novel adsorption mechanism, an exceptional stability in PBS and its narrow pores, it leads to a record ca. 3 days of NO release in biological media; in both cases we demonstrate how these controlled releases lead to cell migration or even angiogenesis that are of a crucial importance for wound healing applications, paving the way for the design of new wound healing therapies.
A second strategy consists of encapsulating dyes into biocompatible large pores Fe-MOFs. Through the protective effect of the pores' confinement considerably slowing down the bleaching of the dye under near infra-red irradiation, as well as the slow release of Fe^{3+} ions once in contact with body fluids leading to the formation of ROS, we demonstrate how these new MOF-dyes composites, through a multimodal based on PTT/PDT and chemo-dynamic therapy, are of interest to treat successfully different anti-biotic resistant infections (Chlamydia…).[4-5]

Biomimetic Mineralization of Ovalbumin in ZIF-8 Enhances Humoral Immune Response—Overcoming the Need for Booster Doses RyanneN. Ehrman; University of Texas at Dallas, United States

Vaccines have saved countless lives throughout history by preventing and even irradicating infectious disease. Commonly used subunit vaccines comprising of one or multiple recombinant proteins isolated from the disease demonstrate a good safety profile. However, the immunogenicity of these vaccines is weak, and therefore, subunit vaccines require a series of doses to achieve sufficient immunity against the disease. Consequently, people's distaste for needles detours them from receiving the vaccination regimen. Here, we show that the encapsulation of the inert model antigen, ovalbumin, in ZIF-8 overcomes the need for these booster doses by significantly improving the humoral immune response over three bolus doses of ovalbumin. We designed two ovalbumin-ZIF-8 composites, a nano-sized (n-OVA@ZIF) and micron-sized (µ-OVA@ZIF). Through preliminary testing, we determined the micron-sized µ-OVA@ZIF to be the better candidate for *in vivo*vaccination studies. Single vaccination of µ-OVA@ZIF demonstrated higher serum antibody titers against ovalbumin as opposed three bolus injections of ovalbumin (OVA 3x). µ-OVA@ZIF vaccinated mice displayed higher populations of germinal center B (GCB) cells and IgG1+ GCB cells as opposed to OVA 3x. This is indicative of class-switching recombination, where B cells begin secreting specialized and higher affinity antibodies. We believe that the mechanism of this phenomena is owed to the sustained release of ovalbumin from the ZIF-8 composite, acting as an antigen reservoir for APCs to trafficking into the draining lymph node, enhancing the humoral response. We show through fluorescent animal imaging and SEM micrographs that the ZIF-8 coating slowly degrades in the body, releasing the antigen over an extended period of time.

2:15 PM SB02.02.03
Multifunctional Enzyme Nanocapsules Boost T Cell Immunity and Efficacy of Cancer Immunotherapy ZhengCao, WentingChen, DuoXu, JingWen and YunfengLu; University of California, Los Angeles, United States

Cancer immunotherapy has reshaped the landscape of cancer treatment, but its effectiveness in treating solid tumors is hindered by overproduction of lactate by cancer cells. Extensive trials are being conducted to regulate lactate levels by inhibiting lactate dehydrogenase, however, such inhibitors can disrupt the metabolism of healthy cells and cause severe non-specific toxicity. In contrast to those strategies, we innovatively target lactate itself by an enzyme, lactate oxidase, which effectively reduces the lactate levels and releases hydrogen peroxide, an immunostimulatory molecule, in the tumor microenvironment. However, recombinant lactate oxidase from microorganisms possesses short circulating half-life, low enzyme activity, and immunogenicity. To circumvent this limitation, we innovatively report herein a nano-encapsulating strategy to encapsulate individual lactate oxidase molecules within a thin polymer shell by in-situ polymerization of monomers and crosslinkers, affording the synthesis of nanocapsules. The nanocapsules stabilize lactate oxidase and prevent it from proteolysis and denature, minimize the immunogenicity, prolong the circulating half-life, enabling their use as a potent therapeutic for cancer immunotherapy. Lactate oxidase nanocapsules can promote the proliferation and activation of effector T cells and suppress tumor-resident regulatory T cells *in vitro*. As further demonstrated in a murine melanoma model and a humanized mouse model of triple-negative breast cancer, nanocapsules of lactate oxidase avert tumor immunosuppression and enhance anti-cancer T cell immunity by upregulating gene expression for T cell recruitment and activation, as confirmed by single-cell RNA sequencing. Such multifunctional lactate oxidase nanocapsules lead to improved efficacy of immunotherapies for solid tumors.

2:30 PM *SB02.02.04
Metal-Organic Frameworks for the Encapsulation of Bio-Entities IoannaChristodoulou[1], JonathanBachir[1], EffrosyniGkaniatsou[1], NathalieSteunou[1] and ClemenceSicard[1,2]; [1]Institut Lavoisier de Versailles, France; [2]Institut Universitaire de France, France

Bio-entities benefit from unparalleled activities of high interest in many applications such as high catalytic activities under mild conditions (aqueous media, room temperature). However, these are fragile entities, easily degraded under non-native conditions. Encapsulation, i.e. inclusion within a host matrix, is particularly interesting for bio-entities stabilization and protection as it can provide controlled environment and protection. Metal-Organic Frameworks (MOFs) have arisen as a host matrix of choice to answer the limitations of traditional immobilization matrices, resulting in the design of novel functional biomaterials.[1] The MOF-bio-entity composites exhibit promising properties, since the biological activity can be preserved while the stability of bio-entities in non-natural environments could be improved. Encapsulation can be performed by diffusion of the biological entities into the porosity of preformed MOF. Alternatively, the MOF can be formed "in-situ" around the bio-entities. Both strategies are limited to a number of MOF/bio-entities couples either due to size matching constraints or to a narrow window of compatible synthetic conditions.

In this communication we will present our efforts to expand synthetic routes and processing methods to explore new compositions and hierarchical structures of bio-entities-MOFs hybrids. We will describe the synthesis and characterization of MOFs-based living materials.[2] The mesoporous iron polycarboxylate MIL-100(Fe) was synthesized in the presence of *Pseudomonas putida bacteria*. The synthesis conditions (aqueous media, 30 °C) were compatible with the preservation of the bacteria integrity. High resolution microscopic techniques (TEM, STEM-XEDS) were applied on cross-sections to study the interface between the two components, revealing the presence of an exoskeleton encapsulating individual bacteria cells. We will also discuss our latest finding on the design of novel bio-entities-porous materials with unique properties for potential application in biocatalysis.[3]

Advanced Porous Framework Materials for the Immobilization of Biomolecules: Beyond Host Matrix Materials ShengqianMa; University of North Texas, United States

Advanced porous framework materials as represented by metal–organic frameworks (MOFs) and covalent organic frameworks (COFs) represent a new class of crystalline materials, and one of their striking features lies in the tunable, designable, and functionalizable nanospace, which allows designed incorporation of different functionalities for targeted applications, such as gas storage/separation, sensing, drug delivery, catalysis, conductivity. We will discuss the systematic development of MOFs and COFs as a new platform for immobilization of biomolecules for

applications in biocatalysis and beyond.

4:00 PM SB02.02.06
Supercritical CO_2 Precipitation of Porphyrin-Based MOFs as Potential Materials for Photodynamic Therapy AnaM. Lopez-Periago[1], MartaKubovics[1], José A.Ayllon[2], ConchaDomingo[1] and CarmeNogués[2]; [1]Consejo Superior de Investigaciones Científicas (CSIC)., Spain; [2]Universitat Autònoma de Barcelona, Spain

In the past few years, our research group has focused on synthesizing metal-organic frameworks (MOFs) using environmentally friendly methods based on supercritical CO_2 ($scCO_2$)[1], where synthesis and pore activation can occur, in many cases, in a single step.
Building upon these advancements, the preparation of MOFs containing porphyrin linkers were of great interest to us, as porphyrins are fundamental building block precursors in various domains of synthetic chemistry. For example, porphyrins can form coordination networks with potential applications in fields such as catalysis, sensors, as well as for cancer treatment.[2]
In the latter, porphyrin and its derivatives remain the most extensively employed materials for photodynamic therapy (PDT)[3], an anticancer therapy based on the local application of a photosensitizer in the affected area that, by light radiation of a certain wavelength, produce reactive oxygen species (ROS)[4], which are able to destroy the harmful cells through either necrosis or apoptosis.
In our reseach, we focused our interest into the possibilities of precipitating MOFs using a porphyrin linker with pyridyl motifs, specifically 5,10,15,20-Tetra(4-pyridyl)porphyrin (H_2TPyP) using exclusively $scCO_2$ as reaction media. The reaction involved the coordination of the binding sites (pyridyl moieties in *meso*- position, and the inner tetrapirrole ring) with different metals. For this purpose, we employed four metal hexafluoroacetylacetonate complexes ($M(hfac)_2$, M = Cu, Zn, Co, Ni) as metal precursors in the production of the metal-organic materials.
Among the obtained samples, the $scCO_2$-precipitated Zn(II) MOF demonstrated exceptional performance when tested as a potential photosensitizer in PDT therapy against the SKBR-3 tumoral cell line. This MOF resulted to be nontoxic, but after 15 min of irradiation at 630 nm, using either 1 or 5 μM concentration of the product, almost 70% of tumor cells died after 72 h.
The most interesting results of this work were recently published in the journal Chemistry of Materials[5].

Broadening the Scope of MOFs for *In Situ* Biomolecule EncapsulationMónicaGiménez-Marqués, JesúsCases Díaz and JanaGlatz; University of Valencia, Spain

The use of metal−organic frameworks (MOFs) as robust coating of fragile biomacromolecules has been demonstrated a valuable strategy for their preservation, enabling their ample implementation in biomedical and biotechnological processes. Essentially, this biomolecule encapsulation requires the MOF assembly under biocompatible conditions and the existence of favorable electrostatic surface conditions at the biomolecule-MOF interface.

Despite recent growth in the field of MOF mineralization, only a limited number of MOFs have been accessed, being ZIFs the most widely explored materials for biohybrid synthesis. However, next directions in the field require revealing the hierarchical organization of these assemblies and for that, it is essential to expand the biohybrid family by using MOFs with distinct nature.

Herein we present alternative synthetic approaches to access previously elusive MOFs that permit to study new biohybrid architectures with undisclosed functionalities.

Enhancing Vaccine Stability and Immunogenicity Through Biomimetic Mineralization using Zeolitic-Imidazole Frameworks (ZIFs) JeremiahJ. Gassensmith; University of Texas-Dallas, United States

Vaccines are susceptible to structural conformational changes under environmental and chemical stressors, compromising their therapeutic efficacy. This lecture presents three innovative case studies that address this challenge to enhance the stability, preservation, and immunogenicity of protein, DNA, and lipid nanoparticle based vaccines.
First, we discuss using zeolitic imidazolate framework-8 (ZIF-8) as a protective agent for a model viral vector against denaturing conditions. Immunoassay and spectroscopy analysis reveal that ZIF-8 provides enhanced thermal and chemical stability to the conformational structure of the encapsulated viral nanoparticle. Long-term biological activity studies in animal models demonstrate the integrity, biosafety, and immunogenicity of the virus-ZIF composite. Furthermore, histological analysis confirms the absence of tissue damage, highlighting ZIF-based protein composites as promising candidates for preserving proteinaceous drugs, ensuring biocompatibility, and controlling drug release in vivo.
Next, we explore stabilizing proteoliposomes, supramolecular lipid-protein assemblies that mimic cellular membranes. We demonstrate that metastable lipid, protein-detergent, and protein-lipid complexes can be successfully immobilized within zeolitic-imidazole framework (ZIF) bio-composites. This immobilization strategy enhances their stability against chemical and physical stressors such as elevated temperatures, chemical denaturants, aging, and mechanical stresses. Extensive morphological and functional characterization confirms that the encapsulated complexes maintain their native morphology, structure, and activity, which would otherwise rapidly degrade without immobilization.
Lastly, we address the pressing need for effective vaccines against pathogenic bacteria in the face of increasing antibiotic resistance. The genetic diversity of bacteria poses challenges in selecting appropriate antigens, hindering vaccine development. We present a proof-of-principle method to enhance the immunogenicity of a model pathogenic E. coli strain by forming a slow-releasing depot. Biomimetic mineralization within a metal-organic framework (MOF) effectively encapsulates the E. coli strain, enhancing antibody production and improving survival in a mouse bacteremia model. This approach surpasses the limitations of whole-cell formulations and demonstrates the potential for successful clinical translation.
These innovative strategies utilizing ZIFs and MOFs hold great promise for revolutionizing vaccine design, preservation, and immunogenicity. By enhancing stability and ensuring effective immune responses, these advancements contribute to developing next-generation approaches for combating bacterial infections and preventing the spread of pathogens.

Immune/Chemo-Active Nanomofs Multitherapy PatriciaHorcajada; IMDEA Energy Institute, Spain

The involvement of Metal-Organic Frameworks (MOFs) in biomedical applications is currently one of the hot topics in the emerging field of hybrid porous solids.[1] Despite their already proven high loadings and progressive release of a wide variety of active ingredients (e.g. drugs, cosmetics, biological gases, macromolecules), the control of the biodistribution of MOF nanocarriers and their involvement as a non-passive carriers (bioactive) is still a challenge.
Several examples of successful formulations able to bypass specific physiological barriers will be presented.[2] In particular, pulmonary administration is a convenient route not only for the

treatment of respiratory diseases (e.g. COPD, asthma, tuberculosis, infection, cancer) but also systemic ones. In this sense, a pioneer combined anti-COVID multi-therapy (3-in-1 effect) will be described, paving the way to future treatment of challenging infectious and/or pulmonary pathologies.[3]

Design of Highly Porous MOFs for Drug Delivery DavidFairen-Jimenez; Department of Chemical Engineering & Biotechnology, University of Cambridge, United Kingdom

Metal-organic frameworks (MOFs) are ideal candidates for payload delivery in drug delivery applications due to their highly tuneable surface properties, with drug capacities as high as 60 wt.%. The use of MOFs can lower the required amount of active pharmaceutical ingredient (API), providing a more efficacious therapy while also decreasing the potential for untargeted and undesired effects. Their controlled and autonomous delivery utilizing such a porous high-capacity loading material ultimately could reduce high dependence on patient compliance.

We have developed a series of nano-sized Zr-MOFs with different pore sizes and volumes, from the microporous UiO-66 family of materials to mesoporous NU-1000, all of them showing minimal cytotoxicity. On the one hand, we show how the post-synthetic modification of the MOFs can allow the controlled release of different payloads, extending the release time from 2 days to 30 days. On the other hand, we show how the particle size and surface chemistry allow tuning the final fate of the MOFs and the metabolic pathways of how they are endocytosed by the cells. By modifying the external surface chemistry of the MOFs or by grafting different motifs, we can extend the release time of the drugs, and improve the efficiency of the MOFs to penetrate the cells and target specific organelles.

Our work has allowed us to understand the fundamental biophysical and biochemical mechanisms of cancer cell death upon treatment with MOFs. The fundamental understanding of the biological aspects of cancer has allowed us to advance not only in small-drug molecule delivery but also in novel solutions based on photodynamic therapy and gene therapy.

Using Zeolitic Imidazolate Frameworks for Creating an Intranasal Depot Effect and Development of a Novel Tuberculosis Subunit Vaccine SnehaKumari[1], RyanneN. Ehrman[1], JonathanMartinez-Garcia[1], YaliniWijesundara[1], ThomasHowlett[1], LenetteLu[2], AngeloIzzo[3], GabrieleMeloni[1] and JeremiahJ. Gassensmith[1]; [1]University of Texas at Dallas, United States; [2]University of Texas at Southwestern, United States; [3]Centenary Institute, Australia

Tuberculosis (TB) is the second leading cause of deaths from infectious diseases in the world after Covid-19. Despite the great strides taken in vaccine development over the last few decades, TB prevention still relies on the century-old BCG formulation, whose efficacy widely varies amongst different populations. Whole cell attenuated vaccines for such pathogenic diseases are a risky avenue of research. Decades of subculturing are required to attenuate the strains, and yet there is always a risk of reverting to virulence. We have hence developed a subunit vaccine candidate which combines two novel antigens, a powerful adjuvant, and a slow-release system using MOFs for depot effect. CtpV and MctB are two membrane-bound metal transporter proteins present on the surface of Mycobacterium tuberculosis that are potential virulence factors of TB and can be used to induce a T-cell mediated response upon vaccination. Class A CpG—a synthetic reproduction of bacterial DNA—has been widely investigated as an adjuvant in research models and fits into our formulation well as it also activates T-cells. It is worth noting that many similar subunit vaccines that fall short in clinical trials are unable to produce high enough antibody titers compared to whole cell vaccines. This is primarily attributed to short exposure time of delicate biomaterials like liposomes, that degrade in the body fast. Our goal is to combat this using zeolitic imidazolate frameworks (ZIF), a metal-organic framework that can be synthesized in biofriendly conditions to build a protective coating around the biomaterial. ZIF degrades slowly inside the body, and a vaccine coated with ZIF would slowly release antigens and provide prolonged presentation, giving the immune system time to develop more antigen-specific antibodies. This formulation also allows us to vary the ZIF coating thickness in order to optimize the duration of antigen presentation. We recently concluded an extensive study which demonstrates the biosafety of a wide range of ZIF doses when delivered intranasally in mice as a first step of this investigation. We found that there was no significant difference in the serum protein and enzyme levels and the lung diffusing capacity of mice administered even up to 1 mg ZIF per animal. No tissue damage was observed in the nasal turbinates, trachea, or lungs either. We are currently working on optimizing the various aspects of our vaccine for an ideal immune response and benchmarking our vaccine candidate's performance against BCG.

10:45 AM SB02.03.05
Label-Free Pore-Level Virus and Particle Detection with Bioinspired Inverse Opal Photonic Crystals NatalieNicolas and JoannaAizenberg; Harvard University, United States

For most methods of viral imaging, it is necessary to bind bulky fluorescent molecules to the virus in order to visualize its location with optical microscopy. This increases the complexity of sample processing and may change viral behavior. In this research, we instead electrostatically bind viruses or charged particles to the surface of an inverse opal, which is a bioinspired self-assembled ordered porous material, to create a label-free method for imaging the location of a virus with a light microscope. Attached viruses increase the energy barrier to liquid infiltration in the re-entrant pores of the inverse opal, such that they remain dry when a test solution fills the non-occluded pores. Polarized light microscopy can then be used to distinguish the non-wetted pores, revealing location and concentration information about the viruses. This can create a customizable label-free tool to study viral behavior in laboratory or medical settings.

Congo Red-Derived Carbon Dots as Dual Inhibitors of Tau and Aβ Aggregation in Alzheimer's Disease WeiZhang[1], NathanSmith[2], YiqunZhou[1,3], CaitlinM. McGee[1], MattiaBartoli[4,5], JiuyanChen[1], JustinB. Domena[1], EmelK. Cilingir[1], SusannaBedendo[5], MatteoL. Claure[1], HannahBurr[2], AlbertoTagliaferro[5], EduardoA. Veliz[6], ChunyuWang[2] and RogerM. Leblanc[1]; [1]University of Miami, United States; [2]Rensselaer Polytechnic Institute, United States; [3]Florida International University, United States; [4]Istituto Italiano di Tecnologia, Italy; [5]Politecnico di Torino, Italy; [6]Miami Dade College, United States

Alzheimer's disease (AD) is the most common form of senile dementia, with few effective treatments. AD pathology is characterized by extracellular amyloid plaques and intraneuronal neurofibrillary tangles. A promising drug discovery approach is to develop molecules capable of targeting both hallmarks of AD, by inhibiting Aβ and tau aggregation. In recent years, carbon dots (CDs) have emerged as novel drug nanocarriers with high biocompatibility, low cytotoxicity, and the ability to cross the blood-brain barrier (BBB).This talk will describe a new type of CDs, Congo red-derived CDs (CRCDs), synthesized using Congo red and citric acid as precursors. We will discuss how different mass ratios of the two precursors can produce CDs with different physicochemical properties. We will describe the successful synthesis of CRCDs which can cross the BBB in a zebrafish model. In addition, our synthesized CRCDs show the ability to inhibit both tau and Aβ aggregation. Our findings demonstrate that CRCDs can function as dual inhibitors for tau and Aβ aggregation, in addition to its capacity to cross BBB, enter the central nervous system (CNS), and to carry drugs. Thus CRCDs-based compounds may be a novel formulation component for the development of multi-functional AD therapeutics.

11:15 AM *SB02.03.07
Smart Materials for Precized Drug Delivery AliTrabolsi; New York University Abu Dhabi, United Arab Emirates

The development of multifunctional drug delivery systems (MDDS) targeting diseased areas arose from the need to overcome drug limitations such as cytotoxicity, immunogenicity, short circulation times, uncontrolled bio-distribution, and the inability to target specific tissues. Significant advances in nanobiotechnology have led to the development of MDDS to serve diagnostic and therapeutic purposes through a single medical device capable of performing bioimaging tasks while improving the therapeutic efficacy of marketed drugs. Stimuli-responsive nanostructures can take advantage of changes in the biological microenvironment of the disease in question and respond to changes in temperature, pH, redox conditions, reactive oxygen species (ROS), and enzyme concentration, with combinations of stimuli increasing the therapeutic versatility of MDDS. This approach, defined as a new paradigm in nanomedicine, has applications in several fields, including cancer therapy, drug delivery, tissue engineering, and even bionics. In this scenario, the intrinsic properties of nanoparticles are used to develop active devices with diagnostic, therapeutic, or even theranostic functions.
Our group has developed several theranostic covalent organic frameworks (COFs) as smart trigger-responsive MDDSs that cover a wide range of applications from cancer therapy to bioimaging to diabetes control. Nanoscale COFs have shown tremendous potential as new candidates for nanomedicine due to their unique properties-large surface area, tunable pore geometry, crystallinity, versatility, as well as responsiveness to physiological environments. COFs exhibit a long-range ordered structure that results in regular pores with diameters that

facilitate the loading and controlled release of prominent drugs and proteins/enzymes. Moreover, their high flexibility in molecular design makes them versatile and uniquely responsive to their environment. Recently, we published the formation of imine-linked nanoscale COFs linked for cancer therapy. The resulting COFs were stable under physiological conditions but disintegrated in an acidic medium, an essential property of the microenvironment of most solid tumors, and facilitated site-specific drug release. On the other hand, we reported a triazine-based COF with high stability under harsh acidic environmental conditions for oral insulin delivery to diabetic rats. The insulin-loaded COF crossed the intestinal barrier and sustainably lowered blood glucose levels in vivo in diabetic rats (T1D), and blood glucose levels completely returned to normal without causing systemic toxicity compared with the control group of nondiabetic rats.
In my talk, I hope to offer some key elements to answer the question, "Can COF nanoparticles serve as effective therapeutics for various disease treatments?"

SESSION SB02.04: Biomimetic Materials for Delivery II

Ion Transport and Molecular Separations in Self-Assembled Membranes with Precisely Defined 1-nm Scale Pores ChinedumOsuji; University of Pennsylvania, United States

Polymeric materials that display simultaneously high selectivity and permeability for a specific ionic or (uncharged) molecular species are of central importance in myriad scenarios, ranging from energy generation and storage to water purification, drug delivery and isolating products of biosynthesis. However, we lack adequate knowledge to enable the design of “fit-for-purpose” materials for controlled species transport under the conditions of nanoscale confinement encountered in these scenarios. The structure-property relationships that govern transport in nanoscale confinement reflect the prevalence of interfacial interactions and the fundamentally altered nature of physico-chemical phenomena at the nanoscale. These relationships diverge strongly from those at continuum length scales and are generally poorly understood. Biological systems such as selectivity filters in ion channels display remarkable transport properties and exploit features that to date have been difficult to incorporate effectively into synthetic materials. These features include uniformity in the structural and chemical characteristics of transport regulating features. Here, we examine molecular self-assembly as a route to mimic such uniformity, with a goal of better understanding nanoscale transport and realizing improved membrane materials. We study lyotropic self-assembly of reactive amphiphiles into gyroid and direct hexagonal mesophases, the fabrication of highly-ordered nanostructured polymer thin films from such mesophases, and the performance of the resulting membranes. We consider a variety of scenarios, including molecular filtration in aqueous and non-aqueous media, and ion transport. These membranes circumvent the limitations of pathway tortuosity and size-dispersity of transport-regulating features found in conventional membranes. As such, they enable highly selective, or precise, molecular separations and ion transport, with pore-size tunable in steps as small as 0.1 nm. We present results highlighting how these precisely-defined membranes are enabling the development of new insight regarding molecular transport under nanoscale confinement in the presence of charge, something that is poorly understood from a fundamental perspective.

2:00 PM *SB02.04.02
Three-Dimensional Visualization of Proteins within Metal-Organic Frameworks JoeP. Patterson; University of California, Irvine, United States

Electron tomography holds great promise as a tool for investigating the three-dimensional (3D) morphologies and internal structures of metal-organic frameworks (MOFs). Understanding the 3D spatial arrangement and density of proteins within protein@MOF biocomposites is paramount for developing synthetic methods to control the location of proteins within the MOF material. The direct visualization of the protein Ferritin (Fn) in Fn@MOF biocomposites was probed through a combination of scanning electron microscopy (SEM), transmission electron microscopy (TEM), and electron tomography (ET). Using con-trolled-dose dry-cryogenic electron tomography (dry-cryoET), we obtain a direct 3D visualization of protein@MOFs with individual protein resolution. These direct observations show that ligand-to-metal ratios for Fn@MOF biocomposites can be tuned to change the spatial arrangement and localization of the proteins within the MOF crystals.

2:30 PM *SB02.04.03
Enzyme-Mimicking of Copper-Sites in Metal-Organic Frameworks for Oxidative Degradation of Phenolic Compounds AinaraValverde[1], StefanWuttke[1,2], José MaríaPorro[1,2], MónicaJiménez-Ruiz[3], Pedro LuisArias[4], IkerAgirrezabal-Telleria[4] and RobertoFernández de Luis[1]; [1]Basque Center for Materials, Applications and Nanostructures, Spain; [2]Ikerbasque, Spain; [3]Institut Laue Langevin, France; [4]University of the Basque Country (UPV/EHU), Spain

Through the sequential assembly of simple repetitive units, biology has built up complex three-dimensional scaffolds of metalloproteins, which deposit functional amino acid residues able to coordinate the metal catalytic site in specific spatial configurations. The chemical arrangement of the amino acid residues that conforms the first and second coordination environment of the metal-sites plays a key role in defining the activity and selectivity of metalloenzymes. Thus, an alteration of any of the amino acid sequence into the heart of the metalloenzyme sites, affects drastically their efficiency, selectivity and function. An important example is the case of copper metalloenzymes, where the coordination of copper ions is usually completed by histidine, cysteine and carboxyl amino acid residues. Depending on the copper-biocatalyst, $Cu^{II/I}$ ions are stabilized as isolated and/or clustered sites able to carry out oxidative catalytic reactions. The overall selectivity and oxidoreductive efficiency of copper-enzymes over a specific substrate is partially defined by the coordination modes of the copper sites. Furthermore, their oxidative capacity has important technological implications in water remediation, since it can be adapted to degrade phenolic pollutants via Catalytic Wet Peroxide Oxidation (CWPO).

Extensive research is being carried out to replicate and expand the metalloenzymes’ pockets and catalytic activity to robust porous materials. In this regard, the chemical encoding of bio-catalytic like sites into a particular class of porous ordered materials called Metal-Organic Frameworks (MOFs) holds an enormous promise. MOFs are crystalline solids built from metal ions or clusters that are connected by organic linkers to form extended, ordered, and highly porous networks. Thanks to their (i) impressive and ordered porosity metrics and (ii) their versatility to be encoded with functionalities placed surgically at specific positions of their frameworks, MOFs have been successfully employed as matrixes to install amino acids and peptides. Once the pore space has been decorated with specific amino acid moieties, metal-sites can be easily installed by adsorbing them from aqueous or non-aqueous solutions.

In this work, we have decorated the mesopore space of the MOF-808 with amino acid and carboxylic acid molecules, to later, stabilize coppers ions with varied coordination modes and clustering degrees. In a second step, we have unraveled the impact of the characteristics of the metal-sites on the catalytic wet oxidation (CWPO) of phenolic compounds. The features of the copper-sites installed within the framework have been studied by a combination of Infrared (IR), Raman, X-ray photoelectron (XPS), electron paramagnetic (EPR) and inelastic neutron scattering (INS) spectroscopies. Local structural models for the copper sites have been proposed after a crystallochemical analysis of the copper coordination modes with (amino)acid molecules found in the Cambridge Structural Database. The efficiency and selectivity of our system to oxidize phenolic pollutants through CWPO have been duly assessed, confirming that both the coordination modes and the clustering degree of the copper sites modulate its efficiency and selectivity to oxidize phenols through the hydrogen peroxide activation. The results presented in this work represent a milestone for the installation of metal-amino catalytic sites into the robust architectural backbone of MOFs, which successfully mimic those oxidative functions of metalloenzymes.

Bio-Inspired Photonic Microcapsules that Change Colors via Reversible Osmotic Actuation Ji-YoungLee[1], JaehyunKim[2], JaekyoungKim[2], DaeyeonLee[2] and LeilaDeravi[1]; [1]Northeastern University, United States; [2]University of Pennsylvania, United States

Animals have evolved complex and sophisticated mechanisms to control coloration, employing a combination of small molecules and nanostructured composites. Notably, chromatophores, specialized organs found in animals such as squids and octopuses, play a crucial role in dynamic color change. Chromatophores have the unique ability to modify their physical shape and size by expanding or contracting pigment-containing cells. This study introduces an artificial chromatophore system that uses osmotic annealing to trigger reversible color switching. To achieve this, we fabricate double emulsion droplets using polystyrene nanoparticles functionalized with the xanthommatin, the primary pigment found in the skin of cephalopods. The particle size and the pigment loading density into the system are influential factors in controlling the oscillation between pigmentary and structural colors which can be manipulated through annealing. We compared the reflectance spectra of photonic capsules from the presence and absence of pigments. Our findings highlight a distinctive and scalable approach for producing color-changing

materials, providing a versatile range of tunable visible colors.

3:45 PM SB02.04.05
Delivery of AuNCs into eXtracellular Vesicles by Fusion Using Ionizable Liposomes Cargos EsterButera[1,2], AnisOuzaid[3], SoleneDucarre[2], GiuseppeMaccarrone[1], AnnalindaContino[1], PascaleEven-Hernandez[2], CeliaRavel[3,4] and ValérieMarchi[2]; [1]University of Catania, Italy; [2]Université de Rennes 1, France; [3]CHU Rennes, France; [4]University of Rennes 1, France

Extracellular vesicles (EVs) are well-known membrane-limited particles secreted by healthy and cancerous cells. EVs have heterogeneous size and three subtypes are described depending on the location of secretion: microvesicles, myelinosomes and exosomes. EVs are identified in human follicular fluid as a mode of communication in the ovarian follicle.[1] In addition EVs involved in cell-cell communication are considered as biomarkers for early cancer diagnosis. The analysis of their content and their labeling with easily detectable nanoparticles could enable the development of a powerful tool for the early diagnosis of specific diseases

In this view, gold nanoclusters (AuNCs) appear as a recent class of non-toxic fluorophores. Their brightness, their ultrasmall size (< 2 nm) and large window of fluorescence lifetime (1ns - 1µs) and their good biocompatibility make them an attractive alternative as fluorescent probes for biological labeling and bioimaging.[2] In addition, their ultra-small size facilitates their clearance when they are injected into the body. Their small size makes them attractive to encapsulate them into liposomes without damaging the compartment integrity and then to be delivered into the extracellular vesicles. We previously demonstrate that their direct attractive electrostatic interaction with extracellular vesicles result into the labelling of their membrane or disruption of the EVs into multilamellar structures.[3]

We investigated encapsulation of ultra-small-sized red and blue emitting Au NCs into liposomes of various sizes and chemical compositions. The efficiency of the process was correlated to the structural and morphological aspect of the AuNCs encapsulating vesicles via complementary analyses by SAXS, cryo-TEM, and confocal microscopy techniques. We confirmed the possible encapsulation of ultra-small-sized red and blue emitting Au NCs into liposomes of various sizes and chemical compositions. Cell-like-sized vesicles (GUVs) encapsulating red or blue Au NCs were successfully obtained by an innovative method using emulsion phase transfer. Finally, exosome-like-sized vesicles (LUVs) containing Au NCs were obtained with an encapsulation yield of 40%, as estimated from ICP-MS.[4]

Herein, we investigate the interaction of fusogenic liposomes encapsulating the AuNCs with EVs extracted from human seminal fluids. The composition of the membrane was optimized to improve the fusion properties of the liposomes. The mixture of the liposomes and EVs results in lipid exchange as demonstrated by FRET experiments and in increased size revealed by flux cytometry. The resulting fused hybridosomes were successfully isolated by size exclusion chromatography. They exhibit typical fluorescence of the AuNCs together with an increased size in agreement with the expected size of the fused exosomes. Besides their interest to analyze the EVs content, such hybridosomes could serve as drug or macromolecule carriers or nanosensors in living organisms.

Potential of Dendrimer-like Silica Nanoparticles Loaded with Cisplatin and Immune-checkpoint Inhibitors for Direct and Indirect Tumor Regression TaihyunKim and JinkeeHong; Yonsei university, Korea (the Republic of)

Since the development of cancer immunotherapy using immune checkpoint inhibitors (ICIs), significant improvements have been made in cancer treatment. However, there are still limitations in their clinical effectiveness, particularly in terms of low delivery to target sites. To address these limitations, we aimed to enhance the existing ICI-based immunotherapy strategies by combining them with chemotherapeutic agents.
To achieve this goal, we employed a one-pot sol-gel reaction to prepare dendrimer-like porous silica nanoparticles (DPSNs). These DPSNs possess a larger surface area compared to spherical particles of the same size, resulting in enhanced stability during long-term storage. Initially, we focused on conjugating cisplatin, a widely used chemotherapeutic anti-cancer agent, onto the surface of DPSNs. By modifying the DPSNs with carboxyl groups and loading cisplatin as a model anticancer drug, we investigated the release behavior of the drug molecules. Our findings revealed that cisplatin remained intact under neutral conditions but was released under acidic conditions, indicating the successful development of pH-responsive DPSNs (referred to as DPSN-cis).
Furthermore, we performed an EDC/NHS-sulfo reaction to modify aPD-1, one of the ICIs, onto the surface of DPSN-cis. This allowed us to create DPSN-ICIS, where both cisplatin and aPD-1 were simultaneously conjugated. Importantly, DPSN-ICIS exhibited no cytotoxicity even after three days of cell culture and demonstrated long-term physicochemical stability. To evaluate the effectiveness of DPSN-ICIS, we conducted in vitro experiments to assess its binding to PD-1 on T cells and its ability to induce cancer cell death. Subsequently, we validated these findings in vivo by demonstrating that DPSN-ICIS effectively performed both functions and led to tumor eradication. These results were further supported by analyzing immune responses to examine the behavior of DPSN-ICIS within a living organism.
Overall, our study highlights the potential of next-generation cancer immunotherapy by simultaneously loading chemotherapeutic agents capable of directly killing tumors and functionalizing various immune enhancers. The development of DPSN-ICIS addresses the limitations of current immunotherapy approaches, offering a promising strategy for more effective cancer treatment.

Vitalizing Immortal Nanodendritic Cells Functionalized with Immune-checkpoint Inhibitors for Tumor-localized Immunotherapy TaihyunKim and JinkeeHong; Yonsei University, Korea (the Republic of)

Recently, cancer immunotherapies combining nanotechnology have been highlighted due to the high impact of substantial clinical potential in various types of solid cancers. Especially, nanoparticle (NP)-based technology is a well-known and powerful tool for manipulating functionalities and ensuring in vivo stability, making it suitable for personalized cancer therapy. As an advanced form of immunotherapy using nanotechnology, the combination of cell-based therapy and NP technology has been emerging, for example, introducing cellular membranes or extracellular vesicles onto the NPs. This delivers the entire information of the cell membrane to the NP surface without damage and could be regarded as a useful technology for cell mimicking.
Meanwhile, dendritic cells (DCs) have been recognized as promising targets for immunotherapy due to their crucial role in T cell activation. However, administrated DCs in patients showed poor lifetime in vivo, which resulted in limited antigen-presenting capabilities in clinical trials. Furthermore, the storage and recovery of DCs for further usage are also challenging to retain DC survival rate and functionalities. To overcome these limitations, we have developed immortalized nanodendritic cells for cancer immunotherapy by combining DC therapy with cell-mimicking nanotechnology.
By utilizing immortalized DCs with extended lifetimes, we believe that continuous antigen presentation and T cell activation can be achieved in vivo. Our idea to prepare immortalized DC was inspired by cell membrane clocking technology which was first developed by L. Zhang et al. Using this technique, the whole DC membrane could be successfully decorated onto gold nanoparticle (Au NP), which is named artificial nanoDCs (anDCs). We optimized the manufacturing process of anDCs both biologically and thermodynamically to enhance their therapeutic efficacy. The optimized anDCs demonstrated thermodynamic stability and retained their functional abilities even after long-term storage of up to 30 days. We also confirmed the strong tumor regression effect of anDCs due to the fact that the nanosized DC can accumulate in the tumor site or lymph node without degradation, resulting in enhanced T cell activation in vivo.
Finally, to boost the T cell activation effect, the anDC was engineered with immune-boosting agents, immune-checkpoint inhibitors (ICIs). By direct engineering anDC with anti-CTLA-4 (aCTLA-4), we could obtain potent anDCs to induce T cell effector function efficiently. In our research, we validated the efficacy of aCTLA-4-conjugated anDCs in three different tumor models (MC38, CT26, and TC-1). Surprisingly, aCTLA-4-conjugated anDCs exhibited substantial tumor regression compared to the control group, as confirmed by in vivo immune analysis, which showed augmented tumor-infiltrating lymphocytes.
In summary, our objective was to develop optimized therapeutic drugs for cancer immunotherapy that can mimic the behavior of DCs. We successfully created a DC-mimicking therapeutic anticancer drug that can continuously and strongly activate tumor-specific T cells, thereby resulting in dramatic tumor regression. Furthermore, by conjugating various immune-boosting agents to anDC, we strongly anticipate that our material could be manufactured as desired and provided for patient-specific needs.

8:00 PM SB02.05.01
Metal-Organic Framework Coordinated with Single Fe Nanozymes and Gold Cluster for Biomedical Applications SubinYu[1,2] and LukeLee[2]; [1]Ewha Woman's University, Korea (the Republic of); [2]Harvard Medical School, United States

Metal-organic frameworks (MOFs) have been extensively utilized as substrates for constructing single-atom catalysts (SACs) due to their abundant ligands, enabling nanozyme-mediated biomedical applications. However, the preparation of SACs using MOF substrates typically involves harsh calcination processes to stabilize the single metal atom catalysts, which can lead to uncertain changes in the oxidation state of the metal centers, impacting the overall catalytic reaction. In this study, we have developed ultrasmall MOF-based single iron (Fe) atom Fenton-like nanozymes (referred to as Fe/MOF) by employing a simple mixing method. These nanozymes were combined with a gold nanocluster-embedded MOF mimic of glucose oxidase (referred to as Au/MOF), enabling cascade enzymatic reactions within living systems. To harness the abundant porosity of MOF and enhance cell cytotoxicity, the anticancer drug doxorubicin (DOX) was loaded inside Fe/MOF (referred to as Fe/DOX/MOF). Additionally, Au/MOF was further modified with a mitochondrial targeting moiety (triphenylphosphonium, TPP) to target the mitochondria and disrupt the cellular redox system. Internalization of Au/MOF into mitochondria resulted in glutathione (GSH) depletion through thiol-gold interactions, leading to mitochondrial excess lipid peroxidation. The constructed Fe/MOF exhibited an oxidation state of 2+ with Fe-N coordination bonds, demonstrating well-established Fenton-like nanozymes characteristics. The overall cascade enzymatic activity effectively generated hydroxyl radicals from glucose as a substrate. The generated gluconic acid induced an acidic environment that further accelerated the overall Fenton reaction. In vitro, studies demonstrated effective cancer eradication through cascade glucose oxidation and hydroxyl radical generation. GSH depletion-mediated down-regulation of GPx4, along with the delivered Fe^{2+}, induced Fenton reaction-mediated lipid peroxidation, indicating ferroptosis. In vivo, studies further confirmed the overall therapeutic effects of the cascade enzymatic activity of Fe/MOF and Au/MOF. Our novel and straightforward synthesis process for MOF-based single-atom nanozymes and metal clusters present a new paradigm for fabricating single-atom nanozymes for multimodal cancer treatment.

8:00 PM SB02.05.02
Antibody Pre-Coated Zr-MOF as a Cloaking and Plug&Playable Platform for Targeted Delivery System Jun YongOh, BatakrishnaJana, JunmoSeong, Eun MinGo, SeongeonJin, Jong-hoonBae, ChaiheonLee, SeonghwanLee, Tae-HyukKwon, Jeong KonSeo, EunshilChoi, Sang KyuKwak, Myoung SooLah and Ja-HyoungRyu; Ulsan Nationa Institute of Science and Technology, Korea (the Republic of)

Metal-organic framework (MOF)-based targeted drug delivery systems have made great strides and are widely used in a variety of scientific disciplines. Nevertheless, the biomolecular corona phenomenon makes it difficult to directly translate MOF agents into focused medication delivery systems. Here, we have established that pre-absorption of antibodies to MOF particle surfaces by supramolecular mixing can decrease protein adhesion in biological contexts, with effects akin to those of stealth shields. Furthermore, we further demonstrated that this mechanism may be influenced by the MOF's surface's pore size. The MOF particle was neither readily swapped with nor covered by biomolecule protein once the antibodies had been stably attached to it, indicating a stealth effect and an improved capacity to target both in-vitro and in-vivo. In addition, the generated antibodies-MOF platform may target various cancer cell lines by plugging multi-antibodies (dual and triple kinds). This study provides insights into the use of “antibody pre-absorption” as a promising method for developing MOF-based drug delivery systems.

8:00 PM SB02.05.03
Dual Drug Delivery Systems Based on Porous Fibers Grafted with ZIF67 JooranKim; Korea Institute of Industrial Technology, Korea (the Republic of)

Metal-organic frameworks (MOFs) have emerged as promising materials for various applications due to their exceptional tunability and high surface area. In recent years, the integration of MOFs with fibers has gained significant attention in the field of drug delivery systems. The combination of MOFs and fibers offers a unique platform for controlled release, targeted therapy, and enhanced drug stability, ultimately revolutionizing the field of therapeutics.
Moreover, researchers have explored the application of dual drug delivery using porous fibers with MOFs in various therapeutic areas, including cancer therapy, antimicrobial treatments, and regenerative medicine. These studies have demonstrated the potential of these systems to overcome drug resistance, reduce side effects, and enhance treatment efficacy by delivering multiple drugs simultaneously.
In this study, we developed porous poly(caprolactone) (PCL) fibers through liquid-liquid phase separation, and then ZIF-67 was grown on the porous PLA fiber through in-situ synthesis. These carriers were investigated the relationship among pore formation, physical properties, and antibacterial activities of the fibers for identifying their potential as drug delivery carriers. Studies have focused on optimizing the synthesis techniques to achieve uniform ZIF67 coatings on the surface of porous PCL fibers.
Suggested dual drug delivery system using porous PCL fibers with ZIF67 are the co-delivery of two drugs including lysozyme and gentamicin with complementary antibacterial effects. By encapsulating dual drugs inside pores of PCL and ZIF67, the dual drug delivery system achieves synergistic effects, improved drug stability, and controlled release kinetics. Furthermore, the selection of appropriate drugs and their optimal ratios play a crucial role in achieving desired antibacterial outcomes.
Overall, the research on dual drug delivery using porous fibers with ZIF67 highlights the potential of these drug carrier systems in achieving controlled release, synergistic effects, and improved antibacterial outcomes. Further advancements in the synthesis techniques, optimization of drug ratios, and comprehensive understanding of the in vivo behavior are crucial to translate these innovative systems into clinical applications and address the challenges associated with their practical implementation.

8:00 PM SB02.05.04
Capping UiO-Based and HKUST-Based Metal Organic Frameworks Towards Trapping and Controlled Release of Guest Molecules SamuelDarer, CalG. Lebak, DavidS. MacLeod, AbigailBerube, ShawnC. Burdette and RonaldL. Grimm; Worcester Polytechnic Institute, United States

Molecular caps for metal organic frameworks (MOFs) are particularly compelling for enabling capping and controlled release of guest payloads. Previously we utilized bulky triphenylacetate-based caps to trap guests within the pores of MOF-5. Presently, we extend these efforts to the UiO and the HKUST families for their tunable porosity, high stability, and varying chemistry to explore the interplay between interfacial chemical properties on the MOFs and the necessary capping chemistry. We utilized capping reactions including acetate exchange, growth with terminating single-acetate-group organics, and established functionalities for monolayer chemistries. Utilizing fluorine-tagged capping organics, X-ray photoelectron spectroscopy established which chemistry successfully capped each MOFs, and supported models of interfacial chemical states that exist on the MOF themselves. We aim to further develop capping abilities, expanding the control and variability of the caps that can be applied to MOFs and applying this research to wider potential applications.

8:00 PM SB02.05.05
Janus Hydrogel-Based Fuel Stimulant Powered Amplification for Multiple Detections of miRNA Biomarkers in Gastric Cancer Eun-KyungLim; Korea Research Institute of Bioscience & Biotechnology, Korea (the Republic of)

MicroRNAs (miRNAs) circulating in body fluid have emerged as potential biomarkers for various diseases; however, owing to their low concentrations and short lengths (~22 nt), their clinical applications are still limited. Therefore, a highly sensitive and selective novel diagnostic platform for miRNA detection is required. Here, we present a hydrogel-based fuel stimulant-powered (FSP) amplification of fluorescent signals to detect circulating miRNAs from clinical samples of human serum. The advantage of this method is that it has high sensitivity as a fuel-assisted DNA cascade reaction that does not require temperature control and enzymes used for nucleic acid amplification. Further, we developed a Janus-type hydrogel for the simultaneous detection of the gastric cancer-associated miRNAs, miR-135b and miR-21. The detection limit of this hydrogel-based FSP amplification using synthetic miRNAs was estimated as < 10 fmol. We also validated the performance of this amplification process in in vitro and in vivo models and clinical samples. Therefore, we demonstrate that Janus hydrogel-based FSP amplification can selectively and sensitively identify the overexpression of miR-135b and miR-21 in clinical samples, thereby helping distinguish gastric cancer patients from healthy donors.

8:00 PM SB02.05.06
The Product Development Process of Single Application Otitis Externa Drug Delivery System EmmaBarrett-Catton, KoltonSandau, ElizabethArrigali, BogdanSerban and MonicaSerban; University of Montana, United States

Background: Otitis externa, also known as outer ear infection, is a pathological condition that affects humans and animals. The standard of care for otitis externa is topical administration of ear drops. However, the high frequency of required administrations and duration of treatment are associated with poor patient compliance and increased risk for complications. We have developed a tetraethyl orthosilicate-based thixogel for use as single application treatment for otitis externa to increase ease of use and improve patient outcomes. For advancement to market, we have assessed the formulation’s repeatability and reproducibility, release profiles of a variety of model drugs, impact of application-specific physiological factors, system scalability, and conducted shelf-life studies.
Methods: Thixogels were prepared by the hydrolysis of tetraethyl orthosilicate (hTEOS) and subsequent combination with aqueous hyaluronan (HA) followed by the adjustment of the solution’s pH to ~7.65. Thixogel properties (elastic modulus, thixotropy, drug release, dry substance) were tested for thixogels made with TEOS and HA from different manufacturers,

different concentrations of aqueous HA, and solution adjustments to a range of pH values. Elastic moduli and thixotropy were both determined with a rheometer. Dry substance content was measured with a moisture analyzer. Drug release was determined in vitro with the amount of drug released into saline at 37 °C measured using absorbance or fluorescence, depending on the model drug. Fluorescein, fluorescein disodium, green fluorescent protein, and blue dextran were all used as model drugs. The impact of ear canal-specific physiological factors, pH and enzymic activity, on drug release was evaluated using fluorescein.
Results: Thixogel properties remained consistent regardless of HA or TEOS manufacturer, aqueous HA concentration. Model drug properties, including molecular weight, and logP, impacted their release. Physiological factors did not seem to have an impact on model drug release profiles. A 100X scale-up from 20 mL to 2L resulted in no significant differences in fluorescein release, storage modulus, thixotropy, and dry substance between hydrogels. The shelf-life of the evaluated thixogels was found to be cold-chain independent, ranged from 4 months to 8.5-month and was dependent on the amount of HA in the formulation. Our data also indicates that longer shelf-life durations could be achieved by stabilizing the constituent HA and/or via product dosage form presentation.
Conclusions: Our results indicate that the developed thixogels are well suited for production and scalability, as they have a robust manufacturing process, have a wide tolerance for pH level, release a variety of model drugs (small molecule, protein, and polymer), and are not impacted by outer ear canal-specific physiological factors.

8:00 PM SB02.05.07

Host Cell-Mimetic Hybrid Nanoparticles as Antiviral Therapeutic Nano-Inhibitors for Influenza Virus EunjiJeong, GeunseonPark and SeungjooHaam; Yonsei University, Korea (the Republic of)

Unpredictable pandemic caused by respiratory virus such as coronavirus disease (COVID-19) poses a great threat to public health due to numerous infections and deaths. Despite the emergence of various diagnostic methods and vaccines, limitations persist in the development of effective antiviral therapeutic agents for promptly addressing newly emerging viruses. Host cell mimetic nanodecoy is an effective strategy to protect against the advancement of infection by neutralizing the virus, impeding its binding and entry into the lung cell membrane, which is the ultimate target of the virus. Herein, we develop an advanced biomimetic nanodecoy capable of trapping the target virus and preventing host cell infection using gold nanoparticles with various topologies and sizes through encapsulating by coating host cell membranes. We fabricated cell membrane-coated Spiky Gold nanoparticles (CM-SGNP) with various topologies, each ranging in size from 50 nm to 120 nm, using a seed-mediated growth method and physical extrusion. The CM-SGNP coated with the Madin-Darby canine kidney cell membrane could efficiently capture Influenza A virus (IAV) virions, providing evidence that the binding event and subsequent infection between host cells and virions will be inhibited. Interestingly, geometry matching between IAV virion and CM-SGNP according to the topology of CM-SGNP suggests that this system has the potential to be customized according to virus type and appearance by controlling the structure of CM-SGNP. Furthermore, CM-SGNP is expected to provide successful delivery and therapeutic effects in-vivo due to its superior biocompatibility characteristics. This system suggests the powerful strategy for treating infectious diseases by combining synthetic and biological materials. It is also the next-generation therapeutic agent that can be widely applied to various virus mutant and newly emerging disease X by setting the ultimate target of the virus to be a nanoinhibitor.

SESSION SB02.06: Biomimetic Self-Assembled Materials I

Self-Assembled Metal-Organic Framework Monolayers (SAMMs) SethM. Cohen; University of California, San Diego, United States

The combination of polymers and metal-organic frameworks to obtain composite materials can take a number of forms, including mixed-matrix membranes (MMMs) prepared with MOFs, polymer-decorated MOF particles, and MOFs constructed from polymer buidling blocks referred to as polyMOFs. It has been demonstrated that polymer-decorated MOF particles, under the correction conditions, can form self-assembled MOF monolayers (SAMMs). These unusual materials allow for the formation of ultrathin MOF membranes and coatings that may find use in a range of MOF-based applications. This presentation will describe the synthesis, characterization, and properties of SAMMs as an interest MOF-polymer composite material.

9:00 AM *SB02.06.02

Supramolecular Self-Associating Amphiphiles (SSAs) – A Therapeutic Technology Platform? Plus, Can You Stop a Bullet with Protien?JenniferHiscock; University of Kent, United Kingdom

Our novel patented (European Patent Application No. 18743767.8, U.S. Patent Application No. 16/632,194), Supramolecular Self-associating Amphiphile (SSA) technology currently incorporates a library of ~ 120 amphiphilic salts and associated compounds, with structures containing an uneven number of hydrogen bond donating and accepting moieties. The anionic component of this class of compounds have been shown to self-associate through the formation of intermolecular hydrogen bonds producing anionic dimers in the polar organic solvent DMSO. Moving into aqueous conditions, SSAs self-associate to form spherical aggregates between 100 nm and 550 nm in hydrodynamic diameter. However, the presence of inorganic salt can cause these spherical aggregates to morph from sphere to fibre, producing a series of hydrogel materials.

Within a biological context we have shown these SSAs to:

- act as antimicrobial agents;[1]

- increase the efficacy of other antibiotic/antiseptic agents and anticancer agents against bacteria[2] and ovarian cancer cells respectively;[3]

- selectively interact with phospholipid membranes of different compositions;[4]

- have the potential to act as drug delivery vehicles;[5]

- exhibit a druggable profile when delivered via i.v. in vivo to mice.[6]

Plus, some novel work from our group - can protien be engineered into a material that can capture supersonic impacts?[7]

Molecular and Polymeric Architectures Enabled by Dynamic Spiroborate Chemistry WeiZhang; University of Colorado-Boulder, United States

Dynamic covalent chemistry (DCvC) has proven to be highly effective toward the construction of well-defined molecular and polymeric architectures. The error-correction mechanism enabled by the reversible formation of dynamic covalent bonds leads to the formation of structurally ordered, thermodynamically favored species. One such example is the solvothermal synthesis of covalent organic frameworks (COFs) with periodic structural order and low defect density. The chemical compositions of such frameworks are usually well-defined and inter-monomer connectivity (covalent bonding) is robust. Bottom-up synthesis of covalently linked polymers through DCvC has many critical advantages, such as easy tunability of functional and structural properties in a controlled fashion through rational design of the precursors, formation of highly stable linkages, minimized structural defect, and possible access to sophisticated architectures that are hard to obtain otherwise. This talk will focus on our recent progress in the development of DCvC, specifically spiroborate bond exchange. This powerful transformation enabled the bottom-up design and synthesis of novel functional materials, such as unprecedented single-crystal DNA-like helical covalent polymers (HCPs) and shape-persistent redox active organic molecular cages.

Engineering Metal–Phenolic Materials via Supramolecular Assembly ZhixingLin[1,2]; [1]The University of Melbourne, Australia; [2]The Univeristy of Melbourne, Australia

Coordination polymers (CPs) and their higher-dimensional and potentially porous subset, metal-organic frameworks (MOFs), are supramolecular materials comprising metal nodes and organic ligands. Over the past three decades, CPs in the crystalline state have been the primary focus of the field due to their defined structures, high internal surface areas, and potential for crystal engineering. The periodic arrangement of metals and ligands has facilitated fundamental research on controlling pore size and surface area, which are crucial for achieving improved performance in various applications. However, the practical application of these crystalline materials poses challenges in terms of maintaining accessible pore volumes, integrating into existing infrastructure, and addressing safety concerns arising from the use of toxic precursors and solvents during synthesis, as well as the rigid, brittle, and often unstable nature of crystalline CPs. In contrast, amorphous CPs have gained significant attention over the past decade due to the presence of amorphous domains, which increase pore size, mechanical robustness, and chemical stability of the materials, leading to improved functionality.

One type of amorphous CPs, known as metal-phenolic networks (MPNs), consists of metal ions and phenolic ligands and can be adhesive to diverse surfaces. Due to their ability to coat nanoscopic and macroscopic templates, MPNs have garnered considerable interest in various applications, including biomedicine, photonics, forensics, and biomolecule and fruit preservation. Different metal ions can be employed to confer specific functionalities to MPNs, such as fluorescence, magnetic resonance imaging, and catalytic activity, or to produce synergistic effects in combination with the phenolic ligand, such as buffering effects. Additionally, the amorphous structure of MPNs can endow them with unique material properties, such as higher mechanical robustness, increased stability, and improved processability. This presentation aims to provide an introduction to MPNs, covering their fundamental aspects and will highlight our recent significant progress in developing MPNs for various biomedical applications, including catalysis, intracellular tracking, and drug delivery.

10:45 AM SB02.06.05
Structure and Dynamics of Self-Assembled Lipid Nanoparticles for Nucleic Acid Delivery ShaynaHilburg and LiloD. Pozzo; University of Washington, United States

Nucleic acids can revolutionize human health outcomes, as evidenced by the mRNA vaccines used to combat COVID-19. Despite the success of these therapeutics, the fundamental physicochemical properties of the non-viral delivery vectors must be better understood to be more easily tuned and optimized. In this work, we use small-angle X-ray (SAXS) and neutron scattering (SANS) to assess how the storage and delivery conditions of the nanoparticles impact their structure and dynamics. The components which come together to encapsulate the nucleic acids have complex non-covalent interactions at the nanoscale which dictate their ability to withstand storage conditions and transport to cells while also disassociating upon intracellular delivery to release cargo. Here we show that the molecular interactions within the drug delivery vehicles, including exchange kinetics of the self-assembled molecules, are impacted by relevant environmental factors, including pH. Such information demonstrates what drives degradation and what parameters can be changed to improve delivery by increasing the efficiency of endosomal escape. Ultimately, these results can be used to optimize efficacy, enabling more flexible storage requirements, lower dosages, and improved therapeutic tolerances.

Injectable Granular Agarose/Alginate Beads - Spray Based Synthesis and Energetic Electron Modification CatharinaKrömmelbein[1,2] and StefanG. Mayr[1,2]; [1]Leibniz-Institute of Surface Engineering (IOM), Germany; [2]University of Leipzig, Germany

Granular hydrogels real highly interesting features for novel biomedical applications, including regeneration and drug delivery. Furthermore, properties like injectability and porosity, making them feasible for applications in 3D bioprinting and tissue engineering. High-energy electron irradiation combines sterilization and tuning of hydrogel properties without adding potentially cytotoxic chemicals. In this study, granular agarose/alginate hydrogels are prepared by electrospraying. Shear-thinning and self-healing characteristics of the entire granular hydrogel are studied employing rheology. Although viscoelasticity changes under irradiation, shear-thinning and self-healing prevails. These dynamic properties enable injection, which is demonstrated for 27 G needles. This study presents a mechanical characterization of high-energy electron irradiated granular agarose/alginate hydrogels that extends the diversity of available injectable hydrogels and provides a basis for biomedical applications of this scaffold.

Visible Light as a Benign Stimulus for Additive Manufacturing of Hydrogels ZachariahA. Page; The University of Texas at Austin, United States

Light as an energy source has enabled transformative technologies in imaging, lithography, adhesives, and 3D printing. Its broad utility arises from the unparalleled spatiotemporal control over chemical transformations that it offers. However, contemporary methods rely on high energy UV light (< 400 nm), which limits biocompatibility due to degradation and attenuation that occurs upon absorption and/or scattering. Excitingly, the recent commercialization of inexpensive light emitting diodes has opened up an avenue to examine mild visible-light induced reactions in the fabrication of biologically relevant scaffolds. This presentation will focus on how the *ZAP Group* has developed low energy light driven reactions to create macroscopic water-swollen scaffolds (i.e., hydrogels) with unprecedented speed and precision. Specifically, catalyst design principles to enable rapid solidification of photopolymer resins using visible-light will be discussed, along with their utility and optimization in high resolution additive manufacturing.

Mimicking Melanin: Nature's Biopolymer of Intrinsic Microporosity as a Therapeutic Material for Tissue Repair NathanC. Gianneschi and KurtLu; Northwestern University, United States

Melanin is a class of essential biopolymer found across plant, animal, bacterial and fungal kingdoms with an astonishing array of functions, including pigmentation, radical scavenging ability, radiation protection, and thermal regulation. Nature synthesizes melanin of five known kinds: eumelanin, pheomelanin, allomelanin, neuromelanin and pyomelanin. Among them, eumelanin (black and brown pigment in dark hair) and pheomelanin (the pigment in red hair) are the two most commonly considered forms. The past two decades have witnessed a flourish of eumelanin-based materials, especially polydopamine. In our own work, we have endeavored to explore synthetic analogues that enhance, extend and build on these biomimetic systems to enrich melanin and melanin-like materials with desirable properties for a range of applications. A key property of interest here is the ability of properly engineered synthetic melanins to perform as high surface area “sponges” for absorbing toxins and to act as an efficient and stable scavenger of radicals. These synthetic porous melanin materials and a variety of modified analogues will be

described in terms of their function in tissue repair. Specifically in topical applications for healing damaged skin from chemical and radiation induced injury.

Construction of Smart Supramolecular Drug Delivery Systems for Biomedical Applications Ying-WeiYang; Jilin University, China

The design, synthesis, recognition, and assembly of functional macrocyclic receptors have been playing a critical role in supramolecular chemistry. Due to their superior properties and functions, supramolecular macrocycles, including cyclodextrins, cucurbiturils, calixarenes, and pillararenes, have attracted broad attention in the fields of organic supramolecular chemistry and materials science. Meanwhile, nanoparticles with unique characteristics and particular properties, such as mesoporous silica nanoparticles, metal-organic frameworks, gold nanoparticles, magnetic nanoparticles, and semiconductor nanocrystals, have shown ever-increasing importance in chemistry, materials science, nanoscience, and biomedicine. Upon combining the porous/nonporous inorganic solid nanoplatforms or even organized organic/polymeric nanosystems with supramolecular macrocycles, there is great potential to enhance the photophysical, chemical, electronic, and other related properties of solid supports and the host-guest property of supramolecular macrocycles expanding and advancing the applications of the resulting organic-inorganic hybrid materials.[1-8] In this talk, I will present our methodology and research progress of the chemical construction of smart supramolecular drug delivery systems hybridized with synthetic macrocycles and nanoparticles and showcase their applications in the areas of antimicrobial, anticancer, cell imaging, crop protection, biosensing, etc.

Engineering of Advanced Biomaterials by Harnessing Biological Organization Principles AlvaroMata; Nottingham University, United Kingdom

Living systems have evolved to grow and heal through biological organization principles (BOPs) capable of organizing molecular and cellular building-blocks at multiple size scales. These BOPs emerge from cooperative interactions and chemical networks between multiple components, which allow biological systems to diversify, respond, and optimize. This talk will present our laboratory's efforts to combine supramolecular events found in nature such as self-assembly, disorder-to-order transitions, or diffusion-reaction processes with engineering processes to design bioinspired materials and devices (Figure 1). I will also describe recent efforts aiming to go beyond "bioinspiration" and into "biocooperation". I will describe methodologies to develop a) dynamic hydrogels and in vitro models for cancer [1,2], b) self-assembling fluidic devices [3,4], and c) regenerative implants [5,6].

Biofilm-Inspired Underwater Peptide Adhesives JingYan, XinHuang and SarvagyaSaluja; Yale University, United States

Bio-adhesives are extensively used in biomedical applications including suture-less seal and wearable electronics, where there is a need to adhere two wet surfaces together. However, existing products, largely inspired by mussel adhesives, are expensive to produce and sensitive to environmental conditions limiting their wide application. We recently made a serendipitous discovery regarding how bacterial biofilms formed by *Vibrio cholerae*, the pathogen responsible for pandemic cholera, adheres to various surfaces using a unique short peptide. In this study, we will show a range of both biotic and biotic surfaces suitable for this biofilm-inspired glue, and the molecular mechanism underlying the adhesive property of this peptide. Finally, I will discuss about our effort in establishing a fermentation-based process to scale up the production of the peptides.

11:15 AM SB03.01.03
Cephalopod-Inspired Optical Engineering of Mammalian Cells GeorgiiBogdanov, NikhilKaimal, AleezaFarrukh, AleksandraA. Strzelecka, AtrouliChatterjee and AlonGorodetsky; University of California, Irvine, United States

During the last several decades, cephalopods (e.g., squids, octopuses, and cuttlefish) have emerged as a powerful source of inspiration for the engineering of dynamic optical systems, due to their complex nervous systems, diverse behavioral patterns, and tunable structural coloration. We drew inspiration from the tunable optical functionality of cephalopod skin cells to engineer human cells for production of reflectin-based high refractive index subcellular architectures and, as a result, to possess tunable transparency-changing and light scattering capabilities (1). Additionally, we improved our control over the production of reflectin in human cells by genetically engineering cell lines to stably express reflectin, which enabled more extensive studies of reflectin-based subcellular architectures under physiological conditions (2). Moreover, we evaluated the optical properties of single cells with three-dimensional label-free holotomographic microscopy and quantitatively characterized their subcellular reflectin-based architectures without and with external chemical stimuli (1,2). Finally, we demonstrated the potential applications of high refractive index reflectin-based subcellular architectures as high contrast genetically encoded biomolecular reporters for various types of microscopy techniques (2,3). Our combined findings validate prior postulates about the mechanisms of cephalopod tunable skin coloration and may lead to the development of unique protein-based tools for various applications in biophotonics and bioengineering.

11:30 AM +SB03.01.04
Molecular Biomimetics - Molecular Technologies of the Future Through Biology MehmetSarikaya; University of Washington, United States

Proteins are the workhorses in biology as they are the fundamental building blocks making up the hierarchical structures of the cells, establishing biomolecular communications via signal transduction, transporting ions, and carrying out enzymatic processes, all vital for life's functions. The proteins, therefore, could be useful tools in developing functional molecular devices, if they can be designed and engineered to function similar to that in organisms. Despite the enormous opportunities provided by proteins as fundamental molecular tools, their utility in engineering and practical technology has not been fully realized, and their use has so far been highly limited for single purposes, e.g., enzymatic functions. In addition to their complexity and cumbersome handling issues, at least for the practical engineer, the main reasons for the limited use of proteins in engineered systems are because of their long amino acid sequences, i.e., 100s of AAs and even 1000s, that lead to unpredictable folding patterns and the resulting functionalities that are not easily predicted or controlled. On the other hand, polypeptides, i.e., short amino acid sequences (10-50 AAs), functional components of proteins, offer similar opportunities as proteins, with the advantage of being easily designed and manipulated, although their folding structures and functions are difficult to control. Despite these difficulties, for more than last two decades, peptides have been used in a variety of practical implementations such as tiny enzymes, drugs, biofunctionalization of nanoparticle drug carriers, probe design for specific targets, and for biomineralization. Especially useful are the fact that peptide sequences can be designed such that they may self-assemble into predictable tertiary structures in aqueous solutions with controlled geometries and shapes such as nanofibers, strips, and 3-dimensional gel-like molecular scaffolds. Since the first publication (below), molecular biomimetics has been emerging as a convergent science and technology field in which hybrid technologies are developed by the tools of molecular biology, genetics, computational sciences, and machine intelligence combined with materials science and engineering. For the last 2+ decades, our laboratory has adapted directed evolution approaches and identified thousands of short peptide sequences (7-15AA) and utilizing them as molecular tool sets in developing molecular technologies. These genetically engineered proteins for inorganics, GEPIs, also dubbed as solid binding peptides, SBPs, can be used as tiny enzymes in, e.g., remineralization, surface functionalization in implants, designing heterofunctional probes and molecular constructs for molecular and ionic targets, and key components of functional nanodevices, such as peptide-enabled field effect transistors. Recent discovery of coherent bio/nano soft interfaces between the self-assembled solid binding peptides forming monomolecular two-dimensional molecular crystals on, and having chiral crystallographic relationships with, single atomic layer solids provides the key element in the development of brain-inspired molecular probes and logic devices by seamlessly integrating biology and solid-state materials at their smallest respective functional units. Based on the three fundamental biological principles of molecular recognition, gene manipulation, and self-assembly, molecular biomimetics is opening a new era in truly genetically engineered functional molecular materials and system of the future. Monday Afternoon, November27, 2023
Hynes, Level 1, Room 101

1:30 PM SB03.02.01
A Novel Bio-Adhesive for Wet Surfaces from *Vibrio Cholerae*SarvagyaSaluja, JingYan and XinHuang; Yale University, United States

Effective adhesion of surfaces in a wet environment is very useful for the biomedical and engineering fields (wearable electronics, suture-less seals, underwater pipeline repair, etc.). However, underwater adhesion has remained a significant challenge. Water prevents effective molecular contact between the adhesive and the substrate, a key step, and prolonged exposure to the aqueous environment deteriorates the adhesive, leading to cohesive failure. Currently, research efforts are taking inspiration from mussels and bacteria, creatures that overcome these challenges and can strongly adhere to underwater surfaces.
We recently discovered that a sequence of 57-amino acids (57-aa) in *Vibrio cholerae* biofilms is the primary contributor to their adherence to a variety of surfaces, both biotic and abiotic, such as glass, plastic, and lipid membranes. We have developed several biochemical and biophysical *in vitro* characterization methods to demonstrate the polypeptide's potential to function as a wet adhesive. Modifying the sequence and applying it to different surfaces has allowed us to identify key parameters of the polypeptide's adhesion ability, including aromaticity, positive charge, linkers, and repeating motifs. We also tested multiple *Vibrio cholerae* mutants to understand the surface adhesion as a biofilm. Finally, we collaborated with simulation groups to corroborate experimental data with theory. Understanding and establishing a model for the adhesion mechanism of the polypeptide enables better engineering of wet adhesives.
Overall, we demonstrate that a 57-aa sequence of a *Vibrio cholerae* biofilm adhesin could be used as a glue for different underwater surfaces. Our findings contribute to the general development of superior wet adhesives.

Intermolecular Interactions of Protein-Mimetic Random Heteropolymers ShaynaHilburg, TianyiJin, PriyaGanesh and AlfredoAlexander-Katz; Massachusetts Institute of Technology, United States

Amphiphilic synthetic random heteropolymers, specifically easily synthesized methacrylate-based polymers with side-chains selected to mimic peptide characteristics, have been demonstrated to provide a bio-inspired means for augmenting and even mimicking bio-macromolecular function. However, the statistical distribution of chains makes a nano-scale molecular analysis of particular moieties and motifs challenging experimentally. Through computational modeling, specifically atomistic molecular dynamics simulations, we provide nanoscale analysis of sequences to provide insight into how these synthetic polymers respond to their environments and interact with molecules around them. Having previously examined the self-assembly of single chains into globules with heterogeneous surfaces for the chains in solution, we now characterize their statistically derived properties in more complex environments. We show how the polymers which have limited dynamics on their own can change significantly as they interact with organic solvents, macromolecules, or surfaces. We explore environmentally-dependent driving forces and the stochastic behavior of the random polymers which impact kinetics and characterize resultant changes in polymer conformation. These changes are shown to be highly dependent upon the properties of both the polymer and the molecular interactions that take place. Our study, leveraging analysis techniques from both polymer physics and protein sciences, illuminates ways in which the polymers are similar to the proteins they are inspired by as well as avenues for applying the synthetic polymer assemblies in solution.

This work was supported by the Defense Threat Reduction Agency contract HDTRA11910011 and HDTRA12210005.

Hierarchical and Stimuli-Responsive Hybrid Materials from High Information Content Building Blocks FrancoisBaneyx; University of Washington, United States

Solid-binding proteins are genetically engineered chimera that incorporate one or more solid-binding sequences at defined locations of their framework while retaining native function. These macromolecules are versatile building blocks for the fabrication of hybrid hierarchical materials that derive unique properties from the organization, interplay, and reconfiguration of organic

and inorganic units. Here, I will discuss how solid-binding proteins can be combined with self-assembled peptoid nanostructures and pre-synthesized or mineralized inorganic elements to create layered 3D architectures, achieve precise control over nanocrystal size, and build photocatalytic nanocomposites. I will also describe recent progress on the use of thermos-responsive solid-binding proteins to control nanoparticle assembly and disassembly and manipulate the outcomes of biomimetic mineralization.

2:30 PM SB03.02.04
Silk-Nanotraps for Selective Molecular Targeting. Understanding Potentials and Limitations of Functional Protein Super-Assemblies Alessandra MariaBossi[1] and DevidManiglio[2]; [1]University of Verona, Italy; [2]University of Trento, Italy

We report about the development of tailor-made biomimetics stemmed from merging biology with polymer chemistry and material science. Aqueous-soluble nanotraps that behave as biomimetic receptors were prepared in the form of proteinaceous disordered super-assemblies, fixed by non-natural crosslinking. The specific formation of the nanotrap started from the biocompatible, nontoxic material, already in use in regenerative medicine, that is silk fibroin [1].
Pioneering a paradigm change, the tailor-made molecular recognition was conveyed to the silk nanotrap by the unconventional exploitation of the molecularly imprinted polymers (MIPs) technique, that is a specifically designed strategy to entail molecular recognition to a nanomaterial by means of a template-assisted synthesis [2,3], but herein methacrylated silk fibroin polypeptides were used as macromolecular building blocks. Such MIP synthetic protocol was optimized with the aid of surface response method. The silk-nanotraps, called bioMIPs, were physically and functionally characterized, demonstrating high affinity binding (nM) for the targets and selectivity [4]. Enzymatic degradation of the bioMIPs was studied. The biocompatibility of the nanotraps was confirmed. The nanotraps were further labelled with fluorescent tags and tested for imaging in cell cultures [6]. The bioMIP's synthesis proved a general route for entailing recognition towards proteins or small molecules [4,5], which let foreseen applications in sequestering molecular players in the onset and progression of diseases, to tackle the onset of molecular changes in cells, and opening for translational studies with roles in long term pathologies.

Molecular Dynamics Simulations of cRGD-Conjugated PEGylated TiO_2 Nanoparticles for Targeted Photodynamic Therapy GiuliaFrigerio, PauloSiani, EdoardoDonadoni and CristianaDi Valentin; Department of Materials Science, University of Milano-Bicocca, Italy

Active targeting strategies, exploiting the biological interaction between ligands on the surface of nanoparticles and the cell targets, are known to increase the therapeutic efficacy of cancer treatments with respect to passive targeting strategies that are mainly based on the enhanced permeability and retention effect of tumor tissues. In this respect, the conjugation of nanoparticles with integrin $\alpha_V\beta_3$-affine cyclic RGD peptides (cRGD) is a promising approach in nanomedicine to efficiently reduce off-targeting effects and enhance the cellular uptake by integrin-overexpressing cancer cells.
We used atomistic molecular dynamics simulations to evaluate key structural-functional parameters of cRGD ligands conjugated to PEGylated TiO_2 nanoparticles for an effective binding activity towards $\alpha_V\beta_3$ integrins. An increasing number of ligands has been conjugated to PEG chains, grafted to highly curved TiO_2 nanoparticles, to unveil the impact of cRGD ligand density on its presentation, diffusion, and conformation in an explicit aqueous environment.
We find that a low density leads to an optimal spatial presentation of cRGD ligands out of the "stealth" PEGylated layer around the nanosystem, favoring a straight upward orientation and a spaced distribution of the targeting ligands in the bulk-water phase. On the contrary, a high density favors the clustering of cRGD ligands, driven by a concerted mechanism of enhanced ligand-ligand interactions and reduced water accessibility to the ligand's molecular surface. These findings strongly suggest that the ligand density modulation is a key factor in the design of cRGD-conjugated nanodevices to maximize their binding efficiency to over-expressed $\alpha_V\beta_3$ integrin receptors.

3:30 PM *SB03.03.02
Computer Simulations of the Interaction of Anaesthetic Molecules Fentanyl and Propofol with Biological Membranes NoraH. de Leeuw; University of Leeds, United Kingdom

Computational techniques are well placed to investigate materials and processes in the body that are difficult to access experimentally. In this work we have used all-atom computer simulations to predict the structures and behaviours with biological membranes in the cell of two important molecules in the process to induce anaesthesia, i.e. propofol and fentanyl. The lipid membrane is considered a crucial component of opioid general anaesthesia and detailed atomic-level insight into the drug-membrane interactions could lead to a better understanding how different drugs exert their anaesthetic properties.
First, we have investigated the opioid analgesic fentanyl on its own, using extensive umbrella sampling molecular dynamics simulations to study the permeation process into a variety of simple phospholipid membrane models, accurately predicting the permeability coefficients, followed by its interactions with the *Gloeobacter violaceus* ligand-gated ion channel (GLIC). The simulations have identified multiple extracellular fentanyl binding sites, which are different from the transmembrane general anaesthetic binding sites observed for propofol and other general anaesthetics, including a novel fentanyl binding site within the GLIC which results in conformational changes that inhibit conduction through the channel.
The second part of our study explicitly includes the interactions between fentanyl and propofol. General anaesthesia is a multi-drug process and our work provides the first insight into how different components in the anaesthesia process interact with each other in a relevant biological environment. For example, using flooding style and gaussian accelerated molecular dynamics (GaMD) simulations, we show fentanyl acting as a stabiliser that holds propofol within binding sites in GLIC, whereas the simulations were also able to show the pathway by which propofol physically blocks the ion-conducting channel pore, which has previously been suggested as a mechanism for ion channel modulation by propofol.

4:00 PM *SB03.03.03
Modeling Peptide-Guided Organization of 2D Materials RuitaoJin, Le NhanPham and TiffanyWalsh; Deakin University, Australia

Peptides have capability to direct organization of nanomaterials in aqueous media. However, for two dimensional (2D) nanosheet structures such as graphene, h-BN, graphene oxide and MoS_2 there is a lack of fundamental knowledge regarding structure/function relationships of the relevant bio-nano interface. Combined with experimental efforts, molecular simulations can provide new insights into the manipulation of these interfaces.[1-3] Here, a strategy based on bioconjugate hybrids of peptides and fatty acids is used to exfoliate materials into 2D nanosheets in liquid water. These simulations reveal the molecular scale characteristics of the peptide-driven exfoliation process, particularly in the role of the fatty acids in potentially reducing graphene defects in the exfoliated material.[3,4] Umbrella sampling simulations also provide new insights into both the peptide-driven exfoliation and colloidal suspension mechanisms.[5] Advancements in the simulation strategy strategy used here hinge on the ability to model peptide/h-BN and peptide/MoS_2 interfaces[6] in aqueous media, based on force-fields obtained from first-principles calculations. Replica-exchange with solute tempering molecular dynamics simulations are used to explore the contact between the peptides and the nanosheets. Ultimately the outcomes of this modeling can guide the design[7] of effective bioconjugates for exfoliation and assembly for 2D heterostructures.

4:30 PM *SB03.03.04
Multiscale Mechanics of Cancer Metastasis to Bone DineshR. Katti, SharadV. Jaswandkar, HanmantGaikwad and KalpanaKatti; North Dakota State University, United States

The World Health Organization reported that over one million deaths occur worldwide due to breast and prostate cancer. The majority of these deaths occur due to metastasis of the cancer to distant locations in the body, which for breast cancer and prostate cancer happens to be bone. At the bone site, the cancer cells colonize, proliferate, and have a very detrimental impact on the bone. Clinically, this is manifested as frequent skeletal failures. In order to recapitulate the metastasis process through a realistic testbed, we have developed an in vitro model of bone metastasis using nanoclay bone mimetic scaffolds. Experiments using commercial and patient-derived cancer cell lines to create metastasized tumors indicate significant changes to the morphology of the cancer cells based on the cancer phenotype. Also, depending on the phenotype, the mechanical properties of the cancer cells extracted from the tumors are dramatically altered. Associated with the observed changes, we observe significant changes in gene expressions related to actin and actin depolymerization factor cofilin (ADF/cofilin). Confocal imaging of cancer tumors during cancer progression reveals significant actin dynamics, both quantitatively and spatially. Label-free discrimination of cancer progression using Raman imaging and cluster analysis also reveals actin dynamics and changes to actin-related bands, which could serve as spectral biomarkers for cancer progression at the bone site. Steered molecular dynamics simulations of actin and actin with ADF/cofilin describe the mechanisms of the resilience of actin molecules and depolymerization of actin by ADF/cofilin, critical players in the actin dynamics during the cancer progression. Hence, actin remodeling plays a vital role in cancer metastasis progression and pertains to cellular behavior inside the cell. In order to evaluate the molecular phenomena outside the cell, we investigate the characteristics of integrin molecules. The integrin protein is a mechanotransducer establishing mechanical reciprocity between the extracellular matrix and cells at integrin-based adhesion sites. This protein plays a critical role in cell-ECM adhesion and cellular signaling. We conducted steered molecular dynamics (SMD) simulations to investigate the mechanical responses of integrin αvβ3 with and without ligand binding for a variety of mechanical loading paths. The ligand-binding integrin confirmed the integrin activation during equilibration by opening the hinge between βA and the hybrid domain. This activation of liganded αvβ3 integrin influenced the molecule's stiffness observed during tensile loading. Furthermore, we observed that the interface interaction between β-tail, hybrid, and epidermal growth factor domains altered integrin dynamics. The deformation of extended integrin models in the bending and unbending directions of integrin reveals the stored folding energy and the directionally dependent stiffnesses of the integrin molecule. Along with experimental data, the SMD simulations were used to evaluate the mechanical properties of integrin and identify the underlying mechanisms of integrin-based adhesion substrates. The investigation of the mechanics of integrin molecules provides new insights into understanding the mechanotransmission between cells, ECM, and the substrate. Overall the mechanotransduction facilitated by integrins to actin remodeling at the cellular insides is a critical molecular phenomenon that exists over a multiscale regime that synergistically creates the metastasis progression of cancer.

SESSION SB03.04: Synthesis, Restoration and Regeneration of Biological Hard Tissues

8:30 AM SB03.04.01
Development of Self-Assembled Organothiol-Based Nanolithography Templates for Biomimetic Synthesis of Calcium Phosphate on Amyloid-Like Amelogenin Nanoribbons JayeshDua[1], StefanHabelitz[2] and JamesJ. De Yoreo[1,3]; [1]University of Washington, United States; [2]School of Dentistry, University of California, San Francisco, United States; [3]Pacific Northwest National Laboratory, United States

Tooth enamel is the hardest tissue in the body mainly due to the intricate interwoven structure of highly organized apatite filaments that form it. It has been theorized that unidirectionally aligned (co-aligned) amyloid-like amelogenin nanoribbons (Amel NR) guide the formation of apatite by providing an energetically and stereochemically favorable scaffold for nucleation and transformation of amorphous calcium phosphate (ACP) precursor to hydroxyapatite (HAP). To understand the efficacy with which protein structures direct the nucleation of ACP and the subsequent transformation to HAP, studies have been carried out to quantitatively analyze the nucleation of ACP by self-assembled NRs of the full-length protein as well as varying sequences of peptides made up of protein subsegments responsible for self-assembly and ACP binding. Supramolecular block-copolymer templates with alternating hydrophilic and hydrophobic regions were also used to direct the self-assembly of amelogenin-derived peptide nanoribbons having discrete, spatially separated domains. These domains in turn templated the mineralization of filamentous and plate-shaped calcium phosphate. To create more versatile templates, we are using AFM-based nanolithography to create highly modifiable nanopatterns of novel organothiol monolayers self-assembled on Muscovite Mica. By using AFM probes, we perform Nanografting on monolayers of hydrophobic organothiols on Mica in predetermined patterns and backfill the patterns with hydrophilic thiols. The proposed system is similar to the block-copolymer system in its basic function, but with the capability of modifying the design on-the-fly to study the effects of geometry. While similar thiol systems on metal substrates (like nearly-atomically flat Au substrates) have been extensively studied and are even now used for a multitude of applications, the proposed system offers significantly better reproducibility, reusability, and affordability. Although the proposed system has been developed for the use of templating the growth of Amel NRs, it has the potential to be employed for a variety of other applications by modifying the surface chemistry of the Organothiol headgroups. Additionally, since Mica is the preferred substrate for the study of many soft matter systems, it provides the possibility of the direct study of many of these systems, eliminating the need for the modification of the parent molecule to enable its binding to the substrate. Monolayers of long chain alkanethiols (like the ones used on gold substrates) with average roughness ≈0.2nm have already been achieved with extremely adaptable grafting pattern thicknesses ranging from 50 nm-200 nm. By manipulating the spacing and dimensions of the 2D-patterns, as well as the composition of the mineralizing solution, we seek to find understand the controls the of scaffold geometry on nucleation and growth rates of the ACP precursor domains, as well as their transformation to HAP. Understanding how manipulating the scaffold geometry affects the fidelity of guided mineralization will move us closer towards the biomimetic synthesis of enamel-like materials.

8:45 AM SB03.04.02
Peptoid-Controlled Synthesis of Hierarchical Composite Nanomaterials Chun-LongChen; Pacific Northwest National Laboratory, United States

In nature, biominerals (e.g. bones and teeth) are excellent examples of hierarchical composite materials whose formation and functions are controlled over multiple length scales by high information content biomacromolecules. Inspired by nature, many biomimetic approaches have been developed for the design and synthesis of composite materials. These approaches are attractive because they generate complex, functional materials under mild aqueous synthetic conditions.[1,2]

As one of the most advanced classes of sequence-defined peptide-mimetics, peptoids offer tremendous opportunities for bio-controlled synthesis of hierarchical composite materials,[3,4,5] mimicking protein- and peptide-like molecular recognition. Due to the lack of backbone hydrogen bonding, tuning peptoid-peptoid and peptoid-particle interactions can be done solely by varying side-chain chemistry.[1,5] Peptoids have been exploited as programmable building blocks to assemble into higly ordered nanostructured materials with a variety of morphologies.[3,6] In this presentation, we will report our recent progress of developing self-assembling peptoids for controlled formation and morphogenesis of hierarchical composite nanomaterials. A combination of *in situ* imaging and molecular simulations were used to elucidate the principles underlying peptoid-controlled inorganic crystallization with the ultimate goal of enabling predictive materials synthesis across scales.

Freeze Casting Peptide-Enabled Biomaterials for Tissue Regeneration Ulrike G. K.Wegst; Northeastern University, United States

While considerable progress has been made over the past years and decades, the challenge persists to synthesize, ideally off-the-shelf materials and scaffolds, with structural, mechanical, and chemical cues akin to the natural tissue or custom- designed for a desired regenerative outcome. Freeze casting permits to manufacture such complex, hybrid materials with excellent control of structural and mechanical properties. As a cold process, freeze casting additionally offers several pathways to introduce what could broadly be called chemical cues such as growth factors, viral vectors and peptides at several processing steps to enhance the functional properties of the final biomaterial. Chemical cues can be introduced already before the freeze casting step

through peptide loading and peptide-functionalized components, such as collagen, chitosan, and nanocellulose for soft and hydroxyapatite and tricalcium phosphate for hard tissues, for example. Alternatively, the hierarchical architecture of the freeze-cast scaffolds can be modified with peptides or peptide-enhanced entities once the structure has been ice-templated and lyophilized (freeze-dried). Freeze casting and related manufacturing techniques therefore hold great promise for the manufacture of peptide-enabled biomaterials.

9:30 AM SB03.04.04
Biomimetic Strontium Sulfate Mineralization Studied by Multiscale Microscopy and Vibrational Spectroscopy AndrienneMartin[1], JordanHachtel[2], OliverWang[1], DawnM. Raja Somu[1], StevenA. Soini[1], DiannelleLacambra-Rivera[1] and VivianMerk[1]; [1]Florida Atlantic University, United States; [2]Oak Ridge National Laboratory, United States

In the present study, we investigated the in-vitro crystallization of strontium sulfate (celestite, $SrSO_4$) in the presence of organic matter, including the synthetic polymer poly(sodium 4-styrenesulfonate), the poly amino acid poly(*L*-glutamic acid), the polysaccharide poly(galacturonic acid) and the amino acid *L*-aspartic acid. In nature, biogenic $SrSO_4$ occurs in the skeleton of the unicellular plankton organisms Acantharia[3],[4]. These biomineral model systems closely mimic fundamental interactions between mineral and organic matrix in living organisms, while eliminating the complexity and heterogeneity associated with biological systems. This investigation enabled a focused fundamental investigation of $SrSO_4$ crystallization across multiple length scales, as biologically grown minerals often contain a variety of organic molecules in small weight percentages as well as considerable amounts of foreign ions, such as magnesium, which complicate data interpretation[1],[2]. Even though all studied biomolecules were included into the growing crystals in high weight percentages, poly(*L*-glutamic acid) had the most profound impact on crystal morphology. Using Scanning Electron Microscopy and Atomic Force Microscopy, we observed mesocrystalline features on the crystal surface, which are consistent with biomolecule incorporation. Apart from studying the chemistry of the nanocomposites using bulk infrared spectroscopy, we discerned intracrystalline organics at the nanoscale using monochromated Electron Energy-loss Spectroscopy in the Scanning Transmission Electron Microscope[5],[6]. By screening the organic-biomineral model systems with synchrotron X-ray powder diffraction[1],[2], we quantified the degree of internal residual strain resulting from biomolecules with diverse functional group chemistry.

Emulating Nature's Way of Making Materials JamesJ. De Yoreo[1,2]; [1]Pacific Northwest National Laboratory, United States; [2]University of Washington, United States

From harvesting solar energy to capturing CO_2 to purifying water, living organisms have solved some of the most vexing challenges now faced by humanity. They have done so by creating a vast library of proteins and other macromolecules that can assemble into complex architectures and direct the mineralization of inorganic components to produce materials characterized by a hierarchy of structure. While the high information content contained within the intricate sequences of the proteins is crucial for accomplishing these tasks, self-assembly and mineralization are nonetheless constrained to proceed according to the physical laws that govern all such processes, even in synthetic systems. An understanding of the mechanisms by which biological systems successfully manipulate those laws to create hierarchical materials would usher in an era of materials design to address our most pressing technological challenges. In this talk, I will present the results of recent research using in situ atomic force microscopy and in situ transmission electron microscopy to directly observe interfacial structure, protein self-assembly, and nanocrystal formation in biomolecular and biomimetic systems, including protein-directed nucleation of calcium carbonate and calcium phosphate and surface-directed nucleation of two-dimensional protein assemblies. The results elucidate the mechanisms by which the interface between biomolecules and materials directs nucleation, self-assembly and crystal growth, leading to unique materials and morphologies. The results reveal the importance of surface charge, facet-specific binding, solvent organization, and, more generally, the balance of protein-substrate-solvent interactions in determining how organized materials emerge in these systems.

Degradation of Natural Molecules on Mineral Surfaces ColinFreeman[1], BiaFonseca[2], MatthewCollins[2,3] and KarinaSand[2]; [1]University of Sheffield, United Kingdom; [2]University of Copenhagen, Denmark; [3]University of Cambridge, United Kingdom

Molecular binding at material interfaces is vitally important within a range of contexts. When a molecule has bound to a surface its structure and that structure of the local solvent can be very different to that in solution which can change its functionality and reactivity. In biology deamidisation and hydrolysis are two very common processes to break up peptides and both dependent on water molecules; therefore understanding the behaviour of the solvent molecules is equally important as that of the biologically active binding molecule. These decay processes are very important in a range of scientific fields including archaeology, palaeontology and surface fouling. Peptides extracted from archaeological digs can be used to indicate the diet and patterns of early humans, while DNA and proteins can be used to provide information on evolution in the fossil record.

We present a combined molecular dynamics and atomic force microscopy study on the binding of biological relevant molecules to calcite mineral surfaces. Out study examines and identifies the key factors involved in the binding of these molecules to the surfaces. We then explore the structural changes in these molecules and how this exposes/shields them from reactive processes that could lead to their decay. Finally we examine the behaviour of the other reactant species (solvent) and determine the role of the surface in enhancing or hindering their contribution to degradation reactions [1]. With this information we are able to comment on recent experimental findings and the potential preservation of different biological molecules.

Optimizing the Information-To-Damage Ratio in Transmission Electron Microscopy of Beam-Sensitive Materials BryanReed[1], RuthS. Bloom[1], GonzaloEyzaguirre[1], AbdolrezaMoghadam[1], CurtHenrichs[1], DanielJ. Masiel[1], HirokiHashiguchi[2], KazukiYagi[2,1], YuJimbo[2], JonathanPeters[3] and LewysJones[3]; [1]IDES, Inc., United States; [2]JEOL, Ltd., Japan; [3]Trinity College Dublin, The University of Dublin, Ireland

One of the biggest challenges in transmission electron microscopy (TEM) of biological materials is their high radiation sensitivity coupled with low contrast, making it hard to extract the desired information before the material is destroyed. There has been considerable progress on this problem, including improvements in sample preparation, data analysis, measurement technique, and dose-efficient acquisition strategies such as ptychography.

We believe that even more can be done, through high-speed timing systems that coordinate signal processing, data analysis, and beam current modulation. Guided by the mathematics of information theory and sparsity-based multidimensional data processing, we will outline a vision that combines ptychography, per-pixel dose modulation, adaptive sampling, and real-time signal response towards maximizing the ratio of relevant information to damage.

A key enabling technology is electrostatic dose modulation (EDM), using a fast electrostatic beam blanker to control exposure times and, using pulse width modulation, beam current. By synchronizing EDM with the timing control signals from a scan generator, we can precisely control the dose in every single pixel of a large scan. This can be done iteratively, using the data returned from previous scans to decide exactly when and where to apportion the dose in future scans. This methodology will enable closed-loop automated data capture, inserting any desired algorithms (machine learning, Bayesian, sparsity-based, etc.) into the loop to customize the acquisition to specific applications.

Improving the ratio of relevant information to damage can be done by:
Increasing the information-to-dose ratio: Using information theory to guide where to put your electron budget to learn the most and when to move on.

Increasing the fraction of relevant information: Adaptive sampling and spatial dose modulation to measure the components you care most about while avoiding delocalized damage from the irradiation of nearby uninteresting material.
Making the best use of the information you collect: Data analysis that takes the best lessons from the compressive sensing literature to leverage prior knowledge into better images.
Reducing the damage-to-dose ratio: Optimally spreading the dose in space and time to limit nonlinear damage effects, and automatically limiting the exposure of any included high-atomic-number material with its associated high energy deposition rate.

These are not mutually exclusive; with a sufficiently advanced, configurable acquisition automation system, one could do all of these at once, compounding the advantages from each. In the end, the microscope stops being a passive tool for taking images to be interpreted by the user and starts being an active participant, seeking out and optimally collecting the information you actually need while carefully minimizing damage to the sample.

Biomaterialomics: Convergence of Data Science with Biomaterials Science BikramjitBasu; Indian Institute of Science, India

Conventional approaches utilise intuitive tailoring of manufacturing protocols and biocompatibility assessment, while developing new biomaterials and implants; leading to longer development cycles, and high costs. For the patient care, it is critical to accelerate the production of implantable biomaterials, implants and biomedical devices. In this perspective, the concept 'Biomaterialomics' (Acta Biomaterialia, 2022) as the integration of high-throughput biocompatibility data together with multiscale physics-based models, E-platform/online databases of clinical studies, with artificial intelligence (AI) tools, will be introduced and discussed in this presentation. It will be argued that such approach will enable the development of the fourth-generation biomaterials and implants, whose clinical performance will be predicted using 'digital twins'. A few representative examples to illustrate the formulation and relevance of the 'Biomaterialomics' approaches for three emerging research themes - patient-specific implants, additive manufacturing, and bioelectronic medicine, will be presented. For example, the high-throughput FEA-analysed biomechanical response (~12, 000 datasets) in tandem with Machine Learning (ML) algorithms and uncertainty predictions were analysed, to accelerate the optimal design of acetabular socket for better bone remodeling. While validating the computational predictions, Bikramjit's group used the Laser- Powder Bed Fusion (L-PBF)-based metal additive manufacturing (AM) of parts with designed features. His group implemented a data science approach to analysing a small volume of processing results (~120 datasets) to reliably predict the weld pool geometry (depth, height, width) and used the optimized parameters to manufacture biomaterial implants with clinically acceptable surface topography and lattice features. In both these exemplary studies, a number of ML algorithms (linear regression, K-nearest neighbour, support vector machines, etc.) were used and the best statistical significance was obtained using Random Forest (RF) algorithm, in terms of correlation coefficient (R^2: 0.99/0.97) and root mean square error (RMSE: 0.02/0.01) on the training/test dataset, in less than a minute.

Multiplexed Breath Biopsy of Lung Disease by Controlled Chemical Signal Activation Shih-TingWang, MelodiAnahtar, DanielKim, TahouraSamad, CathyWang, SahilPatel, ChayanonNgambenjawong, JesseKirkpatrick, HeatherFleming and SangeetaBhatia; Massachusetts Institute of Technology, United States

Breath testing is a fast, non-invasive diagnostic method that can link specific volatile organic compounds (VOCs) in exhaled breath to medical conditions. Complementary to blood and urine assays in clinical disease diagnosis, breath is an informative analyte that can provide real-time information of changes in the body's metabolome affected by disease activity. However, few breath tests are currently used in the clinic to monitor disease due to bottlenecks in biomarker identification and differentiation of endogenous VOCs in complex breath signatures. One approach to overcome this challenge is the in vivo administration of orthogonal exogenous agents with controlled properties that can be expelled from breath upon being metabolized by disease-specific molecular processes. Exogenous agents have been used in clinical breath tests for gastrointestinal and liver diseases and are more recently developed for respiratory disease. As the direct source of breath, the lungs are particularly suited for enzymatic activity-based breath tests. The multiplexed capabilities of designing reliable in vivo probes that release detectable and distinguishable exogenous VOCs are still in the early stages. Here, we report engineered breath biomarkers by protease-sensing nanoparticles for multiplexed detection of dysregulated activities of pulmonary proteases in response to disease and produce volatile reporters that can be detected in the exhaled breath. We show that the nature of proteolytic hydrolysis generating peptide fragments can be engineered to activate and release various types of volatile reporters. Using viral infection and *Alk*-mutant lung cancer mouse models, we show that multiplexed volatile-releasing activity-based nanosensors (vABNs) can detect and dynamically monitor diseases and treatment response.

1:45 PM SB03.05.02
Peptide-Functionalized Graphene Sensors for Selective Odorant Detection YuheiHayamizu; Tokyo Institute of Technology, Japan

Gas sensing based on graphene field-effect transistors (GFETs) has gained broad interest due to their high sensitivity. Further progress in gas sensing with GFETs requires the detection of various odor molecules for applications in environmental monitoring, healthcare, food, and cosmetic industries. To establish an artificial sense of smell with electronic devices by mimicking olfactory receptors, it is desirable to use synthetic molecules with similar functionality. In this work, we designed three new peptides based on a motif sequence in olfactory receptors. These peptides were designed to have two domains: a bio-probe specific to the target molecules and a molecular scaffold [1,2]. The scaffold peptides have the ability to self-assemble into a molecular thin film on GFETs [3].
To demonstrate the biosensing capabilities, we employed limonene, methyl salicylate, and menthol as representative odor molecules of plant flavors. We investigated the conductivity change of GFETs upon binding to odor molecules at various concentrations. The dynamic response of the sensors revealed distinct signatures for each of the three different peptides against individual target molecules. The kinetic response of each peptide exhibited characteristic time constants in the adsorption and desorption processes, which were further supported by principal component analysis. These results demonstrate the selectivity of the designed peptides in detecting odor molecules.
The development of graphene odor sensors using these designed peptides paves the way for future peptide-array sensors with multiple sequences, enabling the realization of an odor-sensing system with higher selectivity. Combining the bio-probe and electrical signal amplification functions, the peptide layer on graphene represents a novel and effective strategy for achieving selective odorant detection under normal atmospheric conditions. This research contributes to the advancement of biomimetic devices and holds potential for various applications in odor detection and identification.
This work was supported by the Cabinet Office (CAO), Cross-ministerial Strategic Innovation Promotion Program (SIP), "Intelligent Processing Infrastructure of Cyber and Physical Systems" (funding agency: NEDO).

Polymorphs of Short-Sequence Peptoid Assembly on MoS_2ShuaiZhang[1], Chun-LongChen[2] and JamesJ. De Yoreo[2]; [1]University of Washington, United States; [2]Pacific Northwest National Laboratory, United States

Peptoid is a biomimetic polymer inspired by peptide, with compatible bio-functions but better thermal and chemical stabilities. It has unique capabilities for creating hierarchical assemblies at solid-liquid interfaces, serving as templates for convincing applications in molecular recognition, fabrication of bio-hybrid materials, (bio)mineralization, energy conversion, storage, and transportation of matter and information, etc.
Recently, we designed short peptoid sequences with assembly capabilities on MoS_2. Using substrates with different hydrophobicity and adjusting the sizes of peptoid hydrophobic side chains and the dehydration process, we demonstrated that the peptoid assembly on MoS2 could have diverse phases, including the monolayer hybrid film with high crystallinity, vesicles, lamella, and single-/multi-strands. We further resolved that these phases can co-exist in a complicated phase diagram and can go through phase transitions between each other. Specifically, the peptoid-

peptoid interaction, peptoid-solvent interaction, and peptoid-MoS_2 interaction, mediated by pH, play crucial roles in this polymorph assembly. These results improve the knowledge of designing hierarchical architectures with biomolecules at solid-liquid interfaces. It also provides opportunities to optimize the future performance of 2D van der Waals materials-based devices.

2:15 PM *SB03.05.04
Subnanoscale Imaging of Nano-Bio Interfaces by 2D and 3D AFM Imaging Techniques TakeshiFukuma; Kanazawa University, Japan

Atomic force microscopy is a powerful technique that can visualize atomic- or molecular-scale structures, dynamics and properties even in liquids regardless of the conductivity of the sample. In the past decade, there has been significant advancement in the in-liquid AFM techniques. Owing to the development of low noise cantilever deflection sensors[1] and small amplitude operation mode, atomic or molecular resolution can be achieved routinely even with dynamic-mode AFM such as frequency modulation[2] and amplitude modulation AFM (FM- and AM-AFM). This allowed us to visualize subnanoscale surface structures of various biological samples[3]. In addition, the tip scanning scheme has been expanded from 2D to 3D[4] and now we can visualize the 3D distribution of water (i.e., hydration structures), organic solvents, ionic liquids and flexible molecular chains[5-7]. These unique capabilities should be particularly useful in the studies of nano-bio interfaces, where biomolecules, water and ions interact with each other to induce various biological phenomena. However, their applications to the studies on biomaterials have yet been limited. In this presentation, I would like to present our recent works to explore applications of high-resolution in-liquid AFM techniques to studies on nano-bio interfaces. Examples include molecular-scale investigations on cellulose[8] and chitin[9] nanocrystals and self-assembled structures of short peptides on graphite[10].

Atom-Condensed Reactivity Descriptors for the Prediction of Biomaterials Degradation IsaacVidal-Daza[1,2], AnnaBachs-Herrera[1] and FranciscoMartin-Martinez[1]; [1]Swansea University, United Kingdom; [2]University of Granada, Spain

Nature has been traditionally mimicked in the design of biomaterials for her capacity to achieve performance, but not that often for her ability to degrade at the end of life. To design materials for degradation as well as performance, molecular degradation needs to be better modelled. Degradation is a complex phenomenon largely dependent on the molecular system, the environmental conditions, and the timescales being considered. A common factor in the degradation process is molecular reactivity, which can be predicted using conceptual density functional theory (DFT). Conceptual DFT reactivity descriptors either quantify the global tendency of a molecule to engage in chemical reactions or the areas of the molecule that would undergo such engagement, but these global and local reactivity descriptors are usually detached. Atomic reactivity is not usually quantified in relation to the global molecular reactivity, and it limits our ability to accurately predict degradation. In fact, quantifying the reactivity of any individual atom within the global reactivity of a molecule, is not a trivial task, and it requires the conjunction of different theories in the framework of quantum chemistry. In this work, we combine a topological analysis of the electron density with a non-arbitrary partition of the molecular space into atomic domains to define topology-based atom-condensed reactivity indexes to predict molecular degradation. High-throughput calculations of these *ab initio* atom-condensed reactivity descriptors enabled the analysis and identification of existing patterns among data, which provides a better understanding of molecular reactivity, and the definition of new indexes that describe the local reactivity of individual atoms, in the global reactivity of target molecules. The data generated can be used to train machine learning (ML) models that predict molecular and biomaterials degradation.

3:30 PM *SB03.05.06
Peptide Designs for On-Demand Multifunctional Surface Functionalization NuritAshkenasy; Ben Gurion University of the Negev, Israel

The development of high-performance devices demands tailoring the properties of surfaces and interfaces of materials. The control of surface properties can be achieved by attaching organic monolayers to the surface. In this talk, I will discuss the design of peptide-based functionalization layers and show that such functionalization layers exploit unique properties of proteins including diversity, modularity, and multi-functionality. Hence, open the way to design highly tunable and smart surfaces.
In the first part of the talk, I will demonstrate *the use of surface binding peptides (SPBs) to tailor the electronic properties of surfaces. The effect of peptide side chains and their backbone connectivity and folding state on the resulting electronic properties will be discussed. I will further show that SPBs can be used to template syntheses of thin films with specifically tailored surface properties in an environmentally friendly approach. The use of such films for volatile organic compound sensing will be demonstrated.*
The utilization of the unique properties of peptides for the development of programmable surfaces will be demonstrated in the second part of the talk. I will present the design of a coiled-coil peptide system in which folding and chemical reactivity is responsive to external stimuli. The responsivity of the system facilitates the ability to control the binding of the peptides to the surface and/ or their folding state, which affects the surface's physico-chemical properties in a reversible manner. These smart dynamic surfaces enable the realization chemically induced computation elements using the surface properties as the readout. The feasibility of applying this approach in biosensing will be demonstrated.
Overall, our work provides a sophisticated surface engineering approach, based on peptide sequence design, which can be utilized in diverse electronics, biotechnology, and medical applications.

4:00 PM *SB03.05.07
Design of Bioinspired Sustainable Materials from Atoms to Micrometers with Molecular Precision—Integration of Simulations, Large Data and Experiments HendrikHeinz; University of Colorado at Boulder, United States

The development of materials inspired by Nature continues to involve extensive trial-and-error studies by experiments. Rational understanding and accelerated design using modeling, simulation, and data science to guide laboratory studies is increasingly feasible due to more accurate models and affordable computing resources. A promising technique to predict materials properties from atoms to the micrometer scale is molecular dynamics simulation in combination with quantum methods and experiments. This talk focuses on advanced simulation techniques and using the Interface Force Field (IFF) and recent cyberinfrastructure implementations in CHARMM-GUI. The tools allow us to understand molecular recognition, assembly, and reactivity of metal, mineral, and polymer nanostructures for diverse applications in 10 to 100 times higher accuracy than possible before. We will describe advances in the representation of chemical bonding, surface chemistry, and electrolyte composition along with scalable validation against experimental data. Major applications concern the tailoring of inorganic nanostructures and interactions with peptides and proteins, understanding of nanocrystal growth and morphology, and design rules for molecular recognition and self-assembly in 4D spatial and temporal resolution. Specifically, we will explain the recognition of amino acids and organic molecules on (hkl) surfaces of hydroxyapatite and ceramic nanoparticles at different pH values, metal surfaces, and 2D materials such as graphene and MoS2. Comparisons to cutting-edge imaging (TEM, AFM), spectroscopy, chirality measurements (VCD), and calorimetry (TPD, SCAC) will be explained. We will also discuss design guidelines for stealth coatings on nanoparticle surfaces using multi-segment ligands, along with implications for the formation of protein coronas. Some applications to ultrastrong bioinspired composites include accelerated predictions of stress-strain curves up to failure using new bond breaking potentials in IFF-R and comparisons to strengths and modulus. Potential applications include biosensors, pharmaceuticals, and structural bioinspired composites. In this talk, we will examine why and how MD simulations of inorganic-organic interfaces with IFF outperform the reliability of DFT simulations and other simulation methods by multiples. Future directions include advancements in open-source cyberinfrastructure to lower the entrance barrier for non-expert users and suitable data science tools to learn and interpret the information contained in large computational and experimental data sets to accelerate property predictions and integration with laboratory testing.

4:30 PM *SB03.05.08
Complex Biomechanics: From Atoms to Patients ChristianHellmich, JohannesKalliauer, NiketaUkaj and StefanScheiner; TU Wien - Vienna University of Technology, Austria

Complex systems are characterized by an overall behavior which is different from that of the components making up the systems - hence, (nonlinear) interactions between the components play a very important role. Taking an interdisciplinary approach rooted in theoretical and applied mechanics and engineering mechanics, we report on two types of recently studied systems where individual system components (atoms and patients) interact in a way which unfolds very interesting emerging patterns that can be mathematically quantified through concepts arising from (bio-)mechanics: (i) the interaction of atoms within a short thread of DNA, which, as a compound, result in a family of a highly nonlinear beam structures with varying, but always coupled

torsion-stretching modes [1]; (ii) the compliance of sets of patients to the lethal effect of SARS-COV-2 [2,3], which follows integro-differential equations reminiscent of those introduced by Boltzmann in the context of creep (or hereditary) mechanics [4]. We conclude that smart classical concepts of applied mechanics and physics continue to show an unparalleled potential for solving pressing global problems in the context of computational modelling of living systems.

SESSION SB03.06: Poster Session
Session Chairs: Hanson Fong and Deniz Yucesoy
Tuesday Afternoon, November28, 2023
Hynes, Level 1, Hall A

8:00 PM SB03.06.01
Breast Cancer Detection using Shear Assay Based Creep Compliance and Functional Principal Component Analysis JoleneCao[1], KillianOnwudiwe[2], JingjieHu[3], MeenalDatta[2] and WinstonO. Soboyejo[1]; [1]Worcester Polytechnic Institute (WPI), United States; [2]University of Notre Dame, United States; [3]North Carolina State University, United States

This presents the mechanical responses of live cells that are subjected to shear flow in micro-fluidic channels under *in-situ* observation with optical, fluorescence, and confocal microscopy. The resulting time-dependent deformation of points within the cells is analyzed using Digital Image Correlation (DIC) techniques. These are used to extract deformation and strain maps of the nuclei, cytoplasm, and actin cytoskeletal structures at different stages of cell viscoelastic deformation. The measured temporal variations in strain are analyzed using Functional Principal Component Analysis (FPCA) approaches (from data science) that use time series data to extract critical features from the *in-situ* temporal creep responses of cells subjected to shear stress. Differences in the creep responses of the nuclei and cytoplasm are elucidated along with the local creep properties of the actin cytoskeletal structures of non-tumorigenic breast cells (MCF-10A), less metastatic triple-negative breast cancer (TNBC) cells (MDA-MB-468), and highly metastatic breast cancer cells (MDA-MB-231). The implications of the results are also discussed for the detection of non-tumorigenic and tumorigenic breast cells at different stages of cancer progression.

Keywords: breast cancer detection, micro-fluidics, shear assay creep compliance, functional principal component analysis, time series data, cell nuclei, cytoplasm and cytoskeletal structures.

8:00 PM SB03.06.02
Deep Learning-Assisted Sensitive Detection of Fentanyl using a Bubbling-Microchip HuiChen, SungwanKim, JosephHardie, PrudhviThirumalaraju, ManojKanakasabapathy and HadiShafiee; Brigham and Women's Hospital, United States

Deep learning-enabled smartphone-based image processing has significant advantages in the development of point-of-care diagnostics. Conventionally, most deep-learning applications require task specific large scale expertly annotated datasets. Therefore, these algorithms are oftentimes limited only to applications that have large retrospective datasets available for network development. Here, we report the possibility of utilizing adversarial neural networks to overcome this challenge by expanding the utility of non-specific data for the development deep learning models. As a clinical model, we report the detection of fentanyl, a small molecular weight drug that is a type of opioid, at the point-of-care using a deep-learning empowered smartphone assay. We used the catalytic property of platinum nanoparticles (PtNPs) in a smartphone-empowered microchip bubbling assay to achieve high analytical sensitivity (detecting fentanyl at concentrations as low as 0.23 ng/mL in phosphate buffered saline (PBS), 0.43 ng/mL in human serum and 0.64 ng/mL in artificial human urine). Image-based inferences were made by our adversarial-based SPyDERMAN network that was developed using a limited dataset of 104 smartphone images of microchips with bubble signals from tests performed with known fentanyl concentrations and using our retrospective library of 17,573 non-specific bubbling-microchip images. The accuracy (± standard error of mean) of the developed system in determining the presence of fentanyl when using a cutoff concentration of 1 ng/mL, was 92.66±0.3% in human serum (n=100) and 94.66±1.2% in artificial human urine (n=100).

8:00 PM SB03.06.03
***Euglena gracilis*–Derived Extracellular Vesicles as a Natural Immune Modulator**SaetbyeolJeon, HwiraBaek and Jin WoongKim; Sungkyunkwan University, Korea (the Republic of)

Since extracellular vesicles (EVs) possess the same cell therapeutic effect due to its similar characteristics to parent cells, they have emerged as an attractive alternative to cell therapy. Taking advantage of this, a variety of EVs have been developed for tissue regeneration, anti-cancer immunotherapy, and intractable disease treatment. In terms of therapeutic application, microalgae-derived EVs has been of great interest because they contain unique physiologically active substances such as polysaccharides, minerals, vitamins and amino acids. However, most microalgae cells are structured with a strong cell membrane which is not easily cleaved and recombine to form EVs. The derivation of EVs from *Euglena gracilis* (*EG*), a microalgae species, warrants special attention due to its relatively flexible cell membrane. Moreover, it can be cultivated in substantial quantities, providing a valuable resource for production purpose while mitigating the risk of viral infection. In this study, we introduce an *EG*-derived EV (EV_{EG}) system with an enhanced immune performance. β-1,3-glucan, which is specifically accumulated in *EG* cells, is a representative substance that activates natural killer cells and macrophages to enhance natural immunity. To efficiently deliver β-1,3-glucan present in the *EG* to immune cells, the EV_{EG} are fabricated by cell extrusion method that can convert cells into vesicles by sequentially passing several micro-sized pores. Basically, the endocytosis mechanism study on the EV_{EG} exhibited notable cellular uptake compared to β-1,3-glucan only. We verified that the EV_{EG} fabricated in this study notably stimulated the mitogen activated protein kinase (MAPK) pathway, resulting in release of inflammatory mediators such as nitro oxide, cyclooxygenase-2 (COX-2) and pro-inflammatory cytokines. The expression level of these immune factors was appropriately leveled to strengthen the immune system, not excessively inducing immune response such as cytokine storms. We also showed that the -1,3-glucan encapsulated in the EV_{EG}, like other polysaccharides, was readily recognized by receptors such as Dectin-1 and TLR4 present on immune cell membranes. These results highlight that our EV_{EG} immunomodulatory system has potential for health promotion and disease treatment in various biomedical applications.

8:00 PM SB03.06.04
Deep Learning-Assisted Nanoplasmonic Digital Immunoassay for Cytokine Profiling in Immune-Suppressed Patients using Designed Peptide Aptamers ShuaiWu, LangZhou and PengyuChen; Auburn University, United States

Cytokine profiling in immune-suppressed patients plays a critical role in understanding their immune status and evaluating the effectiveness of immunomodulatory therapies. However, current immunoassay technologies face challenges in achieving rapid and accurate detection of multiple cytokines over a wide dynamic range. In this study, we propose a novel approach that combines deep learning with a nanoplasmonic digital immunoassay using rationally designed peptide aptamers as probes.
The immunoassay system exhibits three notable features: (i) a simplified high-throughput biosensing chip fabrication process, (ii) an ultrasensitive nanoplasmonic digital imaging technique employing 50nm gold nanocubes (AuNCs) conjugated with antibody-mimicking peptide aptamers as detection probes, and (iii) a rapid and precise deep learning-based image processing method for digital signal analysis.
By utilizing our developed immunoassay, we successfully achieved cytokine profiling with a wide working range of 0.1-10,000 picograms per milliliter (pg/ml) and exceptional detection limits in the femtogram range. This level of sensitivity enables the accurate detection of even trace amounts of cytokines, critical for monitoring immune-suppressed patients.
Our findings demonstrate that this deep learning-assisted nanoplasmonic digital immunoassay, utilizing designed peptide aptamers, holds great potential for precise cytokine profiling in immune-suppressed patients. This innovative approach may contribute to improved clinical outcomes and informed treatment decisions for individuals with rapidly inflammatory disorders and immune suppression.

8:00 PM SB03.06.05
Electrochemical Activity of Molecular Hybrids: Self-Assembly of (XH)4 Peptides and Hemin on Graphite Electrodes MarieSugiyama, WeiLuo and YuheiHayamizu; Tokyo Institute of Technology, Japan

The development of artificial enzymes has gained interest in electrochemical biosensors because natural enzymes have a relatively short lifetime and high cost for practical applications. Peptides with a small number of amino acids compared with proteins can be synthesized and chemically stable, thus they can be a good candidate as an artificial enzyme. Short-chain peptides that self-assemble into fiber-like structures in liquid are known to be catalytically active by forming complex structures with cofactors [1]. These catalytically-active peptides often contain

histidine, which plays a role in stabilizing the structure and coordinating with cofactors at the imidazole group on the side chain, enhancing the catalytic activity. In our previous work, we found that catalytic peptides containing histidine exhibited their self-assembly on graphite surfaces and revealed electrocatalytic activity combined with the coenzyme hemin [2]. More recent work showed that newly-designed peptides (XH peptides) consisting of a repeating structure of two amino acids with histidine and another amino acid, “X”, also exhibited self-assembly on graphite surfaces. These peptides are a useful tool for understanding the role of the counter amino acid X on their surface self-assembly and in tuning the hydrophobicity of the graphite surface [3].
However, the capability of this XH peptide to immobilize cofactor hemins has not yet been investigated. In this study, we studied the interaction between hemin and the (XH)4 peptide on the surface of a graphite electrode by atomic force microscopy (AFM). Three counter amino acids, tyrosine (Y), valine (V), and leucine (L), were employed as counter amino acids X for this study, e.g. YHYHYHYH. AFM showed that each peptide formed uniform linear structures with a height of a few nanometers. They also showed a hexagonal symmetry on the graphite surface, which is commensurate with the lattice structures of graphite. When the cofactor hemin was added, dot-like structures with a height of 0.5 nm~1 nm appeared on the peptide nanowires. The peptide with the highest number of particles on the peptide and the smallest particle size was LH4, followed by VH4 and YH4. Assuming that the particles on the wire were hemins, the XH peptide can be a suitable scaffold for immobilizing hemin. We also performed the electrochemical measurement to evaluate the hydrogen peroxide reduction capacity of the prepared XH peptide-hemin electrodes, and it was found that these peptides with a simple sequence of XH have enzymatic activity. The observations implied that the activity is closely related to the interactions with the hemin and peptides regarding the surface density of the immobilized hemins and their structural stability.

8:00 PM SB03.06.06
Graphene Biosensors for Probing Molecular Interactions of Peptides and RNA Forming Liquid-Liquid Phase Separation KantaroKikuchi, YuiYamazaki and YuheiHayamizu; Tokyo Institute of Technology, Japan

Amyotrophic lateral sclerosis (ALS) is a fatal motor neuron disease affecting both upper and lower motor neurons. Frontotemporal dementia (FTD) is a type of brain disorder with degeneration of the frontal and temporal lobes of the cerebrum. These neurogenerative diseases share the expansion of GGGGCC hexanucleotide repeats in the C9orf72 gene, identified as a major cause of the diseases [1]. The gene produces dipeptide repeats proteins (DPRs) that cause cell death. These peptides contained arginine (Arg) and counter amino acid in the dipeptide sequence and were found to form liquid-liquid phase separation (LLPS), closely related to their cytotoxicity. A previous report indicated that poly-R is highly charged and interacts with anionic molecules such as RNA but exerts no cytotoxic effect. Poly(PR) and poly(GR), on the other hand, entraps proteins via multivalent interaction in LLPS, impairing protein translation. Thus, it is known that the position of Arg in DPRs profoundly affects the interaction [2]. These findings indicate that the interactions between DPRs and RNA should be unique to form LLPS and entrapment the proteins. However, the understanding of the interactions of DPRs is still limited because of the lack of measurement techniques that can distinguish the weak interactions among them.
In this study, we applied graphene field effect transistors (GFETs) to evaluate the biomolecular interactions. Graphene has excellent electrical properties and high specific surface area and has recently shown promise as an ultra-sensitive biosensor. The interaction between biomolecules in the vicinity of the graphene surface can be detected as an electrical conduction change of graphene. We immobilized RNA on the graphene surface via pyrene anchors, as same in other works, and measured the interactions of RNA with DPRs known to form LLPS. The interactions are measured by incubating the DRPs of interest across the RNA-functionalized surface. Atomic force microscopy (AFM) was used to ensure these surface modifications. In electrical measurements, the peptides interacting with the RNA were quantified by the shift of the charge-neutral points in their gate responses of GFETs, and differences in interactions due to peptide species were discussed. From the results, we succeeded in detecting the difference in interaction with RNA by peptide species with high sensitivity at the nano-molar level. We believe that this result is helpful in quantitatively discussing the effect of small amino acid domains of biomolecules on LLPS droplet formation, an event that occurs on a microscopic scale.

8:00 PM SB03.06.07
Layer-by-Layer Nanoparticles for Dexamethasone Targeted Delivery to Hematopoietic Progenitor Cells AlfonsoRestrepo[1], TamaraDacoba[2] and PaulaT. Hammond[1,2]; [1]Massachusetts Institute of Technology, United States; [2]Koch Institute for Integrative Cancer Research, United States

Acute myeloid leukemia (AML) and acute lymphoblastic leukemia (ALL) have particularly dismal patient outcomes, with low 5-year survival rates in adult patients. Outcomes in pediatric patients are more optimistic, mainly due to their ability to withstand more aggressive treatment regimens. Glucocorticoids, although used as a standard treatment, can have severe adverse effects that limit dosing regimens. To address these challenges, directing drugs to hematopoietic progenitor cells implicated in these leukemias via targeted drug delivery therapies would allow for more aggressive and effective treatments, with reduced side effects. Layer-by-layer (LbL) nanoparticles (NPs) are a modular drug delivery system that enables the incorporation of a wide range of charged polymers on the surfaces of a drug-loaded NP core, to tune surface properties, targeting capacity, and biodistribution of NPs. The outer polymers can also be used as scaffolds to conjugate molecules, like antibodies, to aid in targeting drugs to cells of interest. In this work, we developed LbL NPs with dexamethasone loaded in the liposome core and functionalized them with polymers and antibodies to evaluate their targeting capacity to hematopoietic stem and progenitor cells (HSPCs) implicated in AML and ALL.

Dexamethasone palmitate (DXP) was incorporated as part of the lipid bilayer of liposomes using lipid hydration. Drug concentrations were measured via high-performance liquid chromatography (HPLC). Negatively-charged liposomes, empty or encapsulated with DXP, were layered with a cationic polypeptide, followed by a layer of anionic synthetic polymer on top. HSPC-targeting antibodies were then conjugated onto the top polymer layer. NP size and surface charge were monitored throughout the process via dynamic light scattering. NP concentration was determined via fluorescence intensity measurements of dye-conjugated lipids in the liposomal core. A bicinchoninic acid (BCA) assay was used to assess antibody concentration after purification. NP-cell association studies were conducted via fluorescence-activated cell sorting (FACS).

Antibodies were successfully conjugated to the NPs, with no notable impact on their physicochemical properties when measured over a 2-month period. Furthermore, antibody-functionalized LbL NPs demonstrated preferential association with a relevant myeloid progenitor-like cell line (ER-HOXB8), following 90-minute incubation. In fact, two candidate antibodies had a 1.5-fold increase in NP-cell association compared to unconjugated LbL NPs. For DXP-loaded NPs, it was found that the presence of the drug in the liposomal core had minimal impact on the stability of the NP throughout the layering process, with negligible changes in drug loading. Preliminary longitudinal studies found that the presence of the drug had no notable impact on the colloidal stability of the LbL NPs.

Overall, we have shown that LbL NPs can be functionalized with HSC-targeting antibodies, with a preferential association to relevant cell lines, and that the LbL construction of NPs is unhindered by the presence of DXP in the core. Future work would involve combining the drug-loaded NPs and functionalizing them with the candidate antibodies to ensure that similar preferential association is observed in relevant *in vitro* and *in vivo* models of acute leukemias.

Two-Dimensional Flexible Mechanism Design Bioinspired from Sea Horse TailGüncem OcakÜnsal, CerenOzcan, GorkemGonen, HandeYaprak, GulistanMese and VirginiaCouch; Izmir Institute of Technology, Turkey

Flexibility plays a key role in architecture as it harmoniously intertwines the functional requirements of everyday life with the inherent potential and adaptability of architectural design. In the current architectural landscape, various solutions have been proposed to incorporate flexibility into structures. They primarily focus on unidirectional movement. Therefore, these possess certain shortcomings which limit their capacity to address the ever-changing demands of dynamic environmental conditions and user requirements effectively and comprehensively. The aim of this study is to create a system that provides flexibility and adaptability in a bidirectional manner. While doing this research, we were inspired by nature, the most compelling and flawless system, which provides us with reliable and creative results. To provide two-dimensional flexibility, this study examines a system proposal inspired by the seahorse tail. Our methodology involves the initial design concept through meticulous desktop research and research-based initial drawings followed by the finalization of the proposed design and the fabrication of a prototype using a state-of-the-art 3D printer. The seahorse tail has a special articulation driven by a complex system of muscles, tendons, and bones, providing high flexibility in multiple directions. The joints of the seahorse tail exhibit distinctive characteristics and allow for specific types of movement. The joint connecting the lateral processes of the central vertebra and the dorsal dermal plates acts as a ball-and-socket joint. Inspired by this joint structure in the tail of the seahorse. Ridge and roof prismatic joints will provide mobility and adaptability to the proposed architectural model. These joints will contribute to the flexibility and dynamic range of motion of the overall design. It is suggested to use a combination material of natural fiber, natural rubber, and recycled plastic for structural members and joints. Natural fiber composite provides a balance of stiffness, flexibility, and eco-friendliness, while natural rubber provides greater flexibility and water resistance, and recycled plastic increases durability and contributes to its eco-friendly aspect. This combination offers rain, fire, and UV resistance while remaining environmentally sustainable. The results demonstrate the feasibility and effectiveness of our prototype in achieving flexibility and adaptability in bidirectional dynamism. In conclusion, this

study presents an advancement in addressing the limitations of current flexible structures in architecture. The bioinspired approach followed in this study provides a tangible solution to enhance flexibility and adaptability in multidirectional structural behavior. When fully developed, the system proposed in this study offers potential solutions to enhance flexibility and adaptability in multidirectional structural behavior.

8:00 PM SB03.06.09
A Molecular Dynamics Investigation of Synthetic Collagen Thermal Properties MarcDuchatelier and KristenRhinehardt; North Carolina Agricultural and Technical State University, United States

Composite biomaterials have been used for various medical applications as they contain specific physical, chemical and mechanical attributes while evading rejection by the body and encouraging proper function. One common material used for such function is collagen. As a triple helical, extracellular matrix (ECM) protein it constitutes approximately 25% of the total dry weight of mammals. The thermal properties of collagen can vary (320-370K) depending on the source, which impacts its physical properties, assembly, and stability. The social, physical, and financial expense of obtaining collagen, as its traditionally harvested from animals, has led to a need for synthetic collagen-like peptides. Synthetic collagen has a greater versatility due to their customizability, but a thorough investigation of their physical, and thermal properties as well as their binding capabilities must be completed prior to their production or use. This can be done by using computational modeling. In this study, we use molecular dynamics modeling to explore the structure and physics of synthetic collagen 1K6F in a solvent environment in response to thermal alterations. Simulations of 2 and 4 peptides showed a notable influence of structural orientation of the strands. Visual analysis of the simulations showed a interactions between the stands at low temperatures with some structural disturbance at after 330K. The radius of gyration (Rg) showed the backbone of the molecule start to fold over time around 20 ns. Further an exploration of the Radius of Fluctuation showed varying wave patterns with amplitudes between 1.5 and 7.5 nm. However, a sinusoidal behavior was noticeable at 320 and 330K indicating a possible transition point. The observed sinusoidal waveform in the atomic fluctuation can be ascribed to the thermal influences within the system. We found that a higher number of hydrogen bonds appear at low temperature as there was increased interactions below 320K, but the peptides appear to go to the process of denaturation as temperature increase to 340K. Furthermore, the assembly behavior and protein biding sites were analyzed through composite simulation of silk and collagen. Our results highlight that the interaction strength of synthetic collagen with silk depends on the proportion of collagen within the system.

8:00 PM SB03.06.10
Enhanced Detection of Influenza Virus by Viral Membrane Fusion with Membrane Rigidity Modulation of Sialic Acid-Expressing Liposomes HongjunPark[1], ChaewonPark[1], GeunseonPark[1], Jong-WooLim[2], SojeongLee[1], SoohyunChung[1], EunjungKim[3] and SeungjooHaam[1]; [1]Yonsei University, Korea (the Republic of); [2]Seoul National University, Korea (the Republic of); [3]Incheon University, Korea (the Republic of)

Specific interactions between viruses and host cells provide essential insights into materials science-based strategies to deal with emerging viral diseases. In several viral families, pH-triggered viral fusion is universal and important for understanding the viral infection cycle. Inspired by this process, virus detection has been achieved using nanomaterials with host-mimetic membranes that allow interaction with amphiphilic viral haemagglutinin fusion peptides. Most research has focused on the design of functional nanoparticles with fusogenic capability for virus detection, and there has been little exploitation of membrane rigidity to alter the ability of nanoparticles to interact with the viral membrane and improve their sensing performance. In this study, a homogeneous fluorescent assay using sialic acid-expressing liposomes with tunable responsiveness to external stimuli is developed for the rapid and straightforward detection of an activated influenza A virus. Membrane fusion between the liposome and virus can be easily controlled by varying the membrane rigidity, which is determined by the cholesterol ratio, resulting in fluorescent signals within 30 min and detection of several influenza viruses, including H9N2, CA04(H1N1) and H4N6. Therefore, the designs demonstrated in this study propose underlying approaches to utilize engineered liposomes by modulating their membrane rigidity for the direct and sensitive identification of infectious viruses.

8:00 PM SB03.06.11
Biomimetic Synthesis of ZnO Thin Films IvanA. Melara, Jean-EdwardMoise and KristenSiaw; Gordon College, United States

Biomimetic reaction systems, where small proteins and peptides assist in the growth of inorganic materials, has the potential for making complex structures that are otherwise difficult to achieve. Living organisms use a peptide-inorganic matrix to control the morphology of the inorganic structures. Using this method as inspiration we sought a similar approach for novel materials. Zinc oxide as chosen as the target material due to its many exciting optoelectrical properties. Phage display was performed on ZnO sample and used to identify small peptides with high binding affinity for ZnO. By means of an aqueous based synthesis, these high affinity peptides were added at various concentrations to the solution so growth of the ZnO crystals could occur in the presence of the peptides. In the absence of peptides, the ZnO grows with a long needlelike morphology. When peptides are added to the growth solution they are found to dramatically alter the final morphology of the ZnO substrates. By altering the concentrations of these peptides, the morphology of ZnO nanorods can be controlled, ultimately allowing for the formation of thin films. Through the use of these peptides, we form ZnO thin films on a variety of substrates including glass and flexible PET plastic.

8:00 PM SB03.06.12
Demystifying The Synthesis and Preparation of Protein-Mimicking Random Heteropolymers HaoYu, IvanF. Jayapurna and TingXu; University of California, Berkeley, United States

Random heteropolymers (RHPs) with statistically distributed comonomers along the polymer chains are commonly used as functional materials for achieving biomimetic functionality. This is due to their capacity to replicate protein-like phase behavior and functions. However, unlike many branches of chemistry and biology where structures can be constructed precisely on the molecular level, the inherent stochastic nature of monomer sequences in RHPs raises concerns regarding their high material dispersity and difficulties in chemical characterization. Moreover, while extensive research has been conducted on synthesizing and understanding two-monomer systems, there have been limited studies and systematic guidance on the synthesis of multi-monomer copolymers such as RHPs, which involves complex, interdependent reaction kinetics among multiple comonomers. These knowledge gaps present barriers for researchers outside the polymer chemistry community who seek to create protein-mimicking RHPs with targetable structures and properties.
Towards these prospects, here we conduct a comprehensive investigation into the sequence heterogeneity and compositional drift in a family of 4-monomer-based RHPs. We commenced with experimentally determining the relative reactivities of a repertoire of four methacrylate monomers in reversible addition-fragmentation chain-transfer (RAFT) copolymerization. These underlying kinetic factors dictate the sequence heterogeneity of as-synthesized RHPs.Combining with stochastic sequence simulation, we designed four new RHPs, with each ensemble designed to exhibit different levels of hydrophilicity. Of particular interest is our findings that the purification procedures used during RHPs preparation, including pentane precipitation and dialysis against water, can preferentially eliminate different RHP subpopulations. This selectivity can be attributed to the conformations and apparent solubilities exhibited by these subpopulations, which are due to their particular chemical compositions within the whole RHP ensembles. Additionally, we quantitatively mapped out the trajectory of monomer compositions during the whole RHP preparation process. The predicted RHP cumulative compositions are in close agreement with the experimental results. These results validate the fidelity of predictive modeling and multicomponent RHP copolymerization. There are potentially over 300 commodity methacrylate monomers that are available for synthesizing RHPs materials. These findings are readily applicable to study the structure and sequence of heteropolymers beyond those described in this work. Overall, this work provides critically needed information to design and understand RHPs as functional materials while addressing the concerns related to their sequence heterogeneities.

8:00 PM SB03.06.13
Computational Investigation of Unique Structural Proteins in Cephalopod Skin ArseniiP. Panteleev[1], ChristopheMagnan[1], PierreBaldi[1], AlonGorodetsky[1], AndrewCannon[2], AlbertKwansa[2] and YaroslavaG. Yingling[2]; [1]University of California, Irvine, United States; [2]North Carolina State University, United States

Cephalopods (e.g., octopuses, cuttlefishes, and squids) are renowned for their remarkable dynamic color-changing and camouflaging capabilities.[2,4] These animals possess a skin architecture wherein different cells or organs known as chromatophores, iridophores, and leucophores modulate the transmission, absorption, and/or reflection of light.[2,4] Interestingly, these cells or organs all contain light-manipulating nanostructures composed of unique high-refractive index proteins called reflectins.[2,4] In our previous work, based on a bioinformatics analysis of the 51 reported reflectins, we had designed a truncated reflectin variant and studied the structure and self-assembly of this polypeptide via a combination of computationally driven experimental methods.[6] Subsequently, we had selected a prototypical reflectin isoform and investigated the structure and hierarchical self-assembly of this protein via multiple computational and experimental techniques.[1] Recently, we have extended these studies to other truncated and full-length reflectins, obtaining extensive new fundamental insight into their structures and functionalities.[3,5] When taken together, our experimentally validated computational findings provide additional insight into the camouflage capabilities of cephalopods and suggest new directions for the development of bioinspired optical materials and systems.

SESSION SB03.07: High-Throughput Methodologies and Data Science
Session Chairs: Hanson Fong and Christian Hellmich
Wednesday Morning, November29, 2023
Hynes, Level 1, Room 101

8:00 AM SB03.07.01
Bioinspired Cu^{II} Defective Sites in ZIF-8 for Selective Methane Oxidation SumanBhaumik[1], SirilukKanchanakungwankul[1], YingYang[2], DonaldG. Truhlar[1] and JosephT. Hupp[2]; [1]University of Minnesota, Twin Cities, United States; [2]Northwestern University, United States

Activating the C–H bonds of alkanes without further oxidation to more thermodynamically stable products, CO, and CO_2, is a long-sought goal of catalytic chemistry. Inspired by the monocopper active site of methane monooxygenase, a Cu-doped ZIF-8 metal–organic framework is synthesized with 25% Cu and 75% Zn in the nodes and activated by heating to 200 °C and dosing in stepwise fashion with O_2, methane, and steam. We found that it does oxidize methane to methanol and formaldehyde. The catalysis persists through at least five cycles, and beyond the third cycle the selectivity improves to the extent that no CO_2 can be detected. Experimental characterization and analysis were carried out by PXRD, DRUV-Vis, XANES, EXAFS, SEM, and XAS. The reaction is postulated to proceed at an open-coordination Cu^I site generated by defects, and the mechanism of methanol production was explicated by density functional calculations with the revMO6-L exchange–correlation functional. The calculations reveal a catalytic cycle of oxygen-activated Cu^I involving the conversion of two molecules of CH_4 to two molecules of CH_3OH by a sequence of hydrogen atom transfer reactions and rebound steps. For most of the steps in the cycle, the reaction is more favored by singlet species than by triplets. The singlet pathway consists of both closed-shell singlet and open-shell singlet species. The closed-shell singlet calculations were checked for wavefunction stabilities, to ensure the correctness of the calculations. The reaction mechanism along the singlet pathway goes through open-shell singlets until the final step where it passes through a closed-shell singlet transition state to give rise to closed-shell singlet final product, which is a van der Waals complex of Cu^I and CH_3OH. This work provides a bioinspired synthesis of a metal-organic framework, whose defective sites carry out selective methane oxidation to methanol. A biomimetic reaction mechanism is postulated and further validated by density functional theory calculations.

8:15 AM SB03.07.02
Artificial Olfactory Perception System Powered by Synthetic Biology and Machine Learning ZhongmouChao, EleanorBest and SusanDaniel; Cornell University, United States

There are only about 400 types of olfactory receptors making up millions of receptor sites inside the human nose, but they are capable of distinguishing over 1 trillion distinct smells. ORs are seven-helix transmembrane proteins on olfactory sensory neurons that can selectively bind with odor molecules, a process which causes the activation of specific olfactory neurons depending on their binding affinity for a given molecule. This unique firing pattern of neurons in response to odorant binding is then registered and memorized by the brain as a specific “smell.” This kind of sensor system goes well beyond the simple detection function when integrated with the learning element. Replicating such sophisticated biosensing to achieve an artificial olfactory system requires the convergence of two technological fields and we propose it is now possible with protein engineering and artificial intelligence (AI). We have demonstrated olfactory receptor proteins can be integrated into bioelectronics, supporting the differentiation of various odor molecules with different binding affinities using electrical readouts. Additionally, Machine Learning (ML) algorithm is applied to recognize different smells from experimental data collected by an array of sensors. Moving forward, our goal is to create the first-ever artificial olfactory perception system that leverages synthetic biology and ML to overcome the challenges that prevented achievement of such a system to date.

8:30 AM SB03.07.03
Deep Learning Analysis of Scattered Light Intensity for Shape Classification of Nanoparticles Measured by Nano Tracking Analysis KeisukeYamamoto[1], HiroakiFukuda[1], HiromiKuramochi[1], YasushiShibuta[1] and TakanoriIchiki[1,2]; [1]The University of Tokyo, Japan; [2]Innovation Center of NanoMedicine, Japan

Characterizing particles with sizes below 100 nm, such as peptide or protein-based biopharmaceuticals, necessitates single-particle measurement and multi-parametric analysis to distinguish individual particles. Nano Tracking Analysis (NTA) is a widely used technique for single-particle measurement in liquid samples due to its simplicity. By capturing the scattered light from nanoparticles illuminated by laser light, NTA can measure individual particles [a]. To expand the range of evaluatable properties, we are exploring the application of deep learning to the analysis of NTA data. Recently, by utilizing deep learning analysis, we have successfully detected the effect of shape anisotropy, demonstrating the potential for multiparametric analysis of nanoparticles in liquids[b]. In this study, to further enhance our understanding of physical properties, we investigate the potential of shape classification using the luminance information derived from light scattering images of particles measured by NTA.
Experiments were conducted using two types of gold nanoparticles: spherical particles with a diameter of 80 nm and rod-shaped particles with a diameter of 40 nm and a length of 180 nm. The NTA method was employed to capture 100 consecutive frames of images at 100 frames per second. From these images, three types of features were extracted as luminance information: scattered light intensity, cross-sectional area of the scattering pattern, and aspect ratio. Subsequently, a dataset was constructed based on these features.
Our deep learning analysis, utilizing a one-dimensional Convolutional Neural Network (1D-CNN) model, successfully learned all the extracted features. The shape classification accuracy using scattered light intensity was found to be 92%, surpassing the 80% accuracy achieved through shape classification based on Brownian motion trajectories. Moreover, even with a limited number of data frames (20 frames), the accuracy for the analysis based on luminance information reached 85%, compared to 60% for the analysis based on Brownian motion trajectories. These results demonstrate the potential of accurately extracting properties in a shorter timeframe using deep learning analysis of scattered light intensity information acquired by the NTA method.
In conclusion, our study showcases the effectiveness of employing deep learning analysis of scattered light intensity for shape classification of nanoparticles measured by NTA. This approach not only enhances the accuracy of particle characterization but also reduces the analysis time. The proposed method holds promise for further advancements in the field of nanoparticle characterization and analysis.

Mineral: Peptide Interactions: Using Our Understanding of Molecular Interactions to Develop a Time Efficient Biopanning Approach CaroleC. Perry and ValeriaPuddu; Nottingham Trent University, United Kingdom

Minerals and biomolecules can interact via a range of binding modalities from electrostatic interactions, though hydrogen bonding to hydrophobic interactions and van der Waals interactions. These binding possibilities lead to a range of biomolecule sequences that can interact with a particular mineral. From our understanding of peptide-mineral interactions gained by extensive, detailed experimental and computational studies we have developed an optimised biopanning approach, utilising multiple chemical eluants that allows the identification and recovery of a wide mineral binder pool in just one or two biopanning rounds.

A Dynamics-Informed Approach to Prediction of Protein Melting Temperature via Graph Neural Networks Yen-LinChen and Shu-WeiChang; National Taiwan University, Taiwan

A practical design of biomedical materials requires knowledge of their thermal properties. Melting temperature has a direct influence on molecular stability, functionality, and performance in the case of protein engineering. For example, biosensors and enzymes will only operate as intended within a limited thermal range. As such, the prediction of the thermostability of proteins is a crucial factor with implications in various scientific disciplines and technical applications. This task requires an understanding of the hierarchical organization of proteins, which manifests in a dynamically coupled cellular system. The introduction of machine learning methods to biology brought about astounding breakthroughs, such as the prediction of protein structures by AlphaFold. It is a promising approach to undertaking convoluted relationships in protein science. In this study, we propose a machine learning method for the computation of the melting temperature of proteins, taking into account the amino acid sequence, protein structure, and dynamics. Graphs (as in graph theory) are chosen as our data representation due to their rotational invariance and their intuitive mapping to molecular structures. The sequential, structural, and dynamical information are represented as multigraphs, with residues as its nodes, and various node features and edge connections derived from each of these properties. To process the data, a graph neural network architecture that makes use of message passing layers was designed to accommodate the multiple types of connections. Protein structures were computed by AlphaFold and the dynamics were computed based on the torsional network model (TNM) for training. Hence, the learned features and parameters can be readily applied to protein sequences without known experimental structure, satisfying the goal of aiding the prediction of design proteins.

We are also able to identify key domains that contribute to the thermal stability/instability of proteins by computing the graph regression activation map, which is based on the partial derivative of the predicted value with respect to features on the input nodes. Our method gives insight into the mechanism of natural proteins and provides critical information regarding design proteins.

Scientific Analysis of Synthetic Collagen Compounds using Computational Molecular Modeling Methods JordanneA. Davenport and KristenRhinehardt; North Carolina A&T State University, United States

Scientists have proven that the health regimen you follow can have a significant impact on the human body. Collagen is found on multiple parts of the body such as skin, bones, lymphatic, cardiovascular, liver, lung, spline, and intestinal tissue. (Spano, 2019) Although it is prevalent that people lose 1% of collagen each year, there is a way to improve this by maintaining a healthy diet. “Collagen-derived dietary proteins are most commonly extracted from porcine skin (45%), bovine hide (30%), and the bones of both animals (23%) Chicken (bones) and fish (scales and bones) byproducts are also used as production sources of collagen-derived dietary protein” (Holwerda and Loon, 2022). In this research, a biomodel of three synthetic collagen molecules is used to bind biomarker properties including Aptamers, CNA, and Silk. Pymol is a molecular visualization tool that provides an ethically pleasing environment for a three-dimensional structure of a protein molecule to be cleaned by removing water, removing repeated molecules, and retrieving the model sequences. The results from PyMOL are then incorporated into the Basic Local Alignment Search Tool (BLASTp) to generate alignments between a protein sequence (Wheeler, Bhagwat, 2007). The binding energy is calculated along with a visual model of the structural changes of the collagens reaction to its biomarker using HDOCK and PATCHDOCK servers. When docking with PatchDock, the results are collected and refined with a software named FireDock to retrieve the binding energies. The best conformations were compared with differing peptides to see which ligand showed the highest affinity. “While enzyme driven crosslinking plateaus at maturation, connective tissue stiffness has been shown to further increase with age and diabetes. This tissue stiffening has been associated with non-enzymatic, oxidative reactions between glucose and collagen which increases with increased plasma glucose end concentrations associated with advanced aging” (Snedeker, 2014). Further research will utilize molecular dynamics to explore conformational space and explicitly treat structural flexibility and entropic effects of synthetic collagen.

10:15 AM SB03.08.02
Phytochemical-Enriched Plant Extracts Induce Apoptosis in Bone Metastatic Breast Cancer Cells PreethamRavi, HaneeshJasuja, DipayanSarkar, KalidasShetty, DineshR. Katti and KalpanaKatti; North Dakota State University, United States

The WHO reports that breast cancer is the most common occurring type of cancer with nearly 2.26 million cases being diagnosed each year. Breast cancer is also the second leading cause of cancer-death in women. Majority of the deaths occur due to breast cancer metastasis to bone. Breast cancer cells at bone site experience altered growth and chemoresistance. Furthermore, the infrastructure of the bone is compromised, resulting in skeletal failures in patients. Currently, there is no cure for bone metastasis of breast cancer. There is a shortage of effective therapeutics for bone metastatic breast cancer, due to the reported inefficacy of commercialized drugs at bone metastatic site. There is a need for accurate drug screening cancer models, which recapitulate the bone-metastatic condition, to effectively test potential anti-cancer therapies. In addition, therapies are needed not only to treat the tumor, but to heal bone, with limited side-effects. In this study, we employ a unique 3D *in vitro* nanoclay based scaffold model, as a testbed for bone metastatic breast cancer, to screen three phytochemically-enriched plant extracts (Rhodiola Crenulata, Origanum vulgare, and Vaccinium Macrocarpon). These plant extracts have been tested against primary site breast cancer, however, their efficacy against bone metastasized breast cancer cells is unknown. We evaluated the cytotoxicity of the three extracts on bone metastatic breast cancer using the bone-mimetic scaffolds and compared the results with 2D cultured breast cancer cells (MDA-MB-231 and MCF-7). The cell viability studies showed that breast cancer cells growing, both in 2D and 3D Bone-metastatic cultures, were significantly reduced by increasing dosages of all three plant-extracts. Furthermore, it was observed that these extracts induced apoptosis in breast cancer cells grown in 2D and bone-metastatic culture, through upregulation of pro-apoptotic markers, p53, caspase-3, and caspase-9 and downregulation anti-apoptotic markers. Additionally, the bone metastatic breast cancer cultures experienced increased drug resistance. Lastly, we evaluated the effects of these plant extracts on bone cells, and found that they are unaffected after treatment. Overall, our data indicates that these phytochemically-enriched plant extracts can promote cytotoxicity in bone metastatic breast cancer, while unaffecting healthy bone cells. Moreover, these specialty derived compounds can be ideal candidates to be investigated as new therapies to treat bone metastasis of breast cancer.

10:30 AM SB03.08.03
Role of Fluid Induced Shear Stresses in Inducing Bone Metastasis in Prostate Cancer KalpanaKatti, HaneeshJasuja, SharadV. Jaswandkar and DineshR. Katti; North Dakota State University, United States

The World Cancer Research Fund International reports that prostate cancer is the second most commonly occurring cancer in men. In addition, 1,414,259 new cases of prostate cancer were reported in 2020. The World Health Organization, reports 375,304 deaths in 2020 due to prostate cancer. The majority of deaths due to prostate cancer result from the cancer relocating to a distant location in the body through the process of metastasis. The bone is a common niche of relocation of prostate cancer metastasis. Prostate cancer that has metastasized to bone is incurable. We have developed a novel nanoclay-based tissue-engineered polymeric scaffold in order to mimic the bone metastasis site through sequentially seeding with hMSCs and cancer cells. The role of blood flow in cellular processes is well known through the effect of shear forces exerted by the fluid. It is also known that the fluid flow provides unique biochemical cues for metastasis. We have designed and fabricated a bioreactor that enables physiologically relevant interstitial fluid-flow for prostate cancer bone metastasis. We have also conducted computational fluid dynamics studies to establish that a fluid flow of 0.05 ml/min recapitulates the physiological condition. We did extensive gene expression and protein evaluation studies on the cellular materials grown with and without the effect of fluid flow. We observe that the interstitial fluid-flow does not alter the CXCR4 level, an important regulator of metastasis and invasiveness of cancer. On the other hand, a large impact of bone proximity on the CXCR4 levels. The bone proximity upregulates CXCR4 levels enabling increased MMP-9 levels. We also investigated the levels of integrins which are important cellular adhesion proteins and found that avb3 integrins and MMP-9 levels are upregulated by fluid-flow causing increased migration under fluid-flow. Hence our studies indicate that avb3 integrins act as potential mechanosensory agents transducing mechanical signals via avb3-MMP 9 signaling to promote flow induced motility of prostate cancer cells. Overall, these experiments describe the significant role of interstitial fluid-flow in prostate cancer metastasis.

Combining Surface-Enhanced Raman Spectroscopy and Electrokinetics for Bacterial Monitoring in Wastewater YiruiA. Zhang, LiamK. Herndon, PunnagPadhy, BabatundeOgunlade, AlexandriaBoehm and JenniferA. Dionne; Stanford University, United States

Wastewater-based epidemiology can monitor population-level infections, provide early warnings about disease outbreaks, and help to control disease spread at the community level [1]. However, bacterial identification in wastewater presents outstanding challenges; notably, current methods [2] to identify bacteria are slow and costly, not suitable for high-throughput screening of diverse bacterial species, and may not work well in the complex wastewater matrix. Here, we develop a new electro-optical method that has the promise to detect a wide range of pathogenic bacteria in wastewater.

We combine surface-enhanced Raman spectroscopy (SERS) [3] and electrified interfaces, further assisted with machine learning models [4] to realize rapid and amplification-free detection of bacteria, at cell concentrations as low as 10^5 cells/mL in filtered wastewater. First, we collect SERS from bacteria spiked into filtered wastewater, including *Staphylococcus aureus*, *Staphylococcus epidermidis*, and *Escherichia coli*. Here, plasmonic gold nanorods electrostatically bind to the bacteria surface, allowing for rapid biomolecular recognition of the cell surfaces. Additionally, two-dimensional gold microelectrodes are patterned on the sensor surface to apply electrical fields to wastewater, which selectively attracts and enriches bacteria present in the complex wastewater matrices within minutes, driven by dielectrophoretic effects [5]. The enrichment of bacteria is directly observed through microscopy, and Raman signal intensities are increased by five to ten fold under electrical fields for bacterial concentrations ranging from 100 cfu/mL up to 10^8 cfu/mL. Such enhancement enables the detection sensitivity to reach environmentally-relevant concentrations (typically below 10^7 cfu/mL) with just ten seconds of integration times. Finally, using machine learning, we identify biologically-relevant “fingerprint” Raman peaks describing proteins, nucleic acids, and lipids from bacteria surfaces, and achieve rapid and accurate identification of bacteria species in wastewater. The method has the promise for future label-free detection and prediction of bacterial outbreaks through wastewater. It also opens up new directions for generalized pathogen detection and molecular recognition in a broader range of complex liquid samples including wastewater, blood, and seawater.

11:00 AM SB03.08.05
Peptidic Luminescent AuNCs for Biosensing SoleneDucarre[1], RaffaelloPaolini[1], EsterButera[1], DorianLemasson[1], ReginaCheichio[1], PascaleEven-Hernandez[1], CeliaRavel[2], LudovicJullien[3] and ValérieMarchi[1]; [1]Institut des Sciences Chimiques de Rennes, France; [2]CHU Rennes, France; [3]ENS PSL, France

Gold nanoclusters (AuNCs) appear as a recent class of non-toxic fluorophores. Their brightness, their ultrasmall size (< 2 nm) and large window of fluorescence lifetime (1ns – 1ms) and their good biocompatibility make them an attractive alternative as fluorescent probes for biological labeling and bioimaging.
We demonstrated their in vivo targeting ability because of specific peptidic recognition groups (R. Cheichio et al. ACS Nano materials **2023**)
Here we present the direct synthesis of original ultrasmall luminescent peptidic gold nanoclusters sensitive to pH. The versatility of small peptides permits to adjust the emission wavelength and the sensitivity of the emission intensity as well as the luminescent lifetime.

In addition due to their ultra-small size, we demonstrated that these probes are easily internalized into Arabidopsis plant from the roots and the leafs by adjusting the surface charge of the ligands. Their biodistribution in this model plant was evidenced by confocal microscopy. This chemical plateform provides AuNC dual nanoprobes with potential sensitivity to the environment for biosensing applications. Such nanostructures offer promising candidates for fluorescent in vivo biosensing and biolabeling.
We also investigated the interaction of AuNC with Extracellular vesicles (EVs) which are well-known membrane-limited particles that are secreted by healthy and cancerous cells. EVs are heterogeneous in size and three subtypes are described depending on the location of secretion: microvesicles, myelinosomes and exosomes. EVs are identified in human follicular fluid as a mode of communication in the ovarian follicle (Neyroud A. S. et al. Int. J. Molecular Sci. **2022**). In addition EVs involved in cell-cell communication are considered as biomarkers for early cancer diagnosis. The analysis of their content thanks to AuNCs nanoprobes could provide informations about the origin and the biological function of the EVs. The EVs labeling with easily detectable nanoparticles could enable the development of a powerful tool for the early diagnosis of specific diseases.

11:15 AM SB03.08.06
Engineering Antigen Binding and Orientation on Alum Adjuvants for Enhanced Humoral Responses and Immunofocusing DuoXu and PeterS. Kim; Stanford University, United States

A major challenge in vaccine development, especially against rapidly evolving viruses, is the ability to focus the immune response toward evolutionarily conserved antigenic regions to confer broad protection. For example, while many broadly neutralizing antibodies against influenza have been found to target the highly conserved stem region of hemagglutinin (HA-stem), the immune response to seasonal influenza vaccines is predominantly directed to the immunodominant but variable head region (HA-head), leading to narrow-spectrum efficacy. Here, I will first introduce an approach to controlling antigen orientation based on the site-specific insertion of short stretches of aspartate residues (oligoD) that facilitates antigen-binding to alum adjuvants. I will demonstrate the generalizability of this approach to antigens from the Ebola virus, SARS-CoV-2, and influenza and observe enhanced antibody responses following immunization in all cases. Next, I use this approach to reorient HA in an “upside down” configuration, which I envision increases HA-stem exposure, therefore also improving its immunogenicity compared to HA-head. When applied to HA of H2N2 A/Japan/305/1957, the reoriented H2 HA (reoH2HA) on alum induced a stem-directed antibody response that cross-reacted with both group 1 and 2 influenza A HAs. These results demonstrate the possibility and benefits of antigen reorientation by engeering the interaction between antigens and adjuvants, which represents a generalizable immunofocusing approach readily applicable for designing epitope-focused vaccine candidates.

11:30 AM *SB03.08.07
3D Inverse Modelling to Extract Local Hydrogel Remodelling and Stress Fiber Structure in Human Diseased Aortic Heart Valve Interstitial Cells MichaelS. Sacks; The University of Texas at Austin, United States

Direct assessment of three-dimensional (3D) cell single stress fiber (SF) structure and function remains technically challenging, due to the SF feature size falling well below the resolution of light microscopy. Therefore, computational approaches are needed to estimated the effective structures and contractile behavior of SFs in various states. Herein, we developed a 3D computational model of the contracting aortic heart valve interstitial cells (AVICs) embedded in 3D hydrogels to estimate their SF orientations and contractile forces. We first utilized our hydrogel inverse model to estimate the local hydrogel mechanical properties. Briefly, this approach produces a spatially varying hydrogel modulus field or profile that minimizes the error between the experimentally measured and simulated hydrogel deformations produced by a contracting AVIC. It was determined that AVICs both degrade the gel by enzymatic processes, as well as locally stiffen the gel by collagen deposition. Next, we developed two finite element based inverse models that utilized a single direction and dispersed orientation SF structures. Both models estimated that the greatest levels of SF forces occurred at AVIC protrusions. The second model estimated that the greatest levels of SF alignment occurred at AVIC protrusions while the AVIC midsection revealed less-aligned fibers. To the best of our knowledge, we report the first fully 3D computational contractile cell models which can predict locally varying stress fiber orientation and contractile force levels. Looking forward, these models may help us obtain an increased understanding of SF function at sub-cellular length-scales and can be incorporated into multi-scale models of tissue/organ function.

SESSION SB03.09: Applications and Devices in Materials and Medicine II

Thursday Morning, November30, 2023
Hynes, Level 1, Room 109

8:30 AM SB03.09.01
Application of eIF4E Protein-Ligand Modeling for Cancer Drug Discovery MelvinThu[1,2], ParthJain[3,2], EvanXie[4,2], KarinHasegawa[2] and YuefanDeng[2]; [1]Great Neck North High School, United States; [2]Stony Brook University, The State University of New York, United States; [3]Bergen County Academies, United States; [4]The Pingry School, United States

The eIF4F complex recruits ribosomal subunits (40S) to initiate translation and is composed of the eIF4E, eIF4G, and eIF4A subunits. eIF4E is the cap-binding protein and binds to the m7gtp mRNA 5’ cap. eIF4G is the scaffolding protein in the complex and binds eIF4E.
The protein 4E-BPs can bind to eIF4E where eIF4G binds to prevent the eIF4F complex from forming. eIF4F plays a substantial role in cancers since eIF4F preferentially activates the translation of certain mRNAs, encoding proliferation and survival-promoting proteins such as cyclin D1, c-Myc, and VEGF. The pathway involving PI3K phosphorylation of 4E-BPs results in the unbinding of eIF4E from 4E-BPs and the formation of the eIF4F complex resulting in breast, lung, ovarian, and prostate cancers, and the pathway involving Ras phosphorylation of eIF4E results in the formation of an active eIF4F complex resulting in pancreatic, lung, and colorectal cancers.
Our approach to eIF4E inhibition involves designing a compound to restrain the movement of key eIF4E residues involved in the binding of eIF4E to m7GTP, such as W102, W56, and E103, to prevent binding. An issue with m7GTP analogues of similar structure and stronger binding affinity, however, is that many are negatively charged and thus can’t pass through cell membranes. Molecular docking simulations can predict binding orientation and binding affinity of the ligand to target, producing samples of many ligand conformations in the target binding region to find the optimal conformation. However, high throughput screening through brute force molecular docking is computationally expensive and limited as there are only 1010 known compounds as opposed to the 1060 total compounds.
In order to design an effective ligand, we first have to study the structure of eIF4E, and investigate how key residues involved in eIF4E binding to m7GTP undergo conformational change with and without m7GTP. We optimize eIF4E models without m7GTP using principal component analysis (PCA) and free energy landscape (FEL) calculations. We performed PCA on the trajectory data of 2gpq, 4tpw, and AF protein sources of eIF4E to transform the set of possibly correlated variables (the positions of the protein atoms) into a set of values of linearly uncorrelated variables (the principal components). We then calculated FEL of the 2gpq, 4tpw, and AF protein sources of eIF4E using GROMACS to identify the most stable conformations of eIF4E. FEL is a graphical representation of the thermodynamically stable states of a protein and the transitions between them where the local minima represent the most stable protein conformations and the barriers represent the transition states. The stable conformations of 2gpq, 4tpw, and AF were then used in molecular docking simulations of the eIF4E-m7GTP complex in order to determine the m7GTP pose with the most favorable binding energy. It was confirmed that m7GTP binds to the W56, W102, E103 residues for all three sources of eIF4E. We then performed molecular dynamics simulations on the docked eIF4E-m7GTP complexes using GROMACS with the CHARMM36 force field and TIP3P water model.
We are currently working on identifying the regions of m7GTP that are interacting with W56, W102, and E103. We will use these results to design compounds to allosterically inhibit eIF4E

binding to m7GTP, preventing the overexpression of cancer-causing mRNAs.

8:45 AM SB03.09.02

Viability of a Novel Peptide P12 as an Antithrombotic Agent Sai PranavKota[1], RichardA. Wong[2], SamuelD. Coopersmith[3], AviTalsania[4], PiaV. Sodhi[5], SharisHsu[6], AdamHansen[7] and MiriamRafailovich[7]; [1]Cedar Falls High School, United States; [2]Plainview-Old Bethpage John F. Kennedy High School, United States; [3]Casa Grande High School, United States; [4]Sachem High School North, United States; [5]The Brearley School, United States; [6]Valley Christian High School, United States; [7]Stony Brook University, The State University of New York, United States

Medical devices and implants are an ongoing point of research due to their impressive capabilities to enhance and support human infrastructure, but pose major challenges as they must incorporate a biocompatible material that can support endothelialization and prevent thrombosis. Specifically, current cardiovascular devices like stents lack reliable endothelialization and because of exposure to constant contact with blood flow within vasculature, result in life-threatening blood clots. Fibrinogen is a plasma-soluble protein that, once cleaved, results in fibrin monomer polymerization into fibrous clots. Previous studies have demonstrated that most stent materials are subject to fibrinogen deposition and denaturation, which results in conversion into fibrin monomers and polymerization through αC domain connections [1]. A multitude of possible solutions have been studied by utilizing varying hydrophobic or hydrophilic surface properties, which feature different materials or coatings with limited success. Here, we will explore incorporation of a surface coating using P12, a peptide derived from fibronectin, to prevent thrombosis.

Initial studies provided insight on how P12 is effective for inhibiting the fibrin polymerization process on polystyrene (PS) surfaces. We studied various fibrinogen and P12 concentrations, but ultimately we found that incorporation of P12 during the incubation of 4 mg/ml of fibrinogen, the concentration in blood, on PS surfaces prevented substantial fiber formations. We also analyzed this at the molecular level with low concentrations of fibrinogen and by using Atomic Force Microscopy and simulation technology, we concluded that the hydrophobic nature of P12 allowed it to bind to exposed αC domains of fibrin on the PS surface. This prevented aggregation of neighboring fibrin monomers and ultimately prevented polymerization into fibers.

Further studies were conducted to overcome the possible negatives of using P12, which includes the uncertainty of P12 reaching the implant or cytotoxic considerations. In order to utilize P12 properly, we investigated using it as a material coating to enhance its effectiveness in a controlled location. We studied this by applying 100 µM of P12 solution onto PS surfaces until full coverage was achieved. Fibrinogen solutions of 4 mg/ml incubated the coated surface for one hour. The P12 coating resulted in <1% of the surface containing fibers and adversely, without the coating resulted in >50% of the surface covered in fibers. From this data, we concluded that a coating of P12 is very effective in thrombosis prevention.

Cytotoxicity is another major problem with implementation of a biomaterial coating. We therefore plated fibroblasts on P12 coated tissue culture plastic (TCP) and added additional P12 to the media to directly test cell survivability. We found that there were no significant differences on P12 coating or adding P12 to cells. These results are indicative of no associated cytotoxicity of the P12 surface. We further investigated this by testing cell adhesion and proliferation on P12 coated polystyrene and found an increase in cell growth and adhesion by the addition of P12 on an otherwise non-biocompatible polystyrene surface. This data concluded that a P12 coating not only rendered surfaces non-thrombogenic and non-toxic, but also enhanced biocompatibility.

Future research will look to investigate the effects of a P12 coating on its ability to support endothelialization and look to create a robust interface that incorporates P12 directly into the matrix of the material chemically so that the coating cannot be degraded or dislodged from the surface.

Surface Modification of 80S Mesoporous Bioactive Glass using a Low Concentration of Composite Silver-Cerium for Biomedical Applications MannieB. Taye; National Taiwan University of Science and Technology, Taiwan

Researchers are concentrating on discovering reducing treatments for bacterial infections due to the worrisome and quick rise of drug-resistant microbial-related illnesses. Escherichia coli (E. coli) causes post-surgical infections and wound infections, the most serious and drug-resistant diseases in the world. Anatomical sites with insufficient bone tissue due to illness or revision surgery are referred to as having bone defects. Severe bone defects can cause disability, limit an individual's ability to live and work, and impose significant social and economic burdens. composite silver-cerium co-doping mesoporous bioactive glass (MBG) can defend against drug-resistant pathogens of Escherichia coli (E. coli) infection of wounds and solve issues with bone deformities. In this study; un-doped, silver-doped, cerium-doped, and silver-cerium co-doped mesoporous bioactive glass based on the composition of $80SiO_2$-(16-x) CaO-$4P_2O_5$- xAg_2O or xCeO_2 (x=0, 0.35, 0.71 mol%,) and (0.35 mol% Ag/0.35 mol% Ce) co-doped MBG has been successfully synthesized by spray pyrolysis method. Mesoporous bioactive glass powders were produced and characterized in this research. The phase compositions, chemical bonds/functional groups, surface morphologies, chemical compositions, inner structure morphologies, specific surface areas, and elemental compositions on the surface were investigated using X-ray diffraction (XRD), Fourier transform infrared spectroscopy (FTIR), field emission scanning electron microscopy (FE-SEM), energy dispersive X-ray spectroscopy (EDS), transmission electron microscopy (TEM), nitrogen sorption isotherm analysis, and X-ray photoelectron spectroscopy (XPS), respectively. The antibacterial activity against E. coli was determined using the colony count method, and all silver-doped MBG and silver-cerium co-doped MBG were very effective against E. coli. Furthermore, when the glasses were exposed to simulated bodily fluid (SBF), they quickly formed HA on their surfaces, which caused Ag and Ce to be deposited on the surface of the MBG and an intriguing candidate for use in improving the filling of bone defects. Lastly, the MTT assay demonstrated the high biocompatibility of all MBGs When evaluated with MC3T3-E1 osteoblasts in different concentrations. According to our literature analysis, the 80S- Ag-Ce- was the first silver-cerium co-doped mesoporous bioactive glass, however, additional functional studies are required for its advancement.

9:15 AM SB03.09.04

Biomimetic Dentin Repair: Amelogenin-Derived Peptide Guides Occlusion and Peritubular Mineralization of Human Teeth DenizT. Yucesoy[1], HansonD. Fong[2], SamiDogan[2] and MehmetSarikaya[2,2,2]; [1]Izmir Institute of Technology, Turkey; [2]University of Washington, United States

Dentin hypersensitivity, a widespread oral health concern, is primarily caused by the exposure of dentin tubules due to the loss of protective tissues. Despite being a widespread ailment, no permanent solution exists to address this oral condition. Current treatments aim to alleviate pain by employing desensitizing agents or blocking dentin tubules through mineral deposition or solid precipitates, yet these interventions often provide only short-term relief.

To restore the structural and mechanical integrity of teeth with lasting durability, there is a crucial need to reproduce an integrated mineral layer that seals exposed dentin while promoting peritubular mineralization. In this study, we introduce a biomimetic treatment that promotes dentin repair, utilizing a mineralization-directing peptide known as sADP5, derived from amelogenin.

The occlusion of dentin tubules is achieved through a layer-by-layer peptide-guided remineralization process, resulting in the formation of an infiltrating mineral layer on the dentin. The structure, composition, and nanomechanical properties of the remineralized dentin were analyzed by cross-sectional scanning electron microscopy imaging, energy dispersive X-ray spectroscopy, and nanomechanical testing. Elemental analysis revealed calcium and phosphate compositions akin to hydroxyapatite. Furthermore, the measured average hardness and reduced elastic modulus values of the mineral layer were significantly higher than those of the demineralized and sound human dentin. Thermal aging experiments provided evidence of the structural integration between the newly formed mineral layer and the underlying dentin, with no physical separation observed. These findings suggest the creation of a structurally robust and mechanically resilient interface that can endure long-term mechanical and thermal challenges commonly encountered in the oral environment.

The peptide-guided remineralization process outlined herein provide a foundation for the development of highly effective oral care products leading to novel biomimetic treatments for a wide range of demineralization-related ailments and offers a potent long-term solution for dentin hypersensitivity.

Photo-Induced Structural Changes in Oxidoreductase-Inspired Nanogels Chae GyuLee and Tae-HyukKwon; Ulsan National Institute of Science and Technology, Korea (the Republic of)

Under the reductive conditions in cancer cells, cysteine-containing oxidoreductases, such as thioredoxin (Trx), glutaredoxin (Grx), and protein disulfide isomerase (PDI), accelerate thiol-disulfide exchange reactions through a reversible reaction (CysS–SCys↔Cys–SH), rendering upstream and downstream signaling pathways to maintain redox homeostasis in metabolism-activated cancer cells. In addition, it is difficult to differentiate between tumorous and healthy tissues as the intracellular GSH concentrations of both cell types are approximately 2–10 mM. Therefore, disulfide-bond-based nanocarriers have potential to exhibit cytotoxicity due to the unmanageable drug release in normal cells. This study investigates the spatiotemporally-controlled irreversible degradation of Ir-based photosensitizer (TIr3)- encapsulating nanogels (IrNG) through the hyperoxidation of resulting intracellular thiols using reactive oxygen species (ROS).[1,2] By mimicking the reversible redox reaction of Trx and Grx, we developed IrNG that maintains the self-assembled nanostructure through hydrophobic interactions and reversible crosslinking between its disulfide bonds and thiols in the absence of light. When a highly cytotoxic TIr3 was stably encapsulated within IrNG, it exhibited significantly enhanced biocompatibility under normal cellular conditions. However, upon photoirradiation, TIr3 generated high levels of ROS, irreversibly oxidizing the thiols to induce electrostatic repulsion between the polymer molecules, resulting in the TIr3 release and induction of cancer cell apoptosis. Therefore, we could obtain substantially increased changes in cell viability and *in vivo* tumor growth regarding the presence and absence of photoirradiation, confirming the manual control of cytotoxic drug release.

Functional Materials Integrating Synthetic Biological Modules Guided by Machine Learning Algorithms CandanTamerler; University of Kansas, United States

Synthetic biology takes the bio-based and bio-enabled approaches to a step further to enable engineering biology in designing and producing materials and processes with previously unattainable functions. Nature has been a source of inspiration in engineering solutions for many. As our understanding of biological materials and structures expanded, mimicking biological systems for innovative engineering solutions has continued with growing intensity. Our group was among the early adapters of biomimetic principles for harnessing design strategies to develop innovative materials. Mimicking the molecular recognition in biological interactions, we have been exploring the smaller protein domains, i.e., peptides as the key fundamental building blocks. Peptides offer to design hybrid biomaterials that can mimic the functions of proteins, generate biomimetic platforms and modulate microenvironment. Using synthetic biology approaches, we expanded the use of peptide-based building blocks as bioactive modules and design bio-hybrid materials with diverse functions addressing medical and industrial applications. We incorporated machine learning (ML) methods to capture distinct peptide functionalities as elements of critical modular building blocks. We adapted experimental and computational approaches demonstrated transparent ML frameworks for identifying relevant peptide structure features for targeted functions. For antimicrobial hybrid materials, we provided a method for selecting secondary structure features in related to antimicrobial peptides and expanded our predictions to design peptides for metals in biology as biocatalysts, metalation tools, and metal chelates in manufacturing and nutritional immunity. Using synthetic modular domains, we developed peptide-metal and peptide-polymer hybrids as integral of biomaterials and developed models for allosteric-dependent effects of selecting spacers to recover domain function activity. We generated knowledge-potential folded structures to discover rough set theory trends which showed to be relevant for recovering bioactivity. Our examples will include utilization of the biological activity imparted by each biomolecule toward prevention of dental and oral diseases as well as restoration of oral health. Engineered modular peptide and enzyme systems will be also provided as synthetic biohybrid material systems applicable to industrial applications. Enabling synthetic biological modular approach guided by ML algorithms offers a fascinating path to reshape our thinking in engineering and represent the functional frontiers to mimic biological systems.

Sequence-Tunable Materials for Silica Biomineralization KaylynTorkelson[1], NadaY. Naser[1], XinQi[2,1], Chun-LongChen[3,1], FrancoisBaneyx[1] and JimPfaendtner[4,1]; [1]University of Washington, United States; [2]Dartmouth College, United States; [3]Pacific Northwest National Laboratory, United States; [4]North Carolina State University, United States

Silica biomineralization is a naturally occurring process wherein proteins direct the formation of complex, hierarchical nanostructures. Knowledge of these proteins and their underlying mechanisms has spurred significant efforts to identify routes for biomimetic mineralization that aims to reproduce the exquisite shapes and size selectivity found in nature. A common strategy to achieve this has been the use of short peptide sequences with chemistry mimicking those found in natural systems, like the use of the silaffin-derived R5 peptide. While progress has been made using peptides for this approach, there are many limitations that have prevented substantial breakthroughs in biomimicry. To advance our ability to use charged macromolecules for silica formation, we propose to use sequence-defined synthetic polymers known as peptoids, or N-substituted polyglycines, that present significant capability for precise tuning of sequence and structure beyond what can often be achieved with peptides alone.

This work will highlight recent developments in computational methods for understanding the relationship between polymer aggregate structure, silica surface, silica surface adsorption, silicate precursor interactions, and morphology in the biomimetic mineralization process. We use molecular dynamics simulations with the metadynamics family of enhanced sampling methods to analyze binding mechanisms and energetics of the R5 system. Next, we synthesize two R5-inspired peptoids and validate our prediction through characterization using surface plasmon resonance and electron microscopy. This study holds promise for designing new sequences with unprecedented control of the placement of chemical functional groups, thus allowing for further unraveling of silicification mechanisms and eventual design of sequence-defined synthetic polymers leading to the predictive synthesis of nanostructured functional materials.

11:00 AM SB03.09.08
Modeling Molecular Machines with Dynamic Covalent Bonds using REACTER JacobGissinger; Stevens Institute of Technology, United States

Nanoscale devices are the ultimate in mechanical miniaturization. Molecular machines that perform directional transport of small molecules or filaments are a vital aspect of life, performing key biological functions during cell division and muscle contraction. These biomotors have inspired the creation of synthetic versions of molecular ‘walkers’ that can move directionally down a molecular track by the application of stimuli (pH and irradiation) in a specific sequence. The reconfiguration of covalent bonds is achieved by two orthogonal bond exchange reactions: disulfide exchange, which is activated in basic environments, and hydrazone exchange, which occurs under acidic conditions. In this work, we simulate the nanoscale dynamics of molecular machines using REACTER, a method for modeling chemical reactions in classical molecular dynamics (MD) simulations. Although external stimuli such as UV light cannot be modeled directly in classical MD simulations, the dynamics of a molecular walker can be captured explicitly by alternately activating the bond exchange and photoisomerization reactions using REACTER. Certain shape-memory polymers operate via similar bond exchange reactions, and a workflow to model shape-memory effects with atomistic resolution is proposed.

SESSION SB03.10: Virtual Session: Lessons from Biology at the Molecular Dimensions II

8:00 AM SB03.10.01
Zwitterion Functionalization of Polyurethanes via Thiol-ene Click for Antifouling Surfaces—Lessons from Nature ShantanuP. Nikam[1,2], PeiruChen[1], KarissaNettleton[2], Yen-HaoHsu[1] and MatthewBecker[2]; [1]The University of Akron, United States; [2]Duke University, United States

Inspired by the phospholipids on cell membranes, zwitterionic groups have been widely studied for their antifouling property. Equipped with two oppositely charged groups in the same moiety, zwitterions exhibit properties like super hydrophilicity through ionic solvation and tightly bound hydration layer that enables non-specific protein resistance. Additionally, zwitterionic materials also enhance biocompatibility and reduce immune response.
Catheter-associated infections (CAIs) have one of the highest mortality rates among healthcare-associated infections. Besides being a major cause of morbidity and mortality, CAIs also impose a heavy financial burden resulting from prolonged treatment and hospital stays. Increasing cost and health related complications necessitate the research for improving currently employed biomaterials for catheter applications. Creating antifouling surfaces by immobilizing zwitterion molecules on material surfaces has been proved to be a promising strategy. Herein, we investigated zwitterion surface-functionalized thermoplastic polyurethane (TPU) for use in antifouling catheter. The thermoplastic polyurethane was synthesized to have an allyl ether side functionality. Zwitterion surface-functionalization was achieved *via* thiol-ene ‘click’ chemistry in aqueous conditions. The XPS results confirmed the presence of chemically tethered zwitterion moieties on the zwitterion-TPU surface. The Quartz crystal microbalance (QCM) results show reduced fibrinogen attachment for the zwitterion-TPU when compared to its unfunctionalized controls. The zwitterion-TPU also showed a log scale reduction in bacterial adherence. For *P. aeruginosa and S. epidermidis*, the zwitterion-TPU resulted in around a 40% and 50% lower bacterial biomass accumulation, respectively. The fibroblast cell viability of TPU remained unaffected by functionalization with zwitterion thiol. Our results suggest a zwitterion modified TPU is a promising candidate for antifouling catheters.

Carbon Nano-Interfaces for Medical and Biological Applications RogerNarayan; North Carolina State University, United States

Recent studies have evaluated the use of microcrystalline diamond, nanocrystalline diamond, and diamond particles for medical applications. In this talk, materials studies and *in vitro* studies describing the interactions between diamond and medically-relevant eukaryotic cells and prokaryotic cells will be considered. The attachment of eukaryotic cells and prokaryotic cells to diamond surfaces will be considered. In addition, recent developments involving the use of diamond in active medical applications, including electrochemical sensing, will be described. Our recent finding involving diamond surfaces indicate that diamond surfaces may offer significant improvements for the diagnosis and treatment of medical conditions over the next few decades.

8:45 AM *SB03.10.03
Multiscale Small Molecule Interactomics and Behavioural Biomimetics using the CANDO Platform ZackaryFalls[1], WilliamMangione[1], BrennanOverhoff[1,2], LianaBruggemann[1], MatthewHudson[1], JamesSchuler[1], ManojMammen[1] and RamSamudrala[1]; [1]University at Buffalo, United States; [2]Harvard University, United States

Our goal is to understand and engineer small molecule behavior and functionality at multiple scales. We accomplish this by developing technologies to describe small molecule behavior and

function in terms of their multiscale signatures, which are utilised to engineer safe and effective chemicals and materials for the betterment of society by discovering optimal probes and therapeutics; generate safer and better chemicals and materials; and promote health, quality of life, and prosperity.

We elucidate the scientific tenets determining small molecule behavior in a variety of contexts, starting from the atomic and macromolecular scales, proceeding to pathways, cells and beyond, eventually reaching the phenotypic and population scales. The tenets are embedded in the form of multiscale signatures, comprising the sub-signatures at each scale, i.e., small molecule-macromolecule, -pathway, -cell and -phenotype signatures. At each scale, we determine the interaction signature using a combination of calculations and measurements, which will be enhanced with relevant information from lower scales.

We developed the Computational Analysis of Novel Drug Repurposing Opportunities (CANDO) platform for shotgun multitarget drug discovery, repurposing, and design, funded in part by a NIH Director's Pioneer Award and multiple NCATS ASPIRE Awards to implement this paradigm and overcome the limitations of traditional single target approaches. The open source platform screens and ranks drugs/compounds for every disease/indication (and adverse event) through large scale modelling and analytics of interactions between comprehensive libraries of drugs/compounds and protein structures. CANDO is agnostic to the interaction scoring method used; two primary pipelines within the platform allow for rapid screening and assessment of billions of drug/compound to protein interactions with fast bioanalytic docking and machine learning affinity regression protocols. CANDO implements a variety of benchmarking protocols for shotgun repurposing to determine how every known drug is related to every other in the context of the indications/diseases for which they are approved, which enables evaluation of various pipelines and protocols within and external to the platform for their utility in drug discovery. We have performed predictive analytics on the CANDO interaction matrices to classify drug, protein, pathway, disease, and adverse event relationships accurately. The multiple fast and accurate interaction scoring/docking protocols, the proteomic scale, and rigorous all-against-all benchmarking used within the platform make it unique and ideal for the design of novel chemical entities that target a desired proteomic/interactomic space or objective.

CANDO has been extensively validated for drug discovery, repurposing, and design; recent work on COVID-19 shows 25% our top drug candidates having in vitro efficacy including two nanomolar concentration full virus inhibitors of SARS-CoV-2, one of which was ranked #1. We already produced preliminary designs for various indications (such as non-small cell lung cancer, opioid/substance use disorder and pain, and aging) using the design pipelines implemented in CANDO. CANDO is capable of performing analytics on any arbitrary drug/compound, including those chemicals relevant to industrial use such per-and polyfluoroalkyl (PFAS) substances to design safer and better compounds. The most potent designs will be pursued further for development and regulatory approval. Elucidating multiscale signatures of small molecules lends itself to a paradigm-shifting view of small molecule behavior and function that will enable detailed engineering of small molecules for myriad applications. This talk will describe the current state of the CANDO platform and future plans for use in materials research.

9:15 AM SB03.10.04
Harnessing Gradients for Self-Assembly of Peptide-Based Nanocapsules: A Pathway to Advanced Drug Delivery Systems HaopengLi[1], XuliangQian[1], HariniMohanram[1], XiaoHan[1], HuitangQi[2], GuijinZou[3], FenghouYuan[2], AliMiserez[1], QingYang[4], TianLiu[2], HuajianGao[1,3] and JingYu[1,1]; [1]Nanyang Technological University, Singapore; [2]Dalian University of Technology, China; [3]A*STAR, Singapore; [4]Chinese Academy of Agricultural Sciences, China

Biological systems often create materials with intricate structures to achieve specialized functions. In comparison, precise control of structures in man-made materials has been challenging. Here, we report a serendipitous discovery of insect cuticle peptides (ICPs) spontaneously forming nanocapsules through a single-step solvent exchange process, where the concentration gradient resulting from mixing of water and acetone drives the localization and self-assembly of the peptides into hollow nanocapsules. The underlying driving force is the intrinsic affinity of the peptides for a particular solvent concentration, while the diffusion of water and acetone creates a gradient interface that triggers peptide localization and self-assembly. This gradient-mediated self-assembly offers a transformative pathway towards next-generation drug delivery systems based on peptide nanocapsules.

4D Printing of Hydrogels with Hiearchical Surface Wrinkling Patterns MuratGuvendiren; New Jersey Institute of Technology, United States

Additive manufacturing of stimuli responsive materials leads to 3D printed constructs that can adapt their properties in response to an external stimuli. This process is referred as 4D printing. 4D printing is commonly used to fabricate shape-shifting constructs, which change their asprinted shape into a preprogrammed shape post-printing with response to an external stimuli. Although 4D printing of shape-shifting objects have significantly expand the applications of 3D printing, novel ink formulations are needed for 4D printing to create 2D and 3D structures that allow dynamic control of properties beyond shape change. In this study, we present smart inks for material extrusion-based direct ink writing (DIW) printing that display preprogrammed surface wrinkling patterns on 2D and 3D surfaces post-printing, which appear only when exposed to a solvent. Hydrogels displaying surface wrinkling patterns with user-defined order and shape are useful for a range of applications, including microfluidics, flexible electronics, smart adhesives, optical sensors, and cell culture platforms. However, conventional techniques to fabricate wrinkling patterns involve multiple steps and are significantly limited to create hierarchical patterns, wrinkles on 3D and non-planar structure. It is also very difficult to scale-up the manufacturing process and to integrate surfae patterning into a continuous manufacturing process. 4D printing is used in this work to overcome these issues. The use of photocurable ink formulations allow us to tailor flow properties and printability by controlling photopolymerization time and partial crosslinking time. The crosslinker concentration is varied to develop distinct ink formulations with preprogrammed wrinkling morphology, including lamellar, peanut and hexagonal patterns. We demonstrate 4D printing of optical devices, solvent sensors, anti-counterfeit devices and high-throughput cell culture platforms.

10:45 AM *SB04.01.02

Electronic Hydrogels for Plant and Environmental Monitoring EloiseBihar[1,2], ElliotStrand[1], CatherineCrichton[1], MeganN. Renny[1], RobertMcLeod[1] and GregoryL. Whiting[1]; [1]University of Colorado-Boulder, United States; [2]University at Buffalo, The State University of New York, United States

Significant progress has been achieved in the field of electronics dedicated to environmental monitoring in recent decades. Currently, a key challenge lies in establishing an enhanced interface between electronics and living tissues. The proliferation of miniaturized sensors designed for plant and environmental sensing necessitates the development of hybrid sensors that employ cutting-edge techniques and novel organic materials to mitigate the formation of fibrotic tissues.
In this context, we introduce a novel generation of biocompatible and stretchable electronic gels, which showcase remarkable mechanical properties and self-repair capabilities. These gels also exhibit a wide array of functionalities, including exceptional conductivity levels of up to 350 S cm-1, high transconductance ranging within the mS range, and high capacitance values of up to 4.2 mF g-1. Leveraging the unique characteristics of these electronic gels, we can effectively stimulate or record ionic activities both in vivo and ex vivo, enabling the monitoring of plant electrophysiology or serving as energy storage systems for agricultural monitoring.

11:15 AM SB04.01.03
3D Printed Bioelectronics via *In-Situ* Enzymatic Polymerization of Conjugated Oligomer-Based Hydrogel BioinksChangbaiLi, SajjadNaeimipour, FatemehR. Boroojeni, TobiasAbrahamsson, XenofonStrakosas, CarolineLindholm, ChiaraMusumeci, HanneBiemans, MariosSavvakis, MaryJ. Donahue, JenniferGerasimov, RobertSelegård, MagnusBerggren, DanielAili and DanielSimon; Linköping University, Sweden

Hydrogels are an attractive material system for interfacing between medical devices and human neural tissues due to their similar mechanical properties. However, most conventional hydrogel-based bio-interfaces lack electrical conductivity and thereby cannot relay electrical signals related to neural recording and activation. Here we show how in situ enzymatic polymerization of the conjugated oligomer-based hydrogel can be utilized to create cell-compatible and electrically conductive hydrogel structures. Conductive hydrogel structures were fabricated using 3D printing of hydrogel bioinks loaded with conjugated oligomers, followed by enzymatic polymerization of the conjugated oligomers by horseradish peroxidase. The polymerization of the conjugated oligomers modified the electroactivity of the hydrogels and resulted in a significant increase in stiffness from about 0.6 kPa to 1.5 kPa. Both the components and polymerization process as well as the resulting conductive hydrogels were well tolerated by both human primary fibroblasts and PC12 cells. This work thus shows possibilities to fabricate cytocompatibility and conductive hydrogels that can be processed using bioprinting. In addition, these hybrid materials show tissue-like mechanical properties and the hydrogels possess mixed ionic and electronic conductivity, which can provide new means to leverage electricity to manipulate cell behavior in a native-like microenvironment.

11:30 AM SB04.01.04
Achieving Tissue-Like Properties in 3D Printed Conducting Polymer Hydrogels SomtochukwuS. Okafor[1], TianranLiu[1], AnnaP. Goestenkors[1], BarbaraA. Semar[2], RileyAlvarez[1] and AlexandraRutz[1]; [1]Washington University in St Louis, United States; [2]Washington University in St. Louis, United States

Conducting hydrogels are sought for integration into bioelectronic devices to impart soft, hydrated, and tissue-like properties. However, the compatibility of these materials with advanced manufacturing and the ability to tailor functional properties for application remain limitedly reported. With regards to structural design, additive manufacturing offers customization and complexity with respect to object shape, dimensions, and internal microstructure. Additionally, materials processing as part of the additive manufacturing procedure can be used to control functional properties important for cell-material interactions and device performance. In this work, we developed methods for 3D extrusion printing conducting polymer hydrogels based on poly(3,4-ethylenedioxythiophene) polystyrene sulfonate (PEDOT:PSS). We demonstrate control of hydrogel properties by careful pre-printing ink formulation and appropriate post-printing processing. Shear-thinning and self-healing hydrogel inks were developed. Consistent rheological (viscosity, storage and loss modulus) and printing properties (mass flow rate, particle size) were maintained by manipulating the gelation kinetics of PEDOT:PSS using temperature. A gel-based support medium enabled fabrication of multi-layered structures after adding a gelation agent to increase structural resolution. Printed PEDOT:PSS hydrogels exhibited tissue-like properties including an elastic modulus of ~5 kPa and water content >99%. When further treated with heat or solvent, a wide range of conductivity (10 – 10,000 S/m) was achieved. Furthermore, hydrogels printed into microporous scaffolds were stable in physiological conditions for at least 28 days, and supported viability and proliferation of seeded human primary cells. Collectively, these results provide methods of fabricating PEDOT:PSS hydrogels that offer customization for various biointerfacing applications with regards to structural design and functional properties.

SESSION SB04.02/EL05.02: Joint Session: Neuro- and Neuro-Morphic Applications
Session Chairs: Cindy Harnett, Juejun Hu, Seungwoo Lee, Anna-Maria Pappa, Alexandra Rutz, Christina Tringides and Shiming Zhang
Monday Afternoon, November27, 2023

1:30 PM *EL05.02/SB04.02.01
Multifunctional Conducting Polymer Hydrogels for Regenerative Bioelectronics MariaAsplund[1,2], SebastianShaner[3], LukasMatter[1], OliyaAbdullaeva[2], JoseA. Leal Ordonez[3], AnnaSavelyeva[3], BruceHarland[4], BradRaos[4], HanLu[3], MaximilianLenz[3], ChristianBoehler[3], DarrenSvirskis[4] and AndreasVlachos[3]; [1]Chalmers University of Technology, Sweden; [2]Luleå University of Technology, Japan; [3]University of Freiburg, Germany; [4]The University of Auckland, New Zealand

Bioelectronic medicine refers to technology which use electrical signals, either recorded from or injected into tissue, for therapeutic effect. To date, the focus of electrical stimulation has almost exclusively been on excitable tissue, such as nerve and muscle cells, which respond to short stimulation impulses. Nevertheless, a much broader range of cells are able to respond to direct current, e.g. many cells change shape, growth or align their migration trajectories in accordance with an applied electrical field. It is hypothesized that such effects can be used to steer regenerative processes, modulate neural function or explain cancer metastasis, however, there is little technology developed that allows for such investigations in complex biological models. In our research we are developing methodologies that would make such exploration possible, in complex cell cultures, in vivo and at later stages also in patients.
Key to success is to identify electrode materials that make it possible to interface intimately with living tissues and deliver direct current without corrosion. The typical noble metal materials have limitations in terms of charge injection and corrosion resilience, and their electrochemistry is in general not well-matched to ionic current stimulation. Meanwhile, conducting polymer hydrogels show great promise as they can transport and deliver ionic current via biocompatible charge injection mechanisms, even in the direct current domain.
In my talk I will showcase how we employ conducting polymer hydrogels for direct current stimulation, and how such technology allows for new discoveries as well as potential future therapies. One such application field is wound healing, where we have used conducting polymer hydrogels to show how direct current stimulation of an *in vitro* epithelial wound model resulted in 3 times accelerated wound closure. Another possibility is spinal cord repair where we are exploring how to integrate electrodes for direct current stimulation in a flexible implantable bioelectronic system. By paying close attention to aspects such as electrode/electrolyte reactions, substrate electrolyte reactions as well as the interplay between the fundamental properties of the conducting polymer hydrogel and polymer-substrate adhesion layers, we hope to build a concept for fully biocompatible and implantable regenerative DC stimulation.

This work was supported by the European Research Council (ERC) grant agreement No. 759655 (SPEEDER) the CatWalk Spinal Cord Injury Trust and the Health Research Council of New Zealand (Project grant and HRC/Catwalk Partnership 19/895). Further support was provided by the center for Innovative Brain Machine Interfacing Technology at the University of Freiburg.

2:00 PM *EL05.02/SB04.02.02
Conductive and Biofunctional Hydrogels for Regenerative Living Interfaces in the Nervous System RylieGreen; Imperial College London, United Kingdom

Neurological disorders affect more than 60 million people every year and constitute a major clinical challenge. Due to the limited cellular turnover and the significant degeneration triggered by neural injury and disease, regenerative therapies constitute a promising strategy to ameliorate the symptoms. Living bioelectronics offer the potential to create living interactions between implants and the endogenous neural system. By providing a tissue engineered scaffolds containing neuroprogenitor (or stem) cells at the neural interface, this approach can grow connections, creating an intimate and regenerative cell-level interface. The major challenge in this technology is the need to support the cells and encourage their development into mature neurons, while creating functional synapses with target tissue. Hydrogels with conductive elements have been designed with degradation kinetics that are matched to neuronal differentiation and wound healing, while also being electrically addressable. Critically, these hydrogels provide biological and topographical cues that promote the survival of cells and ability to produce neurite processes. A system based on PVA and gelatin has been shown to support the differentiation of neuroprogenitor cells into functional neural networks at the interface of bionic devices. The incorporation of gelatin into poly(vinyl alcohol) - norbornene hydrogels (PVA-Gel-NB) was shown to provide biochemical cues that were able to be modified by the encapsulated progenitors, which ulitmately integrated into brain tissue. In an alternate injectable system, self assembly peptides (SAPs) were modified to form fibers with conductive cores that supported cells in producing directional growth. The use of electrical stimulation that mimicked the pattern of brain activity experienced *in utero* by the developing mammalian CNS, was subsequently demonstrated to increase the number of mature differentiated neurons. Action potentials have been observed within both of the cell populations, showing their development into appropriate cells types. Ultimately, this work demonstrates the ability to bring bioelectronics and tissue engineering concepts together to produce regenerative neural tissue constructs.

2:30 PM EL05.02/SB04.02.03
Development of a Hydrogel-Actuated 3D Micro Electrode Array (MEA) for Neural Spheroids and Organoids OutmanAkouissi, EleonoraMartinelli, LucaLiebi, JanerVan der Graaf Mas, SilvestroMicera and StephanieP. Lacour; Ecole Polytechnique Federale de Lausanne, Switzerland

Organoids and spheroids are versatile tools in research. Their 3D structure can faithfully replicate the complexity and functionality of human organs and tissues, enabling scientists to study biological phenomena in a dish. Specifically, neural organoids and spheroids offer exciting opportunities for understanding neuronal connectivity and exploring neurological disorders. Electrophysiological recordings play a crucial role in assessing these parameters. While micro electrode arrays (MEAs) are commonly used for such measurements, they are mostly limited to 2D (planar) configurations, which do not fully capture the complexity of three dimensional organoids and spheroids.
In this study, we present an intuitive 3D MEA platform based on shape-morphing bilayers to engulf the spheroid and enable recordings from its entire surface. The first layer forms the microelectrode arrays patterned as a thin metal film embedded in polymers such as polyimide and parylene. The second layer consists of a hydrogel membrane covalently grafted onto the MEA and capable of swelling upon immersion in cell culture medium thereby enabling actuation.
By precisely tuning the hydrogel formulation, bilayer thicknesses, and MEA geometry, we successfully designed 3D MEA platforms that accommodate a wide range of tissue sizes and shapes. One device included 32 electrodes, with a radius of 15 µm, distributed onto 4 bilayers folding with a radius of closure 300 µm. To expedite and guide the design and microfabrication process, we conducted comprehensive mechanical and electrical characterization of each component, and developed accurate in silico finite element models. The shape morphing MEAs interface reliably with commercial MEA readout platforms, requiring no additional instrumentation and minimal training.
We aim to study network patterns collected from the volumetric MEA over neural spheroids and hope to collect valuable insights into the connectivity, health, and functionality of neural organoids.

2:45 PMDISCUSSION TIME

3:00 PMBREAK

3:30 PM EL05.02/SB04.02.04
Stretchable Optical Memristor Design, Fabrication and Characterization DingchenWang[1], ShileiDai[1], SongruiWei[2], XiaoTang[2], KunbinHuang[2], DingyaoLiu[1], BinbinCui[1], HanZhang[2], ShimingZhang[1] and ZhongruiWang[1]; [1]Hong Kong University, Hong Kong; [2]Shenzhen University, China

Wearable electronics/photonics are developing rapidly in the era of artificial intelligence (AI) and the Internet of Things (IoT). However, wearable computing devices developed so far are mainly limited to "electronic hardware" implementations, which are incompatible with wearable photonic components. A highly attractive vision is to develop wearable photonic computing devices that can be attachable to the human skin for direct interface with wearable photonic components, such as optical sensors. In this work, we present a novel material combination for a buried waveguide-type, hydrogel-based stretchable optical memristor that can be used for next-generation wearable photonic computing.
To fabricate a stretchable optical memristor, we first fabricate a PDMS substrate with a straight waveguide channel. Then we synthesize polyoxometalates (POMs) doped polyacrylamide (PAAm) hydrogel with a refractive index of 1.43, which is higher than that of PDMS (1.41) at visible light wavelengths thus allowing total internal reflection in the hydrogel, inside the waveguide channel. The POMs within the hydrogel can be switched between a reduced, colored state and an oxidized, uncolored state under UV and oxygen environments, respectively, thereby modulating the transmittance across the visible light spectrum. We use UV light for programming the waveguide transmittance and a 650 nm light for optical readout due to its large photochromic response. By controlling the UV and oxygen environments, we achieve a maximum attenuation of 12 dB, 16 levels of memory, retention over 10000 s, and reversibility under an oxygen environment. Moreover, the stretchable optical memristor exhibits intrinsic stretchability owing to the hydrogel matrix, enabling it to withstand up to 50% strain while maintaining performance after repeated stretching. The combination of POM-doped hydrogel and PDMS substrate enables a buried-type waveguide that functions as an effective optical memristor with inherent stretchability. Such a stretchable optical memristor holds promise for applications in wearable photonic computing, serving as a key component of photonic skin for smart wearable devices, personal healthcare devices, and human-machine interaction interfaces.

3:45 PM *EL05.02/SB04.02.05
Hydrogel-Based Flexible and Multifunctional Fibers for Next-Generation Neural Interfaces SeongjunPark; KAIST, Korea (the Republic of)

To understand the mechanism underlying the function and dynamics of the nervous system or to treat neurological disorders, it is essential to develop the techniques capable of modulating and recording a diversity of signals employed by neurons. However, current approaches are limited in terms of effectiveness, side effects, non-specificity, and mechanical invasiveness. Naturally, there is a huge need for new devices or materials allowing for minimally invasive manipulation and monitoring of neural activity. My talk will introduce the complementary strategy to address these challenges with hydroge-based flexible and stretchable fiber-based probes for interfacing with the brain and spinal cord. This technology enabling the interrogation with neural circuits across their diverse signaling modalities without inducing a foreign-body reaction helps the study of information processing as well as pathologies of the nervous system.

4:15 PM EL05.02/SB04.02.06
Development of 3D Hydrogel-Based *In Vitro* Circuits with Cocultures of Human Sensory Neurons and Schwann CellsBlandineF. Clément[1], ChristinaM. Tringides[1], ViliusDranseika[2], JensDuru[1], TobiasRuff[1] and JanosVörös[1]; [1]ETH Zürich, Switzerland; [2]University of Zürich, Switzerland

Engineered *in vitro* neural networks are promising platforms to rapidly screen drugs and study information flow in the nervous system [1]. While existing polydimethylsiloxane (PDMS)-based microfluidic platforms offer precise architecture and connectivity, the cultured neurons grow inside microchannels on a planar multielectrode array (MEA) substrate in a two-dimensional fashion [2]. To better mimic the native extracellular matrix (ECM) microenvironment, 3D hydrogel scaffolds can be designed so that encapsulated cells can be expected to exhibit more physiological behavior [3].
Here, we propose a hybrid approach by filling the PDMS microstructure with hydrogels to offer both a controlled topology and a physiologically relevant microenvironment to the neuronal culture. First, a gelatin methacryloyl (GelMA) hydrogel was engineered by incorporating ECM components and tuning its mechanical properties to match the native niche environment. The hydrogel material was able to 1) support the growth of human iPSC-derived sensory neurons for more than 9 weeks 2) support co-culture with human Schwann cells where the latter could align along the axons. Next, microchannels were filled with the optimized hydrogel precursor, and after crosslinking, the neurons and glial cells were seeded as pre-aggregated spheroids in desired location(s). This enabled topologically defined growth of neurites in 3D.
By further tuning the hydrogel type and its physico-mechanical properties, the microstructures could be filled and tailored for specific cell types, while the underlying MEA allows for the recording of neuronal activity over time. This platform could offer a promising tool to study cell-cell interactions of single cultures or co-cultures, and to efficiently test the potential of various drugs in a more translational manner.

Biodegradable Materials for Optoelectronic Neural Modulation and Electronic Medicine LanYin; Tsinghua University, China

Devices built on biodegradable materials possess unique characteristics that enable complete biodegradation in physiological environments, thus eliminating the need for retrieval surgery and minimizing the associated risks of infection. These devices can play a critical role in therapeutic and diagnostic processes, including neural modulation, tissue regeneration, etc. Herein, we introduce materials options and fabrication strategies that enable the development of a biodegradable and flexible optoelectronic device, capable of achieving efficient neural stimulation and

functional recovery on peripheral nervous systems. Furthermore, we propose a bioresorbable and self-powered device as electronic medicine for peripheral nerve regeneration. Successful nerve regrowth and motor functional recovery are realized in rodent models. These works provide new insights for modulating neural activities and repairing nerve injuries.

Reprocessable Ion-Conducting Elastomer Formed by Thiourea-Based Dynamic Covalent Network BitgaramKim[1], Yeong JeCho[1], Dong-GyunKim[2] and Ji-HunSeo[1]; [1]Korea University, Korea (the Republic of); [2]Korea Research Institute of Chemical Technology, Korea (the Republic of)

The development of ionic conducting elastomer (ICE) with reprocessing capability is desirable to prevent resource wastage and environmental crises. Traditional elastomers with covalent cross-linking pose challenges for reprocessing due to their thermoset properties. To address this issue, a thiourea-based dynamic covalent network was employed to design the ICE. Through an analysis of the interaction between the lithium salt and the polymer chain, LiTFSI was selected as the ideal choice. Furthermore, the analysis revealed that the behavior of the dynamic covalent network was influenced by the interactions between the polymer chain and lithium salts, not just the network formation itself. The resulting dynamic covalent elastomer can be reprocessed multiple times using various methods such as hot-pressing and solution processes. It demonstrates good dimensional stability and exhibits an ionic conductivity.

8:00 PM SB04.03.02
Minimally Invasive Bioprinting of Conductive Hydrogel for *In Situ* Liver RegenerationYueyingYang and JianfengZang; Huazhong University of Science and Techonology, China

In situ bioprinting is promising for developing scaffolds directly on defect models in operating rooms, which provides a new strategy for *in situ* tissue regeneration. However, due to the limitation of the printing depth and bioink, bioprinting scaffolds in deep dermal or extremity injuries remains a grand challenge. Here, we present a ferromagnetic intravital bioprinting approach for *in situ* tissue regeneration in a minimally invasive manner. The ferromagnetic intravital bioprinting system is able (1) to measure and identify the geometry of organ defects by micro-CT, (2) to plan a matched printing path, and (3) to deliver multiple bioinks to fabricate scaffolds on defects in a minimally invasive manner. The minimally invasive bioprinter is composed of a ferromagnetic soft catheter robot (FSCR) nozzle that can arrive at the deep dermal (0-150 mm) through a small incision (2-4 mm) and a separated remote magnetic actuation system that numerically controls the movement of FSCR. The hydrogel bioink is designed to be electroactive, self-healing, biocompatible, biodegradable, tissue adhesive and extrusion printable. After 3D reconstruction of the defects with computed tomography (CT), conductive hydrogel scaffold is printed within a partial liver resection of live rat, and in situ tissue regeneration is achieved due to the electroactive hydrogel scaffold, promoting the orderly arrangement of fibroblasts and collagen *in vivo*.

8:00 PM SB04.03.03
Magnetic Nanogels for Combined Hyperthermia and Chemotherapy of Prostate Cancer SofiaPatri[1,2], ThanhT. Nguyen[2] and NazilaKamaly[1]; [1]Imperial College London, United Kingdom; [2]University College London, United Kingdom

Iron Oxide Nanoparticles (IONPs) are FDA approved for biomedical applications, such as magnetic hyperthermia: IONPs can generate heat as a consequence of their relaxation mechanism after being placed in an Alternating Magnetic Field (AMF). The heat generation is measured in Specific Absorption Rate (SAR) and agglomerations of IONPs, known as NanoFlowers (NFs), have shown to have some of the highest SAR values out of all the variations of this material. The surface of IONPs and IONFs can be modified with an organic coating to increase their biocompatibility. By selecting the appropriate soft material, the organic shell can also encapsulate a cargo and release it over time: this kind of magnetic composite can combine hyperthermia with drug delivery, making it a highly effective treatment against cancer cells. Nanogels, which are hydrogels in the nanoscale, are highly biocompatible and stable in the biological environment thanks to their crosslinked network; more importantly, they can be engineered to respond to an external stimulus. By including a thermo-responsive unit in the nanogel, an increase in temperature will induce a coil-to-globule transition of the chains causing the shrinkage of the nanogel and the expulsion of water along with the encapsulated cargo.
In this multifunctional therapy, we aim to trigger drug release from a nanogel by using the heat generated by the IONFs in an AMF. To improve the stability of the nanocarrier in the physiological environment, we demonstrate the necessity to anchor the nanogel to the IONFs through a surface ligand. The development of functional and stable magnetic nanogels provides a more effective, localized, and precise therapy that combines the benefit of the monotherapies while minimizing their individual drawbacks whilst establishing synergistic actions.

8:00 PM SB04.03.04
Conducting Hydrogel Based on Novel Polymer Composite PEDOT:DBSA for Bioelectronic ApplicationsŠárkaTumová[1], RomanaMalečková[1], PetrSmísitel[2], LubomírKubáč[3], JiríAkrman[3], JiríSmilek[1], MichaelaPešková[4], JanVíteček[4], MartinVala[1] and MartinWeiter[1]; [1]Brno University of Technology, Czechia; [2]Central European Institute of Technology, Czechia; [3]Centre for Organic Chemistry, Czechia; [4]Institute of Biophysics of the Czech Academy of Sciences, Czechia

Organic bioelectronics represents a potential revolution in medicine as it holds the promise of personalised treatment with reduced side effects compared to conventional pharmaceutical drugs. Despite the big effort dedicated to this field, there are still challenges to be solved. One of them is the form of organic polymers acting as active material, as the commonly used thin films are not very favourable with regard to the tissues that are supposed to be in proximate contact with them. That is mainly due to the dissimilarities in mechanical and physical properties of these two components, which might be an obstacle preventing the formation of a satisfactory interface, thus reducing the efficiency of signal transport. This properties mismatch arises especially from the differences in water content and elastic modulus values. Hence, there is a big demand for a more tissue-like form of these materials as it can significantly promote contact with tissues at the interface, thus reducing the adverse immune responses of the biological system, decreasing the interfacial impedance and enhancing the efficiency of both signal recording and stimulation. Among other structures, hydrogels seem to be the perfect interface to biological tissues due to their structural similarity with the extracellular matrix, tissue-like mechanical properties, water-rich nature, superior biocompatibility, flexibility and adjustable biochemical properties. In this work, we prepared and characterised a conductive hydrogel based on a completely new polymer composite – PEDOT:DBSA. The rheological characterization revealed that the mechanical strength of the hydrogel as well as the gelation time can be easily tailored to the desired application by changing the concentration of cross-linking agent. The electrical properties of the hydrogel were studied using impedance spectroscopy and cyclic voltammetry. It was shown that the total bulk conductivity of prepared hydrogel is 3.8 Sm^{-1}. The LDH cytotoxicity assay showed a very good biocompatibility of hydrogel compared to that of the culture plastic and glass dish. The structure of the hydrogel was investigated using scanning electron microscopy and was found to be of rough, spongy nature. These results indicate that PEDOT:DBSA hydrogel has great potential for creating an interface between the biological environment and electronic devices used in various fields of regenerative medicine.

8:00 PM SB04.03.05
Electrospun Hydrogel Nanoporous Scaffold for Cleaning Ultrafine Contaminants in Semiconductor Manufacturing SominShin, Ji-hunJeong and SanhaKim; Korea Advanced Institute of Science and Technology (KAIST), Korea (the Republic of)

In semiconductor manufacturing, chemical mechanical planarization (CMP) process is an essential step where wafers are polished via chemical and physical actions using externally supplied abrasives. After the CMP step, contaminants which include the remained abrasives and wear debris must be strictly removed from the wafer surface to prevent device failure via unintended particles. Accordingly, CMP cleaning always follows right after the CMP step. Post-CMP cleaning is particularly difficult as the contaminants are strongly adhered on the wafer surface due to as they are mechanical compressed during the polishing step. For such challenges, brush scrubbing techniques are widely employed due to their superb cleaning efficiency. The brush cleaning is in general conducted via porous polyvinyl alcohol (PVA) hydrogel brushes which make a physical contact with the wafer therefore can provide sufficient physical removal force to the surface particles for their removal.
The synthetic PVA hydrogel used as the wafer cleaning brushes comprises micropores, and has high swelling capacity against water-based cleaning solutions. The recent challenge arises as the pore sizes of commercial brush products remain in micro-scale whereas the size of the contaminants to be removed is ever shrinking to even few nanometers. Therefore, the existing brush products cannot effectively deliver the sufficient removal forces on ultrafine particles. In this research, we fabricate a PVA hydrogel scaffold comprising nano-scale porosity which can exhibit high effectiveness in particle removal for cleaning ultrafine contaminants. Insoluble polyvinyl formal (PVF), the raw material of cleaning brush, is synthesized via acid catalyzed acetalization of water-soluble PVA with formaldehyde which occurs with crosslinking of PVA chains by modifying hydroxyl groups. We produce nano-scale fibrous sheets using electrospinning process and investigate the effect of PVA/formaldehyde/sulfuric acid weight ratio as well as the processing conditions on the fiber formation. A heat treatment follows after the electrospinning step which reconstruct the fiber mat into a three-dimensional porous scaffold via creating fiber-to-fiber junctions, resulting in suitable mechanical strength and resilience. To verify the correlation between structural scale and particle removal efficiency, we conduct lab-scale wafer cleaning experiments on substrates contaminated with particles of various sizes, from 12 μm to 80 nm, using conventional microporous brushes and fabricated nanoporous scaffolds. We further experimentally verify that the effect of the structural scale is significantly more dominant. Our new

hydrogel nanoporous scaffold exhibit outstanding removal efficiency for ultrafine particles, thus can provide an effective engineering solution for the current limit in post-CMP ultrafine contaminant cleaning which is of-interest in semiconductor manufacturing industry.

8:00 PM SB04.03.06
Tissue-Adhesive and Anti-Swelling Hydrogel Based Multifunctional Implantable Sensor for Monitoring of Bladder Activity in Overactive Bladder with Surgical-Robot Assisted Laparoscopic Surgery ByungkookOh and StevePark; Korea Advanced Institute of Science and Technology, Korea (the Republic of)

Electrical properties and mechanical properties of a biological bladder tissue provide useful tissue information for preventing disabiling condition of urinary systems as clinical treatments. Recently, there has been a great deal in designing implantable electronics that collect tissue information and provide fundamental treatements. However, intrinsic differences between biological tissues and conventional rigid and dry electronics pose problems with unstable interaction between both surfaces and infection of biological tissues. Here, a highly stretchable and tissue-adhesive multifunctional implantable sensor based on structurally engineered islets embedded in ultra-soft hydrogel is developed for real-time monitoring of bladder activity in overactive bladder (OAB) induced rat and anesthetized pig. One critical issue with hydrogel in general as implantable substrates, however, is their eventual change in mechanical properties and electrical properties due to the gradual absorption of biofluids in the body. To overcome the critical issue, an anti-swelling coating technique that can prevent absorption of water and biofluids in the body is developed. This coating technique is applicable to various hydrogels that have low sol-gel transition temperatures, while imposing negligible changes in mechanical properties. Using tissue-like, anti-swelling hydrogel, which can sustain its initial mechanical & electrical properties as a role of an insulating substrate, can bridge sensory systems to biological tissue with robust seamless interaction without infection of tissues. The sensory systems integrated to soft bridging materials (hydrogel) consist of strain sensors (directly printed micro-capsules of EGaIn on an anti-swelling hydrogel substrate) and multi-array electromyography (EMG) sensors (Ti/Au) on structurally engineered ferris wheel-shaped islets that can make it possible to collect tissue information during repetitive micturition of overactive bladder. On the OAB induced rat, stronger signals (change in resistance and EMG root-mean-square) were detected near intra-bladder pressure maxima, thus showing correlation to bladder activity. Moreover, using robot-assisted laparoscopic surgery, the hydrogel-based implantable sensor was placed onto the bladder of an anesthetized pig. During micturition cycle, bladder strain and EMG were monitored. These results confirm that our proposed sensor is a highly feasible, clinically relevant implantable device for continuous monitoring OAB for diagnosis and treatment.

8:00 PM SB04.03.07
Highly Stretchable Hydrogel Fiber Fabricated by a Self-Coiling Mechanism Maintaining High Water-Content TaoLi and Seon JeongKim; Hanyang University, Korea (the Republic of)

Hydrogels, which are polymer networks dispersed in water, are widely used in biomedical fields, among others, because of their excellent mass transfer efficiency and biocompatibility. However, hydrogels with a high water content usually have poor mechanical properties and are easily broken. To address this issue, many researchers have incorporated one or more complementary materials into the polymer network of the hydrogel to limit its swelling. Although this method enhances the mechanical properties of hydrogels, it also limits the water content; therefore this method cannot be applied to improve the mechanical properties of high-water-content hydrogels. We have observed that a jellyfish called *Physalia physalis* preys on fish through its coiled stinging tentacles. Although the body of *P. physalis* has a water content above 95%, the coiled structure still provides high stretchability. In this study, we developed a coiled hydrophilic polyurethane hydrogel fiber with high stretchability and high water content by mimicking the coiled stinging tentacles of *P. physalis*. Dry hydrophilic polyurethane yarns produced by electrospinning were twisted under an applied load. When the twisted dry hydrophilic polyurethane yarn swelled with water, the change in Young's modulus and shear modulus elicited self-coiling within 1 s and resulted in a coiled hydrophilic polyurethane hydrogel fiber. The morphology of the formed coiled polyurethane hydrogel fibers can be tuned by adjusting the twist density and the stress resulting from the load applied during swelling. Compared with non-coiled hydrophilic polyurethane hydrogel fibers, the coiled hydrophilic polyurethane hydrogel fibers prepared by this method exhibited ultrahigh stretchability due to the coiled structure and elasticity of the material. When the coiled hydrophilic polyurethane hydrogel fibers are stretched, the uncoiling of the coiled structure provides stretchability, and the fibers can be further stretched due to the elasticity of the hydrophilic polyurethane hydrogel. In summary, we developed a coiled hydrophilic polyurethane hydrogel fiber that can rapidly swell and self-coil under aqueous conditions and possesses high stretchability, while maintaining high water content. It is expected to be used in biomedical fields for applications such as surgical sutures, drug delivery systems, and tissue regeneration.

8:00 PM SB04.03.08
Controllable Actuator by Reversible Clustering Transition Composed of Temperature-Responsive Hydrogel JiseongChoi and SeongminKang; Chungnam National University, Korea (the Republic of)

Hydrogel-based soft actuators, which can change their shape according to the various environment and has safe for the human body, are being utilized in various fields such as smart windows, etc. Among the hydrogels, N-isopropylacrylamide (NIPAm), due to its swelling characteristics dependent on the critical solution temperature (32 degree), can be used as a suitable actuator for different situations. Additionally, micropillars with high aspect ratio easily are transformed to clustering state under external forces, and both their original state and clustering state are being utilized as actuators. However, micropillars of clustering state once do not naturally de-clustered, having limitation of application by its non-reversible property of clustering state. In this paper, we fabricate micropillars actuator of a reversible clustering transition composed of thermo-responsive poly(NIPAm-co-acrylamide) hydrogels, verifying the potential applications of soft actuators. The actuator is clustered due to the decrease in mechanical properties of hydrogels by water, but it is de-clustered due to the increase in mechanical properties by hot temperature. Based on this phenomenon, we demonstrated the potential applications of micro grippers for capturing and transporting micro particles in water, as well as smart windows capable of reversible transitions in surface transmittance outside the water.

8:00 PM SB04.03.09
An Efficient Self-Healable and Recyclable Conductive Polymeric Blend with Excellent Mechanical Properties Based on PEDOT:PSS/PU JinsilKim and FabioCicoira; Polytechnique Montreal, Canada

Self-healable conductive polymers have been attracting attention because of the promising advances in electronic devices. Self-healable and conductive coating films are fabricated by blending a conductive polymer, poly (3,4-ethylenedioxythiophene): poly (styrene sulfonate) (PEDOT:PSS) with polyurethane (PU) having excellent mechanical properties. PEDOT:PSS/PU composites are characterized in terms of self-healing properties, recyclable properties, mechanical properties and electrical properties in this study. Polyurethane (PU) is synthesized by reacting with macro diol as a soft segment, isocyanate groups and extender as a hard segment. The two polymers have no noticeable phase separation in blending solutions. The self-healable coating materials exhibit outstanding self-healing capabilities and fast self-healing kinetics and therefore can be used for practical applications like flexible and stretchable electronic devices. The polymeric coating film is cut into two parts completely with a sharp blade then the damaged surfaces are connected under mild temperature for the healing process. The results from experiments exhibit using a mechanical tester to compare the mechanical properties of various compositions of PEDOT:PSS/PU and before and after self-healing processes, respectively. Regarding electrical performance, a cyclic tensile test is also performed to monitor the elasticity. The electrical conductivity maintains constant electrical conductivity under cyclic tensile stress when tensile stress is loaded up to 30% strain. The PEDOT:PSS/PU-based can be reused, improving the sustainability of electronic devices. All these results revealed that PEDOT:PSS/PU have the potential to enable to development of more sustainable and durable electronic devices by reducing electronic waste and improving the lifespan of electronic components.

8:00 PM SB04.03.10
Designing Azo-Based Color-Changing Hydrogels by Sensing pH Response Wei-TingChang, VioletPratt, NeelJoshi and LeilaDeravi; Northeastern University, United States

The wide applications for environmental sensing and responsible sensing materials using hydrogels can be excellent candidates across systems in biology. For instance, most living cells elicit pH changes during metabolism which we leverage as an actuator in the design of new pH-responsive hydrogels. We synthesized azo-based monomers from anthranilic acid and followed by azo coupling by the treatment of phenylpiperazine and acyl amide. These monomers can then be polymerized with bis-acrylamide, acrylic acid, and polyacrylamide as an adaptive hydrogel that change shape and color different pH environments. Applications of these gels are explored both with and without cells in different environments.

8:00 PM SB04.03.11
The Investigation of the Impact of Small Molecule Dopants on PANI/PAAMPSA Conductive Polymer system AryaAjeev; University Of Maine, United States

The use of wearable strain sensors has been advancing in modern life owing to their potential to pinpoint, respond, and interpret mechanical deformations from corresponding electrical signals, which can be measured in terms of electrical resistance. Polymeric piezoresistive sensors with remarked flexibility and wearable features have been extensively used in biosensing, human-motion monitoring and detection, e-skin, and, human-machine interaction. Traditional strain sensors, based on metallic and semiconducting material having low sensitivity and poor resistance response upon straining endow the need for compliant, elastic, stretchable, and self-healable sensors. In this work, the polymer complex to be used as a strain sensor is composed of a templating poly(2-acrylamido-2-methyl-1-propanesulfonic acid), polyaniline, and a small molecule dopant, originally phytic acid. By substituting the small molecule dopant with other small molecule acids, the impact the various dopants have on the strain sensor’s conductivity, mechanical properties, and piezoresistive sensitivity can be studied. Typically, small molecule dopants that increase conductivity decrease stretchability and mechanical stability, which stems from more acidic dopants being able to protonate and facilitate ion transport throughout the sensor. It has been shown that the functional groups with increased hydrogen bonding tend to increase mechanical properties. By increasing our understanding of the impact these various dopants have

on the properties of the strain sensor, the sensor can be tailored to specific applications, allowing for increased sensitivity when needed or increased stretchability when required. This will allow for the development of novel materials as we seek to manufacture better stretchable electronics.

8:00 PM SB04.03.12
Hydrogel-Enhanced Supported Lipid Bilayers (SLBs) Offer Greater Stability and Functionality in Bioelectronic Devices JordanP. Fitzgerald, ZhongmouChao and SusanDaniel; Cornell University, United States

Supported lipid bilayers (SLBs) have emerged as an indispensable material to functionalize the surface of bioelectronic sensors that facilitates the exploration of cellular membrane interactions with a wide range of molecules. SLBs accurately mimic the structure, composition, and diffusive properties of natural membranes, providing a biomimetic experimental model. Particularly noteworthy is the compatibility of SLB bioelectronics with electrochemical impedance spectroscopy (EIS), allowing for real-time monitoring of changes in impedance across SLBs. Such measurements provide valuable insights into changes in membrane properties, drug interactions, and the behavior of embedded proteins and channels. However, one drawback of these sensors currently is their vulnerability and limited shelf-life that impedes their broader application.
In this study, we combine hydrogels with SLB bioelectronic devices and show that the usable shelf-life of these devices can be extended significantly. Our approach exploits a range of hydrogels, each with unique characteristics that enhance system versatility. PEGDA, a UV crosslinked hydrogel, enhances the stability of both model POPC SLBs and native component SLBs. Other hydrogels, such as poloxamer based thermally reversible gel, and chitosan based chemically crosslinked gels, show potential for preserving UV- and temperature-sensitive components within the SLBs. Overall, this strategy extends the shelf life of the SLBs from a single day over 45 days, all while preserving the electrical signal integrity and functionality of proteins within the SLBs. This hydrogel-enhanced approach not only facilitates longer sensing periods, but also enables the long-distance shipping of functional SLB-based devices, necessary steps for translation to the field.
In addition to enhancing the shelf life and stability of the SLB-functionalized bioelectronic devices, the integration of hydrogels also boosts their functionality. The hydrogel layer not only facilitates improved stability but also enables the use of cell-free expression of proteins directly into the membrane. This expands the utility of our method, creating opportunities for more comprehensive investigations into the behavior of specific proteins and their responses to various agents within a highly stable, extended-lifespan SLB-based bioelectronic system. This research lays the groundwork for the development of sophisticated hydrogel-enhanced SLB systems capable of operating in complex environments, bringing us closer to the construction of advanced devices such as electrode arrays, sensors, and biomimetic devices, and expanding the scope of bioelectronic applications in biomedical research and beyond.

8:00 PM SB04.03.13
Thermo-Responsive Emulsion-Embedded Hydrogel Microparticle and Its Application to RT-qPCR SeoyoungLee, Lan KyeongYoon, SeungwonJung and Sang KyungKim; Korea Institute of Science and Technology (KIST), Korea (the Republic of)

Water-oil-water double emulsions (DEs) have been widely used as compartmentalized systems to encapsulate components for controllable and targeted reagent delivery. The components encapsulated in DE could be efficiently released upon various stimuli, such as changes in temperature, light, and chemical environment. Among them, by utilizing the heating as a controllable release stimulus, we herein developed a novel thermo-responsive DE-embedded hydrogel microparticle reactor suitably applicable for one-step quantitative reverse transcription polymerase chain reaction (RT-qPCR), which minimizes the non-specific reaction in the reverse transcription step. For this strategy, we encapsulated target-specific nucleic acid reagents (PCR primers and probes) in DE and subsequently entrapped DE in a micro-sized hydrogel PCR reactor. First of all, we adjusted the surfactant concentrations of DE for enhancing the DNA encapsulation efficiency and optimizing the DNA release efficiency to be maximized in the PCR denaturation step (95 ºC) as well as minimized in the reverse transcription step (55 ºC). From the perspective of DE itself, DNA encapsulation and release efficiencies at both 95 ºC and 55 ºC increased and decreased, respectively, with increasing concentrations of hydrophobic surfactant, while they were independent of hydrophilic surfactant concentrations. Moreover, we also investigated the change in DNA release tendency and optimized the surfactant concentrations when DEs were embedded in hydrogel microparticles. As a result, and importantly, the DNA release efficiency of DE entrapped in hydrogel significantly increased about 4 times at 95 ºC compared to that of DE itself, indicating that the DEs individually located within the hydrogel are more vulnerable to the release of DNA-encapsulated inner water phases. In addition, 8 CMC of hydrophobic surfactant and 37.5 CMC of hydrophilic surfactant were selected as the optimal conditions where 4.6 μM of DNA reagent was encapsulated, and 40% (1.80 μM) and 9% (0.15 μM) of reagent were released at 95 ºC and 55 ºC, respectively, demonstrating target-specific reagent delivery on demand. Consequently, under these conditions, we successfully confirmed the operation of one-step RT-qPCR in the thermo-responsive DE-embedded hydrogel microparticle and the developed hydrogel microparticle could be utilized as a powerful point-of-care testing platform for the multiplexed detection of several RNA biomarkers.

8:00 PM SB04.03.14
Nanoemulsions-Containing Hydrogel Microparticle Array PCR for Multiplex Discrimination of SARS-CoV-2 Variants Yoon-haJang, Eui JuJeon, SeoyoungLee, So YoungJeon, Lan KyeongYoon, SeungwonJung and Sang KyungKim; Korea Institute of Science and Technology (KIST), Korea (the Republic of)

Over time, viruses continually produce new genetic variants of themselves. Surveillance is needed to investigate how mutations in viruses affect the transmissibility and lethality of the virus as well as responses against therapeutic medicines [1]. However, whole genome sequencing, which is currently utilized for variant identification, has a limitation in testing a large number of samples, especially in a pandemic situation. Herein, we present rapid multiplex RT-qPCR for SARS-CoV-2 variant discrimination using the TaqMan probe and primer-incorporated network (TaqPIN). TaqPIN is a hydrogel microparticle where target-specific reagents such as primers and probes are preloaded as encapsulated in nanoemulsions [2]. The main challenge is to fabricate TaqPIN because the photoinitiators (PIs) required for curing hydrogel destabilize nanoemulsions and damage the fluorescently labeled probes encapsulated within the nanoemulsion. We found that free radicals generated by PIs damage the probes encapsulated within the nanoemulsions via the infiltration of PIs into the nanoemulsions. We successfully fabricated TaqPIN by using water-dispersible nanoparticles of 2,4,6-trimethylbenzoyl-diphenylphosphine oxide (TPO) as PIs. We found that fluorescently labeled DNA was well retained in the hydrogel particles even when TaqPIN was subjected to strong agitation, and TaqPIN PCR with the same concentration of sample showed constant Ct values up to 2 months. Finally, we constituted a 9-plex TaqPIN array for the identification of five SARS-CoV-2 variants of concern, including alpha (B.1.1.7), beta (B.1.351), gamma (P.1), delta (B.1.617.2), and omicron (BA.1), and the original Wuhan strain within 40 min. From 76 clinical nasal swab samples, the TaqPIN array RT-qPCR successfully discriminated variants with 95.5% sensitivity and 100% specificity. We envision that the TaqPIN array RT-qPCR can be applied to simple diagnostics to help detect and characterize circulating pathogens.

8:00 PM SB04.03.15
Towards Multi-Responsive Pluronic F127-Based Copolymer Hydrogels for Engineering Living Materials HenriqueSepulveda Del Rio Hamacek[1], LeAnnLe[2], Petri-JaanLahtvee[1], RahulKumar[1] and AlshakimNelson[2]; [1]Tallinn University of Technology, Estonia; [2]University of Washington, United States

Engineered living materials (ELMs) are dynamic systems featuring capabilities such as biosynthesis, self-organization, and self-healing[1]. Integrating polymeric matrices (abiotic) and cellular (biotic) components creates materials with novel functionalities and precise responsiveness[2]. Here, we deployed additive manufacturing using extrusion-based 3D printing to develop hydrogels capable of retaining cells for longer periods due to increased toughness, while facilitating better nutrient transport to the cells through improved ionic conductivity.
Initially, we formulated hydrogels containing Pluronic F127-bisurethane methacrylate (F127-BUM), methacrylic acid (MAA), and dimethylaminoethyl acrylate (DMAEA) at different monomer concentrations. We characterized the rheological and mechanical properties of these hydrogels. Rheological results revealed that all hydrogel compositions decreased viscosity with increasing shear rate while maintaining their shear-thinning properties even after multiple cycles of applied shear. These results indicate the potential for creating high-resolution 3D-printed structures. Additionally, temperature ramp experiments demonstrated that the hydrogels exhibited the characteristic Pluronic F127 temperature-dependent behavior[3], with decreased gelation temperatures upon MAA and DMAEA addition to the precursor mixtures.
Subsequently, tensile mechanical tests were conducted to evaluate the toughness and elasticity of the newly developed hydrogels. The results showed that the hydrogel composition with equimolar concentrations of MAA and DMAEA exhibited a 50% increase in elongation at break compared to control hydrogels consisting solely of F127-BUM. This material could also be elongated up to 600% of its original size, while the modulus of elasticity decreased by 35% compared to the control. These effects were attributed to the disruption of electrostatic interactions between MAA and DMAEA, which carry opposite charges at neutral pH. The formulated hydrogels demonstrated the necessary mechanical properties for cell-loading applications.
Finally, we loaded bakers' yeast (10^7 cells/g of hydrogel) into the selected hydrogels and analyzed their viability, metabolite production, and morphology during cultivation at 50 rpm and 30 °C. The hydrogel with MAA and DMAEA enabled cell retention for longer than previously reported for F127-BUM hydrogels with the same initial cell concentration[4]. Additionally, the cells remained metabolically active throughout the cultivation experiments.
In conclusion, this work demonstrates the potential of the developed hydrogel platform, featuring enhanced mechanical properties and improved ionic conductivity, for the additive manufacturing of ELMs. This platform holds promise for applications in bioengineering and highlights the importance of advanced materials in creating functional ELMs with enhanced capabilities.

Molecular Dynamics Simulation of Free-Formed Nanocomposite Hydrogels EmilySun[1], ShoumikSaha[2], JoseNicasio[2], DilipGersappe[2] and MiriamRafailovich[2]; [1]Westford Academy, United States; [2]Stony Brook University, The State University of New York, United States

Hydrogels are crosslinked polymer networks that can absorb and retain large quantities of water within their structures. Typically made of hydrophilic polymers, their swelling ability gives these materials properties of both solids and liquids alike. Recent studies highlight that combining hydrogel materials with clay-based nanofillers and charged solvents results in a hydrogel with enhanced properties. However, little is known about the theoretical mechanism of the gel's network formation. Here, we explore a system of free-floating polymer chains, clay-based nanofillers, and solvent to determine the specific conditions for a stable network formation, and optimal rheology of the gel. The aim of this study is to produce the strongest hydrogel, which can then be used for soil-strengthening applications.

We performed coarse-grained molecular dynamics with the LAMMPS software. Our polymer chains were constructed using the Kremer-Grest model, which defines bond interaction via the finitely extensible nonlinear elastic (FENE) potential. Other pairwise interactions between monomers were modeled by using the simple 12-6 Lennard Jones potential. We implemented this model for different polymer concentrations of N=300, 600, and 900, with varying distributions for their attractive regions, or "stickers," which were placed uniformly every 5th, 9th, and 14th monomers (5, 3, and 2 stickers). We turned on attractive interaction between stickers, which let polymer chains connect to undergo network formation. The polymers' dynamics were calculated through diffusion coefficients, gathered from mean-squared-displacement (MSD) values. We calculated stress auto-correlation (SAC) to determine the point at which our system forms a gel. We further ran shearing tests and polymer chain orientation during the shearing process will determine the specific shear thinning properties of our system. Our results show that by proper choice of polymer architecture we can design networks that can be used for soil amendment purposes.

Water Treatment: Harnessing the Potential of 2D-Enhanced Hydrogels AhmedM. Aboulella and BanuYildiz; Khalifa University, United Arab Emirates

Water scarcity and pollution are global challenges that demand innovative solutions. In this context, 2D-enhanced hydrogels have emerged as promising materials for advancing water treatment technologies. These hydrogels, composed of a three-dimensional network of hydrophilic polymers combined with two-dimensional nanomaterials, exhibit unique properties that enable their application in various water treatment processes. This review focuses on the synthesis, characterization, and functionalization of 2D-enhanced hydrogels, exploring their potential in addressing water quality and scarcity issues. We begin by discussing the fabrication methods of these hydrogels, highlighting the incorporation of 2D nanomaterials such as graphene oxide, graphene, and transition metal dichalcogenides. Their influence on the hydrogel's structure and properties, including increased mechanical strength, enhanced water absorption, and improved stability, is thoroughly examined. Moreover, the tunable nature of 2D-enhanced hydrogels allows for tailoring their porosity, swelling behavior, and selectivity, making them versatile materials for various water treatment applications. The functionalization of 2D-enhanced hydrogels with specific functional groups and nanoparticles is explored, illustrating their potential for pollutant removal, heavy metal ion adsorption, and advanced oxidation processes. Additionally, the use of these hydrogels as membrane materials, adsorbents, and catalyst supports is discussed in the context of water treatment devices. Their ability to selectively remove contaminants, resist fouling, and enhance overall system performance underscores their suitability for practical implementation. We also delve into the challenges and future directions of utilizing 2D-enhanced hydrogels in water treatment, including scalability, long-term stability, and environmental considerations. The integration of these materials into emerging technologies, such as membrane filtration, adsorption columns, and photocatalytic reactors, holds promise for addressing pressing global water challenges. In conclusion, 2D-enhanced hydrogels represent a transformative approach to advancing water treatment technologies. Their unique combination of 2D nanomaterials with hydrogel matrices offers a multifaceted solution for improving water quality and managing water resources efficiently. This review provides valuable insights into the synthesis, properties, and applications of 2D-enhanced hydrogels, laying the foundation for the development of sustainable and effective water treatment devices and processes.

Utilizing Bioprinting for Hydrogel-Based Electric Double-Layer Capacitor Fabrication BiancaSeufert and ArashTakshi; University of South Florida, United States

While electric vehicles are slowly bringing in a new era of eco-friendly transportation, the mass production and use of Li batteries have raised serious concerns about their impacts on the environment. Hence, supercapacitors that are able to be charged and discharged at high rates with high power densities and a long cycling stability are potential alternatives to batteries. There are three different types of supercapacitors: electric double-layer capacitors (EDLC) supercapacitors, pseudo-supercapacitors, and hybrid-supercapacitor. For the scope of this paper, however, only EDLCs will be discussed. Using biocompatible materials, supercapacitors are a viable charge storage device for implantable electronic sensors. This paper addresses a new approach to supercapacitor fabrication using a bioprinting method. A series of experiments were conducted to derive a conductive bioink capable of being implemented as a viable material for energy storage devices. This bioink in conjunction with a gel electrolyte were utilized for the fabrication of supercapacitors in a planar structure. This study utilizes the testing methods of Cyclic voltammetry (CV) and electrochemical impedance spectroscopy (EIS) using the VersaStat 4 Potentiostat to measure the capacitor response. Devices with capacitances as high as 53.52 µF were fabricated and tested. The results of this study show the feasibility of using the bioprinting method for fabricating prototype storage devices.

Turgor Pressure Reinforces Mineral-Based Composites RanZhao and EstherAmstad; École Polytechnique Fédérale de Lausanne, Switzerland

Nature fabricates hard functional materials from soft organic scaffolds that are mineralized. To overcome the brittleness of inorganic components, biominerals are arranged in hierarchical structures and sometimes develop local compressive or tensile stresses. For example, the precipitation of hydroxyapatite minerals leads to contractile stresses in collagen fibrils, and eventually reinforces mechanical properties of bones [1]. The fibril contraction comes from the dehydration of the polymer matrix, even though it happens in a hydrated environment. Similarly in plant cells, osmotic pressure is used to stiffen leaves by exploiting a strong turgor pressure [2]. Osmotic pressure is well-known to change the mechanical properties of living biological materials. Nevertheless, this strategy has thus far not been leveraged in mineral-based composites. This shortcoming might in part be related to the inferior mechanical behavior of synthetic composites compared to natural counterparts due to the limited structural control over different length scales.

Here, we demonstrate a mineral-based composite whose strength and stiffness can be repeatably adjusted through osmotic pressure driven swelling and de-swelling of confined hydrogels. Specifically, we employ a synthetic porous matrix with a similar degree of structural control from the nanometer up to the centimeter length scale made from an emulsion-based, 3D printable ink [3]. Those pores in the matrix are back-filled with a hydrogel, which can generate internal compressive or tensile stresses triggered by osmotic pressure gradients. The matrix can selectively bind certain cations such as Ca^{2+} ions, which can serve as mineralization sites upon addition of CO_3^{2-}. The hydrogel contractions induced through the mineral precipitations and osmotic pressure gradients lead to a synergetic control over the mechanics of the composite. This work provides an exciting concept for enhancing mechanical properties of mineral-based composites through turgor pressure similar to biological systems, which can be used as soft actuators or intelligent devices for underwater applications.

Nanoengineered Ink for Designing 3D Printable Flexible Bioelectronics AkhileshK. Gaharwar; Texas A&M University, United States

Flexible electronics require elastomeric and conductive biointerfaces with native tissue-like mechanical properties. The conventional approaches to engineer such a biointerface often utilize conductive nanomaterials in combination with polymeric hydrogels that are crosslinked using toxic photo-initiators. Moreover, these systems frequently demonstrate low signal accuracy, poor biocompatibility and face trade-offs between conductivity and mechanical stiffness under physiological conditions. To address these challenges, we introduce a class of shear-thinning hydrogels as biomaterial inks for 3D printing of flexible bioelectronics. These hydrogels are engineered through a facile vacancy-driven gelation of MoS_2 nanosheets and naturally derived polymer. Due to shear-thinning properties, these nanoengineered hydrogels can be printed into complex shapes that can respond to mechanical deformation. The chemically crosslinked nanoengineered hydrogels demonstrate twenty-fold rise in compressive moduli and can withstand up to 80% strain without permanent deformation, meeting human anatomical flexibility. The nanoengineered network exhibits high conductivity, compressive modulus, pseudo-capacitance and biocompatibility. The 3D printed crosslinked structure demonstrate excellent strain sensitivity and can be used as wearable electronics to detect various motion dynamics. Overall, the results suggest that these nanoengineered hydrogels offer superior mechanical, electronical, and biological characteristics for various emerging biomedical applications including 3D printed flexible biosensors, actuators, optoelectronics, and therapeutic delivery devices.

9:00 AM *SB04.04.03
Conducting Polymer Hydrogels for Hydrogel Bioelectronics HyunwooYuk; SanaHeal, Inc., United States

Electrical interfacing with biological tissues for interrogation and modulation of living systems – or bioelectronics – is one of the most important modes of communication between artificial machines and biological organisms. In conventional applications, bioelectronic interfacing has relied on conventional electrodes and devices made of metals and engineering solids like plastics and elastomers. However, the stark dissimilarity between biological tissues and conventional device materials has posed great challenges for long-term bioelectronic interfacing with living systems, especially for implantable devices. To address these challenges, electrically conductive hydrogels – polymer networks infiltrated with large amounts of water with electrical conductivity – have been substantially studied in the last decades owing to their unique advantages including tissue-like mechanical properties and high water contents, favorable electrical properties, and in vivo biocompatibility. However, conducting polymer hydrogels has faced several key challenges in their practical uses including poor electrical and mechanical properties in physiological environments, unreliable integration within devices and to the target biological tissue, and difficulties in small-scale fabrications into functional devices. In this talk, several advances in conducting polymer hydrogels to address these challenges will be discussed toward the vision of hydrogel bioelectronics.

9:30 AM SB04.04.04
Skin-printable, Self-adhesive and Bio-based Hydrogel for the Bioelectronic Interface Jia XiChen[1], Yi XinZhang[1], TerekLi[1], ZiaSaadatnia[1], MilosPopovic[2,1] and HaniNaguib[1,1]; [1]University of Toronto, Canada; [2]University Health Network, Canada

Inspired by the customizability of injectable hydrogels in the medical field as cell cultures and engineered tissues, a conductive and 3D-printable hydrogel based on bio-polymers is developed to interface between the skin and medical devices during rehabilitation treatments of surface functional electrical stimulation (sFES). The sFES treatment involves delivering electric currents through the skin to induce muscle contraction, with clinical evidence supporting the ability of sFES treatments to restore voluntary motor functions in previously paralyzed patients. However, physiological differences in muscle distribution and body curvatures among individuals require sFES treatments to be personalized. Therefore, to increase the accessibility of sFES rehabilitations by enabling remote sessions and shape-configurable electrodes universal to all patients, the authors developed a novel material capable of being adapted to any shape and size, with self-adhesive and electrically conductive properties to ensure conformity to body morphology and to guarantee sFES signal stability. As the electrodes are single-use, the hydrogel is made from naturally occurring, biocompatible, and eco-friendly polymers that are easy to fabricate and process. Carboxymethyl cellulose is adopted as the matrix for its water solubility and mechanical properties, along with poly(3,4-ethylene-dioxythiophene) polystyrene sulfonate (PEDOT:PSS) as the conductive additive and mussel-inspired polydopamine as the adhesive additive. A mild and biocompatible gelation method exploiting hydrogen bonding is implemented by adding phytic acid, with *in situ* formation of the extruded hydrogel taking place minutes after being 3D-printed onto the skin. The gelation process is examined with FTIR spectroscopy, which confirms the molecular interactions between bio-polymer components, scanning electron microscopy, which ensures the macroscopic morphology of the formed hydrogel, and rheological measurements over time, which characterizes the printability of the precursor ink. The pre-gel solution exhibits tailorable viscosity, allowing for facile processability and shape-configurability. Adhesive and electrical properties of the hydrogel are studied in contact with porcine skin over time. Although the self-adhesion of the hydrogel is two folds lower than commercial tissue adhesives, the interfacial electrical impedance is improved by an order of magnitude compared to commercial hydrogel electrodes. The sFES performance of the printable and conductive hydrogel is further assessed with a developed handheld 3D printer, a lightweight instrument to extrude the hydrogel ink in uniformly deposited layers with shape fidelity of mm-thick resolutions. Compared to conventional sFES electrodes of both hydrogel and metal-electrolyte gel systems, the printable hydrogel electrodes can induce muscle movement during sFES with better precision and accuracy, improving the efficiency by 10% when stimulating eye closure to the orbicularis oculi muscle. The printable and conductive hydrogel created for wearable purposes may be adapted for other applications involving bi-directional communications of electric signals across the bioelectronic interface, such as surface electromyography and surface electrocardiography.

9:45 AM SB04.04.05
PEDOT:PSS Hydrogel Based Wearable Biosensor Utilizing Aerosol Jet Printed Organic Electrochemical Transistors (OECTs) for Lactate Detection YuchenShao[1], LuizMarcelo[2], LixinZhang[1] and ManishaGupta[1]; [1]University of Alberta, Canada; [2]Monterrey Institute of Technology and Higher Education, Mexico

Poly (3,4-ethylenedioxythiophene) doped with polystyrene sulfonate (PEDOT:PSS) is a conductive polymer with excellent electrical conductivity, good processibility and biocompatibility. Hydrogels have the advantage of soft, flexible and non-toxicity with cells and tissues. A combination of PEDOT: PSS and a hydrogel offers unique conductivity and mechanical properties, applying an alternative approach for biosensing applications.

In this work, we developed a PEDOT:PSS hydrogel based 3D printed organic electrochemical transistor (OECT) for lactate sensing, since OECTs offer high transconductance, low operation voltage and compatibility with aqueous environments. Optomec Aerosol Jet 5X 3D printer is used to fabricate the biosensors on the flexible Kapton substrate. Au was chosen as the metal contact, Pt as the gate with polyimide as the insulator layer. PEDOT:PSS hydrogel is drop casted on Au as the channel material. For PEDOT:PSS hydrogel, it was synthesized by mixing with dimethyl sulfoxide (DSMO) to improve the conductivity under vigorous magnetic stirring for 24 hours, then drop-casted 0.2uL solution on top of the channel for a printed OECT device and was placed into the oven under 60°C for another 24 hours to generate the partially formed gel. After that, 3 times cyclic annealing was applied for the device for 30 minutes at 130°C. Finally, the device was put under -20°C for 12 hours and took out for extra 12 hours, repeating 2 times. The unfunctionalized device exhibits a transconductance up to 110 mS and is compared to the printed PEDOT:PSS based device. Further, tetrathiafulvalene (TTF), chitosan, lactate oxidase (LoX), bovine serum albumin (BSA) and gelatin help realize the functionalization of the device. The functionalized lactate sensor can be preserved in PBS solution under 4°C for over one month. Spike tests on the PEDOT hydrogel-based lactate sensor was performed and achieved a sensitivity range between 100uM and 10mM. In addition, the combination of the printed PEDOT:PSS channel with drop-casted PEDOT:PSS hydrogel exhibited better performance of the device. The results for this device will be presented along with the material characterization.

Stimuli-Responsive Polymers as Precursors to Conductive Hydrogels LaureV. Kayser; University of Delaware, United States

Electronically-conductive hydrogels, composites of crosslinked and water-swollen polymers with a conducting material (polymer or inorganic nanoparticles) can address the mechanical and electronic mismatch between electronic devices and biological systems. While several methods have been reported to prepare these conductive hydrogels, several issues have to be addressed to enable their translation in bioelectronics. These issues include: (1) the increase in elastic modulus at high loading of conducting material, (2) the irreversibility of the gelation mechanism, which complicates the delivery and potential removal of the conductive hydrogel in vivo, and (3) the difficulty in controlling the micro- and macro-structure of the conductive hydrogels for applications in tissue engineering and wearable electronics. In this talk, I will share our progress towards addressing these issues through the use of synthetic chemistry, particularly using novel stimuli-responsive conducting polymers. In the first part, I will discuss the use of thermo-responsive conducting polymers that displays a reversible sol-gel transition close to body temperature, thereby enabling injectable conductive hydrogels. The second part will be focused on achieving spatiotemporal control by using photo-active polymers to simultaneously photo-catalyze the polymerization of a conducting polymer and photo-crosslink its supporting matrix. This approach has great potential for 3D printing conductive hydrogels with a controlled microstructure and high resolution using light.

11:00 AM *SB04.05.02
Programmable Materials, Structures and Devices for Next Generation Intelligent Machine JiyunKim; Ulsan National Institute of Science and Technology, Korea (the Republic of)

In recent times, virtual intelligence has made significant strides, reaching and even surpassing the functional and cognitive abilities of humans, owing to advancements in computing power and novel operational methodologies. Meanwhile, physical objects or machines in the real world strive to imitate the forms and functions of specific living organisms, such as humans, cheetahs, and octopuses. However, they still lag behind in terms of intelligent and adaptive functions, necessitating the exploration of innovative mechanisms and approaches.

Therefore, our research group aims to develop an integrated robotic platform that possesses the ability to program its morphology, physical properties, interface, and function. This robotic paradigm requires innovation at all levels of the system, including materials, components, architectures for their integration, manufacturing processes, data processing, and operation. In this talk, I will introduce research categories and recent research outcomes from our group. These include (1) the development of programmable robotic components using smart materials such as multifunctional 3D sensors, soft tensile valves, digital metamaterial, and soft end effectors, (2) the exploration of novel algorithmic architecture including tensegrity, lattice metamaterial, and folding-based structures, (3) the exploitation of manufacturing methods realizing the architectures and functions including intuitive pen-drawing and 3D/4D printing, and (4) the excavation of machine design and operation methodology using artificial intelligence for shape-shifting task, in-situ function programming, and robot/HMI device design and operation. Through these works, we aim to blur the boundaries between the virtual and tangible world and, more importantly, between humans and the environment, thereby sharing our vision for the future physical environment for humans.

11:30 AM SB04.05.03
Highly Transparent Conducting Ionic Hydrogels of Double Network Structure for Deformable Electronics JinhwanYoon; Pusan National University, Korea (the Republic of)

Highly deformable soft electrodes have garnered significant attention due to their potential to drive innovation in wearable electronics and soft robotics. To render the soft electrodes, stretchable, conductive, and transparent polymer networks have been studied extensively, but fulfilling these requirements remains challenging. In this work, we developed double-network ionic hydrogels of high transparency and stretchability due to the finely tuned network structure and transparent electrolyte. Based on the high performance of the ionic hydrogels, electroluminescent devices were achieved with an inorganic phosphor emission layer, which exhibits high luminance under extreme deformation. The remarkable transparency of the ionic hydrogels further enabled to fabrication of novel electroluminescent devices of tandem structures, allowing color variation by independent control of each emission layer.

11:45 AM SB04.05.04
Repeatably Autonomously Self-Healing Ultra-Stretchable PAAMPSA/PANI/PA Conductive Polymer Complex as Strain Sensor ColtonDuprey[1], YangLu[2] and EvanK. Wujcik[1]; [1]University of Maine, United States; [2]Georgia Institute of Technology, United States

Wearable strain sensors should be comfortably adhered to the skin and capable of monitoring human motions with high accuracy/sensitivity while remaining robust with excellent durability/longevity. However, it is challenging to develop electronic materials that possess the properties of skin—compliant, elastic, stretchable, and self-healable while also having a high enough conductivity for adequate sensitivty. This work demonstrates a new regenerative polymer complex composed of poly(2-acrylamido-2-methyl-1-propanesulfonic acid), polyaniline, and phytic acid as a skin-like electronic material. The type-2 (zip) templated polymerization of aniline in the presence of poly(2-acrylamido-2-methyl-1-propanesulfonic acid) with phytic acid as a P-type dopant exhibits ultrahigh stretchability (1935%), repeatable autonomous self-healing ability (repeating healing efficiency >98%), quadratic response to strain ($R^2 > 0.9998$), and linear response to flexion bending ($R^2 > 0.9994$), mechanically outperforming current reported wearable strain sensors. Sensitive strain-responsive geometric and piezoresistive mechanisms of the material owing to the homogeneous and viscoelastic nature provide excellent linear responses to omnidirectional tensile strain and bending deformations. Furthermore, this material is scalable and simple to process in an environmentally friendly manner, paving the way for the next-generation flexible electronics.

All-Aqueous Hierachical Hydrogels for Microfluidics AndersonShum[1,2]; [1]University of Hong Kong, Hong Kong; [2]Advanced Biomedical Instrumentation Centre, Hong Kong

Hydrogels have demonstrated promising applications across fields, ranging from delivery of actives, to cell cultures, and to wound protection. Hydrogel designs have focused on the constituent molecules and molecular interactions via modifications of the molecular identities and structures. Hierarchical structures within the hydrogels can also be manipulated by structuring the precursor solution before hydrogel formation. The precursor solution can be directed via the use of microfluidic techniques, achieving underlying hydrogel architectures with different properties. Besides its use for designing and modifying hydrogels, microfluidic devices can also be made formed by hydrogels, rather than traditional elastomer-based materials. In this talk, I will share our works at the interface between hydrogels and microfluidics, and will discuss the potential functions and properties of the resultant hydrogels and microfluidic devices.

2:00 PM SB04.06.02
Acid-Crystallized PEDOT Nanoparticles: Scalable and Biocompatible Fillers for Highly Conductive Hydrogels JoshuaTropp and JonathanRivnay; Northwestern University, United States

Conductive hydrogels are widely used in bioelectronic applications due to their flexibility, biocompatibility, and conductivity. Conductive hydrogels have been leveraged to improve the biocompatibility of electrodes, act as transducing elements within biosensors, and as conductive scaffolds for cells to promote tissue regeneration. While the unique properties of conductive hydrogels make them a promising material for bioelectronics, achieving high conductivity while maintaining mechanical compliance remains a significant challenge. To meet these requirements, functional-pi electron systems (conjugated polymers, carbon nanotubes, graphene, etc.) are typically dispersed within natural or synthetic biomaterials to afford conductive hydrogels. A significant challenge in the field remains the required high nanomaterial loadings to achieve significant conductivity; however, at such loadings the conductive hydrogels become prohibitively rigid for bioelectronic applications. Unlike 2D thin-film applications that leverage the long-range ordering of nanomaterials such as conjugated polymers to achieve significant charge percolation, the 3D, complex, and tortuous structure of hydrogels prevents such material alignment, creating a barrier toward highly conductive soft hydrogels. To overcome this limitation, PEDOT nanoparticles have been developed, which behave as three-dimensional seeds for charge percolation throughout the hydrogel. By carefully controlling nanoparticle surface chemistry and morphology via acid treatment, dispersible and highly conductive particles were afforded. Unlike other carbon nanomaterial fillers, the intrinsic dispersibility of the PEDOT nanoparticles enabled direct incorporation within hydrogels at high loadings (> 100 mg mL^{-1} of precursor), as well as deposition via spray coating and 3D printing without added surfactant or chemical modification. Upon sufficient particle loading, charge percolation is achieved throughout the hydrogel, affording organic gels with high conductivity (> 1 S cm^{-1}) without deleterious hydrogel stiffening. PEDOT nanoparticles were incorporated within various synthetic and natural biomaterials, demonstrating compatibility with common crosslinking modalities (photopolymerization, ionic, thermal, Schiff base). The scalability, conductivity, and biocompatibility of the acid-crystallized PEDOT nanoparticles make them attractive fillers for hydrogels/biomaterials for bioelectronic applications.

2:15 PM SB04.06.03
From Conducting Hydrogel to Semiconducting Hydrogel DingyaoLiu, YanWang and ShimingZhang; The University of Hong Kong, Hong Kong

Thin-film semiconductor-based devices have revolutionized the field of microelectronics. In the realm of biomedical applications, conducting hydrogels have rapidly gained prominence due to their mechanical and biocompatible nature with biological systems. The realization of semiconducting hydrogel materials holds significant value within the field of bioelectronics for developing advanced biologics[1]. Advancing towards flexible and stretchable semiconducting hydrogels can enable direct applications at the interface of soft biological systems [1].

However, the development of semiconducting hydrogels presents challenges, primarily due to the thin-film nature of semiconductors, which are generally less than 1 micrometer in thickness. In contrast, hydrogels tend to have greater thicknesses and struggle to achieve good semiconductor properties.

The advent of organic electrochemical transistors (OECTs) has introduced a new paradigm that can be a powerful testbed to evaluate the performance of a semiconducting hydrogel. In this report, we present the development of the PEDOT:PSS semiconducting hydrogel and its application in the development of OECTs [2]. Furthermore, we provide our insight on how to define a semiconducting hydrogel when using OECT as a testbed. Finally, we delve into the development of stretchable semiconducting hydrogels and explore how they can revolutionize applications in the field of biomedical research.

2:30 PM *SB04.06.04
Conducting Polymers Biointerfaces for Bioelectronics JadrankaTravas-Sejdic; University of Auckland, New Zealand

Conducting polymers (CPs) have been widely used as electroactive biointerfaces in applications such as electrically stimulated tissue engineering and flexible organic bioelectronics. In this talk, several different approaches to advanced electroactive biointerfaces based on conducting polymers will be presented.
The first approach addresses the issue of poor solubility and processability of CP by functionalization of CPs with various moieties, and, in particular, by grafting of CP backbones with polymeric sidechains. That enables modification of optoelectronic, physical and mechanical properties of the CPs and their use as biomimetic biointerfaces, e.g. responsive to stimuli, intrinsically stretchable and self-healing[1].
The second approach addresses the issue that electrodes used in tissue recording and stimulation are commonly 2D and made of rigid conducting materials, and as such cannot adequately probe the actual 3D cell environment within tissues and/or have a significant mechanical mismatch with biological tissue. Our approach to overcome that is based on a precise fabrication of individually addressable, high aspect ratio, soft and flexible 3D CP-pillar microelectrode arrays by means of 'direct 3D writing'. Such 3D microelectrode arrays could be employed in a variety of applications, from biological sensing to recording and electrically stimulating cells and tissues[2], with the array design easily adjustable.
The third approach to electrochemically addressable biointerfaces is based on flexible, microporous, electrochemically switchable membranes that can selectively and efficiently capture, and then non-destructively release, cancer biomarkers, such as cancer cells-shaded extracellular vesicles (EVs)[3] and rare cancer cells[4] The platform allows for the EVs and cells to be captured from large volumes of complex biological samples and released into clean and small volumes of buffers - suitable for further analysis, for example, for medical diagnostics.

Conductive Hydrogels for Multimodal Bioelectronic Interfaces IvanMinev[1,2,3]; [1]Leibniz Institute for Polymer Science, Germany; [2]Technische Universität Dresden, Germany; [3]The University of Sheffield, United Kingdom

Hydrogels are attracting attention as materials for bioelectronic implants because they may solve some long-standing challenges encountered at the tissue-electrode interface. This will require appropriate viscoelasticity, hydration, bioactivity and dual electronic-ionic conductivity. Apart from improved integration with brain tissue, hydrogels may enable electrodes with superior charge injection capacity and capability for neuromodulation beyond the electrical domain (e.g. using biomolecules).
In this talk I will present our efforts to combine Glycosaminoglycans and the conductive polymer PEDOT into interpenetrating network hydrogels that are soft, conductive and bioactive. The material system is highly tunable offering control over electrical and mechanical properties. Furthermore the hybrid material has enabled us to sequester and release small proteins such as growth factors. The release profiles can be electrically tuned. The released proteins are bioactive and can influence cells in culture.
With this work we aim to advance the possibility to engineer synthetic bioelectronic materials that emulate some aspects of the extracellular matrix and may enable applications in next-generation tissue-mimetic bio interfaces.

Conducting Polymer Hydrogels for Soft and 3D Bioelectronic Interfaces AlexandraRutz; Washington University in St. Louis, United States

Hydrogels are insoluble polymer networks swollen with water (>90% water by mass) and are used widely in biomedical applications for their similarities to native extracellular matrix. For bioelectronics, there are many efforts to build devices based on these materials to achieve tissue-matching stiffness and other tissue-inspired properties in order to improve the biointerface. For making electrodes and other device components based on semiconducting materials, conjugated polymers can be gelled into electronically conducting hydrogels. Such methods include simple mix-and-cast techniques, similar to other methods used widely in traditional (non-conducting) hydrogel processing. We have investigated conducting hydrogels based on the conjugated polymer poly(3,4-ethylenedioxythiophene) polystyrene sulfonate (PEDOT:PSS) fabricated by mixing in a gelling agent, ionic liquid. We have studied how the hydrogel precursor formulation and other fabrication variables of this method affect gel properties, such as swelling, conductivity, and elastic modulus. Further, we have evaluated the potential of these PEDOT:PSS hydrogels for biointerfacing applications and have found that these gels when processed appropriately are stable in vitro and support mammalian cell culture. Finally, we are developing these conducting polymer hydrogels for compatibility with additive manufacturing to grant structural control of these soft bioelectronic interfaces. Such techniques provide manipulation of dimensions and microporosity, important for assembling these hydrogels into functional devices and optimizing tissue integration.

4:15 PM SB04.06.07
Ultra-Soft Semiconducting Hydrogels for Tissue-Like Organic Electrochemical Transistors YahaoDai and SihongWang; University of Chicago, United States

The rapid development of wearable/implantable electronics over the past decade opens the next era of human-integrated biosensors in pursuit of higher sensitivity and more seamless tissue-electronics interfaces. Transistor, especially organic electrochemical transistor (OECT)-based biosensor has attracted considerable attention as an advanced biosensing platform due to their high built-in amplification and water-compatible operation. To achieve the intimate biointerface and acquire the biological signal with the highest possible accuracy, the most ideal approach is to prepare the semiconducting materials with tissue-level softness and stretchability, and directly interface with the tissue surface. However, so far no semiconducting material is able to provide modulus even close to the tissue level due to the general paradox that semiconductors rely on stronger intermolecular interactions to facilitate charge transport. In this research, we proposed a novel material design strategy for developing a gel-like semiconductor that is able to simultaneously provide low modulus, high stretchability/elasticity, and high hole mobility. This is achieved by incorporating a secondary hydrogel matrix into a semiconducting polymer network for enhancing the water uptake to soften the composite, and utilizing solvent treatment to form strong percolation between polymer semiconductors to resist the negative effect of swelling. We further use ultra-soft semiconductors to fabricate gel-like OECTs with desired mechanical and electrical performance for human integration, and demonstrate its capability as the advanced platform for biosensing applications.

4:30 PM SB04.06.08
Developing Multifunctional Hydrogels with Tissue-Like Properties for Improved Cell-Material Interfaces ChristinaM. Tringides[1,2], BlandineF. Clément[1], MarjolaineBoulingre[1], ViliusDranseika[3], DavidJ. Mooney[2] and JanosVörös[1]; [1]ETH Zurich, Switzerland; [2]Harvard University, United States; [3]UZH, Switzerland

Biomaterial scaffolds have emerged as a tool to build 3D cultures of cells which better resemble biological systems, while advancements in bioelectronics have enabled the modulation of cell proliferation, differentiation, and migration. Here, we first describe a porous conductive hydrogel with the same mechanical modulus and viscoelasticity as neural tissue. Electrical conductivity is achieved by incorporating low amounts (<0.3% weight) of carbon nanomaterials in an alginate hydrogel matrix, and then freeze-drying to self-organize into highly porous networks. The mechanical and electrical properties of the material can be carefully tuned and used to modulate the growth and differentiation of neural progenitor cells (NPCs). With increasing hydrogel viscoelasticity and conductivity, we observe the formation of denser neurite networks and a higher degree of myelination. Similarly, fibroblasts can be incorporated into the scaffolds and cell migration can be modulated through the application of exogenous electrical stimulation, for applications to wound healing. To investigate the functionality of neural systems, both *in vitro* and *in vivo* platforms can be realized. By placing a polydimethylsiloxane (PDMS) microstructure on an underlying multielectrode array (MEA), we can then explore different materials and techniques to integrate hydrogels into the PDMS microstructures and can facilitate the growth of neuronal networks in 3D. Additionally, implantable surface electrode

arrays can be fabricated, with the ability to record from the brain and heart with enhanced tissue conformability and minimal damage to the biological organs. The described biomaterial platforms can be used to investigate neuronal development and disease progression.

Superstrong Electronic Hydrogel Actuators (ECO) MahiarM. Hamedi; KTH, Sweden

Intelligent systems combine sensing, actuation, and computation to achieve complex tasks and functions. Soft electrically controlled multifunctional materials, especially hydrogels, are the most promising materials for such systems as they are as adaptable as biological systems yet compatible with advanced systems through electronics.
We describe an electroactive hydrogel fabricated from cellulose nanofibrils from trees, and conductive nanomaterials, like CNTs or 2D MXenes. These nanoparticles self-assemble into an anisotropic composite networks with an open mesoporous structure that can hold lots of water and be highly permeable to substances in their surroundings. The anisotropy of the network allows high expansion in one direction while maintaining very high strength and high electric conductivity in the other.
The electrochemical charge/discharge of the conductors in the hydrogels controls the internal salt concentration and consequently their osmotic swelling. This allows direct electrically controlled actuation where around 700 water molecules expand/contract the structure for each ion/electron pair inserted/de-inserted at only ±1 volt, resulting in up to 300% electroosmotic expansion, with very high pressures reaching 1 MPa.

This mode of electronic actuation has not been shown before. We call these electroosmotic (ECO) actuators. Our ECO hydrogel actuators have emergent properties not present in any previously known soft material. ECOs allow formonolithic integration of sensors and many other functions into the same composite, rendering a new form of smart soft material not achieveable with other materials systems.

8:00 PM SB04.07.01
Long-Term Durable and Ultrasensitive Multiple-Crosslinked Ionic Hydrogel Sensors with Multi-Functions for Wearable Electronics Byeong SuKang[1], Jin-YoungYu[1], Jeong HunKim[2] and SeongminKang[1]; [1]Chungnam National University, Korea (the Republic of); [2]Electronics and Telecommunications Research Institute, Korea (the Republic of)

Hydrogels are considered promising for wearable devices because they are soft, flexible, stretchable, and biocompatible. However, existing hydrogels suffer from poor strength, weak and one-time adhesion, non-self-recovery, water evaporation, ice crystallization, and low sensitivity, and these problems have been only partly solved previously. We propose the one-pot synthesis of a multiple-crosslinked poly(2-(methacryloyloxy)ethyl)dimethyl-(3-sulfopropyl)ammonium hydroxide-co-acrylamide (P(SBMA-co-AAm) multifunctional hydrogel to overcome these limitations. The synthetic route provided elasticity, self-healing, and transparency, and the incorporation of glycerol and NaCl ions provided moisture stability (e.g., water retention) and antifreeze properties. Zwitterionic SBMA contributed to the increased gauge factor, resulting in high sensitivity and an ability to detect human movements at a strain of 800%–1600%, making the hydrogel sensor practical. The sensor retained its properties after even 300 cycles, indicating its durability and reliability for long-term applications.

8:00 PM SB04.07.02
Multi-Crosslinked Hydrogel-Based Needle Structure Capacitance Sensor with High Sensitivity and Stability ByeongsuKang[1], Jeong HunKim[2] and SeongminKang[1]; [1]Chungnam National University, Korea (the Republic of); [2]Electronics and Telecommunications Research Institute, Korea (the Republic of)

The hydrogel-based sensor has better elasticity than the existing elastomer sensor, so the distance between the two electrodes can be reduced. Also, since the amount of change in contact area is also large, the amount of change in capacitance is excellent. Especially, by adopting a micro needle structure that can maximize the change in contact area, the change in capacitance is increased. However, the previous hydrogel-based sensor lacks recipe research to create a structure, and adding a structure reduces stability and repeatability, limiting its application as a sensor. In this paper, poly(acrylamide-co-N, N′-methylenebisacrylamide) multifunctional hydrogel can overcome the aforementioned limitations. Then, by making a hydrogel-based sensor with a micro needle structure, high sensitivity is sought by adjusting the amount of N, N′-methylenebisacrylamide. In addition, by adding sodium dodecylbenzenesulfonate lauryl acrylate, the stability of the structure that does not interfere with sensitivity is increased. This hydrogel-based sensor is a human-friendly material that can be applied not only to the biomedical measurement field, but also to fields where existing elastomer sensors are applied, such as robots, hydraulic pressure measurement, and aviation.

8:00 PM SB04.07.03
Robust Integration of Highly Conductive Hydrogels with Stretchable Electronics for Skin-Interfaced Bioelectronics Hyun SuLee and Dae-HyeongKim; Seoul National University, Korea (the Republic of)

Skin-interfaced bioelectronics mounted on human skin has the potential to revolutionize next-generation medical diagnostics and healthcare. To achieve this goal, designing a compliant and stretchable device is highly desirable for device reliability and long-term user comfort. In the material aspect, the limitations of conventional functional device components that originate from rigid and obtrusive interfaces must be overcome by materials with intrinsic softness and stretchability. Conductive hydrogels that possess tissue-level softness owing to their water-rich nature, can be an alternative option. Generally, for the fabrication of hydrogel-based, skin-interfaced bioelectronics, a hydrogel film is cut and placed onto an electrode. However, during device operation, large amount of water inside the hydrogel film tends to form a slippery surface rather than a robust interface between human skin and electronic device. Such poor integration capability could cause the lack of reproducible device performances, difficulty to scale up, and the loss of intimate physical/electrical contacts, which leads to critical problems in signal sensing and electrical actuation from/to human tissue. Here, we suggest direct polymerization and in-situ chemical-integration of hydrogel onto stretchable electronics as a methodology for enhancing the hydrogel-device interface of skin-interfaced bioelectronics. Highly conductive functionalized hydrogels are polymerized inside stretchable wells placed on a multichannel electrode array. The hydrogels are stably immobilized to the electronic devices during fabrication, and the robust interface contributes to the reliable measurement of bio-signals and effective electrical actuation on tissues. The demonstration shows that the direct polymerization and in-situ chemical-integration of hydrogel are key steps towards the realization of practical skin-interface bioelectronics based on functionalized hydrogels.

8:00 PM SB04.07.04
Self-Healing Stretchable Li-Ion Battery Based on a High-Voltage Hydrogel Electrolyte PeishengHe[1], Jong HaPark[1], ChaoFang[1], AnjuToor[2] and LiweiLin[1]; [1]University of California, Berkeley, United States; [2]Georgia Institute of Technology, United States

Safe and deformable batteries that can be conformally embedded onto irregular surfaces of electrical systems and human body are desirable for wearable electronic applications due to low user friction. Commercial state-of-the-art Li-ion batteries are packaged in rigid hermetic sealing materials that are not deformable. State-of-the-art deformable Li-ion batteries reported in research articles show fast degradeation due to severe performance problems such as the penetration of moisture and the leakage of toxic and inflammable electrolytes. Here we report a non-toxic, aqueous hydrogel electrolyte instead of its organic counterpart that is demonstrated to: 1) enable highly safe operations due to its non-toxic and non-flammable nature; 2) alleviate the moisture penetration problem from outside environment; (3) have a high-voltage working window of ~2.8V; and (4) allow the construction of stretchable batteries by using elastic polymer packaging materials instead of rigid hermetic seals. In the prototype tests, fabricated batteries have shown good stretchability (50% strain) and flexibility (radius of curvature < 2mm) to enable conformal attachments to a wide range of geometric surfaces. The prototype battery also shows outstanding cyclic stability, retaining ~90% of the original capacity after 100 cycles for over 2 months in the ambient environment without using any rigid hermetic sealing package. Finally, a prototype battery with a self-healing elastomer package remains functional after being punctured by a needle 5 times at different locations through the package. Furthermore, it can recover >90% of its capacity after being cut through by a razor blade and subsequently healed at 70 for 10 minutes. Such safe and highly stretchable batteries would be useful for several wearable electronic applications such as blood glucose monitoring, hear rate monitoring , temperature monitoring, wireless charging, smart clothing, etc.

8:00 PM SB04.07.05
Highly Sensitive Flexible Sensors using Autonomously Self-Healable and Temperature-Tolerant Eutectogel JinyoungLee and Jeong SookHa; Korea University, Korea (the Republic of)

With the increased demand for advanced wearable electronics, hydrogel-based devices have attracted enormous attention. Hydrogels have many advantages such as excellent flexibility, biocompatibility, ionic conductivity, and self-healing property, adequate for wearable devices. On the other hand, hydrogel-based devices exhibit limit in the performance due to the freezing and evaporation of water in the polymer network at low and high temperatures, respectively. To address such a thermal instability issue, there has been extensive effort on replacing the water within the hydrogel network with ionic liquids of low vapor pressure and high ionic conductivity. However, most ionic liquids are expensive and toxic to hamper the practical application to wearable devices. Therefore, research on deep eutectic solvents, mixtures of two or more components characterized by significant depressions in melting points compared to their neat constituent components, has been recently activated. Deep eutectic solvents show properties similar to those of ionic liquids as well as additional advantages of low-cost, non-toxicity, biocompatibility, and biodegradability. Furthermore, eutectogels having polymer networks composed of deep eutectic solvents have demonstrated the high potential application to wearable devices.
In this paper, we report on the fabrication of resistive-type strain and pressure sensors based on newly synthesized autonomous self-healing and temperature-tolerant eutectogel. Our synthesized eutectogel is prepared by UV polymerization of acrylamide with trehalose and phytic acid as crosslinkers, and choline chloride, glycerol and a small amount of water as solvents. In addition to the inherent low melting point of deep eutectic solvent, inclusion of bio-derived trehalose and phytic acid makes abundant hydrogen bonding, resulting in improved anti-freezing and anti-drying properties. Also, the dynamic hydrogen bond interactions between the polymer network and trehalose, phytic acid, and glycerol endowed the eutectogel with self-healing properties. The synthesized eutectogel exhibits high stretchability (>300%), temperature-tolerance, and good self-healing efficiency (>90%) after 24 hours at room temperature. By incorporating conducting polymer onto the eutectogel, highly sensitive resistive-type strain and pressure sensors are fabricated for detecting bio-signals after attachment onto a finger or wrist. The eutectogel-based wearable sensors demonstrate stable signal detection over a wide temperature range even after repetitive self-healing, thereby expanding their potential application to wearable electronics with longevity under extreme conditions.

8:00 PM SB04.07.06
Topology-Based Dual Lock-and-Key Structures for Hydrogel Self-Assembly in Macroscopic Supramolecular Assembly EunseokHeo, Hye BeenKoo and Jae-ByumChang; Korea Advanced Institute of Science and Technology, Korea (the Republic of)

Macroscopic supramolecular assembly (MSA), which refers to the assembly of building blocks at a macroscopic scale, holds great potential for the fabrication of ordered bulk structures. Thanks to the high design flexibility of the building blocks and the precise controllability of the assembly process, MSA has found applications in a wide range of fields, including the fabrication of tissue scaffolds, soft actuators, and more. Additionally, among the candidates for building blocks, hydrogels are highly favored due to their easily tunable properties and diverse type with different characteristics. In MSA, two challenges need to be addressed to achieve a high level of assembly: enhancing the precision of assembly and increasing the number of orthogonally matching pairs. To date, despite numerous attempts, none have effectively tackled both challenges simultaneously. In this study, we introduce topology-based design criteria for achieving precise and selective self-assembly of hydrogel building blocks. We suggest a unique design approach termed “dual lock-and-key structures,” In this design model, only topologically matching pairs can be assembled with exceptional precision. Through the implementation of dual lock-and-key structures, we establish principles for the selection of multiple orthogonally matching pairs. We demonstrate the selective assembly of both simple one-to-one matching and complex one-to-many assemblies. Moreover, by harnessing the easy property tunability of hydrogel, we synthesize DNA-mimicking single-stranded structures, which hybridize into double-stranded structures with sequence-specific arrangements. Finally, we present a hydrogel logic gate system, consisting of a YES gate, an OR gate, and an AND gate. Utilizing the high selectivity of our dual lock-and-key structures, the desired outputs are exclusively obtained when the appropriate building blocks are assembled, following the logic of each gate: YES, OR, and AND.

8:00 PM SB04.07.07
Conducting Polymer Granular Hydrogel Bioinks for 3D Printed *In Vitro* Bioelectronic DevicesAnnaP. Goestenkors, TianranLiu, SomtochukwuS. Okafor, LiannaFriedman, RileyAlvarez and AlexandraRutz; Washington University in St. Louis, United States

Conjugated polymers have recently been used in their hydrogel form for the creation of soft bioelectronics with improved cell interfacing and the potential for enhanced measurement and stimulation of cellular activities. Cell-encapsulating hydrogels offer a truly 3D culture environment and when designed appropriately can be used as bioinks for 3D printing which grants spatially controlled deposition of cells and materials simultaneously. We developed a bioink based on the conducting polymer poly(3,4-ethylene-dioxythiophene):polystyrene sulfonate (PEDOT:PSS) by creating a granular hydrogel form. Emulsion methodology was developed to fabricate PEDOT:PSS hydrogel microparticles (microgels) with high circularity and monodispersity. Filtration techniques were used to size select microgels with diameters between 10 and 60 µm. When centrifuged to remove significant water, the conducting polymer microgels achieved dense packing characteristic of a granular material state. Increasing centrifugal force decreased the void fraction of the material which increased conductivity. Rheological investigations confirmed shear-thinning and self-healing properties, both ideal for 3D bioprinting for extrusion and ability to keep shape, respectively. Granular PEDOT:PSS hydrogels were in fact 3D printable via pneumatic extrusion and formed various 3D configurations. Evaluation of the material’s printability in the granular state also revealed that increased centrifugal force facilitated better printability as evidenced by increased maximum filament length and filament diameter better matching the chosen nozzle diameter. Structural stability of the material within an aqueous environment for up to three months was achieved using a collagen hydrogel overlay. Human dermal fibroblasts encapsulated and cultured within the granular hydrogel showed high cell viability over fourteen days demonstrating cytocompatibility. This developed conducting granular hydrogel bioink exhibits balanced properties of printability, conductivity, and cellular responses for the additive manufacturing of future in vitro bioelectronics.

8:00 PM SB04.07.08
Extracellular Matrix-Compatible Additive Manufacturing of Bioactive, Conducting Polymer Hydrogel Electrodes TianranLiu, SomtochukwuS. Okafor, AnnaP. Goestenkors, SandraMontgomery, RileyAlvarez and AlexandraRutz; Washington University in St.Louis, United States

Hydrogels of conducting polymers provide a soft and hydrated alternative to metal for interfacing electronic devices with biological systems. To fabricate devices based on conducting polymer hydrogels, the material is often patterned alongside bioinert and stiff substrates such as plastics and elastomers which lead to poor cell-material interactions. In order to further promote device integration with cells and tissue, one strategy is to utilize bioactive materials, such as mammalian extracellular matrix (ECM) components, as the substrate material to present a tissue-like microenvironment to cells. However, traditional semiconductor manufacturing is anticipated to impair the bioactivity of these natural materials. Here, we demonstrate methods for mild temperature additive manufacturing of highly conducting poly(3,4-ethylenedioxythiophene) polystyrene sulfonate (PEDOT:PSS) hydrogels with collagen substrates. Various types and concentrations of gelation agents were investigated to enable sufficient working time after addition to colloidal dispersions and to result in a water-stable hydrogel network once fully crosslinked. Among gelation agents tested, ionic liquid was found to be suitable for extrusion-based printing while an acidic surfactant enabled deposition by jetting due to low surface tension and appropriate viscosity. After room temperature gelation and treatment, hydrated PEDOT:PSS prints exhibited conductivity as high as 37.2 S/cm and were stable in cell culture conditions for at least 28 days. To complete the device, a top layer was fabricated by casting a collagen slurry onto the PEDOT:PSS prints which had a sacrificial material deposited on top to protect the intended electrodes from coverage. Once the collagen layer formed, the sacrificial material was removed with 36 °C water, leaving an unaltered PEDOT:PSS surface for direct biointerfacing. Since the fabrication methods were developed with mild temperatures and processing, the structure and bioactivity of the collagen are believed to be maintained, as evidenced by the support of fibroblast culture that reached confluency and sustained high viability for 28 days. This methodology offers a promising strategy for rapid prototyping soft, hydrated, and bioactive electronic devices that support cell attachment and proliferation.

8:00 PM SB04.07.09
A Zwitterionic Hydrogel-Based Heterogeneous Fenton Catalyst for Efficient Degradation of Persistent Organic Pollutants IanS. Chen, DevashishGokhale and PatrickDoyle; Massachusetts Institute of Technology, United States

Persistent organic pollutants (POPs) are industrial, pharmaceutical, or commercial byproducts that are highly resistant to degradation and decomposition in the environment, while causing significant health and environmental damage even in small concentrations. Significant existing research aims at destroying the POPs in an environmentally safe and cost-effective manner, but challenges remain in destroying POPs at environmental concentrations in scalable and sustainable processes. Many current approaches to degrading POPs require extreme reagents and conditions. One promising candidate, however, for the removal of POPs is the photo-Fenton reaction, where iron(II) ions catalyze the decomposition of hydrogen peroxide, in the presence of UV light, into highly reactive hydroxyl radicals that readily attack organic compounds, including POPs. Fenton oxidation is promising because iron(II) and hydrogen peroxide are low-cost, environmentally-safe materials, and because the process can target a broad range of POPs.

However, the photo-Fenton reaction requires the presence of water-soluble iron(II) ions that are difficult to reuse. As such, methods that immobilize the iron as a catalyst can be constantly reused, while also eliminating the need for further treatment steps to remove iron from water before it can be used. Unfortunately, existing solutions require challenging reaction conditions; due to the higher efficiency of the Fenton reaction at lower pHs, many catalysts require a low pH (usually around 3) to regenerate iron(II) ions, which is unrealistic for large-scale wastewater treatment and can damage the catalyst itself. Furthermore, due to the non-selectivity of the Fenton reaction, catalysts using common polymers such as polyethylene or polyvinyl alcohol to encapsulate iron (II) or iron oxide (in the form of nanoparticles) often degrade easily due to the susceptibility of the polymer to the photo-Fenton reaction, also releasing nanoparticles into the

environment. Other attempts at supported catalysts reduce the surface area and limit kinetics.

To address these issues, we developed an iron(II)-incorporated, zwitterion-based hydrogel catalyst. By complexing the iron(II) ions within a zwitterionic hydrogel, we allow for the photo-Fenton reaction to run efficiently at neutral and even slightly alkaline pHs. Furthermore, due to the high oxidation state of the zwitterions and the saturated backbones, the hydrogel is highly resistant to attack by hydroxyl radicals. A zwitterionic backbone helps us make highly porous materials that bind individual, complexed ions, allowing us to maximize both the effective functional area and rate of pollutant transport within the catalyst. POPs quickly and rapidly diffuse into the catalyst, where they rapidly decompose. Experiments at environmentally relevant concentrations showed that our catalyst was able to degrade 85% of a solution of ethinyl estradiol (a xenoestrogen and common POP) within 1 hour, with near 100% degradation within 24 hours. Furthermore, we observed near 100% degradation of dichlorophenol (a common industrial byproduct) and around 70% degradation of perfluorooctanoic acid (a common perfluorinated pollutant). These results show significant promise for our hydrogel as an efficient and environmentally-safe strategy for rapid water purification of POPs.

8:00 PM SB04.07.10
Thermally Chargeable Stretchable Ionic Thermoelectric Supercapacitors TaehyunPark and XavierCrispin; Linköping University, Sweden

Wearable self-powered devices are in great demand because of the rapid innovation of Internet of Things (IoT), electronic skins, and healthcare monitoring. The two major sources of energy produced by the human body are mechanical (100W) and thermal (100-400W) energies. Thermoelectricity converts heat into electricity. Although the performance of electronic thermoelectric (e-TE) associated with the thermo-diffusion of electrons/holes has been significantly improved, Seebeck coefficients of the e-TE systems remain rather small (~100 $\mu V\ K^{-1}$). As a result, hundreds of p- and n-type TE legs connected in series are often required to generate a practically useful output voltage.
Recently a new thermoelectric concept has been proposed: the charging of a supercapacitor with an ionic thermoelectric (i-TE) effect in the redox-free electrolyte through a temperature gradient. The supercapacitor is composed of an electrolyte layer sandwiched between two electrodes. Giant Seebeck coefficients have been found in electrolytes combined with soft polymers. In contrast to the e-TE materials based on the electron/hole thermo-diffusion, i-TE materials are based on the diffusion of ions under a temperature gradient. i-TE materials produce orders of magnitude higher voltages than e-TE materials but typically have much lower conductivity and the ions cannot pass in the electronic circuit.
We have developed a polymer electrolyte with an apparent Seebeck coefficient (38.9 $mV\ K^{-1}$) and ionic conductivity (3.76×10^{-1} $mS\ cm^{-1}$). It mechanically deformed up to approximately 1500% and exhibited Young's modulus similar to human skin. Performance at 250% strain remained above 90% of its original performance, and there was no significant degradation after consecutive 200 stretching/releasing cycles.
In the development of wearable electronics, researchers have found strategies for making stretchable electrodes. We have then sandwiched our free-standing polymer electrolyte layer between two stretchable electrodes to achieve the first stretchable ionic thermoelectric supercapacitor. The ionic thermoelectric supercapacitor was also thermally charged at approximately 60% strain and exhibited reliable mechanical stability for repetitive 500 cycles of 50% strain.

8:00 PM SB04.07.11
Air-Permeable Hydrogels with High Water Content Xiao-YunYan, ShucongLi and XuanheZhao; Massachusetts Institute of Technology, United States

Hydrogels have gained immense popularity as the interface between biological tissues and the environment due to their exceptional properties and unique features. For biomedical applications like long-term signal monitoring, drug release, or pathogen blocking that necessitate continuous epidermal or tissue adhesion, free water and air exchange between the body and its surroundings become crucial. However, despite their excellent water permeability, hydrogels have over an order of magnitude lower oxygen permeability compared to other 'dry' soft materials (e.g. silicone rubber). This poor oxygen permeability in hydrogels is an intrinsic problem caused by the dense polar hydrogen-bonded network, which has long been a challenge to overcome. Herein, we present a strategy that achieves high oxygen permeability without compromising water content. The key to this approach is the fabrication of interconnecting microchannels within the bulk hydrogel material. More importantly, we demonstrate that the designed materials exhibit high oxygen permeability, allowing for long-term wear without causing itchiness or other uncomfortable sensations.

8:00 PM SB04.07.12
Supramolecular Gels from Pyrene-Functionalized Isophthalic Acids for Biomedical Nanotechnology Applications DarrenMakeiff[1], KhalidAzyat[1], MickieWiebe[1], AriaKhalili[2], Jae-YoungCho[1] and BradleySmith[1]; [1]Nanotechnology Research Centre, Canada; [2]University of Alberta, Canada

Supramolecular gels from low molecular weight gelators (LMWGs) are fascinating functional soft materials with potential for a wide range of applications such as food technology, cosmetics, optics, electronics, sensing, catalysis, environmental remediation, as well as biomedical applications. These unique materials have several advantages over their polymeric counterparts in lower cost, ease of preparation, tunable properties, low gelator concentrations, reversibility, stimuli responsiveness (heat, light, pH, chemicals, mechanical sheer, ultrasound, etc…), biocompatibility and biodegradability. While many LMWGs are known with a wide variety of structural diversity and functionality, the rational design of new functional LMWGs that can undergo hierarchical self-assembly to form gels in specific liquids with specific properties for a given application still remains a major challenge. Here we present the synthesis and characterization of new pH-triggered hydrogels from LWMGs based on pyrene-functionalized isophthalic acids. The rheological, morphological and spectroscopic characterization of the hydrogels formed will be discussed as well as their potential for biomedical nanotechnology materials applications such as encapsulation, drug delivery/controlled release, tissue engineering and 3D printing/bioprinting.

8:00 PM SB04.07.13
Tough and Recyclable Phase-Separated Supramolecular Gels via a Dehydration-Hydration Cycle XiaohuiXu and RodneyPriestley; Princeton University, United States

Hydrogels are compelling materials for emerging applications, including soft robotics and autonomous sensing. Mechanical stability over an extensive range of environmental conditions and considerations of sustainability, both environmentally benign processing and end-of-life use, are enduring challenges. To make progress on these challenges, we designed a dehydration-hydration approach to transform soft and weak hydrogels into tough and recyclable supramolecular phase-separated gels (PSGs) using water as the only solvent. The dehydration-hydration approach led to phase separation and the formation of domains consisting of strong polymer-polymer interactions critical for forming PSGs. The phase-separated segments acted as robust, physical crosslinks to strengthen PSGs, which exhibited enhanced toughness and stretchability in its fully swollen state. PSGs are not prone to over-swelling or severe shrinkage in wet condition and show environmental tolerance in harsh conditions, i.e., organic solvents with pH between 1 to 14. Finally, we demonstrate the use of PSGs as strain sensors in air and aqueous environments.

8:00 PM SB04.07.14
An Elastomer with Giant Strain-Induced Crystallization ChaseHartquist[1], ShaotingLin[2], JamesH. Zhang[1], ShuWang[1], MichaelRubinstein[3,4] and XuanheZhao[1]; [1]Massachusetts Institute of Technology, United States; [2]Michigan State University, United States; [3]Duke University, United States; [4]Hokkaido University, Japan

Strain-induced crystallization prevalently strengthens, toughens, and enables an elastocaloric effect in elastomers. However, the crystallinity induced by mechanical stretching in common elastomers (e.g., natural rubber) is typically below 20%, and the stretchability plateaus due to trapped entanglements, impeding performance for advanced applications. We present a new class of elastomers formed by end-linking then deswelling star polymers with a low fraction of defects and no trapped entanglements, which achieve strain-induced crystallinity of up to 50%. The deswollen end-linked star elastomer (DELSE) reaches an ultra-high stretchability of 12.4-33.3, scaling beyond the saturated limit of common elastomers. The DELSE also exhibits a high fracture energy of 4.2-4.5 kJ/m/m while maintaining low hysteresis. The heightened strain-induced crystallization and stretchability synergistically promote a high elastocaloric effect with an adiabatic temperature change of 9.3 °C at 54 °C, compared with 3.5 °C at 54 °C in natural rubber.

8:00 PM SB04.07.15
Advancing Protein Synthesis and Applications with a Recyclable Genomic DNA Hydrogel Platform in Cell-Free Expression Systems HyangsuNam[1,2] and Jong BumLee[1]; [1]University of Seoul, Korea (the Republic of); [2]Harvard University, United States

Proteins have the most dynamic entities, performing the diverse role of macromolecules in the body, functional interaction network-based biochemical reactions within a cell or from an organ. Recombinant protein-based therapeutics provide an important breakthrough in biomedical biotechnology. Recent technical advances in cell-free protein synthesis (CFPS) offer several advantages over cell-based expression systems, including easy modification to favor protein folding, increased non-toxicity, and capability for high-throughput strategies due to small reaction volume and short synthesis time. Herein, we fabricated the genomic DNA hydrogel (GD-gel) using the dual single-strand circular plasmids employed in cell-free protein expression synthesis. By complementary rolling complementary circle amplification (cRCA) with multi-primers, the genomic hydrogel exhibits a significantly enhanced productivity yield of protein. This synthesis platform has the potential to develop biotechnological in sensing, therapeutics, and diagnosis.

In our study, inspired by the previous DNA hydrogel using a rolling circle amplification technique, we describe a strategy to synthesize genomic DNA hydrogel (GD-gel) via self-assembly of elongated DNA strands encoding multimeric genomic sequences. To achieve the self-assembly of genomic hydrogel, we applied rolling circle chain amplification (RCCA) with the dual

single-stranded circular plasmids. Importantly, GD-gel only consists of numerous tandem repeats of genomic DNA strands by the rolling circle amplification from the plasmid DNA template. This approach allows the genomic DNA itself not only to create a hydrogel structure but also to become a medium for protein expression in GD-gel. Hence, our GD-gel is likely to enable a new route for cell-free protein production via s self-assembly of multimeric genomic DNA.

A Versatile Conductive Ternary Polymer Complex Nanocomposite Sensor with Repeatable, Rapid, Autonomous Self-Healing and Unprecedented Mechanical Properties ColtonDuprey and EvanK. Wujcik; University of Maine, United States

Wearable sensors, stretchable electronics, and many soft robotics materials must have a sufficiently high balance of conductivity, stretchability, and robustness. Intrinsically conductive polymers offer a critical step toward improving wearable sensor materials due to their tunable conductivity, soft/compliant nature, and ability to complex with other synergistic molecules (i.e., polyacids, small molecule dopants). The addition of nanofillers offers the potential to improve the conductivity of polymers for soft robotics and wearable applications, while itand also affects and improves the self-healing and mechanical properties of the material. The development of a robust polymer nanocomposite material that offers ultra-stretchability, an autonomous self-healing ability, and enhanced electronic properties has eluded researchers. Here we show an aqueous polyaniline [PANI]:poly(2-acrylamido-2-methylpropane sulfonic acid) [PAAMPSA]:phytic acid [PA] ternary polymer [TP] complex synthesized with silver nanowires (AgNW) to form a polymer nanocomposite with high electronic sensitivity, unprecedented mechanical properties (a maximum strain of 4693% at ambient humidity; ~52 RH%), and repeatable, autonomous self-healing efficiencies of greater than 98%. The AgNW TP complex has an engineering strain higher than all hydrogel and other polymeric sensor materials, in which the interface between the polymer matrix and the AgNW is hypothesized to be integral for the formation of an active conductive network. To illustrate the remarkable sensitivity, the material was employed as a biomedical sensor (pulse, voice recognition, motion), topographical sensor, and high sensitivity sensor.

Engineering a Reverse Thermo-Responsive, Cross-Linkable, Biodegradable Liquid Embolic Agent for Brain Aneurysm Treatment LamiaAyaz[1], HannahFeng[2], RuoxiJin[3], AnnLee[4], SheldonLiu[5], EvanPang[6], JiaruiPeng[7], GraceQiao[8], RuthPereia[9], RobertWong[9], AaronSloutski[9], ChandramouliSadasivan[9], DanielCohn[10] and MiriamRafailovich[9]; [1]Howard High School, United States; [2]Torrey Pines High School, United States; [3]Beijing National Day School, China; [4]Seoul International Day School, Korea (the Republic of); [5]Stuyvesant High School, United States; [6]Mission San Jose High School, United States; [7]East Lyme High School, United States; [8]The Experimental High School Attached to Beijing Normal University, China; [9]Stony Brook University, The State University of New York, United States; [10]The Hebrew University of Jerusalem, Israel

Cerebral aneurysms are balloon-like dilations in intracranial arteries that can rupture, leading to fatal hemorrhagic stroke. The majority of current aneurysm treatments involve the implantation of catheter-based endovascular coils and meshes, but they result in unfavorable primary outcomes in at least 20% to 30% of cases [1]. This project aims to develop an injectable, controllably cross-linkable, durable, and multi-functional liquid embolic agent (LEA) using F88-DMA polymer that allows for the body's natural mechanisms to heal the aneurysm with personalized biodegradation.

As temperature increases and reaches physiological temperatures, F88-DMA micelles group together and entangle, resulting in mechanically strong physical gelation. Chemical crosslinkers ammonium persulfate (APS) and tetramethylenediamine (TEMED) enhance the long-term stability of the hydrogel, while iohexol acts as a contrast agent.

In order to develop a pluronic-based polymer system that is deliverable in vivo, cold, radiopaque F88-DMA must be injectable through a microcatheter. Gelation must occur at the optimal time and temperature so as not to solidify prematurely or remain liquid within the aneurysm. Various concentrations of F88-DMA and TEMED were tested in vitro to determine the optimal concentration for injectability. Rheology results displayed that a higher concentration of F88-DMA lowers gelation temperature, and this correlation was further confirmed with differential scanning calorimetry for all three concentrations of F88-DMA (27%, 30%, and 33%). Additionally, higher concentrations of TEMED were found to increase the maximum shear modulus and decrease the crosslinking time of F88-DMA gel. To simulate interventional treatment, the LEA was injected into a brain aneurysm model, suggesting 29% F88-DMA to be the most injectable concentration that, when crosslinked, would remain in the aneurysm for prolonged periods of time.

Upon gelation and crosslinking, hydrogels swell in situ due to thermodynamic forces, posing a significant risk for compression or rupture. F88-DMA hydrogel swelling was demonstrated to be dependent on polymer concentration ($p = 0.019695$), and the addition of iohexol significantly decreased swelling over the course of 3 days. Furthermore, hydrogels submerged in flowing saline exhibited less swelling than those submerged in static saline ($p = 0.0001$), an improved durability that originates from the entangled properties of the micelles.

The durable embolic agent must also allow for vascular remodeling and endothelialization in a controlled manner. Thus, cell adhesion and porosity are vital. Imagery of fibrinogen-soaked gel suggests that natural levels of fibrinogen make the cross-linked F88-DMA cell adhesive enough, providing no need to incorporate cell adhesive materials. Sodium phosphate heptahydrate was effectively employed to control pre-determined porosity that initiates the wound healing process.

After the aneurysm has healed, the pluronic implant must be controllably biodegradable. The biodegradability of the LEA is a function of the patient-specific wound healing process such that the blood vessel returns completely to its original healthy state. Naturally occurring enzymatic F88-DMA degradation is currently being investigated with lactide.

Future studies will involve injecting this gel into rabbit models to examine its effects in vivo and determine rates of endothelization post-injection.

Non-Invasive Smart Wearables: Color-Changing Hydrogels via DLP 3D Printing MohamedElnemr and HaiderButt; Khalifa Univeristy, United Arab Emirates

This study explores the development of conducting and functional hydrogels for use in smart wearables, such as eyeglasses frames, bracelets, rings, and watches, through the utilization of a novel approach involving HEMA (Hydroxyethyl Methacrylate), PEGDA (Polyethylene Glycol Diacrylate), and EGDMA (Ethylene Glycol Dimethacrylate) within the context of DLP (Digital Light Processing) 3D printing technology. By introducing thermochromic and photochromic powders into the resin matrix, we achieve dynamic color-changing capabilities in response to changes in temperature and UV light exposure, respectively. The hydrogel formulation, composed of HEMA, PEGDA, and EGDMA, ensures excellent printability and mechanical properties, making it suitable for the creation of complex wearable structures with a focus on comfort and wearability. The incorporation of thermochromic powders enables these smart wearables to undergo vivid color transformations when subjected to temperature fluctuations, enhancing their aesthetic appeal and user experience. Additionally, the integration of photochromic powders facilitates real-time color alterations in response to UV light exposure, allowing the wearables to adapt to varying environmental conditions. This research combines materials science, 3D printing technology, and advanced color-changing effects to develop innovative and customizable smart wearables. These functional hydrogels open up exciting possibilities for dynamic fashion accessories and user-centric designs, enabling wearers to express themselves creatively and interact with their wearables in novel ways. This interdisciplinary approach paves the way for the future of personalized, responsive smart wearables with a focus on aesthetics, functionality, and user engagement.

8:00 PM SB04.07.19

Multi-Scale Chemical Insights into The Static and Dynamic Behaviour of Metallo-Polyelectrolyte Gels SenecaJ. Velling[1], PierreJ. Walker[1], SeolaLee[1], ConnorM. Gallagher[2,2], MichaelD. Schulz[2,2], Zhen-GangWang[1] and JuliaR. Greer[1,1]; [1]California Institute of Technology, United States; [2]Virginia Tech, United States

Metallo-Polyelectrolyte Complexes (MPEC) in the gel state represent a class of multifunctional, weakly ionizing materials with intriguing properties deeply rooted in their coordination chemistry and metal ion exchange. We provide a comprehensive exploration of the underlying chemical principles governing MPECs, with a primary focus on the profound effects of metal ion valency and system pH on bonding thermodynamics, association-dissociation kinetics, and global polymer morphology and their regulation of overall gel behaviour. Employing quantum density functional theory (DFT), we estimate the binding energy between the metal cations and the polymer backbone. Hard mono-, di-, and trivalent metal ions exhibit bidentate bridging coordination environments by carboxylate groups and aqua/hydroxy ligands as verified using FTIR, giving stoichiometric charge balance to the complexes. This results in a range of binding energies of -1 to -8 eV. We corroborated these findings with Isothermal Titration Calorimetry (ITC) to probe the solution-phase binding of metal salts to poly(acrylic acid). We demonstrate that the impact of association kinetics at the molecular level propagates to macroscopic behaviour, with higher valency metal ions distinctly influencing relaxation dynamics, thereby increasing gel stiffness and extending the plateau modulus. The role of proton activity in the solution and gel phases – which systematically modulates polyanion charge sparsity and, accordingly, metal binding sites for the formation of these dynamic bonds – can be readily explained using our theoretical treatment. This treatment is in good agreement with our

experimental exploration of the MPEC phase space (dissolution, homogeneous gel, and phase separated metal-rich vs. metal-poor gel phase). Guided by theory, our experimental observations unveil the profound influence of pH on polymer relaxation. As charge sparsity decreases, MPEC gels transition towards behaviour reminiscent of monovalent gels, accompanied by critical alterations in network topology. These findings underscore a competition for polyanion ($RCOO^-$) association between weakly-bound monovalent species in the buffer (eg. Na^+), strongly-bound, higher-valency metal species (M^{n+}), and the drive for carboxylate protonation when pH < pK_a. This intricate interplay between metal ion valency and pH-regulated charge sparsity fundamentally governs the global thermomechanical response of solvated MPEC gels: from binding site availability to bond dynamics and overall gel morphology. Local chemistry, therefore, has a profound influence on overall thermal, mechanical, and electrical response of metal cross-linked systems. The assumption – and critical role – of solvent in the gel system cannot be overlooked. Our implicit solvent approaches, taken together with DFT and experimental findings on the collective metal-ligand and metal-aqua/hydroxyl ligand complexation character, explain well the bulk-scale observations in the gel phase, providing mechanistic insights into the polymer-metal interactions, transport, and phase-behaviour. This work unravels the intricate & entangled chemistry underpinning MPEC gels, offering critical insights into their valency-driven, pH sensitive, solvent-dependent global responses.

8:00 PM SB04.07.20
Intriguing Thermal and Conductive Behavior of Water-Based Gel Electrolytes for Safer Lithium-Ion Batteries ArthurCresce and MichaelDing; US Army Research Laboratory, United States

Gel electrolytes are a special case of electrolytes for lithium-ion batteries in which the liquid electrolyte is contained in a crosslinked polymer network. In this work, we explore the thermal and conductive properties of a water-based electrolyte with high salt concentration meant for use in lithium-ion batteries. Normally, this water-in-salt electrolyte (WiSE) has a conductivity of around 10 mS/cm at room temperature but experiences a solidus transition around 10 °C that causes a profound drop in electrolyte conductivity which negatively impacts battery operation. Using an automated *in-situ* thermoconductometric measuring technique developed at the US Army Research Laboratory, our team was able to methodically measure and describe the thermal and related conductivity behavior of gel electrolytes made using WiSE as a base liquid system with increasing monomer mass fraction. The thermoconductometric technique allowed for measurements before and after ultraviolet radiation was applied to cure the gels, allowing us to compare the interaction of monomer and WiSE with crosslinked polymer and WiSE across a wide temperature range. We observed that a sufficient monomer concentration in the gel suppressed freezing and melting phase transitions in WiSE, resulting in a smooth conductivity behavior from -60 °C to +50 °C with no discontinuities related to electrolyte phase changes. There is also a decoupling of Li^+ conductivity in the gel electrolyte which is affected by the polymerization of the monomer as evidenced by the emergence of two distinct glass transition temperatures. Additionally, at certain WiSE/monomer compositions, the conductivity of the cured gel electrolyte was higher than that of WiSE with uncured monomer. In this talk, we will discuss our results, the implications of the findings, and potential ways to exploit WiSE gel electrolytes for making safe lithium-ion battery cells.

Unusual Temperature Dependence of Water Sorption in Semi-Crystalline Hydrogels XinyueLiu[1], LenanZhang[2] and EvelynN. Wang[2]; [1]Michigan State University, United States; [2]Massachusetts Institute of Technology, United States

Water vapor sorption is a ubiquitous phenomenon in nature and plays an important role in various applications, including humidity regulation, energy storage, thermal management, and water harvesting. In particular, capturing moisture at elevated temperatures is highly desirable to prevent dehydration and to enlarge the tunability of water uptake. However, owing to the thermodynamic limit of conventional materials, sorbents inevitably tend to capture less water vapor at higher temperatures, impeding their broad applications. Here, an inverse temperature dependence of water sorption in poly(ethylene glycol) (PEG) hydrogels, where their water uptake can be doubled with increasing temperature from 25 to 50 °C, is reported. With mechanistic modeling of water–polymer interactions, this unusual water sorption is attributed to the first-order phase transformation of PEG structures, and the key parameters for a more generalized strategy in materials development are identified. This work elucidates a new regime of water sorption with an unusual temperature dependence, enabling a promising engineering space for harnessing moisture and heat.

SESSION SB04.08: Stimuli-Responsive Materials and Other Special Mechanical Properties II

Energetic Electron Assisted Synthesis of Bioderived Smart Hydrogels and Ferrogels – Fundamentals, Applications, Perspectives StefanG. Mayr[1,2]; [1]Leibniz-Institute of Surface Engineering (IOM), Germany; [2]University of Leipzig, Germany

Energetic electron beams constitute a highly versatile tool for tailoring biomaterials properties of bioderived hydrogels with high spatial resolution. Based on electron-induced hydrolysis, reactions, ranging from crosslinking, chain scission and functionalization to arrest of magnetic nanoparticles, can be induced without the need for adding additional - potentially hazardous – reagents. This allows for synthesis of highly bioactive switchable composites, in particular ferrogels, stimuli responsive gels as well as shape memory gels. Within this presentation we will first review the fundamentals of energetic electron assisted hydrogel modification, regarding particularly the reaction kinetics in collagen. We will then focus on applying these finding for tailored hydrogel modification towards stimuli responsive gels, in particular ferrogels. This includes a collagen-based ferrogel actuator with reversible peak strains as large as 150%. We will also discuss application within the field of biomedicine, that are currently being developed, as well as future visions in an outlook.

8:45 AM *SB04.08.02
Rubbery Bioelectronics CunjiangYu; The Pennsylvania State University, United States

Electronics that can seamlessly integrate with human body could have significant impact in medical diagnostic, therapeutics. However, seamless integration is a grand challenge because of the distinct nature between electronics and human body. Conventional electronics are rigid and planar, made out of rigid materials. Human body are soft, deformable and curvilinear, comprised of biological materials, organs and tissues. This talk will introduce our solution to address the challenge through the recent development of a new class of electronics, namely rubbery electronics. Rubbery electronics is constructed all based on elastic rubber electronic materials of semiconductors, conductors and dielectrics, which possesses tissue-like softness and mechanical stretchability to allow seamless integration with soft deformable tissues and organs. Rubbery electronic materials (semiconductors, conductors, dielectrics) and device innovations set the foundation. This presentation will describe the development the recent advances of rubbery electronics and rubbery bioelectronics. As a platform technology, rubbery electronics could address many challenges in biomedical research and clinical studies.

Fabrication of Multi-Material Stimuli-Responsive Microstructures via Photografting of Functional Microgels to Elastomeric Supports RuiguoYang and StephenA. Morin; University of Nebraska – Lincoln, United States

Hydrogels are functional polymeric materials with stimuli-responsive properties applicable to a wide range of applications including soft electronics and robotics, three-dimensional cell culture, tissue engineering, and adaptive optics. Accordingly, the diversity and reported use cases of these materials has grown tremendously over the past decade, however, the microfabrication of multi-material, hydrogel-based devices remains a challenge. We report a simple microfabrication strategy that enables the facile production of fixed arrays of stimuli-responsive hydrogel microstructures with dynamic microactation functionality. Our approach relies on a soft, stretchable chemical template which directs the assembly of prepolymer droplets into ordered arrays and presents the surface chemical moieties needed to photograft the hydrogel to the support, simultaneously. Specifically, we achieve three critical operations in one seamless fabrication scheme: (i) Mechanically driven assembly of prepolymer solutions into ordered arrays is executed using stretchable wettability patterns; (ii) Photoinitiated free radical polymerization is used to drive crosslinking of the prepolymer into hydrogel networks; and (iii) Reactive moieties of the wettability patterns result in photografting of the microgel structures directly to the support substrate. To demonstrate the pragmatic utility of our approach and the functionality of fixed microgels in liquid phase applications, we designed, fabricated, and operated microgel arrays with stimuli-responsive (e.g., solvothermal and chemical) microactuation functionality inside microfluidic chips. Our strategy overcomes the limitations of existing fabrication techniques that produce poorly adherent materials and require complicated processing schemes. We envision many technologies, for example, liquid phase soft microactuators, stimuli-responsive 3D cell culture platforms, and micro/optofluidic chips, will directly benefit from the reported strategy.

9:30 AM *SB04.08.04

Hydrogel Bioelectronics, Bioacoustics and Biophotonics XuanheZhao; Massachusetts Institute of Technology, United States

Whereas human tissues and organs are mostly soft, wet and bioactive; machines are commonly hard, dry and abiotic. Merging humans and machines is of imminent importance in addressing grand societal challenges in health, sustainability, security, education and joy of living. However, merging humans and machines is also extremely challenging due to their fundamentally contradictory properties. At MIT Zhao Lab, we exploit hydrogels to form long-term, high-efficacy, multi-modal interfaces and merger between humans and machines. In this talk, I will discuss hydrogel bioelectronics, bioacoustics, and biophotonics. Specifically, I will discuss examples including nonfibrotic hydrogel bioelectrodes, hydrogel ultrasound couplants that enable wearable imaging, and hydrogel optical fibers that replace rigid optical fibers. I will conclude the talk with a vision for future human-machine convergence aided by materials science and artificial intelligence.

10:30 AM *SB04.08.05
A Conductive Hydrogel with Tuneable Mechanical and Rapid Self-Healing Properties DamiaMawad and NhiTra; University of New South Wales, Australia

The optimal physical and biological characteristics of a scaffold for tissue engineering include biocompatibility, tissue-like mechanical properties, and a hydrated and porous environment. Hydrogels, 3-dimensional crosslinked polymeric networks, feature many of these characteristics, and thereby, are considered excellent scaffolds for tissue engineering [1]. However, scaffolds tailored for electro-responsive tissues such as neural and cardiac tissue would also benefit from electrical conductivity [2], which has been shown to provide enhanced cell growth and differentiation [3]. Other favourable properties include self-healing [4], providing the scaffold with mechanical and electronic stability under strain, and self-adhesion, enabling the placement of the scaffold at the targeted tissue site in a minimally invasive approach [5]. Here, we report the fabrication and characterisation of a conductive, adhesive, and self-healing hydrogel for tissue engineering applications. We fully characterise its physical and electronic properties. We show that the hydrogel is porous, has high swelling ratio and tuneable mechanical properties, and exhibits very rapid self-healing. We also demonstrate that it is electroactive in physiological buffer and exhibits both ionic and electronic conductivity. Further, its self-adhesion indicates a facile placement on tissues. Coupled together, these properties indicate that the hydrogel with its individual biocompatible components is a suitable scaffold for cell growth and differentiation.

11:00 AM SB04.08.06
Tunable Conductive Hydrogels via Simultaneous Photo-Mediated Polymerization and Crosslinking Dan-MyNguyen, Chun-YuanLo, TaewookChoi, ZacharySwain, YuhangWu, CharlesDhong and LaureV. Kayser; University of Delaware, United States

Conductive hydrogels, particularly those containing poly(3,4-ethylenedioxythiophene):poly(styrene sulfonate) (PEDOT:PSS), have gained popularity in bioelectronic interfaces for their mechanical properties close to that of human body and their electrical properties suitable for electrical recording and stimulation. To minimize the invasiveness of conductive hydrogels for bioelectronics, alternative fabrication methods to the common blending approach have been developed, including the photo-gelation of conducting polymers in aqueous environments. However, the photo-catalyzed formation of conductive hydrogels with complex structures is still a challenging task, as the conductive polymers absorb UV light at a similar wavelength, thereby preventing crosslinking. A photo-mediated method for obtaining conductive hydrogels with good conductivity, tunable mechanical properties, and flexibility akin to human body is still lacking.
We developed an approach that combines the simultaneous photo-crosslinking of a polymeric scaffold and the photo-catalyzed polymerization of a conducting polymer under light irradiation. This approach involved the copolymerization of coumarin-containing monomers with sodium styrene sulfonate to yield water-soluble poly(styrene sulfonate-*co*-coumarin acrylate) (P(SS-*co*-CoumAc)). Under UV irradiation (365 nm), a transparent, non-conducting solution of P(SS-*co*-CoumAc), 3,4-ethylene dioxythiophene (EDOT) and ammonium persulfate transforms to a dark blue, electronically conducting hydrogel. The formation of the conductive hydrogel relies on the simultaneous covalent photo-crosslinking of P(SS-*co*-CoumAc) and the photo-catalyzed oxidative polymerization of EDOT. The resulting conductive hydrogels exhibit both ionic and electronic conductivity to reach bulk conductivity up to 9.2 S m^{-1}. They possess tunable elastic moduli (around 10 MPa), and display a reasonable strain at break (up to 16%). These photo-generated conductive hydrogels have the potential to enable the formation of 3D networks with controlled microstructure and offer new possibilities for applications in bioelectronics, including surface electromyography (sEMG).

11:15 AM SB04.08.07
The Effect of Multivalent Interactions on the Electrostatic Stability of Poly(*N*-isopropylacrylamide) NanogelsYuchenZhu[1], JiaxinHou[1], DominicGray[2], TomO. McDonald[2] and Ahu GumrahDumanli[1]; [1]University of Manchester, United Kingdom; [2]University of Liverpool, United Kingdom

Poly(*N*-isopropylacrylamide) (PNIPAM) nanogels are promising responsive colloidal particles that can be used in pharmaceutical applications as drug carriers. With an attempt to understand the stability of the PNIPAM-based drug carriers in complex chemical environments, in this work, we investigated the temperature-dependent morphological changes and agglomeration dynamics of PNIPAM nanogels in the presence of mono- and multi-valent cationic electrolytes. Our work provides new insights on the deswelling, flocculation and aggregated morphology of PNIPAM nanogels over a range of electrolyte concentrations and temperatures revealing the threshold of stability and spontaneous agglomeration states. To complement our results on flocculation of these colloidal particles, we also implemented a Debye screening model that accounts for the shielding effect of multivalent cationic electrolytes on these nanogel systems. We demonstrated that, while the order of deswelling ability of the electrolytes follows the trend $AlCl_3 > MgCl_2 \geq CaCl_2 > KCl \geq NaCl$, the nanogels reach a minimum hydrodynamic diameter at 10 mM in all electrolyte solutions. The flocculating ability trend and the response time to form aggregates follow a similar order to the deswelling behavior. Interestingly, our statistical analysis on the SEM and TEM images of the PNIPAM nanogels supported our hypothesis on the presence of a shell-like layer around the nanogels with varying density in the electrolyte solutions as compared to those in aqueous medium, and the shell softness of nanogels became harder in multi-valent electrolyte solution than in monovalent system. Furthermore, the retention of the thermo-induced size reversibility for the Na^+ and K^+ below 10 mM and for the Mg^{2+} and Ca^{2+} below 1 mM indicates the effective destabilization of the electrolyte system with multivalence following the Schulze–Hardy rule, except for Al^{3+}. In terms of surface charge screening effect, cations with a higher valence shortened Debye length to a greater extent and this ability was found to be in the order of $Al^{3+} > Mg^{2+} > Ca^{2+} > K^+ > Na^+$.

11:30 AM SB04.08.08
Precision Mechanical Enhancement and Patterning of Hydrogels using Photo-Click Chemistry JunH. Park[1,2], PatrickJ. Grimes[1], HenryE. Symons[1], MarkS. Workentin[2], SebastienRochat[1,1] and PierangeloGobbo[3]; [1]University of Bristol, United Kingdom; [2]The University of Western Ontario, Canada; [3]University of Trieste, Italy

Hydrogels have vast biomedical applications due to their highly tuneable properties, such as biocompatibility, adhesion, permeability, viscoelasticity, and stiffness. These extraordinarily adaptable materials can be engineered to be stimuli-responsive by carefully selecting the crosslinking monomers or polymers that make up the hydrogels. A stimulus that allows for excellent spatio-temporal control is light, and the translucent nature of hydrogels is complementary to its use in these materials. There are various photoactive moieties that have been incorporated into photo-responsive soft materials, however, there are very few systems utilising photo-click reactions to modify the mechanical properties of hydrogels.
Click chemistry has become an established category of reactions characterized by rapid, selective, high yielding, and atom economic transformations that require minimal purification and can be carried out under mild conditions. In 2004, Bertozzi and coworkers established a bioorthogonal, click reaction called the strain-promoted alkyne-azide cycloaddition (SPAAC) by modifying the copper-assisted alkyne-azide cycloaddition (CuAAC) using strained alkynes.[1] These alkynes are more reactive and do not require cytotoxic copper catalysts due to ring strain and bond angle deformation. To circumvent degradation and unwanted side reactivity of the strained alkyne, a cyclopropenone-masked dibenzocyclooctyne (*hv*DIBO) moiety was developed, capable of facile deprotection to the strained alkyne using ultraviolet light.[2] The rapid deprotection can be performed *in situ* and the resulting alkyne is then free to selectively react with an azide *via* a SPAAC. Along with its great stability and simple deprotection, the application of *hv*DIBO onto soft materials introduces precise spatial control due to the sensitivity of the cyclopropenone group to 350 nm UV-A light.
In this communication, the fabrication of photo-responsive hydrogels incorporating *hv*DIBO and azide moieties will be discussed. Photo-click crosslinking reactions between these groups to mechanically strengthen soft materials will be highlighted. The spatio-temporal control of the photo-click reaction was employed to photo-pattern the surface of hydrogels and to study the kinetics of the materials' strengthening. A recently developed methodology designed to study the mechanical properties of soft materials with a micro-indenter was applied. Microindentation analyses were used to spatially characterize viscoelasticity and height profile changes of these hydrogels, and to determine the reaction order kinetics of the photo-click reaction.[3] These analyses aim to relate chemical processes with mechanical measurements. Overall, these photo-responsive hydrogels can be readily strengthened and patterned through clean, facile photo-click chemistry, allowing for exciting potential applications in actuation, soft robotics, biointerfacing, and biomimetic materials.

DNA-Polymer Hybrids for Responsive and Repeatable Gating in Nanostructures KimberleyCallaghan[1], ShelleyWickham[2] and AmandaEllis[1]; [1]The University of Melbourne, Australia; [2]The University of Sydney, Australia

Deoxyribonucleic acid (DNA) is a remarkable molecule, responsible for cellular information storage, exhibiting unique chemical structure and interactions. These properties have enabled its applications in drug delivery, research tools, and novel materials, with many more potential applications as yet unrecognised. This project aims to develop responsive DNA-polymer hybrid materials capable of sensing and responding to environmental stimuli. These materials will capitalise on the dynamic properties of DNA, whilst utilising the favourable material properties of polymeric materials.

In this work, a DNA-polymer hybrid material was designed to form an aqueous hydrogel upon stimuli addition to generate a gate within a DNA-origami nanostructure to form a biological circuit board. The hydrogel was constructed from an acrylamide backbone, with pendant DNA functionality incorporated. DNA oligonucleotides with polymerisable acrydite handles were doped into the polymerisation reaction, resulting in sporadic incorporation of the DNA motifs.

The DNA motifs used were designed to gate the hydrogel structure under orthogonal stimuli. The stimuli investigated included: temperature, through a self-complementary sequence able to form inter-strand duplexes as lower temperatures; pH, via a i-motif formation involving Hoogsteen base pairing between two cytosine bases in which one is protonated below pH 5 with dissociation upon deprotonation above pH 7; and, a metal ion bridge, using silver ions to bridge two cytosine bases followed by addition of a cysteamine ligand to dissociate the strands. The stimuli chosen all generate transient intermolecular interactions and as such can be cycled repeatably, allowing for multiple opening and closing cycles of the gates without the need for replacing DNA-polymer components or damaging DNA-origami structures. By integrating the dynamic properties of DNA with the favourable characteristics of polymeric materials, these nanoscale systems offer a solution for the limitations of traditional electronic devices.

Self-Assembled Nanofibrous Hydrogels with Tunable Porous Network for Highly Efficient Solar Desalination in Strong Brine HaoLi[1], WeixinZhang[2], JiaweiLiu[1], SunMingze[1] and LizhiXu[1,2]; [1]The University of Hong Kong, Hong Kong; [2]Advanced Biomedical Instrumentation Centre Limited, Hong Kong

Hydrogels hold great promise as solar evaporators for highly efficient solar desalination due to the reduced vaporization enthalpy in the hydrated polymeric network. However, rarely hydrogel-based solar evaporators (HSEs) can achieve both excellent evaporation rate and stability when purifying strong brine, mainly limited by the vague understanding of complex nexus between microstructures and evaporation performance. Here, hydrogels based on aramid nanofibers (ANFs) and Polyvinyl alcohol (PVA) with great tunability on microstructures and compositions were proposed as the platform for the engineering of HSEs. The nanofiber hydrogel-based solar evaporator (NHSE) demonstrates open porous network and ultrahigh porosity above 90%, enabling the highly continuous water channels for efficient mass transfer. The hybrid nanofiber network incorporating polypyrrole demonstrates abundant hydrophilic groups for reducing vaporization enthalpy and excellent photothermal conversion performance without compromising the porous structure.[1] Numerical simulations conducted here reveal the complex nexus between microstructures and evaporation performance by coupling water transfer, thermal conduction, and vaporization enthalpy during evaporation. The general insights provided in this work are also conductive to design other HSEs. The optimum NHSE demonstrates a superior evaporation rate of 2.85 kg m^{-2} h^{-1} in 20% brine with continuous desalination for 8 h. This work first develops a tunable hybrid nanofiber network as solar evaporator in strong brine and provides general insights to the design of HSEs for highly efficient solar desalination.

Multifunctional Zwitterionic Hydrogels as a Platform for the Rapid and Simultaneous Elimination of Organic and Inorganic Micropollutants from Water DevashishGokhale, AndreF. Hamelberg and PatrickDoyle; Massachusetts Institute of Technology, United States

The removal of micropollutants from water is made difficult by their chemical diversity, low concentrations, and slow uptake by industrial adsorbents. Traditional adsorbents, like activated carbon and ion-exchange resins, are effective in eliminating only specific classes of micropollutants, necessitating the use of multiple unit operations that sequentially treat water. At the same time, slow kinetics require the unit operations to have long residence times and be much larger to effectively eliminate micropollutants. Here we present a new multifunctional zwitterionic porous hydrogel platform for the single-step bulk absorption of both organic and inorganic micropollutants from water. Shifting from traditional surface adsorbents to hydrogels greatly increases the effective functional area, while allowing us to retain the same process-level equipment that has been well studied in the context of conventional adsorbents. A facile synthesis allows easy functionalization of the hydrogels for eliminating multiple micropollutant classes, while also allowing a measure of selectivity. The hydrogels can be synthesized in several form factors for specific applications, including microparticles for use in packed beds, or tablets for treating water in a glass or canteen. Transport of micropollutants within the hydrogels is sped by ion-conducting zwitterionic backbones, while encapsulated micelles speed the transport of uncharged organics. The zwitterionic hydrogels are shown to remove six chemically diverse micropollutants (including BPA, xenoestrogens, and other organics, and lead and other metals) at least 10 times more rapidly than a commercial activated carbon/ion exchange resin mixture, and 100 times faster than other multifunctional adsorbents reported in literature. Zwitterionic hydrogels treat complex micropollutant mixtures, including in the presence of background hardness. Lower compressibility, extremely rapid mass transport, and high stability make our materials highly scalable for real world applications. We demonstrate the use of a prototype packed bed filter with a practical residence time and containing zwitterionic hydrogel microparticles to clean highly contaminated water to below regulatory limits for a period of two weeks.

2:15 PM SB04.09.03
VOCs-Responsive Hydrogel Electrode based on Changes in Chain Mobilities for Multi-Protection YounaKim and JinkeeHong; Yonsei University, Korea (the Republic of)

Every year, exposure to volatile organic compounds (VOCs) causes fatal accidents including dyspnea and explosions. Personal protection equipment (PPE), such as VOCs sensors to monitor indoor air quality and masks to prevent inhalation of VOCs, is needed to prevent VOC exposure. However, single-functional PPE leads to inconvenience for workers as they must wear multiple pieces of PPE. Therefore, PPE must have the versatility to check not only air quality but also the health condition of workers.
PPE combined with wearable electronics could provide multifunctionality with human health monitoring including strain and motion signals and VOCs detection. The electric materials for wearable electronics should be lightweight, flexible, and stretchable. Hydrogels are attracting attention in wearable electronics because of their flexibility, stretchability, and conductivity. However, it has weak mechanical strength and suffered the deterioration of conductivity and shape shrinkage due to moisture evaporation. Furthermore, few studies have controlled the mechanical and electrical properties of hydrogels due to VOCs exposure except for color changes. In order for VOCs-responsive hydrogels to exhibit various VOC-sensing performances, like actuation and electrical changes, an understanding of polymer behavior caused by VOCs must be investigated.
In this study, we designed a VOC-responsive polymer network (VRN), a wearable electronics that can change its mechanical and electrical properties through VOC reaction. Through a solvation effect by different chemical affinity, the inter/intramolecular interaction and arrangement between polymer chains could be controlled. Based on the solvation effect, we considered (1) the control of polymer chain mobility and hydrogen bonding within VRN and (2) the chemical affinity between the VRN and VOCs.
To control the VRN network, VRN is composed of polyvinyl alcohol (PVA) as hydrophilic semicrystalline and deep eutectic solvents (DES) as ionic liquids. DES is used as a processing and conductive additive to increase the entangled polymer chains and inhibit hydrogen bonding between polymer chains. Accordingly, VRN shows ionic conductivity and stretchability, which can be used for strain-responsive electrodes.
After VOCs exposure, the increased hydrogen bonding and chain relaxation energies affected not only mechanical properties but also the electrical resistance of VRN. A relative resistance change ($\Delta R/R_0$) of VRN is increased by 50% when VRN is exposed to VOCs vapor. The peak voltage based on the triboelectric energy generator (TENG) system decreased by 30% due to VOCs exposure. VRN can be applied to PPE in various forms such as fiber and spray coating.
In addition, we studied the VOCs responsive mechanism of polymer chains using rheological and Raman analysis. We expect VRN to propose VOCs-responsive mechanisms and technologies needed to move towards advanced PPE.

Ingestible Electronic Interfaces for Neuromodulation KhalilRamadi[1,2,3]; [1]New York University Abu Dhabi, United Arab Emirates; [2]New York University, United States; [3]Massachusetts Institute of Technology, United States

Neuromodulation is emerging as a novel approach to treat both neurological and non-neurologic diseases. However, the brain and nervous system are extremely heterogeneous, where cell types and functions vary on scales from sub-millimeters to centimeters. This heterogeneity presents a major obstacle for targeted modulation and interrogation of specific neural structures. This talk will describe non-invasive, ingestible toolkits for high spatial and temporal resolution targeting of neural circuits.

4:00 PM SB04.10.02
Kinetic Control Dictates the Operation of PEDOT:Lignosulfonate Thin-Films for Biosensing at Physiological pH AlexC. Tseng[1], TomaszRebis[2] and ToshiyaSakata[1]; [1]The University of Tokyo, Japan; [2]Poznan University of Technology, Poland

Integrating electrically conductive and redox polymers (RPs) is a promising approach for sustainable development of high-performance electrical and electrochemical materials, not only for energy storage but also for bioelectronics and biosensors. Lignosulfonates (LS) exemplify a particularly green materials selection, being low cost and biorenewable, yet readily providing phenolic groups to access (*ortho*-)quinone redox (i.e., reversible proton coupled electron transfer, PCET) and sulfonic acids for polyanionic doping of conductive polymers (CPs). When blended with oxidatively stable PEDOT (poly(3,4-ethylenedioxythiophene), remarkable specific capacity (170 $F.g^{-1}$) was reported in acidic conditions (0.1 M $HClO_4$) [1] despite significant loading of electrochemically inactive components.
Besides enhancing pseduocapacitance, quinone PCET may be further leveraged to serve as an electrochemical interface between technological devices and biological catalyst cycles [2]. However, in the mild pH conditions amenable to biology, it is well known that *ortho*-quinones exhibit limited stability towards redox cycling. Several possible explanations been offered up over the years, for instance: microstructural changes inhibiting proton diffusion [1,4], dissolution of the redox polymer [3], hydroxylation to higher order polyphenols [2], phase separation of CP and redox polymer [5], and cross-linking by the formation of ether linkages [6] or phenyl dimerization [7].
These varied conclusions are likely views of the same fundamental property of *ortho*-quinone RPs—filtered through a range of fabrication and experimental conditions—which is that reversible quinone PCET is a kinetically controlled process. Future biological applications, therefore, require an understanding of how and when alternate electrochemical pathways become activated by the scarcity of protons in physiological conditions. Hence, we investigated the pH-dependent behaviour of PEDOT:LS thin-films via *in-situ* UV-Vis spectroelectrochemistry, charge transport characterization in an electrochemical transistor, and thermodynamic/kinetic analysis by the Laviron method. Our results paint a surprising picture: PEDOT, typically considered to be a “transparent” conductor serving simply as a wire to enhance electron transfer with quinones, is implicated in the formation of strongly bound complexes that appear to stabilize semiquinone radicals. Accordingly, previously observable PEDOT and quinone states are removed in proportion from measurement on experimental timescales. This kinetic process is mediated by the effective overpotential vs. PCET as a function of pH and polarization, and thus informs the optimal operating conditions for biosensing using PEDOT:LS.

4:15 PM SB04.10.03
Waterproof and Gel-Free E-Textile Wearable Systems for Exercise Physiology and Maternal Health JunyiZhao, ChansooKim and ChuanWang; Washington University in St. Louis, United States

Textile-based electronic systems have emerged as a promising platform for noninvasive and comfortable human-machine interfaces in various applications. These systems integrate multiple technological capabilities such as sensing and wireless communications, making them suitable for daily wearables and physiological monitoring in sports and clinical settings. This work presents a novel E-textile system consisting of printed on-textile electrodes and add-on conductive microfibers, enabling gel-free motion-artifact-tolerant recording of multiple physiological signals, including ECG and EMG from both skeletal and smooth muscles. More specifically, the base layout consists of a screen-printed array of poly(3,4-ethylenedioxythiophene) polystyrene sulfonate (PEDOT:PSS), and the fluffy microfibers coated with PEDOT:PSS are stacked on top. The vertically oriented hairy microfibers offer exceptional conformal and robust contact with the skin, while the spreading-out microfiber electrodes substantially increase the effective contact area. As a result, the contact impedance between the electrode and skin is significantly reduced, enabling comfortable all-day wear under dry conditions without the need for ionic gels. To ensure the durability and functionality of the textile, a self-assembled monolayer (SAM) of trichloro(1H,1H,2H,2H-perfluorooctyl) silane is vaporized as a superhydrophobic coating. This treatment preserves the natural physical properties of the textile while maintaining the intrinsic conductivity of the electrodes. Additionally, a portable mini-circuitry was designed and manufactured to enable multi-channel recording and wireless communications. These advancements contribute to the seamless integration of the E-textile system into everyday life and expand its potential applications. This study explores the application of E-textile systems in real-life scenarios, including strenuous exercise and clinical studies. The study begins by demonstrating the robustness and stability of the E-textile system using E-jersey and E-shorts during a 15-minute cycling training session. Remarkably, the recorded signals remained clear and free from motion artifacts, even in the presence of intense sweating, with a signal-to-noise ratio of approximately 30 dB. Real-time monitoring also allowed for additional real-time data analysis, including heart rate and muscle output. Next, the waterproof capability of the system was tested by creating an E-swimsuit with electrodes placed facing the swimmer's back. Throughout the 12-minute swimming training, the fully submerged E-swimsuit consistently delivered reliable ECG recordings, demonstrating its resilience and suitability for aquatic environments, even when encountering water flows, showcasing its strength and suitability for aquatic environments. Finally, the textile-based E-patch with electrode arrays was employed in clinical studies to monitor maternal health. Multiple pregnant subjects were monitored, capturing multichannel maternal-ECG and uterine-EMG signals. The recorded multichannel uterine-EMG signals were further processed to generate noninvasive and high-resolution three-dimensional (3D) electromyometrial images, providing unique insights into uterine behavior and offering a means of predicting the risk of potential preterm birth. These findings emphasize the versatility and potential of wearable E-textile systems in a wide range of real-world applications. The E-textile systems are specifically designed for convenient and comfortable wearing, paving the way for professional sports tracking and personalized healthcare advancements.

4:30 PM SB04.10.04
Materials Design of Functional Gels to Realize 3D Artificial Skin Device based on Extrusion-Based 3D Printing WoohyeonShin[1,2], Hui JuChoi[1] and KyeongwoonChung[1]; [1]Kyungpook National University, Korea (the Republic of); [2]Ulsan National Institute of Science and Technology, Korea (the Republic of)

Due to unique properties such as biocompatibility, flexibility, and conductivity, hydrogels are widely investigated in various applications, including tissue engineering, E-skin, wearable, and ionic devices. Especially, in the field of E-skin devices, hydrogels are recognized as one of the promising materials due to their flexibility and capability to realize various sensing functionalities. Still, there are challenges that need to be addressed: the structural freedom of devices. Most E-skin devices have been demonstrated with simple structures such as blocks or films due to the demand for complicated multi-layer structures or limitations in the fabrication process. Especially, because body parts with various shapes and movements (e.g., fingers, elbows, and shoulders) are under massive fatigue by strains in various directions and amounts, it is important to realize artificial skin devices with complex 3D structures that are optimized for the targeted body part.
To realize complex 3D structures of hydrogel via extrusion-based 3D printing, we systemically investigated the correlation between materials design and their characteristics including gelation properties, rheological characteristics, and 3D printing processability. From the investigation, we successfully presented the material design window based on the rheological

parameter (G` < 2500 Pa and tan δ < 0.2) to prepare target-oriented 3D structures of the hydrogel via extrusion-based 3D printing.
Based on the defined material design window, we successfully prepared functional hydrogel 3D structures to demonstrate novel artificial skin devices that can detect accurate touch points and spontaneously heal mechanical damage. Ring-shaped and fingertip-shaped artificial skin devices have been successfully prepared to fit the finger model. Furthermore, like human skin, artificial skin devices provide accurate location information for arbitrary touch points without complex device fabrication or data processing.
In hydrogel-based 3D e-skin devices, it is also important to address the inherent drying and freezing problems of hydrogel for practical application. As an approach to these problems, we presented organohydrogel systems via solvent displacement and investigated the correlation between solvent system design and the material properties of organohydrogels. By investigating the rheological properties and ion conductivity of the gels, we provided insights for preparing optimal organohydrogels for various processes and applications. Based on the defined solvent system design, we prepared organohydrogels that show excellent drying resistance even over 1,000 hours and exhibit superior freezing resistance by showing no phase transition down to -60°C. Furthermore, the 3D artificial skin devices are demonstrated based on the organohydrogels, and the artificial skin devices successfully provide the exact position of touchpoints over time and show excellent operation capability even at temperatures below 0°C without losing flexibility.

SESSION SB04.11: Skin and Tissue-Interfacing Hydrogels II

Electrically Induced Shape Memory Hydrogels in Biomedical Applications. GeorgiosMikalef, ArjanSall, ZoeSchofield, AtifShahzad, PatriciaP. Esteban and LiamGrover; Healthcare and Technologies Institute, United Kingdom

Here we report the development of a novel shape memory hydrogel that changes shape on exposure to an electrical field. This material has been designed to enable the minimally invasive administration of a novel sensor system to monitor real-time changes in blood pressure. The hydrogel will encapsulate a sensor coil and protect against biological interference during measurement. Real-time blood pressure measurement will enable the diagnosis and monitoring of conditions as hypertension and cardiomyopathy, which place a significant financial burden on healthcare systems worldwide.

Polyelectrolyte (PE) hydrogels can exhibit a shape memory effect upon exposure to an electrical current, caused by ions that sit within its structure. PE gels are naturally found throughout the body where they are often associated with oppositely charged molecules. One such example is in the aggrecan, which interacts strongly with collagen in cartilage. PE hydrogels have already been used extensively as biomaterials. Their structure has made them ideal scaffolds for tissue engineering, novel drug delivery systems, soft robots particularly in artificial muscle and actuators, smart fabrics, and implantations for minimally invasive surgeries.

Since hydrogels can exhibit poor mechanical properties, we have made efforts to reinforce the shape-memory polymer structure. We explored 2 different formulations have been synthesised containing the smart material 2-acrylamido-2-methylpropanesulfonic acid (AMPs) and either Polyethylene Glycol Diacrylate (PEGDA) or acrylamide. The mechanical performance and chemical structures of these materials have been evaluated. Finally shape memory testing has been performed to determine the effect of curing on the material's ability to change shape.

Further testing will include direct contact cytotoxicity testing to determine cell viability as well as surface modification whereby protein adsorption will be implemented to fix the device and so reduce migration upon implantation.

9:15 AM SB04.11.02
Lightweight, Flexible and Self-Healable Electromagnetic Shielding PEDOT:PSS Hydrogels FlorianeMiquet-Westphal and FabioCicoira; Polytechnique Montréal, Canada

This abstract introduces our advanced EMI shielding hydrogel films, which exhibit exceptional properties for a wide range of applications. our hydrogels offer outstanding EMI shielding performance in the X-Band (8-12.4 GHz). Their lightweight composition makes them ideal for weight-sensitive applications. Additionally, the films' flexibility and free-standing nature enable seamless integration into diverse systems or structures. Notably, our hydrogel films possess self-healing capabilities. These impressive features position our EMI shielding hydrogel films as a leading choice for industries such as electronics, telecommunications, automotive, aerospace, and medical, offering versatile solutions for shielding, lightweight design, flexibility, and self-repair.

9:30 AM *SB04.11.03
Healable and Stretchable Conducting Hydrogels for Epidermal Electronics FabioCicoira; Ecole Polytechnique de Montreal, Canada

Soft and conductive materials with long-term stability have attracted interests in the field of epidermal bioelectronics due to their conformal contacts with skin and the ability to acquire bio-signals for long-term use. Applications include monitoring of vital signs (e.g., electrocardiography (ECG), electromyography (EMG), and electroencephalography (EEG)), measurement of body temperature and blood pressure and detection of analytes in bodily fluids. ECG, EMG, and EEG are typically achieved with metal (ground strap, bar, or cup) or, in most cases, Ag/AgCl gel electrodes. However, rigid metal electrodes are unable to withstand bending or stretching, which can result in skin damage or irritation and lead to high signals noise, whereas Ag/AgCl gel electrodes can lead to skin irritation due to strong adhesion on the skin and are prone to signal degradation in long-term use due to the drying of the gel. Therefore, there is a strong demand for soft conductive electronics that can form conformal interfaces with biological tissues for long-term use without leading to skin damage and irritation.
Various types of conductive soft materials have been used for on-skin electronics, in form of films, bio-inspired adhesives, fabrics, and hydrogels. Conductive hydrogels are promising candidates for epidermal electronics because of their conformal contact with the skin, high water content (70-99%, similar to tissues), ease of processing, tunable electrical and mechanical properties, and biocompatibility. Conductive hydrogels may be obtained from pure conductive polymers, e.g., poly (3,4-ethylenedioxythiophene) doped with polystyrene sulfonate (PEDOT:PSS), polypyrrole (PPy), or polyaniline (PANI)), or, in most of cases, by mixing conductive materials (e.g., conducting polymers, nanoparticles, nanowires, nanosheets, carbon nanotubes (CNTs), and graphene) with polymers, such as poly(vinyl alcohol) (PVA), poly(acrylic acid) (PAA), poly(acrylamide) (PAAM), or polyurethane (PU). A hydrogel prepared by mixing a PEDOT:PSS aqueous suspension with 0.1 M H_2SO_4 exhibited a conductivity of ~9 S/cm after further concentrated sulfuric acid treatment. Our group reported a hydrogel obtained by blending PEDOT:PSS into a PVA/borax system, which showed remarkable compliance on skin, outstanding plastic stretchability (10000% strain), self-healing, high adhesion on porcine skin (1.96 N/cm^2), and low compressive Young's modulus (~4 kPa). Electrodes based on this hydrogel have demonstrated high-quality recordings of ECG and EMG signals.

Tannic Acid, a natural polyphenol, has been widely used to prepare hydrogels from mixtures with PAAM/kaolin, silk fibroin, PVA/PAAM, and CNT/PVA/glycerol. Moreover, TA exhibits biocompatibility and antibacterial, antioxidative, and anti-inflammatory properties, which can be exploited for medical applications, such as wound healing and infection treatments. Polyvinyl alcohol (PVA)-borax hydrogels are widely studied for biomedical applications due to their biocompatibility, biodegradability, water solubility, easy processing and self-healing properties.

Herein, we report conductive organohydrogels obtained from aqueous mixtures of PEDOT:PSS, EG, and TA and PVA, which showed a low compressive Young's modulus of ~20 kPa, high electrical conductivity as well as anti-freezing and water retention properties. Our gels were showed self-healing ability and were used to prepare epidermal electrodes for ECG and EMG recordings, which showed similar performance to that of commercial Ag/AgCl gel electrodes, even after storage in ambient air for 1 week. We also demonstrated the use of gel electrodes as human–machine interfaces to control the opening and closing of a robotic hand in real time. The simple fabrication, high conductivity, and mechanical properties make our gels highly promising for applications in bioelectronics.

***In-Vivo* Polymerization of Conjugated Polyelectrolytes in Plants and Animals**EleniStavrinidou; Linkoping University, Sweden

Leveraging the biocatalytic machinery of living organisms for in-vivo fabrication of functional bioelectronic interfaces enables seamless integration of devices in tissue and formation of biohybrid systems. Previously we have demonstrated that plants can polymerize conjugated oligomers in-vivo forming conductors within their structure. We showed that the polymerization is enzymatically catalyzed by endogenous peroxidases, and we developed a series of conjugated oligomers that can be enzymatically polymerized in physiological conditions. The conjugated polyelectrolytes integrate within the plant cell wall structure adding electronic functionality into the plant that is then explored for energy storage. Recently we demonstrated intact plants with

electronic roots that continue to grow enabling plant-biohybrid systems that maintain fully their biological processes. The electronic roots are used to build supercapacitors and biohybrid circuits to power low power electrochemical devices. Furthermore, we have extended this concept into an animal model system. We demonstrated that Hydra, an invertebrate animal, can polymerize intracellularly conjugated oligomers in cells that expresses peroxidase activity. The conjugated polymer forms electronically conducting and electrochemically active domains in the µm range integrated within the hydra tissue. Our work paves the way for self-organized electronics in plant and animal tissue for modulating biological functions and in-vivo bio-fabrication of hybrid functional materials and devices.

11:00 AM SB04.11.05
Hydrogel for Multiplexed Multiscale Imaging and Phenotyping of the Human-Organ-Scale Biological Tissues JuhyukPark[1], JiWang[1], WebsterGuan[1], LeeKamentsky[1], NicholasEvans[1], JeffreyStirman[2], XinyiGu[1], ChuanxiZhao[1], MinyoungKim[1], Seo WooChoi[1], CloverSu-Arcaro[1], YuxuanTian[1], Dae HeeYun[1], C. DirkKeene[3], PatrickHof[4], MatthewFrosch[5] and KwanghunChung[1]; [1]Massachusetts Institute of Technology, United States; [2]LifeCanvas Technologies, United States; [3]University of Washington, United States; [4]Icahn School of Medicine at Mount Sinai, United States; [5]Harvard Medical School, United States

Understanding the intricate chemoarchitectural details and regional-specific functions and dysfunctions of the human brain poses a formidable challenge in holistic brain imaging and phenotyping. While recent advancements in tissue clearing and labeling techniques have made significant strides, the lack of scalability, thermos-mechanical robustness of tissues, imaging resolution, and cost-effective immunolabeling protocols limit their applicability in multiplexed human brain mapping at various scales. In this study, we present a pioneering hydrogel-based tissue processing technology called mELAST, which transforms biological tissues into soft, tough-elastic, reversibly expandable tissue-hydrogel hybrids, in tandem with mechanical devices and chemicals. Leveraging mELAST, we achieved multi-round immunolabeling and multiscale expansion imaging of volumetric human brain tissues, enabling the comprehensive capture of cytoarchitecture, microenvironment, and synapses within the human brain. We applied the mELAST pipeline to conduct a comparative study of Alzheimer's disease in the human brain, further unraveling neuroscientific enigmas. With mELAST, we anticipate a significant advancement in our ability to navigate deep within the human brain afflicted by pathologies, shedding light on crucial neuroscientific challenges.

11:15 AM SB04.11.06
A Stretchable and Mechanically Stable Bio-Inspired Nanofiber-Reinforced Microfiber for Wearable Electronics AdeelaHanif, JunhoPark, DohuiKim, JaeseungYoon, UnyongJeong and Dong SungKim; Pohang University of Science and Technology, Korea (the Republic of)

Since fiber-based approaches have high stretchability, the devices fabricated on them with limited stretchability cannot fully withstand large stretching, particularly when the wearer participates in vigorous activity. Stretchable systems can replicate the “J-shaped stress-strain or strain-limiting” mechanical behavior of biological tissues under deformations and provide mechanical compliance and comfort to wearers. A network of soft elastin fibers and stiff collagen fibers causes the biological tissues to be stretchable at low strains, and exhibit strain-limiting behavior when deformed at large strains. We developed a combined microfiber and nanofiber (NFs)-based approach to mimic this mechanical behavior of biological tissues, which involved wrapping soft polyurethane (PU) microfiber with stiff and inflexible poly(vinyldenefluoride) (PVDF) NFs and coating them in polydimethylsiloxane (PDMS). By tailoring the loading ratios of the PVDF NFs it is possible to tame the elastic moduli of the bio-inspired microfibers to match well with those of biological tissues. As shown by confocal imaging during stretching, PU microfibers maintain stretchability and stiff PVDF NFs play a role in strain-limiting characteristics. The stretchable poly(3,4-ethylenedioxythiophene) polystyrene sulfonate/ Polyurethane dispersion (PEDOT: PSS/PUD) coating on the bio-inspired microfiber showed a negligible difference in current-time (I-T) response after static stretching (~ up to 30%- human skin stretchability range) which indicated the efficient absorption of stress by the bio-inspired microfiber. An electrical response of a stretchable temperature sensor was measured by directly attaching it to the fist and stitching it into the bandage to demonstrate bio-inspired microfiber's ability to measure skin temperature and accommodate body movements. A light-emitting diode (LED) ON/OFF test was performed to demonstrate that the bio-inspired microfibers could be used as electrodes in the future.Therefore, bio-inspired microfibers could become the frontier of wearable electronics due to their high mechanical and electrical stability, adaptability to non-planar bodies, and ease of sewing.

11:30 AM SB04.11.07
Intraoral Hydrogel-Graphene Biosensors for *In-Situ* Detection of TNF-α in Human SalivaShaotingLin; Michigan State University, United States

Technologies that enable in-situ monitoring of biomarkers in human saliva in oral cavities are highly desirable for timely diagnosis, early intervention, and personized treatment of oral diseases. Existing efforts have been mostly focused on flexible electronics made of rigid materials, which inevitably suffer significant challenges in interfacing soft tissues due to their contradictory properties. Hydrogels, polymer networks infiltrated with water, share similar mechanical and physiological properties as biological tissues, regarded as an ideal material candidate to form long-term, high-efficacy, multi-modal interfaces between electronic components and biological systems. In particular, the recent developments of tissue-adhesive hydrogel patches have shown great success in forming rapid and tough adhesion between wet tissues and electronic devices in various organs, but these efforts have not been implemented in oral cavities. In this work, we focus on developing an intraoral hydrogel-graphene biosensor that can achieve highly sensitive, specific, and durable detection of human tumor necrosis factor-α (TNF-α) in human saliva. The design of hydrogel-graphene biosensor is based on an integration of selective-permeable hydrogel and graphene-based sensing probe, which enables sensitive and specific detection of low-concentration TNF-α in human saliva. This work will not only hold the promise of enabling rapid diagnosis of conditions such as recurrent aphthous stomatitis (RAS), periodontal disease, and oral cancer, but also facilitate the planning of medical treatment policies and evaluation of treatment efficacy.

11:45 AM SB04.11.08
A Damage-Mapping, Self-Healing Electronic Skin for Surgical Simulation Training SamuelE. Root and ZhenanBao; Stanford University, United States

Modern facilities for surgical education make use of inanimate models to simulate surgical tasks. Such models provide trainees with the opportunity to practice and receive feedback on the procedural and motor skills required to perform complex surgeries with expert-level competency. Existing models for surgical simulation rely heavily upon thermoset polymers such as silicones or hydrogels, which deteriorate after single or repeated use. Such disposable models are expensive—especially those with physically realistic properties—and incur a prohibitive cost for training programs, limiting opportunities for students to practice with high fidelity models. Moreover, evaluating the performance of trainees on surgical tasks is difficult and requires direct observation by an expert or the use of motion tracking software. There is a need to develop surgical simulation models with realistic physical properties and functional capabilities mimicking that of living tissue including, i) the ability to heal from damage, and ii) the ability to sense and transduce mechanical stimuli including forces, pressures, rates and depths of incisions and punctures. Over the past decade, advances in the science of dynamic polymeric materials (*i.e.*, polymers that are cross-linked with reversible bonds, such as hydrogen bonds) have enabled the molecular design and device integration of stretchable, conductive, self-healing composites. We have recently reported a strategy for improving the functional self-healing efficacy of multi-layer laminate composites through the molecular design of a pair of dynamic polymers with immiscible polymer backbones (poly(dimethylsiloxane) and poly(propyleneglycol)) but identical dynamic bonding units (a mixture of bisurea-based hydrogen bonding units). These polymers have a strong, adhesive but thermodynamically restricted interface, which results in an autonomous alignment and healing phenomenon, whereby polymer chains directionally diffuse to minimize the interfacial free energy when multi-layered stacks are damaged and misaligned. In this presentation, I will discuss our current efforts building upon this work towards the design of a damage-mapping electronic skin capable of sensing processes such as punctures with needles, scalpels, or sutures--and self-healing to undergo many operational cycles. We have developed a scalable compositing, compression-molding, and layer-based assembly process for fabricating multi-layer soft electronic films. We have implemented a voltage-based sensing mechanism for mapping the location and depth of needle punctures and surgical incisions. Finally, we demonstrate how these electronic skins can be integrated with surgical simulation technology, including rolling the films into vein-like tubes capable of sensing needle punctures for intravenous access training. Overall, we propose that there are many opportunities for bio-mimetic functional materials and device design within surgical simulation technology, including hybrid self-healing hydrogel-elastomer devices.

SESSION SB04.12: Chemistry-Focus of Hydrogels

Protein-Based Ionic Materials NadavAmdursky; Technion--Israel Institute of Technology, Israel

Nature is relying on the capability of proteins to mediate ions in preferred directions, such as the ionic transport across the two sides of a membrane through a protein. Inspired by this natural capability of proteins to mediate ions, we design several protein-based free-standing materials that are capable of mediating ions, specifically protons. By various physical and chemical pre- or post-polymerization modifications, we explore the ionic transport mechanism across the protein-based material, highlighting the important factors associated with its transport efficiency. Post-

polymerization modifications also allow us to chemically graft into the protein-based biopolymer light-sensitive molecule capable of generating opto-ionic materials. We also show the capability to introduce electronic conduction into the protein-based material either by blending or by chemical modifications, thus creating a mixed ionic-electronic conductor. From an application point of view, and due to our choice of using a sustainable source of proteins from waste sources, our protein-based ionic materials can be highly scalable at low cost. Our main application direction for our protein-based conductive biomaterials is for biological interfaces in the field of biosensing. Here, we can either utilize the ionic transport for making sensors for electrophysiological sensing or use the mixed conduction of the functionalized biopolymer for transistor-based sensing.

1:45 PM *SB04.12.02
Conductive or Injectable Hydrogels for Conformal Tissue-Device Interfacing Dae-HyeongKim[1,2]; [1]Institute for Basic Science, Korea (the Republic of); [2]Seoul National University, Korea (the Republic of)

Recent advances in soft electronics have attracted great attention due to its potential applications to personalized health-monitoring and point-of-care devices. The mechanical mismatch between conventional rigid electronic devices and soft human tissues oftentimes causes various issues, such as a low signal-to-noise ratio of biosensors, inflammations on the tissue interfacing with the bioelectronics, skin irritations in the case of long-term wearing of the device, and ineffective electrical stimulations and drug delivery in feedback therapies. Ultra-flexible and stretchable bioelectronic devices have a low system modulus and intrinsic softness, and have a potential to solve these issues. However, locally incomplete contacts are still found in skin-device interfacing and they reduce the sensing efficiency and therapeutic efficacy of the soft bioelectronics. Composites of polymers, nanomaterials, and hydrogels are particularly promising material candidates for solving such issues and achieving ideal biotic-abiotic interface. In this talk, the unique strategies in the synthesis of conductive or injectable hydrogels, their seamless integration with soft bioelectronics, and wearable and/or implantable device applications are presented. These efforts are expected to address unmet clinical challenges.

2:15 PM SB04.12.03
Tuning the Surface Chemistry of 3D Graphene Hydrogels by Covalent Functionalization: A Flow Chemistry Approach Antonino BiagioCarbonaro[1], DanieleFumagalli[2], ValentinaGreco[1], AntoninoGulino[1], ValentinaPifferi[2], LuigiFalciola[2] and AlessandroGiuffrida[1]; [1]University of Catania, Department of Chemical Sciences, Italy; [2]University of Milan-La Statale, Italy

Recently, three-dimensional porous graphene architectures, such as hydrogels and aerogels, have received increasing attention in the scientific literature due to their unique structural, chemical and physical properties. Combined with the well-studied brilliant properties of graphene-based materials, 3D graphene structures find applications in bioelectronics, sensing and energy storage. The meso- and macroporous structure of hydrogels and aerogels allows to overcome some limitations of 2D graphene materials, such as the re-stacking of monolayers, which confers unique properties due to the high active surface area of well-defined 3D graphene architectures. Most applications of graphene hydrogels and aerogels are based on the interaction between the porous carbon structure with molecular species, in the gas or liquid phase. In this context, functionalization strategies that allow the control of surface speciation would be highly welcomed. Functionalization methods for graphene hydrogels include non-covalent approaches where the guest species are physisorbed onto the porous structure during the gelation process. However, this approach can have many disadvantages, such as molecule slippage, and they are difficult to control compared to a covalent functionalization strategy. Keep this in mind, in this work we would like to shed light on the chemical behaviour of graphene hydrogels; in particular, according to the flow chemistry concepts, we propose a facile covalent functionalization strategy through Diazonium Salts Chemistry. The samples were extensively characterized by micro-Raman and ATR-FTIR spectroscopy, X-ray Photoelectron Spectroscopy (XPS), Scanning Electron Microscopy (SEM) and BET. In addition, the electrochemical performances of the 3D porous graphene hydrogel and aerogel structures were investigated by Cyclic Voltammetry (CV), Differential Pulse Voltammetry (DPV) and Electrochemical Impedance Spectroscopy (EIS), focusing on the electrochemical sensing properties of the 3D self-standing structures.

2:30 PM SB04.12.04
PHost–Guest Chemistry for The Design of Functional Polymer–Nanoparticle Hydrogels StephaneBernhard, LauritzRitter, MarcoMüller, GiovanniBovone, EliaGuzzi, WenqingGuo and MarkW. Tibbitt; ETH Zurich, Switzerland

Polymer–nanoparticle (PNP) hydrogels are a class of injectable nanocomposites based on physical interactions between polymers and nanoparticles (NPs). (1) Due to the shear-thinning and self-healing behaviour provided by the reversibility of the polymer–nanoparticle interactions, they have been used in the biomedical field as injectable biomaterials or inks for additive manufacturing. (2-3) Current PNP hydrogels however cover a narrow range of functionality and can be built from a restricted pool of available building blocks due to the constraint presented by the limited versatility of the cross-linking interactions. Here, we present the use of a supramolecular motif based on host–guest interactions for the design of versatile and functional PNP hydrogels.

In this work, two approaches based on cyclodextrin (CD) host–guest interactions were used for the design of PNP hydrogels. In a first approach, alpha-cyclodextrin (αCD) was added to a cellulose- and PEGylated-NP-based hydrogel, to decouple mechanical properties from building blocks via polypseudorotaxane formation. The addition of αCD enabled the exchange of the polymer and nanoparticle for varied biopolymer with secondary cross-links or inorganic nanoparticles with conductive or magnetic characteristics. In a second approach, beta-cyclodextrin (βCD) was used in combination with azobenzene, a photo-responsive guest for the design of light sensitive hydrogels. For this purpose, a host-functionalized polymer (β-CD hyaluronic acid) and guest harboring block copolymer (PEG-*b*-PLA) NPs were synthesized.(5) The presence of the photoresponsive host–guest complex resulted in reversible gelation of the hydrogel via illumination at various wavelengths of light. This work demonstrates how supramolecular interactions can be used to engineer versatile and functional polymer nanocomposite biomaterials and substantially increase the utility of this class of materials.

SESSION SB05.01: Bioelectronic Interfaces I
Session Chairs: Guglielmo Lanzani and Flavia Vitale
Monday Morning, November27, 2023
Hynes, Level 1, Room 102

10:30 AM *SB05.01.01
Modulation of Cell Signaling with Magnetic Nanomaterials PolinaAnikeeva; Massachusetts Institute of Technology, United States

Magnetic fields offer unprecedented access to signaling processes deep within the body due to the low conductivity and negligible magnetic permeability of biological matter. Magnetic fields with a diversity of spatio-temporal characteristics can be transduced into stimuli perceived by biological receptors via tailored magnetic nanomaterials enabling remote modulation of cell function. In this talk, I will highlight physical principles guiding magnetic nanomaterials design with the goal of transducing magnetic fields into mechanical, thermal, chemical, and electric stimuli. I will further describe how these magnetic nanomaterials, coupled with biological mediators, can enable wireless modulation of cell signaling, organ physiology, and animal behavior. Finally, I will discuss strategies to deliver magnetic nanomaterials to specific cells and organs in the body laying a foundation for minimally invasive implant-free and surgery-free bioelectronic interfaces.

11:00 AM SB05.01.02
Directed Assembly Behavior of Optoelectronic Peptide Biomaterials for Excitable Systems Ze-FanYao, YuyaoKuang, EmilLundqvist and Herdeline AnnArdoña; University of California, Irvine, United States

Organic conjugated materials are known to have molecular design-tunable optoelectronic properties while exhibiting intrinsic flexibility and the ability to form soft networks, which are suitable for biological interfacing. To better utilize these properties towards interfacing with living systems, more efforts are required to render biocompatibility and other physiologically relevant characteristics to these materials. Here, we design, synthesize, and characterize π-conjugated peptides with controllable assembly-disassembly behavior in aqueous solutions and directed anisotropic assembly on surfaces for biointerfacing. The peptidic segments serve as a biomimetic template for the stimuli-driven self-assembly process of π-conjugated monomers in aqueous solutions and on nanostructured polymeric surfaces. In solution, the supramolecular assembly and disassembly processes of the designed peptides can be accessed through a carbodiimide-fueled approach that instructs their self-assembly and hydrolysis-induced disassembly. On polymeric surfaces that have anisotropic topography and have chemically analogous π-conjugated chains as the central core of our peptide monomers, the resulting self-assembled optoelectronic peptides can be directed to form 1-D nanostructures on the surface nanofeatures. These peptide-modified surfaces present bioadhesive cues towards achieving cellular anisotropy, therefore providing a potential opportunity for directional stimulation of excitable cells. By having the capability to generate photoinduced currents, substrates bearing these assembled optoelectronic π-conjugated units offer the possibility of light-controlled behavior of excitable cells. In summary, this presentation will discuss the engineering of optoelectronic peptides that form controllable supramolecular structures capable of modulating the behavior of excitable cells and tissues via light.

11:15 AM SB05.01.03
Bioadhesive Polymer Semiconductors and Transistors for Intimate Biointerfaces NanLi and SihongWang; University of Chicago, United States

Integrating biocompatible electronic devices with living biological tissues is emerging as a highly promising avenue for achieving the real-time measurement of biological signals with high spatiotemporal resolutions for biological studies and health monitoring. Polymer semiconductors-based transistors (e.g., organic electrochemical transistors (OECTs)) as an advanced sensing device, are highly desired for direct electrical biointerfacing due to their low operation voltage, mixed electron-ion conduction, and high sensitivity. To interface with wet and dynamically moving tissues, developing intrinsically bioadhesive polymer semiconductors can significantly improve the devices' conformability on tissue surfaces and signal acquisition sensitivity.

In this talk, I will present the design of a BioAdhesive polymer SemiConductor (BASC) film by creating a rationally designed polymer network with interpenetrating semiconducting polymers and adhesive brush polymers. The BASC films can form robust and rapid adhesion with bio-tissues (e.g., heart, lung, spleen) under gentle pressure, while providing high charge-carrier mobility. We further fabricate a bioadhesive OECT with the BASC as the active channel and demonstrate its use for reliably monitoring electrophysiological signals on an isolated rat heart and in vivo muscles.

11:30 AM SB05.01.04
MXene Hydrogels as Soft Bioelectronic Interfaces RaghavGarg[1], StefanoIppolito[2], SpencerR. Averbeck[1], YuryGogotsi[2] and FlaviaVitale[1]; [1]University of Pennsylvania, United States; [2]Drexel University, United States

Biological tissues and organs, such as the cardiac tissue and the brain, are mechanically soft and exhibit viscoelastic behavior. Real-time diagnosis and treatment of diseases of such electrically active tissues requires continuous electrophysiological monitoring stimulation. This has been achieved through implantable bioelectronic platforms. However, current implantable bioelectronics are composed of mechanically rigid materials such as metals (Au, Pt), metal oxides (IrOx), and semiconductors (Si). The large mechanical mismatch between the target tissues and the bioelectronics interfaces has been a bottleneck for chronic clinical applications. Although metal nanoparticles and carbon nanomaterials have been leveraged to fabricate electrically conductive hydrogel bioelectronics, they are limited by their electrochemical functionality, biocompatibility, and processability.
Here we leverage safe liquid-phase processing of two-dimensional $Ti_3C_2T_x$ MXene to fabricate MXene-based hydrogels for implantable bioelectronic interfaces. We achieve a high-density network of MXene flakes by directly crosslinking individual MXene flakes using transition metal ions. The matrix-free structure of the MXene hydrogels endows them with high electrical conductivity and low electrochemical impedances, thus facilitating their integration into soft bioelectronics for electrophysiological recordings with high signal-to-noise ratio. The capacitive nature of $Ti_3C_2T_x$ further allows the hydrogels to exhibit high charge injection capacities for safe delivery of electrical stimulation to target tissues. Finally, we demonstrate modulation of the mechanical properties of the packaged hydrogels by altering the composition and degree of cross-linking of the alginate-based insulation. Our results underscore the application of MXene-based soft bioelectronics in studying neural function and disease pathologies, as well as developing neuromodulation paradigms.

11:45 AM SB05.01.05
Optimizing the Pore Structure of 3D Conducting Polymer Scaffolds for Bioelectronic Devices RachanaAcharya, Douglasvan Niekerk, AimeeWithers and RoisinOwens; University of Cambridge, United Kingdom

The integration of 3D tissue-engineered microporous scaffolds based on conductive polymers (CPs) into bioelectronic devices have led to the possibility of dynamic monitoring of biological phenomena through electrical measurements. The 3D structure and morphology of the porous scaffolds mimics the topographical features of human physiology, while the electrically conductive nature of the polymers allows for electrical measurements for label-free monitoring and live-sensing of cells. 3D scaffolds based on the polymer poly(3,4-ethylenedioxythiophene):poly(styrenesulfonate) (PEDOT:PSS) prepared by the freeze drying process have been the focus of many studies and well integrated into bioelectronic devices such as electrodes[1] and organic electrochemical transistors[2].
The freeze-drying process involves freezing the aqueous dispersion of the conducting polymer, followed by the sublimation of the ice crystals by lowering the pressure in the system, leaving behind a porous network of the conducting polymer. This porous network is representative of the physiological tissue structure, making the ice nucleation and crystallization a crucial component of the scaffold fabrication process. A deeper understanding of the freeze drying process and a higher degree of control on the freezing parameters will help establish the correlation between the material properties of the scaffolds and the biomimetic tissue engineering requirements for optimum cell culture platforms.
Three different freeze drying protocols were employed, with a pre-cooling treatment used before the freeze-drying process. Two different pre-cooling rates, 0.5 °C/min and 1 °C/min along with a control protocol with no treatment were designed to prepare different scaffold types. Within each protocol, the freezing rate was varied between 0.2 °C/min and 1 °C/min and the thermal profile of the aqueous dispersion was recorded during the entire fabrication process.
The influence of the different protocols and freezing rates on the pore size and structure was examined by scanning electron microscopy and micro-computed tomography. Pores of circular and elongated ellipses were observed by SEM and a pore size distribution (the longest dimension of the ellipsoid) between 80 µm and 220 µm was measured. It was observed that a higher cooling rate generated larger pores with more elongated pore morphology as well as a wider pore size distribution. The pre-cooling treatment with 0.5°C/min cooling rate was most useful in generating scaffolds with a more homogenous pore structure and a pore size of approximately 100 µm.
The different scaffolds were incorporated into electronic devices such as transmembrane electrodes to characterize the electrical properties and evaluate the reproducibility of the scaffolds

prior to cell culture. No significant change in the electrochemical impedance spectra was observed despite the large difference in porosity of the different scaffolds. In addition, the different scaffolds were used to host and monitor biological cells like fibroblasts and endothelial cells. Cell growth and proliferation in the different scaffolds was also monitored by immunofluorescence microscopy. It was observed that a pre-cooling protocol and a freezing rate of 0.5°C/min helps to fabricate scaffolds with an optimized, uniform and homogenous pore morphology. This design protocol is highly beneficial in reducing the random artifacts of the nucleation process and generating scaffolds highly conducive to cell growth and survival and to create a versatile bioelectronic platform for studying in-vitro cell models.

Monday Afternoon, November27, 2023
Hynes, Level 1, Room 102

1:30 PM *SB05.02.01
3D Bioelectronic Models of Gut, Brain and Lung RoisinOwens; University of Cambridge, United Kingdom

Physiologically relevant in vitro human models are urgently required to bridge the gap between over-simplified 2D in vitro models and ill-suited animal models, for drug discovery and disease modelling. Bringing together principles of materials science, tissue engineering, 3D cell biology and bioelectronics, we are building advanced models of the gut, brain (neurovascular unit) and the lung. In the case of the gut and NVU, our aim is to elucidate the role of microbiota in the gut-brain axis communication, a particularly challenging system to model with lab animals. In the case of the lung, our interest is in modelling the air-liquid interface to more accurately study lung disease.
Our models are based on the use of electroactive scaffolds which can host tissues, but also monitor their formation, and later their status when challenged with a pathogen or target molecule. Our strategy is to build a stromal layer with the scaffold and layer epithelial or endothelial models on top, preserving tissue stratification. Our most recent work has adapted these scaffolds to the well-known Transwell format, to allowed continued access to both apical and basal aspects.[1] As well as traditional readouts such as immunofluorescence, or biochemical analyses of media, our continuous electrical monitoring readouts from our electroactive scaffolds gives us real-time data on the tissue health.

2:00 PM SB05.02.02
Harnessing Protein Engineering and Bioelectronics for Sensory Perception on a Chip EleanorBest, ZhongmouChao, PoompolBuathong, PeterFrazier and SusanDaniel; Cornell University, United States

As humans, our perception of the world relies on the function of our powerful sensory organs. Olfaction in particular is well-documented as a biosensing modality across species, as dogs and insects have been shown to detect the early onset of disease or even harmful substances as part of airport security protocols. As specific ligands bind to their corresponding sensory receptors, they trigger a unique combination of activated neurons that are interpreted downstream. By merging interspecies sensory systems with bioelectronics, we can create a novel biosensor and simulate sensory perception on a chip. Whilst previous platforms have leveraged gas sensors for compound detection, our system instead employs carefully selected mammalian and insect proteins to replicate and enhance sensory perception. By using innovative protein engineering techniques and deliberately designed electronic devices, we have created a fully customizable approach to sensory perception in a way that carefully combines nature’s original biosensors with synthetic biology. This unique platform provides a novel approach to the conventional biosensor with immense potential for security and medical applications.

2:15 PM *SB05.02.03
Engineering Personalized Tissue Implants: From 3D Printing to Bionic Organs TalDvir; Tel Aviv University, Israel

In this talk, I will describe cutting-edge bio and nanotechnologies for engineering functional tissues and organs, focusing on the design of new biomaterials mimicking the natural microenvironment or releasing biofactors to promote stem cell recruitment and tissue protection. In addition, I will discuss the development of patient-specific materials and 3D printing of personalized vascularized tissues and organs. Finally, I will show a new direction in tissue engineering, where micro and nanoelectronics are integrated within engineered tissues to form cyborg tissues and bionic organs.

2:45 PMBREAK

3:15 PM *SB05.02.04
Deformable Composites: From Photostimulation to Living Bioelectronics BozhiTian; University of Chicago, United States

The field of electronic and photonic biointerfaces continues to evolve, with flexible and living composites playing a key role in advancing the development of multifunctional devices such as sensors and modulators. Our research focuses on creating non-genetic approaches for biological modulation and sensing across different length scales. This presentation will provide insights into some of our recent projects. This includes our work related to photostimulation within clinical environments. We have made new progress in the development of a nanoporous/non-porous heterojunction, exemplifying the level of precision and control achievable in bioelectronic therapies. We have also developed a granular system aimed at focal adhesion in bioelectronics and other interfaces for regenerative medicine. Additionally, we have begun exploring the integration of living cells with wearable bioelectronic devices, a new direction within the sphere of living bioelectronics. Our primary goal is to transition these basic studies of modulation tools into applicable clinical practices, with the potential to influence therapeutic strategies and improve patient outcomes. As I conclude the presentation, I will highlight our future research directions. These are designed to further contribute to the extensive field of biological modulation and sensing, with a specific focus on applications that could have a significant impact in the clinical setting.

3:45 PM SB05.02.05
Tissue-Embedded 3D Stretchable Nanoelectronics for Multimodal Charting of the Human Stem Cell-Derived Organoids RenLiu, QiangLi, ZuwanLin, XinTang and JiaLiu; Harvard University, United States

The development of human induced pluripotent stem cells (hiPSCs) technology has revolutionized the field of disease modeling and holds immense potential for personalized regenerative cell therapies. A comprehensive understanding of stem cell-derived tissues and organoids requires advanced multimodal techniques capable of capturing cell functions with high spatiotemporal resolution in three-dimensional (3D) tissues, profiling numerous genes in recorded cells, and performing multimodal computational analysis. However, none of the existing technologies fullfill these requirements.
In this presentation, I will begin by introducing the development of soft, stretchable mesh nanoelectronics that mimic the physical and mechanical properties of biological tissues. We can distribute these stretchable tissue-like bioelectronics throughout the entire 3D organoids by their organogenetic processes. By establishing seamless and noninvasive connections between electrodes and cells, we can achieve long-term stable electrical contacts with progenitor or stem cells, capturing the emergence of single-cell action potentials. This facilitates continuous, long-term recording from various types of 3D organoids during their development.
Next, I will demonstrate how this technique enables the long-term stable mapping of human 3D cardiac microtissues for the characterization of their functional maturation. Specifically, I will discuss an example in which stretchable mesh electronics were embedded with hiPSC-derived cardiomyocytes (hiPSC-CMs) and hiPSC-derived endothelial cells (hiPSC-ECs). By developing machine learning-based pseudotime trajectory inference of the long-term cardiomyocyte electrical signals from multiple samples, we can quantify the electrical phenotypic transition path during development. Our results showed that hiPSC-ECs drive remarkable hiPSC-CM electrical maturation via multiple intercellular pathways.
Finally, I will discuss our efforts to combine in situ single-cell RNA sequencing with flexible bioelectronics, a methodology we term "in situ electro-seq". This technique allows us to link cell molecular gene expression with electrical activities. Specifically, I will discuss how in situ electro-seq enables systematic and simultaneous investigation of single-cell electrophysiology and gene expression across hiPSC-CMs during their development. Additionally, I will discuss the potential of using in situ electro-seq to create spatiotemporal multimodal maps in electrogenic

tissues, thereby potentiating the discovery of cell types and gene programs responsible for electrophysiological function and dysfunction.

4:00 PM SB05.02.06
Bioelectronic *In Vitro* Cell Membrane Models for Investigating Intestinal Host-Pathogen InteractionsReeceMcCoy[1], JeremyTreiber[2], AlbertoSalleo[2], GeorgeG. Malliaras[1] and RoisinOwens[1]; [1]University of Cambridge, United Kingdom; [2]Stanford University, United States

The early stage of pathogen-related diseases often depend on the initial interaction between the pathogen, or it's secretions, and the host cell membrane. Interfacing cells with electronics allows for quantitative real time monitoring of barrier integrity. Organic electronics coupled with electrochemical impedance spectroscopy (EIS) are used to probe host-pathogen interactions directly with enterocyte plasma membranes using native supported lipid bilayers which are representative of apical and basolateral surfaces of the intestinal epithelium.
PEDOT:PSS is used in both microfabricated planar electrode arrays which can support the formation of supported lipid bilayers. The Caco-2 adenocarcinoma cell line is used to develop a model that reflects in vivo conditions. Cells are differentiated and polarised for 21 days and chemical vesiculation induced to extracted small membrane vesicle biopsies of the apical and basolateral surfaces before being used to form supported lipid bilayers. Fluorescence microscopy is employed to confirm bilayer fluidity with fluorescence recovery after photobleaching (FRAP). EIS is used to determine the impedance of the bilayer across frequencies and models are fit to the data to extract resistance and capacitance values. The ADAM10-receptor mediated effects of *Staphylococcus aureus* alpha hemolysin toxin is demonstrated and found to be highly dependent on the epithelial membrane surface it encounters. The presence on the receptor in the apical bilayer potentiates the effect of alpha hemolysin leading to a pronounced decrease in membrane resistance compared to the basolateral bilayer.
Organic bioelectronics are used to monitor bilayer and barrier impairment caused by pathogens and their secretions. EIS coupled with conventional biological techniques can be used help elucidate pathogen invasion mechanisms and aid discovery of potential therapeutics.

4:15 PM SB05.02.07
Multiscale Material Engineering of a Conductive Polymer/Liquid Metal Platform for Stretchable and Biostable Human-Machine-Interface Bioelectronic Application HuananZhang; University of Utah, United States

Liquid-metal-based stretchable bioelectronics can conform to the dynamic movements of tissues and enable human-interactive biosensors to monitor various physiologic parameters. However, the fluidic nature, surface oxidation, and low biostability of the liquid metals have limited the long-term use of bioelectronics. Here we have developed a rationally designed material engineering approach to overcome these challenges in liquid metal bioelectronics. To our knowledge, this is the first demonstration of stretchable, leak-free, and highly conductive gallium-based bioelectronic devices with exceptional biostability and electrochemical properties. We first utilized unique gallium oxide properties to create 3D microscale wrinkled structures on the gallium surface. Then, gold nanoparticles and biostable poly(3,4-ethylenedioxythiophene) were successively deposited on the wrinkled liquid metal surface. We demonstrated this multilayer encapsulation material could conform to the stretching deformation and showed excellent environmental stabilities while maintaining high electrical properties. Electromyographic measurements were used to evaluate the bioelectrical performance of the stretchable electronics, and the results demonstrated the encapsulated liquid metal device could outperform bare liquid metal devices. Finally, a sensory feedback study demonstrated our liquid metal bioelectronic device could record precise physiologic signals to control robots for mimicking dexterous hand gestures. This study opens the possibility of chronic liquid-metal-based stretchable bioelectronics.

4:30 PM SB05.02.08
Conformable Multimodal Sensory Facemask for Decoding Biological and Environmental Signals Jin-HoonKim and CananDagdeviren; Massachusetts Institute of Technology, United States

Facemasks are considered to be a key instrument in reducing exposure to viruses and other environmental hazards such as air pollution. Current wearable electronics applicable to the facemask have been designed only to monitor biological information such as breathing patterns. However, it remains difficult for the public to assess the status of their facemasks with regard to wearing habits and fit quality. In this work, we developed a widely-deployable, conformable, miniaturized sensory interface, which seamlessly attaches onto the internal side of any user-supplied facemask without compromising fit and protection quality, along with a user-interface capable of interpreting a participant's mask-wearing behavior under various use-case scenarios. Multimodal signals from a variety of sensors were wirelessly transmitted to a server through a custom-made mobile app. Based on the collected data, it was shown that various biological signals related to the signature of infectious diseases could be monitored while determining the fit status of the facemask without using a conventional mask fit tester. A machine learning algorithm was further used to enable the reliable decoding of the facemask position. The novelty of this work lies not only in the system integration, but also in the development of devices which provides real-time mask fit and position analysis, which may benefit medical institutes, industries and the general public in selecting proper facemasks and maintaining a desired mask fit. Additionally, our work could be deployed to multidisciplinary studies such as human behavioral and social sciences to analyze the fit change in real world situations.

4:45 PM SB05.03.08
Paper-Based Wearable Patches for Real-Time, Quantitative Lactate and Temperature Monitoring ElisabettaRuggeri[1], GiusyMatzeu[1], GiuliaGuidetti[1], AndreaVergine[2], MarcoLo Presti[1], GiuseppeDe Nicolao[2] and FiorenzoOmenetto[1]; [1]Tufts University, United States; [2]Università degli Studi di Pavia, Italy

Wearable sensors are establishing themselves as options for real-time continuous health monitoring in health care and wellness. In particular, the use of flexible interfaces that conform to the skin have attracted considerable interest for the extraction of meaningful physiological and pathological information through continuous and painless sampling and analysis of biofluids. In contrast, conventional techniques for biomarkers analysis are difficult to adapt to real-time portable monitoring due to their invasive sampling protocols, biosample preparation and reagent stabilization. In this work, we present shelf-stable, non-invasive, paper-based colorimetric wearable lactate and temperature sensors. These sensors exploit the ability of silk to control the concentration, print, and functionally preserve labile transducing biomolecules in the format of a shelf-stable digital patch for optical readout. This novel approach overcomes major challenges associated with the commercialization of colorimetric wearable sensors (e.g., enzyme thermal instability, narrow sensing range, low sensitivity, and qualitative response) by showing a combination of unprecedented stability (i.e., up to 2 years in refrigerated conditions), wide sensing range, and high sensitivity. Additionally, real-time quantitative signal readouts are achieved using machine learning-driven image analysis enabling physiological status evaluation with a simple smartphone camera.

Large-Area Photo-Patterning of Initially Conductive EGaIn Particle-Assembled Film for Soft Electronics Gun-HeeLee; KAIST, Korea (the Republic of)

Eutectic-gallium-indium particle (EGaIn*) is considered one of the promising conducting materials for soft electronics due to its enhanced mechanical stability and stable conductance under strain compared to bulk EGaIn. However, its practical applicability has thus far been limited due to the challenges of achieving electrical conductivity and the incompatibility with well-developed fabrication strategies. Here, we report materials and manufacturing methods that allow large-area multi-layered patterning of 'polystyrene sulfonate (PSS)-attached EGaIn* (EGaIn*:PSS)' thin-film with the conventional cleanroom process. PSS enhances the stability of EGaIn*, which allow uniform thin-film coating and photographic lift-off at a wafer-scale down to 10 μm features of varying thicknesses. Using dimethyl sulfoxide as the solvent during lift-off induces cohesion between EGaIn*:PSS, resulting in initial electrical conductivity without an additional activation process. Demonstrations of stretchable display, wearable multilayer pressure sensing systems, and soft artificial finger validate the versatility and reliability of this manufacturing strategy for soft electronics.

8:00 PM SB05.03.02
Multifunctional Intelligent Wearable Devices using Logical Circuits of Monolithic Gold Nanowires SangHoonHong, TaeYeonKim and Sei KwangHahn; Pohang University of Science and Technology (POSTECH), Korea (the Republic of)

Although multifunctional wearable devices have been widely investigated for healthcare systems, augmented/virtual realities and telemedicines, there are few reports on multiple signal monitoring and logical signal processing by using one single nanomaterial without additional algorithms or rigid application-specific integrated circuit (ASIC) chips. Here, we develop multifunctional intelligent wearable devices using monolithically patterned gold nanowires for both signal monitoring and processing. Gold bulk and hollow nanowires show distinctive electrical properties with high chemical stability and high stretchability. In accordance, the monolithically patterned gold nanowires can be used to fabricate the robust interfaces,

programmable sensors, on-demand heating systems and strain-gated logical circuits. The stretchable sensors show high sensitivity for strain and temperature changes on the skin. Furthermore, the micro-wrinkle structures of gold nanowires exhibit the negative gauge factor, which can be used for strain-gated logical circuits. Taken together, this multifunctional intelligent wearable device would be harnessed as a promising platform for futuristic electronic and biomedical applications.

8:00 PM SB05.03.03
From Network to Channel—Crack-Based Strain Sensors with High Sensitivity, Stretchability and Linearity via Strain Engineering WanyiWang and YoufanHu; Peking University, China

High-performance stretchable strain sensors are indispensable for mechanical deformation detection in electronic skin applications such as health monitoring and human-robot interfaces. Thus far, achieving a stretchable strain sensor with a high sensitivity that works linearly over a wide working range is still a great challenge. Among various applicable working mechanisms of strain sensors, crack-based strain sensors have the advantages of flexible material selection, easy fabrication, and high sensitivity. Here, we propose a universal strain engineering strategy that introduces an inhomogeneous spatial distribution of stress, which results in a distinguished crack density distribution in space and a critical state of crack propagation behavior between network and channel morphologies. By controlling the occurrence of the critical state, strain sensors are capable to perform high sensitivity, stretchability, and linearity simultaneously. The strain sensors can be tuned to realize a gauge factor of 690.95 in a linear working range of 0-40% (R^2 = 0.993) or a gauge factor of 113.70 in a larger linear working range of 0-120% (R^2 = 0.999). Intraocular pressure monitoring has been demonstrated based on these sensors to show their great application potential.

Stimuli Recognition by Polydiacetylene using Hyperspectral Microscopy JialiChen and KaoriSugihara; The University of Tokyo, Japan

Introduction
Polydiacetylene (PDA)-based chem/bio sensors have garnered significant attention due to their exceptional biocompatibility and ability to respond to various signals, such as heat, pH, force, light, and biomolecules. They exhibit visual blue-to-red color changes and fluorescence emission. However, the poor reproducibility of PDA sensors has hindered their practical implementation. The varying structures of PDA, even under identical synthesis conditions, make it challenging to achieve consistent and highly sensitive responses during mass production. Hyperspectral microscopy, initially developed for geology exploration and earth morphology observation, provides precise spectral analysis at the pixel level with high spatial and spectral resolutions. Recent advancements in detector and computing technology have expanded its applications to fields like agriculture, food, and medicine. In this work, we employed hyperspectral microscopy to visualize the inconsistent distribution of PDA structural domains, which contributes to the poor reproducibility and variations in PDA responses. Additionally, these mixtures of PDA structures exhibit distinct blue-to-red transition pathways upon stimulation, indicating their potential for stimulus identification.[1]

Method
We utilized hyperspectral microscopy to capture detailed spectral information at the sub-crystal level of PDA, allowing differentiation among various PDA structures. Using spectral classification techniques, such as spectral angle mapper, we created distribution maps of PDA structural domains within bulk crystals. Moreover, we developed a pixel transition tracking method using MATLAB to quantitatively monitor the colorimetric response of these structural domains. Based on these technologies and discoveries, we observed that PDA exhibits different response patterns to various stimuli, such as heat and pH. Our aim was to comprehensively understand the dynamic transition pathways associated with PDA structural domains and their response patterns to stimuli.

Result and Discussion
We uncovered mixtures of PDA structural domains within blue and red bulk crystals, which explain the main source of poor reproducibility in traditional PDA sensors. It was the first time that hyperspectral microscopy was applied to examine the non-uniform property of PDA sensors, and we developed a new interpretation tool to track their transition pathways. Different structures of PDA displayed varying affinities to stimuli, leading to unique transition patterns specific to the type of stimulus applied. This indicates that the stimuli leave a potential fingerprint on PDA. The observed good reproducibility holds promise for PDA to serve as an identification array for molecules in the future.

8:00 PM SB05.03.05
Skin-Like Multimodal Sensors Based on Iontronics and Piezoelectricity LirenWang[1,2,3], PeterZalar[4], YuanyuanZhou[1,3,1] and NaojiMatsuhisa[1,3,2]; [1]The University of Tokyo, Japan; [2]Keio University, Japan; [3]Institute of Industrial Science, The University of Tokyo, Japan; [4]Holst Centre / TNO, Netherlands

The skin possesses softness, stretchability, and the ability to sense a variety of environmental signals, including temperature, slow deformation (static strain), and rapid vibration (dynamic strain). Previous attempts to mimic skin with multimodal sensors have been limited by their multimodal sensing capability [1] and interference between different types of signals [2]. In this work, we demonstrate a skin-like multimodal sensor capable of sensing three outputs - temperature, static strain, and dynamic strain - using a soft piezoelectric and ionic composite material. Our sensor is constructed by sandwiching the ionic and piezoelectric composite between a pair of silver-nanowire-based stretchable conductors. Electrochemical impedance provides readings of temperature and static strain, while piezoelectricity measures dynamic strain. We have systematically investigated the influence of ionic conductivity and elasticity of the composite on sensitivity and stretchability. The high conductivity of the silver-nanowire-based stretchable electrodes had a negligible effect on the signal readout. The sensor provided accurate strain-insensitive temperature signals (error ~0.28°C) under 50% strain, and a modest longitudinal piezoelectric coefficient (d_{33}) of ~10 pC/N. Our sensors display skin-like softness and multimodal sensing capability, features which are highly beneficial for human health monitoring and robotic skin applications.

Decoding Silent Speech Commands from Articulatory Movements Through Soft Magnetic Skin and Machine Learning PenghaoDong and ShanshanYao; Stony Brook University, The State University of New York, United States

Silent speech recognition is a promising technique to restore spoken communication for individuals with voice disorders and to facilitate intuitive communications when the acoustic signal is unreliable, inappropriate, or undesired. However, the current methodology for silent speech faces several challenges, including bulkiness, obtrusiveness, limited portability, and susceptibility to interferences. In this work, we present a wireless, unobtrusive, and robust silent speech interface for capturing and decoding speech-relevant movements of the temporomandibular joint. Our solution employs a single ultrasoft magnetic skin placed behind the ear for wireless and more socially acceptable silent speech recognition, greatly alleviate concerns associate with existing interfaces based on face-worn sensors, including large number of sensors, highly visible interfaces on the face, and obtrusive interconnections between sensors and testing unit. Through optimizations in material composition, sensor structure, and sensing location, we present a lightweight wireless sensor that can conform to the skin surface to capture subtle movements induced by speech. With machine learning-based signal processing techniques, good speech recognition accuracy is achieved (92.7% accuracy for phonemes, 85.6% for word pairs from the same viseme group, and 96.7% for sentences/phrases). Moreover, the reported silent speech interface demonstrates robustness against noises from both ambient environment and user's daily motions. Finally, we illustrate the great potential in assistive technology and human-machine interactions through two proof-of-concept demonstrations –silent speech enabled smartphone assistant and drone control.

Wearable Pad for Continuous Monitoring of the Pressure at the Lower-Limb Socket Interface RuiPereira and VitorSencadas; University of Aveiro, Portugal

The data acquired from the biomechanics mapping at the socket-stump interface is referred to as a direct indicator of a comfortable socket fit, and multiple types of sensing approaches have been used to quantify the internal pressure distribution on a prosthetic socket. In this work, an elastomeric capacitive sensor pad device able to be inserted at the distal area of a prosthetic socket was produced by blending polydimethylsiloxane (PDMS) with Ecoflex. By adjusting the PDMS:Ecoflex ratios in the mixture, the mechanical properties of the pad could be tuned to promote comfort to the user. The wearable sensor pad electromechanical characterization revealed an electrical response that follows the applied mechanical inputs, with a Gauge Factor between 0.6 ± 0.04 and 1.3 ± 0.03 and a sensitivity ranging from $4.6x10^{-4} \pm 0.14x10^{-4}$ kPa^{-1} to $7.25x10^{-4} \pm 1.2x10^{-4}$ kPa^{-1}. The device presented high durability (1,000 cycles), linearity, repeatability and stability in a pressure range from 0 to at least 700 kPa. Further, the developed wearable device performance was validated during in-vitro simulations using a real prosthetic socket and a biofidelic residual limb, and the results gathered show similar electromechanical performance. Finally, the wearable sensor was placed in a liner inside the prosthesis and fitted to

a user to monitor the pressure distribution that occurs between the residual limb and the socket during the walking. The results demonstrated the feasibility of employing the developed device within the socket prosthesis and to gather important quantitative data to provide enhanced socket design and comfort.

8:00 PM SB05.03.09
An Advanced Dermal Tissue-Embedding Mesh Sensor for High-Resoluion IL-6 Detection JohnT. Williams[1], HanieYousefi[1], XudongJi[1], HopeBurks[2], JonathanRivnay[1] and ShanaKelley[1,2]; [1]Northwestern University, United States; [2]Chan Zuckerberg Biohub Chicago, United States

In this study, we explore the development and application of a highly sensitive, high temporal-resolution dermal tissue-embedding mesh sensor. We functionalize this sensor using molecular pendulums developed by J. Das *et al.* to measure the concentration of Interleukin-6 (IL-6), a key biomarker in skin inflammation. Miniaturized organ models, including organoids and spheroids, serve as powerful platforms for investigating human physiology and pathology *in-vitro*, and bioelectronic sensors effective, complementary tools for monitoring them. Current bioelectronic sensor technologies provide insights into thermal, electrophysiological, optical, and oxygenation parameters within these models, yet robust and high-fidelity biochemical sensors remain a significant gap. Our device bridges this gap, offering microsecond resolution in the detection and tracking of IL-6 proliferation and movement. This work paves the way for high-resolution interrogation of skin inflammation, significantly enriching our understanding of inflammation, and providing a powerful tool for potential drug efficacy assessment.

8:00 PM SB05.03.10
Poly Vinyl Alcohol and Carbon Nanotube Based Scaffolds for Engineered Biosensors RyanE. Jaworski and IsaacMacwan; Fairfield University, United States

Biosensors are analytical devices that can turn biological responses into electrical signals which can be very useful in the diagnostics of numerous diseases. This work looks into the fabrication of an impedance based biosensor using electrospun Poly Vinyl Alcohol (PVA) and Carbon nanotubes (CNTs) to be used in conjunction with bacteriorhodopsin contained in a purple membrane. Dispersions of PVA are created with and without CNTs in deionized (DI) water, which are then utilized to synthesize porous electrospun nanofibrous scaffolds with fiber diameters ranging from 150nm to 250nm. The detection technique utilized for the fabricated biosensor is through the quantification of electrochemical impedance via the Electrochemical Impedance Spectroscopy (EIS). The parameters for both electrospinning and EIS are carefully optimized to achieve porous nanofibrous scaffolds having expected fiber diameter, porosity and impedance. The parameters which are optimized for the electrospinning process include the flow rate, collection distance, voltage, viscosity of the polymer CNT solution, and the type and configuration of the collector. Similarly, the parameters for the EIS include optimum potential of the applied small ac signal in mV, frequency range, electrolyte concentration and the type of electrodes and their configuration. This careful optimization of the parameters would enable the fabrication and the dynamic response of the designed biosensor to be able to hold its integrity through the entire process of characterization and testing. Two different forms of CNTs are used, which are single-walled carbon nanotubes (SWNTs), and multi-walled carbon nanotubes (MWCNTs). The two different SWNTs used in this study have a (6, 5) chirality and also mixed metallic and semiconducting chirality to assess the differences in the biosensor performance based on the type of SWNT and its comparison to the MWNTs. The synthesized scaffolds are also characterized through atomic force microscopy (AFM) and scanning electron microscopy (SEM), and compared to control samples without CNTs. The synthesized scaffolds are then tested for performance through the detection of a light sensitive protein bacteriorhodopsin (BR), which is a membrane protein found in Archaea, most notably Halobacteria. The primary function of the protein is in its use as a proton pump across the cell membrane and its novel characteristic to detect light of different wavelengths make it attractive for application in optical memory. Although this is a specific example, these scaffolds can accommodate different types of analyte for biosensors in many applications.

8:00 PM SB05.03.11
Fabrication of a Partially Porous Microneedle Array Through Stepwise Integration of Porous and Non-Porous Poly(glycidyl methacrylate) HiroyukiKai[1,2] and AkichikaKumatani[3,4,2]; [1]Toyo University, Japan; [2]Tohoku University, Japan; [3]The University of Tokyo, Japan; [4]Presto, Japan Science and Technology Agency, Japan

The microneedle array, a two-dimensional array of small needles with the height of a few hundreds of micrometers, are being actively studied for the application for minimally invasive transdermal drug delivery and biosensing. Among microneedles of various structures, porous microneedles have the advantages that they have large specific surface area that can be advantageous for high drug loading on the internal pore surface as well as highly sensitive biosensing taking advantage of high electrode area.

Porous polymer microneedle arrays made of crosslinked poly(glycidyl methacrylate) (PGMA), pioneered by Nishizawa's group, have advantages such as easy fabrication by photopolymerization in a mold and tunability of the properties by molecular design [1] as well as capability for functionalization by organic chemistry to fabricate functional microneedles such as organic/inorganic hybrid microneedle electrodes [2]. The existing porous PGMA microneedle arrays are porous throughout the microneedle body: both the base substrate and needles are homogeneously porous. Therefore, the amount of drug and sensor molecules interfaced with skin and biological fluid cannot be controlled, which prevents the quantitative control of drug release and reproducible amperometric biosensing. Considering the porous PGMA microneedles for quantitative applications, spatial control of porosity in the microneedle body is important. Monomers (glycidyl methacrylate, and timethylolpropane trimethacrylate, and triethylene glycol dimethacrylate) are photopolymerized by the irradiation of ultraviolet light in the presence of a photoinitiator to obtain crosslinked PGMA. In the presence of poly(ethylene glycol) (PEG) as a porogen (a template material to make pores), polymerized PGMA has macropores with the diameter of ~1 μm [3]. Therefore, control of addition of the porogen can be utilized to obtain spatially controlled porosity.

In this study, we present a two-step process for creating a porous PGMA microneedle array with a two-section structure: a porous needle section and a non-porous substrate, both made of PGMA. First, the monomer solution mixed with the porogen was poured into an elastic mold of a microneedle array and excess solution over the needle section was removed by carefully scraping on the mold, followed by the polymerization by ultraviolet light irradiation to fabricate porous needles. Then, the monomer solution without the porogen was poured over the polymerized needle section in the mold and polymerized to fabricate a non-porous base substrate. After the removal of the fabricated microneedle array from the mold, the needle section was in a white opaque color resulting from macroporous structures of PGMA and the base substrate was colorless and transparent, indicating PGMA in the substrate was non-porous. The two sections were integrated well and no significant breaking of needles was observed. Water absorption properties of the fabricated microneedle arrays were measured by immersing them into water and measuring the change in total mass. The amount of water absorbed by the partially porous microneedle array was significantly smaller than the homogeneously porous microneedle array, yet higher than homogeneously non-porous microneedle array. The developed two-layer, partially porous microneedle array is potentially useful for quantitative control of drug livery and reproducible biosensing.

8:00 PM SB05.03.12
Highly Accurate Multiplexed Nanoplasmonic Detection of MicroRNAs using Splinted Ligation SihwaJoo[1], YounjuSung[2], Na RaeJo[3], Yong-BeomShin[2] and MinaLee[1]; [1]Korea Research Institute of Standards and Science, Korea (the Republic of); [2]Korea Research Institute of Bioscience and Biotechnology (KRIBB), Korea (the Republic of); [3]Korea Institute of Machinery and Materials (KIMM), Korea (the Republic of)

MicroRNAs (miRNAs) are short, non-coding single-stranded RNAs that regulate gene expression by binding to mRNAs. Because miRNAs are abnormally expressed in cancer cells, they have been considered an important cancer biomarker. However, the short length and high homology of miRNAs make them difficult to detect accurately. In this study, we developed a highly accurate miRNA detection method using a multi-channel localized surface plasmon resonance (LSPR) sensing platform. MiRNAs were labelled with a DNA probe using splinted ligation and immobilized on a gold nano-truncated cone (GNTC) array chip fabricated by nanoimprinting. After enzyme-assisted precipitation was performed, the LSPR spectral shift was measured as a function of miRNA concentration. Three miRNAs (miR-34c, miR-99a, and miR-125b) were sensitively detected with the limit of detection ranging from 1.8 to 26.1 fM. Single nucleotide variation (SNV) was clearly discriminated with high contrast. In addition, several miRNAs could be simultaneously detected in the multi-channels of a GNTC chip with high quantitative accuracy. Furthermore, we demonstrated the clinical applicability of our method by accurately detecting miRNAs in total RNA samples extracted from cancer cells.

8:00 PM SB05.03.13
Flexible Organic Microelectrode Arrays for Long-Term Functional Characterisation of Brain Organoids at the Air-Liquid Interface BelquisHaider, SagnikMiddya, DanielJ. Lloyd-Davies Sánchez, MadelineA. Lancaster, GeorgeG. Malliaras and GabrieleS. Kaminski Schierle; University of Cambridge, United Kingdom

Organoids are three-dimensional biological models that have revolutionised in vitro research by replicating the structure and function of organs. Despite their remarkable potential, the limited diffusion of oxygen and nutrients to their cores has impeded their growth. Recent advances have involved culturing organoids at the air-liquid interface using organotypic slice culture techniques. Air-liquid interface cerebral organoids (ALI-COs) have emerged as powerful tools for studying brain evolution, development, and neurological diseases. However, the full potential of ALI-COs has been limited by the lack of continuous in situ electrophysiological characterisation.
To address this limitation, we present a novel approach utilising organic polymer-based flexible microelectrode arrays (with a thickness of 4 μm) for non-invasive recording of spontaneous extracellular activity from ALI-COs. These bioelectronic devices are designed for compatibility with the air-liquid interface, and are encapsulated in Parylene-C to enhance flexibility and

feature low-impedance poly(3,4-ethylenedioxythiophene) polystyrene sulfonate (PEDOT:PSS)-coated microelectrodes.
By leveraging these devices, which offer a high signal-to-noise ratio, low electrochemical impedance, and mechanical properties matching those of cells, we have successfully achieved continuous recording from the same brain organoid slice for a minimum of two months, without compromising growth or morphology, as evidenced by immunofluorescent staining results. The findings suggest that this approach is a promising tool for long-term, non-invasive recording of extracellular activity from ALI-COs, which has implications for understanding brain development and early disease mechanisms. This work has the potential to facilitate breakthroughs in understanding brain development and disease modelling by enabling continuous functional characterisation of cerebral organoids.

8:00 PM SB05.03.14
Biocompatible Silk Films for Transient Tactile Sensors DonggeunLee[1], Jeong WooChae[2], Sang MinWon[2] and Wi HyoungLee[1]; [1]Konkuk University, Korea (the Republic of); [2]Sungkyunkwan University, Korea (the Republic of)

Research interests in naturally derived polymers with flexibility, stretchability, foldability, transparency, transiency, biocompatibility, and biodegradability has recently received much attention. In addition, the emergence of transient electronics, which are decomposed, absorbed, and disappear after operating for a certain period, can supplement the demerits caused by the survival of implanted devices. These technologies rely heavily on the flexibility, stretchability, biocompatibility, and biodegradability of the used biomaterials. This report presents strategies for utilizing both silk fibroin and silk sericin extracted from silk cocoons of *Bombyx mori* and fabricating silk-based sensors that detects capacitive touching motion and resistance change form mechanical deformation of the sensors. Decomposition and flexibility in humid condition were controlled by annealing fibroin film. Sericin extracted from cocoons in the process of producing fibroin was used to make an adhesive with good biocompatibility. Furthermore, a conductive silk composite was produced through hybridization with tungsten nanoparticles and was used as a piezoresistive/capacitance sensor. The sensitivity of conductive silk composite was confirmed through EEG and EOG tests. The flexibility of wholly silk based sensors was confirmed by measuring the changes in resistance at various bending condition. Acknowledgement: This work was supported by Korea Institute for Advancement of Technology (KIAT) grant funded by the Korea Government (MOTIE) (P0012770) and grant from the Basic Science Research Program of the National Research Foundation of Korea (NRF) funded by the Ministry of Science and ICT (2023-00208902).

8:00 PM SB05.03.15
Impedance-Based Polymer Microneedle Patch Sensor for Continuous Interstitial Fluid Glucose Monitoring HonglinPiao, JaehyunKim, YongHoChoi, Heon-JinChoi and Dahl-YoungKhang; Yonsei University, Korea (the Republic of)

Early diagnosis and control of blood glucose is essential for effective prevention and management of diabetes-related complications. This study aims to develop a microneedle-type glucose sensor patch for minimally invasive, painless and continuous glucose monitoring. In situ monitoring of glucose concentration in interstitial fluid using polymeric microneedle arrays is the method used in this study. The experimental section included four subsections, namely substrates fabrication, sensor fabrication, and characterization of the glucose sensor based on microneedle patches. The experimental findings demonstrate the successful penetration of cylindrical microneedles into skin tissue with minimal force, reaching a depth of approximately 520 μm. The microneedle sensor was produced with high precision using the CMOS process, and the immobilization of glucose oxidase was confirmed through phase angle changes. After conducting long-term tests, the sensor was found to be effective for up to 7 days. Glucose concentration measurements were conducted using the developed sensor, resulting in fitted curves with a mean slope of -27.18 and a mean intercept of 197.27. Random glucose concentration tests were conducted, and the range of values obtained shows strong correlation with those obtained from commercially available glucose detectors. MARD ranges from -0.5% to 11.97%. These results suggest the potential for the microneedle sensor to be used as a reliable and accurate tool for glucose monitoring. The study provides a promising approach for developing a wearable and minimally invasive and painless glucose sensor for continuous glucose monitoring.

8:00 PM SB05.03.16
Wireless, Highly Sensitive Biosensors on Contact Lenses for Intraocular Pressure Monitoring TeXiao; Waseda University, Japan

Glaucoma is one of the common eye diseases to cause a risk of blindness in severe cases. To prevent the blindness by glaucoma, real-time monitoring of intraocular pressure (IOP) becomes particularly important. The contact lenses built-in IOP sensor can contact continuously with the eye, so they are superior to other IOP measurement system in that it can measure constantly. Many researchers have been working on making wireless smart contact lenses that can detect intraocular pressure. By embedding LCR resonators[1-2] in the contact lenses, which can generate changes in inductance, capacitance, or resistance of the pressure sensors., and receiving signals through transmission coils, the purpose of real-time wireless detection of intraocular pressure is achieved. However, the development of smart contact lens remains a challenge, including wireless sensor sensitivity, transparency, durability, and safety.
Here we demonstrate the use of a wireless and highly sensitive IOP monitoring system on pig eyes that is comfortable while wearing. The IOP monitoring system consists of a stretchable gold antenna sensor printed on a moist and soft contact lens for IOP detection. The wireless IOP data reception is made of a reader circuit resonated at 1.39 GHz. We designed a horseshoe-shaped gold antenna, which was then printed on commercially available contact lenses through electrochemical bonding, using poly(3,4-ethylene dioxythiophene) film as an adhesive glue. The printed stretchable IOP sensing lens can be stretched and twisted, which is impossible using a conventional loop antenna[3].

An Electric Contact Lens for Non-Mydriatic Near-Infrared Fundus Imaging YangCui; Waseda University, Japan

Ophthalmic fundus imaging has become an important technique for the diagnosis and treatment of eye diseases[1]. A2n ideal imaging system should have portability, low cost, and high resolution for the remote monitoring of eye health at home; however, the conventional imaging systems are large and heavy and can only be used in hospitals.
To solve this problem, we demonstrate a non-mydriatic near-infrared (NIR) fundus imaging system with light illumination from an electric contact lens (E-lens)[2]. We designed a wireless power transfer system that can be bound to the contact lens and don't block the eye view[3]. and a near-infrared LED is embedded on the contact lens and can be powered wirelessly to light up. The E-lens can illuminate the retinal and choroidal structures in the eyes. The irradiated light is reflected at the layered structures of the fundus, and subsequently, the reflected light passes through the pupil of the eye lens to capture the images with a portable NIR camera.
Because of the strong light scattering effects in the fundus tissue, the captured images are blurred. Therefore, we reconstruct the images with a depth-dependent point-spread function to suppress the scattering effect that eventually visualizes the clear fundus images of the retinal and choroidal vasculature[4]. This method showed superior image reconstruction results compared to other common methods such as high-pass filtering. The proposed imaging system provides a new method for remote monitoring with increased functionality, it makes the portable eye health care possible.

8:00 PM SB05.03.18
Stretchable Microelectrode Arrays for Brain Spheroid Electrophysiology EleonoraMartinelli[1], CamilleL. Delgrange[1], IvanFurfaro[1], LorisGomez Baisac[2], AdrienRoux[2], LucStoppini[2] and StephanieP. Lacour[1]; [1]Ecole Polytechnique Federale de Lausanne, Switzerland; [2]Haute Ecole du Paysage, d'Ingenierie et d'Architecture, Switzerland

Human neural spheroids, i.e. 3D cellular aggregates composed of neurons and glial cells, are a compelling biological model to study neuronal communication both in physiological and pathological conditions. We propose the design of a perforated and stretchable microelectrode array (MEA) to monitor the electrophysiology of brain spheroids under static and dynamic mechanical loading. This is a relevant neuroelectronic system to investigate the consequences of traumatic brain injury (TBI).
The MEAs are prepared with thin-film technology using a platinum thin film sandwiched between two 1 μm thick polyimide films. Stretchability is engineered by design introducing patterns of micron scale, Kirigami-like Y-shaped cuts on the whole MEA surface.
Each MEA hosts 8 Kirigami-patterned recording electrodes (diameter = 70 μm), and a macroscopic ground electrode to probe one brain spheroid (spheroid diameter = 500-1000 μm). Electrode contacts are coated with electrodeposited PEDOT. The coating conformably follows the profile of the Kirigami-patterned electrodes independently of electrode size and reduces the

electrochemical impedance at 1 kHz by 60 folds (n = 24, diameter = 70 μm).
Next, the permeability of the perforated MEAs is quantified as a function of pattern designs and perforation methods; this is to ensure sufficient nutrient and oxygen exchange at the air-liquid interface of the brain spheroid.
The electromechanical properties of the MEAs are then evaluated when subject to uniaxial elongation at a constant speed (100 μm/s). The strain parameters are aligned with typical TBI loadings (5-35%). Kirigami-patterned PEDOT-coated electrodes sustain strains up to 10% without showing significantly increased electrochemical impedance amplitude, while patterned platinum electrodes sustain strains only up to 5%. Similar results are shown with cyclic stretching. The electromechanical properties of the MEAs are also evaluated when subject to fast mechanical loading comparable with TBI impacts (elongation speed 1-2 m/s).
Next, the ability of the Kirigami-patterned electrodes to record neural activity from brain spheroids is verified. The MEA is mounted on a fluidic platform to allow for cell culture media change and the brain spheroids are integrated into the system. Spontaneous neural activity from the brain spheroids is reliably recorded for up to 5 days.
This work paves the way for studying the effect of mechanical loading on neural activity in 3D *in vitro* brain models.

8:00 PM SB05.03.19
Multimodal Wearable Soft Sensors for Real-time Plant Health Detection and Precise Diagnosis QinJiang, XinZhao and ZhigangWu; Huazhong University of Science & Technology, China

Our work presents a soft multimodal sensing system that can be integrated into plants for long-term detection of their physiological data variation without disturbing their growth. It combines multimodal sensor components (temperature and humidity (T&H), spectrum, and volatile organic compounds (VOCs)) with artificial intelligence (AI) system to achieve real-time plant health monitoring and diagnosis. This study may promote a novel way to set intelligent plant management systems, enabling a new level of precision agriculture, botanical research, and intelligent forestry.
Real-time monitoring of a plant's growth status, such as living microclimate, leaf color, and maturing status, is highly significant for plant physiology prediction. Recently, it has been presented that some soft sensors can be directly attached to the plant's surface to detect its physiological data. However, these sensors require more efficient multimodal data fusion to comprehensively reflect plants' growth health and flexibility to accommodate the fast growth of plants.
In this work, by coupling multimodal sensing components (e.g., T&H, spectrum, and VOCs) with the flexible liquid metal circuit, we present a soft and conformal plant-wearable sensor to monitor the plant's health status in situ. By setting the array of T&H sensors, we can record the leaf surface's T&H variation and distinguish the gradient distribution of T&H in a single leaf. With the help of the spectrum sensor, the plant surface's (e.g., leaf and fruit) transmission spectrum wavelength (350 – 1000 nm) can be detected and thus can indicate its color variation and mineral nutrition degrees (e.g., Nitrogen, Phosphorus, and Kalium). Multi-specific types of VOCs (e.g., NO_2, SO_2, and ethylene) are also monitored to reflect plants' stress and development levels. Moreover, we develop an artificial neural network to fuse these multiple sensing data for precisely predicting plants' growth status and diseases. To be compatible with plants' fast and continuous growth, we also present a new fabrication process that can significantly improve the stretchability and conformability of flexible circuits. By adjusting the local cross-linking degree of polydimethylsiloxane(PDMS), we can selectively tune the local stiffness of the PDMS substrate and then decrease the stress concentration between the rigid components and soft rubber under a high strain rate (> 110% stain).
Finally, several demonstrations are presented: 1) The wearable soft sensor is attached to the tomato leaf for long-time monitoring and precisely diagnosing the tomato's disease and abiotic stresses (e.g., water, temperature, salinity, and light intensity). 2) The soft sensor can also be attached to the surface of the tomato fruit to continuously record the fruit's physiological data and mature degree during its growth and expansion.

8:00 PM SB05.03.20
Modified Ultra-Stretchable Elastomers-Based Plant Monitoring Sensors for Stable Sensing with Plant Growth ZishengZong[1], ZhipingChai[1], ShuoZhang[2] and ZhigangWu[1]; [1]Huazhong University of Science and Technology, China; [2]Ningbo Institute of Technology Beihang University (BUAA), China

Recently, owing to their unique flexibility, stretchability, and conformability, soft film sensors for real-time plant monitoring demonstrate relatively little disturbance to plants' natural growth or physiology activities. However, there are still several challenges in plant sensors, including the reliable interface matching between sensor substrates and plants. Most soft film sensors generally take advantage of a flexible substrate to directly attach plant surface and active material with micro/nano structures to sense environmental parameters such as temperature and humidity. However, this attachment strategy may not be adapted to plants' rapid and continuous growth process due to their mismatched mechanical properties and low biocompatibility, leading to undesirable consequences such as sensor detachment or inhibition of plant growth. This paper reports a fully soft plant monitoring sensor for detecting environment humidity, plant circumference and length, with a modified ultra-soft, stretchable, and sticky polydimethylsiloxane-based elastomer (3S-PDMS) as substrate, graphene oxide (GO) as active material, and liquid metal as a conductive material.
In particular, the 3S-PDMS is obtained by adding a small amount (10~30 μL) of ethoxylated polyethylenimine (PEIE) ethanol solution, which contains moderately ample polar groups and shows an inhibitory effect on the catalytic activity of platinum catalysts, into the silicone precursors to weaken the crosslinking of PDMS, and constructs a dual network of solids and liquids. This dual-network accommodates a large number of uncross-linked small molecule monomers and therefore demonstrates low modulus and high adhesion force. Generally, 3S-PDMS demonstrates the mechanical properties of ultra-soft (tuning Young's modulus from 3.2 MPa to 7.5 kPa), stretchable (tuning the breaking elongation from 140% to 720%), and sticky (tuning tenfold adhesion force). Apart from that, 3S-PDMS demonstrates excellent biocompatibility, air and water vapor permeability, and optical transparency, allowing it to grow with plants and not inhibit plants' photosynthesis. Meanwhile, as water molecules are absorbed by GO, the GO can be dissolved and ionized to reduce the impedance of the electrical network, thus GO is adopted as a moisture-sensitive material.
To fabricate the sensors, the atomized liquid alloy was sprayed onto a tape-transferred adhesive mask, which was processed by laser and then attached to the surface of 3S-PDMS substrates. Then, the GO solution was drop-coated onto the liquid alloy electrical circuit. Next, the water-soluble mask and residual GO film were removed after drying. The sensing unit made of liquid alloy and GO film can be stretched as the plant grows and retains its sensing stability. Moreover, a circuit made up of liquid metal can measure the growth of plants by changes in electrical resistance, including growth circumference and length, etc. In conclusion, this paper offers an ultra-soft, stretchable, and sticky elastomer-based sensor for plant monitoring, which achieves high biocompatibility and reliable detection during plant development.

Whole-Cell Biosensing and Remediation of Arsenic using Magnetically Separable E. Coli: Towards Sustainable Materials for Water Treatment EricJ. Sorge, JinggeChen, MeganKizer and VickiL. Colvin; Brown University, United States

The World Health Organization (WHO) identifies arsenic as a carcinogenic toxin with exposure limits in drinking water set as low as 10 ppb. Arsenic is abundant in the Earth's crust and its prevalence in groundwater originates from natural causes as well as anthropogenic activities. Millions of people around the world, especially those in rural areas, are exposed to dangerous levels of arsenic in their water supply each year. Preventing human exposure to arsenic with accessible, inexpensive, and sustainable technology is crucial. We describe a strategy for sensing and removing arsenic from drinking water that exploits the bioaccumulation of arsenic by engineered bacteria and its detection using a whole-cell biosensor (WCB). A gene coding for a chimeric protein with two different arsenic binding domains was transfected into wild type *E. coli*; the resulting microbes could reduce arsenic concentrations in water samples containing up to 500 ppb to our instrument detection limit (~ 10 ppt) within 60 minutes. These microbes remain alive while bioaccumulating arsenic and thus we refer to them as 'living sorbents'. While the dry-weight sorption capacity of these biomaterials is less than commercial inorganic arsenic sorbents, their arsenic affinity and selectivity is much greater. As a result, it is possible to reduce even very low levels of arsenic to acceptable levels using reasonable sorbent loadings.

These organisms may be further engineered to detect arsenic through optical reporters, thus providing an important integrated solution to the problem of arsenic in drinking water. Environmental arsenite binds to the ArsR transcription regulator, a protein that is central to the arsenic bioaccumulation capability described earlier. This same protein may also be applied to upregulate a reporter protein with fluorescent or luminescent properties. Whole cell biosensors should indicate the presence of arsenic at the extremely low levels relevant to meeting global exposure standards, on the order of ppb. Such sensitivity can be achieved through signal amplification strategies such as the use of engineered positive feedback or the application of multiple optical reporters.

Because these living sorbents use proteins evolved for arsenic sequestration, the material performance is independent of local water chemistry. The technology can be applied without customization to a particular site, and is notably independent of silicate and phosphate concentrations. Unlike inorganic sorbents which must be transported to a given site, these WCBs can be stored as dehydrated powders and later reconstituted on-site to levels appropriate for water treatment. Reversible attachment of iron oxide particles to the *E. coli* allows for magnetic capture of the biomass and the production of drinking water with no measurable contamination. This biological approach, employing regenerative and biodegradable materials, provides a sustainable alternative to conventional, inorganic sorbents for arsenic removal.

8:00 PM SB05.03.22
Design and Development of Coatable Strain Sensors for Non-Planar Surfaces ChanPark, ByeongjunLee, JungminKim, HaranLee, CheoljeongPark, ChiwonSong and Seong J.Cho; Chungnam National University, Korea (the Republic of)

Fabricating sensors on non-planar surfaces can significantly enhance the capabilities of traditional soft electronics. However, to apply existing flexible device research to non-planar surfaces, a new sensor must be developed that takes into account both Young's modulus and surface roughness. This is because real-time monitoring on non-planar surfaces, such as basic angular contact with the structure, remains a challenge. This study proposes a Coatable Strain (CS) sensor that can be applied and patterned on surfaces with various elastic moduli, shapes, and non-planar characteristics. Wet processes, regardless of surface roughness, can make contact with the surface depending on the condition of the object. Therefore, CS sensors can be applied to a variety of materials, from low-modulus materials like hydrogels (Young's modulus ≈ 1 kPa) to high-modulus materials like steel (Young's modulus ≈ 200 GPa). As a result, sensors were fabricated on various surfaces that were previously challenging to measure, and the deformation history of the object was evaluated. The CS sensor is a promising new technology for real-time monitoring of non-planar surfaces. It is easy to use and can be applied to a wide variety of materials. The results of this study demonstrate the potential of CS sensors for a variety of applications, such as structural health monitoring, medical diagnostics, and robotics.

8:00 PM SB05.03.23
Ultrafast Light-Activated Polymeric Nanomotors JianhongWang, HanglongWu, JingxinShao and JanVan Hest; Eindhoven University of Technology, Netherlands

Synthetic micro/nanomotors have been extensively exploited to achieve active transportation over the past decade. This interest is a result of their broad range of potential applications, from environmental remediation to nanomedicine. Nevertheless, it still remains a challenge to build a fast-moving biodegradable polymeric nanomotor. Here we present a light-propelled nanomotor by introducing gold nanoparticles (Au NP) onto biodegradable bowl-shaped polymersomes (stomatocytes) via electrostatic interactions. These biodegradable nanomotors show controllable motion and a very high velocity of up to 125 μm s^{-1}. This unique behavior was explained via a thorough three-dimensional characterization of the nanomotor, particularly the size and the spatial distribution of Au NP, with cryogenic transmission electron microscopy and cryo-electron tomography. Our in-depth quantitative 3D analysis revealed that the motile features of these nanomotors were caused by the nonuniform distribution of Au NPs along the axial direction of the polymersome. This study could offers a new perspective for designing robust biodegradable soft nanomotors, thereby facilitating their applications in a bio-friendly manner.

8:00 PM SB05.03.24
Fabrication of Water-Resistant Materials using Nanofiber Membranes Inspired by Penguin Feathers RyosukeKawasaki[1], DaisukeIshii[1], YosukeZaitsu[2] and MasanoriKurita[2]; [1]Nagoya Institute of Technology, Japan; [2]Port Nagoya Public Aquarium, Japan

When diving, penguins do not get wet due to the feathers that cover their skin, and emperor penguins dive to a maximum depth of 564 meters. This is probably due to the penguin's feather density, which is the largest among birds, the hierarchical microstructure of its feathers with gaps of up to 17 μm, and surface-modifying fat secreted by the tail blubber gland. Even with the feathers without the fat removed by organic solvents, contact angles were as high as about 130°. When a water pressure resistance was measured of surface modified feathers and wire meshes with various pore sizes by self-assembled monolayers, the smaller the pore size and the smaller the surface free energy, the better the water resistance. This result suggests that water repellency and water resistance are synergistic effects of microstructure and surface modification.
This study aimed to fabricate water-resistant materials using nanofiber membranes by electrospinning, inspired by the mechanism of penguin feathers. Polyacrylonitrile (PAN) nanofiber membranes fabricated in previous studies had problems with water absorption. A high surface free energy of PAN causes capillary action within the pores of the nanofiber membrane. Therefore, to improve the water absorption phenomenon, we investigated methods of reducing the pore size by heat pressing and changing to a polymer with low surface free energy. The experimental conditions for the electrospinning were a drum collector rotation speed of 15 rpm, a needle diameter of 0.41 mm, a feed rate of 0.10 ml/min, an applied voltage of 20 kV, and a distance between a collector and needle of 10 cm. Samples of heat pressing were yarned from a 12.5 wt% N,N-dimethylformamide (DMF) solution of PAN, and were pressed under three conditions: room temperature (25°C), glass transition temperature (Tg) of PAN (104°C), and 150°C. A hydrophobic polymer nanofibers were spun from DMF solution of Poly(vinylidene fluoride) (PVDF) (15, 20, 25, and 30 wt%). Static contact angles, water absorption , and wetting behaviors of the nanofiber membranes were discussed.
As a result, water absorption was observed in the nanofiber membrane pressed at room temperature, but no water absorption was observed in the heated press at or above the glass transition temperature. The fibers were not adhered each other pressed at room temperature, resulting in capillary action. On the other hand, the fibers pressed over Tg were adhered each other. Then pores of the nanofiber membranes became smaller and capillary action did not take place. The contact angles of the pressed nanofiber membrane at over Tg were about 70°. It is considered that the difference in pressing temperature over Tg has no effect on the surface structure. In the case of PVDF, only beads were formed at 15 and 20 wt%, which resembled "electrospray", and 25 and 30 wt% resulted in fibers, although some beads were formed. The beads were probably caused by aggregation on the collector side because the solvent was not fully volatilized. The PVDF nanofiber membrane did not show water absorption, and the contact angle was about 140°. The contact angle of smooth PVDF was about 85°, suggesting that the microstructure of PVDF improves hydrophobicity. These results indicate that the combination of microstructure and low surface free energy has potential for superhydrophobic fabrics and will contribute to the development of new water resistance mechanisms.

8:00 PM SB05.03.25
Elucidating Biosensing Mechanism of Aptamer Modified Extended-Gate Field-Effect Transistor Biosensor SunghyunPark and JayoungKim; Yonsei University, Korea (the Republic of)

Extended-gate structure biosensors offer a promising field-effect transistor (FET) architecture for point-of-care applications by physically separating the sensing region from the transistor. However, few studies have investigated the sensing mechanism of FET biosensors (not limited to extended-gate structure), but rather have shown excellent label-free sensing performance. Herein, we demonstrate the biosensing mechanism of the aptamer modified extended-gate FET biosensor by modulating the dielectric properties and charge properties on the surface of the gold extended-gate. In the extended-gate FET structure, we can consider two capacitors in series: an extended-gate and a FET, which leads to the phenomenon of capacitive coupling. To show how the capacitive coupling between these two components affects the biosensing performance, we vary the capacitance values by modulating the electrode size of extended gates. Furthermore, by modifying an aptamer on the extended-gate surface for selective recognition of biomarkers and connecting it in series with a FET, the sensing performance can be explained by the capacitive coupling effect, and we further compare the results with those obtained by modulating surface charge and dielectric properties to gain insights into the sensing mechanism of the aptamer modified extended-gate FET biosensor. This in-depth investigation enhances the understanding of the biosensing mechanism in FET biosensors, provides insights for additional amplification strategies, and improves the sensitivity of FET biosensors.

8:00 PM SB05.03.26
Establishment of a Quantitative Method for Comparing The Surface Properties of Natural and Synthetic Leather KazuyaUchida and DaisukeIshii; Nagoya Institute of Technology, Japan

Natural leather is produced by processing the hides of cattle, pigs, and other by-products of the meat industry. Therefore, it is a sustainable material that makes effective use of by-products. However, the metallic salts used in the "tanning" process of converting animal skins into natural leather can cause environmental problems such as water pollution and health hazards to the worker. Although vegetable tanning is an alternative tanning method that does not use metallic salts, the proportion of metal salt tanning is still high in industrial materials. Synthetic and artificial leathers are also becoming popular, but it is difficult to replace natural leathers because the characteristics of synthetic and artificial leathers have not been imitated.
Therefore, we aim to solve this problem by reducing the use of natural leather by focusing on the wettability of the surface of the leather and creating synthetic leather that has properties like natural leather. At first, the surface characteristics of each leather material such as wettability and frictional force were compared quantitatively. Based on the results of these comparative evaluations, we will establish guidelines for the development of synthetic leather with surface properties as close as possible to those of natural leather. The differences in surface properties between commercial natural leather and synthetic leather covered by polyurethane were due to differences in wettability and surface and cross-sectional microstructure. Static contact angle measurements were performed using 10 μL of distilled water to compare wettability. In addition, microscopic contact angle measurements were also performed to evaluate the behavior of absorbing a 30 pL water droplet. To clarify the relationship between these wettabilities and surface structures, the surface microstructures were observed by scanning electron microscopy (SEM). The cross-sectional microstructures were also observed, considering the contribution of not only the surface but also the cross-sectional structure to the water absorption behaviors.
As a result, the SEM observation revealed bubbles in resins and regular structures on the surface of the synthetic leather, and a fluffy structure with non-woven fabrics protruding from the surface of the artificial leather. These microstructures, which differ from the surface of the natural leather, have affected surface wettabilities. In the cross-section, the natural leather showed a tendency for the structure to become rough from the outer to the inner surfaces. On the other hand, a structural gradient was not observed for the other materials, suggesting that the structural gradient affects water absorbency. The static contact angle results showed that natural and synthetic leathers had similar contact angles, although their surface structures differed according to the SEM images. The highest value was obtained for the artificial leather, which is thought to be due to its fluffier surface, which allows for a larger air layer and a more effective pinning effect than the other materials.
Finally, observation of water absorption behavior showed that the contact angle decrease rate of natural leather was greater than that of the other materials, suggesting that it has superior water absorption properties. It was thought that the gradient-like structure was responsible for the superior water absorption property. In the presentation, details of surface properties such as frictional force and mechanical properties, as well as quantitative evaluation methods for comparing the properties of each leather material will be established, and guidelines for the development of alternative materials will be explained.

8:00 PM SB05.03.27
Design and Fabrication of Sustainable Manufacturing of Neural Electrode Array for In Vivo Recording Pei-LingChen[1], Szu-YingLi[2], PochunChen[1], Kuang-ChihTso[3], You-YinChen[2] and JunOhta[3]; [1]National Taipei University of Technology, Taiwan; [2]National Yang Ming Chiao Tung University, Taiwan; [3]Nara Institute of Science and Technology, Japan

Increasing requirements for neural implantation are helping to expand our understanding of nervous systems and generate new developmental approaches. It is thanks to advanced semiconductor technologies that we can achieve the high-density complementary metal-oxide-semiconductor electrode array for the improvement of the quantity and quality of neural recordings. Although the microfabricated neural implantable device holds much promise in the biosensing field, there are some significant technological challenges. The most advanced neural implantable device relies on complex semiconductor manufacturing processes, which are required for the use of expensive masks and specific clean room facilities. In addition, these processes based on a conventional photolithography technique are suitable for mass production, which is not applicable for custom-made manufacturing in response to individual experimental requirements. The microfabricated complexity of the implantable neural device is increasing, as is the associated energy consumption, and corresponding emissions of carbon dioxide and other greenhouse gases, resulting in environmental deterioration. Herein, we developed a fabless fabricated process for a neural electrode array that was simple, fast, sustainable, and customizable. An effective strategy to produce microelectrodes, leads, and bonding pads onto the Parylene C substrate by laser micromachining techniques combined with the drop coating of the silver paste to stack the laser grooving lines. Sequentially, Parylene C was deposited onto the Parylene C substrate to form the insulation layer for the protection of inner circuits. Following the deposition of Parylene C, the via holes over microelectrodes and the corresponding probe shape of the neural electrode array was also etched by laser micromachining. To increase the neural recording capability, three-dimensional microelectrodes with a high surface area were formed by electroplating PEDOT-GO composite. Our eco-electrode array showed reliable electrical characteristics of impedance under harsh cyclic bending conditions of over 90 degrees. For in vivo application, our flexible neural electrode array demonstrated more stable and higher neural recording quality and better biocompatibility as well during the implantation compared with those of the silicon-based neural electrode array. In this study, our proposed eco-manufacturing process for fabricating the neural electrode array reduces carbon emissions compared to the traditional semiconductor manufacturing process and provided freedom in the customized design of the implantable electronic devices as well.

8:00 PM SB05.03.28
Enhanced and Protective Oral Prosthetic Surfaces for Expedited Biological Fusion SeherYaylaci[1], HakanCeylan[2] and HacerEberliköse[3]; [1]Lokman Hekim University, Turkey; [2]Mayo Clinic, United States; [3]Ankara Medipol University, Turkey

Current strategies for enhancing the biological fusion between oral prosthetics and bone often encounter limitations due to mechanical stress at the interface. In this investigation, we present a novel, in situ-applied material designed to facilitate the biological union between the prosthetic and bone tissue. This material expedites the biological incorporation process by modulating bone metabolism through the use of specialized nanoscale fibers. Concurrently, the material possesses properties that inhibit microbial colonization, thereby improving the overall success rate of the prosthetic. A unique aspect of this work is the in situ application of the material during prosthetic placement. The material is injectable, allowing for spontaneous nanoscale fiber formation at the interface during insertion. The composition of the material is designed to emulate certain aspects of the natural extracellular matrix. Initial characterization studies were conducted to assess the material's chemical, physical, and mechanical properties. Subsequent in vitro evaluations were performed to investigate the material's effects on cellular differentiation and antimicrobial efficacy. Finally, in vivo studies were conducted to assess long-term outcomes.

8:00 PM SB05.03.29
Advancing Soil pH Sensing Through Novel, Stabilized, Screen-Printed Electronics CatherineCrichton[1], ElliotStrand[1], Juan PabloCisneros Barba[1], NicholasBruno[1], John-BaptistKauzya[1], AnupamGopalakrishnan[1], MadhurAtreya[1], EloiseBihar[2,1] and GregoryL. Whiting[1]; [1]University of Colorado Boulder, United States; [2]University at Buffalo, The State University of New York, United States

Soil pH significantly affects agriculture by regulating available nutrients and water-soluble chemicals available to plants, thus driving the need for low-cost, durable soil pH sensors. A few potential solutions include expensive commercial pH sensors and printed sensors that only work in liquid media. Each of these solutions poses its own set of unique challenges perpetuating the affordable soil pH sensing dilemma. Here, we present a novel pH sensor platform based on an array of low-cost, durable, screen-printed electronics for in situ soil sensing. We show the stabilization of the pH-sensitive dye, alizarin, in the printed pH devices allowing for extended sensing periods in soil. We compare different alizarin dye immobilization techniques and electrode configurations and have evaluated the effects of soil pH on sensor durability. This new affordable, stable printed pH system pioneers the development of printed electronics for new alternatives to assess soil pH.

8:00 PM SB05.03.30
Bioinspired Transdermal Delivery Patches with Multiscale Adhesive Architectures JihyunLee and ChanghyunPang; Sungkyunkwan University, Korea (the Republic of)

Intelligent bioinspired adhesive devices are attracting attention as a tool for the transdermal drug delivery patch. However, there have been many challenges in delivering drugs from the wrinkled and rough skin surface through the complex stratum corneum into the body. The rough skin surface interferes with the interfacial contact between the drug delivery material and the skin, making close adhesion difficult, which reduces drug delivery efficiency. In addition, the brick-like structure of the stratum corneum, which has a barrier function, is a major obstacle to drug delivery through the skin. Here, we present two strategies to overcome the limitations of transdermal drug delivery based on biomimetics. First, the drug delivery patch, which is designed by combining an adhesive structure that mimics a diving beetle and a drug-loading hydrogel, improves the efficiency of drug delivery through conformal contact. In addition, the asymmetric diving beetle adhesive structure provides directional adhesive performance, enabling hypoallergenic detachment. Second, it is an adhesive interface that provides negative pressure to the skin by mimicking the tentacle of a cephalopod. Negative pressure delivered to the skin induces fine structural deformation of the stratum corneum and creates gaps between the stratum corneum, improving drug delivery efficiency. With the aid of bioinspired adhesive architecture, we demonstrated improved drug delivery efficiency in an *in vivo* model, suggesting a promising development in the medical and skin therapy fields.

8:00 PM SB05.03.31
Permeability and Anti-Fouling Performance of Microfiltration Membrane Modified by Hybrid Structured Omniphobic Coating Method SeonminKim, Moon SuhkSuh, Churl SeungLee and HayoungChoi; Korea Electronics Technology Institute, Korea (the Republic of)

Surface characteristics of polymer membrane plays a significant role in bioprocess such as separation, purification, and so on. Generally, hydrophilicity is recommended for better process efficiencies in various commercial biomedical engineering fields. However, omniphobic properties of these fields could be recommendable for better perfomance because those properties on the surface is more favorable in many reasons. In this study, we try to modify the commercial polyethersulfone (PES) membrane by combining two different coating procedures: electrospinning and spray coating. Poly(vinylidene fluoride) is used to form the nanofiber mat for the robust roughness by the electrospinning technique and various fluoro-silane materials is applied to modify the chemical properties of the surface by spray coating method. The modified membrane was analysed by scanning electron microscopy for surface morphology and characterized by the measurement of contact angle for anti-fouling properties. We also measured the permeabilities of membrane for water and bovine solution to test anti-fouling ability in a simulated bioprocess conditions.

8:00 PM SB05.03.32
Wireless, Fully Implantable and Expandable Bioelectronic Platform for Bidirectional Modulation of the Urinary Bladder Tae-MinJang, Jeong-WoongShin and Suk-WonHwang; Korea University, Korea (the Republic of)

Current standard clinical options for patients with detrusor underactivity (DUA) or underactive bladder -- the inability to release urine naturally -- include the use of medications, voiding techniques, and intermittent catheterization, for which the patient inserts a tube directly into the urethra to eliminate urine. Although those are life-saving techniques, there are still unfavorable side effects, including urinary tract infection (UTI), urethritis, irritation, and discomfort. Here, we report a wireless, fully implantable, and expandable electronic complex that enables elaborate management of abnormal bladder function via seamless integrations with the urinary bladder. Such electronics can not only record multiple physiological parameters simultaneously but also provide direct electrical stimulation based on a feedback control system. Uniform distribution of multiple stimulation electrodes via mesh-type geometry realizes low-impedance characteristics, which improves voiding/urination efficiency at the desired times. In vivo evaluations using live, free-moving animal models demonstrate system-level functionality.

8:00 PM SB05.03.33
A Self-Powered Wearable Sensor based on Triboelectric Nanogenerator for Simultaneous Motion Monitoring and Energy Harvesting AghaA. Jan, SeungbeomKim, JunhyungKim, UhyeonKim and SeokKim; Postech, Korea (the Republic of)

Flexible and biocompatible triboelectric nanogenerators (TENGs) have emerged as promising candidates for mechanical energy harvesting at relatively lower working frequencies and sensing in wearable applications. TENGs work on the contact electrification principle of a tribo-negative and tribo-positive surfaces. The tribo-positive surfaces lack in material choices. Extensive research efforts have primarily focused on optimizing tribo-negative materials. This emphasis stems from the relatively limited selection of suitable tribo-positive materials available. Achieving biocompatibility while maintaining the capability for motion monitoring and energy harvesting is another critical issue for wearable devices. Here we report a laminated flexible TENG composed of polytetrafluoroethylene (PTFE) and polymethyl methacrylate (PMMA) films embedded in flexible and biocompatible polydimethylsiloxane (PDMS) for demonstration of motion monitoring and energy harvesting. A textured PDMS substrate was used to sputter deposit the indium tin oxide-copper (ITO/Cu) electrode and tribo-positive PMMA thin layer over it.

The introduction of the ITO layer onto the Cu electrode significantly improved the overall quality and performance of the electrode. Our TENG sensor displayed good pressure-sensing capabilities, featuring dual pressure sensitivity: 12.3 mV/Pa in the low-pressure range (24.5 to 122.6 Pa) and 0.663 mV/Pa in the higher pressure range (245 to 23,300 Pa). The embedded TENG sensor effectively trace the physiological motions such as wrist and finger bending. Additionally, the device efficiently harnessed energy from everyday activities like walking and jogging, producing peak-to-peak voltages of 18.3 V and 57.4 V during these motions. With its high sensitivity and power density, the laminated flexible TENG holds significant promise for diverse wearable applications, including pressure sensing and self-powered motion monitoring, emphasizing its importance in the ever-evolving field of wearable technology.

8:00 PM SB05.03.34

Use of PMMA as a Deep UV Photoresist to Produce Patterned Substrates for Surface-Aligned DNA Deposition with Potential Application to Sequencing HebaOuerfelli[1,2], BohengCao[3,2], EllenHu[4,2], AditiKiran[5,2], SelinaZhang[6,2], AlexZheng[7,2] and JonathanSokolov[2]; [1]Fort Lee High School, United States; [2]Stony Brook University, United States; [3]North Hollywood High School, United States; [4]C. Leon King High School, United States; [5]BASIS Independent Fremont, United States; [6]North Hunterdon High School, United States; [7]Stuyvesant High School, United States

As genetic sequencing grows widespread in diagnostics and research, increasing its accessibility has become all the more necessary. Current next-generation sequencing (NGS) technologies entail the large-scale assembly of complete sequences from short, free-floating DNA fragments, resulting in high computational costs. Researchers have attempted to address this issue through long-read or third-generation sequencing, extending the length of the contiguous DNA fragments to tens of kilobase pairs. However, repetitive regions of the DNA still limit the ability of software to reassemble unique sequences. Ordered DNA fragmentation is an important tool in reducing the computational bottleneck of rearranging scattered strands in solution. The foundation of our approach lies in the integration of biological materials with a synthetic polymer, creating a novel abiotic-biotic system.

In this work, we explore the use of 996K molecular weight poly(methyl methacrylate) (PMMA)-coated silicon wafers as a suitable substrate for developing suspended DNA segments. The suspended segments provide steric clearance for the application of Tn5 transposases to fragment and label surface-immobilized long DNA molecules. PMMA was used as a deep-UV photoresist to produce latent patterns, followed by DNA deposition and photoresist development. Despite the tendency for UV-exposed PMMA to become more hydrophilic (unfavorable to DNA stretching on surfaces), we were successful in finding a combination of exposure and development times to achieve surface immobilization of long DNA strands such as those of mice genomic DNA and ligated lambda DNA. Initial experiments testing Tn5 activity will also be discussed. The broader implications of this work are a novel and exciting biohybrid way forward in ordered DNA fragmentation for lower-cost sequencing.

8:00 PM SB05.03.35

Impact of Rhizobium Tropici-Produced EPS on Bermuda Grass Root Growth HaarisAlam[1], IsanaAlicea[2], AshrithaKalakuntla[3], EliseNgo[1], BrinleyDai[4], JerryGao[5], TeiKim[6], TonyGuo Feng Tung[7], YiweiFang[8], AaronSloutski[8], MarciaSimon[8], JayGao[8], MiriamRafailovich[8], SteveLarson[9] and FengxiangHan[9]; [1]Portola High School, United States; [2]Patchogue Medford High School, United States; [3]Ed W. Clark High School, United States; [4]Experimental High School Attached to Beijing Normal University, China; [5]Beijing No. 80 High School, China; [6]Stanford Online High School, United States; [7]Shanghai High School International Division, China; [8]Stony Brook University, The State University of New York, United States; [9]US Army Corps of Engineers, United States

Erosion control is imperative to soils vulnerable to flooding, such as watersheds in the Mississippi River Basin. A potential solution is provided by extracellular polymeric substances (EPS): hydrated microbial biopolymers whose high water-holding capacity, entrapment of nutrients, and resistance to environmental stressors can elevate soil fertility. EPS also promotes aggregate formation, which helps maintain a soil's structural integrity. A more indirect benefit of EPS in soil is their ability to enhance subterranean root growth. This corresponding increase in root mass or length can stabilize topsoil and aid in erosion control. However, the specific mechanism by which EPS benefits root growth was studied by different research groups with partial success. This project aimed to further investigate the influence of EPS produced by Rhizobium tropici bacteria (RT-EPS) on Bermuda grass, particularly on its root growth. By gaining a deeper understanding of this impact, a more effective approach for the fabrication and deployment of RT-EPS can be developed, which will be used on large scale applications to minimize the soil damage caused by extreme weather conditions.
EPS produced from the Rhizobium tropici bacteria was used to generate an ethanol precipitate material (EPM). After cell-free biofilms of the bacteria were generated, the cells were removed by centrifuge and the crude EPM collected through precipitation with ethanol, thus producing two forms of EPM: non-dialyzed and dialyzed (where an additional dialysis step was applied). For the plant study, Bermuda grass seeds were germinated in sand treated with non-dialyzed- and dialyzed- EPM (and water as a control). The plants were grown in one of three conditions in the greenhouse: a controlled chamber, inside the greenhouse, or outdoors. After a 60-day period, gravimetric and length measurements were taken of both the roots and shoots, indicating that EPM treatment increased relative root mass growth. The structure, density, and elemental composition of roots from Bermuda grass specimens grown in sand were analyzed by a Keyence VHX-7000 Microscope. After retrieving images, qualitative and quantitative analyses (nodule counting) found higher root density and greater branching in EPM-treated samples, for both dialyzed and non-dialyzed polymers. Additionally, X-ray fluorescence (XRF) spectroscopy was performed to determine the concentration of biologically important ions in roots with EPM, revealing higher amounts of Ca, K, and P. X-ray diffraction (XRD) was then performed to determine the presence of crystalline structures on top of the roots.
In conclusion, it was observed that the Bermuda grass samples treated with non-dialyzed EPM had the highest root-to-shoot mass ratios and coverage from tertiary branching. These samples also contained higher concentrations of ions that promote root growth, demonstrating enrichment of the nutrient profile. Prospective analysis includes in-depth research on the protein fraction EPM contains, with a focus on their influence on root stem cell differentiation. Further experiments will be conducted to compare the impact of different EPM dialysis procedures (by increasing the dialysis pores) on Bermuda grass root growth. The knowledge obtained from these studies will be utilized to conduct open-field experiments to examine the effect of EPM on large-scale growth, including subsequent soil analysis.
The authors would like to thank the US Army Corps of Engineers (ERDC) for their support (W912HZ-20-2-0054) in this research.

Structural Modifications of Nano-Sized Hydrogel via Reversible and Irreversible Redox Reactions of Thiols Chae GyuLee and Tae-HyukKwon; Ulsan National Institute of Science and Technology, Korea (the Republic of)

Cysteine-containing oxidoreductases, such as thioredoxin (Trx) and glutaredoxin (Grx), play crucial roles in maintain cellular redox balance through finely tuned reversible redox signaling pathways. However, elevated levels of reactive oxygen species (ROS), often of exogenous origin, can trigger the irreversible hyperoxidation of cysteine thiols into sulfonic acids ($–SO_3H$), resulting in permanent dysfunction of these proteins. In this study, we present an approach involving a multi-functional nano-sized hydrogel (nanogel, IrNG), encapsulating an iridium-based photosensitizer (TIr3).[1,2] IrNG offers precise control over its nanostructure through reversible and irreversible redox reactions. In the absence of photoirradiation, IrNG maintains its self-assembled nanostructure, even in the presence of high concentrations of reductive glutathione, owing to strong hydrophobic interactions and the reversible self-crosslinking between thiols and disulfides. However, upon the photoirradiation, the disulfide bonds evenly distributed within IrNG undergo hyperoxidation, transforming into negatively charged sulfonates. This transformation results in the rapid degradation of IrNG. The photo-responsive TIr3 generates significant levels of ROS, enabling both spatiotemporally controlled structural modifications in the redox-responsive nanogel and mitochondrial oxidation-mediated cancer cell apoptosis.

Formulation of FITC Embedded ZnO/Silica Quantum Dots for Targeted Drug Delivery KajalDhumal[1], ShreeramJogalekar[2], AmolTagalpallewar[1], AnilPawar[1], AkshayM. Baheti[1] and AartiShastri[1]; [1]School of Health Sciences and Technology MIT world Peace University Pune, India; [2]Dr Vishwanath Karad MIT World Peace University, India

Breast cancer is the most prevalent type of cancer worldwide and one of the leading causes of death in women. Multiple epidemiological interventions have been used up to this point, including chemotherapy, targeted therapy, and laparotomy. Natural plant products have shown promising outcomes as anti-cancer agents. although the scarcity of effective treatments for metastatic breast cancer. Given that natural products are relatively non–toxic. So, in this study, we evaluated the phytochemical screening of Mangifera indica L. leaf extract, and the constituents were analyzed using the HR-LCMS technique. In addition, the anti-cancer activity of the extract was demonstrated by molecular docking studies. Amongst these lead compound, cucurbitacin b were shown to have the highest binding affinity (-22.799 kcal/mol) and positive drug interaction with breast cancer receptor. Quantum dots (QDs) are one of the unique techniques being used in the therapy of breast cancer. ZnO/silica-FITC embedded quantum dots loaded with cucurbitacin b will act as a smart nano-drug carrier and give better cell imaging, diagnosis, and targeted drug delivery. For qualitative examination, the bulk medication was also examined using ultraviolet (UV) spectrophotometry and Fourier Transformation Infra-Red (FT-IR) spectroscopy. The drug-loaded QDs were synthesized using a wet-chemical approach, and the influence of numerous factors such as excipient concentration was evaluated on their entrapment efficiency and percentage yield to create the best and most stable quantum dots formulation. Particle size and distribution (DLS evaluation), zeta potential analysis, FE-SEM, XRD, percent drug

entrapment, and in-vitro drug release study were used to characterize the optimized drug-loaded ZnO/silica FITC embedded QDs. The outcomes demonstrated an abundance of bioactive molecules with anti-tumor potential in M. indica. However, more in vitro and in vivo studies are necessary. before establishing a treatment for breast cancer.

Polymer Dots Stabilized with Bovine Serum Albumin: Characterization, Bioconjugation and Applications YihaoWang, RupsaGupta and RussAlgar; The University of British Columbia, Canada

Fluorescent nanoparticles are popular and still-emerging materials for bioanalysis and imaging. Among the many types fluorescent nanoparticles, semiconducting polymer dots (Pdots) tend to have the highest brightness. Unfortunately, the surface properties and non-covalent and hydrophobic nature of Pdots leads to non-ideal behaviours such as poor colloidal and physical stability and high levels of non-specific binding.

Here, we prepared and characterized Pdots with bovine serum albumin (BSA) as the stabilizing agent (BSA-Pdots) instead of a more conventionally used amphiphilic polymer, both without and with crosslinking of the protein using glutaraldehyde (BSA(GA)-Pdots) or disuccinimidyl glutarate. These materials were then compared to alternate approaches to Pdot preparation, such as co-precipitation of semiconducting polymer with an amphiphilic polymer and post-synthetic silica encapsulation. The BSA-Pdots were generally more stable across wider ranges of pH and ionic strength range and had lower levels of non-specific binding to surfaces and fixed cells. Live cells internalized the BSA-Pdots through a form of receptor-mediated endocytosis with good retention of viability. The Pdots were conjugated with biotin and used for fluorescent immunolabeling of fixed SK-BR_3 human breast cancer cells. Overall, direct BSA stabilization is a very promising strategy for preparing Pdots with improved physical and colloidal stability, reduced non-specific interactions, and utility for in vitro diagnostics and other bioanalyses and imaging.

8:00 PM SB05.03.39
Shear-Reversible Clusters of HIV-1 in Solution: Stabilized by Antibodies, Dispersed by Mucin AyobamiI. Ogundiran, Tzu-LanChang, AndreyIvanov, NamitaKumari, SergeiNekhai and PreethiChandran; Howard University, United States

The behavior of HIV-1 in culture media was tracked with Dynamic Light Scattering (DLS) and complementary atomic force microscopy (AFM) imaging in the presence of lectins, anti-gp120 Antibodies (Abs), mannosidase, and mucin. After excluding the serum contribution to culture media from extracted DLS data, it is observed that there are clusters/ aggregates of about 400-700nm HIV-1 in solutions. The clusters were sheared into single virus particles by filtration but re-clustered back over a short time. It is known that HIV-1 mutates rapidly and is protected by glycan shields of mannose sugars that have challenged the broadly neutralizing of the virus by Abs. In other studies, mannose residues have been reported to be self-adhesive, but it is not known if these mannose adhesions drive HIV-1 to be aggregated in solution, further confounding Ab neutralization. Mannosidase treatment reduced clustering, suggesting the mannose glycan shield is involved in the cluster formation. Mucin molecules (porcine gastric mucin) effectively dispersed HIV-1 clusters, even those stabilized by Abs. It is well known that mucin reduces HIV virulence, but the mechanism has not been clarified. Our findings suggest that mucin reduces HIV-1 virulence by dispersing its clusters, as opposed to the current perspective that mucin aggregates HIV-1.

8:00 PM SB05.03.40
Impact of Surfactant Properties on Phase Transition and Morphology of Thermoresponsive Polysaccharide Biomaterials Rabeya SharminLima, Saniya YesminBubli, KatherineSalvatore, SachinKamath, ZhiyuYang and LinqingLi; University of New Hampshire, United States

Understanding the interactions between various surfactants and thermoresponsive polymers is essential for regulating phase transition and controlling polymer aggregation, offering opportunities in producing biomaterials with diverse morphologies and microstructures. Here we developed a new class of dextran-based thermoresponsive polysaccharides by chemically altering the hydrophilic polymer backbone into hydrophobic derivatives. These thermoresponsive materials exhibited robust, reversible phase transitions and tunable lower critical solution temperatures. Photo-initiated radical polymerization permits facile chemical crosslinking and captures phase separation dynamically, leading to the formation of hydrogels with distinct morphologies. We evaluated the effects of various surfactants – such as anionic sodium dodecyl sulfate (SDS), nonionic pluronic F-127, cationic hexadecyltrimethylammonium bromide (CTAB), and zwitterionic 3-[(3-cholamidopropyl) dimethylammonio]-1-propanesulfonate (CHAPS) – on the phase transition and microdomain morphology of polysaccharides. We found that temperature-triggered hydrophobic interactions and phase transition behaviors are regulated by a combination of surfactant charge density, hydrophilic—lipophilic balance (HLB) values, and critical micelle concentrations (CMC). Surfactants with higher HLB values significantly disrupt phase separation above their CMCs. Notably, the non-ionic pluronic F127 surfactant effectively eliminates phase transitions across a wide range of dextran molecular weights and concentrations even below its CMC. Depending on their charge and CMC, surfactants also modify the microdomain size, shape, and number by altering the balance between continuous and dispersed phases. These findings will expand the selection of appropriate surfactants to regulate the polymer/polymer and polymer/solvent interactions to modulate phase-separation and microstructures morphology that may serve as a potential polymeric carrier for cancer drug delivery.

8:00 PM SB05.03.41
Characterizing Oil-In-Water Emulsions as Muscle and Subcutaneous Adipose Tissue Phantoms for T2 Relaxometry AlexaS. Zammit, SydneySherman and AmenaKhatun; Massachusetts Institute of Technology, United States

Tissue microstructure can be indicative of pathology and varying microstructural properties can contribute to inaccuracies in several diagnostic tools.[1] Skeletal muscle is hierarchical and highly organized. Additionally, skeletal muscle is an important reservoir of fluid and can be an early indicator of a volume overloaded state.[1,2] A recent study demonstrates that point-of-care fluid status determination may be possible with the analysis of T2 relaxometry data collected by a bedside NMR sensor.[2] However, given the clinical setting of the study, fluid overload and a typical fluid state were the only two states available for data collection. Here, oil-in-water emulsions are assessed and characterized on a T2 relaxometer. The properties of the emulsions are compared to dissected murine muscle and subcutaneous adipose tissue after data analysis with a multi-exponential fit. Peanut oil is used in the emulsions, as the NMR signal is comparable to the triglycerides in adipose tissue.[3] Varying the fat fraction of the emulsions by changing the oil to water ratio changes the relative amplitudes of the peaks as determined by the multi-exponential analysis. A comparison of different fat fractions enables us to determine that an emulsion with a fat fraction of 40% can be considered a muscle phantom and an emulsion with a fat fraction of 75% can be considered an adipose tissue phantom. As such, the phantoms can be used as standards for calibration and sensitivity testing for T2 relaxometry purposes.

Bioelectronic Control of Neuronal Activity in Cortical Organoids with Ions and Small Molecules YunjeongPark, SebastianHernandez, Cristian O.Hernandez, HeatherKnight, Hunter E.Schweiger, HoupuLi, KaterynaVoitiuk, HarikaDechiraju, NicoHawthorne, Elana M.Muzzy, John A.Selberg, Frederika N.Sullivan, RobertoUrcuyo, Sofie R.Salama, ElhamAslankoohi, MirceaTeodorescu, Mohammed A.Mostajo Radji and MarcoRolandi; University of California, United States

Cortical organoids are valuable tools for studying brain development, modeling neurological disorders, and testing potential treatments. For these studies, we need to improve the ability to precisely manipulate and modulate the activity of the cortical organoids at a fine time scale in a precise and detailed manner. Here, we have employed a bioelectronic approach with an ion pump, used for selective delivery of ions and neurotransmitters. More specifically, we used these devices to experimentally determine neuronal effects on the organoids with the bioelectronic delivery of potassium ions (K^+), protons (H^+), and γ-aminobutyric acid (GABA). This work is important to reflect bioelectronic device potential in exploring neurological disorders and their potential treatments with a level of precision and detail that was previously challenging to achieve.

Materials and Methods for Programmable Delivery of Therapy via Wearable Bioelectronics for Wound Healing *In Vivo*HoupuLi[1,2], Hsin-yaYang[1,2], NargesAsefifeyzabadi[1,2], SydnieFiguerres[1,2], PrabhatBaniya[1,2], Andrea MedinaLopez[1,2], AnthonyGallegos[1,2], KanZhu[1,2], Hao-ChiehHsieh[1,2], TiffanyNguyen[1,2], Cristian O.Hernandez[1,2], KseniaZlobina[1,2], CynthiaRecendez[1,2], MaryamTebyani[1,2], HectorCarrion[1,2], John A.Selberg[1,2], LeLuo[1,2], Moyasar A.Alhamo[1,2], Athena M.Soulika[1,2], MichaelLevin[1,2], NargesNorouzi[1,2], MarcellaGomez[1,2], MinZhao[1,2], MirceaTeodorescu[1,2], RoslynRivkah Isseroff[1,2] and MarcoRolandi[1,2]; [1]University of California, United States; [2]University of California, Davis, United States

The ability to deliver drugs with precise dosages at specific time points can significantly improve disease treatment while reducing side effects. Drug encapsulation for gradual delivery has opened up the doors for a superior treatment regimen. To expand on this ability, programming bioelectronic devices to deliver small molecules enables ad-hoc personalized therapeutic profiles that are more complex than gradual release. Here, we introduce a wearable bioelectronic bandage with an integrated electrophoretic ion pump that affords on-demand drug delivery with

precise dose control. In this poster, I will present my contribution to the device fabrication that involves hydrogel synthesis in glass capillaries, testing of the hydrogel conductivity, and device testing. With these devices, delivery of fluoxetine to wounds in mice resulted in a 27.2% decrease in the macrophage ratio (M1/M2) and a 39.9% increase in reepithelialization, indicating a shorter inflammatory phase and faster overall healing. Programmable drug delivery using wearable bioelectronics in wounds introduces a broadly applicable strategy for the long-term delivery of a prescribed treatment regimen with minimal external intervention.

8:00 PM SB05.03.44
Materials and Strategies for Integrating Chloride Membrane Channels with Bioelectronics LeLuo, EmilyLee, YunjeongPark and MarcoRolandi; University of California, United States

Biological membrane channels actively mediate information exchange between cells and have a main role in molecular recognition. The 'iono-electronic' gap between these channels and electronics creates a significant challenge in connecting these channels to electronic devices for efficient signal readout from. To address these challenges, we've combined supported lipid bilayers (SLBs) with Ag/AgCl electrodes to specifically target chloride conducting membrane spanning channels. We use the Ag/Ag Cl contacts to translate the ionic signal from the Cl- ions into an electronic signal at the interface by exploiting the Ag/AgCl electrochemical reaction. With this system, we show that Cl- conducting channels and Cl- pumping rhodopsins interface better than with other non-selective contacts (Pt) or proton selective contracts (PdH). In the future, this platform can be used to create complementary hybrid devices with membrane spanning channels that are selective to the desired type of ion.

SESSION SB05.04: Engineering Biohybrid Interfaces

8:00 AM SB05.04.01
Stretchable, High-Modulus Penetrating Microelectrode Arrays for *In Vitro* Intramuscular ElectromyographyQinaiZhao[1], EkaterinaGribkova[2], YiyangShen[1], JilaiCui[2], NoelM. Naughton[2], LiangshuLiu[1], JaeminSeo[1], MattiaGazzola[2], JohnA. Rogers[3], RhanorGillette[2] and HangboZhao[1]; [1]University of Southern California, United States; [2]University of Illinois at Urbana-Champaign, United States; [3]Northwestern University, United States

Three-dimensional (3D) penetrating microelectrode arrays (MEAs) serve as important interfaces with biological tissues in various fields, including neuroscience, tissue engineering, and wearable bioelectronics. These 3D MEAs can penetrate surface layers of tissues, thereby facilitating electrophysiological sensing and electrical stimulation of interior tissues in a minimally invasive manner. Stretchable penetrating MEAs are highly desirable as they can adapt to the deformations of dynamically moving tissues or organs. This adaptability enables stable bioelectronic interfacing, enhances recording signal quality, and reduces tissue damage. However, fabricating stretchable 3D MEAs with high electrode modulus required for penetration and customized geometries presents significant challenges in materials integration and patterning. In this study, we present the design, fabrication, and applications of highly stretchable microneedle electrode arrays (SMNEAs) for sensing localized intramuscular electromyography (iEMG) signals in vitro. We have developed a hybrid fabrication scheme utilizing molding, microfabrication, and transfer printing, which enables scalable fabrication of SMNEAs with high electrode modulus (E = 6.6 GPa) and device stretchability (80%). Our SMNEAs also offer controllable electrode dimensions and recording areas, and low electrode impedance. We demonstrate the use of these SMNEAs in recording iEMG signals from the buccal mass of Aplysia. By inserting a multichannel SMNEA with varying electrode lengths into individual muscle groups of the buccal mass, we achieved high-fidelity, localized iEMG recording during muscle contractions and relaxations. The iEMG signals captured by the SMNEA exhibit distinctive spatiotemporal muscle activation patterns within individual muscle groups of the buccal mass, a level of detail unachievable with surface electromyography (sEMG) using a planar MEA. The high electrode modulus and device stretchability, as well as customized electrode geometries make our SMNEAs potentially useful for local sensing and stimulation of dynamic 3D tissues such as cardiac and neuromuscular tissues.

8:15 AM SB05.04.02
Biomimetic Designs of Organic Electrochemical Transistors for Human-Interfaced Biosensing and Neuromorphic Computing SihongWang; The University of Chicago, United States

The use of electronic devices for acquiring biological information and delivering therapeutic interventions relies on two aspects: the effective acquisition of physiological information through direct contact with soft bio-tissues, and the high-throughput processing of the acquired data using machine learning. To ensure high-quality signal transductions, the interfaces between bioelectronic devices and bio-tissues must combine signal amplification with stable and conformable contact. Organic electrochemical transistors (OECTs) have been developed as one of the most advanced technologies for high-performance bio-sensing and neuromorphic computing. Moreover, the fastest and most energy-efficient data processing through machine learning is directly on the human body. However, the rigid mechanical properties and the lack of tissue/skin adhesion from transistors largely prevent the formation of such intimate and long-term stable bio-interfaces. In the first part of my talk, I will introduce our material and device designs for introducing three highly important biomimetic properties onto OECT-based biosensors—stretchability, tissue-like softness, and bioadhesive properties. Our rationale designs from the material to the device level allow the realization of these properties with state-of-the-art electrical performance. I will also introduce the strategies and advantages of using these new biomimetic properties in bioelectrical and biochemical sensing. In the second part of my talk, I will introduce our research in imparting intrinsic stretchability onto neuromorphic devices that can provide state-of-the-art computing performance. I will also show the practical applicability of this device for implementing machine-learning computing and algorithms for health data analysis, when the computing hardware is under human-body-induced deformation.

8:30 AM SB05.04.03
Human Stem Cell-Based Biohybrid Fish Keel YongLee[1,2], Sung-JinPark[3], Herdeline AnnArdoña[4], Sean L.Kim[2], JohnZimmerman[2], AndreKleber[2], GeorgeLauder[2] and KevinK. Parker[2]; [1]Sejong University, Korea (the Republic of); [2]Harvard University, United States; [3]Emory University, United States; [4]University of California Irvine, United States

Biohybrid muscular systems have emerged as a valuable test platform for engineering and studying various physiological features, encompassing ion channels to system-level performance. The integration of muscle cells into simplified synthetic platforms has provided insight into the intricate mechanisms involved. However, the field of biohybrid technology is still in its nascent stages, encountering challenges in attaining system-level structure and performance comparable to their natural counterparts. This study presents a notable breakthrough in biohybrid technology through the development of a human stem cell-based biohybrid fish capable of self-pacing and self-sustaining coordinated locomotion. Taking inspiration from the structural attributes of the sinoatrial node and the multi-layered myocardium, our design incorporates a geometrically insulated cardiac tissue node and muscular bilayer muscle tissues into the biohybrid platform. This integration facilitates spontaneous activation and enables mechano-electrical signaling coupling between the muscular bilayer muscle tissues. The unique biohybrid design empowers the fish to exhibit spontaneous yet coordinated antagonistic muscle contractions, resulting in self-coordinated body-caudal-fin propulsion. Our autonomous biohybrid fish surpasses existing biohybrid muscular systems in terms of speed and longevity. It attains an optimal performance level comparable to natural body-caudal-fin swimmers, signifying a substantial advancement in the biohybrid technology domain. The achievements of this biohybrid fish lay a remarkable foundation for future autonomous biohybrid species capable of exhibiting complex adaptive behaviors. By harnessing the potential of human stem cells and employing advanced biohybrid designs, we are paving the way for a new era of biohybrid systems that closely mimic and potentially surpass the capabilities of their natural counterparts. These advancements hold immense promise across diverse applications, including regenerative medicine, biomimetic robotics, and enhancing our understanding of the fundamental principles governing biological locomotion.

8:45 AM SB05.04.04
Modular Biomachines Built from Amphibian Stem Cells DouglasBlackiston[1,2], SamKriegman[3], JoshBongard[4] and MichaelLevin[1,2]; [1]Tufts University, United States; [2]Harvard University, United States; [3]Northwestern University, United States; [4]The University of Vermont, United States

Living organisms remain more adaptive, robust, and regenerative than any synthetic system yet developed. It is thus promising that engineering has seen a surge in novel fabrication materials over the past decade, including a growing catalogue of biological cells and tissues. These living materials have the potential to overcome several problems faced by traditional engineering programs: they are biodegradable, self-powered, self-motile, self-healing, nanometer sized, and contain an inherent biochemistry. Efforts have largely coalesced around biohybrid designs, combining synthetic scaffolds or components alongside living cells and tissues. In complement to this approach, we demonstrate a method for constructing fully biological machines from embryonic amphibian cells, engineered to exhibit a specific behavior. AI methods automatically design diverse candidate lifeforms in silico to perform a desired function. The best performing simulation is then selected, and a living biological representation is constructed using a novel cell-based toolkit sourced from amphibian stem cell lineages. These self-powered representations are then released into aquatic arenas and tested for transference of in silico behavior. Further, we show that these modular biomachines survive in varied freshwater and saline environments and can be programmed to respond to varied stimuli across their lifespan. These studies lay the groundwork for future large-scale and automated deployment of fully biological constructs capable of a variety of user specified tasks

9:00 AM *SB05.04.05
Hybrid-Nanomaterials for Cellular Activity Modulation TzahiCohen-Karni; Carnegie Mellon University, United States

My team's efforts are focused on three major thrusts: (i) synthesis and in depth mechanistic investigation of the unique emergent optical, thermal, electrical and electrochemical properties of novel hybrid-nanomaterials and nanomaterials topologies composed on one-dimensional and two-dimensional building blocks, (ii) application and characterization of hybrid-nanomaterials interfaces with cells and tissue, and (iii) development and engineering of nanomaterials-based platforms to interrogate and affect the electrical properties of tissue and cells such as cardiomyocytes, and neurons, with a specific focus to understand electrical signal transduction in complex 3D cellular assemblies. In this talk I will review our current efforts to control cellular activity using photoactive hybrid-nanomaterials. Light has proven itself as a powerful tool to remotely modulate cellular activity with minimal invasiveness. We present a safe neural modulation approach with sub-μJ incident energy using engineered nanostructured Si, Ge, C (out-on-plane grown graphene), and two-dimensional (2D) transition metal carbides nanoflakes without generating cellular stress. Our approach serves as a powerful toolset for studies of cell signaling within and between tissues and can enable therapeutic interventions. Expanding the material library for safe optical modulation and the systematic evaluation of their biosafety will inspire future clinical translation to achieve remote control of cells/tissue in vivo.

9:30 AM *SB05.04.06
Life-Nanomachine Synergism: From Subcellular-Sized Bioelectronic Interfaces to Brain-Like Ultra Energy-Efficient Nanoelectronics DeblinaSarkar; Massachusetts Institute of Technology, United States

Typical biomedical implants are large (mm-cm in scale) and are highly invasive. To overcome these challenges, we are developing sub-cellular sized bioelectronic devices which are much smaller than the size of even a single cell. These devices can either reside inside a cell or in between cells and provide biological interfacing with high spatio temporal precision. These can have applications in sensing biological signals as well as modulating them for therapeutics. Going beyond bio-interfacing, I will also discuss how we can learn from biology and build devices that act like the brain for achieving highly enrgy efficient and environmentally sustainable Artificial Intelligence.

10:30 AM SB05.05.01
Light-Responsive Cationic Membrane-Targeted Dyes for Cell Membrane Stimulation ChiaraBertarelli[1,2], GuglielmoLanzani[2,1], ValentinaSesti[1,2] and PaolaMoretti[1,2]; [1]Politecnico di Milano, Italy; [2]Fondazione Istituto Italiano di Tecnologia, Italy

In the last few decades, photoswitches are being widely studied as a promising tool for photopharmacology. Light-responsive switches offer the possibility of using light as a clean, non-invasive, and spatio-temporally precise tool to trigger cell signalling and control a variety of biochemical functions. In this framework, reversible light-sensitive ligands successfully allow for a selective and reversible stimulation by means of the photoisomerization of dyes freely diffusing or covalently linked to channels, receptors, or other specific binding sites.[1]
Cationic membrane-targeted photochromic materials offer a rather different approach, where the amphiphilic character of the dyes drives their spontaneous partitioning within the cell membrane, with a specific affinity to lipid rafts. The cell signalling is the result of modification of the characteristics of the cell membranes induced by the light-driven conversion of the photoswitch to a metastable isomer.
Here, we show the molecular design of these amphiphilic dyes, which combine different families of photochromic compounds and cationic heads targeting the membrane, spaced by alkyl chains. Moreover, the presence of electroactive substituents allows for a high quantum efficiency in the visible range, modifies the isomerization kinetics and the stability in aqueous environment. Among the classes of switching units, azobenzenes demonstrated to be highly promising, and the most effective has proven to be the azepane- aminoazobenzene pyridinum-terminated Ziapin2.[2,3] Nevertheless, the use of indigos and Donor-Acceptor Stenhouse Adducts (DASAs) have been also explored.
The cationic membrane-targeted azobenzenes have been proven effective in the stimulation of neurons, muscular contraction and in driving optical modulation of bacterial membrane potential.[4,5] Finally, we demonstrate that the number and the structure of the capping head influence the solubility of the dye, the partitioning, and the stability within the cell membrane, rather than the targeting of membrane-bound cell organelles.

Sustainable and sustainable development has been generating new perspectives in manufacturing and production processes. Solar cell technologies have suffered from its influences, generating research for the development of more accessible, biocompatible, efficient and environmentally friendly materials. Among the advances that have been made, hybrid devices between organic, inorganic and biological materials stand out. The latter includes molecules that have evolved over millions of years to perfection as biological light-harvesting machines. Membrane protein-pigment complexes are the molecules of interest for these biosensitized solar cells, specifically when they have retinal terminals or complexes with chlorophylls directly associated with photosynthesis. The best power conversion efficiencies in these hybrids are generated with wide bandgap nanostructured semiconductors. For these reasons, the optimization of the fabrication process of photovoltaic-hybrid devices from flexible and renewable carbon materials was performed in this study. Photoanodes of TiO_2 nanoparticles sensitized with bacteriorhodopsin or photosystem I were developed, with their respective electrolytes of benzoquinone/hydroquinone and water-soluble cobalt (II/III) bipyridine, and with a PEDOT (poly(3,4-ethylenedioxythiophene)) counter electrode functionalized with multi-walled carbon nanotubes synthesized by electrodeposition. Each device was fully characterized by observing its morphology by SEM and TEM images, while chemical confirmation was performed by RAMAN and finally the electrochemical behavior was studied by linear scanning voltammetry (LSV), open circuit potential decay (V_{OC}) and impedance spectroscopic analysis (EIS).

Unlocking the Potential and Lessons of 3D Porous Electrodes in Living Biophotoelectrochemical Systems LinyingShang[1], JoshuaLawrence[1], LauraWey[2], BartekWitek[1], EvanWroe[1], RachelEgan[1], AlyssaSmith[1], SilviaVignolini[1] and JennyZhang[1]; [1]University of Cambridge, United Kingdom; [2]University of Turku, Finland

Living biophotoelectrochemical systems are devices that 'wire' photosynthetic microorganisms (i.e., scalable and sustainable biocatalysts) to 3D-architectured electrodes to catalyse reactions for solar-power generation and fuel production using sunlight and water. Despite excellent progress over the last decade, large enhancements in solar-to-charge conversion efficiency are needed to enable real-world applications. One major challenge lies in optimising the bio-electrode interface, where the material and structure of the electrodes play a crucial role.
State-of-the-art electrodes in this field are micro-pillar and inverse opal (IO) electrodes fabricated from indium-tin-oxide (ITO) nanoparticles.[1] Here, we provide important lessons for electrode design by tuning the pore sizes and homogeneity of IO-ITO electrodes, characterising their light management ability, surface morphology, electroactive surface area, cells wiring efficiency, and relating these to their biophotoelectrochemical performance.

Our results indicate that the bare IO-ITO electrodes of different pore sizes (10-42 µm in diameter) managed light similarly and the larger pore-sized IO-ITO gave rise to the highest photocurrent output. Further attempts to boost light utilisation on these electrodes by adding a bio-mimicking reflective layer at the back of the electrode resulted in increased light reflection but did not influence the photocurrent output significantly, implying the light utilisation of the structure has been optimised.
In conclusion, presented is the most comprehensive systematic study in the structure-activity relationship of electrode architecture to biophotoelectrochemcial output to our knowledge.

Multifunctional Hybrid Interfaces for Energy Applications MaurizioPrato[1,2]; [1]Universitá Degli Studi di Trieste, Italy; [2]CIC biomaGUNE, Spain

Among the most innovative strategies in the energy transition, photo-electrocatalytic splitting of water for the production of "green hydrogen" plays a key role, as it provides an ideal energy carrier, obtained from renewable and circular resources and whose production and combustion fuels the H2O/O2 cycle, activated by sunlight. Currently, hydrogen production is mainly obtained from fossil sources, and in particular from natural gas, through thermochemical processes (reforming/pyrolysis) that generate quantities of carbon dioxide with high environmental impact. The perfect mechanisms of the leaf, realized in an artificial environment, allows for the production of hydrogen as a solar fuel, an ideal solution for sustainable development. In particular, a new catalytic system, based on the combination of perylene bisimides and polyoxometalates, arranged in a hierarchical assembly, offers new opportunities for the biomimetic splitting of water.

Membrane Targeted Azobenzene Drives Optical Modulation of Bacterial Membrane Potential Giuseppe MariaPaternò; Politecnico di Milano, Department of Physics, Italy

The possibility to control living matter with exogenous stimuli can have tremendous impact on synthetic biology, medicine and materials science, among others. For instance achieving control over cells behaviour remains a challenge at the interface between living and non-living matter,[1] and would enable the development of new bio-mimetic and bio-enabled materials able to perform tasks.[2] Within this context, bacteria have arisen as “active and actively-controllable materials”, exhibiting neuro-like behaviour, extended bioelectric signalling[3,4] and tunable assembly properties.[5] In the last decade, it has been observed that the regulatory element of such an active behaviour is the electrical potential across the membrane, which governs bacteria electrophysiology, metabolisms and bioenergetics.[6] Light can be a powerful tool in these regards, as one can control the membrane potential and, thus, cell function and behaviour remotely and with relatively high spatiotemporal precision.
Here, I will show that a membrane-targeted azobenzene can be used to photo-modulate precisely the membrane potential in cells of the Gram-positive bacterium Bacillus subtilis. We found that upon exposure to blue- green light, the isomerization reaction in the bacteria membrane induces hyperpolarisation of the potential ($\Delta V = 20$ mV), within a bio-mimetic mechanism reproducing the initial fate of retinal. Apart from being promising results in the view to photocontrol bacterial motion and assembly behavior in consortia, this approach also highlights the role of previously uncharacterized ion channels in bacteria electrophysiology.[7]

2:00 PM SB05.06.02
A Membrane-Targeted Push-Pull Azobenzene for the Optical Modulation of the Membrane Potential AriannaMagni[1,2], ValentinaSesti[1,2], MatteoMoschetta[2], Giuseppe MariaPaternò[1,2], ChiaraBertarelli[1,2] and GuglielmoLanzani[2,1]; [1]Politecnico di Milano, Italy; [2]Istituto Italiano di Tecnologia, Italy

In the last years, the use of light as a tool for modulating membrane potential and bioelectricity has emerged as a fascinating opportunity, with the broad aim of establishing life-machine symbiosis that can help in healing disorders and restoring biological functions. An approach to induce light sensitivity in animal cells, which are usually transparent to visible light, is the use of photoactuators. These are photoactive materials that can decorate or localize into the cell membrane and are able to transduce light into a signal that can be processed by the cells. A variety of materials are suitable for the non-genetic optostimulation of cells, ranging from inorganic nanoparticles to organic polymer films and nanostructures.
The cell membrane and its electrical potential represent the core of bioelectricity, hence constituting an ideal target for exogenous modulation of signalling. For this reason, we chose a push-pull azobenzene molecule (PP-2Pyr) as a membrane-targeting photoactuator that induces a charge displacement upon isomerization. The work comprises the photophysical characterization of the photoactuator, focusing on the isomerization dynamics, and the evaluation of the photoinduced effects on HEK-293 cells. The focus is on unveiling the photostimulation mechanism, intending to link the photophysical changes occurring in the molecular photoactuator after light absorption, to the biological effects on *in vitro* cell models. The proposed light-driven mechanism originates from inferences on the molecular partitioning of PP-2Pyr in the two membrane leaflets and on the rearrangement of the charges adsorbed to the membrane due to variations in the molecular dipole moment upon light excitation.

2:15 PM SB05.06.03
Surprising Enhancement of Extracellular Electron Transfer (EET) from Electroactive Bacteria to Charge Collectors by Fumarate and Further Enhancement of EET by Functionalized Carbon Nanotubes (CNTs)GáborMéhes[1] and ArghyamalyaRoy[2]; [1]Waseda University, Japan; [2]Linköping University, Sweden

We are witnessing the convergence of organic electronics with applied microbial electrochemistry for applications of energy harvesting, biosensing, electrosynthesis and others. In other words, biocompatible films made of conducting organic molecules interface electroactive (and other) bacteria in electronic and electrochemical devices, such as microbial electrochemical cells, biobatteries and transistors. Recently we have contributed to these efforts by creating a 3D hybrid bioelectrode based on PEDOT:PSS and *Shewanella oneidensis* MR-1 for enhancing the output of MESs[1], and by the first demonstration of amplification of EET by organic electrochemical transistors [2]. After shortly introducing these two papers, we will discuss two ways EET can be enhanced to yield MESs with electrical performances closer to realistic applications. More concretely, we have been investigating the effect of chemically-functionalized CNTs, as well as the biomolecule fumarate, on the magnitude and temporal dynamics of EET. We observed distinctively different effects on EET based on the chemical agent for functionalization of CNTs, and an unexpected role of fumarate in EET dynamics.

2:30 PM *SB05.06.04
Seeing the Sound—An Ultrasound-Mediated Intravascular Light Source for Noninvasive Brain Modulation GuosongHong; Stanford University, United States

Understanding the inner workings of the brain requires a bidirectional interface that enables causal manipulation and simultaneous interrogation of neural activity. Existing electrical and optical brain interfaces are usually based on implanted devices and invasive procedures that necessarily damage the endogenous brain tissue and constrain the subject's free behavior. To address these challenges, our lab leverages the latest advances in materials science to develop minimally-invasive functional interfaces for monitoring and modulating the brain. Specifically, in this talk, I will present three materials-inspired strategies: 1) light sculpting in the tissue with ultrasound by turning the endogenous circulatory system into an "optical flow battery", 2) an intravascular light source inspired by the biomineralization process in nature, and 3) deep-brain neuromodulation inspired by the infrared sensitivity of rattlesnakes. I will conclude my talk by presenting an outlook on how advances in materials science may facilitate the development of next-generation brain-machine interfaces.

Integration of Polymers with Synthetic Soft Matter and Biological Matter Towards Sensing AlbertoSalleo; Stanford University, United States

An attractive feature of polymeric mixed conductors is their ability to swell in water thus forming a soft interface amenable to interacting with biological matter. Further, their ability to transduce ionic fluxes into electronic fluxes opens opportunities in sensing. Indeed, one can imagine combining the specificity and sensitivity of biological matter with the functionality of semiconductors in a single hybrid device. In this talk I will describe our work on integrating lipid bilayers, either synthetic or obtained from cell walls to sense a variety of environmental cues. For instance, we demonstrate specific sensing of toxins and viral fusion as well as the detection of opening and closing of selected ion channel. I will describe the surface treatments needed to enable such hybrid interface to retain its functionality as well as modeling of the device response and its limitations.

4:00 PM SB05.06.06
Vertical Organic Electrochemical Transistors for Enhanced Performance and Circuit Integration AntonioFacchetti; Northwestern University/Flexterra Inc, United States

Organic electrochemical transistors (OECTs) have been intensively investigated for applications in state-of-the-art wearable electronics and next-generation biosensor technologies due to their outstanding amplification, sensitivity to ionic and ultra-small electrical potential signals, compatibility with roll-to-roll fabrication processing, and low driving voltages. The far majority of OECT studies are based on a device structure comprising coplanar source-drain electrodes in contact with the organic semiconductor. Recently we proposed a new architecture where the electrodes are vertically stacked achieving high transconductance and current on-off ratio for both p- and n-type semiconductors. This vertical OECT architecture (vOECT) is also attracting for dramatically increase transistor density for high-resolution OECT sensors and complementary driving circuits. However, scalable patterning methods for organic semiconductors and optimization of the semiconductor topology for efficient monolithic integration of vOECTs remains technologically challenging, but essential for applications in complex and high-density OECT circuit arrays and multi-functional data analysis. In this presentation we report on the monolithic integration of flexible vOECT arrays for driving high-density (> 7 M OECT/cm2) active-matrix complementary logic circuits.

4:15 PM SB05.06.07
Stand-Alone Conformable Bioelectronics Based on Integrated Internal Ion-Gated Organic Electrochemical Transistors ClaudiaCea[1,2], ZifangZhao[1], JenniferGelinas[1] and DionKhodagholy[1]; [1]Columbia University, United States; [2]Massachusetts Institute of Technology, United States

Effectiveness of medical treatments can be greatly influenced by individual variations, prompting the need for methods that enable continuous monitoring of physiological signals and personalized responsive delivery of therapeutics. Implanted bioelectronic devices play a crucial role in these methods, but there are challenges that prevent their widespread adoption. The ability to perform these demanding electronic functions in the complex physiological environment with minimum disruption to the biological tissue remains a big challenge. An optimal fully implantable bioelectronic device would require each component from the front-end to the data transmission unit to be conformable and biocompatible. For this reason, organic material-based conformable electronics are ideal candidates for components of bioelectronic circuits due to their inherent flexibility, and soft nature. Here, we present a vertical internal ion-gated organic electrochemical transistors (vIGT) as a high-density, high-amplification sensing component as well as a low leakage, high- speed processing unit. In addition, a novel wireless, battery-free strategy for electrophysiological signal acquisition, processing, and transmission that employs IGTs and an ionic communication circuit (IC) is introduced. We show that the wirelessly-powered IGTs are able to acquire and modulate neurophysiological data in vivo and transmit them transdermally, eliminating the need for any hard Si-based electronics in the implant.

4:30 PM SB05.06.08
Organic Electrochemical Transistors as On-Site Signal Amplifiers for Electrochemical Aptamer-Based Sensing XudongJi and JonathanRivnay; Northwestern University, United States

Electrochemical aptamer-based sensors are typically deployed as individual, passive, surface-functionalized electrodes, but they exhibit limited sensitivity especially when the area of the electrode is reduced for miniaturization purposes. We demonstrate that organic electrochemical transistors (electrolyte gated transistors with volumetric gating) can serve as on-site amplifiers to improve the sensitivity of electrochemical aptamer-based sensors. By monolithically integrating an Au working/sensing electrode, on-chip Ag/AgCl reference electrode, and Poly(3,4-ethylenedioxythiophene)-poly(styrenesulfonate) counter electrode — also serving as the channel of an organic electrochemical transistor, we can simultaneously perform testing of organic electrochemical transistors and traditional electroanalytical measurement on electrochemical aptamer-based sensors including cyclic voltammetry and square-wave voltammetry. This device can directly amplify the current from the electrochemical aptamer-based sensor via the in-plane current modulation in the counter electrode/transistor channel. The integrated sensor can sense transforming growth factor beta 1 with 3 to 4 orders of magnitude enhancement in sensitivity compared to that in an electrochemical aptamer-based sensor (292 µA/dec vs. 85 nA/dec). This approach is believed to be universal, and can be applied to a wide range of tethered electrochemical reporter-based sensors to enhance sensitivity, aiding in sensor miniaturization and easing the burden on backend signal processing.

4:45 PM SB05.06.09
Soft Polymer for Enhanced Electron Transfer RossellaLabarile[1], DaniloVona[2], MariaVarsalona[2], MatteoGrattieri[2], MelaniaReggente[3], ArdemisBoghossian[3], FabianFischer[4] and MassimoTrotta[1]; [1]Consiglio Nazionale delle Ricerche, Italy; [2]Università degli Studi di Bari Aldo Moro, Italy; [3]Ecole Polytechnique Fédérale de Lausanne, Switzerland; [4]Haute école Spécialisée de Suisse Occidentale, Switzerland

Photosynthetic bacteria are anoxygenic microorganisms with highly versatile metabolism, as they use sunlight to oxidize a broad variety of organic compounds in addition to heterotrophic and photoautotropic alternative metabolisms. Conductive polymer layers on the surface of several bacterial species have been used to intercept and funnel the electron flow produced by microbial metabolism outside the cells and transfer it to an electronic circuit of a biohybrid device.
Polydopamine (PDA), produced by self-assembly of dopamine, is a very versatile and bioinspired polymer with widespread applications[1] mostly due its ability to adhere and cover surfaces of different chemical composition. The oxidative conditions employed for the formation of this dark insoluble polymer are mild and biocompatible and have inspired scientists to develop novel nanomaterials. Post-functionalization of PDA[2] also enables fine tuning of properties.
Furthermore, the ability of this monomer to self-assemble and polymerize in the bacterial growth medium was considered one of the requirements of the polymer to be used as coating material beside the tunable conductive properties and the flexible structure.
Biocompatibility of dopamine was tested by *in vivo* addition in the growth media of the photosynthetic purple non sulphur *Rhodobacter (R.) sphaeroides*[3] in anoxygenic conditions.
We have used PDA conductive coatings as biotic-abiotic interfaces in biohybrid photoelectrochemical devices through the encapsulation of entire bacterial cells or single components – e.g. photosynthetic reaction center (RC) - of *R. sphaeroides*[4,5], ensuring electronic communication of the biological component with the electrodes' surfaces in photoelectrochemical cells.

5:00 PM SB05.06.10
Soft and Ultra-Thin Wearable Tactile Interface with Electrical Impedance Tomography for High Spatiotemporal Resolution KyubeenKim, Jung-HoonHong and Ki JunYu; Yonsei University, Korea (the Republic of)

Wearable tactile mapping devices, a burgeoning area in human-computer interaction, have gained significant attraction due to their wide range of applications. These include interfaces for virtual reality and gaming devices, haptic feedback systems, and artificial skin for medical and robotic applications. Tactile sensors, as a cornerstone of this technology, must achieve high spatiotemporal resolution while maintaining soft mechanical properties to replicate the human sense of touch accurately. This is paramount in creating seamless and immersive user experiences, whether it's in navigating virtual environments or enabling prosthetic devices to mimic real tactile feedback. However, the development of these sensors presents distinct challenges. Current high resolution tactile sensing technologies predominantly rely on inorganic material-based sensors, which, despite offering high spatial resolution and reliability, pose significant limitations. They are inherently brittle and ill-suited to accommodate mechanical deformation, a critical attribute for wearable sensors meant to conform to human skin. On the other hand, soft materials, characterized by a low Young's modulus, are mechanically desirable for wearable tactile systems as they can conform to varied and changing surfaces. However, the fabrication processes for these materials tend to deviate from conventional microelectronics manufacturing techniques. This divergence often results in less sophisticated device structures, hindering the development of advanced and intricate tactile sensing systems.

To overcome these limitations, we propose an ultra-thin tactile sensor offering single-cell based multi-channel array functionality via the application of electrical impedance tomography (EIT). The sensor's stretchable sensing area consists of an elastomeric substrate and encapsulation, alongside a conductive functional layer comprising multi-wall carbon nanotube (MWCNT) layers. With a thickness of just 50 microns, this low-modulus, highly stretchable sensor can conformably adhere to human skin, maintaining robust functionality under applied force and mechanical deformation. The EIT computational analysis method allows our single-cell device to operate as a multi-channel array by reconstructing high-resolution conductivity changes within the broad sensing area. Piezoresistive effect-induced conductivity changes in the MWCNT-based conductive layer occur when external forces are applied, causing mechanical deformation, bending, and stretching. These changes can be mapped by EIT measurements using surrounding electrodes, achieving high-resolution detection of force applications. This EIT-based soft tactile interface can differentiate external pressures down to a 1mm scale, and vertical deformation of a few hundred micrometres. We validated our tactile sensor's functionality through two real-time applications: a wearable drone controller and a handwriting recognition interface. Our work illustrates the potential of applying EIT to soft, ultra-thin elastomeric devices for the development of high-performance wearable tactile sensing systems. These systems could find potential applications in healthcare, robotics, and human-machine interfaces, paving the way for more advanced tactile sensors in the future.

SESSION SB05.07: Poster Session II: Functional Soft Materials for Biointerfacing

8:00 PM SB05.07.01
Battery-Free, Fully Implantable Optoelectronic System for Programmable Photodynamic Therapy and Tumor Growth Monitoring In SikMin, KihoKim and Ki JunYu; Yonsei University, Korea (the Republic of)

Photodynamic therapy (PDT) is garnering attention as a prominent next-generation cancer treatment modality that utilizes specific wavelengths of light and photosensitizers to target and treat malignant tumors with high selectivity, resulting in minimal side effects and exclusively targeting cancer cells. Photosensitizers, selectively accumulated in cancer cells, transition into an excited state upon exposure to incident light energy. Subsequently, the surrounding oxygen is converted into reactive oxygen species, which serve as the mechanism for destroying cancer cells without inflicting significant damage or pain on normal cells, thus enabling the destruction of malignant tissue. Due to the limited penetration of light into deep tissues within living organisms, conventional PDT has predominantly been confined to epithelial cancers such as skin cancer, bladder cancer, and bronchial carcinoma. Furthermore, light delivery systems for PDT have relied on bulky and expensive laser-based equipment, posing significant constraints on user accessibility. To overcome these challenges, various LED-based fully implantable PDT systems have recently been developed. However, existing fully implantable PDT systems have faced limitations in precise light intensity control and adjustment of PDT parameters, as they are based on passive electronics or simple circuits incapable of performing advanced functions. Moreover, the implementation of wireless systems solely for power delivery has hindered the realization of tumor-related data monitoring based on bidirectional communication systems. Here, we introduce a battery-free and fully implantable optoelectronic system for PDT that enables precise light intensity control and scattered light measurement for tumor growth monitoring. This system involves the insertion of a μ-LED probe into the tumor to deliver light of 624 nm wavelength for PDT. The system allows for precise control of LED light intensity from 0% to 100% through wireless user control using a Bluetooth Low Energy communication. Additionally, the system incorporates the capability to monitor tumor growth by measuring the scattering of light within the tumor tissue through an external phototransistor placed outside the tumor. We performed in vitro experiments to confirm that the therapeutic effects vary at different light intensities of 0%, 30%, 70%, and 100%, and observed tumor growth inhibition through 624 nm-based PDT performed on a nude mouse model during a three-week in vivo experiment. Furthermore, we validated the feasibility of a system for monitoring relative changes in tumor size by measuring the scattered light from the tumor using a phototransistor, through ray-tracing simulation, ex vivo and in vivo experiments. This wireless electronics-based PDT system holds significant potential for expansion into a multimodal system with diverse functionalities such as a closed-loop system based on simultaneous treating and monitoring system, providing an opportunity to realize an effective and low side-effect cancer treatment while simultaneously collecting valuable feedback data related to the treatment.

8:00 PM SB05.07.02
The Relationship Between Surface Oxidation States and Antiviral Activity of Nano-Columnar Copper Thin Films KeisukeShigetoh, RieHirao and NobuhiroIshida; Toyota Central R&D Labs Incorporated, Japan

Antiviral coatings capable of inactivating a broad spectrum of viruses are crucial in the fight against viral mutation and emergence. Drawing inspiration from cicada wings known for their mechano-bactericidal properties, this study proposes the use of nano-columnar Cu thin films [1]. These thin films of Cu and its oxides were fabricated on a polymer surface by a sputtering technique, and their virus-inactivate capabilities were tested against both enveloped bacteriophage Φ6 and non-enveloped bacteriophage Qβ. Among the fabricated films, the Cu thin films showed the highest antiviral properties. The Cu thin films diminished the infectious activity of the bacteriophages by five orders of magnitude within half an hour, the Cu_2O thin films reduced it by three orders of magnitude, while the CuO thin films lessened it by less than one order of magnitude. Moreover, the excellent antiviral activity of Cu thin films was confirmed under the pseud-practical conditions using viral solutions that contain contaminating proteins, assuming such as in human saliva. After being exposed to ambient air for a month, the antiviral activity of the Cu_2O thin film dropped by one order of magnitude. Nevertheless, the Cu thin films consistently demonstrated a higher degree of antiviral activity compared to the Cu_2O thin films. A detailed analysis of the surface chemical states via X-ray photoelectron spectroscopy indicated that the fabricated Cu thin films showed slower oxidation to CuO than that of the Cu_2O thin films. Therefore, the formation of CuO possibly worked as a passivation layer for antiviral activity. The significant antiviral activity and oxidation durability of the Cu thin films can have immense practical utility, while their oxidation resistance might be a characteristic property of nanostructured Cu fabricated by the sputtering method. Finally, the antiviral activity of the nano-columnar Cu thin films against infectious viruses in humans was demonstrated by the binding inhibition of the SARS-CoV-2 spike protein to the angiotensin-converting enzyme 2 receptor (ACE2). The cleavage of the disulfide bonds in the spike proteins by copper ions is thought to have led to a significant reduction in binding affinity between spike protein and ACE2. The small mass loading (6 μg cm^{-2}) of the Cu thin films ensured transparency and flexibility of the substrates, with a low environmental risk; this is particularly useful for coating applications on disposable masks and filters.

8:00 PM SB05.07.03

Novel Structural Concept for High-Performance Gold Nanowire Stretchable Electrode Toward Ultra-Flexible Biomedical Applications SatoshiTakane[1,2], YukiNoda[1], NaomiToyoshima[1], TakafumiUemura[1,2] and TsuyoshiSekitani[1,2]; [1]Osaka University, Japan; [2]National Institute of Advanced Industrial Science and Technology, Japan

Gold nanowires (AuNWs) are attractive candidates to develop stretchable/biocompatible electrodes for use in biomedical sensors and neural interfaces. In this study, we propose a novel structural concept to enhance the strain-conductive performance of stretchable AuNW electrodes, the formation of a “macroscale mesh”-shaped “nanowire-thin film composite” structure in the AuNW electrodes. The AuNW-Au thin film (AuTF) composite electrodes with a mesh structure using an Ecoflex substrate decrease the absolute resistance by 22% and the normalized resistance changes by 24% compared with the AuNW electrode without a composite or mesh structure under 80% strain. Furthermore, our stretchable electrodes, composed of AuNWs, AuTFs, and Ecoflex have excellent biocompatibility and thus have great potential for use in biomedical applications.
Due to the growing demand for biomedical devices that are mechanically/biologically compatible with human organs, stretchable AuNW electrodes have attracted considerable attention because of their stable strain-conductive performance and biocompatibility owing to the nanowire network structure and the chemical inertness of gold, respectively. Although numerous studies have been conducted on stretchable AuNW electrodes, further improvements in the inadequate performance are required for these electrodes to appear in the industrial market.
As performance indicators of stretchable electrodes, two parameters are used to evaluate their strain-conductive properties: absolute resistance and normalized resistance change. Previous studies have suggested unique methods to improve the parameters of stretchable metal nanowire electrodes. For instance, the deposition of metal thin film on metal nanowire electrodes to form nanowire-thin film composite electrodes can reduce the absolute resistance of pristine metal nanowire electrodes over a broad strain range. However, this method may increase the normalized resistance change owing to the mechanical degradation of the metal thin film. In contrast, the formation of a mesh structure over metal nanowire electrodes can suppress the normalized resistance change under tensile strain. However, the formation of the mesh structure decreases the conductive area of the electrodes, which can induce a higher absolute resistance.
In this study, we integrate these two unique but imperfect methods and introduce this novel structural concept to AuNW electrodes to improve both their absolute resistance and normalized resistance change simultaneously for the realization of a high-performance and biocompatible electrode. The AuNW-AuTF composite electrodes with a mesh structure demonstrate 22% lower absolute resistance and 24% smaller normalized resistance change than those of the pristine AuNW electrode without a composite or mesh structure under 80% strain. From the result, we consider the AuTF in the composite electrode facilitates the current flow although the mesh structure decreases the conductive area of the electrode, whereas the mesh structure suppresses the mechanical failure of the AuTF by reducing the tensile stress. Additionally, the AuNWs, AuTFs, and Ecoflex have been previously used in biomedical devices and confirmed to be biocompatible. Therefore, mesh-shaped AuNW-AuTF composite electrodes can be applied to biomedical devices.
This novel structural concept which can improve strain-conductive performance is versatile for any type of stretchable metal nanowire electrodes. Using the AuNWs, we developed high-performance, elastic, and biocompatible electrodes suitable for use in biomedical devices. Our findings will accelerate the development of biomedical applications not only in academia but also in industry.

Silk Fibroin: An Adaptive Natural Surfactant for Aqueous Solution-Processed Nanoelectronics over All Substrates TaehoonKim and FiorenzoOmenetto; Tufts University, United States

Universal wettability is especially relevant for aqueous solution processing, which has gained prominence due to the growing demand for water-based fabrication of electronic and photonic components. Although water is an ideal solvent in terms of abundance and environmental sustainability, its relatively high surface tension limits its wetting capabilities. Surface pre-treatments, surfactants, or organic co-solvents are commonly used to enable aqueous solution processing. However, these methods have drawbacks, including their potential to impact material composition and morphology, increase costs, and raise environmental concerns. Thus, the development of a practical, versatile, and sustainable strategy for achieving universal wettability of aqueous solvents is of significant importance.

In this study, we present the utilization of silk fibroin (SF), a natural biopolymer, to modulate the interfacial energy landscape of hydrophobic surfaces. By incorporating small amounts of SF in thin-film precursor solutions, we demonstrate its role as an adaptive molecular bridge that enables the deposition of aqueous solutions on otherwise unwettable substrates. The amphiphilic composition of SF chains confers exceptional interfacial energy control, resulting in enhanced wetting behavior. Furthermore, we investigate the vertical self-segregation mechanism of SF during the formation of metal-oxide thin films, which can be harnessed to preserve the electronic properties of the active layers. By combining these effects, we successfully fabricate (opto)electronic structures on substrates with significantly different surface energies using all water-based precursor solutions, without compromising device performance due to the presence of the bioinspired surfactant.

Overall, these results present a comprehensive exploration of SF as a means to regulate the interfacial energy for achieving universal wettability in aqueous solution processing. The findings contribute to the development of practical and sustainable approaches for fabricating electronic and photonic thin films, offering potential benefits in terms of cost, energy consumption, and environmental impact.

Universal Assembly of Liquid Metal Particles in Polymers for Elastic PCB WonbeomLee, HyunjunKim and JiheongKang; Korea Advanced Institute of Science and Technology, Korea (the Republic of)

An elastic printed circuit board (E-PCB) is a conductive framework utilized for the facile assembly of system-level stretchable electronics. E-PCBs require elastic conductors having both high electrical conductivity and stretchability, tough adhesion to various electronic components, and negligible resistance changes even under large strain. Here, I present a new class of elastic conductor based on liquid metal particle assembled-network (LMPNet). The LMPNet conductor satisfies all the aforementioned requirements and enables the fabrication of a multilayered high-density E-PCB. Therefore, numerous electronic components could be intimately integrated to create highly stretchable skin electronics. Furthermore, I could generate LMPNet in various polymer matrices including hydrogels, self-healing elastomers and photoresists, and it shows the potential of the LMPNet for use in soft electronics. In my presentation, I will discuss the details of the synthesis of LMPNet and its exceptional properties.

Thermo-Responsive Shape Memory Polymer for use in Implantable Blood Pressure Measurement Device ArjanSall, ZoeSchofield and LiamGrover; University of Birmingham, United Kingdom

Hypertension or high blood pressure is a worldwide problem as it has become the leading cause in the growth of cardiovascular disease and premature death. This is especially true in countries of low to middle income [1]. As a result of this it is critical that patient’s blood pressure is measured on a regular basis in order to provide the correct treatment. Current methods of blood pressure measurement such as the sphygmomanometer or ambulatory methods in a clinical setting or electronic monitors used at home are either too invasive for the patient, are subject to the general fluctuation of blood pressure throughout the day or are only able to take singular measurements [2][3]. This has produced a need for a method of blood pressure measurement that is non-invasive and is able to provide continuous and reliable blood pressure measurement throughout the day. The focus of this presentation will be the development of a biocompatible shape memory polymer (SMP) that will be used in the fabrication of a blood pressure sensor that will allow a non-invasive implantation of the device into the subcutaneous layer of the wrist.
Mechanical characterisation of the current sensor material, polydimethylsiloxane (PDMS), will be presented to provide a reference point for the development of the SMP. The fabrication process of the SMP based on a blend of PDMS and Polycaprolactone will be described, and the systematic variation of the polymer composition will be explained detailing its impact on the shape memory effect elicited, while also comparing the mechanical properties of the SMP formulations to the pure PDMS. The mechanical characterisation carried out will focus on the compressive strength of the material where cyclic loading tests will determine the fatigue behaviour of the SMP and maximum compression tests will allow the calculation of the elastic modulus of the material. This will help determine the longevity of the implant. Aging of the samples using PBS at 37°C and 70°C will assess the ability of the material to withstand prolonged subcutaneous implantation. Dynamic mechanical analysis and dynamic scanning calorimetry will be used to determine the transition temperatures (T_g) of each of the SMP formulations with 37°C being the target temperature. Once an SMP with the target T_g has been produced the shape fixity, shape recovery and recovery rate will be tested. The goal for this project is to create a material that is able to withstand both the mechanical and biological stresses of blood pressure measurement and subcutaneous implantation which will allow the sensor to provide a reliable and consistent blood pressure measurement.

Mechanical Characterisation of Bio-Inspired, Multi-Compartment Soft Materials Endowed with Photo-Responsivity PatrickJ. Grimes[1], AgostinoGalanti[2], PierangeloGobbo[2], HenryE. Symons[1], SebastienRochat[1] and JunH. Park[1]; [1]University of Bristol, United Kingdom; [2]University of Trieste, Italy

Novel bio-inspired materials are of great interest to both the materials science and synthetic biology communities. The Gobbo group has recently developed “protocellular materials” (PCMs) assembled from protein-polymer protocell units (called proteinosomes) that are annealed into sheets through interfacial strain-promoted alkyne-azide cycloaddition (I-SPAAC).[1] Proteinosomes are comprised of a self-assembled, crosslinked nanoparticle membrane with an inherent molecular weight cut off (MWCO) (*ca*. 40 kDa) that allows the entrapment of cargoes of sufficiently high molecular weight.[2] The resultant PCMs formed of a population of covalently bound proteinosomes have been demonstrated to be robust and free standing in water.
The current trajectory of research in this area is towards improving the mechanical properties of the PCM's constituent proteinosomes, such that the resultant PCM can more closely mimic biological cell consortia. Moreover, developing the responsivity of PCMs to physiochemical stimuli is of great interest to allow the use of PCMs in a range of applications, including their potential use as a substrate on which to grow communities of living cells. The characterisation of PCMs has been restricted to confocal and electron microscopy, which, although both powerful techniques, is naturally limiting in the context of mechanical properties.[1]
In this communication I will show how a novel photosensitive crosslinker and a reactive thermoresponsive polymer can be combined to generate three-dimensional hydrogel “protocytoskeletons” within the proteinosomes of PCMs. This protocytoskeleton can be disassembled on irradiation, leading to the loss of mechanical integrity of the PCM. The selective disassembly of PCMs can be achieved with high spatio-temporal control on irradiation with UV light, and that disassembly can be monitored through the use of microindentation using a recently developed methodology.[3] Moreover, the photolabile proteinosomes of the PCM can be precisely photo-patterned to generate new, complex three-dimensional architectures. Whilst these novel materials are still in the early stages of development, they have the potential to be used in diverse applications from drug delivery to soft robotics.

8:00 PM SB05.07.08
Progress on Synthetic Mucin Mimics for Bacteriostatic Control of Wound Infections KeithE. Whitener[1], JeremyS. Marshall[2], KenanFears[1], MatthewD. Thum[1] and JinnyLiu[1]; [1]Naval Research Laboratory, United States; [2]Nova Research, United States

Mucins are high molecular weight glycoproteins which interact with bacteria to inhibit biofilm formation and therefore decrease the likelihood of infection establishment. However, the physical and biochemical makeup of mucins are highly dependent on their processing and environmental factors such as pH, temperature, ionic strength, and hydration level. Native mucins with prominent bacteriostatic activity are therefore too fragile to be deployed in the field as solutions for wound infection at this time. The work described here is part of NRL’s ongoing effort to find a robust fieldable polymeric platform which mimics the physical and biochemical structure of mucin and therefore recapitulates its bacteriostatic properties.
Mucin-O-glycans were cleaved from the peptide backbones of commercial porcine gastric mucin and native mucus obtained from pig stomach scrapings. The mucin mimic backbone we chose was carboxymethyl cellulose (CMC), as we have found that this polymer has a good cytotoxicity profile and rheological behavior that matches native mucin. Cleaved glycans were attached using EDC/NHS amidation and alkyne/azide click chemistry. Analysis was performed using MALDI mass spectrometry, rheometry, and viscometry. Cytotoxicity was determined by applying solutions to human fibroblasts and monitoring via fluorescence live/dead staining. Bacteriostatic and biofilm inhibition activity were determined by applying solutions to liquid and solid supported cultures of Pseudomonas aeruginosa and monitoring optical density.
Commercial mucins differ dramatically from native mucins in their physical and biochemical makeup: the glycans cleaved from native mucins do not match those cleaved from commercial mucins, the rheology is different and commercial mucins do not readily form hydrogels, the bacteriostatic properties are worse for commercial mucins than native mucins, and commercial mucins are far more cytotoxic than native mucins. However, we also found that the properties of the native mucins themselves change markedly as they go through the purification process. We are currently evaluating both the mucin glycan composition and the rheometry of the mucins and the CMC mimics, and we intend to evaluate their bacteriostatic properties under a variety of environmental stresses including pH and temperature changes.

8:00 PM SB05.07.09
Hofmeister Salts Enhance the Water-Responsive Actuation Energy of *Bacillus Subtilis* Cell WallsSeungriKim[1,2], HaozhenWang[2,3], DarjanPodbevšek[2] and XiChen[1,2,3]; [1]The City College of New York, United States; [2]CUNY Advanced Science and Research Center, United States; [3]The City University of New York, United States

Water-responsive (WR) materials have attracted significant attention due to their potential applications as high-energy actuators for soft robotics, smart structures, and energy harvesting devices. Recently, the cell walls of *Bacillus* (*B.*) *subtilis* have shown a high WR energy density of 72.6 MJ m^{-3}, surpassing that of existing actuator materials. In this study, we found that the exceptional WR energy density of the cell walls is attributed to nanoconfined liquids' properties. Furthermore, we discovered that strengthening the hydrogen (H-) bonding network of these nanoconfined liquids could further increase this energy density. To investigate this, we systematically modulated the H-bonding network using Hofmeister salts, specifically potassium sulfate (K_2SO_4) and potassium iodide (KI), which respectively strengthen and weaken the H-bonding network. Cell walls treated with a 10 mM K_2SO_4 solution exhibited a 22.4 % enhancement in energy density, reaching 101.8 MJ m^{-3}. However, higher concentrations (30-50 mM) of K_2SO_4 or any KI solutions led to reduced WR energy densities. These observations highlight the crucial role of the enhanced H-bonding network in achieving high-performance WR materials and emphasize the existence of a certain range of H-bonding strength for optimizing WR performance. Moreover, our study presents a cost-effective and scalable approach that utilizes Hofmeister salts to manipulate and enhance the WR performance of hygroscopic materials.

Tunable Interface of Polymeric Composite of Electroactive P3HT-MWCNT Thin Film for Bioelectronics Applications PaolaCampione[1,2,3], Grazia Maria LuciaMessina[1], FrancescaSantoro[3,2] and GiovanniMarletta[1]; [1]University of Catania, Italy; [2]Forschungszentrum Juelich, Germany; [3]RWTH Aachen University, Germany

One of the main challenges in bioelectronics concerns the development of materials able to respond to external stimuli and that are compatible with excitable tissues. In the last decades, conductive polymers (CPs) have been widely studied and developed as electroactive materials for applications in interfacing with biological systems. Their conductive properties allow cells or tissues growth upon stimulation, and their “soft” nature allows to form a better biotic-abiotic interface and reduce the mechanical mismatch between material and cells thanks to the elasticity of polymeric films that is similar to biological tissues [1]. CPs’ physical and iontronic-electronic properties can be optimized through the formation of composites enriched with carbon nanotubes or graphene in order to improve electron transport capacity, decrease impedance and increase flexibility. Their biocompatibility can be improved using functionalization methods with biologically active molecules [2] even if the influence of blending agents is still under investigation. The precise control of CP films nano-topography may have interesting effects for biointerfacing and improving the cell-chip coupling for cell activity recording and stimulation, acting on protein adsorption and cell adhesion.
In this work, we report on how to obtain stable electroactive nanocomposite dispersion using semiconducting regioregular poly(3-hexylthiophene-2,5-diyl) (P3HT), with different percentages in weight of multi-walled carbon nanotubes (MWCNT) and how to deposit to form homogeneous thin films. Their morphologies have been investigated by means of atomic force microscopy (AFM) and scanning electron microscopy (SEM), and the attention has been focused on the “cushion” effect due to the presence of the filler in the polymeric matrix that allow an interesting modification in mechanical properties (Young’s Modulus), analyzed by nanoindentation with atomic force microscopy (AFM), and the formation of a “softer” interface. Considering the central role of extracellular matrix protein in cell adhesion, their interactions at the interface with our systems were investigated by means of quartz crystal microbalance with dissipation monitoring (QCM-D). Noteworthy, it has been found that thanks to the larger available surface area of the blend thin film that act like a sponge, proteins are adsorbed in a very different way with respect to the bare semiconducting P3HT. Indeed, both the adsorption kinetics and the adsorbed mass are increased for each extracellular matrix proteins. The biocompatibility of the systems with different cell lines has been investigated as well as the effect on cell metabolism. Moreover, the effect of the systems on the variation of the distance between cell and electrode has been analyzed by focused ion beam - scanning electron microscopy (FIB-SEM). The realization of this nanostructured bioelectronic interface represents an example of 2.5D cell culture and promotes the optimization of the cell-chip coupling by tuning the cleft between the membrane of the cell and the electrode, also acting on the formation of the extracellular matrix protein coating that helps cells attach to, and communicate with, nearby cells, and plays an important role in cell growth, cell movement, and other cell functions.

Harnessing Cell-Free Protein Synthesis to Synthesize and Repurpose Viral Fusion Machinery EkaterinaSelivanovitch and SusanDaniel; Cornell University, United States

Viruses present one of the most efficient mechanisms for intracellular cargo (i.e. viral genome) delivery in which interactions at the virus-host cell interface dictate the delivery pathway. For instance, enveloped viruses- those that are 'wrapped' in a lipid bilayer, deliver their genetic cargo by first interacting with extracellular receptors, triggering a reaction cascade that results in fusion of the virus- and host cell lipid membranes and cargo release into the cytosol. Harnessing the efficiency of this translocation mechanism would drastically improve cellular uptake of therapeutic and bioactive cargo, currently a major obstacle in both agricultural and pharmaceutical scientific communities. In this work, we propose that viral fusion machinery can be repurposed for delivering user-defined cargo to cells containing the appropriate receptors. Hemagglutinin (HA), which is a protein found on the surface of influenza viruses and is known to mediate the virus-cell fusion mechanisms, is one of the proteins explored for this goal, along with several other viral membrane proteins including NiV-F and Spike (SARS 2). To circumvent

challenges associated with using infectious viruses or isolating/reconstituting membrane proteins, we use cell-free synthesis techniques to directly insert the proteins into our delivery vehicles of choice- liposomes. Not only can this approach be used to synthesize and design functional proteoliposomes, it provides synthetic mimics for isolating biological processes with control over the proteoliposome environment, which can be designed to be rudimentary or increasingly more complex.

8:00 PM SB05.07.12
Modulating Light Transmission using Particle-Based Displays PatrickA. Sullivan, DanielWilson and LeilaDeravi; Northeastern University, United States

E-inks utilize reflected ambient light rather than emitted light to display changes in text or images. As such, they can generate and hold patterns using very low power. Electrophoretic, electrofluidic and electrochromic techniques have been used commonly in this space together with homogenous materials designed specifically adapt to a biased stimulus to create these low power displays. We asked whether inherently asymmetric materials like Janus particles can be similarly used in low energy adaptive displace. In this work we investigate methods to synthesize and manipulate the transmissivity of Janus particles made with a metal and a dielectric material. Using custom designed optical chambers, we assayed the effect of electric field on particle rotation which ultimately correlated to a change in the transmission of visible light. Our preliminary results demonstrate a realistic approach to using asymmetric Janus materials as active elements for future display applications.

8:00 PM SB05.07.13
3D-Printed, Biomimetic, Electroconductive Scaffolds for the Promotion of Axonal Regrowth after Spinal Cord Injury LiamLeahy[1,2], IanWoods[1,2], JackMaughan[1,2,3], JavierGutierrez Gonzalez[1,2,3], MichaelMonaghan[2,3], AdrianG. Dervan[1,2] and FergalO'Brien[1,2,3]; [1]RCSI, Ireland; [2]RCSI and TCD, Ireland; [3]Trinity College Dublin, The University of Dublin, Ireland

Spinal cord injury (SCI) induces paralysis by damaging axons, neuronal processes that carry signals about the body. Injured axons are unable to regrow through the injury site, preventing functional recovery. Electrical stimulation (ES) has shown signs of being capable of inducing neuronal regrowth and support functional recovery. We propose that a tailored, electroconductive scaffold with composition designed to support and direct ES to regrowing axons may help drive them toward their distal targets and restore function. This is a difficult challenge to tackle, as the spinal cord is a complex tissue comprising discrete axonal tracts. An ideal scaffold for this system must mimic the structure of the cord and provide the supportive cell environment of the native extracellular matrix (ECM). To overcome this challenge, ECM-functionalised electroconductive scaffolds designed to mimic the axonal tract structure of the human spinal cord were fabricated by coating 3D-printed polycaprolactone (PCL) with conductive polypyrrole (PPy) nanoparticles and filling the structure with freeze-dried ECM to direct ES to promote neurite outgrowth.
Biomimetic PCL scaffolds were 3D-printed with an Allevi 2 printer to produce uniaxially aligned, interlocking cylindrical architectures, with several channel sizes to match the diameters of human spinal cord axonal tracts. PPy was polymerised *in situ* to form an electroconductive nanoparticle coating on PCL scaffolds, verified via FTIR and SEM imaging. Electroconductivity was measured via the 4-point probe method. Scaffold biocompatibility was assessed by growing neurons on 2D PPy/PCL films and measuring metabolic activity, cellular DNA and neurite outgrowth. Neurotrophic ECM was directionally freeze-dried within scaffold channels to mimic the native spinal cord environment and further promote neurite extension[1]. Neurons were electrically stimulated on ECM-functionalised PPy/PCL and PCL scaffolds using an Ionoptix bioreactor and imaged to assess the effect of ES-induced neurite extension over 7 days.
3D-printed PCL scaffolds of all channel sizes were successfully coated with PPy nanoparticles. Conductivity of the PPy coating was measured at 15±5S/m, 30 times higher than native spinal cord tissue. PPy/PCL substrates were as biocompatible as PCL, indicating the suitability of PPy coated scaffolds for neuronal tissue engineering. Freeze-dried ECM formed aligned pore structures within scaffold channels, providing a physical guide for neurite outgrowth. No difference in electrical properties or cell activity were measured in scaffolds of various channel sizes, showing scaffolds can be scaled to match native cord structures without losing functionality. Electrically stimulated neurons on PPy/PCL scaffolds showed increased average neurite length and total cellular DNA compared to PCL scaffolds, suggesting ES via a conductive scaffold promotes healthy neuronal growth.
In conclusion, biomimetic 3D-printed electroconductive scaffolds were manufactured and characterized and demonstrated excellent biocompatibility. Scaffolds were successfully scaled to match the sizes of axonal tracts, and electrically stimulated neurons exhibited increased neuite extension within PPy/PCL scaffolds compared to inert PCL controls, showing the potential of the electroconductive scaffold to direct neurite growth. Taken together, these results show that ES applied via ECM-functionalised electroconductive scaffolds drives neurite outgrowth, a key requirement to achieving functional recovery post-injury, highlighting the potential use of this novel combination therapy for SCI repair.

Nuclease Responsive DNA Probe Conjugated Particles for Efficient Detection of Bacteria Sun-JungKim[1] and Yong-BeomShin[1,2]; [1]Bionano Health Guard Research Center, Korea (the Republic of); [2]Korea Research Institute of Bioscience and Biotechnology, Korea (the Republic of)

Recently, poisoning due to microbial contamination of food is continuously increasing, and interest in food safety is increasing. Therefore, it is important to quickly detect microorganisms in the field to eliminate contamination. Microorganisms can be contaminated not only by the food itself but also by the cook's hands and tools, so a technology capable of quickly detecting microbial contamination is very necessary. Traditionally, detection of microorganisms is done through culture-based assay, which has the disadvantage of taking too long, so fast and accurate molecular biological tests are attracting attention. Polymerase chain reaction (PCR) is widely used because it is accurate and has specificity, but it has to go through several steps and it takes some time to use it as a detection system directly in the field. Although adenosine triphosphate (ATP)-based detection system has been widely used for fast and simple, it is difficult to know the exact level of contamination because it detects not only live cells but also dead cells and other impurities such as organic debris. Therefore, there is a problem that the level may appear even after sterilization through disinfection. Bacteria produce various nuclease such as exo, endo for various biological function and the degree of bacterial contamination can be estimated through the activity of nucleases. In this study, we prepared nuclease responsive DNA conjugated particles. We designed various nuclease responsive DNAs to detect bacteria by various methods such as color reaction, fluorescence and luminescence. In our system, the DNA probe bound to the particles is cut off by the nuclease secreted during the lysis of the bacteria and a signal is generated so that the presence or absence of bacterial contamination can be easily measured in a short time. Moreover since only live bacteria can be detected, the exact degree of contamination can be confirmed and it is thought that it will be able to be used quickly in the field.

Nanomaterials and Additive Processes for Transparent and Stretchable Organic Electrochemical Transistor TakaakiAbe, TeppeiAraki, ShoyaMatsuda, NaokoKurihira, MihokoAkiyama, TakafumiUemura and TsuyoshiSekitani; SANKEN (The Institute of Scientific and Industrial Research), Japan

Flexible electronic devices with optical transparency exhibit biocompatibility and increase the versatility of measurement methods, such as multimodal sensing that enables simultaneous usage in optical, electrical, and ionic methods. In this study, we develop fully transparent and flexible organic electrochemical transistors (OECTs) using transparent conductors of Ag nanowires (AgNWs) and conductive polymers. They demonstrate the feasibility of multimodal acquisition of biological signals. In addition, stretchable materials are newly developed to construct fully transparent and stretchable OECTs, which can contribute to the creation of next-generation medical sensors.
Sensors for use as personal healthcare devices that can measure biological signals continuously and for a long time for the early detection of diseases have been expected [1-2]. OECTs can be used to fabricate circuits suitable for such biological signal measurements owing to their advantages of low operating voltage, mechanical flexibility, and high mutual transconductance [3]. In particular, the high mechanical flexibility decreases the wearing discomfort because flexible biological tissues change their shape. Additionally, if the device has high transparency, it enables multimodal sensing that can utilize electronic, optical, and ionic methods simultaneously, as well as miniaturization through the stacking of devices. Therefore, stretchable and transparent conductors and semiconductor materials for electronic devices can facilitate a new electronic design.
In this study, we develop highly transparent and flexible OECTs using AgNWs and poly(3,4-ethylenedioxythiophene):poly(styrene sulfonate) (PEDOT:PSS) [4]. High bending durability and high visible transmittance (>90%) are achieved by controlling the orientations of the AgNWs used for wiring. Furthermore, additive layering techniques, such as printing and lamination processes, are employed to decrease damage to the nanomaterials constituting the OECT. In addition, these transparent and flexible OECTs exhibit properties comparable to those of conventional opaque OECTs. Consequently, low-noise measurements of brain waves and ion concentrations, as well as simultaneous optical measurements of blood flow and pulse waves, are feasible and a step toward the quantification of human stress.
Furthermore, stretchable channel materials are developed to create more flexible OECTs. A patterning process of AgNW-based conductors and semiconductors on elastomers is concurrently developed to fabricate fully stretchable and transparent OECTs. In particular, the stretchable conductors and channel materials exhibit durability under 50%–100% strain; thus, they can be used for fully transparent and stretchable sensors for the long-term and multimodal assessment using electrophysiological, optical, and ionic methods.

Transforming the Brain to Transparent Hydrogels for Long-Range Microscopic Analysis of the Nanoparticles Interactions with Brain Tumors MaryamGolshahi, HamedArami and LaylaKhalifehzadeh; Arizona State University, United States

Microscopic analysis of the tumor response to therapeutics reagents such as nanoparticles and chemotherapy drugs is limited to conventional tissue sectioning, which is followed by immunostaining and optical microscopy. Tissue sectioning is destructive and microscopic data obtained from a limited number of thin tissue slices (typically with 5-50 μm thickness) are not representative of the efficacy of the treatment over the entire tumor mass. Microscopic results obtained from a single or limited number of tissue slices can be even more misleading for brain tumors with high levels of heterogeneity such as glioblastoma multiforme (GBM). Therefore, developing methods for microscopic analysis of the whole tumor tissue without any sectioning can be beneficial by providing an overall feedback about the treatment rates at different parts of the tumor mass. This capability can potentially enhance the treatment effects and minimize the probability of the tumor recurrence by optimizing the treatments to target the entire tumor. Here, we used a polymerization method that helps to transform the whole mouse brain to optically transparent acrylamide-based hydrogels without losing the microscopic or nanoscale structure of the tumors at both extracellular and intercellular levels. Orthotopic U87 tumors (human-derived GBM cells with GFP signal) were generated in mouse brains (n=3). Therapeutic nanoparticles (gold nanoparticles tagged with Cy5 fluorescent molecules) were injected into tumors stereotactically using a magnetic resonance imaging (MRI) guided approach. Mice were euthanized 24h post-injection and brains were excised and immersed in a monomer solution, followed by a low-temperature polymerization and tissue-clearing technique known as CLARITY. Then, the entire volume of these transparent brains were analyzed using different microscopy techniques, including confocal and light-sheet microscopy. The interaction of the nanoparticles with tumors was investigated using their Cy5 and GFP signals, respectively. We were able to generate three-dimensional maps verifying the distribution of the nanoparticles in tumors and other parts of the brains (e.g., the ventricles). Immunostaining of these brains is a reversible process and a series of staining and microscopies can be used for analyzing different treatment biomarkers (such as cell death, necrosis, and immune response) separately. Expansion of this method will enable more accurate pre-clinical and clinical investigations to evaluate the efficacy of a variety of therapeutic agents and their potential side-effects within the entire tumors and other parts of the brain.

Aptamer-Decorated Prussian Blue Nanozymes for Selective Detection of Dopamine Han BeenLee, Do HyeonKim, Se HwaCheon, Chang HyeonHa, Su JeongLee and Gi hunSeong; Hanyang University, Korea (the Republic of)

Dopamine (DA) is a catecholamine neurotransmitter that plays a significant role in the central nervous and hormone systems of humans. Abnormal levels of DA can lead to various diseases, including Parkinson's disease and depression. While electrochemical measurements have gained considerable attention for their simplicity and responsiveness, the electrochemical detection of DA is easily influenced by the simultaneous presence of ascorbic acid (AA) or uric acid (UA). This is because AA and UA can also undergo oxidation at a potential similar to that of DA. Therefore, it is crucial to develop a sensitive and selective detection method for DA in biological fluids to overcome these challenges.
Colorimetric assays have obtained much attention due to their rapid observation by the naked eye and user-friendly operation. However, assays relying on the reduction of the substrate of DA have limitations in terms of selectivity because substances such as AA and UA, which have a similar structure to DA, also possess the ability to reduce substrates. To address this issue, we employ an aptamer to ensure high selectivity in real samples. Aptamers are molecular recognition components based on nucleic acids. These functional single-stranded nucleic acids can adopt a three-dimensional structure and exhibit exceptional specificity and affinity for target molecules.
Nanozymes, nanomaterials that exhibit enzyme-mimicking activities, have emerged as promising alternatives to natural enzymes like horseradish peroxidase (HRP) due to their exceptional catalytic activity, ease of modification, and remarkable stability. Given their intriguing and practical characteristics, nanozymes have been employed in various biomedical point-of-care applications, including biosensing and immunoassays. Among the different types of nanozymes, prussian blue nanoparticles (PBNPs) have gained widespread use in the field of biosensing and immunoassays. This is attributed to their outstanding peroxidase-like activity, robust stability, and high sensitivity.
In this study, we employed chitosan (CS), a polycationic biopolymer with amine groups in its backbone, to stabilize PBNPs. This resulted in the formation of CS-coated prussian blue nanoparticles (CS/PBNPs), which modified the surface charges of the PBNPs to a positive state. By virtue of the positive charges conferred by CS, the negatively charged dopamine binding aptamer (DBA) could be immobilized onto the CS/PBNPs through electrostatic interactions.
DBA molecules, known for their specific affinity towards DA, were adsorbed onto the surface of CS/PBNPs, leading to the inhibition of the peroxidase-mimicking activity of the CS/PBNPs. However, upon the introduction of a DA sample solution, the DBA molecules on the CS/PBNPs surface strongly bound to the DA, inducing a conformational change in the aptamer and causing its separation from the CS/PBNPs. Consequently, as the concentration of DA increased, more surface area of CS/PBNPs became exposed, resulting in an elevation of their peroxidase-like activity.
In conclusion, we successfully developed an aptamer-based colorimetric assay utilizing CS/PBNPs for the detection of DA in concentrations ranging from 0.25 μM to 100 μM, with a limit of detection (LOD) of 0.16 μM. The recovery results of DA concentrations (0.25 μM, 0.5 μM, and 1 μM) in spiked human serum were 92.6%, 102.1%, and 103.9%, demonstrating high reproducibility and reliability of the CS/PBNP-based apta-sensor for determining DA levels in clinical applications. Furthermore, compared to typical immunoassays, this aptamer-based nanozyme inhibition/activation assay eliminates the need for a washing step, making it highly practical in terms of reducing assay time and maintaining high sensitivity. Based on its excellent performance, this biosensor holds promise as a valuable tool for the rapid, selective, and sensitive detection of clinically significant small molecules, such as hormones, in practical applications.

8:00 PM SB05.07.18
Modification of Conductive Surfaces via Tailored Dyes Derivatives for Bacterial Detection SvenjaHerdan[1], LaurieNeumann[1], LeaKönemund[1,2], RebekkaBiedendieck[1], Hans-HermannJohannes[1,2], DieterJahn[1] and WolfgangKowalsky[1,2]; [1]Technische Universität Braunschweig, Germany; [2]Cluster of Excellence PhoenixD, Germany

The improvement of a biosensor which combines fast and highly sensitive detection of bacteria with easy handling is of great interest, for example, in the fields of medicine or the food industry. In the future, pathogenic bacteria could be detected at an early stage. Conventional methods such as enzyme-linked immunosorbent assay (ELISA) or polymerase chain reaction (PCR) are time-consuming, expensive and require professional expertise. Therefore, a sensor with low costs and fast, reliable results is of great importance.
In previous works, functionalized porphyrins with two different linkers have been synthesized for a bacteria sensing system. The linkers are divided into two different groups: linker **A** which can bind to an electrode (gold or indium tin oxide) and linker **B** which can bind to bacteria. For linker **B** there are two possible bio receptors a peptide group and cysteine group enabled to connect the Gram-negative bacterium *Escherichia coli* (*E. coli*) K12, a common well investigated apathogenic model strain. An analysis with fluorescence-lifetime imaging microscopy (FLIM) could already show a decrease of the fluorescence lifetime of the porphyrin molecule due to changes in their chemical environment or conformation as they have an interaction with cell components of the bacteria cells. These results show that both bio receptors in combination with the porphyrin molecule can be used as a bio linker on an electrode surface for further bacteria detection methods. (Neumann, 2021).
The goal of this research is to extend the existing system. For this purpose, porphyrin was replaced by another dye, boron-dipyrromethene (BODIPY). Reasons for this are that BODIPYs are thermally and photochemically stable, have a higher fluorescence quantum yield (BODIPYs ≈ 90%; porphyrins ≈ 5%; depending on the substitution of the dyes), are well soluble and chemically stable and they are biocompatible. Furthermore, it should be emphasized that the synthetic effort and thus also the yield loss can be reduced, because only two steps are necessary for the BODIPY linker synthesis and six steps have so far been necessary for the porphyrin linker synthesis. In addition, it is possible to use a boronic acid instead of a peptide or cysteine group for linker **B**. Boronic acids have the property to bind to *cis*-diols, which are located on bacterial cell wall. By adapting linker **B** as previously mentioned, a general sensor could be developed regardless of whether the bacteria are Gram-negative or Gram-positive.

Key words: porphyrin, BODIPY, *E. coli* immobilization, biosensing

8:00 PM SB05.07.19
Mediated Electron Transfer in Bacteria for Charge Generation NdepanaG. Andrew and HemaliRathnayake; University of North Carolina at Greensboro, United States

The increase in energy demand led to remarkable research activities on energy generation, storage, and conversion, and many different kinds of nanoscale materials have been explored to harness energy. However, recently microorganisms including bacteria and algae have been shown to display significant roles in developing high-performance probes owing to their abilities to reproduce fast, self-repair, self-assembly, and wide range of biosynthetic capabilities. Among a wide variety of microbes, bacteria have been well studied offering their adaptation to broaden research directions for developing a variety of sustainable energy generation, conversion, and storage systems with either improved or new capabilities and performance.
However, adapting bacteria to develop the aforesaid systems with required performance entails a clear understanding of how bacteria interact with the surface or mediator and how chemical, physical, and intrinsic properties of the “mediator” affect interaction with bacteria to produce expected results and programmable characteristics. The processes of metabolic electron transfer from bacteria to an extracellular mediator and vice versa in diverse exoelectrogenic and non-exoelectrogenic bacteria have been studied but only a few have been investigated in-depth to understand bacteria responses and study their electron transfer processes at their respective biotic interfaces with a variety of organic and inorganic mediators. Electron transfer in bacteria can

occur either directly or indirectly, however, only a limited set of bacterial species can transfer electrons directly to the electrodes, most bacteria require an external electron transfer mediator to transfer charges to the electrode for efficient energy generation. Although Various compounds have been tested in the past as exogenous mediators, there are potential classes of compounds that are yet to be explored.
Herein, we gather a new concept of using a metal-organic framework as an external mediator for electron transfer at the interface of *E.coli*, we grow live *E.coli* cells on a functional MIL-88B MOF to construct a charge capacitive bio interface. The aim is to study the interactions at the bio interface and employ these interactions to generate a charge-capacitive smart interface for energy storage and study the metabolic electron transfer mechanism at the bio interface resulting in the generation of energy at the bio interface. In theory, the MIL-MOF will stimulate the bacteria's metabolic electron transfer processes by modulating charge injections at the *E.coli*/MOF interface to generate charge capacity through electron transfer processes. So far from our preliminary result, we obtained a charge capacity of 399 Fg^{-1} at a scan rate of 5 mV/s generated at the *E.coli*/MOF interface as compared to 195 Fg^{-1} generated at the *E.coli* (control) interface only at the same scan rate. Our results suggest the potential of MIL-88B MOF as an external mediator in facilitating electron transfer at the *E.coli* interface to generate a higher charge capacity twice the magnitude of *E.coli* charge capacity.
This study proposes that by combining the distinctive functionalities of living bacteria with biocompatible abiotic MIL-MOFs, it is possible to create smart interfacial biosystems for charge generation and storage with programmable features.

8:00 PM SB05.07.20
The "SLIC" Idea: Superhydrophobic Lubricant Infused Composite (SLIC) is a Non-Toxic, Inexpensive Polymer Composite Coating that Prevents Biofouling ThomasLeFevre, JosephDaddona, WilaiwanChouyyok, StonyAkins, GeorgeBonheyo, CurtisLarimer and RaymondS. Addleman; Pacific Northwest National Laboratory, United States

This poster will describe the development and testing of a Superhydrophobic Lubricant-Infused Composite (SLIC) coating that inhibits the attachment of organic and biological matter. Biofouling is the unwanted accumulation of biological material, such as bacteria, algae, mussels, and barnacles, on a surface. Biofouling is an expensive and disruptive problem in many water-related industries such as shipping, hydropower, and aquaculture. Antifouling coatings are commonly utilized to mitigate fouling, but the existing coatings that are effective are also toxic or extremely expensive.

To address the toxicity and expense of existing coatings, SLIC is a PDMS-based coating with several additional ingredients that provide strength, texture, and porosity in the coating. This work will describe the design, selection, and optimization of biomimetic additives designed to provide strength, abrasion resistance, and a surface microstructure that mimics the superhydrophobic texture of natural surfaces such as the lotus leaf. We will outline a process for incorporating lubricant oil into the coating to provide a low surface energy liquid layer, similar to fish slime, that inhibits biological adhesion. The oil can flow into cracks and crevices in the coating, providing a self-healing mechanism when the coating is scratched. SLIC was designed to be an antifouling coating that is tough, long lasting, economical, and toxin-free. It can also be easily customized for specific use cases such as nets that require a flexible coating.

Results of experiments to quantify antifouling performance by exposing varying formulations of SLIC to mussels at different life stages will be presented. Use of a machine learning algorithm to assist in the detection and counting of mussel larvae on surfaces will be described. Results of antifouling performance tests showed that SLIC prevented mussel larvae attachment in static conditions is better than the leading antifouling paint and significantly better than uncoated stone, metal, and plastic surfaces. In summary, SLIC was designed as a high performance low-cost antifouling coating. It can prevent mussel adhesion and other types of fouling while remaining nontoxic.

8:00 PM SB05.07.21
A Smart Coating with Integrated Physical Antimicrobial and Strain-Mapping Functionalities for Orthopedic Implants YiZhang and QingCao; University of Illinois at Urbana-Champaign, United States

As the prevalence of orthopedic implants increases within the aging population, these patients become increasingly vulnerable to risks associated with periprosthetic infections and instrument failures. There have been attempts to reduce the risk of infection by modifying the implant surface to impede bacterial adhesion or applying antibiotics to the surface to kill local bacterial populations. But these methods are rarely used due to their own limitations. For instance, coating implant surfaces with hydrophilic molecules or quorum-sensing inhibitors can block bacterial adhesion, but this strategy fails if even a few bacteria manage to attach and form an antibiotic-resistant biofilm. Another significant complication associated with orthopedic implants is aseptic implant failures, which require surgical revisions and affect over 10% of patients. These failures manifest primarily as loosening caused by mechanical shielding or implant breakage due to fatigue failure. Presently, these complications are diagnosed using x-ray or bone scan imaging. However, these techniques only detect gross implant movement, which occurs long after the inception of loosening or implant-related microfractures, even with harmful radiation and high costs.

To address these challenges, we develop the design of a smart-coating foil that can be applied to the surfaces of orthopedic implants. This foil provides both long-term physical bactericidal action and sensitive strain mapping to mitigate both septic and aseptic orthopedic failures. The outer surface of the foil is designed with high-density nanopillars, mimicking the surface nanotopology of cicada wings. These structures exhibit strong mechanical bactericidal effects against bacteria commonly associated with orthopedic implant infections without directly releasing any chemicals. A multiplexed strain-sensing array is integrated into the foil. The high piezoresistive coefficient of single-crystalline silicon ensures accurate detection of strain down to 0.01% experienced by orthopedic implants. The nanometer-scale film thickness allows the foil to bond with the implant surface, while the integration of silicon gauges with multiplexing transistors enables strain mapping across the implant surface. This can assist in the detection of early-stage spinal fusion and pedicle-screw loosening, guiding patient-specific care and early intervention against aseptic instrument failures. The strain-mapping array and mechano-bactericidal nanostructures both showed excellent biocompatibility and long-term stability in vivo.

8:00 PM SB05.07.22
Specific Protein Metalization in Cell-Derived Extracellular Matrix via Antibody-Guided Biotemplating for Utilization in Hydrogen Production and Sensing Chang WooSong and JaewanAhn; Korea Advanced Institute of Science and Technology, Korea (the Republic of)

In nature, there is a myriad of hierarchical biological structures consisting of various proteins that are challenging to replicate by artificial synthetic methods. To exploit such complex structures in material science, biotemplating has attracted great attention over the past decades, wherein exotic functionalities from inorganic materials were able to impart into the biological scaffolds by electroless plating or physical vapor deposition of metal. However, the biological architectures used in prior reports were stereotypical and ordinary with the lack of ways to manipulate their morphological features such as porosity, alignment, and organization, limiting their usage in more broad fields. To this end, we propose the cell-derived extracellular matrix (ECM) is an excellent option to be used as a template for achieving diverse biomimetic architectures. ECM has evolved into intricate mesh structures intertwined with various fibrillar protein assemblies to conduct mechanical support of cells, assist in the proliferation and migration of cells, and transport the signal to the cells. Because of these important biological roles of ECM, a variety of ECM have been created with customized morphological and chemical characteristics, especially for cell biology, pharmacology, and tissue engineering. Despite already developed diverse protein assemblies in ECM, there was no attempt to use them as a biological scaffold for metallization. To use a specific ECM protein as a template, we introduced 1.4-nm nanogold-conjugated antibodies and labeled them to a specific protein called fibronectin within the ECM, and then the nanogold acted as the nucleation sites for Au growth. The metalized ECM could be electrically conductive after thermal sintering or second metal growth (e.g., Pd and PdPt alloy) with additional functionality. Following the deposition of PtNPs, the fabricated conductive biocomposite showed catalytic activity in the hydrogen evolution reaction (HER), maintaining its stability for up to 500 repeated cycles. In addition to hydrogen production, the electrically conductive biocomposites by the second metal growth demonstrated the prominent hydrogen sensing performance at room temperature.

8:00 PM SB05.07.23
A Photo-Patternable Stretchable Gold Conductor by Electroless Plating Process HinataMitomo[1,2,3], KeitaSuzuki[4], KatsuyaTennichi[5], YuanyuanZhou[1,2,3] and NaojiMatsuhisa[1,2,3]; [1]Research Center for Advanced Science and Technology, The University of Tokyo, Japan; [2]Institute of Industrial Science, The University of Tokyo, Japan; [3]Department of Electrical Engineering and Information Systems, Graduate School of Engineering, The University of Tokyo, Japan; [4]Tanaka Kikinzoku Kogyo K.K., Japan; [5]EEJA Ltd., Japan

Stretchable gold thin-film electrodes exhibit superior biocompatibility and conductivity. In previous studies, stretchable gold thin films have typically been prepared by thermal evaporation [1,2]. However, to maintain high stretchability, the sheet resistance was limited to an order of 10 Ohm/Sq. Moreover, it is crucial to minimize gold waste resulting from deposition in unnecessary areas.
In this study, we present highly stretchable and conductive gold electrodes fabricated by a photo-patternable electroless plating process. Our gold thin film exhibited a remarkably low sheet resistance of 0.25 Ohm/Sq. at 0% strain and 2.7 Ohm/Sq. at 50% strain. The film remained highly conductive, even under a 200% strain. These electrical and mechanical characteristics were preserved when the gold was patterned to a resolution of 100 µm. Fabrication began by spin-coating a primer polymer layer, which adheres gold nanoparticles from the colloid solution. Deep ultraviolet exposure can deactivate the capacity to capture gold nanoparticles, enabling patterning. Subsequent electroless plating allowed the gold nanoparticles to grow into a uniform film with a thickness of 200 nm. We controlled the aforementioned plating conditions to regulate microcrack formation under strain, and obtained the high stretchability of our gold. The high conductivity and patternability of our stretchable gold pave the way for the development of stretchable, high-density electrodes for electrophysiology measurements, and stretchable antennas for wireless wearable electronic devices.

8:00 PM SB05.07.24

Design and Characterization of Magnetically Controlled Minicell-Driven Biohybrid Microswimmers for Targeted Drug Delivery Applications SaadetF. Baltaci Demir[1,2], IrinaKalita[3], BirgulAkolpoglu[1,4] and MetinSitti[1,4,5]; [1]Max Planck Institute for Intelligent Systems, Germany; [2]University of Stuttgart, Germany; [3]Max Planck Institute for Terrestrial Microbiology, Germany; [4]ETH Zürich, Switzerland; [5]Koc University, Turkey

Bacteria-based biohybrid microswimmers, combining motile bacteria cells with synthetic materials, have emerged as promising vehicles for alternative therapeutic applications such as active drug delivery. However, existing biohybrids face many limitations that hinder their translation to clinical applications considering the poor penetration ability through the barrier or tissue, biostability and limited payload capacity. Here, we propose a magnetically controllable drug-loaded biohybrid microswimmer driven by a bacterial outer membrane vesicle, referred to as minicell, which offers unique capabilities such as enhanced penetration capability thanks to its sub-micron size and long-term stability with self-propulsion because of its non-dividing but metabolically active nature. Additionally, minicells exhibit a large drug encapsulation capacity compared to traditional nanocarriers. In this study, we fabricated motile minicells produced by engineered *Escherichia coli* strain inducibly expressing a biotin display system on their surface, enabling us to benefit from the robust biotin-avidin interaction with streptavidin-coated magnetic nanoparticles onto the minicells. We optimized the production of self-propelled minicells via several purification methods and investigated their growth and motile behavior in various culture and physiological media over time. We showed the magnetic control and guidance of minicell-driven biohybrids by an external magnetic field, and compared their 2D swimming motility with and without applying uniform magnetic fields. Furthermore, we optimized the loading efficiency of the chemotherapeutic drug doxorubicin into the minicells and demonstrated the time-dependent release of the drug molecules. Overall, the minicell-driven biohybrid design proposed here offers a magnetically guided active drug-carrying nanosized platform for targeted delivery while preserving its motility and durability during the extended application period.

8:00 PM SB05.07.25
Designed Nanoparticle-Polymer Conjugates as Nucleants for Multiple Protein Types XiaotingGuo and VickiL. Colvin; Brown University, United States

Determining the three-dimensional structure of proteins is crucial for understanding their function, but the limited ability to form protein crystals suitable for X-ray diffraction has become a bottleneck problem in this field. Through the control of nanocrystal and protein interactions, it is possible to both enhance the nucleation of protein crystals as well as create three-dimensional structures of nanoparticles within the protein crystals. The length of polymers (e.g. poly(ethylene) glycol) bound to a nanocrystal surface can mediate protein interactions with the nanocrystal-polymer conjugates: specifically, longer polymers at the nanoparticle surface allow for more protein association with conjugates.
We showed that the addition of AuNP-PEG to hen egg white lysozyme (HEWL) led to an increase in the number of crystal hits across a wide range of crystallization conditions. The compared result in crystallography indicates with the incorporation of conjugate system, protein structures can be dissolved with the existence of the nano-nucleant inside the protein matrices. Surprisingly, the incorporation of AuNP-PEG inside the crystals did not affect their quality. The statistical values listed in Table 1 for the AuNP-HEWL co-crystal remained consistent with those obtained for the pure HEWL crystal, indicating that the addition of AuNPs did not alter the crystal properties in any way.
AuNP-PEG can also be used as a general nucleant for different protein species. 5 illustrate a comparison of hit counts for eight proteins, namely Ferritin, Proteinase K, Thaumatin, p-HSA, Concanavalin A, Glucose Isomerase, Insulin, and Xylanase, based on 48 screening conditions. The results indicate that the addition of AuNP-PEG increased the number of hits in each protein species compared to the control group without the presence of AuNP solution.
The potential of AuNP-PEG to affect liquid-liquid phase separation (LLPS) of FUS-LC proteins was also investigated, which plays a crucial role in understanding the formation and solubilization of protein droplets in cellular processes. The addition of AuNP-PEG to FUS-LC led to an acceleration of LLPS and the formation of more condensates.
Within the protein-nanoparticle conjugate co-crystals, we further demonstrated that the incorporation and arrangement of nanoparticles at regular distances within the protein crystal is reflective of the fact that the protein crystal nuclei form on the nanoparticle surface; for lysozyme, these nuclei have been studied via both light scattering and diffraction. Most studies find that they consist of four or more lysozymes with dimensions near 9 to 18 nm. In the presence of nanoparticles, these proto-nuclei form in and around nanoparticle-polymer conjugates that can themselves have polymer shells as thick as 30 nm. This would suggest that incorporated nanoparticles could have as much as 40 to 50 nm of surface polymer and protein surrounding them, giving rise to a lower limit for the interparticle separations that is in good agreement with that found from the radial distribution function (e.g. 47 nm). The composites grow when these protein-nuclei encounter other similar structures and begin to crystallize, leading to the formation of composite crystals. Anisotropic materials align due to the faster spreading of proteins along the a-b face of crystal during growth which causes the preferential orientation of the rods perpendicular to the c-axis.

8:00 PM SB05.07.26
Strain Dependency of Charge Transport of Stretchable Conjugated Polymers Seung HyunKim and KilwonCho; Pohang University of Science and Technology, Korea (the Republic of)

Stretchable polymer semiconductors have attracted significant interest for their potential in flexible and stretchable electronics. However, there remains challenging work in controlling the strain-induced properties of conjugated polymers (CPs), such as crystallinity, morphology, and charge transport properties. Herein, we delve into the contribution of microstructures to their mechanical and electrical stretchability. To achieve stable electrical properties during deformation, specific structural requirements are discussed, such as the inclusion of a less-rigid donor moiety between diketopyrrolopyrrole (DPP) acceptors. This addition reduces crystalline packing, thereby significantly enhancing the mechanical deformability of the CP films. Furthermore, the multiscale structural and electrical analyses revealed that a less-rigid backbone allows for the strain-induced flattening of the polymer chains. The flattening of polymer chains reduces the activation energy barrier for hopping transport to 38 meV at 80% strain. Consequently, strain-induced alignment and conformational changes of polymer chains provide favorable pathways for charge transport, resulting in a significant increase in hole mobility of up to 180% under an 80 % tensile strain. We believe that our study on the strain-induced structural changes in CP films, ranging from molecular to mesoscale, would contribute to a better understanding of the strain dependency of charger transport of stretchable conjugated polymers.

8:00 PM SB05.07.27
Fabrication and Characterization of Electrospun PU and Vapor Phase Polymerized PEDOT:Tos Fibers for Flexible Electronics JiaxinFan, JinsilKim and FabioCicoira; Polytechnique Montreal, Canada

Soft conductive materials have gained considerable attention owing to their vast potential in wearable sensors, biomedical devices, and flexible displays. The successful implementation of high-performance flexible electronics requires exploring suitable materials with superior electrical and mechanical properties.[1] Poly-(3,4 ethylenedioxythiophene) (PEDOT) doped with various counterions has been extensively studied for flexible and stretchable electronics due to their ambient stability and solution processability. Additionally, their electrical conductivity and mechanical properties can be further tailored by blending with additives based on the application requirements.[2] PEDOT-based materials are also compatible with various fabrication and processing techniques, such as drop-casting, spin-coating, printing, and electrospinning. Among various techniques, electrospinning offers unique advantages, including a straightforward setup, versatile material choice, scalable production, tunable fiber properties, and compatibility with various substrates. Electrospun nanofibers exhibit desired properties for soft electronics.[3] For PEODT-based materials, the spinnability can be improved by adding carrier polymers.

In this study, we focus on the preparation of conductive fiber mats based on a mixture of polyurethane (PU) and PEDOT doped with tosylate (PEDOT:Tos). The fabrication process involved electrospinning the mixture of PU and oxidant, iron (III) p-toluenesulfonate (tosylate), followed by vapor phase polymerization (VPP) to obtain PEDOT:Tos. PU was utilized as both carrier polymer and an additive for enhancing the electrical and mechanical properties. The resulting fibers have an average diameter of ~ 800 nm. An average sheet resistance of 16.4 ± 1.5 kΩ/sq was obtained for the PU/PEDOT:ToS fiber mat after VPP. To investigate the influence of different electrospinning solution mixtures and conditions, we analyzed the morphology, electrical conductivity, electrochemical behaviors, and mechanical properties of the fiber mats fabricated with various spinning solution mixtures and fabrication conditions. Preliminary demonstration of utilizing the conductive fiber mats for flexible electronics will also be presented. This comprehensive investigation provides insights into optimizing and engineering the properties of fiber mats for their application in soft electronics.

Silent Speech Interface using Wearable Strain Sensors Based on Crystalline Silicon Nanomembrane KihoKim, TaeminKim, KyowonKang and Ki JunYu; Yonsei University, Korea (the Republic of)

The Silent Speech Interface (SSI), which uses non-verbal forms of communication like sign language, provides a promising alternative for those unable to vocalize. This technology interprets intended words by monitoring facial muscle and skin movements during verbal communication. Notably, SSI benefits from wearable sensors that use surface electromyography (sEMG), as it doesn't necessitate constant video surveillance in a fixed setting. However, conventional sEMG electrodes face issues related to signal quality, such as low signal-to-noise ratio and interelectrode interference, obstructing the precision of facial mapping.

In this study, we have developed an innovative SSI incorporating epidermal strain sensors made from crystalline silicon nanomembrane (SiNM). These sensors, thanks to their piezoresistive

properties, are considerably more sensitive than standard metal foil-based strain gauges. Each sensor includes two strain gauges placed perpendicularly to measure biaxial strain independently. We attached four sensors to four facial regions with the greatest areal changes, as identified by vision recognition.

We selected 100 English words at random from the Lip Reading in Wild benchmark set and trained 100 strain data sets for each word on a deep-learning-based classifier. To evaluate the classification performance of our system, we used a 5-fold cross validation which resulted in an average accuracy of 87.53%. In the same validation, a 4-channel sEMG system of identical dimensions (< 0.1mm^2) to our unit strain gauge exhibited only 41.53% accuracy due to its low SNR caused by high impedance. We also conducted an experiment with 200-word classification to check the effect of spatial resolution on accuracy. Under identical conditions, the 16-channel and 8-channel systems showed 81.87% and 71.63% accuracy, respectively. This demonstrates the potential for this technology to support everyday conversation in the future.

SESSION SB05.08: Bioinspired Adaptive Systems and Biosensing Platfoms

Soft Transparent Microelectrodes based Multimodal Devices for Biointerfacing LuyaoLu; The George Washington University, United States

Optically transparent microelectrodes are important technologies that can integrate with tissues and allow light to transmit in both directions for co-localized and crosstalk-free electrical recording, optical imaging, and optogenetics. Existing transparent microelectrodes rely on external optical fiber, camera, or microscope setups for optical biointerfacing. In this talk, I will discuss several of our recent examples of soft transparent microelectrodes based multimodal optoelectronic devices enabled by new concepts in materials, micro- and nano-fabrication techniques, and engineering designs. Those innovative devices integrate microscale light-emitting diodes, photodetectors, with transparent microelectrodes on a chip. They are designed in flexible formats and allow for stable, high-fidelity, high-content electrical and optical recording and modulation of many important cellular parameters (intracellular calcium dynamics, metabolic activity, biopotentials, etc.) across different spatiotemporal resolutions. We envision those multimodal devices will open up new windows to understand important biological processes at the cellular, tissue, and organ levels with high spatiotemporal resolution and selectivity.

8:15 AM SB05.08.02
Bio-Inspired Multiple Tactile Sensing System for Simultaneous and Real-Time Perception Bo-YeonLee, SeonggiKim, SunjongOh, YoungdoJung and HyuneuiLim; Korea Institute of Machinery and Materials, Korea (the Republic of)

A human can intuitively perceive and comprehend complicated tactile information. Because the cutaneous receptors distributed in the fingertip skin receive different tactile stimuli simultaneously, and the tactile signals are immediately transmitted to the brain. Although many research groups have attempted to mimic the structure and the function of human skin, it remains a challenge to implement human-like tactile perception process within one system.
In this work, we developed a real-time and multimodal tactile sensing system, mimicking the function of cutaneous receptors and the transmission of tactile signals from receptors to the brain, by using multiple sensors, a signal processing and transmission circuit module and a signal analysis module. The proposed system is capable of simultaneously acquiring four types of decoupled tactile information within a compact system, thereby enabling differentiation between various tactile stimuli, texture characteristics, and consecutive complex motions. This skin-like three dimensional integrated design provides further opportunities in multimodal tactile sensing systems.

8:30 AM SB05.08.03
Advancing High-Performance Printed Soft Mechanical Sensors Through Microstructure Control of Conductive Composites Yi-FeiWang, AyakoYoshida, YasunoriTakeda, TomohitoSekine, DaisukeKumaki and ShizuoTokito; Yamagata University, Japan

Soft mechanical sensors have emerged as highly desirable components for the next generation of biomedical devices, wearable electronics, and soft robotics [1]. Their inherent flexibility and stretchability enable seamless integration onto soft and irregular surfaces, empowering them with advanced sensing capabilities for a wide range of external mechanical stimuli. Recently, conductive composites have garnered significant attention in the research community as promising materials for soft mechanical sensors due to their cost-effectiveness, ease of processing, and the ability to tune their electromechanical performance [2]. A key aspect of achieving high-performance sensors lies in the effective control of the conductive composite's microstructure, as it directly impacts its electromechanical properties [3]. For instance, introducing microcracks in the conductive film significantly enhances its strain sensitivity, while constructing a conductive layer with a porous structure or micropatterning surface is commonly employed to achieve high sensitivity in pressure sensors. However, previous approaches have often relied on complex material synthesis and expensive manufacturing processes, presenting scalability challenges and severely limiting their practical applications.

This report highlights our recent progress in materials design aimed at controlling the microstructure of conductive composites to realize high-performance printed soft mechanical sensors. We have developed a novel brittle-stretchable conductive network that generates controllable microcracks, resulting in high sensitivity to applied strain while maintaining a large working range [4]. This innovative approach successfully overcomes the trade-off between sensitivity and sensing range commonly encountered in stretchable strain sensors. We have also successfully formulated a novel printable ink by mixing PDMS, CB, and a deep eutectic solvent (DES). This ink spontaneously forms a microporous conductive architecture without the need for complex processing [5, 6, 7]. Leveraging this composite, we have achieved highly sensitive pressure sensors and low hysteresis stretchable strain sensors using straightforward manufacturing techniques. Furthermore, we have utilized thermally expandable microspheres to create irregular microdome surfaces, facilitating the easy fabrication of flexible printed pressure sensors with superior reliability and uniform performance. When compared to previous studies, our approaches offer significant advantages: (i) simple ink preparation without the need for complex materials synthesis; (ii) compatibility with printing technologies, ensuring superior scalability, patternability, and cost-effectiveness; and (iii) easy microstructure control in conductive composites, resulting in soft mechanical sensors with exceptional performance in terms of sensitivity, working range, reliability, and uniformity. We are confident that these achievements will provide valuable insights into materials design and microstructure control of conductive composites, thereby advancing their practical applications in the field of soft electronics.

This study was partially supported by JSPS KAKENHI Grant Number 23K13806.

Engineering Flexible Electronics for Monitoring Epithelial Integrity *In-Vitro* and *Ex-Vivo*SophieOldroyd, SarahBarron, DavidBulmer and RoisinOwens; University of Cambridge, United Kingdom

Inflammatory bowel disease (IBD) is a widespread condition, with a forecasted prevalence of 1.1% by 2025 [1]. It presents with chronic symptoms such as abdominal pain and diarrhoea and is characterised by a leaky gut barrier, which has increased permeability due to changes in localisation of tight junction proteins [2]. However, a detailed understanding of the disease pathway is limited, and current methods of assessing gut tissue health *ex vivo* are impeding progress in the field. The techniques need re-designing in the modern era given advancements in technology. This work presents flexible bioelectronic devices that permit real-time recordings of changes in gut tissue. The ability to assess gut health in living tissue is important in establishing and monitoring phenotypes associated with gastrointestinal diseases.

All-planar conformable devices with multiple working electrode sizes (from 25 to 1000 µm) and an internal counter/reference electrode (CE/RE) were fabricated using previously developed techniques [3]. On the bottom, and between each of the layers, parylene C was used for insulation. Conductive tracks, outlines, and contact pads for the electrodes were formed using photolithography and gold deposition. Electrodes were coated with PEDOT:PSS, a conducting polymer used to increase volumetric capacitance. The electrodes were characterised by

electrochemical impedance spectroscopy (EIS) and brightfield microscopy. *In-vitro* testing utilized a human colonic epithelial cell line, Caco-2. The cells were grown on Transwell® inserts and differentiated for 21 days. The ability of the device to measure barrier integrity, perturbations, and recovery in real-time was assessed via the transient addition of EGTA. The devices were tested e*x-vivo* on small intestine and colonic tissue from wild type-C57BI6 male mice. Cell viability was confirmed with confocal microscopy and staining. Extracted transepithelial resistance values, based on simple equivalent circuit models, were confirmed against the gold standard methods for *in-vitro* and *ex-vivo*, using the EVOM3™ and Ussing Chambers respectively.

This work highlights the first instance of an all-planar flexible electronic device that can monitor epithelial barrier function and perturbations at the air liquid interface. The mechanical flexibility of the device allows for direct and conformable contact with biological surfaces, to provide a quantifiable electrical readout under physiological conditions. The multi-electrode design established a minimum electrode radius (400 µm) needed to capture the epithelial properties, and chemical disruption, of colon cell lines and mouse colon tissue. The sensing area achieved is one order of magnitude smaller than previously reported, highlighting the increased sensing efficiency of the design. The device achieves comparable sensitivity with a planar CE/RE compared to an external CE/RE. As this device was the first of its kind, readouts were validated against gold standard TEER measurements, which showed comparable trends with a reduction in measurement error. We confirm the device is biocompatible and does not negatively affect the barrier properties under study. Future work could look to apply this technology for spatially mapping local and real-time changes in epithelial barrier properties for toxicology and drug screening applications.

Multimodal Flexible Fiber Antenna Sensor for Physiological and Environmental Sensing MerveGokce[1], EilamSmolinsky[1], Louisvan der Elst[1], CreasyClauser Huntsman[2] and AlexanderGumennik[1]; [1]Indiana University Bloomington, United States; [2]Cook Medical Technologies, United States

The real-time monitoring of a patient's health condition during medical operations is crucial to the patient's comfort, safety, and treatment success. While there are many advanced biomedical devices on the market that monitor various physiological parameters, they are limited with respect to sensitivity, accuracy, compatibility, and durability. It is vital to improve physiological monitoring limitations to minimize potential trauma, discomfort, and complications after surgery. Fiber device technology enables the designing of fiber-embedded sensors that provide higher sensitivity, accuracy, and spatial resolution through its complex cross-sectional geometry and material properties [1]. Thermally drawn polymer fibers offer high flexibility, durability, and better compatibility, making integrating fiber sensors into fabrics and biomedical devices easier [2].
Here we present the first sub-terahertz fiber antenna sensor capable of high spatial resolution, high sensitivity, and large dynamic range physiological monitoring and cyber-physical interfacing. The sensitivity and spatial resolution of the fiber sensor are high enough for practical operations such as integrating the flexible fiber sensor into medical devices. The fiber sensor monitors physiological and environmental signals in real-time, where the sensing modality, either physiological or environmental, is defined by the electronics used to control the order of the mode coupled to the fiber sensor. While the high sensitivity of the fiber sensor is derived from its unique geometry, materials, and unique manufacturing approach [3], its spatial resolution results from the frequency decomposition of the reflected signal off the sensing point along the fiber and thus is the function of the operation bandwidth. Our multimodal flexible fiber sensor is a better candidate for improved monitoring of patients' well-being and better patient care than the current sensors used in minimally invasive operations. The application area of our fiber sensor is not limited to the biomedical field but also smart fabrics, cyber-physical and human-robot interactions, and environmental detections due to its ability to perform selective, multimodal measurements.

Biomimetic Sequence-Templating Approach Towards a Multiscale Modulation of Chromogenic Polymer Material Properties YuyaoKuang, Ze-FanYao, SujeungLim, CatherineNgo, MeganRocha, DmitryFishman and Herdeline AnnArdoña; University of California Irvine, United States

Polydiacetylene (PDA) is an established conjugated polymer material useful as a colorimetric indicator of environmental conditions, such as small molecule binding, mechanical force, heat, or solvent, for multiple sensing applications due to the structural dependence of their optical and electronic properties. With its emerging utility for biological applications, there is a critical need to develop PDAs that can be processed in the physiological-relevant environment with predictive structures and properties. Using sequence-tunable peptidic supramolecular interactions to template diacetylene monomer assembly offers a facile synthetic approach and enables a way to rationally influence PDA structure and properties via peptide sequence engineering. This presentation focuses on investigating the structural influences of peptide templating groups on PDA structures and functional properties across length scales by molecularly controlling the properties of peptide moieties through steric effects and hydrophobic interactions. In particular, a library of peptide-PDA conjugates with systematically varied dipeptide segments is established to demonstrate the influence of residue sterics, polarity, and position of substitution on multiscale PDA material properties. We show that steric effects predominantly influence the electronic structure and resulting trends in chain conformation-dependent photophysical properties. On the other hand, distinct trends were observed for bulk properties, such as film conductivity and cellular response to material interfacing. By tuning peptidic molecular volume and polarity, we exhibited a general increase in conductivity with smaller peptide molecular volume and higher hydrophobicity. The properties of peptide-PDA films suggest more interplay between residue size and hydrophobicity at larger length scales. In summary, this work provides new molecular-level insights on how sequence-tunable sterics and polarity can be used as a synthetic handle to rationally modulate multiscale structure-function correlations for peptide-PDAs as functional biomaterials. These findings pave the way for further developing sequence-defined programmable properties and complex behavior for peptide-PDAs, such as the adaptive evolution of their properties in response to living systems interfaced with these functional biomaterials in physiologically relevant environments.

9:30 AM *SB05.08.07
Biomaterials Strategies Towards Multimodal Neural Probes for Chronic Neural Recording, Chemical Sensing and Delivery XinyanT. Cui; University of Pittsburgh, United States

Microelectrode array (MEA) devices, placed in the nervous system to record and modulate neuroactivity have demonstrated success in neuroscience research and neural prosthesis applications. Functionalizing the microelectrode sites on MEAs to enable neurochemical sensing and delivery adds additional dimensions of information, and presents tremendous potential for understanding neural circuits and treating neurological diseases. In this talk, I will introduce the methods by which we enable chemical sensing and delivery from MEAs. By incorporating nanocarbon into the conducting polymer electrode coating, we achieved direct detection of electroactive species such as dopamine, melatonin, and serotonin. By immobilizing enzymes or aptamers on nanostructured electrodes, we achieved multisite detection of glutamate, GABA, and cocaine. By incorporating nanocarriers into conducting polymer coating, we enabled on-demand drug delivery. Multisite and multiple analyte detection or neurotransmitter delivery along with neural recording have been demonstrated with these MEAs. Chronic neural interface performance has been sub-optimum. Quantitative histology, explant analysis, and 2-photon imaging revealed biofouling, neuronal damage, inflammation, and oxidative stress at the site of implants, as well as material degradations. We use several bioengineering strategies to minimize these failure modes. First, materials and devices that mimic the mechanical properties of the neural tissue have been developed and shown to significantly improve device-tissue integration. Secondly, biomimetic coatings and drug delivery have been applied to reduce biofouling and inflammatory responses. These approaches may be combined to achieve long-term and high-fidelity multimodal neural interfacing.

Magnetoelectric Metamaterials and Miniature Bioelectronics JacobT. Robinson; Rice University, United States

Magnetic fields show very little absorption or reflection in bone and tissue, making these fields magnetic materials ideal as a transducer for bioelectronic systems. Here I will discuss how we can engineer the properties of magnetoelectric materials to show electrical and optical properties not found in nature. With these magnetoelectric metamaterials, we can rapidly control nerve

impulses in rodent models for nerve injury and control the activity of engineer cells. Furthermore, magnetoelectrics enables us to create highly efficient, miniature battery-free bioelectronic networks for cardiac and neural applications. Overall, engineering the material properties of magnetoelectrics and magnetoelectric metamaterials provides a route to multifunctional miniature bioelectronic networks.

Cell Mechanotransduction Driven by Bio-Organic Optoelectronic Devices VanessaSpagnolo[1], Leonardomaver[1], JohannesGladisch[2], IwonaBernacka Wojcik[2], GabrieleTullii[1], EleniStavrinidou[2] and Maria RosaAntognazza[1]; [1]Istituto Italiano di Tecnologia, Italy; [2]Linkoping University, Sweden

Biophysical cues, especially mechanosensation, play a fundamental role throughout life, starting from early embryonic development over function and interplay of cells and tissues in the adult body up to regeneration processes. Tissue regeneration, which includes phenomena like cell division, differentiation, migration and expulsion is triggered by extracellular mechanical cues. The body's capability to regenerate decreases with age and therefore impacts our life in sometimes detrimental aspects.
Currently available tools to modulate or control mechanosensation often lack features necessary for *in vitro* and *in vivo* applications, in terms of efficiency, reliability, reversibility and spatial sensitivity. Here we show a novel approach to control mechanosensitive ion channels, through exogenous organic semiconductors. Materials in this class are fully biocompatible, thus offering the perspective for *in vivo* application, they can be easily processed in several forms, such as thin films, microstructured devices or nanoparticles. Most importantly, they are characterized by distinctive opto-electrical properties, providing excellent visible light responsivity, as well as electron and ion conductivity.
In this work we explore the opportunity to use organic semiconductors, and in particular conjugated polymers, to control the activation of mechano-sensitive ion channels, in a reliable and effective manner. We critically discuss results obtained with different tools, including polymer thin films and microstructured devices. In more detail, we present first examples, to the best of our knowledge, of devices based on conjugated polymers to activate PIEZO channels in mammal cells.
Our results may contribute to develop innovative smart materials for tissue regeneration and pathologies involving mechanosensation driven by physical cues.

Monitoring Water Permeation in Flexible Bioelectronic Devices MassimoMariello and StephanieP. Lacour; Ecole Polytechnique Federale de Lausanne, Switzerland

Most bioelectronic interfaces call for long-term operation. Their formfactor requires new packaging strategies to ensure hermeticity, thinness and mechanical compliance. Inspired from display technologies, organic-inorganic multilayers are promising candidates to package thin, flexible and miniaturised bioelectronic devices. Besides the materials challenges associated with the choice of suitable thin films, stacking and deposition methods, quantitative evaluation of their barrier performance is a must. We have developed real-time monitoring methods of permeability or water transmission rate of thin film multilayers leveraging magnesium (Mg) degradation under physiological conditions. Water permeation drives Mg hydrolysis. Using Mg film electrical and electrochemical sensors prepared with thin-film microfabrication, embedded in bioelectronic interfaces, ultra-low detection of water permeation (as low as of 3.3×10^{-8} g/m^2/day at room temperature) can be achieved. This method should provide useful information on novel encapsulation strategies for miniaturised, long-term bioelectronic implantable systems.

Noninvasive Optogenetics to Study Brain-Body Circuits RitchieChen; University of California, San Francisco, United States

Viscerosensory signals, such as hunger pangs, pain, and a racing heart, shape our cognitive state and behavior. However, the neural basis that drives these adaptive behaviors remains poorly characterized, largely due to a lack of tools to map, record, and modulate specific cell types within a dynamically moving body. This presentation will highlight recent advances in optogenetics that enable noninvasive photoactivation of electroactive cell types in the body using external, distally placed light sources. I will demonstrate how these methods can be applied to manipulate cardiac physiology and establish causal roles of visceral cardiac signals in influencing anxiety-like behavior in mice.

2:00 PM SB05.10.02
Nanoparticles for Wireless Magnetoelectric Neural Modulation Ye JiKim, NoahKent, FlorianKoehler, EmmanuelPaniagua, NicoletteDriscoll, MarieManthey and PolinaAnikeeva; Massachusetts Institute of Technology, United States

Magnetic nanomaterials offer a minimally invasive alternative to invasive neuromodulation implants. A variety of magnetic nanomaterials have been developed to transduce physiologically benign magnetic signals (field-frequency product $H \times f < 5 \times 10^8$ Am^{-1}s^{-1}) to signals perceived by biological receptors including heat, mechanical stimulation, chemical release, and electric field. Magnetoelectric nanomaterials composed of magnetostrictive (magnetic field to strain) cores and piezoelectric (strain to electric polarization) shells are particularly promising candidates for wireless transgene-free neuromodulation in deep-brain structures. Although strain-mediated magnetoelectric (ME) materials have been shown effective for neuromodulation at the millimeter and micrometer scale, achieving efficient ME coupling at the nanoscale remains a challenge. Here we report a strategy for enhancing the strain-mediated ME coupling at the nanoscale. We synthesize core-double shell magnetoelectric nanodiscs (MENDs) with Fe_3O_4 - $CoFe_2O_4$ - $BaTiO_3$ architecture. In these nanodiscs, magnetostriction is enhanced through anisotropic shape and interfacial strain between Fe_3O_4 and $CoFe_2O_4$, which collectively enable the generation of 30 μV in $BaTiO_3$ piezoelectric shell, which predicted numerically and measured experimentally via an electrochemical three-electrode cell. Although the electric field generated by individual MENDs is far below than the necessary potential change to reach the action potential threshold in neurons, we find that MENDs robustly evoke neural activity in vitro in the presence of a magnetic field. To explain this finding we propose a biophysical model of repeated neuronal depolarization based on cable theory and stochastic membrane potential fluctuations. Using the proposed model, we optimize the stimulation parameters in vitro, and then translate our approach to neuromodulation in vivo. Specifically, we show remote control of behavior in mice following 1.5 μL MEND injections at 1 mg/mL concentration (~100 times lower concentration than previous studies involving nanomagnetic transduction regardless of mechanism). We offer a mechanistic approach for further refinement of magnetoelectric neuromodulation at the nanoscale with the goal of empowering neurobiological discovery.

Engineering a Biohybrid Neural Interface for Synaptic Deep Brain StimulationLéoSifringer[1], AlexFratzl[2], StephanIhle[1], ParthChansoria[1], JensDuru[1], BlandineF. Clément[1], SineadConolly[1], BenediktMaurer[1], ChristinaM. Tringides[1], LeahMönkemöller[1], GiuliaAmos[1], SeanWeaver[1], SophieGirardin[1], KatarinaVulić[1], SimonSteffens[1], AnnaBeltraminelli[1], EylulCeylan[1], SrinivasMadduri[3], MarcyZenobi-Wong[1], BotondRoska[2], JanosVörös[1] and TobiasRuff[1]; [1]ETH Zürich, Switzerland; [2]IOB Basel, Switzerland; [3]University Geneva, Switzerland

Restoring functional vision in blind patients lacking a healthy optic nerve requires bypassing retinal circuits. This can be achieved by high resolution stimulation of the visual thalamus, which is located deep inside the brain and serves as the main input to cortical circuits underlying vision. However, available deep brain stimulation electrodes suffer from low stimulation resolution, limited biocompatibility and limited coverage of the targeted tissue. To overcome those limitations, we propose a novel living biohybrid neural interface with the goal of restoring functional vision in the blind without a healthy optic nerve. Our interface uses living on-chip grown retinal neurons as relays to convert electrical signals from a stretchable microelectrode array into synaptic stimulation of a neural target tissue.
Our interface is based on a stretchable micropatterned microelectrode[1,2] array onto which we align axon guiding microfluidic structures that enable unidirectional guidance and merging of axons to form an artificial optic nerve. We increase the biocompatibility of our device by replacing the Polydimethylsiloxane (PDMS) based nerve forming channel with a collagen or gelatin methacryloyl (GelMA)[3] tube that is only 300 μm in diameter and directly integrated onto the PDMS device.
We demonstrate the seeding of retinal spheroids into our biohybrid devices using a modified fluid force microscope. The retinal ganglion cells form an artificial optic nerve up to 3mm long that can transit from the device into the PDMS-bound hydrogel tube to reinnervate a matrigel-based target structure in vitro. We show that we can stimulate individual retinal spheroids using our stretchable microelectrode array. We also present in vitro data on how spikes propagate within the biohybrid implant to modulate thalamic target activity using glass and CMOS[4] multielectrode arrays. Finally, we present first progress towards in vivo implantation.

Biohybrid Interfaces with Light-Sensitive Dynamic Polymers for Neuroelectronic Applications FrancescaSantoro; Forschungszentrum Jülich/RWTH Aachen University, Germany

Bioelectronic platforms more and more aim to integrate into tissues and organs in a seamless way to monitor and eventually restore loss functionalities. This is particularly relevant for brain implants where the functional electrical connections can be restored by the use of functional electrodes to stimulate injured area due to pathologies such as neurodegenerative diseases. In this scenario, polymers have found a major use in the last decade to design and engineer organic biointerfaces[1] between electronics and brain cells also with their integration into soft flexible probes. However, existing platforms still lack: 1) 2.5-3D features to locally better anchor to the target area, 2) undergoing on demand mechanical plasticity which is greatly required because of micromovements and tissue reshaping over time and 3) materials which exhibit also electrical plasticity and not only conventional passive behavior to better enhance the ion-electronic transduction process which is at the core of the neuronal communication in the brain. Here, we will present how conjugated polymers can be engineered with azopolymers (opto-sensitive polymers which switch from cis to trans conformation upon certain light exposure) to feature diverse optoelectro-mechanical properties from nano to macroscale lever in organic bioelectronic platforms. In particular, we will discuss how azo-based materials can be patterned into 2.5-3D designs to locally couple to cells and thus dynamically tune the cell electrode interface over time[2]. Furthermore, these films can be further engineered with PEDOT:PSS to create dynamic organic electrochemical transistors (OECT, Figure 1) which also exhibit opto-electronic short and long term plasticity, enabling the use of such platforms as neurohybrid[3] devices.
This new class of on demand organic opto-electronic devices[4] paves the new for bioelectronic implantable platforms to be more biomimetic as they can adapt to the 3D environment of the neuronal tissue and its continuous reshaping, also featuring neuromorphic electrical behavior.

Hair-Compatible Sponge Electrodes Integrated on VR Headset for Electroencephalography HongbianLi, HyonyoungShin, MinsuZhang, Jose del R.Millán and NanshuLu; The University of Texas at Austin, United States

Electroencephalography (EEG) combined with virtual reality (VR) represents a promising method for the measurement of brain activity in an immersive and interactive environment, which can provide insights into cognitive and neural processes. However, current VR-EEG headsets mainly rely on rigid comb electrodes, which are uncomfortable after prolonged wear. To address this limitation, we created soft, porous, and hair-compatible sponge electrodes based on conductive poly(3,4-ethylenedioxythiophene) polystyrene sulfonate (PEDOT:PSS)/melamine (PMA), and integrated them onto a VR headset through a customized flexible circuit for multichannel EEG during VR task performing. Our PMA sponge electrodes can deform to make contact with the scalp skin through hairs under the pressure naturally applied by the strap of the VR headset. As a result, our VR-EEG headset is capable of recording alpha rhythms during eye-closure at both hairless and hairy sites. Furthermore, we developed a VR task to evoke the contingent negative variation (CNV) potential and achieved a classification accuracy of 0.66±0.07. Our sponge-electrode-integrated VR headset is user-friendly and easy to set up, marking a step toward future reliable, comfortable, and reusable VR-EEG technology.

A Flexible and Switch-Matrix-Addressable Active Electrode Array Based on Complementary Organic Electrochemical Transistor and p-n Diode Technology IlkeUguz[1], DavidOhayon[2], SophieGriggs[3], SahikaInal[2] and KennethL. Shepard[1]; [1]Columbia University, United States; [2]King Abdullah University of Science and Technology, Saudi Arabia; [3]University of Oxford, United Kingdom

Due to their effective ionic-to-electronic signal conversion and mechanical flexibility, organic neural implants hold considerable promise for biocompatible neural interfaces. Current approaches are, however, primarily limited to passive electrodes due to a lack of circuit components to realize complex active circuits at the front-end. Here, we introduce a p-n organic electrochemical diode (OED) using complementary p- and n-type conducting polymer films embedded in a 15-µm -diameter vertical stack. Leveraging the efficient motion of encapsulated cations inside this polymer stack and the opposite doping mechanisms of the constituent polymers, we demonstrate high current rectification ratios and fast switching speeds. We integrate p-n OEDs with organic electrochemical transistors (OECT) in the front-end pixel of a recording array. This configuration facilitates the access of OECT output currents within a large network operating in the same electrolyte, while minimizing crosstalk and interference from neighboring elements. We further demonstrate it to generate time-division-multiplexed amplifier arrays. When fabricated in a shank format, this technology enables the multiplexing of amplified local field potentials directly in the active recording pixel in a minimally invasive form factor.

Investigating the Effect of Photopharmacological Interventions on Cortical Seizures using Organic Perforated Multielectrode Arrays SofiaDrakopoulou, LintaSohail, JeroenSpanoghe, DinaK.C., RobrechtRaedt and GeorgiosD. Spyropoulos; Gent University, Belgium

Epilepsy is a chronic neurological disorder characterized by recurrent seizures, affecting millions of people worldwide. Current treatment methods have limitations such as side effects and incomplete seizure control. One potential approach to address these challenges is by targeting the adenosine type 1 receptor, which is abundantly present in the body, for epilepsy suppression. However, it is important to note that this approach may introduce multiple undesired side effects such as dizziness, sleep disturbances, mood, cognitive, memory changes etc.
Optopharmacology is an emerging approach for the treatment of focal epileptic seizures by activating and deactivating photoswitchable/photocaged molecules with light. It is a particularly interesting treatment solution which could result in powerful suppression of focal seizures with a limited number of side effects.
In this work, we study the neural dynamics of epileptic networks (in rodent model) and the effect of timely photo-release of a caged adenosine type 1 receptor agonist (caged CPA; N6-cyclopentyladenosine) hereon. To achieve that, we had to develop: i) animal protocols with evoked epileptic seizures, ii) illumination protocols proper for photorelease of the novel caged CPA molecule, iii) efficient microelectrode arrays, to trace the corresponding electrophysiology, that can simultaneously offer large spatial epidural coverage and high signal to noise ratio without sacrificing resolution or hindering illumination and drug appliance. In more detail, we performed craniotomies on several subjects to place semitransparent microelectrode array based on organic electronics on dura and trace electrophysiology. To provoke focal random epileptic seizures 4 - Aminopyridine (4-AP) was microinjected in different areas of the rat brain through specifically designed perforation paths. Upon microinjection of caged CPA epileptic activity continued but when the brain was exposed to pulses of 405nm light for uncaging of cCPA, local epileptic activity was strongly attenuated.
The results of this study provide a better understanding of propagation of 4AP induced seizures and confinement dynamics upon spatially resolved optopharmacological interventions. These findings are significant because they will positively impact the development of optopharmacological molecules and protocols, microelectrode arrays and therapeutic systems.

4:45 PM SB05.10.08
Surface Modification with Biocompatible Polymer Conductors for Stable and Compliant Electrode Interfaces for Communicating with Neurons RachelBlau[1], AbdulhameedAbdal[2], WadeShipley[1], YiQie[1], AllisonLim[1], SamanthaRussman[2], AlexanderX. Chen[1], GuillermoEsparza[1], ShadiDayeh[2] and DarrenJ. Lipomi[1]; [1]University of California; San Diego, United States; [2]University of California San Diego, United States

Neural interfaces for recording or stimulating cells and tissues require long-term stability, mechanical compliance, low impedance, and high charge injection capacity. However, the mechanical mismatch between stiff metal electrodes (e.g., gold, platinum, and iridium oxide) and soft biological tissue poses a significant challenge, hindering optimal performance. To address this, conductive polymers have been used as an additional interface layer, with poly(3,4 ethylenedioxythiophene):poly(styrenesulfonate) (PEDOT:PSS) being a widely utilized material. While PEDOT:PSS offers good charge injection capacity and lowers impedance, its long-term stability when implanted in the body remains a bottleneck due to delamination, pH changes, charge injection, and immune responses.
In this work, we propose a chemical approach to enhance the adhesion between gold electrodes and PEDOT:PSS by covalently attaching the polymer to the gold surface, i.e., generating polymer brushes. We designed and synthesized polymer brushes made of block copolymer scaffold using a surface-initiated living radical polymerization (grafting-from). Our polymer brushes comprise a poly(styrenesulfonate) (PSS) block and a soft poly(polyethylene glycol methyl ether methacrylate) (PPEGMEMA) segment. This scaffold serves as a platform for polymerizing PEDOT, creating an adhesive and compliant interface with the brain tissue.
We successfully implemented this approach on a flexible microarrayed neural probe and evaluated its electrical charge transport and long-term stability for brain activity recording. The covalently attached polymer brushes significantly enhanced the adhesion between gold and PEDOT:PSS coating, addressing the challenges associated with delamination over time. The resulting interface exhibited improved long-term stability, and reduced impedance compared to traditional PEDOT:PSS-coated gold electrodes.
Our findings offer insights into the development of more reliable and efficient neuroprosthetic devices. By enhancing the stability of PEDOT:PSS coatings, we pave the way for improved neural interfaces with long-term functionality in neuroscientific research and clinical applications.

5:00 PM SB05.10.09
Photosynthetic Microorganisms in Coffee-Based Photoelectrochemical Systems RossellaLabarile[1], PaoloStufano[1], MatteoGrattieri[2,1], MariaVarsalona[2,1] and MassimoTrotta[1]; [1]Consiglio Nazionale delle Ricerche, Italy; [2]Università degli Studi di Bari Aldo Moro, Italy

Evidence collected in the last years indicates that the application of redox mediators in bioelectrochemical systems enhanced the electron transfer from microorganisms to anodes and from cathodes to microorganisms [1]. Some artificial redox mediators are expensive chemicals and are putatively toxic to the environment, so downstream removal techniques or biodegradable electron shuttles are highly desirable.
Coffee is one of the most consumed beverages in the world. As a direct consequence of the global coffee consumption, the wastes and byproducts generated along the entire value chain (from the agricultural production, through industrial transformation, until the brewing and the final user consumption) can enter in a circular development model for a sustainable society [2].
The use of photosynthetic bacteria for the valorization of waste produced by agricultural systems represents an eco-friendly, cost-effective, and socially acceptable agri-waste management technology [3]. Here, the versatile metabolism of photosynthetic purple non sulfur bacteria was exploited to develop bio-hybrid photoelectrochemical systems. The performance of poorly electroactive bacteria, such as *Rhodobacter sphaeroides* and *capsulatus* [4] were improved using green coffee extracts as effective mediators for extracelluar electron transfer. Moreover, the preliminary results obtained by coupling such system with bio-based carbon composite electrodes recently developed, pose the foundation for a new class of circular coffee-based photoelectrochemical systems.

Engineering Extracellular Electron Transfer in Escherichia Coli for Microbial Electrochemical Devices MohammedMouhib[1], MelaniaReggente[1], LinLi[1,2], NilsSchuergers[1,3] and ArdemisBoghossian[1]; [1]École Polytechnique Fédérale de Lausanne, Switzerland; [2]Chongqing University, China; [3]Universität Freiburg, Germany

Microbes hold great potential for green electrochemical synthesis as well as bio-electricity generation from organic waste. The key to the successful development of microbial electrochemical devices lies in the ability of the microbes to transport electrons across their outer membranes. These devices thus often rely on the use of microbes known as exoelectrogens, which include bacteria that have evolved metabolic pathways that enable extracellular electron transfer (EET) to solid substrates for cellular respiration. While exoelectrogens demonstrate facilitated electron transfer with the electrodes of these devices, natural exoelectrogens are often restricted to utilizing a narrow range of substrates that limits their versatility for processing different organic wastes and electrosynthesizing a rich diversity of high-value chemicals. By contrast, non-exoelectrogenic microbes such as *Escherichia coli* that lack efficient EET pathways are host to rich metabolic reaction networks that can be more readily tailored for various applications using synthetic biology.

In this work, we biologically engineer *E. coli* for enhanced EET. To this end, we expressed different combinations of proteins from the natural exoelectrogen *S. oneidensis* MR-1, as well as *E. coli* native proteins to optimize EET of the bioengineered strain [1]. We further introduced biosynthesis pathways for redox mediators to facilitate EET [2]. The bioengineered strains show significant improvements in electron transfer rates, as confirmed through colorimetric reduction assays of soluble electron acceptors and electrochemical characterizations following electrode reduction. The improved EET demonstrated in this work paves the way for increasing the efficiency of existing *E. coli*-based electrochemical devices while opening the doors to new applications that benefit from the broad chemical repertoire of these microbes.

Soft Device for Simultaneous Measurements of Contractility and Electrophysiology of Neuromuscular Tissue PoppyJ. Oldroyd[1], SophieOldroyd[1], RajeshMakwana[2], GarethSanger[2], DavidBulmer[1], GeorgeG. Malliaras[1] and RoisinOwens[1]; [1]University of Cambridge, United Kingdom; [2]Queen Mary University of London, United Kingdom

Biological tissues serve as rich sources of electrical and mechanical signals that offer valuable insights into their function, disease conditions, and metabolic activity. However, certain neuromuscular tissues, such as those in the gastrointestinal (GI) tract, can undergo significant conformational changes when physiologically active. These tissues have received limited research attention due to challenges faced by rigid probes in conforming to their dynamic surface, which can experience strain levels of up to 40%. Conventional inextensible devices cannot capture the relationship between electrophysiological and mechanical responses of these tissues. This hinders the acquisition of crucial neuromechanical information in the gastrointestinal system, essential for understanding GI homeostasis and the connections between the enteric and central nervous systems.
To address these challenges, this study introduces bimodal electrodes made from poly(3,4-ethylenedioxythiophene):poly(styrenesulfonate) (PEDOT:PSS) and polydimethylsiloxane (PDMS) that enable simultaneous monitoring of electrical and mechanical responses of gut tissue. PEDOT:PSS demonstrates long-term stability and outperforms metal electrodes that delaminate, crack, and degrade over time. PDMS, used as a substrate and insulation material, shows promise due to its superior intrinsic strain properties surpassing popular polymers like polyimide and parylene C.
In contrast to traditional electrode fabrication methods, this work utilizes shadow masks and solution-processable spin coating techniques, resulting in a faster and simpler fabrication process. To optimize the spin coating of PEDOT:PSS on PDMS, Capstone FS-300 was added for stability and film homogeneity. Polyethylene glycol (PEG) was incorporated to maintain electrical conductivity during stretch, enabling mechanical monitoring. The PEG concentration can be adjusted to tune the device's electrical sensitivity to strain changes. A low PEG concentration improves sensitivity to smaller strains for measuring spontaneous contractions, while a higher concentration makes the device strain insensitive for pure electrophysiology data. The PDMS-PEDOT:PSS-PDMS devices exhibit reduced delamination and cracking during accelerated aging compared to metal-based and parylene C devices.
The device was validated on *ex vivo* mouse and human gastrointestinal tissues. The device successfully monitored muscle electrical activity and motility. During induced propulsive

movements through the mouse small intestine, the device recorded electrophysiological voltage amplitude changes ranging from 2.1 to 3.5 times, corresponding to the strength of the contraction. These voltage changes were temporally correlated with resistance variations resulting from mechanical propulsion. The signals observed from the human stomach were similar in nature to those observed when monitoring the mouse small intestine, highlighting the variety of *ex vivo* applications of the devices and ability to detect signals in relatively thick (human) and thin (mouse) tissues. Furthermore, the ability to wrap the electrode system around a small diameter tissue as well as affixing it to a flat surface demonstrates the adaptability of device.
In conclusion, the presented bimodal tissue monitoring device integrates soft, flexible, and stretchable electrodes using thin PDMS and PEDOT:PSS layers doped with PEG and Capstone. Its electrical sensitivity to strain can be finely tuned for specific applications by adjusting the dopants in the PEDOT:PSS. The device's flexibility and stretchability make it suitable for monitoring gastrointestinal function, including motility and electrical activity, as demonstrated on mouse small intestine and human stomach tissue. It has the potential to provide clinical insights into complex disorders like irritable bowel syndrome and gastroparesis.

8:15 AM SB05.11.02
Modular Skeletal Muscle Biohybrid Robots: Creation & Multi-Unit Assembly of Functional Muscle Building Blocks AisteBalciunaite[1], OncayYasa[1], MiriamFilippi[1], NiklasKönig[2] and RobertK. Katzschmann[1]; [1]ETH Zürich, Switzerland; [2]Xolo GmbH, Germany

The emerging field of biohybrid robotics aims to create the next generation of soft and sustainable robots by using engineered biological muscle tissues, integrated with soft materials, as actuators. Alongside robotics, such biohybrid muscles will also find biomedical applications in prostheses and drug development and screening. Current skeletal muscle tissue-based robots are powered by bulk-grown 3D configurations of muscle tissue (*e.g.*, blocks or ring-like tissues). The size of these constructs is restricted to the sub-cm scale due to biofabrication constraints and limited nutrient perfusion. Further, lack of internal topography within bulk constructs results in poor control of myofiber formation and thus low contraction force. Therefore, to generate larger biohybrid constructs capable of complex motion while avoiding the issues of bulk muscle tissue manufacture, we have developed a bottom-up fabrication approach based on the assembly of muscle building blocks into designs that exploit the characteristics of the single actuators to form a multi-unit configuration. We created the muscle building blocks by integrating thin layers of muscle-cell laden hydrogels onto hydrogel-based exoskeletons characterized by material properties and microtopographic patterns that enhance muscle tissue development (*i.e.*, microgrooves). Our thin cell-laden hydrogel layers allowed nutrient diffusion throughout the layer, and we incorporated microtopography with a layer-by-layer approach.

We used a novel linear volumetric printing technique, named xolography, to form the hydrogel exoskeletons (< 1 mm x 5 mm x 8 mm). Adapting xolography for aqueous hydrogel printing allowed us to take advantage of the quick speed, high resolution, and achievable geometric complexity of the technique. We printed exoskeletons with different mechanical properties by combining polyethylene glycol diacrylates with gelatin methacryloyl, e.g. 15% PEGDA700 and 5% GelMA (P700/GelMA, Young's Modulus 140 kPa) and 15% PEGDA575 and 5% GelMA (P575/GelMA, Young's Modulus 270 kPa) . The exoskeletons featured microgrooves of 100 – 300 µm in width to guide formation of uniaxially oriented myofibers. To stably integrate the exoskeletal and the cellular hydrogels, we developed a Matrigel, collagen, and gelatin methacrylate-based cellular hydrogel that, when seeded with myoblasts, allowed for both contractile myofiber formation and effective cross-linking with the exoskeletal hydrogel, as shown via confocal and brightfield imaging and histological analysis.

Directionality analysis of confocal microscopy images of samples stained to visualize myofibers (F-Actin) showed uniaxial alignment in the channel direction with a standard deviation of 10°-20°. The structural deformation of these constructs caused by the contraction via electrical stimulation of their muscle tissue component depended on the exoskeleton composition. Constructs based on P700/GelMA contracted 4% in the direction of myofiber contraction, while constructs based on P575/GelMA contracted <1%. Finally, to form modular multi-unit biohybrid robots with predictable motion abilities, we assembled the muscle building blocks by cross-linking the residual unreacted acrylate groups in the PEGDA/GelMA exoskeletons under UV irradiation.

In conclusion, we developed a method that builds biohybrid robots by the assembly of muscle building blocks with tunable mechanical properties and actuation performance. We have reduced the complexity and increased the predictability of biohybrid muscle fabrication, thus unlocking the potential of engineered muscle tissue as an actuating technology.

8:30 AM SB05.11.03
Integration of Laser-Induced Graphene Strain Gauges and Stimulation Electrodes into 3D Muscle on a Chip Devices AnastasiaSvetlova, AbdulrahmanAl-Shami, AliSoleimani, Hiu TungJ. Law, RiyaVerma, StephanieDo, SamuelKohan, RaymondA. Peck, MaralMousavi, GeraldE. Loeb and MeganL. McCain; University of Southern California, United States

The emerging technique of direct laser carbonization of polymers to convert them into conductive graphene foam has opened new possibilities for prototyping and fabrication of electronic devices. For example, polyimide (PI) undergoes a photothermal conversion into a 3-dimensional (3D) carbon foam called laser-induced graphene (LIG). This technically simple procedure can be implemented for the photolithography-free fabrication of electronic devices in the absence of a cleanroom, with faster turnover of prototypes, and at a lower cost. The technique has similar spatial resolution to inkjet printing but is more straightforward in implementation.
Muscle on a Chip models have been developed to gain insight into disease mechanisms from the molecular to the tissue scale and test new therapies. Systems that engineer muscle tissue in 3D bundles are especially beneficial for inducing more physiologically relevant tissue architecture. 3D muscle bundles are commonly fabricated by injecting a mixture of muscle cells and hydrogel into an elongated chamber with two flexible anchors. The muscle cells compact into an aligned 3D bundle that mimics native muscle tissue. The flexible anchors are embedded into the tissue during compaction and deflect with muscle contractions. However, the conventionally used method to evaluate muscle contractions by optically monitoring the anchors has low throughput, and limited options for continuous monitoring. To overcome these bottlenecks in Muscle on a Chip systems, we integrated LIG electrodes in our devices. Based on the same engraving technique, we fabricated electrodes for the electrical stimulation and the contractility measurement.
To fabricate LIG on PI films (LIG-PI), we used an Epilog Mini laser engraver equipped with a CO_2 10.6 µm wavelength laser with maximum power of 30 W. By engraving patterns as an array of raster dots or overlapping vector “lines”, and varying laser power and speed, we obtained LIG layers with sheet resistance from 120±17 Ω/sq to 32±4 Ω/sq.
This electrode demonstrated a charge injection capacity in the range of 0.2 mC/cm^2 for cathodic and 0.1 mC/cm^2 for anodic current pulse. Stability of the material after thousands of stimulation pulses was confirmed by measuring Ferricyanide-ferrocyanide oxidation/reduction currents in cyclic voltammetry and calculating the electrochemically active surface area.
We transferred LIG foam into polydimethylsiloxane (PDMS) films by pouring liquid PDMS on LIG-PI, curing it until solid, and peeling off the PI film. This created a stretchable PDMS film embedded with LIG foam (LIG-PDMS), the conductivity of which responded to the stress applied to the layer. We demonstrated that LIG-PI and LIG-PDMS were not toxic by culturing HL-1 cardiomyocyte-like cells on the materials for 1 week.
To fabricate the strain gauge, we engraved LIG in a serpentine line pattern on PI films and transferred it onto PDMS. We further shaped this layer by laser cutting excess PDMS to create flexible anchors for the 3D tissue device, which should change resistivity upon deflection caused by the contracting muscle. To fabricate muscle chambers, we replica molded top and bottom pieces of PDMS from templates 3D printed in a Digital Light Processing printer. After 7 days of culture required for tissue compaction, LIG-PI stimulation electrodes were used to induce contractions of a primary muscle bundle at 2 Hz (twitch) and 20 Hz (tetanus).
We plan to use the developed device to evaluate physiological responses of two tissue models: healthy and diseased cardiomyocytes derived from human induced pluripotent stem cells, and primary skeletal muscle cells with continuous electrical stimulation and monitoring of muscle maturation.

8:45 AM SB05.11.04
Development of a Biohybrid Tendon Interface for Muscle-Powered Robots NicolasCastro; Massachusetts Institute of Technology, United States

Introduction: Unlike abiotic materials like metal and plastic, biotic materials can communicate with their surroundings, adapt to stimuli, and self-repair damage. Incorporating these materials into engineered systems could foster smarter, more adaptable machines. We have shown that engineered skeletal muscle stretched around a flexible elastomer ‘skeleton’ can generate force and drive locomotion. Since these locomotive robots are powered by ‘living’ actuators, they can strengthen with exercise and heal from damage, capabilities not possible with abiotic systems [1]. However, the interface between biotic (muscle) and abiotic (skeleton) components in our robot is driven by friction, leading to slippage and inefficient force transmission. In the body, muscle is covalently tethered to the skeleton via tendons, which efficiently transmit force. Thus, we have developed a synthetic tendon to act as a biohybrid interface, enabling the design of more modular, efficient, and adaptive biohybrid machines.

Methods: We developed an adhesive tendon in collaboration with Professor Xuanhe Zhao’s lab at MIT. It is composed of a poly(acrylic acid) hydrogel functionalized for tissue adhesion with N-Hydroxysuccinimide ester groups. To characterize the interface between synthetic tendon and muscle, we performed tensile tests on differentiated and undifferentiated muscle samples (n=3) bound to the synthetic tendon. Muscle samples were manufactured from C2C12 mouse myoblasts. Cell populations were seeded into a fibrin and matrigel matrix, then cast into polydimethylsiloxane molds. Tensile tests were performed by layering muscle between two pieces of tendon, and pulling the assembly apart until interface failure was observed.
To understand the effect of the synthetic tendon on cell viability, a colorimetric MTS assay was performed, along with a pH exposure test. Absorbance readings were taken at 490nm from control and experimental C2C12 myoblast cultures that had been incubated with synthetic tendon overnight (n=3). pH readings were probed at 0 and 30 minutes of control and experimental samples of DMEM culture medium that had also been exposed to the synthetic tendon (n=3).

Results and Discussion: Our experiments demonstrated that differentiated muscle had a greater mean force-at-break value (~680mN) than undifferentiated muscle (~520mN) at their interfaces, although this difference was not statistically significant. Both values are magnitudes greater than the mean contractile force generated by our muscle actuators (~300uN) [1], indicating that the interfacial strength far exceeds our target metric and that the muscle-tendon assembly should remain intact over multiple cycles of use. We also observed no statistically significant difference in cell viability from absorbance readings or media pH in response to tendon exposure, indicating biocompatibility.

Furthermore, current preliminary tests evaluating the tendon-skeleton interface indicate a robust connection as well, asserting that the whole biohybrid assembly should be resilient to repeated use. We are also now quantifying the improvement in force transmission efficiency enabled by the interface, increasing the performance of our muscle bioactuators.

Conclusion: We have developed a hydrogel tendon that serves as a robust biocompatible musculoskeletal interface. The unconstrained nature of this innovation will enable the design of novel robotic architectures capable of functional applications like walking, swimming, pumping, and gripping that were previously not possible to manufacture. We also anticipate our biohybrid interface will advance the fundamental understanding of how passive tension generated by tendons guides muscle fiber alignment during growth and in response to injury. Our work sets the stage for fabricating next generation biohybrid robots that can dynamically adapt to the unpredictability of the real-world.

Electrically Conductive Nano-Biomaterials and Wirelessly Powered Cell Stimulator for Engineering and Controlling Biohybrid Soft Robots Su RyonShin; Harvard Medical School, United States

Engineered living-synthetic systems possess functions to dynamically control their shape and movements in biological environments that are pertinent to various biomedical applications, such as building biorobots and artificial muscles. To create functional bio-hybrid systems, in vivo-like living natural components such as 2D and 3D muscle tissue constructs, and their contractile function are required to be integrated into artificial platforms. Among various biomaterials, electrically conductive nanoparticles-incorporated hydrogels, which can improve the nanofibrous morphology and electrical and mechanical properties of conventional hydrogels while maintaining the hydrogels' beneficial properties, such as high porosity, biocompatibility, and biodegradability, are required to develop scaffolds mimicking biological and physical properties of native extracellular matrices (ECMs). These nanofibrous and electrically conductive scaffolds showed excellent myofiber maturation and organization along with cell-cell junction formation, providing self-actuating motions. Also, these nano-biomaterials can be engineered by various microfabrication techniques (i.e., bioprinting) to create 3D complex architectures, such as accordion-inspired hydrogel-based scaffolds which replicated the native myofiber architecture together with its function in terms of robustness and enhanced contractibility after culturing with cardiomyocytes. Recently, the maneuvering of bio-hybrid soft robots has been controlled by various strategies, such as by electrical and optical stimulations. We have developed advanced technologies to control the biohybrid soft robots by integrating flexible microelectrodes into soft and deformable engineered scaffolds to stimulate muscle actuators locally. Harnessing wireless power transfer technology without requiring batteries and wires, we developed untethered biohybrid soft robots that could swim; whereby, the steering of this swimming motion could be remotely controlled by transmitting electrical power into a cell simulator wirelessly. To this end, wirelessly powered, stretchable, and lightweight cell stimulators were successfully integrated into self-actuating soft muscle bodies without impeding the robot's underwater swimming ability. Wirelessly modulated electrical frequencies enabled us to control the speed and direction of the biohybrid soft robots. This innovative approach should provide a platform for building untethered biohybrid systems for various biomedical applications.

Arts & Crafts or Engineering? Tissue Engineered Hearts KevinK. Parker; Harvard University, United States

The three biggest questions in engineering human organs are 1) *What are the Design specs?* 2) *Who Builds the nano?* and 3) *How do you Test how good you are?* The responses to these questions are confused by variations in clinical endpoints and diagnostics, knowledge gaps in the basic science, and difficulty in the proper design of control experiments. This talk will review our efforts to address these three questions in regards to building a heart that include the development of new additive manufacturing techniques, understanding the living cell as an engineering material, and a foray into marine biology.

Living Bioelectrochemical Composites Incorporating Conjugated Polyelectrolytes GuillermoBazan; National University of Singapore, Singapore

Composites, in which two or more material elements are combined to provide properties unattainable by single components, have a historical record dating to ancient times. Few include a living microbial community as a key design element. A logical basis for enabling bioelectronic composites stems from the phenomenon that certain microorganisms transfer electrons to external surfaces. A bioelectronic composite which allows one to electronically address cells beyond the confines of an electrode surface can impact bioelectrochemical technologies, including microbial fuel cells for power production and bioelectrosynthesis platforms where microbes produce desired chemicals. In this presentation we show that the p-type conjugated polyelectrolyte (CPE) CPE-K functions as a conductive matrix to electronically connect a three-dimensional network of *Shewanella oneidensis* MR-1 to a gold electrode, thereby increasing the extracted biocurrent ~150-fold over control biofilms. While increased biocurrent is due to more cells in communication with the electrode, current extracted per cell is also enhanced indicating efficient long-range electron transport. More recent developments demonstrated that extracellular materials released by *Shewanella oneidensis* MR-1 has a profound influence on the rheological properties of the composite. It is also possible to design CPEs capable of enhancing bidirectional extracellular electron transfer by forming self-assembled coatings on individual cells. Specifically, the n-type conjugated polyelectrolyte p(cNDI-gT2) exhibits a reduction potential window between –0.1 V and –0.8 V (vs Ag/AgCl), thereby driving thermodynamically favored electron transfer in both directions across the abiotic-biotic interface that involves the outer membrane cytochromes and flavins of *Shewanella oneidensis* MR-1. Electrochemical tests show that injection from an external electrode into *Shewanella oneidensis* MR-1 is enabled at negative potentials (–0.6 V), while electron extraction is possible at positive potentials (0.2 V). Relative to controls, the biohybrid shows a 6-fold increase in biocurrent generation and a 35-fold increase in current uptake for the bioelectrosynthesis of succinate from fumarate. This demonstrated abiotic-biotic synergy provides new strategies for designing multifunctional biohybrids.

11:00 AM SB05.12.02
Living Diatom Microalgae as Robust Bioanodes for Biophotovoltaic Devices CesarVicente-Garcia[1], GabriellaBuscemi[1], DaniloVona[1], RobertaRagni[1], MatteoGrattieri[1], FrancescoMilano[2] and Gianluca MariaFarinola[1]; [1]University of Bari, Italy; [2]CNR-ISPA, c/o Campus Ecotekne, Italy

Biophotovoltaic devices are a promising source of renewable energy, given they can generate electrical current from the photosynthetic activity of microalgae, cyanobacteria, or their isolated proteins. Different strategies such as direct electron transfer or, more commonly, the use of soluble mediators allow to directly harvest electrons from the cells of photosynthetic organisms and feed them to a closed circuit to generate current. Green microalgae have been extensively studied for the extraction of photocurrent, yielding promising outputs, mainly thanks to their ease of culture and fast growth. Alternatively, only a few examples are present in literature about the use of Diatom Microalgae for photocurrent extraction. Besides providing significant photocurrent intensities, diatom microalgae exhibit particular resistance to different kinds of stressors such as desiccation, temperature and mechanical pressure, which comes as an advantage when it comes to processing them into living bioandoes. Their sensibility to different contaminants makes them good candidates for the development of electrochemical biosensing devices. Moreover, diatoms hold the unique characteristic of bearing nanostructured biosilica microscopic shells (frustules), that can be functionalized with active molecules or polymers, opening the door to enhancing electron flow through conductive polymers, or to light absorption modulation for example via introduction of external antennae. This work aims to study the photocurrent extraction from different species of diatom microalgae deposited onto ITO, used as working electrode in a photovoltaic cell, evaluate their interaction with the electrode both in the presence and absence of a soluble mediator, and their resistance to the electrochemical process itself. Cyclovoltammetry and chronoamperometry measurements have been performed; optical and fluorescence microscopies, and metabolic assays have been used to study the microalgae's state under the different conditions studied. We have standarized a method that allows to produce bioanodes resistant to dessication from several different species of diatoms, that provide significant levels of power output, and are more resistant to repeated cycles of desiccation/photocurrent than a model green alga.

11:15 AM SB05.12.03
Polymer-Modified 3D Electrode Interfaces for Efficient Charge Extraction from Photosynthetic Microorganisms RachelEgan[1], JonasHonacker[2], JoshuaLawrence[1], LinyingShang[1], LauraWey[3], BartekWitek[1], NicolasPlumeré[2], ErwinReisner[1] and JennyZhang[1]; [1]University of Cambridge, United Kingdom; [2]Technical University of Munich, Germany; [3]University of Turku, Finland

Cyanobacteria are abundant photosynthetic microorganisms that can be interfaced with electrodes in semi-artificial photosynthetic systems for solar-electricity or solar-fuel generation. [1] This approach relies on the ability of the living organisms to exchange electrons efficiently with the electrode. Redox-active and conductive polymers may be introduced at the cell-electrode interface to improve charge transfer efficiency by providing a direct route for electrons to reach the electrode thus overcoming sluggish diffusional kinetics. At present, the polymer properties that are key for efficient wiring of cyanobacteria to electrodes are poorly understood.
In this study, we systematically tested and compared the capacity of a common osmium-based redox polymer (P_{Os}) and the conductive polymer poly(3,4-ethylenedioxythiophene) (PEDOT) to act as a wiring tool for *Synechocystis* sp. PCC 6803 on hierarchically-structured inverse opal indium tin oxide (IO-ITO) electrodes. By using stepped chronoamperometry and normalising photocurrents against cell loading, we were able to identify the conditions under which each polymer served only as an immobilisation matrix, enhancing the photocurrent by means of increasing the cell loading rather than by mediation. The contribution of various parameters including polymer type (redox vs conductive), deposition method (dropcasting vs electropolymerisation), deposition geometry (layered vs mixed), polymer morphology and polymer loading towards optimal photocurrent outputs were deconvoluted. Increasing the polymer loading in both cases led to an enhanced mediation effect up until a to a certain point when photocurrents were reduced presumably by a shading effect. This problem was overcome by changing the electrode geometry to micropillar ITO electrodes in which the light path can penetrate through the structure unimpeded. We also investigated the interaction of the polymer with a Synechocystis mutant lacking extracellular polymeric substances (EPS). The PEDOT-modified electrodes produced higher photocurrents overall vs the P_{Os}-modified electrodes (20-fold vs 5-fold enhancement respectively) relative to unmodified electrodes at a low light intensity of 1 mW cm^{-2}. However, the larger photocurrents extracted using PEDOT come at a thermodynamic cost, as the onset potential for mediation is 200 mV higher for PEDOT than for P_{Os}. Overall, this study identifies polymer properties that are essential for successful cyanobacteria-electrode wiring and informs future interface design strategies for photosynthetic organisms on complex 3D structures.

Nanomaterial and Biological Engineering of Living Electronics ArdemisBoghossian; EPFL SB ISIC LNB, Switzerland

The vast expansion of available synthetic biology tools has led to explosive developments in the field of materials science. The increased accessibility of these tools has pushed the frontier of materials science into the field of engineering biological and even living materials. By coupling the tunability of nanomaterials with the prospect of re-programming living devices, one can re-purpose biology to fulfil needs that are otherwise intractable using traditional engineering approaches.

Optical technologies in particular stand to benefit from the untapped potential in coupling the optical properties of nanomaterials with the specificity and scalability of biological materials. This presentation highlights applications in sensing and energy technologies that exploit the synergistic coupling of nanobio-hybrid materials. This talk will focus on the development of living electronics, such as photovoltaics based on photosynthetic organisms with augmented capabilities.

SESSION SB05.13: Functional Interfaces with Microorganisms II
Session Chairs: Ardemis Boghossian and Guglielmo Lanzani
Thursday Afternoon, November30, 2023

1:30 PM *SB05.13.01
Photosynthetic Microorganisms for Optoelectronics Gianluca MariaFarinola; Universita' degli Studi di Bari Aldo Moro, Italy

Photosynthetic microorganisms and their molecular components for light absorption and photoconversion, optimized over billions of years of evolution, represent attractive tools for harvesting and conversion of solar light in sustainable and cost-effective transducers. The new era of biohybrid devices relies on the exploitation of isolated structures from these microorganisms, or the entire living cells, as the active components for photoconversion in optoelectronic devices and photoelectrochemical cells [1].
The bacterial reaction center (RC) extracted from the purple non-sulphur bacterium *Rhodobacter (R.) sphaeroides* has been initially modified by covalent functionalization with organic molecules specifically designated to act as artificial antennas to increase its light absorption capability [2].
The same RC has been also integrated into photoactive transistors [3], using molecular or polymeric semiconductor thin films deposited onto metal electrodes as interfaces [4]. Among them polydopamine (PDA), a biocompatible polymer produced *via* self-oxidative polymerization of the dopamine monomer, gave very interesting results for the stabilization of *R. sphaeroides* RCs. RC has been immobilized both in PDA thin films on the electrode surfaces or in PDA nanoparticles, without altering the enzymatic photoactivity, and producing photocurrents in photoelectrochemical cells [5]. PDA has been modified with diamines, leading to more transparent nanostructures incorporating RC molecules, which outperform RC/PDA structures in light transmission and photoconversion [6].
Finally, we have been investigated different approaches for interfacing intact photosynthetic microorganisms with electrodes, enabling photoconversion of whole living cells of *R. sphaeroides* and *R. capsulatus*, using PDA as the interface material either as a coating on the cells' surface, or as a film entrapping the cells on the electrode surface [7].
Furthermore, eukaryotic diatoms have been also selected for their efficiency in harvesting and converting sunlight into chemical energy and the feasibility of silica shell functionalization. Electrochemical characterizations have been performed to understand the electronic transfer between diatoms and electrodes, using different redox mediators.

Polydopamine-Coated Photoautotrophic Bacteria For Improved Extracellular Electron Transfer in Living Photovoltaics MelaniaReggente[1], CharlotteRoullier[1], MohammedMouhib[1], RossellaLabarile[2], MassimoTrotta[2], FabianFischer[3] and ArdemisBoghossian[1]; [1]École Polytechnique Fédérale de Lausanne, Switzerland; [2]CNR-IPCF Consiglio Nazionale delle Ricerche, Switzerland; [3]HES-SO Valais-Wallis, Switzerland

Living photovoltaics represent a growing class of microbial electrochemical devices based on whole cell–electrode interactions able to convert solar energy into electricity. The bottleneck in current microbial electrochemical technologies is the limited electron transfer between the microbe and the electrode surface. This study focuses on the development of a polydopamine (PDA) coating on the outer-membrane of the photosynthetic organism *Synechocystis* sp. PCC6803. This encapsulation provides a conductive shell to enhance electrode adhesion and improve microbial charge extraction. Cell encapsulation was obtained through an oxygenic dopamine (DA) polymerization in slightly alkaline conditions and the effect of two pH levels (7.5 and 8.2) were examined. PDA-coated cells were characterized and optimized using scanning and transmission electron microscopy (SEM and TEM, respectively) as well as confocal microscopy, UV-Vis and Raman spectroscopies. The microbial exoelectrogenicity was assessed through chronoamperometric measurements. PDA-coated microbes showed three-fold enhanced electron transfer with retained viability and photosynthetic activity.

Engineered Living Electronic Interface ClaudiaTortiglione[1], GiuseppinaTommasini[2,1], MariarosariaDe Simone[1], SilviaSantillo[1], MarikaIencharelli[1], GwennaëlDufil[3], DanieleMantione[4], NataliaDell'Aversano[1], EleniStavrinidou[3] and AngelaTino[1]; [1]Istituto di Scienze Applicate e Sistemi Intelligenti, Consiglio Nazionale delle Ricerche, Italy; [2]Instituto de Nanociencia y

Materiales de Aragón (INMA), Spain; [3]Linkoping University, Sweden; [4]University of the Basque Country UPV/EHU, Spain

Cells can be considered as nanomaterial factories able to build structures of amazing complexity starting from a few molecular building blocks. The introduction into the cell of an exogenous chemical input may result in the fabrication of hybrid materials with unique functionalities, that can be exploited for diverse applications (from biomedicine to bioelectronics). We exploited this potential in a simple tissue-like organism, the freshwater polyp *Hydra vulgaris*, shown able to produce electronically conductive interface starting from thiophene based compounds. By simply incubating living polyps in a solution containing organic semiconductor oligomers the spontaneous polymerization into microstructures presenting electronic conductivity and electrochemical capacitance was observed[1]. In addition, for the first time their neuromodulatory function was demonstrated by behavioral and electrophysiological approaches. Here we provide an overview of recent results obtained by challenging Hydra with different chemical inputs and envisage the possibility of manufacturing living electronics, acting as highly performant electrodes to monitor and control important processes, from development to regeneration. These interfaces, seamlessly integrated into the cells and naturally evolving with the polyp life cycle, overcoming the issues of tissue-interface mismatch, adverse cell response, and low biocompatibility, suggest the possibility of augmenting electronic functionality in animals and the fabrication of a new class of engineered living materials.

Light Management by Algal Aggregates in Living Photosynthetic Hydrogels SilviaVignolini; University of Cambridge, United Kingdom

Rapid advancements in algal biotechnology have fueled a growing interest in hydrogel-encapsulated microalgal cultivation, particularly for the development of functional photosynthetic materials and biomass production. A previously overlooked aspect of gel-encapsulated cultures is the emergence of cell aggregates, resulting from the mechanical confinement of cells. These aggregates significantly impact light management within photobioreactors, consequently influencing the photosynthetic output. To assess this phenomenon, we conducted experimental investigations on the optical response of hydrogels containing algal aggregates and developed optical simulations to analyze the resulting light intensity profiles. The simulations were validated through transmittance measurements using an integrating sphere and aggregate volume analysis with confocal microscopy. Our findings reveal that the heterogeneous distribution of cell aggregates in a gel matrix enhances light penetration and mitigates photoinhibition compared to a flat biofilm. Moreover, we demonstrate that the introduction of scattering particles within the hydrogel matrix further enhances light harvesting efficiency, resulting in a four-fold increase in biomass growth. Consequently, our study presents a novel strategy for designing spatially efficient photosynthetic living materials, which hold significant implications for future photobioreactor engineering.

Controlling the Properties of Macroscopic Living Materials by Genetically Altering Their Matrix EstherJimenez, CarlsonNguyen and CarolineAjo-Franklin; Rice University, United States

Living cells assemble into hierarchical structures, forming complex materials with remarkable properties. Inspired by nature, the emerging field of Engineered Living Materials (ELMs) aims to predictively design cells to grow into materials with tailored properties. Contributing to this goal, our lab has recently reported the first **B**ottom-**U**p ***De novo*** **E**ngineered **L**iving **M**aterials (**BUD-ELMs**) using the bacterium *Caulobacter crescentus.* BUD-ELMs are comprised of a secreted protein matrix consisting of surface-layer protein and an elastin-like polypeptide (**ELP**) domain that assembles cells into centimeter-scale materials and defines their mechanical and physical characteristics. However, a fundamental knowledge gap we have yet to address is understanding how genetic modifications affect bulk material characteristics. Thus, our goal is to elucidate sequence-structure-property relationships of BUD-ELMs to achieve predictive design for targeted mechanical properties. We hypothesized that the mechanical properties of the purified ELPs, which are known to be tunable as a factor of sequence length, would be mimicked in BUD-ELMs. Therefore, to test this hypothesis, we engineered strains expressing ELPs of different lengths, grew the strains to form BUD-ELMs, and characterized each material's viscoelastic behavior by rheology measurements. Our frequency sweep results show that shortening the ELP increases the storage and loss moduli, showing stiffer resulting material, while lengthening the ELP does not affect the moduli. Interestingly, flow sweeps show strong shear-thinning under low shear rates, implying a fragile microstructure network among all the resulting materials from each strain. Additionally, to elucidate the relationship between each material's mechanical properties and microstructure, we employed confocal microscopy. The results show clear differences in each variant's matrix structure. The shorter ELP variant produces spiderweb-like strands over the cells, while the longer ELP sequence forms thinner fiber-like strands between cells. Based on this data, we attribute the changes in this material's mechanical properties to the interconnected network formed by the matrix of the shorter ELP. In comparison, the thin fiber-like strand formation formed by the longer ELP does not impact its rheological characteristics. Furthermore, the different structures produced by each material result in distinct yield stresses. Thus, this exploration into the genetic tunability of BUD-ELMs leads us toward establishing sequence-structure-property relationships for ELMs with programmable mechanical and structural properties for applications such as 3D printing and tissue engineering.

4:00 PM SB05.13.06
Motile Microorganisms in Intelligent Biohybrid Microrobots: Enhancing Propulsion, Control and Therapeutic Capabilities with Microalgae and Bacteria BirgulAkolpoglu[1,2], SaadetF. Baltaci Demir[1,3] and MetinSitti[1,2,3]; [1]Max Planck Institute for Intelligent Systems, Germany; [2]ETH Zürich, Switzerland; [3]University of Stuttgart, Germany

Biohybrid microrobots incorporate motile microorganisms and artificial components to construct self-powered devices capable of sensing, control, targeting, and delivery at small scales. The integration of such motile microorganisms including microalgae, bacteria, spermatozoa or macrophages as the biological component, combined with artificial components such as polymer coatings, liposomes, and micro- and nanoparticles, enhances the functionalities of biohybrid designs. The careful selection of both biological and artificial units is essential in the design of biohybrid microrobots, as the biological component plays a pivotal role in propulsion, control, and sensing, while the artificial component influences crucial aspects such as biocompatibility, biodegradability, and therapeutic capabilities. However, existing design strategies for biohybrid microrobots encounter challenges concerning low production efficiencies, limited multifunctionality and control over swarm navigation. To overcome these limitations, we propose and conceptualize a range of biohybrid microrobotic designs achieved through facile, robust, and high-throughput fabrication methods, capable of simultaneously executing multiple functions with intelligent complexity.

Specifically, we present two distinct types of biohybrid sytems: microalgae- and bacteria-driven microrobots. In the case of microalgae-driven biohybrids, *Chlamydomonas reinhardtii*, a single-cell green alga, serves as the biological model microorganism. By employing a noncovalent assembly approach, a thin, soft uniform coating layer is constructed using a polymer-nanoparticle matrix, resulting in a production efficiency of approximately 90%. This soft surface coating effectively preserves the microalgae's viability and phototactic ability while accommodating the incorporation of drug molecules and enabling active magnetic steerability. The magnetic steering capability of microalgae-driven microrobots is demonstrated in various microenvironments through adjustments in viscosity and confinement, emulating real-world settings that mirror the complexities of the human body. Furthermore, as a proof-of-concept, we showcase the controlled, on-demand drug delivery to tumor cells by conjugating nanoparticles embedded in the thin coating with chemotherapeutic agent doxorubicin, facilitated by a photocleavable linker.

On the other hand, bacteria-driven biohybrids are realized through the development of a magnetically controlled system that enables targeted localization and multistimuli-responsive drug release within three-dimensional (3D) biological matrices. *Escherichia coli* bacteria are integrated with magnetic nanoparticles and nanoliposomes via biotin-streptavidin complex, resulting in a high biohybrid construction yield. These bacterial biohybrids retain their original motility and exhibit enhanced capabilities for navigation through complex biological matrices, including 3D biological gels and tumor spheroids. Under the influence of external magnetic fields, they can effectively localize within specific regions and colonize tumor spheroids, enabling precise and on-demand release of therapeutic molecules upon near-infrared and pH stimuli.

The proposed biohybrid microrobotic designs presented in these studies hold significant promise for future medical applications by addressing current limitations and employing advanced fabrication techniques. These designs offer improved production efficiencies, enhanced control over locomotion, and various medical functionalities.

4:15 PM SB05.13.07
Catalytic Materials Enabled by a Programmable Assembly of Synthetic Polymers and Engineered Bacterial Spores MasamuKawada, HyunaJo, AlexisMedina and SeunghyunSim; University of California, Irvine, United States

Natural biological materials are formed by self-assembly processes and catalyze a myriad of reactions. Inspired by such materials, we developed a programmable molecular assembly of designed synthetic polymers with engineered bacterial spores. This self-assembly process is driven by dynamic covalent bond formation on spore surface glycan and yields macroscopic materials that are structurally stable, self-healing, and recyclable. Molecular programming of polymer species shapes the physical properties of these materials while metabolically dormant spores allow for prolonged ambient storage. Incorporation of spores with genetically encoded functionalities enables operationally simple and repeated enzymatic catalysis. Our work lays an

important foundation for scalable and programmable synthesis of robust materials for sustainable biocatalysis.

4:30 PM SB05.13.08
Synergy Between Bacteria and Conjugated Polyelectrolytes to Form Functional Biomaterials SamanthaMcCuskey[1], GlennQuek[1], Ricardo JavierVazquez[1], BinuKundukad[2] and GuillermoBazan[1]; [1]National University of Singapore, Singapore; [2]Nanyang Technological University, Singapore

Combining conjugated polyelectrolytes with electroactive bacteria leads to the formation of living functional materials that improve the performance of bioelectrochemical technologies for biosensing, electricity generation, and electrosynthesis. However, the organization of these hydrogel composites and their effect on microbe physiology remain unexplored. In this study, mixing of a p-type conjugated polyelectrolyte (CPE-K) with *Shewanella oneidensis* MR-1 leads to a three-dimensional organization that generates ~30-fold greater biocurrent density than control biofilms in electrochemical cells. Further, respiration of the bacteria through the polymer promotes conductive network formation with a lower charge transfer resistance than neat CPE-K by itself. Total RNA-sequencing analysis revealed differential gene expression between cells in the polymer composite versus standard biofilm. Genes related to bacteriophages (biofilm development) and energy metabolism were upregulated in the composite compared to control biofilms. Correlating, extracellular polymeric substance (EPS) quantity and lactate coulombic efficiency increased in the composite. Cyclic voltammetry, fluorescent staining, and rheological measurements before and after enzymatic treatment in the living composite show the importance of the extracellular matrix for cohesion. EPS components added to neat CPE-K do not achieve the same properties. Taken all together, the demonstrated abiotic/biotic synergy between microbe and polymer provides new strategies for designing multifunctional living composite materials.

SESSION SB05.14: Implantable and Wearable Devices

Wearable *In Situ* Sweat Sensors for Health—On-Skin Electrochemical Real-Time SensorsLeYang[1,2]; [1]Institute of Materials Research and Engineering A*STAR, Singapore; [2]National University of Singapore, Singapore

In an increasingly health-aware population and a move towards remote diagnostics, remote healthcare monitoring, cloud-based med-tech, etc, we tap on the ubiquitous and unlimited reservoir of on-skin biomarkers, including sweat metabolites, in developing a wearable, non-invasive, continuous and real-time sensor – a printed, multiplexed biosensor. Our integrated devices are designed and developed with scalability and translation in mind – ensuring printability (for scalable manufacturing), ease of fabrication routes, and solid-state and miniaturised prototype.[1-5] We also aim for better validation and correlation studies of non-invasive biomarkers to ensure useful relevance of such non-gold standard devices. Carbon-based electrodes are promising candidates for developing cheap, miniaturized, and disposable biosensors for effective wearable applications. From developing our own printable carbon-based ink, to screen-printing the electrodes, to functionalising each electrode into a specific biosensor, and finally to multiplexing and integration and incorporating of cheap paper-based sweat channels - we show how these devices can potentially add value to home-based/DIY biomarker monitoring. We look at a variation of our flexible electrode, a graphite/carbon fiber (G/CF) hybrid resembling a super-efficient 3D highway network where ample expressways (CF) run through numerous small factories (locally distributed graphite flakes) for rapid goods pick-up and transportation (electron transfer).[6] Lastly, we zoom in on the top-most layer of the device, theKirigami paper sweat channel, critical in enabling real-time fresh-sweat reading.[7]

8:30 AM SB05.14.02
Materials for Cut-And-Seam Fabrication of Soft Functional Interfaces CindyK. Harnett[1] and SamanthaMusante[2]; [1]University of Louisville, United States; [2]Trinity College, United States

Interfaces between inorganic and biological systems need to be mechanically compatible with soft surfaces that grow, stretch, and distort over time. This requirement has driven the development of soft photonic and electronic circuits. However, the evolving shape of these circuits poses a problem when connecting circuits together: how can we match up distorted contacts that may be impossible to align? The problem comes up not only when repairing, modifying, or temporarily connecting to a stretchable circuit that's already attached to a biological system, but also when connecting circuit pieces into custom 3D structures to cover one-of-a-kind biological shapes. The usual solution to the distortion problem is to create a stiffened connector region that prevents the circuit from deforming, which is good for alignment but doesn't conform to biological surfaces as closely as a soft region does. The 3D structure problem may be solved by laying out a new electronic circuit for each individual interface, but this makes it difficult to use woven meshes and other regular structures as bases for soft functional interfaces.

This presentation describes our approach to connect signals across thin seams between soft materials without precise alignment at the connections. Our method relies on mm- and smaller scale electrical components inserted into thin adhesive tapes, producing materials with anisotropic electrical conductivity.

The alignment error tolerances we target are 2 mm in the direction perpendicular to the circuit edge, 2 cm parallel to the circuit edge, and a 70 degree angular tolerance. The reason for the large angular tolerance is that 3D cut-and-seam structures are often made from anisotropic woven or knit materials, often have curved seams, and are subject to external constraints such as packing cuts into a sheet to conserve material. These factors mean there is no guarantee that wires, optical fibers, and other anisotropic features will meet at the same angle along every seam, or even within a single seam.

The cut-and-seam fabrication method will also be discussed here as an interface for highly porous mesh-based biosensor circuits. Mesh circuits' applications in tissue engineering and biosensing are promising because meshes permit vapor transport, can be perfused with nutrients, and provide paths for cells to extend through during growth. However, the task of collecting signals from individual wires in a mesh is laborious, and mesh materials are often made from fibers that can't be soldered because of a too-low operating temperature range (for example, metallized polymer threads) or because harsh chemicals are required for solder wetting (for example, stainless steel wires and threads). The seaming materials and methods in this work are designed to make contact to those conductors, forming a distribution network for power and data in the soft sensor interface.

In this presentation, we investigate the above alignment tolerances in circuits made from thin films and fibers, focusing on methods such as capacitance, temperature, strain, and light intensity measurements that function when encapsulated by parylene, silicone and other conformal biocompatible coatings.

8:45 AM SB05.14.03
Microneedle Array Optical Sensing for Wearable Real-Time Hydration Monitoring LawrenceRenna[1], KyleBrubaker[1], EricKroon[1], MeganSax van der Weyden[2], ShaneCaswell[2], JoelMartin[2] and AndrewKoch[3]; [1]Intelligent Optical Systems, Inc., United States; [2]Sports Medicine Assessment Research & Testing (SMART) Laboratory; George Mason University, United States; [3]Naval Air Warfare Center Aircraft Division (NAWCAD), United States

The escalating occurrence of physiological episodes leading to flight termination, combined with concerns over dehydration arising from prolonged missions, inadequate relief equipment, and environmental factors, has underscored the necessity for a real-time aviator hydration monitoring system to mitigate cognitive deficits and optimize in-flight performance. Dehydration-induced fatigue prominently impairs physical performance, particularly under heat stress, while also compromising various aspects of fitness such as aerobic capacity, strength, power, and balance. Even a 2% body weight loss due to dehydration can significantly impair cognitive abilities related to attention, executive function, and motor coordination, with more severe dehydration exacerbating cognitive impairment in tasks involving attention, psychomotor function, and short-term memory. To address these challenges, we have developed a wearable, real-time hydration monitor tailored specifically for military personnel, incorporating a novel technology that monitors subdermal chemistry, specifically the interstitial fluid derived from plasma,

which is in equilibrium with plasma composition. The wearable device directly tracks a distinct set of biomarkers—sodium ions, proton activity (pH), and water activity—in the interstitial fluid, effectively overcoming the limitations and inaccuracies encountered by existing consumer-oriented products that solely measure surface sweat properties.
The integrated system incorporates a sensor-integrated hydrogel microneedle array (MNA) capable of detecting intradermal hydration biomarkers. The MNAs are equipped with embedded luminescent indicators designed to be sensitive to the target biomarkers. Leveraging the microneedles as conduits, light is efficiently delivered to and from the subdermal sensor, unaffected by variations in skin tone. The sensors are built on luminescence lifetime measurements, a robust optical process ensuring reliable and continuous signal readings even in dynamic and rapidly changing environments. Specifically, our approach involves employing a Dual Luminophore/Lifetime Referencing (DLR) methodology, utilizing two different luminophores with distinct lifetimes or a single material with multiple excited states that possess different lifetimes, that are sensitive to different biomarkers.
To validate our system, a human-subject hydration study was conducted (n=8). They underwent alternating periods of pedaling a stationary bicycle and sitting without water intake over a span of approximately 5 hours, while wearing the hydration monitor continuously. Urine specific gravity (USG) measurements were obtained at hourly intervals. Through the utilization of a random forest regressor model trained on the hydration monitor data, linearly interpolated USG values were predicted. Pairwise correlation analysis was performed to assess the predictive accuracy. The obtained results demonstrated a statistically significant rejection of the null hypothesis ($p = 0.038$), indicating that the predicted and actual USG values were not drawn from different distributions. Furthermore, both the Pearson Correlation and Spearman Correlation tests yielded highly significant p-values ($p < 0.0001$), affirming a strong positive correlation between the actual and predicted USG values.
In conclusion, the development of our wearable real-time hydration monitor, leveraging a microneedle array optical sensing approach, holds substantial promise in addressing the risks associated with dehydration among aviators. This innovative solution provides a reliable means of monitoring hydration status, facilitating proactive interventions to optimize performance and enhance the well-being of military aircrews.

9:00 AM SB05.14.04
Development of a Wearable Sensor to Monitor Pulmonary Function BernardoA. Vicente, VitorSencadas and RaquelSebastião; Universidade de Aveiro, Portugal

Pulmonary function testing (PFT) plays a crucial role in assessing lung and health conditions. However, the COVID-19 pandemic has imposed restrictions on traditional PFT methods, highlighting the need for alternative measurement techniques. Wearable sensors have emerged in the last decade as a promising solution, enabling continuous respiratory monitoring without hindering daily activities. These sensors offer the potential to accurately measure key parameters such as respiratory rate (RR) and breathing patterns, which are vital for diagnosing lung diseases like chronic obstructive pulmonary disease (COPD) and asthma. However, currently, available wearable sensors often lack the ability to precisely assess lung volumes, particularly tidal volume (TV), which is essential to evaluate ventilatory disorders. This work aims to develop a capacitive wearable sensor capable of measuring respiratory waveforms through the movements of the rib cage, using poly(glycerol sebacate) (PGS), a biodegradable elastomeric polymer, as the substrate material. This non-invasive device aims to provide pertinent respiratory metrics and track tidal volume changes associated with various pulmonary diseases. Moreover, this study plans to apply machine learning (ML) techniques to enhance the accuracy of PFTs and develop ML-based prediction models for ventilatory volumes. Machine learning approaches have shown great potential in healthcare, particularly in improving decision-making and reducing patient risks in critical scenarios. Through the analysis of respiratory patterns, the extraction of ventilatory parameters such as TV and RR is possible, enabling the identification and interpretation of pulmonary conditions. In this work, ML algorithms will be tested, to identify respiratory parameters in healthy subjects, improving the reliability of the wearable sensor. To validate the performance of the wearable, standard spirometry protocols will be used for data verification and calibration. The developed device will be evaluated in non-invasive settings, placed in the right lower-chest region, allowing for the collection of relevant respiratory metrics related to ribcage expansion and retraction. The collected data will also serve to train and test ML models to accurately estimate changes in ventilatory volumes. The outcomes of this research hold significant implications for pulmonary diagnostics since the development of a wearable sensor with the ability to measure respiratory waveforms and accurately track tidal volume changes can enhance the accessibility and efficacy of PFTs. Furthermore, the integration of ML techniques enables advanced analysis of ventilatory volumes, providing valuable insights for the diagnosis and monitoring of lung diseases. This study contributes to the ongoing efforts in improving non-invasive pulmonary function testing and has the potential to transform the way lung conditions are diagnosed and managed.

9:15 AM SB05.14.05
Atomically Thin Boundary Between Wearable and Implantable Bioelectronic Interfaces DmitryKireev; University of Massachusetts Amherst, United States

Modern biosensors reveal a notable trend toward mobile and personalized health monitoring. Monitoring health-related electrophysiological signals, such as brain activity, heart activity, body hydration, or temperature, is essential for better comprehension of human physiology. Continuous long-term monitoring of those signals from individuals of different health conditions is essential to understanding systematic health risk factors and building preventative care solutions, which is paramount for intricate conditions like cardiovascular. However, modern wearable and implantable technologies require substantial improvement in terms of their ability to interact with the tissue without causing harmful consequences. In this work, we report on a substantial advancement of graphene electronic tattoos and use them for bioelectronic applications on the wearable and implantable fronts.
In a groundbreaking advancement in healthcare technology, we have harnessed the power of graphene to create wearable and implantable bioelectronic devices that revolutionize health monitoring and treatment. Using atomically thin and electrically conductive graphene electronic tattoos (GETs), we developed imperceptible monitoring technologies for measuring blood pressure with Grade-A accuracy. Unlike other wearables, GETs are lightweight and skin-conformable, eliminating discomfort during long-term measurements.
Recently, we also translated this technology into implantable sensors, demonstrating the sensing and stimulation of the mammalian heart, including treatment of arrhythmia with graphene pacemakers. The arrays show superior electrochemical properties, and the transparency of the graphene structures allows for simultaneous optical mapping of cardiac action potentials and optogenetic stimulation. Additionally, we advanced in creating tissue-integratable bioelectronic systems resembling biological neurons using soft, flexible, and biocompatible artificial synaptic transistors based on graphene and Nafion, boasting superior energy efficiency. These breakthroughs open up new possibilities for wearable and implantable graphene bioelectronics to transform healthcare and improve patient outcomes.

9:30 AM *SB05.14.06
Intrinsically-Stretchable Cardiac Interfacing Devices for Heart Failure and Ventricular Tachycardia Dae-HyeongKim[1,2]; [1]Institute for Basic Science, Korea (the Republic of); [2]Seoul National University, Korea (the Republic of)

Recent advances in flexible and stretchable electronics have attracted great attention due to its potential applications to personalized bio-integrated healthcare devices. The mechanical mismatch between conventional rigid electronic devices and soft human tissues oftentimes causes various issues, such as a low signal-to-noise ratio of biosensors, inflammations on the tissue interfacing with the bioelectronics, skin irritations in the case of long-term wearing of the device, and ineffective electrical stimulations in feedback therapies. Such issues can be amplified in the case of interfacing with dynamically moving organs including the heart, and lead to unsatisfactory monitoring efficiency and therapeutic efficacy. Intrinsically-stretchable bioelectronic devices have a low system modulus and intrinsic softness, and thereby have a potential to solve these issues. Nanomaterials and their composites with the elastomeric matrix are a particularly promising material candidate for realizing this soft bioelectronics concept. In this talk, the unique strategies in the synthesis of nanmaterials, processing as stretchable functional nanocomposites, their seamless integration with dynamically-moving caridac muscles are presented. These efforts have combined recent breakthroughs in nanomaterials and soft electronics, and are expected to address unmet clinical challenges.

Advances in Plant Nanobionics MichaelS. Strano; Massachusetts Institute of Technology, United States

Plants have evolved complex internal signaling pathways to swiftly adapt to diverse environmental conditions, but these pathways are difficult to probe *in-planta* with the conventional mass spectrometry–based quantification technologies. In contrast, embedding nondestructive nanosensors in plants offer real-time, spatial and temporal measurements of plant responses toward various abiotic and biotic stimuli. This field of interfacing living plants with nanomaterials to impart non-native functions to plants, termed plant nanobionics, has been pioneered by the Strano group. We have successfully developed species-agnostic carbon nanotube sensors targeting a wide range of plant signaling molecules and environmental analytes including nitric oxide, hydrogen peroxide, auxins, salicylic acid, gibberellic acid, jasmonic acid, saccharides, arsenics and nitroaromatics. These sensors can detect waveforms associated with wound signaling, hormonal changes, and priming events to provide a new basis to understand plant defense and stress responses. Coupled with portable and cost-effective probes, these species-independent

sensors open the door for real-time monitoring of plant physiology and the environment, offering key advantages in understanding plant biology and precision agriculture.

11:00 AM SB05.15.02
Plant Electrophysiology with Conformable Organic Electronics Abdul MananDar[1], AdamArmada-Moreira[1], ZifangZhao[2], DionKhodagholy[2] and EleniStavrinidou[1]; [1]Linköping University, Sweden; [2]Columbia University,, United States

Plant electrical signals are mediators of long-distance signaling and correlate with plant movements and responses to stress. Presently, these signals are studied with macro single surface electrodes that cannot resolve signal propagation patterns and integration, thus impeding their decoding and link to function. Unlike conventional extracellular electrodes, multielectrode (MEA) technology records the distribution patterns of electrical activity in cellular networks using a non-invasive, dense array of electrodes embedded in a substrate. The MEA technology is extensively used in brain and cardiac tissue research to decode the brain connectivity and potential propagation patterns in cardiac myocytes respectively. However, for plant electrophysiology the MEA technology remains fairly unexplored. Here we developed a conformable multielectrode array based on organic electronics for large-scale high-resolution plant electrophysiology. The MEA is developed with standard photolithography fabrication techniques, with parylene C as substrate and encapsulation layer resulting in total device thickness as low as 5 micrometers. The MEA is therefore highly conformable to the plant tissue leading to high Signal to Noise Ratio (SNR). With the conformable MEA we performed spatiotemporal mapping of the electrical activity of the carnivorous plant Dionaea muscipula a.k.a Venus Flytrap (VFT). VFT consists of a bilobed traps having three trigger hairs in each lobe which serve as mechanosensors. When the mechanosensitive hair is deflected, the mechanical stimulus is translated into an action potential (AP), by sensory cells at the base of the hair. Two action potentials (or two touches) in a short period (less than 30 secs) are required to induce closure of the trap. We found that the AP actively propagates through the tissue with constant speed and without strong directionality. We also found that spontaneously generated APs can originate from unstimulated hairs and that they correlate with trap movement. Finally, we demonstrate that the VFT circuitry can be activated by cells other than the sensory hairs. Our work reveals key properties of the AP and establishes the capacity of organic bioelectronics for resolving plants electrical signaling contributing to the mechanistic understanding of plants long-distance responses.

11:15 AM SB05.15.03
Soft Optical Implant for Measuring Water Potential in Plants VesnaBacheva, EricWu, PiyushJain, SabyasachiSen, AliceGevorgyan, MargaretFrank and AbrahamStroock; Cornell University, United States

Spending their lives rooted in one place, plants exhibit remarkable adaptability in their metabolism and development in response to the changing environment [1]. One crucial aspect for their survival is the control of water uptake and the maintenance of water status (water potential) [2], which is influenced by environmental factors such as soil moisture, air temperature, and humidity. Evidence suggests that the changing water potential of plants not only results from these factors but also serves as a long-distance signaling mechanism that enables plants to communicate these changes effectively [3-5]. Therefore, measuring water potential would improve our understanding of whole-plant signaling and responses to environmental stresses, allowing us to develop effective strategies for plant health and productivity in a changing climate. However, currently, there is lack of tools for measuring water potential that are suitable for field studies and for a variety of plant species.

Here, we present the development of a soft implant for measuring water potential in plants. The implant contains water-sensitive nanoparticles that exhibit a fluorescence spectrum dependent on the water potential [6]. The nanoparticles can resolve water potentials across the physiologically relevant range (−3 to 0 MPa) while exhibiting minimal sensitivity to other physical factors like temperature and pH. We use fiber optics to illuminate the implant and capture the fluorescence spectrum to determine the water potential. With its small footprint, the implant can be easily embedded into various plant species. To assess the biocompatibility of the implant, we are examining histological sections of the local tissue at the insertion site. In recent years, several polymer-based materials have been developed for packaging of implantable sensors in mammals. Since the effect of these materials has not been studied in plants yet, we are also exploring different polymer- and plant-based materials to enhance the long-term stability of the implant. Additionally, we are considering the integration of a second optical fiber for simultaneous monitoring of sugar concentration, thereby enabling assessment of the osmotic potential.

We believe that the ability to accurately measure the total water and osmotic potential *in planta* will enable unprecedented access to the dynamics of water in plants and shed light on the propagation of long-distance hydraulic signaling. Moreover, the implant can be used beyond the context of plants by measuring water potentials in various environments such as soil, food, cosmetics, medicines, and cement.

Bioelectronic Platform for Enhancing Plant Growth AlexandraH. Sandéhn[1,2], VasileiosOikonomou[1,2], TorgnyNäsholm[3] and EleniStavrinidou[1,2,3]; [1]Linköping University, Sweden; [2]Linköping university, Sweden; [3]Swedish University of Agricultural Sciences, Sweden

To cover the food demands of the growing population in the changing climate we need to increase crop yield in a sustainable manner. Hydroponics cultivation minimizes water and fertilizer use while it can be integrated in the urban environment. However, so far the substrates used in hydroponics mainly offer support to the root system. Here, we developed a bioelectronic platform that stimulates the growth of plants in a hydroponics culture. We demonstrate that Barley, one of the most important crops, grows well within the bioelectronic platform. When stimulated, the biomass of the Barley increases by 40%, and the effect is evident in both root and leaf development during the growth period after the stimulation treatment. Results also show that stimulated plants reduce and assimilate $NO3^-$ more efficiently than controls, a finding that can have implications on minimizing fertilizers use. Our work opens the pathway for enhancing plant growth in a hydroponics setting using bioelectronics which may result in more sustainable food production.

Biomimetic Reactive Oxygen Species (ROS) Scavenging System for Stability Enhancement of Thylakoid Membrane-Based Photosynthetic Biosolar Cells JaeHyoungYun, JongHyunKim and WonHyoungRyu; Yonsei University, Korea (the Republic of)

Since photosynthesis of plants has a high quantum yield close to 100%, many studies have been conducted to utilize the photosynthesis for bio-energy harvesting using algal cells, chloroplasts, thylakoid membranes (TMs), and isolated photosystems (PS I, II). The extracted photosynthetic organelles are preferred among these for their direct contact with the electrode and easier transfer of photosynthetic electrons (PEs). However, under high light intensity, reactive oxygen species (ROS) are generated during photosynthesis, causing damage to lipid membranes or proteins. Therefore, for long-term stability, a closed system capable of scavenging ROS like chloroplasts is required. In this study, we propose a biomimetic ROS scavenging system for stability enhancement of bio-solar cells. We used catalase to scavenge ROS, which causes the damage to extracted photosynthetic organelles and apparatuses. As a popular extracted photosynthetic organelle, TMs were used for bioenergy harvesting, and an artificial independent closed environment that did not interfere with PEs transport was constructed using alginate as extracellular matrix and the Nafion membrane. First, dye release test and catalase assay either in the presence or absence of Nafion membrane were performed to measure the leakage of catalase. The tests confirmed that the release of dye and catalase from the film coated with the Nafion membrane was negligible. However, the Nafion solution used for coating contains aliphatic alcohol that can damage lipid membranes or proteins. To analysis the effect of alcohol on TMs, photocurrents from TMs for different ethanol concentrations used in Nafion membrane wer measured. TMs treated with 5% ethanol concentration produced about 82% of photocurrents from the non-treated TMs. Therefore, it was concluded that a sufficiently diluted Nafion solution did not significantly affect the production of TM photocurrent. Based on this, a 10-fold diluted Nafion solution was used for the coating of TM/alginate mixture film containing catalase. Furthermore, the film fabrication conditions were optimized through the photocurrent results according to the ratio among TMs, alginate, and catalse. Finally, in order to confirm the stability improvement of a photosynthetic bio-solar cell by catalase encapsulated system, the photocurrent from the system was observed for 5 hours under AM 1.5G (1 sun = 100 mW/cm^2) illumination at intervals of 1,000 s. Afterwards, the stability improvement was evaluated by comparing the initial photocurrent and the photocurrent after 5 hours illumination. As a result, it was confirmed that about 4.3 times improved stability was achieved by the biomimetic ROS scavenging system.

Smart Wearable Healthcare Devices for On-Demand Theranostic Applications Sei KwangHahn, SangHoonHong and TaeYeonKim; Pohang University of Science and Technology, Korea (the Republic of)

A variety of diagnostic and therapeutic devices are routinely used in the clinic. While these devices have a familiar look as wall-plugged in hard packages or placed at patients' bedsides, there has recently been a rapid expansion of new ideas on wearable healthcare devices for greatly improved patients' compliance. Here, we developed smart contact lenses and smart wearable devices for both continuous diabetic monitoring and diabetic retinopathy therapy. Smart contact lens could measure tear glucose levels as a non-invasive alternative to the conventional blood glucose tests and deliver drugs from gold coated reservoirs for the treatment of diabetic retinopathy. On the basis of these results, we also developed a smart wearable device for highly sensitive glucose monitoring in sweat for clinically feasible diabetic diagnosis. A blue-tooth system could send data wirelessly allowing patients to check their diabetic diagnosis results on the mobile phones. Furthermore, we developed cell-integrated poly(ethylene glycol) hydrogels for in vivo optogenetic sensing and therapy. The real-time optical readout of encapsulated heat-shock-protein-coupled fluorescent reporter cells made it possible to measure the nanotoxicity of cadmium-based quantum dots in vivo. Using optogenetic cells producing glucagon-like peptide-1, we performed light-controlled therapy and obtained improved glucose homeostasis in diabetic model mice. Taken together, this presentation will provide the current state-of-the-art smart wearable devices for further clinical applications.

2:00 PM SB05.16.02
Stimuli Responsive Thin Films and Their Applications as Actuators and on Skin Sensors Anna MariaCoclite; Graz University of Technology, Austria

Stimuli responsive materials are those that change their properties, as shape, wettability, optical properties depending on environmental cues, like pH, temperature, humidity. Such dynamic property can be used in several modern devices. In addition, when the stimuli-responsive material has the shape of a thin film, the response, which is based on diffusion, is very fast and reversible.

Functional and responsive surfaces have been successfully deposited by initiated Chemical Vapor Deposition (iCVD) on a variety of substrates.[1] Such method allows the full retention of the functional groups of the monomer structure and this is important to obtain a large responsiveness amplitude. This presentation will focus on the applications of stimuli responsive nanofilms for sensors and actuators. The high versatility of iCVD in driving application-specific properties into the material, creating a platform for the implementation of polymeric coatings into device fabrication, will be discussed.

Fast response and large signal amplitude are fundamental requirements for good sensors. Fast and ultra-fast humidity sensors based on the optical detection of the change in thickness of the iCVD hydrogels will be shown.[2] The implemented sensor prototype delivered reproducible relative humidity values and the achieved response time for an abrupt change of the humidity was about three times faster compared to one of the fastest commercially available sensors on the market.

The combination of materials with different properties in nanostructures is required to meet the needs of modern intelligent devices. Several examples of such type of hybrid devices will be presented. In particular, an electronic skin concept was realized by combining stimuli responsive thin films with piezoelectric zinc oxide in core shell geometries.[3] Such device geometry was obtained by templated atomic layer deposition of the ZnO followed by the iCVD of the stimuli responsive film. The nanostructuration of the films lead to a location-specific signal detection. In addition, the combination of two different materials allowed the detection of three stimuli: force, humidity and temperature. The whole sensor device could be deposited on flexible substrates and used for on-skin sensor or as electronic skin. While the piezoelectricity of ZnO provides sensitivity to external force, the thermoresponsiveness of the hydrogel core provides sensitivity to surrounding temperature and humidity changes. The hydrogel core exerts mechanical stress onto the ZnO shell, which is translated to a measurable piezoelectric signal. A localized force sensitivity of 364 pC N^{-1} is achieved with very low cross talk between 0.25 mm^2 pixels. Additionally, the sensor's sensitivity to humidity is demonstrated at 20° and 40 °C, i.e., above and below the hydrogel's lower critical solution temperature (LCST) of 34 °C. The largest response to temperature is obtained at high humidity and below the hydrogel's LCST. The sensor response to force, humidity, and temperature is significantly faster than the system's intrinsic or excitation-induced time scale. Finally, the sensor response to touch and breath demonstrates its applicability as e-skin in real- life environment.

Cephalopod-Inspired Bioelectronic Control of Cellular Differentiation DavidBerlin, AleezaFarrukh, GeorgiiBogdanov and AlonGorodetsky; University of California, Irvine, United States

Cephalopods (e.g., squids, octopuses, and cuttlefish) have recently become recognized as a promising source of natural conductive biopolymers (1,2). Within this context, our laboratory has studied the proton conducting properties of unique cephalopod structural proteins called reflectins, and we have leveraged these proteins for applications in protonic transistors, photochemically dopable devices, and protochromic color-changing platforms (1,2). Moreover, we have demonstrated that reflectin films are inherently biocompatible, as exemplified by their ability to support the growth and proliferation of both human and murine neural stem/progenitor cells (3,4). Recently, we have extended these efforts to the development of cephalopod-inspired bioelectronic devices that afford the voltage-controlled regulation of cellular differentiation in real-time (5). Our combined findings suggest that reflectins are promising materials for applications in cell- and tissue-interfaced bioelectronic platforms.

2:30 PM SB05.16.04
Soft, Skin-Safe Electronic Device Interfaces for Continuous Health Monitoring SeonggwangYoo and JohnA. Rogers; Northwestern University, United States

Abstract
Soft electronic device interface directly with the skin surface allows essential physiological health monitoring. These devices, featuring soft and miniaturized architecture, wireless communication capabilities, and an independent power system, significantly reduce patient burden by eliminating wired connections and bulky hardware of traditional hospital-grade systems. Previous efforts by soft, thin structures with high biocompatibility addressed the many skin damage problems but still present challenges, especially when in direct contact with the delicate skin of ill infants with small anatomical bodies and low-risk perception ability. Here, we report materials and structural design strategies to enhance skin safety during clinical use, especially for infants, without hampering the unique characteristics of the device architectures and the electronic performance. Pre-curved and holey design conforms to the anatomical body and rapidly and effectively releases interface adhesion, significantly reducing skin irritation. Furthermore, an ultrathin, flexible bladder containing small amounts of liquid with a low boiling point provides an active thermal safety system to these soft, skin electronic devices. In a thermal malfunction, the heat evaporates the liquid inside the bladder, forming an effective thermal barrier and automatically delaminating the device from the skin. Our material and structural design approach aims to ensure the safe and reliable use of soft electronic devices for infant health monitoring, promoting overall well-being and comfort during usage.

Controlling Mesenchymal Stem Cell Differentiation using Oxide Thin Films WilfridPrellier; Crismat Laboratory, France

Although oxide compounds are well recognized for their ability to change from insulator to metal, or other electronic properties, they may also be used therapeutically to address significant medical issues. In this study, we used vanadium oxide thin films synthesized by the pulsed laser deposition (PLD) technique to examine human stem cells generated from bone marrow. We used a variety of techniques, such as differentiation staining, phase contrast microscopy, and real-time reverse transcription-polymerase chain reaction (RT-PCR), to examine the growth, adhesion, proliferation, and differentiation of human bone marrow mesenchymal stem cells (hBMMSCs) on these oxide films over time. Our results indicated that oxide films alter hBMMSCs adhesion and growth and affect their differentiation. We conclude that the use of oxide films in biological and medical materials, as well as future research on cells, are all made possible by these findings, which also improve our understanding of the biological actions of vanadium compounds.

3:30 PM SB05.17.01
Amphiphilic Light-Driven Push-Pull Azobenzenes (ppABs) as Cell Membrane-Targeted Nanoactuators ValentinaSesti[1,2], MatteoMoschetta[2], AriannaMagni[2], PaolaMoretti[1,2], Giuseppe MariaPaternò[1,2], MatteoTommasini[1], GuglielmoLanzani[2,1] and ChiaraBertarelli[1,2]; [1]Politecnico di Milano, Italy; [2]Istituto Italiano di Tecnologia, Italy

Cationic membrane-targeted azobenzenes have been recently proposed as light-induced nanoactuators for neuronal photostimulation.[1,2] In previous works, we developed an azobenzene as a promising nanoscale tool for cell photostimulation, namely Ziapin2. Our approach resides in non-specific binding, and Ziapin2 has an amphiphilic character allowing it to partition spontaneously within the cell membrane. The cationic terminal groups interact with the phospholipid polar heads of the membrane while the hydrophobic part of the molecule stabilizes inside the lipidic region. We demonstrated that this azobenzene is an effective light-driven intramembrane actuator, able to modulate neuronal firing both in vitro and in vivo.[1]
These previous results open to the next generation of light-driven photoswitches aimed at enhancing the performances and improving the partition stability. In this work, new amphiphilic push-pull azobenzenes (ppABs) were designed and synthesized, which feature a strong electron donor group in the *para*-position on one phenyl ring and a strong electron acceptor group in the *para*-position on the opposite phenyl ring. This push-pull substitution of the phenyl rings delocalizes electrons of the azobenzene and shifts the absorption wavelengths towards red, which is a valuable feature for biological application, allowing for a better light penetration in tissues. Interestingly, light-activated electrophysiology of cells loaded with ppABs shows a depolarization of the membrane followed by a small hyperpolarization, and this is owed to the significant variation of the dipole moment.[3] Within this series of homologous ppABs, we also identified the key role of the cationic heads in the partitioning and potential modulation of the cell membrane.

3:45 PM SB05.17.02
Integrated Design and Synthesis of Soft Matrices with High Permittivity DylanM. Barber and JenniferA. Lewis; Harvard University, United States

Emerging applications, such as dielectric elastomer actuators (DEAs), haptics, and bioelectronics, would benefit from soft matrices that simultaneously exhibit high permittivity (relative permittivity $\varepsilon_r \geq 10$) and low elastic moduli ($E \leq 1$ MPa). For example, the energy density of DEAs depends on ε_r^2, while their actuation strain scales with ε_r. However, most soft elastomers and gels that serve as compliant dielectric layers exhibit low permittivity ($\varepsilon_r \leq 10$). Consequently, the operation of DEAs requires kilovolt-scale potentials to achieve targeted actuation strains and energy densities. The incorporation of high-ε_r fillers affords little improvement, since liquid fillers (*e.g.*, liquid metals) decrease breakdown strength, while solid fillers (*i.e.*, strontium titanate particles) increase modulus. In this talk, we will describe recent advances to design and synthesize intrinsically polarizable elastomers and gels based on a library of small molecules with a large dipole moment and a low melting point – each of which exhibits exceptional permittivity ($\varepsilon_r \geq 250$) in the low frequency limit. Their synthesis is both facile (3-5 synthetic steps) and scalable (up to 250 g) from inexpensive starting materials. Using this library, we have created elastomers and gels with $\varepsilon_r \geq 100$ and $E < 1$ MPa, which may find potential application in high-strain and energy-dense DEA, haptic, and bioelectronic-based devices.

4:00 PM SB05.17.03
Non-Invasive Actuation of Chemical Reactions Through Mechanochemistry and Gas Vesicle Proteins YuxingYao, MollyMcFadden, MikhailShapiro and MaxwellRobb; California Institute of Technology, United States

Recent advances in molecular engineering and biomedical ultrasound provide means to apply physical effects, including mechanical stress, deep inside tissues, but limited capability to enact specific chemical processes for applications including drug delivery and non-invasive control of cellular functions. In this work, we show that mechanochemistry, chemical processes initiated by mechanical stress, can be activated with biocompatible focused ultrasound assisted by acoustically-active proteins. Previously, activation of mechanochemistry relies on ultrasound with parameters that are likely to damage tissues. Through acoustic cavitation seeded by genetically encoded, air-filled protein nanostructures called gas vesicles, polymers undergo bond cleavage at the designed, weakest position in backbones and thus release small molecular payloads, including fluorophores and therapeutic drugs by chemical cascade. The efficiency of mechanochemical activation is comparable to what has been achieved with bulk sonication, though with weaker ultrasound parameters. Focused ultrasound further enables the activation of mechanochemistry with spatial resolution in millimeter range as well as the programmable payload release kinetics. Furthermore, we demonstrate the stimulation of mechanochemistry in tissue-mimicking gels, suggesting its potential applications in remotely controlled drug release inside body. Our platform represents a novel modality for controlling chemical reactivity non-invasively in biological systems and unlocks the translational potential of polymer mechanochemistry for therapeutic and bioimaging applications.

4:15 PM SB05.17.04
Nanoparticle-Virus Chimeras as a Novel Strategy for Nanoparticle Delivery KeisukeNagao, KatherineLei, PeytonWorthington, EmmanuelPaniagua, RobertJ. Macfarlane and PolinaAnikeeva; Massachusetts Institute of Technology, United States

The systemic delivery of nanoparticles (NPs) has garnered significant attention from researchers due to its clinical promise. Various strategies have been developed thus far, including the utilization of the enhanced permeability and retention (EPR) effect to target tumors or the modification of NPs with antibodies to target specific proteins. However, delivering NPs to the brain through the blood-brain barrier (BBB) remains a challenge. Additionally, the importance of the communication between the central nervous system (CNS) and the peripheral nervous system (PNS) has been increasingly recognized, leading to a high demand for delivery systems that can flexibly change their target between the CNS and PNS. Translation of delivery strategies between species offers another challenge, especially in the context of bridging the divide between fundamental research in rodents and clinical research in larger models such as non-human primates (NHPs). Therefore, there is a pressing need for a novel strategy for systemic delivery of nanomaterials that is both translational and capable of flexibly selecting targets.

For decades the field of gene therapy has applied engineered viruses to deliver therapeutic transgenes to particular organs or cells of interest. Adeno-associated viruses (AAVs) are the most ubiquitous gene-therapy tools, particularly in neuroscience, owing to their advantageous characteristics: AAVs are non-pathogenic, easily reproducible, and have numerous accessible serotypes, each with distinct tropism. State-of-the-art serotypes, such as AAV.CAP-B10 and AAV.MaCPNS2, have demonstrated the ability to deliver genes to the brain or PNS in mice following intravenous (IV) injection, while simultaneously suppressing gene expression in the liver. These serotypes have also shown promise for gene delivery in NHPs.

In this study, we hypothesized that AAVs could be employed to guide magnetic nanoparticles (MNPs) to particular organs through IV injection. This approach allows for easy modification of

the target by swapping AAV serotypes, for instance, from the brain to the PNS. Furthermore, the target species can also be altered based on the serotypes of AAVs. This concept, termed viral guidance of MNPs, has the potential to serve as a versatile targeting strategy.

We covalently conjugated MNPs and AAVs (MNP-AAV chimeras) through click chemistry. The structure of these chimeras was controlled by adjusting the reaction conditions. In vitro tests were conducted to investigate the efficiency of AAVs in guiding MNPs using MNP-AAV chimeras formed from several different serotypes. As a result, MNP-AAV chimeras retained the tropism of original AAV serotype used, indicating that the delivery target is serotype-dependent and can be easily modified by changing the AAV serotype used for conjugation.

We also investigated an opposite application of MNP-AAV chimeras, namely, the magnetic guidance of AAVs. Since AAVs were conjugated to MNPs, we could manipulate the chimeras using an external magnetic field to exert a magnetic force on the MNPs. HEK293 cells were incubated with MNP-AAV chimeras in a presence of a magnetic field. Following a 24-hour incubation period, the HEK cells expressed high levels of fluorescent protein, which was encoded by the AAVs in the chimeras, near the center of the magnetic field. This result suggests that magnetic guidance of AAVs is feasible, and that AAVs in chimera form (conjugated to MNPs) are capable of transducing cells. The specificity of gene delivery targeting with AAV was previously determined by a combination of two factors: serotype (capsid) and regulatory elements (promoter, enhancer, Cre-lox system, etc.). Now, our chimeras enable spatial restriction of transduction, which adds another layer of control to gene delivery. To the best of our knowledge, this is the first report of magnetically controlled transduction with AAVs.

4:30 PM SB05.17.05
An n-Type Conjugated Oligoelectrolyte Mimics Transmembrane Electron Transport Proteins for Enhanced Microbial Electrosynthesis GlennQuek, GuillermoBazan, RicardoJ. Vázquez, SamanthaMcCuskey and FernandoLopez-Garcia; National University of Singapore, Singapore

Interfacing bacteria as biocatalysts with an electrode provides the basis for emerging bioelectrochemical systems that enable sustainable energy interconversion between electrical and chemical energy. Electron transfer rates at the abiotic-biotic interface are, however, often limited by poor electrical contacts and the intrinsically insulating cell membranes. Herein, we report the first example of an n-type redox-active conjugated oligoelectrolyte, namely **COE-NDI**, which spontaneously intercalates into cell membranes and mimics the function of endogenous transmembrane electron transport proteins. The incorporation of **COE-NDI** into *Shewanella oneidensis* MR-1 cells amplifies current uptake from the electrode by 4-fold, resulting in the enhanced bio-electroreduction of fumarate to succinate. Moreover, **COE-NDI** can serve as a “protein prosthetic” to rescue current uptake in non-electrogenic knockout mutants.

4:45 PM SB05.17.06
Exploring Cell Behavior Through Blanket and Patterned Reprogramming of Nanotopography MonaH. Abostate[1], NikolaosLiaros[1], MatthewJ. Hourwitz[1], WolfgangLosert[2,3] and JohnFourkas[1,3,4]; [1]Department of Chemistry and Biochemistry University of Maryland, United States; [2]Department of Physics, University of Maryland, College Park, MD, USA, United States; [3]Institute for Physical Science & Technology, University of Maryland, College Park, MD, USA, United States; [4]Maryland Quantum Materials Center, University of Maryland, College Park, MD, USA, United States

Cellular responses to external stimuli arise from a complex integration of various biochemical and biophysical signals that can occur concurrently, and that exhibit distinct spatial and temporal patterns. Of these signals, nanotopography, which is present in the extracellular matrix, holds special significance in influencing and controlling cell behavior. Nanotopography has the ability to initiate and direct waves of actin polymerization in a phenomenon called esotaxis, which is closely linked to the inherent excitability of cells. For instance, nanoridges can induce a transition from the 2D spreading waves observed on flat substrates to 1D waves.
We have molded large-area master patterns created using conventional lithography, and then replicated these masters using soft lithography. Replicas created using poly (Disperse Red 1 methacrylate, pDR1m), an azobenzene-containing polymer, can be reconfigured with light. The azobenzene moieties undergo photoisomerization from the *trans* isomer to the *cis* isomer, inducing macroscopic alterations in the polymer structure that dépend on the polarization of the light.
With this technology, a single nanoridge master can be used to generate a wide range of patterns with different surface features. Photomodification of pDR1m nanoridges was achieved through two different methods: blanket exposure and patterned exposure. The newly patterned surfaces can be replicated in a material that is not photosensitive through a straightforward molding procedure.
We have examined the response of cells to surfaces featuring buckled nanoridges created through. The presence of buckling has a significant influence on esotaxis, ultimately impacting cell migration. Because this effect is cell-type-specific, and depends on the degree of buckling, it is possible to create surfaces that impact different types of cells in different manners.

10:30 AM SB05.18.01
Stretchable Silent Speech Glove using Myopotentials and Machine Learning YutaKurotaki[1,2] and HirokiOta[1]; [1]Yokohama National University, Japan; [2]Pepabo Research and Development Institute, GMO Pepabo, Inc., Japan

The field of Silent Speech Interface (SSI) exists as an interface for sending information without speaking. Personal and confidential information can be heard by others when spoken, but if speech can be recognized without voice, confidential information can be transmitted safely. In addition, silent speech can send information to machines and people without disturbing the environment. There are many methods for predicting what is uttered from silent speech, one of which is the use of muscle potentials around the mouth. Recently, it has been shown that muscle potentials can be measured by placing sensors around the mouth, but the integration of a mechanism that uses soft materials to recognize speech using electrodes, muscle potential amplification circuits, and machine learning models has not yet been realized. Although it is possible to place circuits and elements as well as sensors around the mouth, the area around the mouth is limited, and attaching sensors would interfere with mouth movements. The myopotential amplification circuit requires many elements to be placed on the circuit, which would result in a loss of aesthetics in terms of appearance.

To solve these problems, we developed a myopotential measurement device that can be attached to the human hand using soft materials, liquid metal, transparent FPCs (Flexible Printed Circuits), and a microcomputer. The device can be placed near the mouth and electrodes placed around the mouth to collect myopotential information, which can then be used in a machine learning model to classify speech only when speech recognition is performed without speech. By enabling sensing by placing electrodes on the mouth only when the device is being used, there is no need to worry about information being read at times other than when the device is being used, and since there is no need to always wear sensors or circuitry around the mouth, speech will not be read at unintended times. It does not interfere with the movement of the face or mouth, eliminating aesthetic concerns.

In this study, electrodes based on soft materials were created to realize a device that is worn on the hand and repeatedly measures myoelectric potentials around the mouth. The electrodes were wired to circuits on transparent polyimide film using a liquid metal mixture of Galinstan and nickel powder and bonded with a hard-soft pattern of silicone rubber and epoxy. The electrodes and substrate, which fit the human hand, can capture information around the mouth without breaking, even when the hand is moved, or the fingers are bent. In addition, a speech classification model was created using machine learning based on the acquired data of myoelectric potentials in silent speech around the mouth. We propose a new form of silent speech interface that allows many people to send information to machines and people in more situations and with the same privacy as in their conventional lives.

10:45 AM SB05.18.02
Permeable Electronic Skins for Health Monitoring YanWang[1,2]; [1]Guangdong Technion–Israel Institute of Technology, China; [2]Technion–Israel Institute of Technology, Israel

One limitation of commercialized wearables, such as smartwatches and bands, is that they cannot form conformable contact with human skin due to their rigid form factor, thereby limiting their monitoring capabilities. Soft bioelectronics, on the other hand, are touted as an ideal platform for personalized health care owing to unique characteristics, such as thinness, lightweight, good biocompatibility, excellent mechanical robustness, and great skin conformability. Permeable skin-mountable electronics that are capable of long-term applications have emerged as promising tools for early disease prevention, screening, diagnosis, and treatment[1,2]. Dr. Wang’s research interests mainly focus on the development of wearable electronics for biomedical health monitoring, including stretchable conductors, sensors, and soft energy devices. In today’s talk, she will introduce high-performance skin bioelectronics developed by ultrasoft nanomesh systems, which can realize the accurate measurement of minus skin deformations and finger touch without disturbing natural skin motions and sensations, as well as long-term applications for health monitoring[3-5].

Thin-Film Encapsulations for Compliant Implantable Bioelectronics: Advanced Materials and Characterisation Methods Based on Bioresorbable Magnesium Permeability-Sensing Structures MassimoMariello[1,2], YvesLeterrier[2] and StephanieP. Lacour[2]; [1]University of Oxford, United Kingdom; [2]Ecole Polytechnique Federale de Lausanne, Switzerland

The next-generation bioelectronic implants will be microfabricated, soft and compliant; they need to be protected from the body environment through encapsulations that must guarantee simultaneously hermeticity, biocompatibility, mechanical compliance, compatibility with microfabrication processes, and long-term reliability. This still represents an unsolved challenge: standard biocompatible barrier technologies based on rigid Ti/silicone capsules do not answer such needs. Advanced hermetic barriers should instead rely on thin-film encapsulations (TFE), based on organic or inorganic films. However, water permeation and mechanical defects are prime drivers for TFE failure, especially for *in vivo* and flexible implantable systems, so a universal solution is still missing. Conventional strategies rely on multilayer architectures, consisting of alternating dyads made of organic and inorganic layers. The accurate evaluation of their barrier performances is challenging because standard measuring systems display too high sensitivity limits (~ 10-5 g/m2/day) which cannot detect the ultra-low permeation capabilities of the coatings, and are not suitable for flexible microsystem formfactors. We present here for the first time a comprehensive accelerated-aging method to quantify ultra-low permeability of TFE engineered for bioelectronic micro-devices. The method relies on bioresorbable magnesium (Mg) thin films. Corrosion of Mg induced by water diffusion through the barrier coating is real-time monitored in several testing conditions, including exposure to wet air, soaking in a phosphate buffer saline (PBS) solution that mimics the body biofluids (in vitro), and in biological tissues (in vivo). The electrical properties of Mg are then monitored and analysed. High temperatures for in vitro tests are chosen to perform accelerated aging whereas specific novel analytical/computational models are used to extract from the measurements the water transmission rates (WTR) of the barriers. The advantages of this approach are that Mg does not need a fully inert atmosphere and it can be easily integrated in the microfabrication processes of implantable bioelectronic devices. Therefore, the proposed characterization strategy answers a long-term need to assess reliably and universally thin-film hermeticity in situ, and for any types of conformal TFE for bioelectronic systems.

N-Acetyl-β-D-Glucosaminidase Activity Assay for Monitoring Insulin-Dependent Diabetes using Ag-Porous Si SERS Platform Narsingh RawNirala and GiorgiShtenberg; Institute of Agricultural Engineering, ARO, The Volcani Center, Israel

N-acetyl-β-D-glucosaminidase (NAG; EC 3.2.1.30) is an intracellular lysosomal glycosidase that catalyzes the hydrolysis of terminal glucose residues in glycolipids and glycoproteins. Specifically, the elevation of serum NAG activity serves as a surrogate for assessment of disease severity and progression in diabetes mellitus, myocardial infarction, liver damage, malignancies and hypertension. Early and rapid biomarker detection is an important element of medical diagnosis, facilitating prompt therapeutic decisions and prognosis evaluation. Herein, we present a modified sensing approach for a rapid and reliable NAG activity determination in complex media using surface-enhanced Raman spectroscopy (SERS). Porous silicon (PSi) Fabry-Perot interferometers were redesigned as sensitive SERS platforms utilizing the vast inherent surface area for silver (Ag) nanoparticles embedment. Interaction of the porous nanostructures with specific NAG-enzymatic products produces an indicative spectral fingerprint proportional in magnitude to its concentration. The sensitivity of Ag–PSi SERS substrates was evaluated in complex matrices presenting sufficient limits of detection compared with other advanced assays and techniques (0.07, 0.47 and 0.50 mU mL^{-1} for urine, milk and plasma, respectively). The augmented optical performance revealed recovery values of 96–109%, indicating successful and selective NAG recognition in biological fluids. Finally, the potential applicability of the suggested prototype for real-life scenarios was evaluated in vivo, in a model of insulin-dependent diabetes induced in sheep. Overall, the robust data confirm the application of SERS analysis for early diagnosis of pathology and for evaluation of clinical responses to pharmacological treatments.
Keywords: N-acetyl-β-D-glucosaminidase (NAG), insulin-dependent diabetes, plasma, Ag-PSi and SERS.

Modulation of Curli Production on Redox Challenged PEDOT:PSS Surfaces SanhitaRay[1,2], SusanneLöffler[1,2] and AgnetaRichter Dahlfors[1,2]; [1]Karolinska Institutet, Sweden; [2]AIMES, Sweden

Biofouling is a major problem caused by bacteria colonizing abiotic surfaces, such as medical devices. Biofilms are formed as the bacterial metabolism adapts to an attached growth state. We have previously found that electrically charged surfaces with high charge storage capacity like PEDOT-based conducting polymers can be used to modulate the amount of gross biomass attaching by altering the surfaces redox state(*1*).
Here, we are delivering an in-depth analysis on the process of biofilm formation on redox-challenged PEDOT: PSS surfaces. We are using GFP tagged *Salmonella* bacteria and a marker for the *Salmonella* extracellular matrix components curli and cellulose (EbbaBiolight 680) to decipher the relationship between the amount of bacterial cells and extracellular matrix produced by bacteria in *Salmonella* wt bacteria as well as mutants deficient in curli (ΔcsgA) or curli as well as cellulose (ΔcsgD)(*2*). We are using a semi-quantitative spectroscopy method to determine relative amounts of bacterial cells and extracellular matrix (ECM) on a large surface area and are performing detailed microscopic analysis to understand biofilm distribution and structure. When the redox challenge was carried out in a fast-charging whole-cell setup, higher amounts of cells and ECM were found on oxidized PEDOT:PSS surfaces compared to their reduced counterpart. When electrodes were separated and charging was carried out with respect to a Pt electrode, the charging process was slower and incomplete. This resulted in almost similar cell numbers for the two cases but showed much higher amounts of ECM on reduced surfaces. A curli mutant, grown under the same conditions produced biofilms that didn’t respond to the redox challenge. The microscopic structure of the biofilm showed uniform cell and ECM distribution on all oxidized surfaces but showed high-density local clusters of around 100-200 µm diameter on all unchallenged and reduced surfaces.
This leads us to believe that redox modulation of biofilm formation mainly depends on curli production. We forward a theory where an oxidized PEDOT:PSS surface works as an alternate terminal electron acceptor for interfacial biofilm, which might be able to boost ATP production and curli formation. We reason that the negative charge of PEDOT:PSS on unchallenged and reduced surfaces leads to a spotty attachment of the bacteria and to the formation of microcolonies, instead of evenly distributed films.

Toward Enhancing Critical Care Monitoring: Continuous Assessment of Blood Lactate and Potassium with Fiber Optic Sensors Integrated into Intravascular Catheters LawrenceRenna[1,2], NarcisoGuzman[1], EmilyVuu[1], GeorgeHarea[2], GerardoIco[1], TerynRoberts[2] and AndriyBatchinsky[2]; [1]Intelligent Optical Systems, Inc., United States; [2]Autonomous Reanimation and Evacuation Research Program, The Geneva Foundation, United States

The determination of disease severity and prediction of outcomes in emergency medicine heavily rely on blood lactate (Lac) and potassium (K^+) levels. Traditionally, these biomarkers are assessed through repeated invasive blood sampling and subsequent analysis using laboratory blood gas analyzers. However, recent studies have emphasized the dynamic nature of these biomarkers, highlighting the need for continuous monitoring. In trauma cases, elevated blood Lac levels and poor Lac clearance have been associated with higher mortality rates, demonstrating potential for effectively triaging conditions such as lung cancer, lacunar infarction, sepsis, and cardiac failure. Likewise, high K^+ levels, known as hyperkalemia, are linked to life-threatening conditions including arrhythmias and mortality following severe trauma, kidney disease, hemolysis, and acid-base imbalances. In hemorrhaging patients, hyperkalemia can be induced by tissue ischemia, blood transfusion, and acidosis, significantly heightening the risk of death. Consequently, there is an urgent demand for continuous monitoring of blood Lac and K^+ levels in critical care settings. This study aims to develop and evaluate the performance of specialized fiber optic sensors that enable real-time monitoring of Lac and K^+, thereby providing healthcare providers with timely guidance in rapidly changing situations.
The sensors in this study employ a measurement method known as dual lifetime/luminophore referencing (DLR), which ensures high accuracy and mitigates sensitivity to the amplitude of the

optical signal. In contrast to previous fiber optic sensors that are single point sensors located at the tip of the fiber and are susceptible to intermittent contact with tissue, a phenomenon referred to as the "wall-effect," the current sensors utilize a tunable distributed sensing approach. This is accomplished by incorporating redundant "mini-sensors" along a specific section of the optical fiber. Furthermore, optimization of sensor fabrication was conducted to enhance sensitivity specifically for physiologic concentrations. The Lac sensor utilized in this research consists of multiple layers, including a luminescent transducer layer for measuring partial pressure of oxygen, a catalytic enzymatic hydrogel layer, and a diffusion barrier layer to overcome substrate-dependent inhibition. The K^+ sensor is designed as a hydrogel that incorporates a luminescent ionophore for K^+ detection, and a separate reference luminophore. Finally, sensor-integrated catheter prototypes were tested in an ex vivo flow circuit with fresh porcine blood. The sensor-integrated catheter prototypes showed strong pairwise correlation between the optical sensor measurements and blood gas analysis (Spearman correlation $R^2 = 0.981$ and 0.970, p-value: <0.0001 and <0.0001 for Lac and K^+, respectively).
In summary, our study has successfully shown that the DLR-based fiber optic sensors for continuous Lac and K^+ monitoring, when integrated into intravascular catheters and evaluated under ex vivo circulation conditions using donor blood, offer a viable alternative to repetitive blood gas analysis. These sensors hold great promise in enhancing clinical decision-making and are now poised for further validation in translational studies focusing on trauma and critical care scenarios under in vivo conditions.

Single-Protein Electronics: Effect of Surface Mutagenesis and Multiheme Redox Cofactors Ismael DDiez Perez[1], AlbertC. Aragones[2], KavitaGarg[1], MartaRuiz[2], GuilhermeVilhena[3], Linda AngelaZotti[3], JuleaButt[4], ZdenekFutera[5], XiaojingWu[6] and JochenBlumberger[6]; [1]Kings College London, United Kingdom; [2]Universitat de Barcelona, Spain; [3]Universidad Autónoma de Madrid, Spain; [4]University of East Anglia, United Kingdom; [5]University of South Bohemia, Czechia; [6]University College London, United Kingdom

Bioelectronics is a rapidly evolving field moving towards designing nanoscale electronic platforms that allow *in vivo* sensing, fuel cell powering and chemical biosynthesis. Such devices typically require interfacing a complex biomolecular moiety as the active component to an electronic platform for signal transduction and/or electron source wiring. Inevitably, a true systematic design goes through a bottom-up understanding of the structurally related electrical signatures of such hybrid biomolecular circuits, which will ultimately lead us to tailor its electrical properties and exploit them as high performance bioelectronic devices with a wide variety of applications in organic electronics, sensing, biomanufacturing, *etc*.
In this contribution, we will present our latest efforts on understanding and control charge transport in a single-protein junction. Our approach relies on trapping individual redox proteins in a tunneling junction under electrochemical control to characterize their main electrical signatures. The method can capture very fine details of the charge transport mechanisms across proteins in an aqueous environment [1,2]. Our studies start with a benchmark redox protein model such as a bacterial blue Cu-Azurin. We will show first the main observed electrical signatures of these systems that make them particularly efficient in transporting charge. We then bioengineer the outer protein surface using point-site mutagenesis as a mean to get a more detailed picture of possible electron pathways through the protein backbone [2,3]. Our results suggest that the protein might not use distinct physical electron pathways across its structure, but transport mechanism can be switched upon quenching of particular motions in the protein structure via surface mutations. We then compare the above redox protein model to a natural multiheme molecular wire. Multiheme proteins have been recently discovered as the building blocks in highly conducting pili and transmembrane structures of certain species of the so called electrical bacteria [4]. Such large supramolecular ensembles of multiheme protein complexes support long-range charge transport in record distances over micrometres [5]. We have trapped individual small tetraheme proteins (STC) in our tunnelling gap and measured conductance. STC constitutes a well-known repeating arrangement of *heme* cofactors along larger multiheme complex structures. Our first results suggest a single STC unit can transport electrons via efficient electron tunnelling process along the ~4 nm long protein axis with very shallow electron decay constant. We believe these results contribute to the observed long-range charge transport behaviour observed in these multiheme-based molecular wires.
Summing up, the above work shows the potential of electrochemically controlled nanoscale protein junctions to both elucidating charge transport mechanisms in biological systems as well as in enabling a bottom-up design of electrode/protein interfaces for the future generations of bioelectronic devices.

9:35 AM *SB06.01.02
Implantable Materials for Chronic Disease Monitoring HanieYousefi[1], XudongJi[1], JagotamoyDas[1], YiLi[1], JonathanRivnay[1] and ShanaKelley[1,2]; [1]Northwestern University, United States; [2]Chan Zuckerberg Biohub, United States

Chronic diseases such as heart failure (HF) are increasingly prevalent conditions that are difficult to manage. Patients often experience significant deterioration between clinic visits, and by the time they become symptomatic, their condition cannot be managed outside of the hospital. Inflammation has recently been identified to take roles on promoting and inducing HF but there are no insights on the mechanisms of disease progression. The ability to perform continuous monitoring of protein biomarkers on a body-implanted device will transform our capacity to diagnose disease, preserve wellness, and propose potential treatments. Using Flexible and Implantable sub-millimeter polymeric substrates, we propose a new solution for remote, continuous monitoring of chronic disease clinical biomarkers (BNP, Troponin I, IL6, TNFα as proof of concept) to manage patients' health. We recently developed the first of-its-kind reagent-less molecular sensor for in situ detection of a wide range of targets, such as viral particles and proteins. However, continuous monitoring of chronic disease requires installing a miniature device inside the human body and continuously monitoring the patient for an extended period. The small device provides efficient reaction rates with a sub-millisecond resolution, which has not been achieved using the current common diagnostics paradigm. By moving from materials used in traditional electrochemistry to using unconventional recent developments in the fields of material science, we introduce a new generation of sensing platforms that are biocompatible, affordable, reliable, and environmentally friendly to deliver the promised goals of chronic disease

management. Using an HF rat model and accessing interstitial fluid via contact with the device's implantable part, we will be able to monitor disease progression, inflammation, and biomarker levels. This technology will provide a new generation of devices for the continuous monitoring of vital biomarkers in HF rat models.

10:30 AM *SB06.01.03
Molecular Junction with a Single Biomolecule: Self-Restoring Device and Phosphorylation Assay TomoakiNishino; Tokyo Institute of Technology, Japan

Single-molecule junctions, where a single molecule is trapped in a nanogap between metal electrodes, play pivotal roles in nanoscience and nanotechnology. Measuring biomolecules in the single-molecule junctions offers a unique means to develop single-molecule devices with sophisticated functionalities, to realize novel biomedical and pharmaceutical applications, and so on. Regarding the device development, the structural, physical, and chemical properties of DNA at the nanoscale have attracted attention to the prospect of using DNA as a building block in single-molecule devices, which leads to extensive investigations into electron transport through a single DNA molecule. Although significant advances have been made in understanding the transport phenomena through a single DNA molecule, the previous studies mainly focused on the transport phenomena in static DNA structure at thermodynamic equilibria. Against this, we expect that electron transport through DNA under the deliberate control of its structure paves the way for DNA electronic devices with functional controllability in a dynamic manner. To prove this, we investigated the electron transport through the single-molecule junction of DNA that orthogonally clamps a metal nanogap. This DNA single-molecule junction differs from conventional ones in the DNA configuration; the present and conventional junctions contain a DNA molecule oriented in perpendicular and parallel directions to the axis of the nanogap, respectively. The STM measurement of the unzipping dynamics revealed that the present DNA junction enables spontaneous restoration of the molecular junction after its electrical failure and thereby improves the reproducibility of the junction formation. Our study demonstrated that a DNA dynamic structural change could be applied to a single-molecule junction by using the perpendicular configuration.
Single-molecule detection of biologically relevant substances has attracted rapidly growing interest. One successful example of single-molecule technology is the detection of DNA achieved using nanogaps between metal electrodes or nanopore devices. Given their primary role in diverse biological functions, proteins have been regarded as the next challenging target in single-molecule studies. In particular, the detection of post-translational modifications (PTMs) of proteins at the single-molecule level is in high demand, since PTMs constitute an essential regulatory mechanism involved in almost all cellular events. Single-molecule studies would revolutionize medical diagnoses through PTM detection primarily because of their high sensitivity and concomitant high-throughput assays. However, the detection of PTMs at the single-protein level is not trivial, since the chemical structure of an amino acid residue is only slightly altered upon modification. Stringent selectivity or specificity for a PTM of interest is consequently vital for single-molecule detection. In this study, we focused on phosphorylation, which is a biologically important PTM, and demonstrated specific single-molecule detection of peptide phosphorylation by electrical conductance measurements. First, we found that a single orthophosphate anion exhibits a conductance value significantly higher than the peptides and their amino acid residues. This unique electronic property of the phosphate serves as a specific marker, enabling the detection of phosphorylation on a single peptide molecule. Based on this unique electrical signature of phosphate, an *in situ* single-molecule assay of enzymatic phosphorylation was achieved with 95% accuracy and 91% specificity for signal discrimination between phosphorylated and non-phosphorylated peptides. The present study demonstrates novel and specific single-molecule detection of PTMs, which will help elucidate their biological functions and facilitate the development of novel medical diagnostics.

11:00 AM *SB06.01.04
Beyond the Diffraction Limit—Optomechanics in Biomolecular Contacts Albert C.Aragonès; University of Barcelona, Spain

Molecular trapping approaches[1] that rely on the electrical detection of single-molecule (SM) junctions[2,3] often face a significant challenge of short lifetimes, typically ranging from tens to hundreds of milliseconds,[4] primarily due to thermally activated junction breaking.[5] The limited detection timescales hinder comprehensive fundamental studies, making the extension of detection times a crucial challenge in SM detection. Our plasmon-supported break-junction (PBJ) technique[6] addresses this issue by significantly increasing the lifetime of SM junctions while preserving the native structure of the target molecule. Remarkably, the optical stabilizing force exerted by the nearfield gradient in PBJ enhances the stability of SM junctions, eliminating the need for chemical modifications of the target molecule or the electrode.
In the first part, we will explore how the nearfield manipulation influences capture and release mechanisms.[7] As the field strength increases, the rate constant of capture kinetics rises while the release kinetics decrease, favouring the capture state over the release state. Consequently, the SM capture state becomes more likely and more stable than the release state above a specific nearfield strength threshold.
In the second part, we will delve into how the PBJ trapping technique can be further enhanced for biomolecular contacts[8] through the manipulation of two physical features: (i) the optical resonance of the target molecule and (ii) the energy of the localized surface plasmon resonance in the nanogap. By leveraging these factors, we can extend the effectiveness of PBJ trapping in capturing and biomolecules.

DNA Guided Self-Assembly of Organic Materials JamesCanary, RuojieSha, ThanukaUdumulla and ChufanYang; New York University, United States

We have developed a highly versatile system for the organization of 2-dimensional (2D) materials on the nanoscale. This system is predicated on the use of DNA-based information as an organizing principle, and on our ability to design DNA to encapsulate and orient other molecular and nanoscopic species in a diverse and effective fashion. We apply branched DNA molecules, not simple linear DNA, to the formation of connected networks of materials in a predictable fashion [1]. We are able to build robust DNA 2D assemblies. Each of these assemblies can be filled as desired, with any molecules, macromolecules or nanoparticles that can be derivatized to interact, bond or bind with the DNA.

In earlier work, chemistry was developed to enable covalent attachment of organic groups to the 2'-O-ribosyl position of RNA nucleotides. Such an attachment strategy minimizes distortion in DNA duplexes by directing appended groups to minimize unfavorable steric interactions with A-form helical structures. A variety of synthetic approaches were examined, involving modifications at different points in DNA oligonucleotide synthesis. Much of the chemistry was tested in the context of appended oligomers of nylon and poly(ethyleneglycol).

Monodisperse oligomers of electroactive organic polymers were synthesized and appended to DNA oligonucleotides. An octamer of polyaniline, which shows rich electrochemical behavior, was incorporated into a rhombohedral DNA lattice. The resulting crystal showed excellent optical response consistent with cycling between its redox forms [2]. It was later studied in a smaller assembly showing reconfigurable excitonic interactions [3]. A heptamer molecule related to poly(phenylenevinylene) was included in a DNA crystal and found to show strong polarization properties [4].

This presentation will describe unpublished work on the synthesis and assembly of DNA-GNR chimeras within DNA nanostructures.

DNA Encoded Self-Assembly of Molecular Semiconductors for Light-Harvesting JeffreyGorman, StephanieM. Hart, TorstenJohn, MariaA. Castellanos, AdamWillard, GabrielaSchalu-Cohen and MarkBathe; MIT, United States

Plants transport and convert solar energy into radical-pairs at the ‘reaction center’ to generate fuel. Nature achieves this with a homogeneous set of pigments, where the host protein environment facilitates tailored couplings between many pigments each with their own function. In contrast, exquisite control over artificial semiconductors for exciton circuits and solar cells remains lacking. Our ability to synthetically generate molecular networks with prescribed nanoscale structure is lacking. To address this gap towards well-designed molecular optoelectronics, we report the development of DNA scaffolds hosting chromophores,[1] to enhance excited state evolution for solar light harvesting.

Here we study the exciton evolution between strongly coupled perylene diimide (PDI) dye pairs scaffolded in DNA. PDIs are exemplar molecular aggregates as they produce a range of photoinduced excited states, depending on their spatial organization.[2] To study how we can map a specific excited-state pathway to a PDI-DNA structure, we exploited the molecular precision of DNA base-pairing and nanoscale rigidity of DNA origami to generate a library of optoelectronic constructs. We make hundreds of nucleic acid-chromophore conjugates and self-assemble them intro prescribed shapes. Using ultrafast spectroscopy, we identified designs that gave rise to different photoinduced species, including excimers and charge-transfer states. Next, we use computational modelling to pinpoint geometrical features that can be linked to a specific excited-state pathway. Our synthetic DNA platform offers the ability to rapidly survey the structure-property of molecular aggregates and identify optimized structures that can be useful for applications in excitonic devices, including solar conversion and quantum information.

Antigens and Nucleic-Acid Strands Single-Molecule Bioelectronic Reliable Detection at the 10^-20 Molar Concentration LuisaTorsi; University of Bari A. Moro, Italy

Single-molecule detection can be accomplished through two approaches: utilizing a nanometric interface or employing an amplification mechanism. In the former scenario, various noteworthy studies have explored nanometric detection interfaces such as transistor nanowires or nanotubes. These interfaces allow for the investigation of individual selective interactions involving proteins and nucleic acid-based targets, as the size of the target matches the detecting surface area. However, due to the "diffusion barrier issue," the target concentration must be at least in the range of 10^-9 molar (M).

To overcome this challenge, an amplification mechanism is employed to amplify the signal by a million-fold. For nucleic acid-based targets, the polymerase chain reaction (PCR) serves this purpose, but a similar amplification mechanism is required for proteins.

This lecture focuses on the "Single Molecule with a Large Transistor – SiMoT" platform, which enables the reliable detection of single molecules in 0.1 mL of both antigens and nucleic acid strands at concentrations as low as 10^-20 molar. This breakthrough is made possible by a domino-like amplification mechanism. Additionally, the lecture will delve into the significant applications of this technology.

DNA as a vehicle for molecular programming relies on the predictability and information storage capability of the canonical Watson-Crick base pairs, A:T and G:C. With only four Watson-Crick nucleobases and the poor electronic conduction in A:T pairs, it has become clear that there are strong limitations on the diversity and ensuing complexity of DNA-based electronic systems. To address this limitation, we present an expanded DNA alphabet based on metal-mediated DNA (mmDNA) base pairing in which we substitute hydrogen bonds between pyrimidine nucleobases with templated metal ion coordination.

We employ a self-assembling 3D DNA crystal system, the tensegrity triangle, to determine the biomolecular structures of 30+ metal ion (Ag^+, Hg^{2+}, Au^+, and Cd^{2+})-mediated DNA (mmDNA) base pairs, and we further use this comprehensive structural library to elucidate fundamental design rules for an expanded DNA metal coding system. Energy gap calculations elucidate an electronic fingerprint for the baes pair classes in our library, and show additional levels in the lowest unoccupied molecular orbitals (LUMO) of mmDNA structures, rendering them attractive molecular electronic candidates. Our results are consistent with previous studies in which mmDNA base pairs have been shown to have superlative electronic and magnetic properties, and we suggest a transmission mechanism to describe this behavior.

We further manipulate our self-assembled DNA crystals using pH to capture by x-ray diffraction a series of reversible, pH-driven chemical reactions involving silver, mercury and gold ions, with implications for bandgap tuning. Importantly, we identify titration points at which mmDNA pairs exist in a heterobimetallic state, where a single DNA base pair binds to both Ag^+ and Hg^{2+} in tandem. The precision self-assembly of heterobimetallic DNA chemistry at the sub-nanometer scale will drive atomistic design frameworks for more elaborate mmDNA-based nanodevices and nanotechnologies. We anticipate the integration of this expanded mmDNA alphabet as a means of programming specific interactions into DNA nanostructures to enable the exploitation of their electronic, magnetic, and catalytic properties for future nanotechnology applications.

Selectivity and Real-Time Potassium Ion Sensor Based on dsDNA Sequences Aptamer in ZnO Thin-Film Transistors with Floating Structure Yen ShuoChen[1], Chun ChiChen[2], Hsin-ChiangYou[3] and Fu-HsiangKo[1]; [1]National Yang Ming Chiao Tung University, Taiwan; [2]Taiwan Semiconductor Research Institute, Taiwan; [3]National Chin-Yi University of Technology, Taiwan

The level of potassium ions in clinical diagnosis is most associated with chronic kidney disease (CKD) and the pathophysiology of insulin secretion. The normal concentration in human blood of potassium ions is 2.5 to 5.5 mEq/L. In the past, the assay was mostly done by Blood Potassium Content Assay Kit, which provided that the potassium ions in the serum interact with sodium tetraphenylborate to form water-insoluble, which is time-consuming. Therefore, a rapid and immediate of detecting potassium ions is helpful for this issue. Recently, thin film transistors (TFTs) such as zinc oxide (ZnO) for biosensors have become the focus of increased research interest due to their high transparency and non-toxicity, and several reports have discussed the impact of floating gate structures on the sensing and reproducibility aspects of biosensors in solution.
In this study, unique double-stranded deoxyribonucleic acid (dsDNA) was used in combination with different concentrations of K ions detected through ZnO-based biosensors with a floating-gate structure. The TFTs were successfully operated as a switching device at a low operating voltage of 5 V. Here, ZnO TFTs with floating gate structures were used to sense dsDNA bound to metal ions in solution by non-contact sensing, and more than 50 detection times were achieved by removing solutions and low-temperature annealing, which is useful for biosensing. The dsDNA at 100 μM was dissolved in DI water and TE buffer to form a solution. The ratio of DI water to Tris-EDTA (TE) buffer was 1:10, and the molecular weight of the dsDNA (GGTTGGTGTGGTTGG) was 359.8. The KCl concentrations were 0.01 M (0.8 mEq/L), 0.03 M (2.5 mEq/L), and 0.1 M (5.5 mEq/L), respectively. To understand the relationship between the number of combinations of different concentrations of potassium ions and the potential of the DNA sequence, the number of zeta potentials for each concentration was measured. The zeta potential of dsDNA was -23.63 mV. The stability of 0.01 M KCl solution was tested with -15.01 and -14.41 mV, respectively. The zeta potential was measured within an inaccuracy of 0.6 mV because a few ions flowing into the solution were unaffected. A positive charge is generated when the DNA sequence binds to potassium ions showing a glove-like shape and can completely wrap around K^+. When the DNA sequence was bound to K^+ in the 0.01 M KCl solution, the zeta potential was -15.01 mV. The zeta potential was -2 mV when the concentration of the KCl solution was 0.03 M; the zeta potential was 52.53 mV when the concentration was 0.1 M. These results showed that the KCL elevated by 6.75 mV per 0.01 M concentration.

To investigate ZnO-TFT-based potassium ion detectors, the performance of the ZnO TFT was assessed by analyzing the field-effect mobility (μFE), threshold voltage (V_{TH}), and threshold voltage shift ($\triangle V_{TH}$) for carrier transport. In the initial state, the TFTs exhibited typically electrical performance. Specifically, I_{on}/I_{off} was 2.3×10^4 A, the threshold voltage (V_{TH}) was -2 V, and the field-effect mobility (μFE) was 0.006 $cm^2 V^{-1} s^{-1}$. A unique ssDNA sequence combined with 0.01, 0.03, and 0.1 M KCl. The TFTs exhibited selective and sensitive electrical performance: $I_{on}/I_{off} = 3.8 \times 10^4$ A, $V_{TH} = 2.5$ V, and = 0.0052 $cm^2 V^{-1} s^{-1}$; $I_{on}/I_{off} = 2.9 \times 10^4$ A, $V_{TH} = 2$ V, and = 0.0059 $cm^2 V^{-1} s^{-1}$; and $I_{on}/I_{off} = 3.6 \times 10^4$ A, = -0.5 V, and = 0.0068 $cm^2V^{-1}s^{-1}$. The ZnO-based TFT showed that KCL was elevated by 0.5 V per 0.01 M of concentration of K^+. As the concentration rises, dsDNA binds to more K^+, suggesting that the detected positively and negatively charged objects affect the turn-on voltage of ZnO TFTs. The increase in ΔV_{TH} also indicated increased binding of dsDNA to K+ with potassium concentrations ranging from 0.01 M to 0.1 M and showed a linear correlation (0.99706). This ZnO-based TFT with DNA sequences aptamer could be used as a biosensor.

Long Range Conductivity in Non-Redox Active Proteins StuartM. Lindsay[1], DmitryMatyushov[1], AlekseiAksimentiev[2] and SiddharthKrishnan[2]; [1]Arizona State University, United States; [2]University of Illinois at Urbana-Champaign, United States

It is widely assumed that efficient charge transfer in proteins requires the presence of redox cofactors, but we have found long-range (nS over > 10 nm) conductance in many proteins that do not contain redox cofactors. This is important because it means that fluctuations of many proteins can be followed electrically, as their conductance changes with conformation. For example, we have been able to follow the fluctuations in a DNA polymerase as it actively processes a template.
The conductivity of a hopping conductor is proportional to the quantity nD, where n is the carrier density and D is the diffusion constant for carriers. Since proteins do not possess a Fermi sea, charge injection (n>0) is required for conductivity. This is in line with our observations that the protein needs to be coupled to the electrodes via ligands or specific chemical bonds for conductivity to be observed, though adventitious reactive groups on the protein can serve the same purpose.
A diffusion constant D> 2x 10^{-4} cm^2/s is required to account for the most highly conductive protein wires (OmcS cytochrome wires) and this, in turn, requires a reorganization energy on the order of kT, a small fraction of the value derived from the Stokes shift in classical Marcus theory. Molecular dynamics simulations of a series of linear proteins (whose electronic properties have been measured) show that the Marcus picture is not valid, the free energy parabolas associated with charge transfer between aromatic residues being broader than predicted from the Stokes shift. As a consequence, the reaction barriers are typically ~ 40 meV, almost equal to 3/2 kT. The calculated diffusion constant is 2x 10^{-4} cm^2/s, accounting for the observed decay length. A model for charge injection determines n with one adjustable parameter that is bounded by electrochemical data, and the resulting conductivity is in agreement with experimental data.

Combinations of Analytical and Machine Learning Methods in a Single Simulations Framework for Modelling of BioFETs ViharP. Georgiev[1], NaveenKumar[1] and CesarPascual Garcia[2]; [1]University of Glasgow, United Kingdom; [2]Luxembourg Institute of Science and Technology, Luxembourg

In this paper, we present the simulation results of a BioFET using a novel simulation methodology implemented in a computational framework called the Biomolecule-Oxide Simulator (BOxSim). Our novel simulation methodology is based on Gouy-Chapman-Stern and the modified Site-binding models in combination with a machine learning methodology.

Moreover, our "**BOxSim**" framework is the computational simulation framework that works on the hierarchical inclusion of interdependent functions to operate multiple models simultaneously. BOxSim is flexible simulation environment which considers the problems of reactive sites from oxide surfaces or non-specific bindings along with the noise present in the experimental signal to calibrate and extract the required device output characteristics. It can help in generating the sensor response which can be experimentally calibrated to confirm the surface density of the specific and non-specific binding as a yield of the process while filtering the noise with the help of the developed methodology. BOxSim is designed in a way that can interact with the commercial tool (e.g., Synopsys TCAD) and our inhouse-simulator called Nano-electronic Simulation Software (NESS) to simulate the main device characteristics for designing either Ion-sensitive FET (ISFET) or Chem/Bio-FET based on the application. Industry-standard compact (BSIM) models can also be used to interact with the BOxSim which takes the generated surface potential from the BOxSim simulator and transfers it into a circuit simulator to evaluate various ISFET circuit designs.

To show the capabilities of our BOxSim framework, as input we have considered several oxides, amino acids (AA) and short peptides which generate distinct signatures for arch AA or peptide. We have investigated the impact of various high-k dielectric materials as the gate oxide on important Figures of Merit (FoM) such as current in the channel of the device, surface potential (Ψ_o), sensitivity and intrinsic buffer capacitance. More importantly, the variation of differential capacitance (C_T) with the second gradient of drain current (d^2I_o/dpH^2) and surface potential ($d^2\Psi_o/dpH^2$) are used to uniquely identify the signatures of different amino acids or peptides. The surface potential of oxides is dependent on the affinity constants and the zero-crossover point represents the zwitterion state. Similarly, we have simulated the detection process of different AA such as Glutamic Acid (E) and Lysine (K) immobilized with carboxyl (C-Imm.) or amine (N-Imm.) terminal. The affinity constants, isoelectric point, and density of amino acids can be extracted from the $d^2\Psi_o/dpH^2$ variation with the bulk pH. Other than amino acids, we have shown the distinct features of short a peptide Phenylalanine-Proline (FP) immobilized with carboxyl-terminal and the addition of Glutamic Acid to the sequence The sensor output can be observed as the variation of drain current with the pH for the immobilized peptide sequence on the sensing surface. We have also confirmed the reliability of the designed model by calibrating the simulated results with the experimental data for different physical conditions. The proposed method can be helpful in defining an efficient method for label-free protein sequencing.

Electron Transport Through Proteins beyond the Conventional Tunneling Limit DavidCahen and SudiptaBera; Weizmann Institute of Science, Israel

A key conundrum of bio-molecular electronics is the quite efficient electron transport (ETp) through solid-state junctions wider than a few nm, often without temperature activation. Such a behavior challenges known transport mechanisms, given that proteins, lacking extended conjugation, are low charge carrier density molecules and the experimental ETp results are surprising. A wide range of electron transport (ETp) studies has been done, mostly on protein films of comparable thickness, one that is within the limit of quantum mechanical tunneling (2, or for conjugated systems ~5 nm). Typically, for polymer junctions, current decays exponentially with junction width, limiting detection beyond a certain thickness and this should hold also with biopolymers, such as proteins. We find now (Bera et al, submitted) that we can detect and measure protein conduction of from 9 - 60 nm thick junctions of self-assembled *bacteriorhodopsin* multilayers to test the limit of ETp as a function of junction thickness, in a large (~10^{-3} cm^2) area configuration. Junction quality was confirmed by impedance spectroscopy and voltage breakdown. Such junctions show near or complete activation-less transport with the most-efficient length-normalized electron transport reported so far (0.06-0.53 nm^{-1}).
The small to negligible (<200K) temperature dependence, among other things, excludes hopping as a plausible mechanism. While a modified Landauer model could be a possibility, *the large transport distance (60 nm) makes coherent quantum mechanical tunneling physically implausible.* The results may be understood by assuming that ETp is limited by injection at (via tunneling through) one of the contacts, followed by a much more efficient charge propagation across the proteins. Additionally, electrostatics of the protein film, whose dielectric constant we measured by impedance, will further limit the number of charge carriers in the protein film. Such a view also defines the question to tackle now, namely how electrons can pass through such wide protein layers at a rate that is measurable by our electronics and, apparently, more efficient than the rate of injection through the contacts.

Charge Transport Through Self-Assembled Monolayers—The Roles of Conformation and Chelation SamuelE. Root, GeorgeM. Whitesides, YuanLi and LeeBelding; Harvard University, United States

To elucidate charge transport mechanisms through complex biomolecules--involving conformationally flexible, supramolecular systems--and isolate effects arising from different molecular scale features, it is useful to investigate simple, well-defined model systems. The “EGaIn junction," which uses a liquid metal electrode to measure charge transport through self-assembled monolayers (SAM), paired with a physical-organic approach to systematically modify the molecules within the SAM, provides a powerful platform for approaching this problem. I will discuss two recent works using this approach to understand (1) the role of molecular conformation (and specifically conformational disorder) on tunneling and rectification of current, and (2) charge transport through SAMs terminated by a chelating group and the influence of the binding of different metal ions.

1) Conformation. This work demonstrates that molecular conformation of molecules making up self-assembled monolayers (SAMs) influences the rates of charge tunneling (CT) through them, in molecular junctions of the form AuTS/S(CH2)2CONR1R2//Ga2O3/EGaIn, where R1 and R2 were alkyl chains of different length. The lengths of chains R1 and R2 were selected to influence the conformational structure of the molecules in the monolayer. The conformations of the molecules influence the thickness of the monolayer and their rectification ratios at ±1.0 V. When R1 = H, the molecules are well ordered and exist predominantly in trans-extended conformations. When R1 is an alkyl group (e.g., R1 ≠ H) however, their conformations can no longer be all-trans-extended, and the molecules adopt more gauche dihedral angles. This change in type of conformation decreases conformational order and influences rates of tunneling. When R1 = R2, the rates of CT decrease (up to 6.3x), relative to rates of CT observed through SAMs having the same total chain lengths, or thicknesses, when R1 = H. When R1 ≠ H ≠ R2, there is a weaker correlation (relative to when R1 = H or R2) between current density and chain length or monolayer thickness, and in some cases the rates of CT through SAMs made from molecules with different R2 groups are different, even when the thickness of the SAM (as determined by XPS) is the same.

2) Chelation. This paper describes a surface analysis technique that uses the “EGaIn junction” to measure tunneling current densities (J(V), amps/cm2) through self-assembled monolayers (SAMs) terminated in a chelating group and incorporating different transition metal ions. Comparisons of J(V) measurements (performed ex-situ, in air) between bare chelating groups and chelates—formed through incubation of the SAM within a solution of bivalent metal ions—are used to characterize the composition of the SAM and infer the dissociation constant (Kd, mol/L), as well as kinetic rate constants (koff, L/mol s; kon, 1/s) of the reversible chelate-metal reaction. To demonstrate the concept, SAMs incorporating a chelating terminal group were incubated within ethanol solutions of metal salts (CuCl2, NiCl2, and AgClO4). After rinsing and drying the surface, measurements of tunneling current as a function of incubation time and concentration in solution are analyzed with a simple model to infer koff, kon, and Kd. X-ray photoelectron spectroscopy (XPS) provides an independent measure of surface composition to confirm inferences from J(V) measurements, as well as to characterize the stoichiometry and oxidation states of the bound metal ions. The titration experiments establish that: (i) bound metal ions are stable to the rinsing step as long as the rinsing time, τ_rinse is at least 10 × lower than 1/koff; (ii) the bound metal ions increase the current density at the negative bias and reduce the rectification observed with free bpy terminal groups; (iii) the values of Kd measured using tunneling currents are comparable to those measured using XPS, but larger than those measured in solution.

Tunneling-to-Hopping Transition in Multiheme Cytochrome Bioelectronic Junctions JochenBlumberger[1], XiaojingWu[1] and ZdenekFutera[2]; [1]University College London, United Kingdom; [2]University of South Bohemia, Czechia

Multiheme cytochromes (MHCs) have attracted much interest for use in nanobioelectronic junctions due to their high electronic conductances.

Recent measurements on dry MHC junctions suggested that a coherent tunneling mechanism is operative over surprisingly long distances (>3 nm), which challenges our understanding of coherent transport phenomena. In my talk I will present large-scale electronic structure calculations of gold-MHC-gold junctions that have allowed us to obtain the current-voltage characteristic of these proteins in well defined adsorption geometries and orientations[1,2]. We show that the high electronic conductances of MHC proteins is due to (i) a low exponential distance decay constant for coherent conduction (beta = 0.2 Angstrom^−1) and (ii) a large density of protein electronic states which prolongs the coherent tunneling regime to distances that exceed those in molecular wires made of small molecules. We also find that incoherent hopping conduction is uncompetitive in the experimental setup due to the large energy level offset at the protein−electrode interface. Removing this offset, e.g., by gating, we predict that the transport mechanism crosses over from coherent tunneling to incoherent hopping at a protein size of ∼7 nm, thus enabling electron transport on the micrometer scale with a shallow polynomial (∼1/r) distance decay.

Modeling Spin Transport in Multi-Heme Cytochromes WilliamLivernois and AnantAnantram; University of Washington, United States

Multi-heme cytochromes have attracted attention due to their conductive properties [1] and, more recently, their spin-selective properties [2]. The small tetraheme cytochrome (STC), a c-type cytochrome prominently found in Shewanella oneidensis, has been experimentally validated to act as a spin filter [3], highlighting its potential integration into the burgeoning field of nano-scale spintronic devices. A spin-dependent transport model was used to model this system, building upon prior work that has proven effective in analyzing similar biomaterials and cytochromes [4]. The improved model incorporates non-collinear effects such as spin-orbit coupling using generalized open shell density functional theory (DFT) in order to analyze the electronic structure of the cytochrome and spin-dependent transport properties. Preliminary findings indicate that collinear effects, arising from electron exchange and spin state, predominantly influence the transport pathway while spin-orbit effects only cause minor shifts in orbital energies.

To complement our electronic structure and transport studies, we have undertaken a detailed analysis of the role of the peptide backbone, employing hybrid Quantum Mechanics/Molecular Mechanics (QM/MM) modeling methods. The modeling results indicate that the peptide backbone functions primarily as a structural scaffold facilitating heme-to-heme electron transport, rather than directly contributing to electron conduction. Additionally, recognizing the importance of solvation effects in biological systems, we have investigated the impact of solvation on the cytochrome’s properties. The solvent, modeled using an implicit model and counterions, was found to modulate the coupling between heme sites and the overall conductivity of the cytochrome.

The research was supported by National Science Foundation NSF Grant Number 2317843, NSF Future of Manufacturing Grant No. 2229131 and the NDSEG fellowship.

Introducing Solid-State Biomolecular Protonics—Lateral Proton Conduction Across Biological Membranes NadavAmdursky; Technion--Israel Institute of Technology, Israel

Nature is full of various charge transfer circuits that are at the heart of our existence, such as in our aerobic respiration system or the plant’s photosystem. While the focus of this symposium is Biomolecular Electronics, meaning following electron transport (ET) across biomaterials, proton transport (PT) is equivalent in its importance, and in some cases, such as in the mentioned examples, the role of the ET chain reaction is to facilitate PT. As one can imagine, the mechanisms behind ET and PT are different, having different aspects within the biomolecule that are important for the transport mechanism. Moreover, from an experimental point of view, in electronic devices, it might be hard to distinguish between PT and ET. Here, we introduce a new

experimental approach to investigate lateral PT across membranes, which is based on measuring long-range lateral proton conduction via a few layers of lipid bilayers in a solid-state-like environment, i.e., without having bulk water surrounding the membrane. This configuration enables focusing on the surface of the membrane while decoupling it from bulk water. Hence, by controlling the relative humidity of the environment, we can directly explore the role of water in the lateral PT process. We show that proton conduction is highly dependent on the membrane composition, where we explore the role of the head group, the level of tail saturation, and the role of the membrane phase and fluidity. The measured PT as a function of temperature shows an inverse temperature dependency, which we explain by the desorption/adsorption of water molecules into the solid membrane platform. We explain our findings by discussing the role of percolating hydrogen bonding within the membrane structure in a Grotthuss-like mechanism. Our new understanding of the specific role of the membrane interface in supporting lateral long-range PT is not only providing new information related to this fundamental biochemical and biophysical process but also very important to any use of membranes in various applications, from biomedical applications to the use of proton-conductive membranes in energy-related applications.

2:00 PM SB06.04.02

Current Rectification via Photosystem I Monolayers Induced by Their Orientation on Hydrophilic Self-Assembled Monolayers on Titanium Nitride HectorJ. Rojas Rojas[1], FengLiu[2], JerryA. Fereiro[3], DomenikosChryssikos[1], DarioLeister[2] and MarcTornow[1]; [1]Technical University of Munich, Germany; [2]Ludwig-Maximilians-Universität München, Germany; [3]Indian Institute of Science Education and Research, India

The photosensitive protein Photosystem I (PSI) is considered one of the most efficient light-harvesting molecular complexes in nature [1]. The electron transport studies carried out on PSI monolayer(s) formed on (quasi-) metallic contacts (highly doped silicon, indium tin oxide, silver, or, in the majority of cases, gold) using reliable soft top contacts show high reproducibility [2-5], along with its peculiar ability to rectify electrical current [2,4,5]. In the present study, we introduce titanium nitride (TiN) as a promising alternative bottom contact material to investigate the electronic transport properties of PSI. TiN is a hard, conductive ceramic well-established in CMOS technology, chemically inert, and biocompatible. Self-assembled monolayers (SAMs) of various hydrophilic group-terminated phosphonic acids covalently bound to the TiN surface were used to attach PSI layers onto its head surface electrostatically. Specifically, we investigated -OH, -COOH, and -NH_2 terminal head groups and tailored mixtures of these. We used atomic force microscopy to confirm the formation of a PSI monolayer of thickness approx. 6 nm, with about 80% surface coverage. DC electrical measurements using eutectic gallium-indium (EGaIn) soft top contacts showed asymmetric I-V curves, with rectification ratio (RR) values varying from 150 to 460. We assign the observed rectification to possible PSI orientation preferences on a particular linker head group. Current rectification in PSI has been previously attributed to an internal electric dipole originating from charged states of the protein residual groups [4,5]. Our data indicate an orientation in which the stromal side of the protein complex is predominantly in contact with the hydrophilic linker surface. We analyze our data within the framework of tunneling through an asymmetric trapezoidal barrier [6].

Modeling Quantum Charge Transport Through Nucleic Acid Structures: Role of Decoherence HashemMohammad[1] and AnantAnantram[2]; [1]Kuwait University, Kuwait; [2]University of Washington, United States

Understanding the conductance of DNA helps in the development of new sequencing techniques, methods to sense biological processes, disease detection techniques, and future DNA-based nanoelectronics. The challenges in understanding the underlying transport phenomena stem from the facts that: 1) DNA is a floppy molecule that exists in a solvent environment, 2) sequence and conformation affect the energy levels distribution along the strand, and 3) the need to account for the details of the DNA-electrode junction.
Modeling of charge transport through nanoscale nucleic acid structures requires careful attention to the quantum effects. The fluctuating nature of the molecule and the surrounding solvent environment can affect the electron transport process depending on the length scale, going from coherent to decoherent transport, or to an intermediate state of coherent-decoherent transport. One prominent method to model charge transport through nanoscale devices is the Green's function formalism. This formalism uses the Hamiltonian obtained from quantum mechanical simulations such as DFT to calculate the electron transmission properties. From the transmission, we can calculate other physical properties such as conductance and current-voltage characteristics. This formalism allows us to include the effect of attaching metallic contacts to the DNA through self-energy terms, removing the need for explicitly including them in the quantum-based simulations step. Additionally, it can incorporate decoherence due to scattering through self-energy terms as well.
This presentation focuses on the theory and modeling of quantum transport through nucleic acid structures using Green's function method with decoherence probes. We model a DNA connected to two metallic contacts in a contact-DNA-contact setup. For a weakly-coupled system such as DNA, we use the decoherence probes method to account for scattering events. This technique uses phenomenological probes to mimic the interaction of electrons with the environment as they lose phase information and/or gain and lose energy (inelastic scattering). Decoherence broadens the energy levels and allows electrons to traverse the structure at energies that were not originally accessible to the electrons. The broadening of energy levels increases the transmission probability across the DNA. This constitutes the main difference between coherent and decoherent charge transport. Thus, the inclusion of decoherence allows us to obtain conductance values within the range of the experimental values, something that the coherent transport could not achieve.
The decoherence probes are included in the model as self-energies controlled by a spatially dependent parameter that represents the average scattering time for the electron. In the previous work, the decoherence parameter used was energy independent. The drawback of this is that it overestimates the transmission in the HOMO-LUMO gap and washes out distinct transmission features within the HOMO or LUMO bands. Therefore, we present an energy-dependent decoherence model that allows us to better describe the transmission spectra. We demonstrate that this model can generate the expected exponential decay of conductance with the increase in DNA length, and yields conductance values that agree with experiments.
We apply the decoherence probe method to a variety of DNA strands to demonstrate its use. The applications involve (i) detecting a single base mutation in a 15-base-pair long DNA strand, (ii) studying the properties of heterostructures created with DNA strands analogous to solid-state heterojunctions, and (iii) doping of DNA by an intercalating molecule (anthraquinone) between the base pairs, which allows a change in conductance depending on the redox state of the intercalator.

How Do Electric Bacteria Breathe Without Oxygen or Soluble Electron Acceptors? Protein Nanowires: Structures, Functions, and Ultrafast Electron Transfer Mechanisms NikhilS. Malvankar; Yale University, United States

Deep in the ocean or underground, where there is no oxygen, *Geobacter* "breathe" by projecting tiny hair-like protein filaments called "nanowires" into the soil, to dispose of excess electrons resulting from the conversion of nutrients to energy, cleaning up radioactive sites. Although it is long known that *Geobacter* use filaments for electron transfer (*Nature* 2002, 2005), it was not clear what they are actually made of and why they are conductive.
Our studies have revealed a surprise: the nanowires have a core of hemes lining up to create a continuous path along which electrons travel (*Cell*'19, *Nature Chem.Bio.*'20, *Nature Micro '*23) and and can be engineered with atomic precision using recombinant DNA technology, making for remarkably versatile electronic components.
We have further found that *Geobacter* pili remain hidden inside the cell and serve as a piston to secrete nanowire-forming cytochromes (*Nature* 2021) rather than functioning as a nanowire themselves as previously thought (*Current Opinion* 2020).
These studies solve a longstanding mystery to explain our previous findings that these bacteria transport electrons via nanowires (*Nature Nano*. 2014) over 100-times their size to electron acceptors (*Nature Nano.* 2011) and partner cells (*Science* 2010) and store electrons when acceptors are absent akin to how humans use their lungs (*ChemPhysChem* 2012) .
Our contact-free measurements of intrinsic electron conductivity in individual protein nanowires reveals how energetics and proximity of proton acceptors modulate conductivity by 100-fold (*PNAS* 2021, *Biochem. Journal* 2021). We have also developed synthetic protein nanowires with tunable conductivity and programmable self-assembly using non-natural click chemistry functionality (*Nature Comm.* 2022).
In this talk I will present our efforts to identify the physical and molecular mechanism of high conductivity of microbial cytochrome nanowires. Our conducting-probe AFM measurements show one of the highest electronic conductivity ever reported in proteins (> 100 S/cm) (*Nature Chem.Bio.*'20). Femtosecond transient absorption spectroscopy and quantum dynamics simulations reveal ultrafast (<200 fs) electron transfer between nanowire hemes upon photoexcitation, enhancing carrier density and mobility. Photoconductive atomic force microscopy shows up to 100-fold increase in photocurrent in purified individual nanowires. Photocurrents respond rapidly (<100 ms) to the excitation and persist reversibly for hours (*Nature Comm.*'22). Furthermore, nanowires and biofilms show non-classical temperature dependence of conductivity with cooling accelerating electron transport by 300-fold.

Our efforts to computationally model the heme redox potential and conductivity of nanowires yielded up to a billion-fold lower conductivity than experiments (*JPCB'21, JPCB'22*), illustrating that the existing computational models based on electron hopping assumption fail to capture electron transfer in biological nanowires. This raises the possibility that biological nanowires employ a fundamentally different, currently unknown mechanism. Thus, existing models predict the same conductivity for all nanowires with computed timescales for heme-to-heme electron transfers (100 ns), million-fold lower than that measured using transient absorption in excited-state (*Nature Comm.*) and conductivity in ground-state for fully hydrated (*Nature* & *Cell*) or air-dried nanowires (*Science Adv.*).

Notably, multiple computational studies have predicted that invoking quantum effects could account for the high conductivity of these nanowires (*Nanotechology*'20, *IEEE*'21, *ACS Nano*'23). I will present our efforts to experimentally assess these computational predictions using multiple probes such as light, temperature, electric and magnetic fields. I will also discuss how our studies are helping to understand, predict and control extracellular electron transfer by nanowires used by diverse environmental microbes to capture, convert and store energy.

Combination of Droplet Oscillation and Dielectrophoresis to Increase the Sensitivity of Biosensors MartenMusiol[1], MarteThorns[1], BenitaHafemann[1], FenjaSchröder[1], FelixHirschberg[1], AnnalenaEckert[1], RebekkaBiedendieck[1], Hans-HermannJohannes[1,2], DieterJahn[1] and WolfgangKowalsky[1,2]; [1]Technische Universität Braunschweig, Germany; [2]Leibniz Universität Hannover, Germany

Biosensors have become a research field of high interest over the last few years. Especially the detection of bacteria is one of the main issues for biosensors. To prevent human health risks and detect even a small quantity of bacteria e.g. in water sources, reliable and accurate detection of bacteria must be guaranteed even for small concentration of bacteria. To increase the sensitivity of such biosensors it is of high importance to increase the number of bacteria on the sensing area. In this work dielectrophoresis (DEP) is utilized to improve bacteria collection at the sensing area.

DEP accelerates dielectric particles suspended in a liquid towards regions of either high or low electric field gradient by applying an alternating inhomogeneous electric field. The force associated with DEP is called dielectrophoretic force (DEP force). This force operates in a radius of micrometers. The transport of particles to the operating area of the DEP force is improved by droplet oscillation. This method provides liquid turbulences inside the particle solution. Thereby, more bacterial cells are collected on the sensing area.

The droplet oscillations are generated by two oscillation electrodes. Those electrodes are implemented beneath the DEP setup with a distance of micrometers. Between the DEP and oscillation electrodes a droplet of a polar liquid is located. By applying a voltage to one of the droplet oscillation electrodes the polar molecules of the liquid align with the electric field. The alignment of the molecules leads to a decrease of surface tension in the area of the electric field. As a response the liquid starts to flow towards the region of low surface tension. To get a consistent flow inside the droplet the applied voltage switches between the two oscillation electrodes.

This research focuses on optimizing the reciprocal influence of the DEP field and the electric field for the droplet oscillation. In order to enhance the experimental setup, the simulation software COMSOL Multiphysics® was used. In this simulation parameters like the frequencies of the electric fields or electrode geometries were taken into account. The results of the simulations should allow us to construct a setup combining droplet oscillation and DEP, that is capable of improving the sensitivity of biosensors.

Key words: droplet oscillation, dielectrophoresis, liquid turbulences, biosensors, bacteria

4:00 PM *SB06.04.06
Seeing is Believing: Quantitative Imaging of Bacterial Electron Export Correlated with Protein Structure and Mechanical Properties SibelE. Yalcin; Yale University, United States

Protein nanowires enable *Geobacter* to survive without-oxygen like soluble electron acceptors perform important functions such as cleaning up radioactive sites, generating electricity (*Nature Nano.* 2011, or sharing electrons with other bacteria (*Science* 2010). Although it is known for more than two decades that *Geobacter* make nanowires (*Nature* 2002, 2005), it was not clear what they are actually made of and why they are conductive. I will present recent discoveries that resolve two decades of confounding observations in thousands of publications that thought these nanowires as pili filaments (*Current Opinion in Chemical Biology* 2020).
Our studies have revealed a surprise: the protein nanowires have a core of metal-containing molecules called hemes Combining high-resolution cryo-electron microscopy with multimodal functional imaging, we found that hemes line up to create a continuous path along which electrons travel. Using multimodal functional imaging (*Physical Biology* 2020) and a suite of electrical, biochemical and physiological studies, we find that rather than pili, nanowires are composed of cytochromes OmcS and OmcZ that transport electrons via seamless stacking of hemes over micrometers (*Cell* 2019, *Nature Chem.Bio.* 2020). I will discuss the physiological need for two different nanowires and their potential applications for sensing, synthesis, and energy production.
As this area of research is in its infancy, many of our advancements are made possible by the new nanoscopic imaging techniques we have developed to address major bottlenecks for the field by quantitatively visualizing the electron export via protein nanowires (*Nature Nano.* 2014) and also by living diverse bacteria at single-cell-level.. For example, the studies described above (*Nature Chem._Bio*) also established a new atomic force microscopy-based multimodal imaging platform to correlate protein structures with electrical and mechanical properties in response to environmental changes, such as pH and redox potential. Using this platform, we found that the rate of electron transfer in protein nanowires depends on the environment. Thus, we were able to make electron transfer 100-times faster by changing environmental conditions, suggesting a possible path to engineering even more conductive protein nanowires. Furthermore, methodological innovation has been a cornerstone of my lab, as the availability of new methods has enabled us to make unexpected discoveries and challenge thinking in the field. For example, our method for growing biofilms in electric fields, allowed not only the first electrogenetic control of biofilm growth (*Nature Chem._Bio*), but enabled us to make the initial discovery that bacterial biofilms conduct electricity (prior to our work, bacterial biofilms had been thought to be electronically non-conducting).
Our nanoscopic imaging methods are widely applicable to diverse biological systems. For example, we have applied these imaging methods for nanoscopic visualization of water binding to minerals (*Sciences_ Adv.*). We revealed that, instead of growing layer by layer as previously thought, water growth starts near edges before surface tension takes over to engulf the surface and forms droplets. This methodology is allowing us to directly visualize how bacteria export electrons to minerals.
I will present our recent experimental and computational studies to identify the mechanism of electron transfer that occurs at unprecedented ultrafast (< 200 fs) rates and over centimeter distances, 10,000-times the size of a bacterium, through measurements of DC and THz conductivity as a function of nanowire length, temperature, frequency, pH and heme stacking (*Science Adv.* 2022). I will also present how we are experimentally assessing computational prediction of quantum effects accounting for the high conductivity of these nanowires (*Nanotechology*'20, *IEEE*'21, *ACS Nano*'23), using multiple probes such as light, temperature, electric and magnetic fields.

4:30 PM SB06.04.07
Quantum Transport with Two Interacting Conduction Channels in Gold-Azurin-Bismuth Solid-State Junctions Ping'anLi[1], SudiptaBera[2], ShailendraKumer-Saxena[2], DavidCahen[2] and YoramSelzer[1]; [1]Tel Aviv University, Israel; [2]Weizmann Institute of Science, Israel

The fundamental question of 'what is the transport path of electrons through proteins?' initially introduced while studying long-range electron transfer between localized redox centers separated by proteins *in vivo* is also highly relevant to the transport properties of solid-state, dry metal-protein-metal junctions because the characteristic Fermi wavelength, λ_F, of the involved electrons is smaller than the contact footprint of the proteins. Under such conditions, the transport path appears to depend on the coupling of the proteins to the leads. For example, in one of the 'work horses' of biomolecular electronics, Au-*Azurin(Az)*-Au junctions, the electrons characterized by $\lambda_F \sim 0.5$ nm appear to be transported coherently by off-resonance tunneling if Az is strongly coupled to the leads and by coherent resonance tunneling associated with levels of the redox center, if it is weakly coupled to the leads. Transport in the latter case is especially puzzling because the modest coupling values invoked for its quantification are sufficiently small to allow the tunneling charges to reside in the resonance levels a sufficient time for structural relaxation (reorganization), which should then entail non-coherent transport by a hopping, i.e., activated hops with tunneling between them.
Here, we report of conductance measurements of molecular ensemble nanopore junctions of Au-Az-bismuth(Bi), with well-defined geometry and containing ~2000 proteins in each pore. We argue that since electrons in Bi have λ_F longer than the protein footprint, transport takes place in these junctions by two interacting conducting channels, characterized by different time scales. The slow and fast channels are associated with the redox center and the protein matrix, respectively, and consequently transport takes place in the first channel by a sequential (non-coherent) process and by coherent non-resonant tunneling in the second channel. The resulting overall observed conductance behavior suggests that the two channels are capacitively coupled and that the broad level responsible for the off-resonance tunneling changes its energy in response to the charge occupation of the weakly coupled (redox) channel. This in turn also suggests that transport in these junctions is dominated by the off-resonance (fast) channel, while the slow (redox) channel contribute directly to conductance only negligibly and instead affects transport by intramolecular gating.

4:45 PM SB06.04.08
Single-Molecule Electrical Detection Methods for Public Health Applications: Towards Sustainble Biosensing AjokeWilliams and JuanM. Artes Vivancos; University of Massachusetts Lowell, United States

In the face of escalating climate change, which significantly impacts both

the global economy and public health, changes in environmental conditions can favor the spread of pathogens and the development of new mutants.[1] Early detection and control of pathogen spread are pivotal in enhancing health outcomes on a broader scale. Among the diverse pathways of pathogen screening, nanotechnology has made remarkable advancements in the last decade. It has also extended its applications to biomolecules, giving rise to BioMolecular Electronics.[2] Notably, the Scanning Tunneling Microscopic (STM)-assisted break junction method (STM-BJ)[3] has led to biophysical studies of individual molecules at the single-molecule level. It stands out as a promising approach for single-molecule biomolecular detection. This concept emerges as a compelling solution for the real-time identification of individual biological molecules. Our research leverages the potential of the STM-BJ method to showcase the electrical detection of RNA cancer biomarkers, distinguishing KRAS mutants G12V and G12C from the wild type.[4] Furthermore, our investigation highlights the remarkable sensitivity and specificity of this technique in identifying RNA coronavirus biomarkers, even at the sub-variant level.[5] This tool can also be applied for the electrical measurement of biomolecular interactions at the single-molecule level.[6] Beyond these pioneering advancements, our focus extends now to the sustainability and life cycle analysis of biosensors. Our future research will focus on minimizing the environmental impact of biosensors by utilizing sustainable materials and processes.[7]

SESSION SB07.01: Soft Bioelectronics
Session Chairs: Achilleas Savva and Georgios Spyropoulos
Monday Morning, November27, 2023
Hynes, Level 1, Room 110

10:30 AM SB07.01.01
Soft Actuator-Assisted Minimally Invasive Peripheral Nerve Interfaces ChaoqunDong, AlejandroCarnicer Lombarte and GeorgeG. Malliaras; University of Cambridge, United Kingdom

Peripheral nerve interfacing has emerged as a highly promising therapeutic technology in various applications, including prosthetic limbs, chronic pain modulation, and the treatment of visceral organ disorders. However, current electrode designs present challenges related to complex handling and implantation-associated irreversible neural damage. This abstract proposes an alternative approach by introducing novel actuatable electrodes that might address these limitations. Our research leverages recent advancements in thin film bioelectronics and soft robotics to develop thin, flexible, and importantly, shape-morphing nerve cuff electrodes. The microfabricated device allows for programming the shape of the electrodes, enabling it to enclose the nerve while maintaining the flexibility to loosen or tighten as needed. This feature ensures a close-fitting conformal interface between the electrode and the nerve, meanwhile enabling straightforward and minimally invasive device explantation steps. Our work presents a promising pathway towards the development of bioelectronic devices that can be manipulated by surgeons to enhance the minimally invasive nature of neurosurgery while achieving optimal electrode-nerve interactions.

10:45 AM SB07.01.02
Thermo-Responsive Conductive Gels for Injectable Bioelectronics VidhikaS. Damani[1], XinranXie[2], KhushbooSuman[1], RachelDaso[2], GianaAlepa[1], JulianAlberto[1], CaseyLorch[1], Ai NinYang[1], YuhangWu[1], NormanWagner[1], JonathanRivnay[2] and LaureV. Kayser[1,1]; [1]University of Delaware, United States; [2]Northwestern University, United States

Conductive hydrogels have gained traction to interface biological systems with electronics for use in sensing and monitoring, tissue engineering, cell adhesion, and implantable electronics. Most bioelectronic implants depend on inorganic nanoparticles such as carbon nanotubes, metals and graphene for conductivity, but these materials lack mechanical compatibility with biological tissue causing scarring and short-term stability. Hydrogels based on water-dispersible conducting polymers such as PEDOT:PSS have been developed to overcome this challenge, due to their lower Young's modulus. However, these gels must either be pre-formed before inserting into the body or, if injected as a fluid, require the presence of external trigger methods and small molecules, such as chemical crosslinkers or endogenous metabolites for crosslinking *in vivo*. Therefore, there is a need for minimally invasive injectable conductive liquids which can gel rapidly in the body irrespective of the type of tissue, are biocompatible, and do not rely on externally applied triggers. To that end, we have developed a thermo-responsive conducting polymer which forms a stable dispersion in water and gels in 41 seconds at 37 °C. We employ the reversible hydrophilic-hydrophobic transition of poly(N-isopropylacrylamide) close to body temperature, which, when combined with the mixed ionic-electronic conduction of PEDOT:PSS yields a fully reversible and conductive gel with a modulus of 20 Pa. In addition, the mechanical and electronic properties can be tuned by changing the concentration of the dispersion in water. The material has shown biocompatibility with L929 cells both by indirect and direct contact assays. This is the world's first fully reversible conductive gel and has potential for use in cardiac patches, scaffolds for tissue engineering and wound healing and for better contact between electrodes and cells for biosensing.

11:00 AM SB07.01.03
Conductive Polymer Enabled Biostable Liquid Metal Electrodes for Neural Interface HuananZhang; University of Utah, United States

Gallium (Ga)-based liquid metal materials have emerged as a promising material platform for soft bioelectronics. Unfortunately, Ga has limited biostability and electrochemical performance under physiological conditions, which can hinder the implementation of its use in bioelectronic devices. Here, an effective conductive polymer deposition strategy on the liquid metal surface to improve the biostability and electrochemical performance of Ga-based liquid metals for use under physiological conditions is demonstrated. The conductive polymer [poly(3,4-ethylene dioxythiophene):tetrafluoroborate]-modified liquid metal surface significantly outperforms the liquid metal.based electrode in mechanical, biological, and electrochemical studies. In vivo action potential recordings in behaving nonhuman primate and invertebrate models demonstrate the feasibility of using liquid metal electrodes for high-performance neural recording applications. This is the first demonstration of single-unit neural recording using Ga-based liquid metal bioelectronic devices to date. The results determine that the electrochemical deposition of conductive polymer over liquid metal can improve the material properties of liquid metal electrodes for use under physiological conditions and open numerous design opportunities for next-generation liquid metal-based neural electrodes

11:15 AM SB07.01.04
Identification of Mitral Valve Disease from Cardiac Potentials in Canine Patients with High-Density, E-Textile, Conducting Polymer BSPM Arrays RubenRuiz-Mateos Serrano[1], SantiagoVelasco Bosom[1], AntonioDominguez-Alfaro[2,1], MatiasL. Picchio[2], DanieleMantione[2], DavidMecerreyes[2] and GeorgeG. Malliaras[1]; [1]University of Cambridge, United Kingdom; [2]University of the Basque Country UPV/EHU, Spain

Valvular heart diseases (VHD) are a major contributor to cardiovascular mortality worldwide, affecting ~75 million people every year . The detection of VHD is currently achieved by means of non-invasive mechanical activity imaging modalities such as magnetic resonance imaging (MRI), computed tomography (CT) or echocardiography. These techniques require expensive equipment and technical user expertise which hinder their employment in general practice clinics. As a consequence, VHD can be only diagnosed at larger medical centres where these machines and the personnel required to operate them are available. In addition, these imaging modalities cannot be employed for the long-term monitoring of acute conditions outside healthcare centres, which forces patients with these conditions to remain in hospital for long periods of time.

Electrocardiography (ECG) is a well-established and inexpensive method for the identification of electrical heart conditions, or rhythms, which is readily available in most local clinics. Despite the fact that ECG is designed to detect electrical activity, it has been shown to be able to capture some of the symptoms caused by VHD. Furthermore, the implementation of deep learning (DL) algorithms which analyse conventional 12-lead ECG data has recently demonstrated the ability of ECG to fully characterise and classify between different types of VHD.

Even though DL algorithms are able to identify VHD, the maximum accuracy they can achieve is limited to ~80%. Furthermore, these complex classifiers require vast amounts of fitting data, long training times and offer little clinical insights into what features of ECG are involved in the identification of VHD. One of the primary factors which restricts the performance of these classifiers is the limited amount of spatial data the 12-lead ECG offers. The sampling of multiple cardiac sites across the torso by means of high-density electrodes in the form of body surface potential maps (BSPM) offers the opportunity to train classical machine learning algorithms on temporal and spatial ECG features, thus increasing both the explainability and the maximum achievable accuracy of VHD classifiers.

In this work, a novel high-density electrode array fabrication technique on e-textiles with conducting polymer coatings is presented through the implementation of a tailored vest for canine models. The data obtained from this vest is presented and specific temporal and spatial features are employed to train a classical machine learning algorithm able to identify mitral valve disease in a canine patient cohort. The results from the classifier are presented in a human-readable format and performance and training metrics are compared and shown to surpass those of state-of-the-art models in the literature. The results hereby obtained pave the way towards the use of BSPM as an affordable and scalable screening technique for VHD.

SESSION SB07.02: Multifunctional Bioelectronics
Session Chairs: Achilleas Savva and Georgios Spyropoulos
Monday Afternoon, November27, 2023
Hynes, Level 1, Room 110

1:30 PM *SB07.02.01
Multifunctional Fiber-Based Interfaces with Central and Peripheral Circuits PolinaAnikeeva; Massachusetts Institute of Technology, United States

To probe the complexity of neuronal signaling between the central and peripheral nervous systems our group designs multifunctional, multimaterial fibers based on soft polymers, composites, and hydrogels. Previously limited to passive electrical, optical, and microfluidic features, these fibers have been augmented with active solid-state devices to record and deliver signals to organs as diverse as the brain and the gastrointestinal tract in freely-behaving rodents. Integration of solid-state components further enabled wireless operation of these fibers. In addition to probing electrophysiological activity, we have recently explored optical recording of neurochemistry using multifunctional fibers in conjunction with fluorescent activity indicators. Photometric recordings revealed the effects of drugs of abuse on neural circuits, and for the first time, permitted recording of signaling of non-neuronal tumor cells in vivo, empowering studies of tumor growth and informing brain-cancer therapies.

2:00 PM SB07.02.02

High-Density Soft Bioelectronic Fibers MuhammadKhatib and ZhenanBao; Stanford University, Israel

Bioelectronic fiber devices hold tremendous potential for both research and clinical applications due to their compactness, ease of implantation, and ability to incorporate advanced functionalities such as sensing/recording, stimulation/modulation, and imaging. However, existing devices are hindered by issues such as bulkiness, rigidity, limited functionality, and low density of active components. These limitations stem from the challenges associated with integrating multiple components on one-dimensional (1D) devices, as they are not compatible with conventional microfabrication methods like photolithography, primarily due to their thin, curved, and elongated structures. In this work, we present a fabrication approach called spiral transformation that overcomes these obstacles by converting 2D thin films containing pertinent microfabricated devices into 1D fibers. This approach allows for the creation of bioelectronic fibers that offer a high density (300 channels on a 250-micron fiber) and variety of components while enabling precise control over their longitudinal, angular, and radial positioning. We have successfully demonstrated the utility of these fibers for motility and serotonin sensing and tissue stimulation within the dynamic and soft gastrointestinal (GI) system. Notably, our soft fibers have shown minimal interference to GI tissue structure and natural movements. Taken together, the developed bioelectronic fibers showcase significant promise for next-generation clinical monitoring and modulation applications, particularly in minimally invasive deployments within the GI tract and other curved and confined regions of the body.

2:15 PM SB07.02.03
Multifunctional Microelectronic Fibers Enable Wireless Modulation of Gut-Brain Axis AtharvaSahasrabudhe[1], LauraRupprecht[2], SirmaOrguc[1], DiegoBohorquez[2] and PolinaAnikeeva[1]; [1]Massachusetts Institute of Technology, United States; [2]Duke University, United States

The peripheral organs of the body are in a constant bidirectional cross-talk with the brain, that generates a cognitive map of body's physiological state which is vital for survival. This is exemplified by the gut-brain communication; wherein hormonally and neurally mediated signals emerging from the abdominal viscera transduce metabolic information to the brain for maintaining energy homeostasis. Although these internally arising brain-to-body sensory cues are consciously imperceptible, recently they have been shown to influence higher level neurocognitive processes such as motivation and affect. These findings create opportunities for co-opting organ-to-brain neural circuits to develop new paradigms for autonomic neuromodulation therapies. However, probing and understanding critical brain-body circuits presents a neurotechnology challenge due to contrasting design criteria imposed on the implantable devices by drastic anatomical differences between the skull-encased brain tissue and mobile, delicate peripheral organs in behaving animal models.
In this talk I will describe our efforts in addressing this challenge. Seeking inspiration from nerve fibers, we design a soft, flexible polymer fiber-based organ-brain neurotechnology. In order to match the inherent signaling complexity of the nervous system we envisaged probes that integrate multiple functionalities while still retaining a miniature device foot print to facilitate chronic bio-integration. To create such a multifunctional and multi-organ neurotechnology we combine the scalability and rapid customization of fiber drawing with functional sophistication of solid-state microdevices. With this approach we successfully produce hundreds of meters of flexible polymer filamentary probes integrating microscale light emitting devices, thermal sensors, microelectrodes, and microfluidic channels. The ability to process thermoplastic elastomers with the same route enables deterministic tunability of device mechanics and allows probes for targeting deep-brain structures and/or various regions of the murine intestine. We custom design a light-weight and modular wireless control circuit, NeuroStack, that offers bidirectional wireless control and real-time programmability of in-fiber microdevices along with an intuitive user interface. The brain fibers offer gene delivery for cell-type specific optogenetic neuromodulation, single-neuron recordings, thermometry, and tetherless control of mesolimbic reward pathway. The soft gut fibers grant access to anatomically challenging and delicate intestinal lumen, allowing intraluminal optofluidic control of sensory epithelial cells that guide feeding behaviors. Using this technology, we uncover that optogenetic stimulation of vagal afferents from the intestinal lumen is sufficient to drive reward behavior in untethered mice.
We anticipate that these illustrative applications will foreshadow widespread use of wireless multifunctional microelectronic fibers to study the roles of specific cells in bidirectional communication between the peripheral organs and the brain. This will not only empower the field of interoception, but also pave the way for mechanistically guided improved autonomic neuromodulation therapies.

***In Vivo* Bioengineering of Conductive Microfibers: From *In Vivo* Biosynthesis to Advanced Characterization**ClaudiaTortiglione[1], MarikaIencharelli[1], GiuseppinaTommasini[2], ValentinaDi Meo[1], GennaroSanità[1], AlessioCrescitelli[1], EmanuelaEsposito[1], Maria AntoniettaFerrara[1], GiuseppeCoppola[1], FrancescaDi Maria[3], MattiaZangoli[3], MariaMoros[2] and AngelaTino[1]; [1]Istituto di Scienze Applicate e Sistemi Intelligenti, CNR, Italy; [2]Instituto de Nanociencia y Materiales de Aragón (INMA), Spain; [3]Istituto per la Sintesi Organica e Fotoreattività, CNR, Italy

The unmatchable capability of living cells to fabricate complex structure starting from simple building blocks offers new paradigms to seamlessly integrate new electronic structures into the living matter, creating new hybrid devices. We have previously shown the capability of the living tissue-like organism, the freshwater polyp *Hydra vulgaris*, to produce fluorescent and conductive interface embedded into the animal tissues, starting from thiophene-based compounds, demonstrating the feasibility to use these organisms as biofactories of novel biocompatible and conformable bioelectronic interfaces [1-2]. Here we show that the potential of biofiber production is broadly valid in other biological systems, and showed that it can be promoted by different human and murine cell lines and by other invertebrate *in vivo* models (such as the sea anemone *Nematostella vectensis*). The cell type influences the fiber shape, amount and optical properties. In order to understand the mechanism underlaying the fiber biogenesis, on one side we performed a systematic chemical engineering approach to identify the structure/groups involved in the spontaneous fiber assembling. On the other, we performed several physical and chemical treatments to identify the cell machinery components involved in the biosynthetic process. Finally, by mean of advanced characterization methods (ultrastructural, spectroscopical and imaging techniques) we shed light on the mechanism of biofiber production and the fine structure, paving the way to new bioengineering concepts to fabricate novel living conductive materials.

SESSION SB07.03: Bioelectronic Prototypes
Session Chairs: Maria Asplund and Alexandra Paterson
Monday Afternoon, November27, 2023
Hynes, Level 1, Room 110

3:15 PM *SB07.03.01
Prototyping Neuroelectronic Device Concepts in Low-Cost Invertebrate Model Organisms EricD. Glowacki[1], PetraOndrackova[1], MaryJ. Donahue[2] and MalinSilvera Ejneby[2]; [1]Brno University of Technology, Czechia; [2]Linkoping University, Sweden

Next-generation bioelectronics hardware evolves through interdisciplinary collaborations between materials and device engineers and neuroscientists, with certain barriers existing between design/fabrication, in vitro, and finally in vivo testing. It is rare for research teams handling device development to have in-house capability for electrophysiology in animals. I will describe our recent work on using simple invertebrate models for in vivo testing of novel recording and stimulation hardware: namely leeches (*Hirudo medicinalis*) and locusts (*Locusta migratoria*). Several showcase examples will be discussed. The leech nerve cord provides a suitable testing platform for prototyping nerve cuff devices for recording and stimulation. Stimulation can be validated using highly reproducible muscle electrophysiology or force transduction measurements. The locust, with its segmented body and well-defined skeletal muscle, is a convenient model for testing neurostimulation techniques, including noninvasive electrical stimulation which can be validated by precise activation of limb movements. The overall goal of this work is to present a toolbox of low-cost and ethically favorable approaches to test new device concepts before they are deployed on mammals.

3:45 PM SB07.03.02
High-Density, Large-Scale Recording and Stimulating Neural Probes with Integrated ASIC YuhangMa, YingyingFan, WeinanWang, PavloZolotavin, HanlinZhu, TaiyunChi and ChongXie; Rice University, United States

Ultraflexible probes enable stable neural recording and stimulation by building a glial scar-free neuronal interface using biocompatible materials with small cross-sectional areas. However, these probes don't have an equivalent number of electrodes within the same invasive footprint as the rigid probes have. This limitation stems from photolithography, which is currently used for fabricating ultraflexible probes, is not capable of yielding a similar high electrode density. Here, to maximize the number of accessible neurons per implantation, we present the method of using electron-beam lithography (EBL) to pattern densely-packed electrodes on the polyimide encapsulations. We design and fabricate a 128-channel probe that presents the highest electrode density per cross-sectional area in flexible probes. The ability of oversampling can isolate highly clustered single units locally and across the brain regions, for example, the motor cortex and the hippocampus, for up to 3 months in freely behaving mice and 2 months in rats. Using 4 modules, more than 270 single units are recorded simultaneously with 1/3 of them decoded from the visual receptive field. We also propose an approach to design and fabricate a large-scale flexible EBL array with 5,376 simultaneously recording electrodes which equalize the total channel count of the state-of-the-art active probes. The first design will have 12 penetrating shanks, each of which has 448 recording electrodes at a density of 100 sites per millimeter of depth. To record, amplify and digitize all the channels simultaneously, we use gold ball bonding to connect with a customized application-specific integrated circuit (ASIC). This combination of large channel count flexible EBL-probe and ASIC will provide neuroscience studies in animal models with chronic, stable electrophysiology data at a large scale.

An Experimental Platform to Study Axonal Guidance and Function KatarinaVulić, GiuliaAmos, SeanWeaver, TobiasRuff and JanosVörös; ETH Zurich, Switzerland

Studying neurons and axons in vivo poses a significant challenge due to the complex nature of the nervous system. The living environment makes it difficult to observe and manipulate individual axons effectively. In response to these limitations, researchers turn to in vitro models to gain insights into axon function and development from the bottom up. Our approach involves culturing neurons within polydimethylsiloxane (PDMS) microstructures on multielectrode arrays (MEAs) [1], [2], providing a controlled environment for studying axonal growth and activity. By utilizing these easily controllable and tunable systems, we aim to uncover the spatial limitations of axonal growth and determine the optimal spatial constraints for promoting healthy and robust axonal growth.
In this work, we study axonal growth dynamics using rat primary neurons cultured in custom-designed PDMS microfluidic devices containing nanochannels [3] of minimal size 100 nm. To generate the nanoscale features, a thin 350 nm layer of silicon dioxide (SiO 2) was deposited on a silicon wafer followed by a thin layer of photoresist that was then patterned using E-beam before the structures were etched in the SiO 2 using reactive ion etching. After stripping the remaining photoresist, the two subsequent layers were patterned in SU8 using conventional photolithography. The resulting microstructure design allows for separation of cell soma from axons and thus studying axons in detail. By varying the nano-/microchannel size, we show the spatial limitations for axonal growth and observe changes in axonal guidance depending on the channel width. We note that there is almost no penetration in the channels below 400 nm in width. Furthermore, we analyze the formation and structuring of axonal bundles, their dependence on cell density, and on the type of spatial constraint. We observe more frequent formation of bundles in cases where we topologically force the narrowing. The opposite is seen in the channels that are orders of magnitude larger than the average axon size, where they tend to spread along the available space. We also see that bundling is present in the nodes with lower cell density. We also see that axons grow the longest in the channels of 10-12 µm width range. Finally, we assess neuronal activity by culturing neurons in PDMS microstructures on MEAs. The temporal precision of action potentials recorded by MEAs in combination with spatial precision of axonal growth within the PDMS, enabled to analyze action potential fidelity, e.g. it's velocity, shape and amplitude depending on the the number of cells, the width of the formed axonal bundle and the age of an in vitro culture.
Looking forward, we aim to improve the system further by modifying substrate stiffness to make it more physiologically relevant, by adding hydrogels into the microstructures. The potential to expand our findings on human induced pluripotent stem cell (hiPSC) derived neurons and the diseased cells, offers yet another application. Additionally, a promising direction is the investigation of axon fasciculation [4] by alternating the angle at which axons approach one another with PDMS. With its wide range of capabilities, this highly tunable system holds promise for unlocking new insights and advancing our understanding of axon function and pathology.

Laminin Adsorption and Adhesion of Neurons and Glial Cells on Carbon Implanted Titania Nanotube Scaffolds for Neural Implant Applications JanFrenzel[1,2], AstridKupferer[1,2] and StefanG. Mayr[1,2]; [1]Leibniz Institute of Surface Engineering, Germany; [2]Universität Leipzig, Germany

As the world's population ages, the incidence of neurodegenerative disorders such as Parkinson's disease inevitably increases. Currently, brain-machine interfaces are used to study these diseases *ex vivo*, while neural electrodes are employed to treat them symptomatically *in vivo*. However, numerous obstacles arise at the interface between the brain and the brain-machine interface. Long-term adhesion is often weak, and rejection reactions such as glial scarring occur. We demonstrate that ion-implanted titania nanotube scaffolds are a promising candidate to overcome these problems, as they combine high biocompatibility with appropriate electrical conductivity.
In our systematic study, we show how implantation-induced tube shrinkage and altered electrical conductivity of titania nanotube scaffolds influence protein adsorption kinetics. Interestingly, laminin adsorption is affected by changes in surface free energy upon implantation. An increase in the pH-dependent ζ-potential of the surfaces leads to changes of the laminin binding.
In addition, viability, toxicity and morphology of U87MG glial cells and differentiated SH-SY5Y neurons is analyzed after one and four days, respectively, and correlated with surface characteristics. Environmental electron microscope images reveal that cells on all scaffolds stretch out and expand even after one day. This first evidence of biocompatibility is confirmed by a high cell viability. Significant differences of cell viability are explained by changes of protein adsorption induced by ion implantation. Additionally, the increase in conductivity does not affect neuronal viability after four days but inhibits glial cell proliferation.
Based on these findings, there is great potential for novel neural electrode materials with tailored morphology and unique conductivity that suppress glial scar formation.
We gratefully acknowledge funding from the Saxon State Ministry for Higher Education, Research and the Arts, project MUDIplex, grant number 100331694.

Monolithic Silicon Devices for Multisite, Multiscale and Translational Photostimulation PengjuLi and BozhiTian; University of Chicago, United States

Electrode-based electrical stimulation is foundational for numerous clinical bioelectronic devices, including deep brain stimulators and cardiac pacemakers. However, achieving multisite or random access stimulation, vital for high-fidelity and efficient biological regulation, remains challenging even in high-density electrode arrays due to spatial access constraints. While optogenetics offers high-spatiotemporal multisite stimulation capabilities, its clinical adoption presents hurdles. In this work, we introduce a multisite photostimulation technique for cardiac systems via a non-genetic platform utilizing semiconductor-based biomodulation interfaces. We investigate the precision, accuracy, and resolution of the photostimulation by analyzing spatiotemporal photoelectrochemical currents in four leadless silicon-based monolithic photoelectrochemical devices. Our study validates the multisite stimulation capacity of these systems through optical overdrive pacing applied to cultured cardiomyocytes targeting multiple regions and length scales, isolated rat hearts in a Langendorff setup, and in vivo rat heart ischemia models. To demonstrate cardiac control under clinical conditions, we also perform the first optical pacing of a pig heart in vivo. To further solidify the clinical potentials, we fabricated minimally invasive device delivery and fiberoptics platform and successfully performed pig heart stimulation without opening the chest. Our findings underscore the potential of this leadless, lightweight photostimulation platform, possibly revolutionizing cardiac pacemaking in treatments like cardiac resynchronization therapy where lead-placement complications often arise.

4:45 PM SB07.03.06
Organic Semiconducting Nanoparticles for Neural Interfacing: Integrating Mechanical, Chemical and Optoelectronic Stimuli for Wireless Neuromodulation RafaelCrovador[1,2], JessiePosar[3,4], PaulDastoor[2], AlanBrichta[1], RebeccaLim[1] and MatthewGriffith[5,3]; [1]University of Newcastle, Australia; [2]The University of Newcastle, Australia; [3]The University of Sydney, Australia; [4]University of Wollongong, Australia; [5]University of South Australia, Australia

Electronic devices capable of stimulating neurons have revolutionized the treatment of several neurological conditions by providing a direct interface with the nervous system. These devices hold great potential for treating disorders such as Parkinson's disease, epilepsy, spinal cord injuries, and even blindness.[1] However, the use of traditional electronic materials such as metals and silicon in such devices have significant limitations due to poor biocompatibility,[2] mechanical mismatch with tissue, low spatial selectivity, and the requirement for external power supplies. Soft and flexible organic semiconducting materials represent a new frontier in electronic materials that are capable of overcoming these challenges.[3] The solution processability of organic semiconductors also enable several additional attractive features, including low-cost manufacturing of devices on flexible substrates using industrial scale printing techniques, addition of neurotransmitter molecules to the electroactive solutions to chemically assist neuromodulation, adjustable surface topography to induce mechanical cues for neuron attachment and growth, and optically triggered charge generation for wireless electrical neuromodulation.

In this study, we present our recent endeavours to tackle these challenges of mechanical, chemical and electronic stimulation of neuronal cells simultaneously in a single bioelectrode. We achieve this by forming soft carbon-based organic conductors into aqueous nanoparticle dispersions using established solution-based mini-emulsion chemistry methods.[4] We subsequently integrate the organic nanoparticle dispersions with neurotrophic factors prior to the device fabrication process. These pharmaceutical components subsequently enhance cell adhesion and neural network outgrowth upon release from solid films cast from the electroactive nanoparticle dispersions.

Bioelectronic nanoparticle-based devices were fabricated from n-type material *Poly(9,9-dioctylfluorene-alt-bithiophene* (F8T2), which were shown to exhibit high biocompatibility with primary neuron cultures from mice via anatomical (live-dead assay) and functional (neuronal cell stain) protocols. Kelvin Probe Force Microscopy measurements demonstrated the creation of photo-capacitive charge under direct light stimulus, potentially capable of depolarising the neuronal cell membrane and generating action potentials (*wireless electronic neuromodulation*). By adjusting the surface roughness of devices by tailoring the nanoparticle size during synthesis, we verified by AFM analysis an optimal nano-topography that promotes neuronal cell growth (*mechanical neuromodulation*). Finally, by extensive neuronal morphology analysis we demonstrated the direct effect of sustained and locally delivered neurotrophic factors (*chemical neuromodulation*) on cell survival and neuronal outgrowth through neurite elongation.

9:00 AM *SB07.04.01
Transient Bioelectronic Medicines JohnA. Rogers; Northwestern University, United States

Advanced electronic/optoelectronic technologies designed to allow stable, intimate integration with living organisms will accelerate progress in biomedical research; they will also serve as the foundations for new approaches in monitoring and treating diseases. Specifically, capabilities for injecting miniaturized electronic systems and other components into soft tissues or for softly laminating them onto the surfaces of vital organs will open up unique and important opportunities in tracking and manipulating biological processes. This presentation describes the core concepts in materials science, circuit design and manufacturing that underpin these types of technologies, with a focus on bioresorbable, or ‘transient’, devices designed to disappear into the body on timescales matched to natural processes. Examples include bioelectronic ‘medicines’ for neuroregeneration, pain mitigation and temporary cardiac pacing.

E-Sutures: Electrical and Ionic Conductive Sutures for Medicine and Bioelectronics OnniRauhala, JenniferGelinas and DionKhodagholy; Columbia University, United States

Metals have long served as the foundational electrode and wiring materials for implantable bioelectronics due to their high conductivity and processability to achieve the small size necessary for *in vivo* electrophysiological signal acquisition and stimulation. However, metal-based wires are susceptible to mechanical damage due to material rigidity, and in bulky, high-density systems, they may contribute to patient discomfort. The ideal bioelectronic wire is thus soft, highly conductive, mechanically and chemically resilient and biocompatible. Most importantly, such a wire should also leverage modern polymer chemistry to enable multi-modal interventions, namely mixed-conductors that facilitate delivery of positive and negative charges. In this work, we use PEDOT:PSS to turn silk sutures into flexible, mixed-conducting and biocompatible wires (e-sutures) that can be used for suturing, acquiring electrophysiological signals, delivering electrical stimulation and finally, delivering drug molecules as ion pump channels.
We fabricate e-sutures by coating silk sutures with PEDOT:PSS to produce a mixed conducting suture and then create an insulation layer (jacket) on the fiber using subsequent coatings of PDMS and parylene-C to preserve the conductive properties in an ionic environment. We demonstrate the high conductivity and stability of e-sutures as well as their ability to form robust mechanical connections with metallic circuit components to facilitate integration to a complete bioelectronic device. Further, the conductive nature of e-sutures *in vivo* is demonstrated by recording electrocardiogram (ECG) from mouse pups, elicitation and recording of intramuscular electromyogram (EMG) in rats as well as local field potential (LFP) from the surface of a rat brain using e-sutures as electrodes. Finally, we demonstrate that e-sutures can serve as an ion pump channel and deliver positively charged molecules from a hydration reservoir to the target tissue without generating volumetric pressure in the delivery target. In summary, the work highlights the capability of PEDOT:PSS coated silk fibers to serve as a soft, biocompatible alternative to metallic wires and electrodes in a research and clinical setting while providing the additional capability of drug-delivery through ion pumping.

Implantable Iontophoretic Devices for Cancer Therapy XudongTao, TobiasNaegele and GeorgeG. Malliaras; University of Cambridge, United Kingdom

Chemotherapy has a fundamental limitation for the treatment of brain tumours – poor penetration through the blood-brain barrier, leading to sub-therapeutic concentrations in brain tumours. This study focuses on an implantable electrophoretic drug delivery device (left behind in the tumour after biopsy), which uses an electric field to improve drug transport. The technology is called iontophoresis – a ‘dry’ delivery that only delivers the charged drug ions into the tumour region by electric fields and avoids pressure-related problems. This study explores a novel iontophoretic device which significantly improves the efficiency of drug delivery.

Tuesday Morning, November28, 2023
Hynes, Level 1, Room 110

10:30 AM *SB07.05.01
Translational Neuroelectronics DionKhodagholy; Columbia University, United States

Our understanding of the brain’s pathophysiology relies on discoveries in neuroscience and neurology fueled by sophisticated bioelectronics enabling visualization and manipulation of neural circuits at multiple spatial and temporal resolutions. In parallel, to facilitate clinical translation of advanced materials, devices, and technologies, all components of bioelectronic devices have to be considered. Organic electronics offer a unique approach to device design, due to their mixed ionic/electronic conduction, mechanical flexibility, enhanced biocompatibility, and capability for drug delivery. We design, develop, and characterize conformable, stretchable organic electronic devices based on conducting polymer-based electrodes, particulate electronic composites, high-performance transistors, conformable integrated circuits, and ion-based data communication.
These devices established new experimental paradigms that allowed monitoring of the emergence of neural circuits during development in rodents and elucidated patterns of neural network maturation in the developing brain. Furthermore, the biocompatibility of the devices also allowed intra-operative recording from patients undergoing epilepsy and deep brain stimulation surgeries, highlighting the translational capacity of this class of neural interface devices.
In parallel, we are developing the fully-implantable, conformable implantable integrated circuits based on high-speed internal ionic gated organic electrochemical transistors that can perform the entire chain of signal acquisition, processing, and transmission without the need of hard Si-based devices. This multidisciplinary approach will enable the development of new devices

based on organic electronics, with broad applicability to the understanding of physiologic and pathologic network activity, control of brain-machine interfaces, and therapeutic closed-loop devices.

11:00 AM *SB07.05.02

Graphene-Based Active Neural Sensors for Brain Monitoring and Mapping EduardMasvidal-Codina[1], RamonGarcía-Cortadella[1,2], XaviIlla[3], RobWykes[4], AntonSirota[2], AntonGuimerà-Brunet[3] and JoseA. Garrido[1,5]; [1]Catalan Institute of Nanoscience and Nanotechnology, (ICN2), CSIC and BIST, Spain; [2]Bernstein Center for Computational Neuroscience Munich (SyNergy), LMU, Germany; [3]Instituto de Microelectrónica de Barcelona IMB-CNM (CSIC), Esfera UAB, Spain; [4]Institute of Neurology, UCL, Queen Square, United Kingdom; [5]ICREA, Spain

Large effort is being dedicated to the integration of novel materials into neural interface devices that offer certain advantages in terms of recording and/or stimulation of neural activity. In the particular case of the recording capabilities, they need to be such to allow the detection of brain activity over large areas and with a high spatial resolution. Because its two-dimensional nature, graphene exhibits a rather unique combination of physicochemical properties which make it attractive for the development of active sensors for neural technologies.
This contribution will focus on the recording capabilities of active sensor technology based on single-layer graphene, highlighting its potential for the development of the next-generation neural prostheses and brain-computer interfaces. Recently, solution-gated field-effect transistors (SGFET) based on graphene are being explored with increasing interest as novel transducers for neural signals. The electrochemical stability of graphene and its facile integration with flexible substrates were among the initial triggers that attracted the interest of the community to develop flexible neural probes for brain interfacing. In addition, other properties such as the high carrier mobility and the field effect associated to single-layer graphene allows for the implementation of an active sensor configuration that will be shown in this contribution to offer significant advantages with respect to the classical passive metallic electrodes. Further, this presentation will discuss how SGFET-type sensors allow us the implementation of multiplexing strategies, time-domain and frequency-domain multiplexing, that reduce the footprint of connectivity, permitting an aggressive scaling up in the number of recording sites. Very interestingly, we will demonstrate that SGFETs also have a distinctive capability to expand the temporal resolution of classical electrocorticography technologies, allowing the recording of the relatively unexplored infra-slow brain activity and, thus, potentially enabling the study of novel biomarkers for monitoring neurological disorders.

This work has received funding from the European Union's Horizon 2020 research and innovation programme under grant agreement N. 881603 (GrapheneCore3)

11:30 AM SB07.05.03

Spatially Controlled Microcortical Stimulation using High-Density PEDOT:PSS Surface Electrodes IlkeUguz and KennethL. Shepard; Columbia University, United States

Most neuromodulation approaches rely on extracellular electrical stimulation with penetrating electrodes at the cost of cortical damage. Surface electrodes, in contrast, are much less invasive but are challenged by the lack of proximity to axonal processes leading to poor resolution. Here, we demonstrate that high density (40 μm pitch), high capacitance (> 1 nF), single neuronal resolution PEDOT:PSS electrodes can be programmed to shape the charge injection front selectively at depths approaching 300 μm with a lateral resolution better than 100 μm. These electrodes, patterned on thin film parylene substrate, can be subdurally implanted and adhere to the pial surface in chronic settings. By leveraging surface arrays that are optically transparent with PEDOT:PSS local interconnects and integrated with depth electrodes, we are able to combine surface stimulation and recording with calcium imaging and depth recording to demonstrate these spatial limits of bidirectional communication with pyramidal neurons in mouse visual cortex both laterally and at depth from the surface.

11:45 AM SB07.05.04

Foldable Three Dimensional Neural Electrode Arrays for Simultaneous Brain Interfacing of Cortical Surface and Intracortical Multilayers Ju YoungLee, Young UkCho and Ki JunYu; Yonsei University, Korea (the Republic of)

The brain is a complex three-dimensional network composed of billions of interconnected neurons that respond to important activities such as cognitive function, memory, or even communication by transmitting neural signals. The development of neural interfaces that can precisely measure the complex activities of neurons are helping to understand for identifying unpredicted neuronal diseases and brain functions. Therefore, to understand the functionality of the brain via these diverse activities, it is essential to measure the brain activity with three-dimensional structure.
Current diagnostic methods for brain disorders involve functional magnetic resonance imaging (fMRI) that detect the changes of related cerebral blood flow and positron emission tomography (PET) that detect emits positrons distribution in the body through receptor or metabolic imaging. These imaging techniques can capture the changes in brain signals in three-dimensions by combining continuous two-dimensional sectional imaging frames. However, despite their excellent spatial resolution, these methods suffer from poor temporal resolution because of the limitations of captured series of two-dimensional frames. To overcome these time-resolution limitation, for the proper neuropathological analysis, electrophysiological approach serves as a major strength as it provides an excellent temporal readout resolution compared to upper imaging method.
The electrophysiological approach to the measuring the neural propagation is broadly classified into three methods, 1) Electrocorticography (ECoG), 2) Michigan probe, 3) Utah array. However, these traditional methods have limitation of two-dimensional measurements. Frist, ECoG arrays for brain surface recording provide high-resolution signals over a large area but cannot map the intracortical area. In contrast, Michigan probe and Utah arrays for intracortical or deep brain recording do not provide clues about the propagation of expressed signals from inside the brain to the surface. Several attempts have been made to measure neural signals in three-dimensional form to overcome this limitation, but these efforts have encountered challenges due to the separate devices for simultaneous measurement of surface and intracortical area that leading to recording mismatch, or due to the use of rigid shanks for device implantation that leading to immune response with mechanical mismatches between the brain recording surface and the device.
Here, we introduce the foldable, flexible three-dimensional neural mapping electrode that achieved by extending the three-dimensional structure of the neural interface in way to accurately analyse complex neural signalling. The device establishes a single integrated platform with four flexible penetrating shanks and surface electrodes by combining advantages of the ECoG arrays and neural probe with Utah array shape for multisite recording. This system can simultaneously measure both surface signals of the brain and neural activity occurring in the intracortical area. To provide sufficient insertion of the device, the penetrating shanks were coated with a biocompatible/bioresorbable stiffener. To demonstrate the performance of the device, inserting the device into the somatosensory cortex of mice and stimulating whisker of the mice. The device can measure both the local field potential (LFP) and single neuron spike in simultaneously from the surface and intracortical area of the brain. Consequently, this platform will pave the way for neuroscience studies and biomedical practices by providing unprecedented electrophysiological signals in three-dimensional form.

SESSION SB07.06: Minimally Invasive Neuroengineering
Session Chairs: Achilleas Savva and Georgios Spyropoulos
Tuesday Afternoon, November28, 2023
Hynes, Level 1, Room 110

1:30 PM *SB07.06.01

Ultrasound Microsystems for Minimally-Invasive Neuromodulation via Low-Intensity Focused Ultrasound TiagoCosta; Delft University of Technology, Netherlands

Minimally-invasive neuromodulation using low-intensity focused ultrasound (LIFU) holds great promise for treating various neurological disorders. It has been demonstrated to modulate neural activity, promoting both excitatory and inhibitory effects. This capability allows for restoring aberrant neural circuitry or suppressing hyperactive regions, thereby alleviating symptoms associated with conditions such as Parkinson's disease, epilepsy, chronic pain, and depression.
One of the key advantages of LIFU neuromodulation is its combination of high spatial resolution, minimal invasiveness, and extensive coverage of the nervous system. Unlike traditional electrical, magnetic, or optical neuromodulation techniques, which can achieve high-spatial resolution at the expense of high invasiveness and reduced brain coverage, ultrasound waves benefit from low wavelengths, scattering, and absorption in brain tissue and hence, can be focused virtually anywhere in the brain, with high-spatial-resolution and without requiring brain surgery. This reduces the risk of infection, tissue damage, and other complications associated with invasive procedures, making it a safer option for patients, and also allows for accessing a broader range of neural circuits with high precision.
Despite the abovementioned promise, there is still a knowledge and technological gap in LIFU neuromodulation to maximize its potential. LIFU neuromodulation is achieved by means of an ultrasound transducer. These transducers generate low-intensity focused ultrasound waves that can penetrate deep into tissues while maintaining spatial specificity. By adjusting the parameters of the ultrasound waves, specific regions of the brain or peripheral nerves can be targeted with precision. However, similar to their use in medical diagnostic imaging, conventional ultrasound transducers used in LIFU neuromodulation have hand-held form factors and require off-the-shelf equipment. These bulky setups lead to two severe limitations: in pre-clinical research, the mismatch of size between bulky transducers and in-vitro/in vivo models (mice, rats) impose severe limitations in understanding the effects of ultrasound on the nervous system and how to better apply LIFU neuromodulation for different disease models; secondly, in clinical applications, the use of LIFU neuromodulation can only be applied in a bed-side scenario, where the patient either would visit the clinic once or twice per week to receive a treatment or would operate a LIFU neuromodulation system at home.

This talk will describe the recent research in the field of ultrasound microsystems towards developing the next generation of LIFU neuromodulation systems that can be seamlessly integrated into in vitro/in vivo experimental setups in pre-clinical settings and used as wearable and minimally-invasive devices for clinical treatments. This description will answer two questions: how to massively integrate all the necessary LIFU neuromodulation functionality into a single-miniaturized and battery-powered microsystem? How can ultrasound microsystems be designed to be mechanically flexible to better adjust to the body's natural curvature?
To answer these questions, the talk will focus on novel ultrasound microfabrication and microsystem integration methods and next-generation ultrasound electronics. Furthermore, the talk will also show a few examples of ongoing projects featuring *in vitro* and *in vivo* validation, showcasing the potential of LIFU microsystems for minimally invasive and precise neuromodulation for treating neurological diseases.

2:00 PM *SB07.06.02
Learning in Spiking Neural Networks with a Calcium-Based Hebbian Learning Rule WillianSoares Girão and ElisabettaChicca; University of Groningen, Netherlands

The effectiveness of neural interfaces depends on the ability of electronic systems to speak the same language of the biological counterpart. Furthermore, the mechanisms underling learning in biological systems should be better understood to harness the adaptability of the brain when interfacing it to artificial systems. In particular, understanding how biological neural networks are shaped via local plasticity mechanisms can lead to energy-efficient and self-adaptive brain-like information processing systems which can enhance neural interfaces with unprecedented adaptability.
In this work, we present a Hebbian local learning rule, the Bistable Calcium-based Local Learning (BCaLL) rule, that models synaptic modification as a function of pre- and post-synaptic calcium traces tracking neuronal activity, based on a large body of work that has established the role of calcium transients in modulating plasticity. The calcium trace variable, modeled via a first-order differential equation, integrates neuronal activity over time such that both the time since the last spike and mean firing rate information can be encoded in this trace. The learning rule we propose reads out the calcium traces from the neurons it connects and computes whether its weight should be increased or decreased. We show that BCaLL is able to reproduce both spike-time dependent plasticity (STDP) and spike rate plasticity outcomes. With it, we are able to demonstrate that temporal correlations added at the spike-pair level can modulate the learning rate in spiking neural networks, without modifying the rule's parameters or the mean rate activity of neurons in the network.
We showcase this property by simulating and comparing recurrent Spiking Neural Networks (SNNs) with and without excitatory neurons' subthreshold membrane oscillations. We demonstrate that in the networks where the neurons oscillate, the learning rate of attractors is increased due to an increase in their synchronicity. This is particularly interesting for simulating and studying learning in models of brain structures like the Inferior Olivary Nucleus, where previous work has shown that the lack of electronic coupling, which plays an important role in synchronizing the activity of neurons within the nucleus, leads to impaired learning of motor tasks. This modulated learning rate via synchronization we show can provide a starting point in understanding such learning dynamics.
By applying BCaLL to feedforward SNNs, we describe the mechanisms necessary to train such networks for classification problems and how these mechanisms resolve the coding-level problem that arises from learning with binary synapses. Thanks to our simulations, we find that allowing the networks' transient activity during the switching of input patterns to interact increases classification performance, contrary to what previous work has reported, by reducing overlaps in the learned class representations. This could be a benefit of tracking spiking activity via traces: while some models might rely on the neuron's membrane voltage to compute weight updates, utilizing traces allows us to decouple from the membrane dynamics the extent to which correlated activity in time can be measured.
Elucidating how computation in such systems can benefit from encoding information in traces is not only important for better modeling the complex biochemical machinery existing in biological neural networks but also for the design of analog application-specific integrated circuits (ASIC) implementing these algorithms. This integration step is crucial for the embedding of such algorithm into neural interfaces.

2:30 PM SB07.06.03
Origami-Inspired Smart Implants for New-Age Neurology PrasanthVelvaluri[1], HuanLiu[2], LarsThormählen[1], HannaLewitz[1], OlavJansen[3], RichardD. James[2], DirkMeyners[1], NianSun[4] and EckhardQuandt[1]; [1]Kiel University, Germany; [2]University of Minnesota, United States; [3]University Hospital Schleswig-Holstein, Germany; [4]Northeastern University, Germany

Intracranial aneurysms are balloon-like disfigurations along the brain blood vessels. If not treated such aneurysms can rupture and cause brain hemorrhage. Many different implants are available in the market for intracranial aneurysm treatment. Though the available implants fabricated from wire braiding and laser cutting are successful, specific gaps must be filled to allow for low treatment complications. One such gap is that all the available implants have simple geometries and do not allow any personalization. Such individualization of implants is essential to provide safer treatments to patients with complex aneurysms. Second, all available implants have passive operation and currently, there are no “smart aneurysm implants” that could potentially monitor the treatment over time. Such a smart implant could detect if the intended blood flow reduction is not achieved after its placement and could potentially alert to early intervention. Smart implants require integrated antennas for data and energy transfer as well as sensors for the measurement of blood flow.
Magnetoelectric (ME) antennas consisting of magnetostrictive and piezoelectric layers have shown that they can be scaled down by orders of magnitude in size compared to conventional electromagnetic antennas [1]. This is because the ME antennas operate at their acoustic resonance rather than at their electromagnetic resonance. Such compact miniaturized ME antennas on the implant surface provide an optimal way to transmit the data wirelessly for a smart implant operation. However, there are certain difficulties to integrating such antennas into conventional implants as their fabrication technology of wire braiding and laser cutting does not allow monolithic integration of ME composites. Second, the conventional implant design does not allow such sensitive components to survive the harsh crimping process, which is pre-requirement for a minimally invasive treatment.
On the other hand, the origami-based design approach provides an attractive alternative for implant design. It consists of a 2D pattern with regions of rigid panels and flexible hinges. The folding pattern for origami can be generated from a flat 2D sheet and converted into a complex 3D shape on folding. Such structures have great potential as medical implants as they provide two major advantages (1) they allow the folding of large implants into a compact area to be loaded into a catheter and (2) certain regions in the origami pattern are almost stress-free during folding, making them ideal sites for loading sensitive elements such as sensors and antennas. The main challenge lies in fabricating these microscale devices without compromising the quality and performance.
Recent developments in microsystem technology offer a method to fabricate freestanding nitinol (NiTi) shape memory thin films. The fabricated implants are flexible, biocompatible, and have high design freedom, e.g., allowing films with multiple thicknesses [2]. Thus, providing a solution for origami-based implant fabrication. The wafer-based approach allows the monolithic integration of functional layers for biosensing and smart implant functioning. Thus, allowing for the incorporation of ME antennas on the NiTi implant surface.
The current work focuses on fabricating an ME antenna on top of a NiTi substrate using microsystem technologies, as a first step in realizing origami-based smart implants. In this work, we discuss the various challenges and possible solutions for integrating an ME antenna on top of a NiTi substrate. Furthermore, we consider the choice of magnetostrictive and piezoelectric materials that are essential for the required antenna operation at a frequency that is permissible for human use. We intend to demonstrate the potential of an origami-based design approach for fabricating brain implants.

Atomic Layer Infiltration for the Enhanced Longevity of Thin-Film Polymer Implant Encapsulation MartinNiemiec and KyungjinKim; University of Connecticut, United States

Bioelectronic interface technology has advanced significantly since its inception, as implantable devices develop smaller form factors and better integration with the human body. Advanced implants have thousands of channels interfacing with hundreds of neurons, and often feature wireless transmission of power and data enabled by miniaturized active electronic components and multiplexing techniques. However, while the technical capabilities of implantable bioelectronics continue to increase at an astounding rate, their ability to remain functional after long periods of implanted time has not seen significant improvement, especially in the field of flexible polymer-based thin film devices. Due to their inherently poor barrier properties, polymer implants require additional hermetic encapsulation to become viable therapeutic instruments for several decades of constant use. In this regard, metal oxide, nitride, and carbide materials deposited by atomic layer deposition (ALD) represent some of the best-performing barrier materials in terms of low permeability to water and ionic species, yet they are mechanically incompatible with flexible electronic substrates: bending and stretching of the flexible substrate invariably results in cracking or delamination of the rigid barrier coating, reducing its protective capability to near zero. Here, we explore a method of increasing the mechanical compatibility of inorganic barrier coatings with flexible substrates by means of a modified ALD technique alternately known as atomic layer infiltration (ALI), vapor phase infiltration (VPI), or sequential infiltration synthesis (SIS), which results in a gradual transition between the mechanical properties of the substrate and coating, reducing the susceptibility of the interface to such catastrophic failure modes. During ALI, precursors are allowed to remain in the reaction chamber for longer times at higher pressures than ALD. This allows precursors to diffuse into the substrate and reaction products to form at depth, resulting in a gradient from pure substrate to pure coating material. This technique has been used to create flexible, nearly impermeable coatings for organic electronics applications, but to our knowledge has not been demonstrated in implantable bioelectronics. We demonstrate water vapor barrier performance of the ALI encapsulation strategy on the order of 10^{-4}g/m^2/day, as well as high mechanical compliance (*i.e.*, critical bending radius below 500µm without delamination). In addition, we fabricate test devices featuring interdigitated electrodes on flexible substrates and encapsulate them via 3-dimensional ALI using a custom stand within a domed reaction chamber, then study the effects of ALI encapsulation on device lifespan in physiological conditions by means of accelerated aging tests in phosphate buffered saline (PBS). We investigate the accelerated aging results of current bioelectronic implant encapsulation strategies and compare them with our own results. Our uncoated polyimide devices failed after 80-100 days at 37°C, while coated devices have exceeded 230 days of 37°C-equivalent aging and continue to remain below failure thresholds. Optimization of the encapsulation via material selection (*e.g.*, polyimide vs. parylene substrates, Al_2O_3 vs. TiO_2 ALI) and multilayered structure is explored. In-depth failure mode analysis of the tested thin film devices is performed,

analyzing cracking, delamination, moisture permeation, and connector failures using optical and scanning electron microscopy and permeation analyzer; critical failures modes upon specific loading are discussed.

A Subdural Bioelectronic Implant to Obtain Recordings of Spinal Cord Activity and to Deliver Electroceutical Therapy Following Spinal Cord Injury in Rats DarrenSvirskis[1], BruceHarland[1], BradRaos[1], BrittanyHazelgrove[1], SimonO'Carroll[1], LukasMatter[2] and MariaAsplund[2]; [1]University of Auckland, New Zealand; [2]Chalmers, Sweden

Bioelectronic devices have found use at the interface with neural tissue to investigate and treat nervous system disorders. We have developed and characterized a very thin flexible polyimide-based bioelectronic implant that is inserted along the thoracic spinal cord in rats directly in contact with the dorsal surface of the spinal cord. This has no negative impact on hind-limb functionality nor any change in the volume or shape of the spinal cord. We routinely maintain the bioelectronic implant in rats for a period of 3 months.
We have obtained the first subdural recordings of spinal cord activity in freely moving animals. Recordings contain action potentials from fibre tracks in the cord. Following spike extraction propagation velocities were analyzed. Propagation was predominately in the afferent direction, with a smaller proportion of spikes propagating in the efferent direction.
A clinically relevant spinal contusion injury can be achieved with the implant in place. The bioelectronic implant contains stimulating electrodes with relatively larger areas than the recording electrodes that are capable of delivering precise, strong electric field therapies (electroceuticals) directly to the injured spinal cord tissue. The effects of these therapies are currently being investigated, early data is demonstrating a different recovery profile compared to control animals who do not receive the treatment. Over the course of the 12-week experiment, the animals receiving electroceutical therapy show improved hind limb function determined in open field assessment and an enhanced recovery of touch sensitivity as determined by the Von Frey test. This device has great potential to monitor electrical signaling in the spinal cord after an injury, and in the future, this implant will facilitate the identification of biomarkers in spinal cord injury and recovery. We are exploring further development of this implant to deliver localized treatments to the spinal cord towards regeneration of damaged tissues to recover lost function. Localized therapies are being developed not only in the form of electroceutical treatment through precise electrical field stimulation, but also through the local and sustained delivery of neurotrophic factors.

Soft and Stretchable Neural Electrodes Based on Gold Nanowire Composites LauraSeufert, MohammedElmahmoudy, MaryJ. Donahue, YuyangLi, SamuelLienemann, SimonFarnebo and KlasTybrandt; Linkoping University, Sweden

Two-way communication between electronics and neural tissue is key for advancing diagnosis and therapies for neurological diseases and disorders. Establishing such neural interfaces is a major challenge, as the tissue response to implants can have a detrimental effect on the signal quality and functionality of the implant. Matching of the mechanical properties of the electronic implant to the soft interfaced tissue can reduce the tissue response and improve the long-term performance of the device. This requires soft and stretchable conductors, which typically are composed of elastomer/hydrogels and conductive fillers. However, the tough materials requirements on biomedical implants, including material chemistry, mechanical and electromechanical properties, and long-term stability, disqualifies most of the developed stretchable electronic materials for such applications. Here I will present our efforts in developing inert soft neural electrodes based on stretchable gold nanowire composites, covering aspects ranging from synthesis and processing to devices and applications.

4:15 PM SB07.07.03
Ultraconformable Cuff Implants for Long-Term Bidirectional Interfacing of Peripheral Nerves at Sub-Nerve Resolutions AlejandroCarnicer Lombarte, AlexanderJ. Boys, AmparoGuemes, JohannesGurke, SantiagoVelasco Bosom, SamHilton, DamianoBarone and GeorgeG. Malliaras; University of Cambridge, United Kingdom

The peripheral nervous system is crucial for the communication between the brain and the rest of the body. Implantable devices interfacing with this part of the nervous system hold great potential for the development of treatments for a wide range of clinical conditions, whether by recording electrical activity carried by nerves, or influencing it through electrical stimulation. However, current nerve interfacing technologies lack the necessary resolution to selectively record and stimulate from nerves at the sufficient resolution and stability to enable their therapeutic use.

Here, we present a nerve cuff implant with an ultraconformable design that achieves high-quality and stable interfacing with nerves in chronic implantation scenarios. The cuffs are comprised of a parylene-C body 4 μm in thickness, rendering them highly flexible and able to conform to the surface of nerves. Combined with low impedance PEDOT:PSS microelectrodes, we show that these features allow the ultraflexible cuffs to record neural signals from awake animals for 21 days while exhibiting minimal fibrotic scarring. We furthermore show that high-resolution interfacing capabilities of the cuffs can be used to record action potentials with fascicle-specific resolution and extract from these physiologically-relevant features such as conduction velocity and direction of propagation. We evaluate the potential of this technology in two nerve systems in freely-moving rodent animal models: movement and sensory perception in the arm, and monitoring and control of bladder function.

The developed implantable devices represent a platform enabling new forms of fine nerve signal sensing and modulation, with applications in physiology research and closed-loop therapeutics.

4:30 PM SB07.07.04
Towards Longer Working Times for Implanted Electrodes through Integration of Perpetual Antioxidants at Device Interfaces VickiL. Colvin; Brown University, United States

Medical devices implanted in the human body are increasingly common in the management and treatment of disease. An important and growing subset of these devices termed here ‘active’ implants, require electrical contact with tissues. For these devices the foreign body response to an electrode can preclude chronic function and limit many applications. The local delivery of an antioxidant able to protect tissue for months or even years is one possible solution. Nanoparticle ceria is a perpetual antioxidant due to its large cerium(III) content and the possibility of recovering cerium(III) from cerium(IV) after use.[1] For this work its antioxidant capacity was augmented by the use of molecular tethers that stabilized the reactive Ce(III) state. The efficacy of these materials was evaluated in a three-dimensional in vitro model by seeding primary cortical cells around microwires to reveal independent innate neuroinflammation. We demonstrated the use of ceria nanoparticles for reducing oxidative stress, increasing neuronal density, and reducing functional connectivity in wire implanted samples. These results indicate that antioxidant ceria nanoparticles may be efficacious drug treatment for protecting neural function at the device-tissue interface. We optimized ceria nanoparticles for small diameter, biocompatibility, and colloidal stability using reactive polymer coatings. To evaluate their utility in combating inflammation, we developed a 3D in vitro model of the device-tissue interface. This system can disentangle the different contributions of the innate immune system to neuroinflammatory device responses. Ceria nanoparticles reduced the oxidative stress, increased neuronal density, and reduced functional connectivity in wire-implanted samples [2]. The development and characterization of a novel 3D in vitro model of the device-tissue interface revealed a significant innate immune response to neural implants. This study has broad implications for the role of the innate immune system and potential treatment strategies for the chronic foreign body response to neural implants. The mitigation of oxidative stress, neuronal density, and functional connectivity with antioxidant ceria nanoparticles offers significant supporting evidence to indicate that many symptoms of the tissue reaction are related to redox dysregulation. Successful treatment of the device-tissue interface with long-acting antioxidant ceria nanoparticles shows potential for a local long-term antioxidant treatment strategy for clinical applications that need the long-term use of implanted neural devices.

4:45 PM SB07.07.05
Improving Cytocompatibility of Commercial PEDOT:PSS for Bioelectronic Applications AaronLee[1], JoshuaKillilea[1], EstelleCuttaz[1], ChristopherChapman[2], JosefGoding[1] and RylieGreen[1]; [1]Imperial College London, United Kingdom; [2]Queen Mary University of London, United Kingdom

Conducting polymers have emerged as a strong candidate material for bioelectronic applications owing to their mixed ionic-electronic conduction which allows them to efficiently transfer

charge in aqueous environments. Commercial formulations of water-dispersible poly(3,4-ethylenedioxythiophene):poly(styrene sulfonate) (PEDOT:PSS) have facilitated development of flexible conductors, sensors, organic electronics and electrode interfaces. While PSS is an efficient counterion and dopant for PEDOT , its presence in excess to enable water-based processing can result in variable processability and electrochemical performance. While chemical crosslinking approaches can be used to address the stability of PEDOT:PSS in aqueous environments, it can hinder further processing. Importantly for bioelectronic applications, the release of excess PSS in aqueous environments from commercially based PEDOT:PSS materials can result in cytotoxicity. To ameliorate these effects, the use of physical separation was explored to remove the excess dopant. PEDOT:PSS dispersions were produced in N,N'-dimethylacetamide and separated by centrifugation. Analysis of the supernatant by NMR indicated the presence of PSS and the remaining polymer was blended with a polyurethane to produce a conductive elastomer. The electrochemical performance of the conductive elastomer and its resultant cytotoxicity profile were assessed as a function of PSS removal. Reducing the amount of PSS prior to preparation of the final conductive elastomer material was demonstrated to markedly improve the cytocompatibility of the material while retaining a degree of electrochemical functionality. These findings represent a key step in facilitating the translation of PEDOT:PSS-based materials to clinical applications.

SESSION SB07.08: Poster Session

An Extended-Gate Field-Effect Transistor as a Highly Sensitive Biosensor to Detect Bacteria LeaKönemund[1,2], AaronBongartz[1], FenjaSchröder[1], SvenjaHerdan[1], LaurieNeumann[1], RebekkaBiedendieck[1], DieterJahn[1], Hans-HermannJohannes[1,2] and WolfgangKowalsky[1,2]; [1]TU Braunschweig, Germany; [2]Cluster of Excellence PhoenixD (Photonics, Optics, and Engineering—Innovation Across Disciplines), Germany

The detection of bacteria requires full-fledged qualified employees to prepare individual samples for corresponding machine-based analysis. This process is highly time-consuming and cost-intensive. Therefore, there is a great demand for more rapid, portable, and cost-effective sensors for the detection of bacteria.
For this, well-established electrical measurement methods might be transferred to the investigation of biological systems. Our approach is the development of an extended-gate field-effect transistor (EGFET) as a biosensor. The EGFET is composed of a standard metal-oxide semiconductor field-effect transistor (MOSFET) and a physically separated but electrically connected sensor unit produced as a thin-film device.[1] The connection is realized by extending the MOSFET's gate electrode into the sensor unit. The potential of the gate-electrode is regulated by the electrical impact of the sensor unit on the MOSFET which further gates the measurable current between its drain and source electrode. The main constituent of the sensor unit is a suspension containing the bacteria of interest, which connects the extended-gate with a control-gate electrode. Both electrodes are functionalized with A_2BC-type porphyrins to link the bacterial cells to the electrode surfaces to shift the electrical potential of the extended-gate electrode on the gate-solution interface.[2] Different optical and electrochemical methods verified clearly the successful formation of the functional layer. Further, the successful linkage of bacteria on the functionalized electrode were analyzed by fluorescence lifetime imaging microcopy (FLIM).[3] The transfer characteristic of the EGFET also clearly indicated the impact of trapped bacterial cells due to lower potential values on the extended-gate electrode.[1] However, our latest results indicate a non-homogeneous coverage of the electrodes by the bacteria.[3]
Further investigations focus on the increase of trapped bacteria to improve the sensitivity of the biosensor. Here, one of our approaches is the integration of dielectrophoresis (DEP) to the electrodes of the sensor unit. DEP is a highly flexible and multifunctional method to immobilize, separate, and concentrate biological particles such as whole cells but also dissolved molecules in a liquid. In addition, an optimized measurement setup or different functional layers based on e.g. boron-dipyrromethene (BODIPY) might also improve the sensitivity. The synthesis of BODIPYs compared to the A_2BC-type porphyrins are less complex which fulfills the requirement of a lean device.

Kirigami-Based Stretchable Interconnects for Robust, Soft Neural Interfaces LaurineKolly, Florent-ValéryCoen and StephanieP. Lacour; École Polytechnique Fédérale de Lausanne, Switzerland

Recording or modulating neural activity using implanted electrode arrays has enabled advancements in the restoration of sensory-motor pathways and brain-computer interfaces. Long-term reliability of these interfaces (>6 months) is paramount to their deployment in neuroprosthetic medicine. Furthermore, hermetic encapsulation of conductive components within electrode arrays is required for long-term protection against the moisture and ions from the physiological environment to avoid electrical failure over time.

We have developed a kirigami-based technology to engineer elasticity within thin films of metal and thermoplastic polymer. The periodic cuts (kirigami) patterned and replicated across a thin stack of Polyimide/Platinum/Polyimide of 1/0.1/1 µm thicknesses program stretchability within interconnect tracks as narrow as 52 µm width. The Polyimide layer is patterned with a 1 µm width offset to that of the Platinum layer, such that the metallization is fully encapsulated, top, bottom, and sideways with Polyimide, thereby providing a built-in long-term hermetic barrier.

We assessed the robustness of the kirigami-based interconnects through a set of *in vitro* accelerated aging tests and repeated mechanical loading tests. We monitored the evolution of leakage current between two interdigitated tracks (IDE) biased at 5 V and soaked in phosphate-buffered saline (PBS) at 67 °C for 20 days. The elastic regime and plastic onset of the interconnects were measured during incremental uniaxial tensile stretching cycles. The electro-mechanical fatigue was assessed through uniaxially stretching linear interconnects for 1 million cycles at 10% strain, within the elastic regime.

The results of the accelerated aging showed that the leakage current remained below 0.2 µA after 20 days. These findings indicate that the interconnects maintain a high level of hermeticity, equivalent to >25 MΩ after 160 days at 37 °C, in accordance with Arrhenius law.
The electro-mechanical characterization demonstrated that the Polyimide-encapsulated kirigami interconnects can deform reversibly up to 15% of applied strain. Moreover, cyclic stretching for 1 million cycles at 10% strain resulted in a slight increase of 5% in relative resistance, indicating minimal mechanical fatigue.

The *in vitro* characterization demonstrated that the kirigami micro-patterning strategy used to fabricate stretchable interconnects can achieve a high level of hermeticity and exhibit low mechanical fatigue. Ongoing research efforts are focused on integrating materials with superior moisture barrier properties, such as silicon carbide, and further tuning the kirigami geometry to achieve a higher range of stretchability. These advancements aim to design functionally stable and longer-lasting neural interfaces that can withstand the mechanical challenges associated with chronic applications.

8:00 PM SB07.08.03
Flexible and Transparent Microelectrode Array for Simultaneous 2-Photon Imaging and Electrical Recordings VikrantKumar[1], ConnorMcCullough[2], EmilyGibson[2], DiegoRestrepo[2] and IoannisKymissis[1]; [1]Columbia University, United States; [2]University of Colorado, United States

Combining two modalities, optical imaging and electrical recordings of neural cells, can shed light on a more profound understanding of neural circuits. Microelectrode arrays with high optical transparency in the near-infrared (NIR) and high electrical conductivity are required to enable simultaneous 2-photon imaging and electrical recording. A transparent microelectrode array allows us to perform imaging and electrical recording at the exact location for improved correlation between the two modalities, with imaging having a better spatial resolution and electrical recording having a better temporal resolution. We present an ITO-based transparent microelectrode array's design, fabrication, and testing. The microelectrode array has 16 recording sites, with each electrode size of 20 µm x 20 µm. The microelectrode array uses 3 µm parylene-C as a substrate and encapsulation layer maintaining excellent flexibility. Bending tests for different radii are performed to characterize the array's flexibility. The 2-photon imaging through the electrode array shows optical transparency at the desired wavelength of 920 nm. Electrochemical impedance spectroscopy (EIS) is done to characterize the electrical characteristics of the microelectrode array. Finally, the simultaneous 2-photon imaging and electrical recording through the array on a head-fixed animal is underway for the final testing of the microelectrode array. The microelectrode array is connected to a custom PCB using heat seal connectors for further connection to the data acquisition system.

8:00 PM SB07.08.04
Nanomesh microelectrode Arrays on 10µm-Thick PDMS for Ultrasoft Neuroelectronics JaehyeonRyu[1,2]; [1]Dartmouth College, United States; [2]Northeastern University, United States

Ultrasoft neuroelectronics are highly interesting because they enable conformal and compliant interfacing with the soft, curvilinear surface of the neural tissue. However, current ultrasoft neural interfaces are usually limited by their electrode performance and scalability for neuroelectronic applications. Here, we present multi-functional nanomesh as an approach to achieve ultrasoft microelectrode arrays (MEAs) with excellent scalability. By stacking mechanical supporting polymer, metal, and low impedance coating, here we demonstrate an Au/PEDOT:PSS bilayer-nanomesh-based MEAs on ultrathin Polydimethylsiloxane (PDMS) substrate. We have successfully fabricated 32-channel, bilayer-nanomesh-based MEAs on PDMS with total device thickness down to only 10µm. The 32-channel bilayer-nanomesh arrays have demonstrated over 90% yield on average. We also achieved low impedance of 60 kilohms at 1 kHz with site area down to 400 μm^2, comparable to the size of a single neuron. The performance of this bilayer-nanomesh MEAs has been characterized through bench testing. This MEA achieves excellent and stable electrochemical performance and also demonstrates good optical transparency over a broad wavelength spectrum. Other achievements of this research are hydrophilic surface modification on the MEA surface along its stability and great sterilization compatibility with ethylene oxide (EtO) sterilization which highlights the practical utilization of this novel device for advanced neural interfacing. This multi-functional bilayer-nanomesh approach provides a promising pathway toward ultrasoft neural interfaces with excellent electrochemical performance and large throughput for applications ranging from neuroscience to biomedical devices.

8:00 PM SB07.08.05
Optimization of Parylene Coatings for Implantable Neural Devices SamanEbrahimibasabi, LaylaKhalifehzadeh and HamedArami; Arizona State University, United States

Parylene C is a widely utilized biocompatible thin-film polymer coating for implantable devices, specifically neural implants, due to its ability to cover uniformly complex shapes, protect the implants against corrosive body fluids such as CSF (cerebrospinal fluid), electrical insulation, chemical stability, and durability. However, weak adhesion to the various types of device substrates remains a significant challenge for this promising coating material. Here, we will present the impact of substrate material selection,silanization (as adhesion promoter), different deposition parameters (such as silane concentration) and post-deposition annealing on overall characteristics of the coating layer (such as thickness and adhesion strengths). First, silicon wafers were coated with different thicknesses of Parylene C using SCS coating machine, followed by annealing in Ar atmosphere at temperatures of 150, 200, and 250°C. Additionally, the effect of thickness (1 and 3µm), and silane A-174 concentration (0.5, 1, and 1.5%) on adhesion strength were investigated. To assess long-term adhesion of Parylene, samples were submerged in an in-vitro accelerated aging bath consisting of PBS at 87°C for 7 days, and the properties were compared before and after the aging, to estimate the coating's stability in body environment after implantation. Coating thickness and molecular structure were investigated using Ellipsometry and FT-IR, respectively. Adhesion strength was determined using ASTM D3359 tape test. Our initial results indicated that 1µm Parylene coating with 1.5 vol% silane as adhesion promoter, and annealed at 150°C can potentially result in optimal adhesion for silicon substrates. We are pursuing follow up studies on silicon and other types of substrates (such as polyimide, which is a common flexible substrate for a variety of brain and neural implants) to further validate these observations. We envision that our results are critical to address unmet challenges for prolonging the lifetime of the implantable neural devices.

8:00 PM SB07.08.06
Frequency-Dependent Mechanism of Magnetic Nanoparticle Re-Laxation MinguSong, DowooKim and Heon-JinChoi; Yonsei University, Korea (the Republic of)

Magnetic nanoparticles (MNPs) play a central role in magnetogenetics as energy transducers, delivering the external energy in focus to neighboring cell membranes. Especially, magnetothermal heat conversion is held by two major relaxation mechanism: Neél relaxation (spin) and Brownian relaxation (rotative). As of now, efforts have been ongoing to accurately reflect stochastic nano system with refining mathematical model as more sophisticated. Here, our idea is "there is no gold model". We carefully argue that particle dynamics between forward field alignment and backward thermal randomization is clearly different. By coining the very field-dependent alignment mechanism as "laxation", we differentiate alignment and relaxation, also integrate suitable expressions that have been examined so far. Then we compute and visualize theoretical boundaries of Neél & Brownian movement. This approach allows us to decode the frequency sensitivity of heat conversion of magnetic nanoparticles based on relaxation mechanism. Relatively small, less anisotropic particles tend to spin-relax; thus, they efficiently convert high frequency field (~MHz). On the other hand, big, anisotropic particles are inclined to rotative-relax so that they could react only low frequency field (~few kHz). Moreover, we illuminate the enigmatic mixed mechanism, optimistic waveform, field amplitude dependency, and shape factors of MNPs. We support our arguments through experiments. Finally, we propose a simple fabrication method for transition of relaxation mechanism to regulate activation frequency. This frequency tuning may provide a range of possibilities for magnetogenetics, such as multi-channel activation of noninvasive deep brain stimulation (NIDBS).

8:00 PM SB07.08.07
3D-Microelectrode Arrays (MEAs) for *In Vitro* ApplicationsInolaKopic[1], HuPeng[1], SebastianSchmidt[1], AnnikaWeisse[2], Richard MiruGeorge[2], GilWestmeyer[1], ChristianMayr[2] and BernhardWolfrum[1]; [1]Technische Universität München, Germany; [2]Technische Universität Dresden, Germany

Abstract:
In the realm of 3D cell cultures and organoids, capturing electrical activity across multiple planes is essential for a comprehensive understanding of their behavior. Conventional microelectrode arrays (MEAs) with surface recordings fall short in addressing this requirement. The limitations of clean-room methods restrict electrode design possibilities and can impede effective cell-electrode coupling. To tackle this challenge, we present a novel approach that leverages rapid prototyping processes to enhance electrode fabrication. Our laser-patterned MEA incorporates printed 3D-electrode structures, enabling precise recording and stimulation within cell tissues. This advancement improves signal quality through enhanced cell-electrode coupling and provides greater flexibility in electrode placement. We believe this innovative approach will significantly contribute to improvements in 3D cell cultures and organoids, opening new avenues for understanding complex biological systems and developing targeted therapeutic interventions.

Introduction:
Standard planar MEAs can only record electrophysiological signals in 2D, making them unsuitable for capturing the complexity of emerging 3D cell cultures or organoids [1]. To overcome this limitation, we design and fabricate 3D MEAs using additive manufacturing techniques [2]. These 3D MEAs hold promise for studying neuronal functions and diseases using neuronally differentiated human-induced pluripotent stem cells (hiPSC) in vitro.

Results and Discussion:
Here, we present the microfabrication of our 3D MEAs. In the first step, silver ink pillars are printed on suitable substrates, followed by sputtering with gold to create a biocompatible electrode interface. Individual electrodes and feedlines are then generated through laser ablation, with feedline structures patterned within minutes, representing a significant improvement over conventional lift-off techniques. The chips are fully passivated with a parylene C layer deposited via vapor deposition. Laser ablation at different angles is used to open the tips of the pillars precisely, and partial etching is employed to create tubular structures. In the final step, individual pillars undergo stepwise electroplating with gold and PEDOT:PSS to prevent silver contamination during long-term cell culture. Our fabrication method offers a fast and easily adjustable approach compared to traditional clean-room techniques. Using the inkjet printing process with laser ablation and electroplating, the height of each pillar can be accurately determined. This enables the realization of multiple pillars with various heights on a single chip. Moreover, the design of the MEA aligns the electrodes in a manner that simplifies their insertion into organoids or 3D cell models. With this highly flexible approach, we aim to record cellular signals from various planes within the targeted tissue.

Conclusion:
This work demonstrates a process for fabricating MEAs with integrated 3D electrodes, providing a platform that facilitates recording and stimulation within 3D cell aggregates or organoid models.

Brain-Machine Interfaces—Taking the Next Step Towards Translational Devices SantiagoVelasco Bosom and GeorgeG. Malliaras; University of Cambridge, United Kingdom

Aphasia is defined as the impairment of speech as a result of acquired brain injury, rapidly hindering communication skills in the patient. Current therapeutical approaches are complex and rely on compensatory strategies to regain the lost communicating abilities.

Based on the concept proved by Khodagoly et al, multielectrode arrays (MEA) using electrodes as small as 10x10 μm^2 are sufficient to capture both local field potential and putative single neuron activity when used for electrocorticography, causing minimal tissue damage. To date, MEAs have predominately been used for investigating human neural network mechanisms and better understanding of brain disorders. Nonetheless, better interpreting these mechanisms carries the potential to open an entire new medical field to use brain signal recordings for healthcare applications and personalized medicine.

In this work, we present the first translational Neurogrid (ultraconformal ECoG multielectrode array) that will be used for the chronic study of cortical neural signals and its decodification into conversation. By complying with European medical regulation in the development of the device, we aim to increase the duration of the implantation in awake human studies, to better understand the potential of this technology with respect to long-term human-machine interfaces. Integrating state-of-the-art machine learning algorithms to the brain signals recorded by the Neurogrid, we aim to decode neural activity in patients suffering from aphasia and translate it into speech.

The combination of these powerful technologies can pave the way for brain-machine interfaces to become powerful clinical tools that increase the wellbeing of patients with neurological disorders. However, to champion the way of this technology into a final clinical product, it should still undergo multiple intermediate steps to prove its safety and reliability.

8:00 PM SB07.08.09
Flexible Printed Circuit Board (fPCB) Neural Probes for Monitoring Neural Signals DaerlPark[1], HyeonyeongJeong[1] and JungsikChoi[2]; [1]Yonsei University, Korea (the Republic of); [2]Nformare, Korea (the Republic of)

Neural activity monitoring in the central nervous system often utilizes silicon-based micro electro mechanical systems (MEMS) probes. Despite their strength in monitoring ant stimulating capabilities, these probes are fragile due to the brittle nature of silicon materials limiting their application in various fields. Here, we introduce flexible printed circuit board (fPCB) neural probes that have robust mechanical and electrical properties. The probes fabricated via a roll-to-roll process on films with thickness of 3.5 μm and 10 μm line width of electrodes exhibit an impedance of approximately 1.5 MΩ, reducing to about 120 KΩ after typical platinum colloidal coating. This impedance range is suitable for multiunit recordings, enabling simultaneous monitoring of a large population of neurons in the brain. The probes are mechanically very flexible and thus shows no fracture or mechanical/electrical failure under repeated bending test of up to 500 times, and also in the course of handling and monitoring. Furthermore, it is thermally stable that can endure the properties up to 175 degree Celsius and also chemically stable under acidic/alkaline condition that make possible to modify the electrodes easily under harsh conditions such as CVD (chemical vapor deposition) or electro-deposition. In fact, any mechanical failures, or degradation of monitoring capabilities has not been observed in the courses of modification. It indicates that the fPCB probes can be used as a “DO IT YOURSELF” type chronic, tailorable neural probes for chronic neural signal monitoring.

Fully 3D Printed Bio-Electronic Devices for Nerve Regeneration Ju-YongLee[1], JooikJeon[2], Joo-HyeonPark[1], Yea-SeulPark[1], Se-HunKang[1], Min-SungChae[1], Kang-SikLee[3], Jung KeunHyun[2] and Seung-KyunKang[1,4,5]; [1]Seoul National University, Korea (the Republic of); [2]Dankook University, Korea (the Democratic People's Republic of); [3]Asan Medical Center, Korea (the Republic of); [4]Soft Foundry Nano Systems Institute (NSI), Seoul National University, Korea (the Republic of); [5]Research Institute of Advanced Materials (RIAM), Seoul National University, Korea (the Republic of)

Advancements in miniaturization, wireless technology, and flexible electronic components have led to the development of diverse bio-interfaced electronics for medical devices. Extensive research has focused on implantable electronic components that can be precisely positioned within the body to record or stimulate specific areas. A significant challenge in this field is achieving a seamless interface between the inserted electronic component and the complex surface or irregular structure of the body. To overcome this challenge, customization of the electrode part and the main body of the device is necessary to adapt to the intricate body surface. Moreover, optimizing space utilization is essential to enable smooth packaging of components in limited spaces, requiring a compact form factor. Therefore, the utilization of additive manufacturing for configuring data-driven voxelated electronic materials within a three-dimensional space holds great potential for integrating electronic components in customized forms. Additionally, it is crucial to prevent infections or internal damage caused by permanent implantation or removal surgery in implantable electronic components. Ultimately, addressing these concerns necessitates biodegradation after the device's operational lifespan. In this study, a fully printed wireless electroceutical tube was developed, capable of treating injuries by inserting it as a tube into peripheral nerves. This achievement was based on the use of biodegradable voxelated electronic ink. Notably, the integration of biodegradable voxelated semiconductors with conductors and dielectrics enabled the creation of a device that generates wireless-controlled monophasic pulses, demonstrating its significant potential for biomedical applications. The suitability for in vivo application was evaluated in small and large animals, and the validity of the findings was confirmed through biological verification, which involved confirming therapeutic effects and assessing their impact on actual functional recovery.

8:00 PM SB07.08.11
Using Digital Image Speckle Correlation (DISC) to Identify Micro Emotions ShirleyXiong[1], HyeonjiAhn[2], ElainaHeghes[3], AnushaMisra[4], ElaineZhang[5], JessicaHofflich[6], ShiFu[6], PawelPolak[6] and MiriamRafailovich[6]; [1]Ward Melville High School, United States; [2]St. Mark's School, United States; [3]South Side High School, United States; [4]Dana Hills High School, United States; [5]Jericho Senior High School, United States; [6]Stony Brook University, The State University of New York, United States

Facial expressions are one of the most basic and natural forms of communication between humans. Alongside general facial expressions, micro-emotions are spontaneous changes in facial muscles that indicate hidden emotions. Micro-emotions become apparent in response to specific emotion-inducing stimuli, such as pictures and videos. These fleeting expressions are low in intensity and are, therefore, significantly more difficult to identify than visible facial expressions and emotions.[1] This study uses Digital Image Speckle Correlation (DISC) to identify micro-emotions by analyzing subcutaneous facial muscle displacement through a contact-free, non-invasive method.

To verify the validity of DISC for tracking facial muscle movement, a video was taken of identical twins and a control performing the same facial actions of frowning and smiling. The control was a subject with no relation to the twins. While the twins used similar parts of muscles to perform actions, the control used quite different parts of facial muscles to perform the same actions. For instance, when frowning, the identical twin’s forehead muscles toward the inside of the face. However, the control’s forehead muscles moved downward toward the outside of the face.

Sets of ten images were obtained from the International Affective Picture System (IAPS) and categorized using a valence and arousal scale. Valence denotes the emotional value, while arousal characterizes its level of stimulation. The analysis of the participants' faces shows that high-valence images tend to evoke positive emotions, translating to more pronounced movement in the cheeks and mouth region. When the subject saw an image with positive valence and high arousal, large levels of displacement occurred in those areas. The magnitude of facial displacement in four quadrants of the face was represented through a graph. In the graph, visible spikes span approximately a second. These peaks represent fleeting muscle movements that correlate to micro-emotions, which can be detected through displacement. On the other hand, the negative valence images induced significant amounts of micro-emotions in the upper quadrants, specifically in the forehead and eyebrow areas, commonly associated with reactions to sad emotions.

DISC has the potential to be used to analyze the efficacy of treatments for certain psychological disorders. Major Depressive Disorder (MDD) presents with non-verbal indicators such as the lack of or abundance of specific facial movements and reactions. Hence, changes in facial expressions and movements as identified by DISC can be used to diagnose and understand depression and track the progression and regression of depressive symptoms.[2] For example, esketamine is approved by the FDA to treat MDD that cannot be treated through other antidepressants.

In particular, a case study involving an esketamine patient before and after receiving treatment was utilized to analyze the effects of this treatment on patients. Analysis of the video images indicated differences in the intensity of the patient's reactions before and within an hour after treatment. The time to react to the different images was also measured and could be a measure of the impact on the information processing ability of the patient. These results will be correlated to the known physiological impact of esketamine as a sedative agent[3] and the answers to the self-report questionnaire administered to the patient, such as BDI or HAM-D which are used to assess the severity of depressive symptoms.

Soft Electronic Interface with Biological Systems ZhenanBao; Stanford University, United States

In this talk, I will discuss soft materials, sensors and devices we are developing for an intimate interface with biological systems.

9:15 AM SB07.09.02
Design and Fabrication of a Flexible Implantable Microelectrode Array for Electrophysiological and Non-Enzymatic Glucose Recording in an Artificial Brain Prosthesis Che-HungChu, Pei-LingChen and PochunChen; National Taipei University of Technology, Taiwan

For neuroscience research, scalability in regard to the length and dimension of implantable neuro devices was required owing to differences in species and brain regions. For the clinical investigation of neurological disorders, including Alzheimer's disease, Parkinson's disease, and epilepsy, specifically designed implantable neuro devices for precise focus localization have emerged. Among them, in Alzheimer's disease (AD) studies, the metabolic hypothesis of AD is among the models that have gained much traction because glucose hypometabolism is one of the early markers of AD that precede clinical dementia. While a strong argument can be made that reduced glucose uptake is merely a consequence of neurodegeneration, the metabolic hypothesis asserts that brain glucose metabolism is nonetheless an integral part of AD progression and the precipitation of cognitive deficits.
In this study, a flexible microelectrode array device is developed with a polyimide substrate, nanoporous platinum microelectrode array, and a biocompatible Parylene C package. This device has low electrochemical impedance with an improved signal-to-noise ratio and high sensitivity of glucose concentration by non-enzymatic electrochemical detection. The nanoporous Pt microelectrode demonstrated excellent electrochemical performance of 88.2 ($\mu Acm^{-2}mM^{-1}$) and 37.02 ($\mu Acm^{-2}mM^{-1}$) using a chronoamperometry (i-t) test method in PBS and ACSF, respectively.
Additionally, we dedicate to maintaining animal welfare ethics and reducing the consumption of animal experiments by developing an artificial prosthesis with agarose to mimic the brain tissue. We successfully developed a prosthesis with tunable impedance, in which we can simulate different neural diseases by adjusting its conductivity to reduce unnecessary animal experiments. The flexible platinum microelectrode shows its high sensitivity to the variation of glucose concentration in the agarose brain prosthesis.

9:30 AM SB07.09.03
Decorating Bioelectronic Surface with Supported Lipid Bilayer to Study Viral Entry and More ZhongmouChao[1], EkaterinaSelivanovitch[1], ZixuanLu[2], KonstantinosKallitsis[2], RoisinOwens[2] and SusanDaniel[1]; [1]Cornell University, United States; [2]University of Cambridge, United Kingdom

There are two pathways for the entry of SARS-CoV-2: early (cell surface) entry and late (endosomal) entry. In both pathways it requires the initial binding of SARS-CoV-2 spike proteins with host cell membrane receptor (ACE2), followed by the cleavage of spike protein by either TMPRSS2 (early entry) or cathepsin L (late entry). We have previously demonstrated a supported lipid bilayer (SLB) containing native membrane component can maintain membrane fluidity and thus its biological functionalities, making SLB a desirable platform to recapitulate the conditions in vitro that support virus infection of a host cell. In this work, by forming SLB containing ACE2 receptors on a conductive polymer-based substrate, we have probed the two entry pathways of SARS-CoV-2 using electrical signal. Our results suggest the specific binding between spike protein containing virus pseudo particles and ACE2 receptors will increase membrane electrical resistance, while the fusion events catalyzed either by TMPRSS2 and cathepsin L will further increase membrane resistance. Our work shows the electrical readout of membrane properties based on SLB platform can be a powerful tool in detecting SARS-CoV-2 virus entry without the complications of working with live cells. In addition to viral entry, the versatile SLB based bioelectronic sensors are also applied to investigate the interactions between chemical permeation enhancer (CPD) and lipid bilayers, providing insights in the drug development against otitis media.

9:45 AM SB07.09.04
Lactate Biosensor Based on Aerosol Jet Printed Organic Electrochemical Transistors (OECTs) for Real Time Monitoring YuchenShao, PaulLavryshyn, JiaxinFan and ManishaGupta; University of Alberta, Canada

Diabetic patients have an increasing risk of developing the foot ulcers. Diabetic foot ulcer (DFU), as one of the complications for diabetics, has bothered people for many years. Clinical research has shown that real time monitoring of the lactate concentration helps guide therapy and improve patient outcome [1]. To reduce blood tests for lactate level measurements, non-invasive and low-cost reliable biosensors need to be developed for monitoring.

In this research, we developed a 3D-printed lactate sensor on top of the flexible Kapton substrate. Organic electrochemical transistors (OECTs) are chosen for the biosensors because of its good performance under aqueous environments and signal amplification. Sensors are fabricated using Optomec Aerosol Jet 5X printer with Au as the source and drain electrode, Pt as the gate, poly(3,4-ethylenedioxythiophene) doped with polystyrene sulfonate (PEDOT:PSS) as the channel and polyimide as the insulator layer. Layer by layer strategy is applied for functionalization, tetrathiafulvalene (TTF), chitosan, lactate oxidase (LoX) and bovine serum albumin (BSA) are drop-casted on top of the gate area and then both channel and gate are covered by gelatin to further improve the repeatability of the lactate sensor. Functionalized sensors can be stored in 1X PBS solution for over one month without any deterioration in their sensitivity. The device was measured in both PBS and artificial sweat buffer for comparison and obtained a broad sensitivity range between 10uM up to at least 50mM, which is far beyond the desired range. Blood lactate meter was using as the reference to calibrate the lactate sensor. The printed lactate sensor includes the ZIF connector which can be inserted onto a PCB board and will be used for further diabetic model test.

10:30 AM *SB07.10.01
Integration of Soft Materials in Microfabrication for Auditory Neuroprostheses AlixTrouillet[1], EmilieRevol[1], Florent-ValeryCoen[1], DanielLee[2] and StephanieP. Lacour[1]; [1]Ecole Polytechnique Federale de Lausanne, Switzerland; [2]Harvard University, United States

Implantable neuromodulation systems often rely on macroscopic electrodes to deliver streams of electrical pulses to a small targeted region of the nervous system. Miniaturisation and design of electrode materials can help improving on the spatial selectivity and electrode reliability over time. In the context of auditory neuroprostheses, we are designing, scaling and implementing soft microelectrode arrays to generate resolutive sound percept with minimal off-target effects in a pre-clinical model of auditory brainstem implants (ABI).
Using microfabrication, we manufactured a macaque sized multichannel, MRI compatible, soft auditory brainstem implant (150µm thick silicone carrier, 11 platinum-silicone composite electrodes of 300µm diameter) that delivers selective electrical stimulation. We engineered customised biodegradable implant holder to ease handling and implantable without compromising the ABI compliance, as well as connectors to reliably interface mechanically and electrically the soft implant with flexible cables and a head-mounted pedestal. The ABI is surgically implanted through a retro-sigmoid craniotomy under endoscopic visualisation at the surface of the cochlear nucleus (<5 mm^2 surface area).
We evaluated the efficacy of the soft ABI by monitoring the animal's performance in a behavioural task. Using burst of electrical pulses (ranging from 50-100 pulses per second at 0.1-2 mA) applied through the ABI electrodes, we confirmed the resolutive capability of the implant: the animal was able to differentiate percept generated from different electrode pairs, with distinct activation threshold for each electrode, indicating good spatial resolution.
Systematic characterisation of the materials and processes at each step of the manufacturing of the implant enabled the successful deployment of the soft auditory neuroprosthesis.

11:00 AM *SB07.10.02
Waveguide-Based Optical Modules for Cochlear Implant Applications ChristianGoßler[1,2], MichaelRibeiro Stührenberg[1,2], KatharinaKunze[3], DanielKeppeler[1], Ulrich T.Schwarz[3] and TobiasMoser[1,2]; [1]University Medical Center Göttingen, Germany; [2]German Primate Center, Germany; [3]Technical University of Chemnitz, Germany

Cochlear implants (CIs) enable open speech comprehension in otherwise deaf patients. Potential improvements affect the limited spatial resolution of the electric stimulus. Optogenetic activation promises a better spatial resolution due to high-precision activation with micro-scaled light emitters. Here, we discuss the development of passive optical modules with integrated micro-optics and laser diode arrays. Remote red-emitting laser diodes are placed outside the cochlea and coupled to polymer-based waveguides with lens-based systems. The waveguides, which are directing the light towards and into the cochlea need to be highly flexible to enable precise placement in the scala tympani with a bending radius of down to 2.5 mm for the human cochlea. Ridge waveguide laser diodes are used due to their available power of several tens of milliwatts. Multibeam applications are enabled by emitter chips with a multitude of parallel aligned laser ridges with a lateral spacing in the 100 µm range. The astigmatic emission profiles of the ridge laser diodes has to be addressed in the optics design, as well as the integration of a transparent sapphire window into the beam path. We evaluate different optical systems on the path towards a human optical cochlear implant prototype, including macroscopic aspherical lenses, which enable medium-scaled optics with beam path length in the range of 15 mm. Further miniaturization of the beam path length to less than 2 mm can be achieved via a micro-lens-based approach. Here, we discuss the different optical systems in terms of channel scalability and waveguide coupling.

11:30 AM SB07.10.03
Acousto-Sensitive Ion-Based Transistors and Soft Electronics for Artificial Basilar Membrane LintaSohail, SofiaDrakopoulou and GeorgiosD. Spyropoulos; University of Ghent, Belgium

Current solutions for hearing impairment lie vastly in cochlear implants (CIs). However, they are limited by bulky, power-demanding external discomfortable components that hinder sound localization and suboptimal neural interfaces which negatively impact the efficiency of hearing restoration. To overcome these issues, we exploit novel internal ion-gated electrochemical transistors (IGTs) and piezoelectric (PVDF) nanofibers to establish a soft, biocompatible artificial basilar membrane (ABM) for a fully implantable and self-contained CI. We hypothesized that organic electronics can create all the required components; IGT-based acousto-electrical transducers with a high signal-to-noise ratio (SNR), and low-impedance, stable stimulation electrodes. To achieve that, we created efficient and fast acousto-sensitive IGTs ($gm/\tau > 10^6$ mSs^{-1}), high capacitance conductive polymer films, overcome stability issues and design smart fabrication routes that allow the development of all components into a single conformable substrate. We tuned materials composition, improved designs, and investigated the geometry and morphology effects on piezoelectric nanofibers. We explored IGT-arrays gated by continuous electrospun PVDF nanofiber (~0.6µm diameter fiber) films with gradually decreasing areas, to provide a deeper understanding of the device physics and elucidate their exact operating principle under various acoustic stimulations (0.1-10kHz).. This work lead to an ABM with 8 intracochlear excitation points that conforms to the intact basilar membrane, generates, and amplifies electrical pulses ($>x10^3$) according to incoming acoustic stimuli, to stimulate the spiral ganglion neurons and restore hearing without external components. We examined the performance of the ABM in-vivo by recording the electrically evoked auditory brain recordings (ABRs) in a rat model.

This project will generate safer, smaller, and more conformable acoustic-sensitive devices and stimulation electrodes that will build an ABM that can modulate electrically the neurophysiological activity of the spiral ganglion neurons. Further, the materials and methods that will be used in this project will lay the foundation for cost-effective and improved neurological devices such as micro-EEG systems and brain stem implants.

Coin-Sized, Fully Integrated and Minimally Invasive Continuous Glucose Monitoring System based on Organic Electrochemical Transistors JingBai, XinyuTian and ShimingZhang; The University of Hong Kong, Hong Kong

Continuous glucose monitoring (CGM) systems are currently a major focus of research in advanced diabetes management. The rapid development in this field calls for next-generation CGMs with improved sensitivity, reliability, and wearability.

Here, we propose a coin-sized, fully-integrated, wearable CGM system [1] that combines cutting-edge technologies from the intersecting fields of biosensors, minimally invasive tools, and hydrogels.

This CGM system includes: 1) an emerging biochemical amplifier, the organic electrochemical transistor (OECT), to improve sensitivity beyond traditional electrochemical modules; 2) a microneedle array for interstitial-fluid (ISF) sampling with reduced pain during skin penetration ; and 3) a tough, adhesive enzymatic-hydrogel-membrane to enhance reliability of glucose sensing on skin. Unlike conventional CGMs, the employed OECT amplifier empowers the OECT-CGM with a high anti-noise ability, an on-demand-tunable sensitivity and current regeneration ability, enabling long-term stable glucose sensing within specific clinical ranges (1~20 mM).

This work paves the way for the development of next-generation CGMs that can simultaneously deliver high and adjustable sensitivity, minimal invasiveness, and improved wearability.

[1]. Submitted.

1:45 PM SB07.11.02
Artificial Retina with Three-Dimensional Microelectrodes of Liquid Metals for Vision Restoration Won GiChung[1], JiukJang[1], GangCui[2], SanghoonLee[1] and Jang-ungPark[1,2]; [1]Yonsei University, Korea (the Republic of); [2]Yonsei University College of Medicine, Korea (the Republic of)

Inherited retinal degenerative diseases can lead to both gradual loss or permanent damage of photoreceptor cells, resulting in the impairment of vision, or even blindness. However, as inner retinal neurons can be preserved even when this degeneration of photoreceptor cells, various approaches by stimulating the inner retinal neurons to restore vision have been developed. Electronic retinal prosthesis, which uses photo-responsive devices to electrically stimulate inner retinal neurons, has emerged as a promising approach to restore vision. Over the past decade, this electronic retinal prosthesis has been adapted to clinical trials, although being still limited by low visual acuity. One of the main limitations is the low proximity that results from the unconformities between the retina and the implant. Since the stimulation threshold that elicits retinal responses strongly depends on the electrode-cell distance, it is important to reduce this distance. Also, the imprecise stimulation on the epiretinal surface caused by this low proximity can inevitably excite the axons of retinal ganglion cells (RGCs), generating irregular visual perceptions to patients. In this regard, 3D electrodes show promise for effectively stimulating the nervous system, dramatically reducing this electrode-cell distance by positioning the stimulation site adjacent to the target cell. Also, compared to the electrodes that have flat surfaces, these 3D electrodes enable their stimulation to selective local areas, bypassing neurons that should not be stimulated, thereby providing excellent selectivity and high spatial resolution. However, previous 3D neural electrodes have been formed using rigid solid-state materials, showing a significant mismatch of mechanical properties at their interface with soft biological tissues, which can directly damage the soft retina, or cause inflammatory responses within the retina.
Herein, we present an artificial retina where flexible ultrathin phototransistors are integrated with 3D microelectrodes of liquid metals. These phototransistors directly convert light into electrical stimuli, stimulating the retina through our soft 3D microelectrodes. The flexible ultrathin layer of this artificial retina can be conformably laminated on the innermost surface of the retina, directly stimulating the RGCs using the softly protrudent pillars of 3D liquid-metal electrodes. The developments of this artificial retina include several unique strategies as follows: First, these 3D microelectrodes can enhance the proximity to the target cells and provide effective charge injections to elicit neural responses in the RGCs. These soft stimulation electrodes are directly printed in a pillar shape on the top surfaces of the drain electrodes to overcome the geometrical gap at the interface between the device and the locally nonuniform surface of degenerative retina, enhancing the proximity to the target RGCs. Here, these 3D electrodes can be printed with desired heights to selectively reach target cells. Also, the Pt nanoclusters locally coated only on the tip of these 3D electrodes show advantages to reducing the impedance of the stimulation electrodes, and injecting charges effectively into the retinal neurons. Second, their low Young's modulus owing to their liquid form, can minimize the undesired damage to the interfacing biological tissues. Third, unsupervised machine learning approach can effectively classify the evoked spikes, and the results indicate the potential for the selective stimulation of RGC somas using our 3D microelectrodes. Lastly, in-vivo experiments using a retinal degeneration mouse model demonstrate that the spatiotemporal distribution of neural responses on their retina can be mapped under selective localized illumination areas of light, suggesting the restoration of their vision.

Flexible Pressure Sensor for Continuous Physiological Monitoring HemanthKalluru Nagarajarao, MaryamGolshahi and LaylaKhalifehzadeh; Arizona State University, United States

The field of bioelectronics has witnessed remarkable advancements in recent years, playing a crucial role in biomedical applications such as home-based monitoring of blood pressure and blood glucose levels. To expand the potential of bioelectronics, researchers have focused on developing advanced pressure sensors capable of monitoring various health parameters, including intraocular glaucoma, tendon repair and cardiovascular health. Meeting the growing demand for accurate pressure measurements, a multitude of flexible sensing technologies have been devised. These technologies employ techniques such as capacitive, piezoelectric, and piezoresistive sensors to convert external pressure into measurable signals. The success of these mechanical sensors hinges on their ability to compress under applied pressure. Notably, studies have demonstrated that capacitive pressure sensors outperform other options in faithfully reproducing the desired sensing behavior. Capacitive pressure sensors operate by detecting changes in initial capacitance caused by applied pressure. These sensors consist of a dielectric layer sandwiched between two parallel conductive plates. The sensitivity of these sensors increases with higher capacitance. Increasing capacitance can be achieved by reducing the plate distance or selecting a material with a high dielectric constant. This study aims to assess and compare the sensitivity of capacitors using five distinct viscoelastic polymers. The selection of these materials is guided by several factors, including their general properties such as biocompatibility, thermal stability, and cost-effectiveness. Moreover, their mechanical properties, such as high compressibility, low hysteresis, and high tensile strength, are carefully considered. These characteristics are crucial in determining the suitability of the polymers for capacitive pressure sensors, as they directly impact the sensor's performance and reliability. By leveraging these insights and engineering the materials and designs, the sensitivity and overall performance of capacitive pressure sensors can be significantly improved, paving the way for more precise and reliable biophysical pressure measurements in various biomedical applications.

2:45 PM SB07.11.05
Flexible Electrochemical Sensors for Detection of Neurotransmitter FarbodAmirghasemi, AliSoleimani, SinaGharahtekan, MonaAbdelmonem, AbdulrahmanAl-Shami and MaralMousavi; University of Southern California, United States

Acetylcholine (ACh) functions simultaneously as a neuromodulator and neuromuscular transmitter in the brain, thus playing critical roles in learning, recognition, motivation, and muscle control. Alterations in ACh concentration in the cerebral cortex were correlated to dementia and Alzheimer's disease, psychiatric disorders, anxiety, and depression. Therefore, developing instruments for selective sensing of ACh is essential to enhance the fundamental biological understanding of the role of this neurotransmitter in disease progression, as well as the rational design and testing of therapeutics that interact with the cholinergic receptors. Here, we are developing a sensor for the in-vivo recording of ACh levels in the brain tissue to address current challenges in ACh detection, including bulky and rigid neural probes and low selectivity in biofluids.
I am utilizing potentiometric sensing, which offers direct selective measurement by eliminating separation and sample processing. Potentiometric sensors offer detection in a physiologically relevant concentration range and are a passive sensing mechanism that does not consume or perturb the analyte. These characteristics make potentiometric sensing a robust analytical technique that has grown in popularity for analyzing inorganic ions, including potassium (K+) and sodium (Na+) but has^{+}) and sodium (Na^{+}), but has remained underutilized for detecting neurotransmitters. We developed a proof-of-concept flexible potentiometric sensor for detecting ACh with less than one-second temporal resolution based on flexible parylene electrodes via utilizing a calixarene-based ionophore for ACh.
Using parylene as the structural material for developing neuroprostheses has been validated and could be compared with technologies based on other materials such as PDMS, polyimide, and silicon. However, we are reporting the first potentiometric parylene-based ACh-selective neural probe. We are utilizing parylene due to providing a pinhole-free, highly flexible, sturdy mechanical strength, and biocompatible platform to construct implantable ACh-detecting sensors consisting of a working electrode (containing an acetylcholine organic sensing membrane) and a reference electrode (having a reference membrane). The parylene C substrate encompasses three 200 nM thick Pt electrodes with a 200 μm radius. The electrical potential (emf or electromotive force) between the ACh sensor and reference electrode correlates to the activity of ACh levels in the biofluid, according to the Nernst Equation ($E=E^{\circ}+(RT/zF)\log a_i$), where E° shows the standard potential, R the universal gas constant, T temperature, F the Faraday constant, z the charge of the ion, and a_i the activity of ACh. A theoretical slope of 61.5 mV/decade is expected at body temperature and is defined as the Nernstian slope. The ACh-sensing membrane will be drop-cased onto the circular area of the platinum contact. To optimize the high signal stability, we will modify the surface of platinum with the variation of carbon nanotubes (CNTs) due to CNTs' capability to generate a stable and reliable interfacial potential in potentiometric sensors with an organic sensing membrane.

Multiphoton Lithography of Organic Semiconductor Devices for 3D Printing of Flexible Electronic Circuits, Biosensors and Bioelectronics Mohammad RezaAbidian; University of Houston, United States

In recent years, 3D printing of electronics have received growing attention due to their potential applications in emerging fields such as nanoelectronics and nanophotonics. Multiphoton lithography (MPL) is considered the state-of-the-art amongst the microfabrication techniques with true 3D fabrication capability owing to its excellent level of spatial and temporal control. Here we introduce a homogenous and transparent photosensitive resin doped with an organic semiconductor material (OS) compatible with MPL process to fabricate variety of 3D OS composite microstructures (OSCMs) and microelectronic devices. Inclusion of 0.5 wt% OS in the resin enhanced the electrical conductivity of the composite polymer about 10 orders of magnitude and compared to other MPL-based methods, the resultant OSCMs offered high specific electrical conductivity. As a model protein, laminin was incorporated into these OSCMs without a significant loss of activity. The OSCMs were biocompatible and supported cell adhesion and growth. Glucose oxidase encapsulated OSCMs offered a highly sensitive glucose sensing platform with nearly 10-fold higher sensitivity compared to previous glucose biosensors. In addition, this biosensor exhibited excellent specificity and high reproducibility. Overall, these results demonstrate the great potential of these novel MPL-fabricated OSCM devices for a range of applications from flexible bioelectronics/biosensors, to nanoelectronics and organ-on-a-chip devices.

11:00 AM SB06/SB07.02
Photocapacitive Electrostimulation with Hybrid Silicon/Organic Heterojunction Devices VedranDerek[1], AleksandarOpančar[1], TonySchmidt[2] and RainerSchindl[2]; [1]University of Zagreb, Croatia; [2]Medical University of Graz, Austria

Wireless electrostimulation by silicon photodiodes[1], as well as with organic photocapacitive devices[2,3] has been reported earlier, by *in-vitro* and *in-vivo* measurements on single cells and tissues. Organic electrolytic photocapacitor (OEPC) devices can be fabricated on micrometre-thin flexible substrates, with the entire active device stack thinner than 100 nm. Even though large optical absorption coefficients of organic materials allow for very thin and conformable devices, their inherently lower photo-conversion efficiencies require relatively large, millimetre-scale devices for effective stimulation. Silicon photodiodes, due to order of magnitude higher photo-conversion efficiencies, can be scaled down to a size of tens of micrometres while still being able to effectively stimulate. However, silicon photodiodes are based on high thermal budget dopant-diffusion and annealing processes, time-consuming and complex steps which in turn increase per unit cost of the devices[4]. We will present novel hybrid inorganic/organic photovoltaic-like devices based on *n*-type silicon as a substrate and a photo-active material and spin-coated and crosslinked PEDOT:PSS as a hole-collecting contact, with the heterojunction region being responsible for the charge separation and PEDOT:PSS additionally enhancing the capacitive properties of the device. Such solution-processed hybrid devices retain high photo-conversion efficiencies of traditional silicon *pn* homojunction photodiodes, yet can be fabricated cheaply and rapidly, enabling quick turnover times for device customization when being used as test beds for in-vitro experiments. We will demonstrate enhanced efficiency, spatial resolution

and stability in aqueous environments of hybrid devices in comparison to purely organic OEPCs by measurements of the 3D transductive extracellular potential and corresponding E-fields. In addition, we will show in-vitro photo-induced modulation of the cell membrane potential of the human embryonic kidney (HEK) cells with heterologously expressed voltage-gated K+ channels, in comparison with OEPC devices.

11:15 AM SB06/SB07.03

Biocompatibility of PEDOT:DNA and PPy:DNA for Bioelectronics SerpilTekoglu[1], SarkaHradilova[2], KaterinaPolakova[2] and SerdarN. Sariciftci[1]; [1]Johannes Kepler University Linz, Austria; [2]Czech Advanced Technology and Research Institute, Czechia

Poly(3,4-ethylenedioxythiophene):polystyrene sulfonate (PEDOT:PSS) has showed promising potential for soft and implantable bioelectronics due to mixed ionic-electronic transport[1]. On the other hand, natural biopolymers and their composites with synthetic conductive polymers have attracted researchers for biomedical applications due to their biocompatibility, biodegradability, and low toxicity nature[2]. They can be utilized for a variety of applications, including drug delivery, tissue engineering, and medical implants and grafts[3]. Although biomaterial properties of polypyrrole (PPy) and PEDOT have been extensively studied for implantable electrodes, introducing acidic the surfactants, such as PSS might be cons to this approach. The long-term effects of PSS in the brain have not yet been fully investigated.

The aim of the present study is to investigate cytotoxicity of PEDOT:PSS as well as the new composite materials previously suggested for bioelectronics by our group.[4] Deoxyribonucleic acid (DNA) was extracted from salmon fish residuals and implemented as secondary dopant during the template synthesis of biocomposites. PEDOT:DNA and PPy:DNA were synthesized by following the same procedure.[4] As a follow up study, we performed a comprehensive set of cytotoxicity testing of PEDOT:PSS, PEDOT:DNA and PPy:DNA films using NIH3T3 mouse fibroblast cell line. The thin-films of the materials were deposited on glass and used as specimen which allowed cells to grow and proliferate on the surface. The cross-linker glycidoxypropyltrimethoxysilane (GOPS) was added into the dispersed solution of composites against film delamination. We monitored the morphological changes via fluorescence microcopy. The live/dead cytotoxicity/viability tests were determined by flow cytometry. The results show that the novel composites are promising with high biocompatibility to living cells while preserving the benefits of electrical conduction for future biomedical applications. Overall, the implementation of natural polymers in biocomposites for medicine has the potential to revolutionize the field by providing safer, more effective treatments for a range of medical conditions.

Towards the Development of an Electrochemical Random Access DNA Memory (e-RADM) MiguelA. Jimenez-Munoz, ChristopherWood and ChristophWalti; University of Leeds, United Kingdom

Over the last decades, we have produced an unprecedented and exponentially growing amount of information, now approaching the limit that current technology can physically store. Storage demand is in fact likely to exceed the capacity of silicon-based devices within 20 years. Current storage technologies, such as magnetic tapes, have limitations such as large power requirements and cooling systems, as well as only offering limited lifetime that requires periodically transferring data to new devices. As a result, new alternative data storage technologies are required that are space and cost-effective, and able to store large amounts of information in a small contained volume, with minimum power consumption.

As an alternative data storage material, DNA has attracted a lot of attention thanks to several intrinsic properties that make it a desirable data storage medium. First, even very long DNA molecules can be condensed into a small physical space as seen in living organisms, and it can hold 2 bits of information per nucleotide. A single gram of DNA has the potential to store two orders of magnitude more data than the amount of data expected to be produced by 2025. The DNA’s extraordinary capacity is also coupled with an excellent inherent stability. But the most important aspect that makes DNA such a viable material is the large number of biotechnological tools that have been developed for the manipulation of this biopolymer.

Current strategies aiming to use DNA as a data storage material rely on sequencing technologies for data recovery. However, on a DNA-based memory, having to fully sequence all DNA strands for retrieving a specific subset of information would imply very high levels of latency and risking integrity of information. As a result, random access strategies are required.

Here, we present the first stages of an electrochemical Random Access DNA memory (e-RADM), which utilizes DNA origami nanostructures and localized strand displacement reactions (SDRs) for data manipulation. Short DNA hairpins containing toeholds complementary to the sequences of adjacent hairpins are attached to the DNA origami such that cascades of SDRs can occur. When a data retrieval query is submitted in the form of a short oligonucleotide, only those hairpins with toeholds complementary to the oligo will open, potentially triggering a cascade reaction. After the cascade reaction, the loops of the hairpins are exposed, containing the information related to the query. The unzipping of these hairpins can be monitored by electrochemical means (Squarewave Voltammetry, SWV), as opened hairpins increase the average distance to the surface, preventing electrons from a redox active molecule attached to the end of the sequence to be transferred to the electrode. The final aim of this work is to develop a fully functional electrochemical device in which functionalized DNA origami structures are immobilize on a gold microelectrode array.

Harnessing the Potential of Biobased Furandicarboxylate Polyesters in Manufacturing Sustainable Films, Fibers and Nanofibers GiuliaFredi[1,2], SofiaSanti[1], DavidePerin[1,2], DanieleRigotti[1,2], MichelinaSoccio[3], NadiaLotti[3], DimitriosN. Bikiaris[4], AndreaDorigato[1,2] and AlessandroPegoretti[1,2]; [1]Università di Trento, Italy; [2]Consorzio Interuniversitario Nazionale per la Scienza e Tecnologia dei Materiali (INSTM), Italy; [3]Università di Bologna, Italy; [4]Aristotle University of Thessaloniki, Greece

Poly(alkylene furanoate)s (PAF) are the most credible bioderived alternative to oil-based poly(alkylene terephthalate)s, as they show superior thermomechanical and functional properties and are therefore attractive for applications in the packaging, textile, and biomedical fields. This work summarizes some of the most recent and promising developments in the processing and characterization of PAFs with variable alkyl chain length and PAF/polylactide (PLA) blends and nanocomposites, highlighting the advantages and challenges of each processing technique and the main thermomechanical and functional properties of the resulting films, fibers, and nanofibrous mats.

Solvent mixing and casting have been used to prepare PLA/PAF films, and their microstructural and thermomechanical properties were evaluated as a function of PAF concentration (5–30 wt%) and type (4–10 carbon atoms in the alkyl subunit). For neat PAFs, an increase in the alkyl chain length promotes a decrease in T_g and T_m and an increasing tendency to crystallize. However, the latter is true only for PAFs with an even number of methylene groups in the alkyl subunit, while crystallization is generally hindered for the odd-numbered ones. For PLA/PAF blends, the added PAFs are effective in mitigating one of the most important drawbacks of PLA, i.e., its brittleness, as the strain at break of the resulting blends is up to 30 times higher than that of neat PLA. Adding PAFs to PLA also increases its gas- and UV-shielding properties while keeping good transparency in the visible range, which is very desirable for packaging applications. The permeability and diffusivity to N_2, O_2, and CO_2 further decreases with the addition of reduced graphene oxide (rGO), which also promotes blend compatibilization and microstructural refinement [1-3].

The same PLA/PAF blends were also processed to produce fibers, both through solutions spinning and through melt spinning, and a detailed statistical analysis was performed to establish the optimal drawing conditions for each composition. Also in this case, the addition of a small (5-10 wt%) fraction of PAFs (with either short- or long alkyl subunits) promotes a remarkable increase in the strain at break compared to neat PLA [4] and, in some cases, also a simultaneous enhancement in the mechanical strength and elastic modulus. Following SEM observations, this effect has been attributed to the orientation and possible crystallization of the PAF phase and a plastic-rubber transition of PAF domains in the strain-hardening phase of the stress-strain curve.

Finally, we explored, for the first time, the production of nanofibrous mats made of poly(butylene 2,5-furanoate) (PBF) and poly(pentamethylene 2,5-furanoate) (PPeF), which have very similar chemical structures but remarkably different physical and mechanical properties [5]. A detailed morphological analysis of the resulting non-woven mats, carried out through SEM analysis, allowed the screening of the best processing conditions for PBF and PPeF. The resulting mats are not cytotoxic, promote cell adhesion without any surface treatment, and allow the retainment and controlled release of model drugs (e.g., dexamethasone), thus being promising for biomedical applications, for example as patches for transdermal drug delivery.

10:45 AM SB08.01.02
A Green Conformable Thermoformed Printed Circuit Board Sourced from Renewable Materials PietroCataldi; Italian Institute of Technology, Italy

Printed Circuit Boards (PCBs) physically support and connect electronic components to implement complex circuits. The most widespread insulating substrate that also acts as a mechanical support in PCBs is commercially known as FR4 and is a glass fiber-reinforced epoxy resin laminate. FR4 has exceptional dielectric, mechanical, and thermal properties. However, it was designed without considering sustainability and end-of-life aspects, heavily contributing to electronic waste accumulation in the environment. Thus, greener alternatives are needed that can be reprocessed, reused, or biodegraded/composted at the end of their function.
This work introduces diverse PCB substrates based on biobased and/or biodegradable polymers and fibers, a sustainable alternative to the conventional FR4. The substrates have been developed by compression molding, a process compatible with the polymer industry. We demonstrate that conductive silver ink can be additively printed on the substrate's surfaces, as their morphology and wettability are similar to those of FR4. The PCBs have tunable mechanical properties depending on the polymer-fiber combination, ranging from Young moduli of tens of MPa to GPa, and are thus flexible or rigid. Furthermore, they can be thermoformed to curved surfaces at low temperatures while preserving the conductivity of the silver tracks. The green substrates have a dielectric constant comparable to the standard FR4, while they are suitable for micro-drilling, a fundamental process for integrating electronic components into the PCB. The

substrate's biodegradability is tested both in seawater and in soil. We implemented a proof-of-principle circuit to control the blinking of LEDs on top of the PCB, comprising resistors, capacitors, LEDs, and a dual in-line package circuit timer. The developed PCB substrate represents a sustainable alternative to standard FR4 and could reduce the overwhelming load of electronic waste in landfills.

11:00 AM SB08.01.03
Sustainable Photoluminescent Materials Based on Bio-Based Photocurable Functional Inks for Digital Light Processing CristianMendes-Felipe[1,2], BárbaraCruz[3], DanielaM. Correia[3], Veronicade Zea-Bermudez[4], MarcoSangermano[2] and SenentxuLanceros-Mendez[1]; [1]BCMaterials - Basque Center for Materials, Applications and Nanostructures, Spain; [2]Politecnico di Torino, Italy; [3]University of Minho, Portugal; [4]University of Trás-os-Montes e Alto Douro, Portugal

The increasing demand for additive manufacturing, particularly digital light processing (DLP) printing, has raised concerns regarding its environmental impact. Conventional materials used in DLP printing, such as petroleum-based resins, often pose challenges in terms of sustainability, resource depletion, and waste generation. To address these issues, it is required to explore sustainable alternatives derived from natural sources.
Natural polymers have gained significant attention as potential ink materials due to their availability, low cost, biodegradability, and compatibility with various printing techniques. The formulation of natural polymer-based inks involves careful consideration of their rheological properties, stability, and printability, while maintaining biocompatibility and environmental sustainability. This work highlights the key factors influencing ink development, including material selection, ink formulation, and process parameters optimization, to achieve reliable and high-quality 3D printed objects. Thus, different reactive diluents have tested in soybean oil-based ink in order to optimize the ink viscosity with the aim to produce a completely DLP printable formulation. Furthermore, photopolymerization process of obtained materials denotes to be comparable with commercially available resins maintaining high biorenewable carbon content and presenting high quality in printing parts.
Furthermore, the incorporation of fillers into natural polymer-based inks has opened up new possibilities for functionalizing printed objects. By incorporating photoluminescent materials into the ink formulation, printed objects have been fabricated that exhibit luminescent characteristics, making them suitable for applications such as signalling, identification, security features, or decorative elements.
This work delves into the potential of photoluminescent salt fillers based on lanthanide ions as they possess several unique luminescent features of high technological interest: long luminescence lifetimes (μs to ms), fingerprint emission profiles, fine emission bands, and large pseudo-Stokes shifts. Thus, five photoluminescent salts are used, three of them that emit efficiently in the visible spectral region based on Eu^{3+} (red, 612 nm), Tb^{3+} (green, 544 nm) or Tm^{3+} (blue, 440 nm), and two more emitting in the near infrared spectral region, the Yb^{3+} (1000 nm) and the Nd^{3+} (808 nm). The impact of filler type and dispersion on the optical properties and overall performance of printed structures will be discussed, showing quantitative signal even at low concentration of 5 wt.%, together with a high quality of printing parts. In addition, the challenges associated with natural polymer-based ink development, such as achieving sufficient mechanical strength due to the negative impact of the addition of fillers into the polymer, optimizing print conditions ascribed to the light absorption of the fillers that difficult the photopolymerization process during printing, and ensuring good photoluminescent properties will be addressed.
Overall, this work sheds light on the advancements in natural polymer-based ink development for additive manufacturing, specifically targeting DLP technology, and emphasizes the potential of integrating photoluminescent fillers to expand the functional capabilities of 3D printed objects. The findings presented in this abstract contribute to the broader understanding of materials development in additive manufacturing.

11:15 AM SB08.01.04
Stretchable and Biodegradable Plant-Based Organic Batteries AimanRahmanudin, MohsenMohammadi, NaraKim and KlasTybrandt; Linkoping University, Sweden

Next-generation electronics will interface intimately with the human body. This requires devices with high degrees of conformability and autonomy, where integrated soft and stretchable batteries are an essential component. However, existing stretchable batteries are predominantly based on unsustainable transition metal-based active materials and use non-biodegradable petroleum-based elastomers. Such batteries cause environmental issues like waste generation upon disposal and the use of finite resources during manufacturing. To address this, we present a stretchable and biodegradable organic battery employing sustainable plant-based materials with cellulose as a structural component in the electrode, separator, and current collector, and with redox-active biomaterials for energy storge and a biomass-derived biodegradable elastomer for encapsulation. Our 3D porous scaffold design allows for high mass loadings of redox-active biomolecules, in combination with a low Young's modulus. The full cell showed reversible electrochemical performance under stretching and is biodegradable.

11:30 AM *SB08.01.05
Lignin-Based Thermosets via Direct Functionalization using an Efficient and Solvent-Free Valorization Method DeanC. Webster, AlexanderHart and EricKrall; North Dakota State University, United States

Since lignin is the most abundant aromatic biopolymer, there has been significant interest in identifying ways to convert lignin into useful materials. Degradation of lignin into oligomers and monomers has been a potential approach, however, involves additional processing steps and creates waste. Lignin has abundant hydroxyl groups which can be used for further functionalization to enable crosslinking through a variety of mechanisms. To enable functionalization, lignin—which is a solid material—needs to be converted into a homogeneous mixture for the functionalization reaction. Most commonly, lignin is dissolved in a solvent, functionalized, and then the solvent removed. This process creates waste. We have discovered that lignin is soluble in polyols—such as ethylene glycol, butane diol, glycerol—and the mixture of lignin and polyol can be functionalized together creating a 100% solids crosslinkable liquid resin without creating solvent waste. This approach has been demonstrated with two functionalization chemistries. First, lignin/polyol was functionalized with acetoacetate groups which can be cured using multifunctional amines at ambient conditions. This approach also lends itself to the formation of rigid foams without the use of isocyanates. Lignin/polyol can also be functionalized using methacrylate groups. These can then be cured via free radical initiated crosslinking either thermally or using UV. Due to the aromatic content of the lignin as well as the high functionality of the resins, the thermosets are very hard, with high modulus.

SESSION SB08.02: Development and Applications of Bio-Based Polymers II

How to Implement a Recyclable Materials—Considerations for Scaling, Sourcing, Polymerization and Performance of Bio-Derivable Resins NicholasA. Rorrer, RobynneMurray, ErikRognerud and RyanClarke; NREL, United States

Thermoset materials have many energy relevant applications due to their excellence performance, versatility, and long material lifetimes. Despite this, at the end of their material life they are often rendered unrecycable by virtue of the the chemical bond topology, namely highly crosslinked networks. Recently, there has been a growing interest in making these materials from biobased sources and recyclable, both of which are feasible to do. In fact, thermosets represent an ideal market for these materials due to their robust performance and cost premium. Despite the interest and potential, scaling the manufacturing of these materials goes beyond hitting performance specifications; other parameters such as cure time, peak exotherm, and creep must all be considered the entice further interest in material perforamcne. In this work, we will present upon a bioderivable polyester covalently adaptable networks (PECAN) and its many uses in manufacturing, such as fiber reinforce plastics for wind turbine blades, dual cures for accelerated and decarbonized manufacture, and carbon fiber composites for vehicles applications. The benefit in the experimental work will be coupled with technoeconomic and supply chain analysis demonstrating the potential of these recyclable and bioderivable systems.

2:00 PM SB08.02.02
Nature-Derived Polymer, Lignin as n- and p-Type Dopants for Tuning the Thermoelectric Properties of Nano-Carbon Materials YoohyeonChoi[1], TuanTran[1], DoojoonJang[1], Jin YoungKim[2], Hyun JooLee[1] and HeesukKim[1]; [1]Korea Institute of Science and Technology, Korea (the Republic of); [2]Seoul National University, Korea (the Republic of)

Commercial polymers play a crucial role in controlling the electrical properties of organic electronic materials, particularly through the widely adopted charge-transfer doping. Charge-transfer doping is an essential technique in the industry for modifying the electrical properties by controlling the Fermi level of both host materials and dopants. The dopants involve electron-withdrawing groups (EWGs) that exhibit strong electrophilicity, making them suitable for p-doping. Conversely, n-dopants consist of electron-donating groups (EDGs) that enhance the nucleophilicity of the dopants by increasing the electron concentration. However, the production of these commercial organic dopants from fossil fuels is environmentally problematic, necessitating the development of nature-derived dopants to meet global carbon-neutrality (net zero) policies. As a possible candidate, lignin, an abundant biopolymer found in nature, possesses a phenolic structure that can be modified through various functionalization reactions, similar to commercial polymers.

In this study, we propose a lignin as a dopant for tuning the electrical properties of carbon nanotubes (CNTs) by functionalization. This can be achieved by employing electron-withdrawing groups (EWGs) and electron-donating groups (EDGs) *via* fluorination and amination, respectively, using by a simple and eco-friendly synthesizing method, microwave-assisted synthesis. The fluorinated lignin works as a p-dopant and the aminated one acts as an n-dopant. Furthermore, the thermoelectric properties of lignin-doped CNTs and their devices are demonstrated for their applications to flexible energy harvesting systems. The fluorinated lignin exhibits the high Seebeck coefficient and electrical conductivity, increasing the power factor by 117% compared to the pristine CNT films. The aminated lignin shows the Seebeck coefficient of -48 μV/K with good electrical conductivity of 246 S/cm and the high power factor. It should be mentioned that the n-type characteristics of aminated lignin-doped CNTs are valuable due to the inherent p-type properties of pristine CNTs. We also demonstrated a thermoelectric generator (TEG) only with lignin-doped CNT films of 10 pn pairs in series, exhibiting an output voltage of 7.86 mV and an output power of 247.3 nW at a temperature difference of 15 K. This study promises the realization of nature-derived n- and p-dopants by an easy modification to improve the thermoelectric performance of CNTs, which performs similar to or superior to those of commercial dopants.

2:15 PM SB08.02.03
Computationally Developed Bio-Based Pressure-Sensitive Adhesives for Healthcare Applications ManjinderSingh[1,2], AlessioAlexiadis[2], MichaelJ. Adams[2] and GauravManik[1]; [1]Indian Institute of Technology Roorkee, India; [2]University of Birmingham, United Kingdom

The adhesive materials used in healthcare sectors for developing adhesive bandages and transdermal patches have been using petro-based components, which cause contact allergy and allergic contact disease, such as dermatitis and stomatitis. In this investigation, linseed oil has been modified to acrylated epoxidized linseed oil (AELO) and acrylated epoxidized methyl ester (AEME) and further used as a low T_g component to develop bio-based pressure-sensitive adhesives (PSAs) computationally using molecular dynamics simulations. The bulk polymer adhesive properties such as density, solubility parameter, and glass transition temperature have been estimated and compared with previously reported literature. The values for density and solubility parameters for the control system have been closely related to the experimental as well as simulated values reported earlier. The glass transition temperature was observed to be in close proximity to the Fox equation values as well as the reported literature, verifying the simulation protocols adopted. Further, surface properties were evaluated in order to understand the adhesive behavior and estimate the interfacial strength with the substrate. The human skin has been considered as a substrate for analysis to understand the interfacial behavior of PSAs and suitability in healthcare industries. The surface energy of human skin was found to be in range with the experimental value, verifying the human skin model adopted for this study. The surface energy for all the developed systems has been estimated, and the AELO-based PSA surface energy value was found to be the highest among all the PSAs. Moreover, the interfacial adhesion strength of AELO-based PSA with human skin was found to be superior to that of AEME-based and control PSAs. An in-depth analysis suggests that the addition of polar groups in AELO and AEME was governing factor affecting the surface properties positively. This study paves the way for exploring the potential of AELO and AEME to formulate novel PSAs with desirable properties for the healthcare industries.

3:00 PM SB08.02.04
Biomimetic Multifunctional Nanocomposites from Naturally Derived Materials: Exploring the Functionalities of Conductive Melanin and Crystalline Nanocellulose Bong SupShim; Inha University, Korea (the Republic of)

Emulating the sophistication and functionality inherent in natural systems, we have designed multifunctional nanocomposites from naturally derived materials such as conductive melanin-like polydopamine (PDA) and crystalline nanocellulose. Nature employs a bottom-up assembly of nanomaterials to create multiphasic structures with hierarchical organization, providing inspiration for our work.
PDA, despite its historical limitation due to low electrical conductivity and limited material functionalities, has been restructured in our laboratory to possess tunable electrochemical conductivities, optical reflectivity, and casting shape stability, while maintaining inherent biocompatibility. This presentation will highlight these innovative modifications, focusing on the unique functional features of PDA in the realm of biosensors and bionic interfaces.
Additionally, our research has expanded to include crystalline nanocellulose, another naturally derived material with promising potential in the creation of multifunctional nanocomposites. Its exceptional strength, biocompatibility, and eco-friendly nature make it a promising candidate for applications alongside conductive melanin.
We will also share insights on our newly developed process for creating electrically conductive PDA, setting the stage for its role in emerging bioelectronic applications such as biotic-abiotic interfaces, edible sensors and actuators, and sustainable electronics. This presentation ultimately bridges the gap between nature-inspired designs and cutting-edge material sciences, pointing to an exciting future in multifunctional biomimetic nanocomposites.

3:15 PM SB08.02.05
Nature's Way: Hierarchical Manufacturing with Biotic Composites SabrinaShen and MarkusJ. Buehler; Massachusetts Institute of Technology, United States

Industrial material production is responsible for over half of greenhouse gas emissions from industry which, coupled with biodiversity decline and depletion of critical resources, threatens the livelihood of current and future generations of both humans and non-human species. Conversely, the natural world manufactures enormous quantities of materials that can dramatically outperform human engineering while empowering, rather than degrading, the environment, by architecting simple and common building blocks in creative ways, tuning molecular composition, then nanoscale and macroscale geometries to derive highly specialized properties. This work proposes a new paradigm for materials design that achieves goals of sustainability by aligning and integrating models of material production with natural systems, utilizing modern computation and additive manufacturing technology while drawing source and inspiration from nature. We develop a library of 3D-printable functional composites from fully biotic and non-toxic building blocks, and characterize their mechanical, surface, and biodegradation characteristics. We moreover investigate the advantages afforded by additive manufacturing, including fabrication of hierarchical architectures similar to those found in nature. Finally, we explore strategies to further functionalize similar material platforms with computation-guided biocomposite optimization, generative microstructure design, and incorporation of living components for novel hybrid-living materials.

3:30 PM SB08.02.06
Alternatives to Traditional Plastic: PHB-Based Biodegradable Polymer Composite Films and Disposable Tableware JihyeonKim and Kwan-SooLee; Los Alamos National Laboratory, United States

Nowadays, plastic materials are taking an important place in our everyday life. Plastic production has soared since it became commercially produced more than 50 years ago. This growth has seen plastic become one of the biggest environmental issues worldwide, with plastic waste polluting land, oceans, air, and even food and human blood. The majority of U.S. plastic waste is landfilled. Of the estimated 40 million tons of municipal plastic waste generated in the U.S. in 2021, at least 85% was sent to landfill sites. Biodegradable polymers have emerged as an alternative. However, certain types of biodegradable polymers, such as PLA, PBAT, Bio-PP, and Bio-PE, require specific environmental conditions or microbial activity to initiate the degradation process. In natural environments where these conditions are not present, such as in landfills or marine environments, the biodegradable polymers may persist for extended periods without undergoing significant degradation. This leads to the accumulation of non-degraded biodegradable polymers, which can contribute to environmental pollution and waste management challenges. Polyhydroxybutyrate (PHB) is a class of polymers naturally created by living microorganisms or synthetically produced from biorenewable feedstocks. They're biodegradable in the ambient environment, including oceans and soil. However, the PHB has a long-standing problem, due mainly to its inherent brittleness (ε = 3-5%) and poor melt-processability. In this study, we have developed new compositions of PHB-based polymer (≥ 90 wt.%) film/tableware bearing green additives (i.e. FDA approved) to overcome the mechanical instability of PHB and optimize their processability. Furthermore, various formulations developed not only increased the elongation properties of the films but also improved processability by lowering the melt temperature of the plasticware. This result has important implications for disposable plastic applications, as it removes the often-cited inferior mechanical properties of currently available bioplastics.

Rhizobium Tropici-Produced Biopolymer: Chemical Characterization and Modeling its Interactions with Clay TeiKim[1], BrinleyDai[2], JerryGao[3], TonyGuo Feng Tung[4], AshrithaKalakuntla[5], HaarisAlam[6], EliseNgo[6], IsanaAlicea[7], AaronSloutski[8], YiweiFang[8], MarciaSimon[8], JayGao[8], MiriamRafailovich[8], SteveLarson[9] and FengxiangHan[9]; [1]Stanford Online High School, United States; [2]Experimental High School Attached to Beijing Normal University, China; [3]Beijing No. 80 High School, China; [4]Shanghai High School International Division, China; [5]Ed W. Clark High School, United States; [6]Portola High School, United States; [7]Patchogue Medford High School, United States; [8]Stony Brook University, The State University of New York, United States; [9]US Army Corps of Engineers Research and Development Center, United States

Preventing soil erosion is important in areas vulnerable to flooding, such as watersheds in the Mississippi River Basin. A potential solution is extracellular polymeric substances (EPS), which can increase and maintain the structural stability of soil by increasing resistance to environmental stresses. EPS can improve subterranean root growth, which can stabilize topsoil and help in erosion control. Furthermore, much research in the last decade has focused on explaining EPS-clay/soil interaction in order to improve its applicability. This project aims to investigate the chemical properties of Rhizobium tropici bacteria-derived EPS (RT-EPS) and its interactions with clay to model the on-site interactions with soil. EPS produced from the bacteria was used to generate an Ethanol Precipitate Material, RT-EPM, whose chemistry was researched in depth.

First, the chemical composition of RT-EPM was analyzed with thermogravimetric analysis (TGA) and high-performance liquid chromatography (HPLC). TGA results indicated that most of the EPM was organic matter, and HPLC results demonstrated a significant presence of polysaccharides, with glucose being the main component (73%) and a significant presence of galactose (25%). Moreover, the chromatography also showed a dispersity of 1.013, indicating uniformity of the polysaccharides obtained from the RT bacteria.
The interactions between RT-EPM and clay was explored through rheology. To examine the reformability of EPM-clay interactions in aqueous medium, an amplitude sweep, an angular frequency test, and a shear rate test were conducted. Comparing the viscosity values across the three freeze-dry and hydration cycles of the EPM, a negligible change in the mechanical properties was identified, indicating the reversible nature of the dynamic cross-linking.To examine the anchoring properties of the EPM to the soil, the rheological properties of the EPM mixed with various concentrations of clay were tested. An overall increasing soil shear strength as the clay concentration increased was found, demonstrating the anchoring capabilities of the EPM to clay. Rheology displayed the mixture's desirable mechanical properties, which simulate RT-EPM's on-site reinforcement of soil via shear strength enhancement.
In conclusion, beside a significant polysaccharide presence, a small fraction of proteins was also found by running respective BSA-assays. It was also determined that the EPM, due to its adhesive properties, once mixed with clay forms interactions that are reversible, significant, and are environmentally-influenced.
Future directions include in-depth research on the protein fraction RT-EPM contains, with a focus on their influence on the interactions with clay. In order to study the EPM-production influence on the interactions with clay, different dialysis cutoff standards will be applied to treat the EPM. Then, HPLC and rheology tests will be run separately for each cutoff (2K and 14K dialysis). C-NMR and H-NMR will also be applied to further shed light on the chemical composition of the EPM and interactions with clay. Zeta potential of the RT-EPM and clay solution will be used to measure the electrochemical potential and the stability of the particle interactions.
The authors would like to thank the US Army Corps of Engineers (ERDC) for their support (W912HZ-20-2-0054) in this research.

SESSION SB08.03: Poster Session: Sustainable Polymers and Composites

Study of Vitrimerization of Thermosetting Liquid Crystal Epoxy Resin via Chemical Reprocessing and Recycling KyosunKu and HyeonukYeo; Kyungpook National University, Korea (the Republic of)

Thermosetting polymers are applied in various industrial fields due to their excellent physical properties, high thermal and mechanical stability. In particular, epoxy materials are attracting attention as next-generation electronic materials due to their bio-friendliness, electronic insulation, and thermal mechanical stability. However, most thermosetting polymers including epoxy resins, still face challenges from insoluble and non-recyclability. In this study, Liquid Crystal Epoxy Resin (LCER) are synthesized which can be reproduced to overcome the limitations of thermosetting polymers. Also, for application as an electronic material, high thermal conductivity are realized. These results suggest the applicability as electronic materials.

8:00 PM SB08.03.02
Interfacial Assembly of Cellulose Nanofibers at Oil/Water Interface via Tailored Electrostatic Attraction to Establish Surfactant-Free Emulsion Stabilization JaewonShin, BokgiSeo and Jin WoongKim; Sungkyunkwan University, Korea (the Republic of)

The pervasive utilization of petroleum-based cationic surfactants has led to significant pollution of aquatic environments, emphasizing the urgent need to explore sustainable alternatives. Aligned with this concern, this study introduces a novel bio-friendly natural cellulose nanofiber system for surfactant-free emulsion stabilization. To achieve this, glycidyltrimethylammonium chloride was incorporated into bacterial cellulose fibers to enable cationization and nanofibrillation. The newly developed ammonium-functionalized bacterial cellulose (ABC) exhibited electrostatic adsorption at the oil/water interface, facilitated by the spontaneous negative charge present on interfacial hydrocarbon oil drops. Through theoretical considerations that employed the Young's equation and contact angle measurements of three-phase sessile droplets, we observed that current ABC-based solid interface displayed approximately 10-fold higher adsorption energy compared to hydroxylated solid interface. This unique interfacial adsorption behavior of ABC not only reduced interfacial tension but also promoted the formation of a robust interfacial membrane. Importantly, these interfacial properties are corresponding to the high aspect ratio of nanofibers, which provide a larger surface area and, consequently, an increased adsorption energy. Furthermore, our rheological studies revealed that the presence of a fibril network formed by the adsobed ABC nanofibers facilitated the association of droplets and gelling of the continuous phase, thereby improving the durability of emulsion drops against applied shear stress. Collectively, our findings highlight that our innovative surfactant-free emulsion system would pave the way for development of environment-friendly complex fluids.

8:00 PM SB08.03.03
Scalable R2R Processing of Regenerated Silk Fibroin Film JeffRoshko and FiorenzoOmenetto; Tufts University, United States

Owing to its tunable physical, chemical, and biological properties, regenerated silk fibroin (RSF) has been studied extensively in the film format for potential use in many applications, namely drug delivery, medical/environmental diagnostics, electronics, optics, and tissue engineering. Methods such as spin coating and drop casting are routinely employed to create films from RSF solution in the laboratory for research sample production. However, these techniques do not necessarily translate to larger scales without considerable waste or inconsistency, potentially limiting widespread adoption of useful engineering devices developed from RSF. Meanwhile, techniques developed to produce films industrially such as roll-to-roll (R2R) processing are utilized to manufacture large areas of sensitive coatings and intricate devices, such as microfluidics and flexible solar panels. Herein, we present the development of a scalable means of producing RSF films employing techniques from R2R manufacturing using aqueous processing of RSF. This includes the optimization of RSF-inks that are conducive to solution coating and the comparison of knife-blade sheet-coating at the laboratory scale and slot die R2R coating at multi-meter production scale. This work demonstrates that scalable production is possible for widespread adoption of RSF-based functional devices.

8:00 PM SB08.03.04
Tensile and Compressive Properties of PLA-Based Polymeric Blends Depending on PBS, PBAT and TPS Content and Testing Temperature AnnaDmitruk, JoannaM. Ludwiczak, MateuszSkwarski, PiotrMakula and PawelKaczynski; Wroclaw University of Science and Technology, Poland

Environmentally friendly biopolymeric materials can be utilized to replace commonly used plastics, what leads to a noticeable reduction of the pollution level, caused by their processing and exploitation. Nevertheless, in comparison with their non-biodegradable precursors, they suffer from some severe limitations, such as their capability to be untimely decomposed during long-term work, lowered mechanical properties and impaired thermal resistance. Therefore, it is crucial to make efforts to surpass the mentioned constraints by modification of the properties of biodegradable polymers. Among the possible solutions to advance their development a preparation of variously composed biopolymeric blends seems to be a promising route. Poly(lactic acid) (PLA), being widely applied, is one of the most popular biodegradable plastics, characterized with rather high mechanical properties, but with reduced deformability at the same time. To overcome its brittleness, it can be joined together with more ductile additives, namely: polycaprolactone (PCL), poly(propylene carbonate) (PPC), poly (butylene succinate) (PBS), poly(butylene-succinate-co-adipate) (PBSA), poly(butyleneadipate-co-terephthalate) (PBAT), thermoplastic starch (TPS) and polyamide 11(PA11) [1-5]. This work was focused on PLA-based compositions doped with different ratios of PBS, PBAT and TPS to evaluate their mechanical (tensile and compressive) properties in various temperatures (-20°C, 0°C, 20°C, 40°C). Specimens for testing were obtained by preliminary extrusion, subsequent injection molding and final cutting into the intended dimensions. Mechanical properties e.g. tensile strength, elongation at break, Young's modulus, yield strength and compressive strength for the deformation of 0.4 were investigated. No additional modification step, as for example, addition of compatibilizers was necessary to be involved in the manufacturing method, what significantly simplified this process without impairing the properties exhibited by the obtained blends. Each of the tested plasticizing secondary compounds positively influenced the elongation at break of PLA – increasing it especially in the case of PBAT and TPS. Simultaneously, together with the increasing content of a ductile component, other mechanical properties i.e. tensile and compressive strength were decreased. The stability of the mechanical performance of thus fabricated mixtures was assessed taking into account also the test conditions (strain rate and temperature), aiming to understand its dependence on these parameters. To gain a deeper insight into the potential applicability of the hereby proposed materials also some selected processing parameters were investigated, namely: melt flow ratio (MFR), melt volume ratio (MVR), heat deflection temperatures for 1.8 MPa and 8 MPa (HDT A and HDT C) and Vicat softening temperatures for two loadings of 10 N and 50 N (VST A and VST B). Finally, the DSC test results were used to complement the study, providing information on the softening, glass transition, cold crystallization and crystallization temperatures of the developed mixtures. It can be concluded that the elaborated biodegradable blends provide a desired compromise between the mechanical properties, in terms of both tensile and compressive characteristics, and deformability of durable and brittle PLA and ductile PBS, PBAT and TPS additives. Hereby described biomaterials aim to find their use in energy absorption applications, as for the manufacturing of thin-walled, cellular inserts filling sports helmets, acting as energy absorbers and replacing regularly utilized foamed materials in protection of their users during an accident.

Funding: This work was supported by the project BIOKASK ‘‘Development of innovative, replaceable, energy-absorbing structures based on biodegradable plastics for protective helmets”

(0223/L-11/2019, LIDER, NCBR).

8:00 PM SB08.03.05
Evaluation of Mechanical Properties of Wood, Changed by Structural Changes in Alkali Treatment and Liquid Impregnation RikaTakenaka and DaisukeIshii; Nagoya Institute of Technology, Japan

One of the increasingly serious environmental problems is plastic waste disposal. In addition to direct solutions such as reducing the amount of plastic used, there are indirect solutions such as using less environmentally hazardous materials as substitutes for plastic materials. Familiar examples include the widespread use of paper bags and straws. In this research, we focused on wood, whose main component is cellulose, as a natural polymeric material with the potential to have the same properties as light and strong plastic. In order to increase its versatility and make it an excellent substitute for plastic, we aimed to investigate novel mechanical properties, such as controlled flexibility, by treating it with alkaline solutions and impregnating it with various liquids.
Commercially available balsa wood was used as the experiment material. Alkaline mixture solutions of NaOH 2.5 mol/L and Na_2SO_3 0.4 mol/L were prepared, and the balsa wood was immersed in the prepared alkaline mixture solutions on a hot stirrer set at 212 °F . Duration times of alkali treatment were 0 h (untreated) and 6 h. The alkali-treated balsa wood was washed with pure water and freeze-dried. Structural observation and mechanical strength measurements were performed on these two types of samples.
Scanning electron microscopy (SEM) was used to observe the cross-sectional structure in each cellulose fiber direction. In particular, cross-sectional observation in the vertical fiber direction showed that the cell wall thickness increased in the alkali-treated samples. This is thought that the cellulose fibers unraveled and swelled by dissolving some of the hemicellulose and lignin that bind the cellulose fibers together. It is expected that this structural change affects the novel mechanical properties.
In the compression test, dry samples before liquid impregnation and liquid-impregnated samples of pure water, ethanol, ethylene glycol, and silicone oil of various kinematic viscosities up to equilibrium were prepared. All measurements were performed in the direction parallel to the cellulose fiber. The results showed that strength varied significantly depending on the alkali treatment and the liquid impregnation. The samples without alkali treatment showed no significant difference in strength depending on the type of impregnating liquid. On the other hand, the alkali-treated samples were softer in water and ethylene glycol and harder in ethanol. This led us to believe that the ratio of hydrophilic to hydrophobic groups was a factor in determining whether the liquid acted as a cushion between the cellulose fibers. With silicone oil, the smaller the viscosity, the stiffer the sample. This is expected to be due to the degree of penetration of the liquid, i.e., the degree to which the molecular chains of the silicone fluid entangle with the loosened cellulose fibers.
In the bending test and the falling-ball impact test, two types of samples were prepared, one in a dry state before liquid impregnation and the other in a liquid-impregnated state after absorption of pure water. Measurements were performed in the direction parallel and vartical to the cellulose fiber. As a result, it was found that the tenacity against bending and the tendency of the force to receive impact differed depending on the fiber direction. We believe that this is due to the effect of structural changes identified by SEM.
As described above, it is possible to control the physical properties of wood using a relatively simple method, and it is hoped that this research will contribute to the development of highly functional sustainable materials that can replace plastics in the future.

8:00 PM SB08.03.06
Lignin-Silica Bio-Composite: A Sustainable Solution for Wastewater Purification NataliiaSmyk[1,2], OlegTkachenko[3], TetyanaBudnyak[3] and OlenaSevastyanova[2]; [1]Taras Schevchenko National University of Kyiv, Ukraine; [2]KTH Royal Institute of Technology, Sweden; [3]Uppsala University, Sweden

The proper purification of wastewater is a pressing environmental concern, given the wide range of pollutants it can contain. In this study, a groundbreaking approach utilizing lignin-silica bio-composite as an effective and sustainable sorbent for removing cationic-type contaminants from wastewater is presented. The research team conducted a comprehensive characterization of the proposed sorbent using SEM, FTIR, XPS, and adsorption methods, ensuring its structural integrity and functionality. This attention to detail instills confidence in the efficacy and reliability of the lignin-silica bio-composite. One of the key strengths of this sorbent is its high sorption capacity. The lignin-silica bio-composite demonstrates an impressive ability to attract and retain heavy metal cations, dyes, and cationic medicines, thereby effectively reducing their presence in wastewater. This feature is particularly noteworthy as it addresses a diverse array of cationic pollutants commonly found in both industrial and domestic wastewater. Furthermore, the sorption kinetics of the lignin-silica bio-composite are commendably rapid. Its efficient adsorption process allows for the removal of contaminants within a short period, ensuring swift and effective treatment of wastewater. This attribute is of utmost importance when considering large-scale implementation and practical application.
At room temperature and near-neutral pH, the sorbent exhibited an adsorption capacity of 0.98 mmol Cu(II) and 1.21 mmol Cr(III) per gram of dry adsorbent. These values were three times higher than those achieved by using lignin or silica alone as starting materials. The kinetics study further demonstrated the efficiency of the composite sorbent. Within a short span of 20 minutes, it was able to effectively extract copper(II) and chromium(III) from the solution. Additionally, the adsorption capacity of the immobilized lignin towards brilliant green dye was found to be relatively high. Furthermore, the capacity of the initial silicas and lignin significantly increased when combined in the bio-composite. This enhancement can be attributed to the "extended" conformation of lignin, which allows for better accessibility of various functional groups when adsorbed onto the charged silica surface.
By utilizing lignin, a byproduct of the pulp and paper industry, as a key component of the sorbent, the researchers have showcased a valuable and eco-friendly approach to wastewater treatment. This not only provides an innovative solution but also contributes to the broader goal of promoting a circular economy and reducing waste. The robust characterization methods employed, combined with the sorbent's impressive sorption capacity and rapid kinetics, make it a promising candidate for large-scale wastewater purification. Moreover, its sustainable nature aligns with the increasing need for eco-friendly solutions.

8:00 PM SB08.03.07
Scalable and Sustainable Valorization of Lignin using Single-Step Aerosol Method SujitModi[1], OnochieC. Okonkwo[1], SulaySaha[1], HaoZhou[1], ShalineeKavadiya[2], MarcusFoston[1] and PratimBiswas[2]; [1]Washington University in Saint Louis, United States; [2]University of Miami, United States

Growing demand for energy and materials has led to increased greenhouse gas emissions from the use of fossil resources. Lignocellulose biomass, one of the few renewable resources of carbon, has an abundance and geographical distribution to displace fossil resources. However, the under-utilization of by-products (i.e., lignin fraction) remains one of the challenges to the rapid growth of biorefinery. Thus, developing technologies that can valorize lignin to high-value products is crucial. Lignin could be used as a precursor for the synthesis of a diverse range of high-value nanomaterials, including lignin nanoparticles (NPs), carbon NPs, and functionalized carbons. However, conventional synthesis methods of these nanomaterials are limited by multistep and batch processes or large volumes of solvents/activating agents. To overcome these challenges of conventional synthesis methods, the present work explores the synthesis of high-value nanomaterials from lignin using a novel and simple furnace aerosol reactor (FuAR) technique.

First, the FuAR is demonstrated for controlled synthesis of lignin NPs of mean sizes between 50 and 68 nm. The as-synthesized lignin NPs are analyzed for their size and functional groups. The mean size of lignin NPs showed an increasing trend with lignin solution concentration. Based on the changes in functional groups, the maximum temperature in FuAR to obtain lignin NPs without significant chemical degradation was found to be around 300 ^oC (at a residence time of 5.8 s). Furthermore, the bulk and as-synthesized LNPs were tested for UV protection applications. The observed improvement in UV protection with a decrease in lignin particle size is systematically investigated using the optical absorption parameter [1].

Next, temperature and residence time are expected to have a key impact on products obtained from the pyrolysis of lignin. With the systematic understanding of the role of these parameters, carbon nanoparticles with high surface area (up to 925 m2/g) are synthesized in FuAR without the use of activating/templating chemicals. This one-step approach requires significantly less time for synthesis: an order of seconds in comparison to hours for conventional methods. Furthermore, the as-obtained carbon nanoparticles are tested for specific capacitance which showed a linear trend with surface area. The best-performing material (with the highest surface area) exhibited a specific capacitance of 247 F/g at 0.5 A/g with excellent capacity retainment of over 98 % after 10,000 cycles [2,3].

Finally, the FuAR is used for in-situ nitrogen functionalization to synthesize nitrogen-functionalized porous carbons.Urea is added to the lignin solution as a precursor for nitrogen functional groups. Furthermore, the as-obtained carbon nanoparticles are tested for CO_2 adsorption and the material with a maximum surface area of 1051 m^2/g exhibited a CO_2 adsorption capacity of 62 mg/(g of carbon) and excellent cyclability.
Overall, these studies demonstrate the unexplored potential of FuAR for the scalable valorization of lignin as well as the excellent performance of obtained nanomaterials in respective applications, which will help advance displacing the fossils with renewable resources.

Bacterial Factories for the Production of Functional Lubricants StephenF. Bartolucci, CameronM. Longo, EricaRichael and JoshuaA. Maurer; U.S. Army DEVCOM Armaments Center, United States

The use of bacteria to produce novel materials is a rapidly expanding arena across many sectors of industry. These “bacterial factories” can be engineered to produce a wide variety of moderately valuable materials. This has been demonstrated both in academia and industry, with the production of such resources as biofuels, natural products, and pharmaceuticals. The use of bacterial factories offers several advantages to other means of production, namely that production can occur at the point of use, and can be fed waste products as feedstock, which otherwise would have little to no value. These two factors make bacterial factories an attractive method for production of kilogram scale quantities of various supplies. One such material which serves as a useful foray into this field is the production of mucin-like greases. Mucins are naturally-produced lubricating substances, the structures of which can be altered to produce materials with varying properties, including lubricity, viscosity, and thermal stability. We hypothesize that by intelligently designing mucin-like compounds, and hijacking the biosynthetic pathways of *E. coli* to produce these proteins, we can construct bacterial factories which produce water-based, ecofriendly lubricants, which can then be compared in terms of performance to traditional, petroleum-based greases. We demonstrate here, the work thus far in the design, transfection, and expression of these proteins, as well as preliminary results of their glycosylation and functionalization towards a functional lubricant.

8:00 PM SB08.03.09
Relationship Between the Structure and Properties of Recycled High-Density Polyethylene Reinforced with Rice Husk Biochar HusseinS. Alrobei; Prince Sattam Bin Abulaziz, Saudi Arabia

The focus of this investigation is on how recycled High Density Polyethylene (HDPE) is affected by rice husk biochar in terms of its structural, thermal, flammable, and mechanical characteristics. The different ratios of recycled HDPE to rice husk biochar were prepared and the best ratios were discovered for different kinds of features. Tensile, flexural, and impact properties were considered when evaluating mechanical features. In order to expound on this fluctuation in attributes, Scanning Electron Microscopy and Fourier Transform Infrared Spectroscopy were carried out. All of these experiments demonstrated the importance of rice husk biochar as an additive for improving the mechanical properties of recycled HDPE.

8:00 PM SB08.03.10
Improving Water Resistance and Film Forming Ability of Cellulose Based Film with Lotus Leaf Extract and Gelatin BehrokhShams, EvanK. Wujcik and DouglasBousfield; University of Maine, United States

Cellulose is extensively employed in food packaging to enhance moisture barrier properties. However, cellulose nanofibrils face challenges such as low flexibility and high water vapor permeability. Utilizing hydrophobic materials, like lotus leaves, is a promising approach to improve water vapor transmission rates. Gelatin can help with film forming and flexibility. In this research, cellulose nanofibrils are combined with a natural hydrophobic extract and gelatin to enhance moisture resistance and film forming process.

8:00 PM SB08.03.11
Algae-Powered Sustainability via Hydrothermal Liquefaction: Revolutionizing Epoxy Resins KeshanLighty, PhillipAgbo, AbhijeetMali, LijunWang and LifengZhang; North Carolina A&T State University, United States

In the growing field of materials science, our study establishes a revolutionary creative approach in the area of biocomposites for sustainable manufacturing. We present research using the hydrothermal liquefaction process used to produce eco-friendly epoxy resins from algae. The materials science community will be interested in this study since it has the potential to alter how epoxy resin is made in the future.

Traditional epoxy resins come from petroleum sources and are necessary but have a significant environmental impact. Through the use of algae, a plentiful, quickly expanding, and underutilized resource, our work reimagines these resins. We unlock the potential of algae using hydrothermal liquefaction to produce a bio-binder that is not only competitive with conventional components in terms of performance but also a champion of sustainability. The biomass is subsequently transformed into a versatile bio-binder by the state-of-the-art conversion method known as hydrothermal liquefaction, which is prepared to give epoxy resin compositions new life.

The incorporation of bio-binders made from algae not only improves the performance of epoxy resins but also tells a captivating story of ethical material development. Our discovery also changes the paradigm by decreasing reliance on limited fossil fuel resources, which helps lessen the carbon load on our world. The size of the world's epoxy resin market was approximately USD 8.70 billion in 2020, and it is anticipated that it will increase from USD 11.59 billion in 2021 to USD 17.10 billion by 2028. When it comes to these widely utilized composite materials, our capacity to reduce the consumption of fossil fuels while incorporating sustainability will have an enormous impact on society as a whole for the better.

With the help of this scientific development, we are encouraging researchers, thinkers, and proponents of sustainable materials to set off on an exploration that will not only enhance the study of materials but also fundamentally alter the way that Epoxy Resin can be manufactured. This research can make an impact in the areas of painting/coatings, electronics, wind turbines & composites, construction, and adhesive/sealants.

We look to encourage creativity, foster teamwork, and bring in a new era of sustainable materials for a more promising, responsible future. I want to assist society in both self-healing and improving the quality of life through sustainable manufacturing and this research assists with that but this is only the beginning. The goal is to help build a better tomorrow starting today.

8:00 PM SB08.03.12
***In-Situ* Treatment of Flexible Polylactic Acid (PLA) using Non-Thermal Plasma and Various Electrode Geometries: Towards Developing Advanced Analytical and Machine Learning based Hybrid Methodologies to Study The Wettability Characteristics using Surface Topography, Contact Angle Characteristics and Electrical Impedance Spectroscopy**DerekXiong[1], KaiyuVang[1], PrakhyatGautam[1], ParshwaKhane[1], DavidRyman[1], HarshkumarBhatt[1], EdberthoLeal-Quiros[2], SaquibAhmed[3,3] and SankhaBanerjee[1,4]; [1]California State University, Fresno, United States; [2]University of California, Merced, United States; [3]Buffalo State College, United States; [4]University of California, Davis, United States

Polymer and polymer composite-based 3D printing processes allow users to fabricate multiple prototypes and proofs of concept, making it an excellent method for testing concepts in the early stages of development. However, the layer-by-layer printing procedure can result in issues with surface properties and the strength of the finished printed geometry, making the product an inaccurate representation of the design. The current work involves the in-situ treatment of biocompatible and flexible-PLA, with non-thermal and room-temperature microplasma-based corona discharge to address this problem and try to optimize the surface properties. The work also involves the evaluation of the effects of plasma-treated 3D printed polymer materials as compared to non-treated samples. This will involve tailoring the polymer properties in the layer-by-layer process to create stronger and more cohesive bonds between each layer through the modification of the surface characteristics of each of the printed layers. Advanced hybrid machine learning models will be developed in combination with analytical methods and empirical data sets to develop strategies for tailoring surface properties of these materials. Additionally, the work involves the characterization of the surface electrical properties using impedance spectroscopy, surface energy and topographical properties using profilometry, and hydrophobic or hydrophilic properties using water contact angle measurements. This will provide valuable insights into the effects of room temperature-based plasma-based surface modification of the printed layers towards enhancement of surface properties of the samples and which electrode will be the most effective.

SESSION SB08.04: Lignocellulosic Technologies

Nanocellulose as a Sustainable Alternative to Improve the Performance of Resins for Additive Manufacturing Maria SoledadS. Peresin, LauraAlvarez and ZahraNaghizadeh; Auburn University, United States

In a plea to become more sustainable, the construction industry is increasing the demand for research on partially replacing synthetic resins with renewable and more environmentally friendly

resources, such as biomass. Having good properties, epoxy resins have been an excellent candidate in composites for construction applications. However, it is a relatively brittle material, with a poor resistance to crack initiation and growth. Reinforcing epoxy composites with renewable and mechanically strong materials like nanocellulose is progressively considered recently. In this research, different percentage of bleached and unbleached cellulose nanofibers (BCNF/LCNF) were used to reinforce and partially replace epoxy resin in composites containing Epon 828 and Jeffamine d-400 catalyst. The chemical interaction between cellulose nanofiber and epoxy resin was investigated by quartz crystal microbalance with dissipation monitoring (QCM-D). Mechanical and thermal performances of the reinforced resin were studied using tensile test and thermal gravimetric analysis (TGA) method, and the elemental analysis, Fourier transform infrared spectroscopy (FTIR), was employed on the cured reinforced resin in order to understand the composition of the mixtures after nanocellulose addition. The results proved that the nanocellulose addition changes the chemical composition of epoxy resin, and based on the QCM-D data, BCNF showed favorable chemical interactions with the resin. The mechanical tests indicated the promising results and they proved that the BCNF can be used as a biodegradable and sustainable additive and partially replacement for epoxy resin in composite materials. BCNF reinforced epoxy showed better tensile performance compare to LCNF one. For both LCNF and BCNF dispersed epoxy, the maximum enhancement in tensile properties occurred with 1 wt.% nanomaterial added. It should be noted that the moisture stability of the wood composites was not significantly affected by the nanocellulose content, however, the thermal stability decreased slightly.

9:00 AM SB08.04.02
Towards Sustainable, Environment-Friendly and Low-Waste Gas and Photoactivated Sensors for Low-Power Health and Air Monitoring and Medical Diagnostics SheidaFaraji[1,2], AbdouK. Diallo[3], LeszekA. Majewski[2] and TuranOzturk[1]; [1]Istanbul Technical University, Turkey; [2]The University of Manchester, United Kingdom; [3]Gaston Berger University, Senegal

In the recent years, organic phototransistors (OPTs) have attracted considerable interest due to their unique capability of delivering flexible and wearable photosensor modules for various applications in the rapidly growing field of flexible electronics. Compared to conventional photodetectors and inorganic phototransistors, OPTs have an advantage of low-cost fabrication when it comes to their low processing temperature, as well as their mechanical flexibility and versatile chemical functionality of the organic materials. OPT structure is identical to that of an organic field-effect transistor (OFET), where the channel layer simultaneously plays the sensing role. The three-electrode geometry of an OPT controls and amplifies signal, while reducing noise and hence improves photosensitivity by simply adjusting the gate voltage (V_G).
Recent advances on OPTs have been particularly focused on detection in the ultraviolet (UV) and near infrared (NIR) regions. UV sensors are gaining increasing attention for utilisation in the health NIR light-sensing OPTs has become one of the most important foundations for advanced control and sensing systems such as night vision for cars and airplanes, light detection and ranging (LiDAR) sensors for autonomous cars and drones, probe beams for biomedical devices and diagnostics, and optical communications and medical fields to prevent sunburn and skin cancer caused by sunlight. Numerous researches have been dedicated to NIR sensors for medical diagnostics, for instance, pulse oximetry or monitoring blood pressure. Home-assisted (bio)medical sensors have gained more demand than ever before, due to increased hospitalisation and hospitals overcrowding during the Covid-19 pandemic. Photoplethysmography (PPG) sensors can be integrated into home-assisted kits and offer tremendous advantage to monitor cardiovascular and atherosclerosis disease markers, such as heart rate (HR), blood pressure (BP), heart rate variability (HRV), arterial oxygen saturation (SpO_2), arterial ageing. Most basic human characteristics can be evaluated by the flow of blood in the subcutaneous tissue. PPG sensors can detect these indicators by monitoring pulsatile changes in blood flow. However, the NIR-absorbing organic materials are very rare because of the difficulty in synthesis to meet the narrow energy band (level) gap of ca. 0.89~1.65 eV, which corresponds to the wavelength (λ) range of ca. 750~1400 nm. In this regard, conjugated donor-acceptor (DA) polymers have been considered viable NIR-absorbing materials since their energy band gaps can be altered by combinations of electron-donating and electron-accepting monomers. Moreover, when used as gas and bio-sensors, sensitivity, selectivity and drift control are critical parameters of consideration.
In this work, we proposed novel, low-power, highly sensitive, sustainable OFETs and OPTs based on naturally occurring, biodegradable and low-waste materials. We applied and modified aloe vera (aloin) and cellulose as natural dielectric materials to operate devices at low voltages. For the active material, we synthesised a selection of DA polymers based on thieno-thiophene (TT) and naphthalene diimide (NDI) as the donor and acceptor respectively, with different substituents, as well as metal phthalocyanine, to verify their electrical and sensing performances. The dielectric layers are separately characterised in parallel-plate capacitors and electrical and sensing (both as light-receiving device and chemical sensors) of the OFETs are fully tested. We believe that these natural, low-waste OFET devices can be used as gas, chemical and photoactivated light-receiving, sensing devices with low-operating voltage and good environmental and bias stress stability.

Cellulose Nanocrystals-Based Membrane: Enhancing Dimensional Stability and Water Uptake for Alkaline Fuel Cells YuanLu[1] and SoydanOzcan[2]; [1]LL products, United States; [2]Oak Ridge National Laboratory, United States

The design of anion-conducting polymeric materials has been an active field of research, driven by their application in alkaline fuel cells. These membranes offer advantages such as higher cell efficiencies and cost-effectiveness. However, a major challenge lies in balancing high conductivity with excessive water uptake, which can lead to uncontrolled dimensional swelling or membrane disintegration. In this study, we present a unique approach to address this challenge by utilizing cellulose nanocrystals as the basis for a membrane design. Cellulose nanocrystals, derived from cellulose-rich sources through acid or base hydrolysis, possess exceptional mechanical properties and are known for their high water absorption capabilities while maintaining excellent dimensional stability. By incorporating cellulose nanocrystals with various commercially available polymeric binder systems, we prepared an electrolyte membrane for alkaline fuel cells. We systematically investigated the impact of cellulose nanocrystal content, binder formulations, and temperature on water absorption, swelling, and hydroxide conductivity. Our results demonstrate that the resulting membrane exhibits improved dimensional stability, with less than 10% swelling, and excellent water uptake exceeding 100% compared to membranes solely based on polymer binders. Importantly, the presence of cellulose nanocrystals does not compromise the hydroxide conductivity of the polymer binder system. This approach offers a facile and renewable strategy for preparing solid electrolytes with exceptional dimensional stability and high hydroxide conductivity. It represents a promising avenue for the development of solid electrolytes in alkaline fuel cells, offering a simpler alternative to complex polymer synthesis routes.

Hybrids Comprising Cellulose Nanocrystals and Percolated Networks of Carbon Nanotubes RachelYerushalmi - Rozen; Ben-Gurion University of the Negev, Israel

Cellulose nanocrystals (CNC) are being used in high performance coatings utilizing their anisotropic geometry and their consequential assembly into mesophase with non- isotropic physical properties (1). Yet, CNC are insulating materials and thus could benefit from the incorporation of conductive additives such as single walled carbon nanotubes (SWNT). CNCs are inherently renewable, low cost environmentally friendly and biocompatible rod-shaped crystalline nanoparticles. CNCs that are extracted from plant sources (cotton, wood and more) via acid-hydrolysis are known to disperse SWNTs in dilute suspensions, probably via interactions with the π electrons of the SWNTs. The CNC-dispersed SWNTs are excluded from the *chiral nematic, N** phase (2,3) of the CNCs but can be trapped in thin dried films formed via water evaporation from a CNCs suspension. The balance of intermolecular interactions in liquid mixtures of CNCs and SWNTs, and in particular the exclusion of SWNTs from the *N**, are not yet well understood. It was suggested that both size-mismatch and hydrophobic interactions dominate the mixtures (2,3). Here we report the formation of percolated networks of SWNTs within the LC phase of the CNCs in the presence of minute concentrations of surface-active molecules that are used to mediate the SWNTs-CNCs interactions. Small Angle X-Ray Scattering (SAXS) measurements indicate that the effect of the surfactant molecules is minor, and the assembly of the CNCs into an optically active birefringent phase is not modified. Cryo-Transmission electron microscopy and Raman spectroscopy indicate that surfactant-decorated SWNTs are equally distributed within the isotropic and LC phase of the CNCs and form percolated networks within the phases, already at the liquid state (the colloidal ink). These findings are expected to enable the design of new pathways for preparation of optically active and conducting coatings based on CNCs-SWNTs hybrids (4).

Utilizing Cellulose Nanofibrils (CNFs) in Additive Manufacturing: Multilayer Porous Structure using Microwave Irradiation Md MusfiqurRahman[1], IslamHafez[2] and MehdiTajvidi[1]; [1]University of Maine, United States; [2]Oregon State University, United States

Cellulose nanofibrils (CNFs)–based foams and aerogels have distinctive features such as high porosity and low density which enables their application in diverse fields. This type of porous structures is typically produced from water-based suspensions using an energy and time-intensive freeze-drying or supercritical CO_2 drying, making these products particularly unattractive to industry. In addition to this, the 3D printability of CNF–based bio ink is also limited due to the fact of using cost intensive functionalized CNFs or the overall high manufacturing cost especially for drying. As additive manufacturing is essential for accurate development and control of micro-to-macrostructures, this is also a key necessity for the market to adopt the green technology employing CNFs instead of synthetic polymeric materials. In this work sophisticated multilayered infill structures have been prepared through additive manufacturing and by optimizing the solid content of CNFs with the addition of carboxymethyl cellulose (CMC) and urea. The structures were frozen in a freezer to maintain their structural integrity. Finally, microwave irradiation was applied to completely dry the structure with a minimum time and energy. The continuing research consists of rheological study, physical, chemical, and mechanical characteristics of the 3D-printed CNF-based infill structures.

Lignocellulose-Based Separators for Aqueous Zinc-Ion Battery HuisiLi, OlenaSevastyanova and SadeghAskari; KTH, Sweden

The rapidly growing demand for energy storage systems has promoted extensive research on sustainable and cost-effective alternatives to lithium-ion batteries. Zinc-ion batteries (ZIBs) have emerged as promising candidates due to their inherent advantages. ZIBs offer cost-effectiveness in large-scale applications, such as grid energy storage, due to the abundance and lower cost of zinc compared to lithium. They exhibit superior safety with a reduced risk of thermal runaway, making them less prone to fires or explosions. Additionally, ZIBs demonstrate excellent stability over multiple cycles, resulting in a longer lifespan, and the use of zinc as a more environmentally friendly element contributes to their sustainability and lower environmental impact. The investigation of efficient and reliable separators remains a critical challenge in the development of ZIBs since the performance of ZIBs can be significantly influenced by separators. Nevertheless, most research in ZIBs focuses on electrode materials, and little effort has been made on next-generation separators.
Herein, this research aims to present an innovative solution to this challenge by introducing a lignocellulose-based separator for Zn-ion batteries. Lignocellulosic materials, derived from renewable biomass resources, offer a sustainable and abundant alternative to conventional separators, typically composed of non-renewable and costly materials.
The proposed lignocellulose-based separator exhibits several compelling advantages, such as excellent mechanical strength, superior electrolyte uptake, good ionic conductivity and high thermal stability. These properties are crucial for enhancing the overall performances and safety of ZIBs. Moreover, the utilization of lignocellulosic materials promotes a circular economy and reduces the environmental impact associated with battery manufacturing and disposal.
This study will delve into the fabrication process of the lignocellulose-based separator. Furthermore, comprehensive electrochemical characterization results will be presented, demonstrating the separator's superior performance when integrated into the electrochemical cells. Specifically, a better cycling performance and lower impedance of the cell is achieved in comparison to the cells with commercial separators.
Our research findings indicate that the lignocellulose-based separator holds great promise in overcoming the existing limitations of ZIBs separators. It can contribute to the advancement of sustainable energy storage technologies and it aligns with the global drive towards achieving a more sustainable and eco-friendly future.

10:45 AM SB08.04.07
Preparation of Low-Density Foamed Lignocellulosic Structures Enabled by Cellulose Nanofibrils (CNFs) MaryamEl Hajam; The University of Maine, United States

Nowadays, there is an increase in interest in biodegradable, renewable, and eco-friendly lightweight materials for use in packaging, building insulation, sound absorption, and other areas. This interest stems from the desire to develop low-density bio-based materials that can replace petroleum-based polymers and other non-renewable materials. Lignocellulosic fibers represent the most suitable alternative to meet this challenge. In addition to being sustainable, many inherent lignocellulosic fiber characteristics, namely strength and stiffness, surpass those of fossil-fuel-based products.
In this work we have focused on foam-forming method as a technology to manufacture lightweight materials based on natural fibers enabled by cellulose nanofibrils (CNFs). In comparison with the water-forming used for conventional products, where a sample filtration results in the formation of thin fibrous sheets, the foam-forming method is based on the use of liquid wet foam as a carrier medium for dispersed natural fibers, and after the molding, the samples are allowed to slowly drain and dry until all foam has disappeared, so that a highly porous, deformable fiber network is formed.
Thermomechanical pulp fibers (TMP), refined wood fibers (RWF) and pine flour (PF), were chosen as the natural lignocellulosic fibers. These fibers differ by their particle size and shape; TMP has long and thin fibers with an aspect ratio of about 21.8 ± 23.4, followed by RWF, which is characterized by short and large fibers with the presence of some fine particles (aspect ratio 9.4 ± 9.4) and then PF in where the fine particles are abundant (aspect ratio 3.2 ± 1.8). Different concentrations of liquid foaming agents (Lutensol TDA 10 (TDA 10), Sodium Dodecyl Sulfate (SDS) and Polyvinyl Alcohol (PVA)) were mixed with different concentrations of CNFs in a blender to prepare the foam and after that a determined amount of TMP, RWF and PF fibers in their dry state was added separately to the foam. The foam-fibers suspensions were well agitated and poured into square metal molds with mesh filter sheets. The materials were kept for drainage for 30 min and then were placed in an oven at 70 °C for 24 hours up to an average solid content of about 99 % prior to density measurement. The obtained results showed that among the three tested natural fibers, TMP is the best for the preparation of low-density foamed materials without any collapse during the foam forming, the drainage and the drying, because of the high aspect ratio of its fibers. In this case, a concentration of 10 g/l of PVA leads to a foamed material with a density of about 0.039 g/cm^3, and concentrations of 15 and 20 g/l leads to the lowest density of 0.035 g/cm^3. However, at 10 g/l of TDA 10, we obtained a material with a density of 0.031 g/cm^3 and the mixture of TMP with 2 g/l of SDS is able to give a low-density material (0.011 g/cm^3). These low-density structures are enabled by the excellent bonding capability of CNFs that will be further discussed in this presentation.

11:00 AM SB08.04.08
Highly Filled Short Banana Fiber-Polypropylene Composites: Fiber Concentration and Interfacial Adhesion Effects on Damping and Mechanical Performance CaitlynClarkson[1], SanjitaWasti[1,2], AmberM. Hubbard[2], SoydanOzcan[1,2] and UdayVaidya[2,1]; [1]Oak Ridge National Laboratory, United States; [2]The University of Tennessee, Knoxville, United States

Natural fiber-hybrid composites are gaining significant interest from automotive applications because these composites meet performance requirements but are often lighter and lower cost than other fiber composites, therein reducing the environmental burden of the vehicle during its use phase. In the case of natural fibers, the inherent hydrophilicity of natural fibers is one of the biggest challenges to overcome as these materials take up moisture at a significantly higher rate and most thermoplastic matrices are hydrophobic, resulting in poor interfacial bonding between the dissimilar fiber and matrix. In this work, composites are prepared by first creating a non-woven fiber mat of polymer fiber and natural fiber in a wet-lay process, drying, and then compression molding to the final desired shape. A water-based sizing agent is added directly to the process to size fibers in situ during wet-lay. The composite properties are evaluated including the tensile strength and impact resistance, damping, heat distortion temperature and water uptake. Finally, demonstration parts will be shown that are compression molded from the wet-laid non-woven process.

11:15 AM SB08.04.09
Ultra-Strong and Tough Bacterial Nanocellulose Sheets and Fibers via Rotational Fluid Flow Assisted Shear Alignment Md Abid Shahriar RahmanSaadi[1], YufeiCui[2], ShyamBhakta[1], MatthewBennet[1], PulickelAjayan[1] and MuhammadM. Rahman[1]; [1]Rice University, United States; [2]Massachusetts Institute of Technology, United States

Bacterial nanocellulose (BC) has emerged as an excellent alternative candidate to non-biodegradable polymers due to the remarkable mechanical properties of its basic nano-fibrillar building blocks. However, full utilization of the mechanical properties in BC structures is yet to be achieved due to the challenge of alignment of the nanofibrils. Herein, we report a facile bottom-up fabrication technique for producing ultra-strong BC sheets by using shear alignment from fluid flow in a rotational culture device, which enables in-situ layer-by-layer deposition of anisotropic cellulose nanofibrils. Specifically, we introduce a custom-designed culture device where the cellulose-producing bacteria are cultured in a cylindrical oxygen-permeable incubator that is continuously spun using a central shaft to produce a directional fluid flow. This flow results in consistent directional motion of the bacteria that significantly improves nanofibril alignment in the bulk BC sheets. The BC sheets produced from the rotation culture device after stretching displayed specific tensile strength (up to ~ 1 GPa/g-cm^{-3}) and are comparable to the highest tensile strength of BC sheet ever reported yet showing excellent flexibility that allows forming into desired shapes. We show that the BC sheets can be twisted and stretched to make BC micro-fibers of ~200 μm diameter with tensile strength of 1.3 GPa, the highest reported to date among strong natural fibers. We also compare the mechanical, environmental, and cost-effective aspects of the BC fiber with widely used structural fibers such as E-glass and lightweight steel, showing the superiority of BC fiber. This fabrication technique yielding highly aligned, ultra-strong BC sheets and fibers would pave the way toward extensive applications of BC in a range of bio-degradable structural and functional materials.

11:30 AM SB08.04.10
Self-Organized Mycelium-Based Biocomposites for Sustainable Buildings: From Structure to Fracture and Toughening Mechanics PreciousO. Etinosa[1], AliSalifu[2], SarahOsafo[1], JohnObayemi[1] and WinstonO. Soboyejo[1]; [1]Worcester Polytechnic Institute, United States; [2]Boston College, United States

This work presents the results of a combined experimental and analytical study of the structure and fracture/toughening of bioprocessed mycelium composites. The mycelium composites are reinforced with self-organized cellulose/hemicellulose hemp ducts and varying laterite proportions. In-situ studies of crack growth are used to provide insights into the underlying toughening mechanism that gives rise to resistance-curve behavior. The crack-tip shielding contributions from the observed crack bridging and crack deflection mechanisms are then quantified using fracture mechanics models. The results show that toughening is dominated by crack-bridging at low volume fractions of laterite (≤ 20%), while a combination of crack-bridging and crack deflection is observed to occur at increased laterite volume fractions (20 – 60 %). Finally, toughening is shown to occur predominantly by crack deflection at higher volume fractions (≥ 60 %).

The implications of the results are discussed for the microstructural design of mycelium and mycelium-laterite composites for potential applications in sustainable buildings.

SESSION SB08.05: Novel Bio-Based Materials
Session Chairs: Katherine Copenhaver and Heli Kangas
Tuesday Afternoon, November28, 2023
Hynes, Level 1, Room 109

High Specific Surface Areas and Interconnected Pore Networks of Porous Pectin Particles for Enhancement of Protein Adsorption Capacity Tue TriNguyen and TakashiOgi; Hiroshima University, Japan

The aging population is leading to an increasing demand for nutritional supplements, including functional foods. Functional foods aim to provide essential nutrients and proteins to the human body. Porous particles, specifically macroporous particles with pores size larger than 50 nm, have emerged as promising carrier materials for efficient delivery of bioactive compounds. While macroporous particles have been developed from various inorganic and organic materials, their application to natural polymer-derived materials remains unexplored.
This study focuses on the synthesis and characterization of porous pectin particles, utilizing a template-assisted spray drying method combined with a chemical etching process to prevent thermal decomposition of the natural polymer. Calcium carbonate ($CaCO_3$) was used as templates to investigate the formation of porous structures. The incorporation of $CaCO_3$ significantly increased the specific surface area and pore volume, with the porous pectin particles offering interconnected pore networks for penetration and binding. The porous particles had the large specific surface area (171.2 $m^2 g^{-1}$), and 114 times compared with non-porous particles prepared without $CaCO_3$ particles (1.5 $m^2 g^{-1}$). The study also explored the application of porous pectin particles in protein adsorption using lysozyme as a model protein, providing insights into the adsorption kinetics and isotherm parameters. By comparing the adsorption kinetics of different materials, it was found that increasing $CaCO_3$ concentrations led to enhanced specific surface areas and total pore volumes, thereby promoting protein adsorption capacity. All porous pectin particles performed rapid adsorption and high uptake capacity on lysozyme, in which PPT-C has the highest adsorption capacity of 2621 mg lysozyme/g adsorbent for the same amount of adsorbent particles. The adsorption isotherm analysis confirmed the formation of a monolayer following the Langmuir model.
In summary, this report highlights the synthesis of porous pectin particles using a template-assisted spray drying method with $CaCO_3$ templates. Since this technique is rapid, continuous, reproducible, and one-step, it is attractive both in laboratories and in the industrial setting. Thus, it shows significant promise for developing materials on a large-scale in the future. The porous pectin particles exhibited increased specific surface areas compared to pure pectin particles. Notably, the porous pectin particles utilizing $CaCO_3$ templates displayed excellent lysozyme adsorption capacity, making them promising adsorbents for various applications such as protein and antibodies purification, virus capture, and micro- and nanoplastic recovery from the environment.

1:45 PM SB08.05.02
Unleashing Nature's Potential: Mycelium-Based Innovation in Bio-Composites ChiaraDognini and Laura EleonoraDepero; Università degli Studi di Brescia, Italy

Mycelium-based composites are groundbreaking biomaterials that are attracting considerable attention in the European Union and the United States. They have tremendous potential for commercializing sustainable products and offer numerous advantages over traditional materials in industrial sectors like construction, packaging, and textiles. These composites are derived from the vegetative part of fungi, which grows on a substrate, often made from agricultural or other renewable waste materials. They can be utilized in the production of various goods, ranging from furniture to insulation panels and eco-friendly leather, aligning with the principles of the circular economy.

Compared to conventional building materials, mycelium-based composites are more environmentally friendly as their production requires fewer resources and generates less waste and pollution. Moreover, they possess superior technical characteristics and can be molded into different shapes and sizes, opening new design possibilities. These adaptable biomaterials possess physical and mechanical properties that can be customized to meet specific requirements. This unique characteristic holds the potential to make a substantial impact on reducing the construction industry's carbon footprint, which currently contributes to around 40% of the total CO_2 emissions.
Building materials contribute to various forms of pollution during their life cycle, caused by production, transport, installation, use, and disposal procedures. Addressing the pollution associated with building materials requires sustainable practices throughout the construction industry. Developing solutions without exploiting natural resources whilst safeguarding the environment is crucial for the ecological transition and the future of a green building market.

In recent years, microorganisms have been validated as a promising alternative to highly polluting products, such as foam insulation boards, particle boards, packaging materials, concrete, non-structural furniture elements, textiles, automotive and aerospace materials, and even medical applications. Mycelium-based composites consist of a lightweight material developed by an interwoven three-dimensional filamentous network of hyphae able to bind the feedstock. The use of biomaterials may have seemed like a utopian concept less than a decade ago, but today, they are gaining increased attention due to their customizable properties achieved through specific cultivation procedures.

Key factors that influence the mechanical behavior of mycelium-based composites include the selection of fungal strains, substrates, and cultivation conditions. Despite the exciting opportunity presented by the development of mycelium-based composites to create sustainable and environmentally friendly materials for the manufacturing industry, their widespread adoption has been limited by the lack of efficient manufacturing processes at the industrial level. The presentation discusses and compares various protocols to standardize an efficient manufacturing process for potential industrial scale-up.

2:00 PM SB08.05.03
Design of Novel Chitosan Nanoparticles for Antimicrobial Applications MagdalenaHudek, KarinaKubiak-Ossowska, KarenJohnston, ValerieA. Ferro and PaulA. Mulheran; University of Strathclyde, United Kingdom

Chitin and chitosan (de-acetylated chitin) are biopolymers derived mainly from langoustine shell waste and are considered potential candidates for novel antimicrobial applications. Chitosan is soluble in weakly acidic aqueous solutions and is polycationic, which gives rise to its antimicrobial properties. We have employed computational simulations to study the binding of chitosan to two different substrates to design new composite nanoparticles with antimicrobial properties. The model substrates studied are chitin nanocrystals and silica nanoparticles. Chitin nanocrystals are stable, biocompatible and biodegradable, and silica nanoparticles have been used for medical applications for a long time and are readily available. Using fully atomistic molecular dynamics and enhanced sampling methods, we evaluated the binding energies of chitosan to the substrates and studied the dynamics of the adsorption process. We show that the adsorption of chitosan to the chitin nanocrystal surface is driven by dispersion forces and hydrogen bonding, while the adsorption to the silica surface is driven by electrostatics. Furthermore, we have simulated the development of a biopolymer film with the substrates, providing insight into the loading capacity of the nanoparticles and the availability of the chitosan to interact with its environment. Our work therefore shows how computational simulations can be used to guide the design of novel composite materials for antimicrobial applications.

2:15 PM SB08.05.04
Data-Driven Representative Models of Bio-Oils for Atomistic Simulations of Biobased Asphalt Rejuvenators DanielJ. York[1], IsaacVidal-Daza[1,2], CristinaSegura[3], JoseNorambuena-Contreras[4] and FranciscoMartin-Martinez[1]; [1]Swansea University, United Kingdom; [2]University of Granada, Spain; [3]Universidad de Concepción, Chile; [4]Universidad del Bío Bío, Chile

A large variety of waste can be transformed into bio-oils and biocrude oils via processing techniques such as pyrolysis and hydrothermal liquefaction (HTL), respectively.[1] These techniques provide a waste valorization route with applications such as the production of biofuel precursors, asphalt additives and other carbon-based materials, which can be derived from plastics, lignocellulosic biomass, chitin, etc. However, there are challenges in the fundamental understanding of the structure-property relationships within these bio-based oils, which are exasperated with difficulty in experimental characterisation of these complex bitumen-like materials. To address this lack of understanding, the development of molecular models for density functional theory and molecular dynamics (MD) studies is key and has potential to identify applications for oils produced by the pyrolysis or HTL of plastics and bio-based polymers (i.e shopping bags, food utensils, packaging) at the end of their life cycle. Computational studies have been carried out to elucidate the mechanisms occurring during production of bio-based oils during hydrothermal liquefaction[2,3] but there are few of these studies investigating the properties and behaviours of the produced bio-based oils with only one comprehensive atomistic model having currently been developed for algae-derived biocrude[4]. This model is based on existing models for crude oil and asphaltenes[5,6], which are based off years of development and research but are tailored to a specific material. In this work, we present a methodology to generate data-driven representative models from pyrolysis gas-chromotography (py-GC-MS) experimental characterization of any complex organic fluid, e.g., bio-oil, biocrude oil, or asphalt samples by generating a selection of statistically representative models that simplify the complexity of the fluid into a limited group of molecules. A variety of different molecular models have generated using a range of different approaches to evaluate the best method for capturing the key chemical features a complex organic fluid that are required for further computational chemistry calculations and large scale molecular dynamic simulations. These atomistic models are key to

understanding and implementing waste valorization routes to sustainable, added-value products with potential to accelerate material development from waste. A computational framework has been developed to automate model creation from py-GC-MS data, which could enable future high-throughput MD simulations; ultimately helping to shape future waste-to-materials strategies.

Biomechanics of Biogenic Termite Structures ZionMichael[1], Sang-binLee[2], ThomasChouvenc[2] and AnamikaPrasad[1]; [1]Florida International University, United States; [2]University of Florida, United States

Cellulose-based composites possess notable properties such as high-strength to weight ratio, non-toxicity and biodegradability which make them suitable for applications ranging from aerospace to construction. Due to challenges with manufacturability, synthetic production of cellulose-based composites has failed to achieve comparable outcomes to their natural counterparts. One solution is to look to nature for insights and apply biomimetic principles of design to the development of novel fabrication techniques. Here we focused on the cellulose-based structures created by termites to explore the rules and design principles.

Subterranean Termites produce a cellulose-based composite called Carton that is used as a construction material during nest formation. Carton is a sponge-like material that consists of biocemented fecal matter, soil, and saliva. Despite relatively weak microconstituents, Carton is light, resistant to weathering, and multi-functional, adapting macroscopic composition and architecture according to function. Although the macroscopic features of nests have been evaluated in existing literature, there are few studies on material structure, and those that exist are limited by specie, variable and test type. Elucidating the compositional properties of cartons at the microscale may yield learning about interfacial interactions between cellulose polymer and its matrix and solvents for solubilizing cellulose.

Samples of carton from Coptotermes Gestroi were obtained from 4 yr-old laboratory reared colonies. After termite extraction and drying, carton was cut and sectioned according to distinct morphological characteristics, correlated with functional architectural features. These features are referred to in this study as nursery, high-cellulose and high-soil regions. Duplicates of samples were taken from each region and embedded in resin. The embedded media was sanded then polished to prepare for material characterization.

Here we perform imaging, Raman Spectroscopy, and Nanoindentation to determine the underlying structure-function-compositional characteristics of the carton and use that to elucidate design principles for cellulose-based structural composite design. The above-proposed research area remains largely unexplored, and this study represents the first of its kind for biogenic structures produced by subterranean termites.

3:15 PM SB08.05.06
Eco-Voxels: Building Blocks for Sustainable Terrestrial and Extraterrestrial Lattice Structures ChristosE. Athanasiou; Georgia Institute of Technology, United States

The environmental impact of construction is significant, with buildings consuming 5% of global energy and contributing to 10% of global greenhouse gas emissions. Concrete production, the most widely used building material, has also led to an alarming 35-fold increase in the last 65 years, accounting for 8% of global CO2 emissions. In addition to these Earth-bound challenges, humanity faces the task of finding livable spaces beyond our planet within the next century. Astronauts are anticipated to reach Mars by the end of this decade or earlier, necessitating space structures for protection against harsh conditions and radiation. However, manufacturing and assembling structures in space present formidable complexities and obstacles. Expensive transportation of materials and tools from Earth, coupled with the limitations imposed by extreme environments, reduced gravity, and limited labor resources, pose significant barriers to achieving sustainable space structures.

In this talk, I will present a new approach to address these challenges by utilizing tiny, lightweight pieces, termed eco-voxels, made from a renewably sourced bio-composite material that can be mass-produced through injection molding and create lattice structures offering a sustainable solution for rapidly constructing shelters at scale. The mechanical performance of the lattice structures will be evaluated both experimentally and using finite element simulations, and a life cycle assessment will be conducted to analyze the environmental impacts of this novel building system. Through these assessments, the advantages of our eco-building system will be highlighted, paving the way for advanced on- and off- earth construction systems.

3:30 PM SB08.05.08
Peptide Nanowire Coated Jute as Hydrophobic Bio-Based Filter for Oil Water Separation NoahHann-Deschaine, JeikoJ. Pujols and RameshAdhikari; Colgate University, United States

Solutions to oil-water separation have received a great deal of attention recently in an attempt to address the environmental damage of oil spills. However, many of these separation methods are materially expensive, environmentally hazardous, require elaborate fabrication, or rely on large amounts of energy to function. Herein we provide an effective, low-cost, and environmentally sustainable method for oil-water separation based on the hydrophobicity of self-assembling diphenylalanine nanowires grown on jute fabric. This modified jute fabric exhibits high levels of both hydrophobicity and oleophilicity due to the nanoscale surface roughness created by the growth of the self-assembling peptides on the jute fibers. The treated jute fabric also achieves consistent oil separation efficiencies of 98% via filtration and high levels of efficiency in a novel boat method of separation. Due to the high efficiency and low environmental impact of this method, we believe our diphenylalanine treated jute fabric has a promising potential in the field of oil-water separation.

3:45 PM *SB08.05.09
Novel Recyclable Bio-Based Materials and Technologies for Sustainable Biocomposite Applications KatariinaTorvinen and KirsiImmonen; VTT Technical Research Centre of Finland Ltd, Finland

Due to challenges in global climate change and related regulations of EU Green Deal, there is a growing need in markets to have sustainable and low carbon footprint materials and products, which are recyclable and utilize bio-based additives. In this paper, we will present novel results in terms of biocomposite material development as well as manufacturing point of view. In addition, we will discuss possibilities to upscale solutions in different end-use sectors, e.g. automotive, construction and packaging.
An optimization of composition and structure of thermoplastic biocomposites having improved functionalities (e.g. fire resistance) is crucial. We have studied sustainable solutions using PLA (polylactid acid) and cellulose esters, and show characteristics of those composites regarding of density, strength and structural properties. We will also address 3D-printable cellulose-based composite material solution, which can be recycled several times without to deteriorate mechanical properties of it.
We will introduce an innovative up-scalable web-forming manufacturing method to produce thermoplastic composites with raw materials like long fibers (natural and synthetic ones), bio-based polymers and additives. Thermoformed products are lightweight, strong and sustainable. The target is to enable the full reinforcing potential of long fibres in thermoplastic composites for high performance applications. In this paper, the selected applications will be highlighted and discussed.

SESSION SB08.06: Sustainable Composites and Recycling I

Trojan Horse PET Counits for Facile Chemical Recycling EricCochran, Ting-HanLee, GeorgeKraus, DhananjayDileep, MichaelForrester and NacuHernandez; Iowa State University of Science and Technology, United States

In this talk I will review our efforts to develop PET copolymers designed for low-energy chemical recycling. For example, PET copolymers with diethyl 2,5-dihydroxyterephthalate (DHTE) undergo selective hydrolysis at DHTE sites, autocatalyzed by neighboring group participation (NGP). Liberated oligomeric subchains further hydrolyze until only small molecules remain. Copolymers were synthesized via melt polycondensation and then hydrolyzed in 150-200 °C water with. Degradation progress was tracked via measurement of retained solids and quantiative analysis of the aqueous phase. With increasing DHTE loading, the rate constant increased monotonically while the thermal activation barrier decreased. The depolymerization products were ethylene glycol, terephthalic acid, 2,5-dihydroxyterephthalic acid, and bis(2-hydroxyethyl) terephthalate dimer, which could be used to regenerate virgin polymer. Composition-optimized copolymers showed a decrease of nearly 50% in the Arrhenius activation energy, suggesting a 6-order reduction in depolymerization time under ambient conditions compared to that of PET homopolymer. Thermomechanical properties were in general similar to PET, with increased tensile strength and reduced extensibility the most notable differences. This approach is readily extended to other "Trojan Horse" counits that provide internal cataylsis for facile hydrolysis, methanolysis, or glycolysis.

9:00 AM SB08.06.02
Additive Manufacturing of Hybrid Cellulose Fibers Reinforced Polymer Nanocomposites BivekBista[1], XianhuiZhao[2], LuWang[1], DouglasGardner[1] and SoydanOzcan[2]; [1]University of Maine, United States; [2]Oak Ridge National Laboratory, United States

Hybrid reinforced polymer composites are materials in which a particular polymer matrix is reinforced with more than one reinforcing materials, or one type of reinforcing material is incorporated into two similar or different polymer matrix mixtures. Hybrid reinforced polymer composites are among multifunctional materials when more than one characteristic benefit (e.g., mechanical strength, conductivity) is needed. In this study, pulp and nanocellulose fibers were used for reinforcing polylactic acid (PLA) because of their relatively low cost, abundance, and biodegradability. The hybrid nanocomposites were produced with nanocellulose loading between 0 and 20 wt% to investigate the effect of fiber loading on the composite tensile performance. The hybrid nanocomposites obtained were characterized using tensile testing, differential scanning calorimetry (DSC), and scanning electron microscopy (SEM). In addition, a demonstration of additive manufacturing (i.e., 3D printing) of hybrid nanocomposites was carried out. Results show that cellulose fibers can provide PLA with a higher tensile performance.

9:15 AM SB08.06.03
Bamboo-Alginate Composite as a Sustainable Structural Material with High Mechanical Properties MinjaeSong, DaewoongKim, HyunsooHan and SangminJeon; POSTECH, Korea (the Republic of)

In the current era of heightened environmental awareness and energy crises, there is growing interest in wood-based composites as sustainable materials. However, the mechanical properties of these composites need significant improvement. In this study, we present a groundbreaking method for developing bamboo composites that exhibit exceptional mechanical properties and enhanced formability. Our approach involved delignifying bamboo and subsequently filling the resulting voids with an alginate solution under reduced pressure, leading to the formation of alginate-impregnated delignified bamboo (ADB). Subsequently, the alginate within ADB was subjected to sequential ionic and chemical cross-linking using CaCl2 and glutaraldehyde, respectively. By employing a hot-press forming process, we effectively eliminated unfilled voids in the dually cross-linked ADB (DCB), thereby enhancing its mechanical strength. Remarkably, the tensile and flexural strengths of the resulting hot-pressed DCB (HP-DCB) reached unprecedented values for wood composites, measuring at 1.12 GPa and 678 MPa, respectively. These remarkable properties can be attributed to the robust adhesion and efficient load transfer resulting from the dual cross-linking of alginate between the bamboo fibers. Notably, the presence of flexible and adhesive alginate enabled the reshaping of HP-DCB into desired forms through rehydration and molding processes, underscoring its potential for various applications that demand environmentally friendly, high-strength, and lightweight materials.

9:30 AM SB08.06.04
Using Waste Organic Matter from Landfills to Create Lignocellulosic Filler Materials for Biocomposite Plastic Products RogerB. Tipton[1,2]; [1]University of North Carolina at Charlotte, United States; [2]Newell Brands, United States

Utilization of waste materials in the production of new materials is a fundamental component of the circular economy. We experimentally evaluated four different levels of upcycled organic trash material as filler material in a polyethylene wastebasket. We found that we could include up to 7% upcycled organic waste material into existing wastebasket designs as a filler before product requirements were out of tolerance. Upcycled trash, at production volumes, can be a usable filler in low concentrations in industrial plastic products which has the potential reduce landfill waste and reduce virgin resin requirements.

10:15 AM SB08.06.05
Understanding the Fragmentation and Transformation Behavior of Plastics in Marine Environments under the Weathering Effect via Ultrasonication-Assisted Mimicking KyungtaePark and JinkeeHong; Yonsei University, Korea (the Republic of)

As the amount of plastic usage increases, environmentally exposed plastics rapidly accumulate, with a significant portion eventually ending up in the ocean. The fragmentation of plastics has raised considerable concerns regarding microplastics (MPs) as pollutants and potentially toxic substances to ecosystems and human beings. Previous research has highlighted the threat of fragmentation and surface changes caused by eco-corona or weathering, which can result in severe damage to human beings.
Despite the importance of understanding plastic fragmentation, the influence of weathering and the prediction of fragmentation behavior have not been thoroughly investigated. Therefore, it is important to establish an analytical model that can simulate the behavior of environmentally weathered plastics and their transformation. In this study, we focused on the ocean environment, which is considered the ultimate destination for discarded plastics, as our target environment. Our aim is to conduct a comprehensive study on the effects of weathering and the potential threats posed by weathered plastics.
To understand the weathering effect in marine environments, we employed focused ultrasound irradiation. As the cavitation and collapse process repeated during ultrasound irradiation, sonoluminescence emitted ultraviolet (UV) energy to the microplastics. We analyzed the morphological and functional group changes on the surface of particles, comparing manufactured plastic with fragmented nano plastics. Our results showed an oxidation process occurring around the microplastics' surfaces, which we detected through FT-IR and XPS analysis. By comparing the oxidation rate of ultrasound-irradiated microplastics with aged microplastics, we aimed to establish an analytical model for mimicking weathered plastics in marine environments.
While increasing research has highlighted the toxicity of microplastics to the human body, the potential toxicity of naturally fragmented and weathered nano plastics has not been clearly investigated. However, microplastics can transform into nano plastics and undergo changes in surface characteristics due to external physical and biological stresses in the ocean. In this study, we focused on manufactured polyethylene plastic particles and used ultrasound to simulate the natural fragmentation of nano plastic particles caused by weathering in the ocean. We examined the potential threats posed by fragmented nano plastic particles to the human body through immune-cytokine analysis, cytotoxicity tests, and co-culture with human umbilical vein endothelial cells. Our study implemented naturally transformed nano plastics through weathering and evaluated their potential toxicity.

10:30 AM SB08.06.06
All Green Microwave Assisted 99% Depolymerisation of Polyethylene Terephthalate into Value Added Products via Glycerol Pretreatment and Hydrolysis Reaction MuhammadAzeem and MargaretB. Fournet; Technological University of the Shannon, Ireland

Energy-efficient and fast depolymerisation technologies present as new sustainable and green recycling routes for achieving a circular economy for plastics. Herein, we present a highly efficient 2-step microwave-based (MW) degradation of polyeth- ylene terephthalate (PET). Initially, a MW-assisted pre-treatment was evaluated using glycerol as a non-toxic reagent for the conversion of PET into a modified form that makes it easily depolymerised. Box Behnken Design was employed to determine the optimised pre-treatment conditions attaining maximum PET weight loss and favourable crystallinity and carbonyl indices for the pre-treated PET. Glycerol of 12 mL volume and 3 min of 182W MW irradiation resulted in 11% PET weight loss at onset temperature of degradation and gave rise to carbonyl index up to 4.22 and 33% crystallinity of pre-treated PET. MW assisted hydrolysis of the pre-treated PET was then performed in the presence of sodium bicarbonate and ethylene glycol as depolymerizing agents. Within 3 min, the proposed depolymerisation methodology provided 99.9% conversion of PET into 79.1% terephthalic acid (TPA), 17.6% monohydroxyethyl terephthalate (MHET), and 1.8% bis (2-hydroxyethyl) terephtha- late (BHET). The obtained TPA was separated from the monomers mixtures and its purification was evaluated via different characterization techniques against a standard TPA. A purity of 95%, 82.4 APHA colour value, 645.3 mgKOH/g acid number and acceptable heavy metal content indicated that the purified TPA can be repolymerised as virgin PET.

10:45 AM SB08.06.07
Bioinspired Biomaterial Composite for All-Water-Based High-Performance Adhesives MarcoLo Presti[1], NicholasOstrovsky-Snider[1], GiorgioRizzo[2], DavideBlasi[2], MarinaPortoghese[2], Gianluca MariaFarinola[2] and FiorenzoOmenetto[1]; [1]Tufts University, United States; [2]Università degli Studi di Bari Aldo Moro, Italy

Nature has ingeniously developed adaptable adhesive materials by utilizing versatile chemistry centered around two fundamental components: catechols and polypeptides. This chemistry

enables adhesive processes even in underwater environments using water-soluble biological substances, presenting a technological challenge that current synthetic adhesives are unable to meet. In this study, we present a bioinspired adhesive composite that aims to integrate the adhesive mechanisms observed in mussels and barnacles. The composite formulation comprises silk, polydopamine, and Fe^{3+} ions, all derived from organic and non-toxic sources in a water-based medium. By combining the adhesive properties exhibited by *Mytilus sp.* (mussels) and *Cirripedia sp.* (barnacles), which rely on proteinaceous filaments and proteic cement, respectively, the composite demonstrates remarkable adhesion capabilities in both dry and wet conditions. In lap-shear tests, it outperforms synthetic commercial glues and other adhesives based on natural polymers, rivaling the effectiveness of leading underwater adhesives. It is worth noting that the composite is entirely biologically sourced, eliminating the necessity for synthetic processes. Moreover, the adhesive production method can be extended to utilize proteins beyond silk by fine-tuning the tyrosine:catechol molar ratio to optimize bonding strength. These findings present a cost-effective and sustainable approach that leverages easily accessible raw materials to develop high-performance adhesives suitable for underwater applications.

11:00 AM SB08.06.08
Scalable Synthesis of Biodegradable Polyesters Based on Interfacial Polymerization CecileChazot and SaraE. Johnson; Northwestern University, United States

Biodegradable polyesters have gained increasing attention as environmentally friendly alternatives to polyolefins, due to their attractive mechanical properties and thermal processability through thermoforming and melt processing. State-of-the-art synthetic routes for aliphatic and aliphatic-aromatic polyesters employ reaction conditions that are not conducive to industrial scale production, such as inert gas environments, high reaction temperatures, long reaction times, and applied vacuum. These complex reaction conditions are a result of oxidation and slow reaction rates due to limited functional group reactivity of the monomers. Here we discuss the development of an open-air, room temperature and scalable synthesis of polyesters based on interfacial polymerization (IP). We investigate the suitability of environmentally friendly solvents and solvent blends in inducing simultaneous fast polycondensation and polymer precipitation in IP and characterize how reaction conditions depend on the backbone chemistry of the synthesized polyesters. This IP route has the potential to enable large-scale production of biodegradable polyesters for applications in consumer products such as packaging and textiles.

11:15 AM SB08.06.09
Hybrid Polylactic Acid (PLA) Composites: Impact of Varying the Cellulose Material (CM) Source AmberM. Hubbard, KatherineE. Copenhaver, CaitlynClarkson, MeghanLamm and SoydanOzcan; Oak Ridge National Laboratory, United States

Thermoplastic composites are of significant interest in a variety of industries ranging from automotive to construction as they present a recyclable, low cost, and lightweight alternative material without sacrificing performance. Additionally, hybrid composites which contain more than one type of reinforcement (*e.g.*, natural fibers and cellulose materials (CM)) have gained increasing attention where target properties are enhanced via composite formulations. Herein, three different fibers (*i.e.*, creafill, flax, and wheat straw) are mixed with three different CM and incorporated into polylactic acid (PLA) via melt compounding. PLA was chosen as the matrix material for all hybrid composites due to its industrial compostability and its demonstrated applicability in 3D printing. The mechanical and thermomechanical properties of the resulting thermoplastic, hybrid composites are reported where the composite strength and modulus exhibit marked increases compared to the non-hybrid composites. In addition, by matching the fiber and CM, the material demonstrates further improvements; the mechanism for property enhancement is explored as a function of CM. Finally, these hybrid composites are formulated and targeted for automotive and tooling applications.

11:30 AM *SB08.06.10
Bio-Based Feedstock Development for Large Scale Additive Manufacturing HabibDagher and DouglasGardner; University of Maine Advanced Structures and Composites Center, United States

The commercial availability of bio-based thermoplastic resins and filled composite feedstocks for large scale 3D printing is currently limited because large scale 3D printers have only been available for a few years, and the material supply chain is not well developed for these specific applications. It is anticipated that feedstock materials for 3D printing can be widely varied when considering options for thermoplastic resin types, fillers or biofiber reinforcement type(s), and filler/fiber loading levels. Most of the research efforts on bio-based thermoplastics and composite feedstocks for AM have taken place on smaller bench scale 3D printers. For extrusion-based AM on the small scale, both filament and pellet fed printers have been used in feedstock development, although pellet fed extruders will be the norm for large scale AM. Relevant to large scale 3D printer materials development, there exists a great opportunity to adopt feedstocks long utilized for extrusion-based processing of bio-based (wood and lignocellulosic fiber-filled) thermoplastic composites used in the production of linear profiles as well as compression and injection molding composite parts. It is envisioned that the bio-based filler technology already existing for profile extrusion should be easily transferrable to large scale 3D printing with processing and feedstock development efforts. The addition of biobased fillers in AM feedstocks increases mechanical properties, i.e., strength and stiffness. Important processing parameters to consider with bio-based feedstocks for large scale AM include print time, temperature control, and print layer resolution. Material issues for higher filler loadings in AM feedstocks include viscosity increases and poor interlayer adhesion. Structure property-relationships from extrusion processing in large scale AM need further work to provide improved understanding of material properties for bio-based feedstocks.

Renewable Fiber-Based Prepregs for Composite Laminates VikramYadama, AvishekChanda, MuhammadBakri and LloydSmith; Washington State University, United States

Forming bio-based materials into complex three dimensional shapes can be enhanced using a “prepreg” like material. Adapting bio-based materials into material forms that have successfully been used with synthetic composites allows downstream manufacturing of compression molded panels for a variety of higher value applications. This presentation will discuss the development of a natural fiber prepreg for a variety of applications including automotive interior and exterior panels. Wood strands produced from small diameter trees were stitched to make a preform, which was then injected with a liquid thermoplastic resin, Elium® (produced by Arkema), using a vacuum assisted resin transfer molding (VARTM) technique. The outcome was a thin and flexible thermoplastic wood prepreg with an average thickness of 0.017-in.
Lumens of wood strands were completely filled with the thermoplastic resin resulting in 38% and 124% higher Young’s modulus and strength, respectively, of the saturated wood strands compared to wood strands prior to being infused with resin. A temperature and pressure for the thermoforming process were determined, and these thin and flexible thermoplastic wood-strand prepregs were then laminated by compression molding into panels that are flat or profiled with three-dimensional cross-sections. Compared to wood-strand panels produced using compression resin transfer molding (CRTM) and epoxy resin, Young’s modulus and strength of a flat laminate, made of 12 layers of wood prepreg, were 73% and 20% higher, respectively. Prepreg laminates are resistant to moisture uptake and are dimensionally stable as reflected in the water absorption and thickness swelling results. The ability to recycle these thermoplastic composites reinforced with renewable fibers at the end of their service life fits within the circular economy model. These new opportunities and applications for wood strands from small diameter timber would also contribute to sustainable forest management.

2:00 PM SB08.07.02
Economic and Environmental Viability of Mixed Polyester Chemical Recycling for a Circular and Sustainable Plastic Economy TaylorUekert, JasonDesVeaux and KatrinaKnauer; National Renewable Energy Laboratory, United States

Biodegradable polyesters offer an attractive solution to the plastic pollution problem, as they can biodegrade in composting facilities and specific natural environments. However, these valuable materials should ideally be kept in circulation rather than permitted to degrade. While biodegradable plastics subjected to mechanical recycling often exhibit sub-optimal properties, chemical recycling techniques could potentially retain quality while keeping these materials in a circular economy. Here, we conduct a comprehensive technoeconomic analysis and life cycle assessment of three chemical recycling methods: methanolysis, glycolysis, and acid hydrolysis. Our analysis focuses on mixed polyester feedstocks containing polylactic acid (PLA), polybutylene adipate terephthalate (PBAT), and polyethylene terephthalate (PET). We demonstrate that methanolysis economically and environmentally outperforms the other chemical recycling strategies as well as virgin manufacturing of the assessed polymers. The costs and life cycle impacts of methanolysis also tend to decrease with increasing biodegradable polyester content, indicating the suitability of this technology for emerging plastic materials. We conclude by highlighting the challenges and opportunities facing chemical recycling of mixed polyesters and its role in a more sustainable, circular, and pollution-free plastics system.

2:15 PM SB08.07.03

Biopolymers from a Sustainable Source of Proteins—From Biodegradable Bioplastic Alternatives to Functional Conductive Materials NadavAmdursky; Technion--Israel Institute of Technology, Israel

Protein polymers, which are an indispensable part of a living system for maintaining biological information, are also gaining interest due to their inherent structural organizations enriched with easy availability, degradability, and multifunctional properties for the making of functional polymers. Exploring these characteristics features, protein polymers are considered a sustainable building block to develop tailored materials for on-demand applications, which can be an alternative to petroleum-based synthetic polymers in the modern era. The plant-derived protein polymers are gaining a special interest as they are extracted from waste food products in a less environmentally impact sustainable manner contrary to animal-sourced protein polymers. However, the generation of tailored materials for large-scale applications from plant-derived protein polymers has remained challenging due to their limited solubility in water, tedious multistep processes involving toxic chemicals, and/or using non-environmental solvents whilst processing the protein polymers. To overcome these mentioned issues, we exploit plant-derived protein polymers' internal molecular interactions through a unique one-pot processing method, which is helpful to develop its corresponding transparent free-standing bioplastic. The processed film shows improved barrier properties with degradability, which can be fruitful for degradable bioplastic for packaging applications. In the second part of my talk, I will discuss how protein-based biopolymers can be further utilized as functional materials while focusing on their improved charge-conduction capabilities. Currently, our main targeted application for our new family of conductive protein-based biopolymers is for biological interfaces, and we show their use in biosensing applications, while other lines of applications include the use of our biopolymers for biomedical and energy applications.

2:30 PM SB08.07.04
Surface Functionalized Approaches of Dry Mycelium Membranes for Enhanced Lead Removal MrugankaParasnis, YuFu, ErdaDeng, FeiYao, HaiqingLin and PrathimaNalam; University at Buffalo, The State University of New York, United States

Mycelium hyphae are biomanufactured to grow into 3-dimensional porous networks, which presents a promise for developing sustainable filtration membranes. The hyphal surface is decorated with various biomacromolecules and enzymes that facilitate the remediation of toxic contaminants from the surrounding environments. In this study, we explore various approaches to enhance the filtration efficacy of membranes for lead removal by surface functionalizing dried mycelium hyphae.
Firstly, we aim to present the bioadsorption capacity of untreated, dry mycelium membranes as a function of environmental parameters such as lead concentration, pH, and the duration of Pb[II] exposure to mycelium. A thermodynamic investigation for lead adsorption is conducted to estimate the adsorption capacities and the kinetic rate constants of Pb[II] adsorption onto the mycelium network. Secondly, hyphal surfaces' surface-functionalization using phosphate is explored to remediate lead via pH-dependent biomineralization pathways. Stable lead-based salt crystals formed at the hyphal cell wall (biomineralization), synergistically assisted with the bioadsorption of lead ions, especially at high lead concentrations (1500 ppm), showed 42% enhancement in lead remediation efficiency compared to sole bioadsorption. Moreover, crossflow filtration demonstrated a 90% removal of Pb[II] within 30 minutes of filtration, offering the potential for permeate reuse and metal recovery from the retentate.
Lastly, we achieve the uniform functionalization of the hyphal surface in the mycelium network through electrochemical deposition using low-dimensional layered MXene structures. This innovative approach amplifies the surface-to-volume functional area and permeability of filtrate via mycelium membrane. The preliminary results show an 83% increase in the kinetic rate of Pb[II] removal for the hybrid membrane compared to the unfunctionalized mycelium membrane. Ongoing studies aim to determine the mechanisms underpinning Pb[II] adsorption within the hybrid membrane. Harnessing the intrinsic chemical functionalities of mycelium hyphae presents a promising approach for advancing mycelium-based biomaterials. This research explores novel, sustainable alternatives to synthetic microporous filter membranes exhibiting comparable or higher remediation efficiencies.
Keywords: mycelium membrane, biomineralization, biosorption, MXene

2:45 PM SB08.07.05
Functional Polyurathane Foams with Sustainable Micro- and Nanoscale Reinforcing Agents ZeynepIyigundogdu; Adana Science and Techology University, Turkey

Incorporating additives and structural fillers into polyurethane foams can provide improved mechanical, thermal, electrical properties to create higher performance components made from such foams and can provide improved noise vibration harshness (NVH) and antimicrobial properties. This study explores the effect of adding micro and nanoscale fillers (nanocellulose, biocarbon, graphite, etc.) from sustainable sources as reinforcing agent on thermal stability and mechanical, physical, and sound absorption and antimicrobial properties of flexible polyurethane foam. The incorporation of sustainable micro-and nanoscale reinforcing agents increased the compression modulus and Young's Modulus significantly compared to the control. The addition of reinforcing agents at low concentration (less than 0.25wt.%) showed improvement in sound absorption of plane waves at low frequency range. Minimum inhibitory concentration values were determined by the lowest concentration of the graphite that inhibits the growth of microorganisms. Adding sustainable micro and nanoscale reinforcing agents from the natural sources or recycling products into polyurethane foam reduced waste to landfill and created a superior foam product. This presentation also exemplifies the benefits of creating a closed-loop plastic industry to improve polymer materials and protect the mother earth

Sustainable Manufacturing of Acrylonitrile LieslSchindler; Trillium Renewable Chemicals, United States

Trillium Renewable Chemicals is scaling a two-step thermochemical process that converts a biobased feedstock (glycerol) into valuable chemicals (acrylonitrile and acetonitrile). Acrylonitrile (ACN) is used to manufacture a wide-range of materials (e.g., acrylonitrile-butadiene-styrene (ABS) plastic, carbon fiber, acrylic fiber, nitrile butadiene rubber (NBR), acrylamide, specialty amines) with a wide range of end uses including aerospace, automotive, apparel, toys, energy, personal care products, pharmaceuticals, consumer electronics, and wastewater treatment. The presentation will focus on the progress toward the ultimate goal: de-risking Trillium's bio-ACN™ technology for commercialization while achieving stretch targets for sustainability through a combination of low carbon raw materials and innovative process intensification concepts as well as meeting unit cost economics at parity or below the incumbent process to produce acrylonitrile.

11:00 AM *SB08.08.02
Industry–Academic Partnerships: Valorizing Lignin Through De-Aromatization and COOH Functionalization MitraGanewatta[1], QiWang[1], ThomasSisson[1], MariolaBeresniewicz-Kopcinski[1], DaniellaMartinez[2], JaySalinas[2], MichaelKent[2], JiHyuanHwang[3] and ChuanbingTang[3]; [1]Ingevity Corporation, United States; [2]Sandia National Laboratories, United States; [3]University of South Carolina, United States

Lignin is a valuable biomass feedstock that has the potential to produce advanced chemicals and materials. Lignin comprises 15-30% of lignocellulosic biomass and is mostly burned for its heating value within the paper pulping industry. Generating greater value out of this renewable and abundant material is critical for the establishment of a sustainable bioeconomy. We report an industry-academic partnership established to develop high-performance polymeric products from lignin. A near-room temperature aqueous oxidative process was developed to open the aromatic rings within the lignin structure and resulting in carboxylic acid-functionalized lignins. These lignin polyacid materials were evaluated as commercial agricultural dispersants, micronutrient complexation agents, or water-absorbent materials.

11:30 AM SB08.08.03
Optimization of the Dissolution of Nanopolymer (Bacterial Nanocellulose) into Deep Eutectic Solvents Loaded with Polyphenols Maurelio JrC. Cabo and DennisLaJeunesse; The University of North Carolina at Greensboro, United States

Deep eutectic solvents (DESs) are now generally recognized as a distinct form of ionic liquid (IL) containing massive, nonsymmetric ions with low lattice energy and, hence, low melting temperatures. They are typically generated when a quaternary ammonium salt reacts with a metal salt or hydrogen bond donor (HBD). Hydrophilic ionic solutions, in general, can dissolve cellulose. Although ILs are extremely valuable in the fine chemical industry, their application has been limited because of concerns about toxicity, purity, and high cost. Because of these constraints, DES, a groundbreaking green alternative solvent, was employed. And within these limits, DES, a revolutionary green alternative solvent, was used. These eco-friendly solvents have the potential to be next-generation reagents for more environmentally friendly industrial development and sustainability. Furthermore, the presence of polyphenols and their interactions with bacterial nanocellulose will result in the production of a bioactive complex, which has the potential to provide a wide variety of biological and biocomposites applications. Here, using

Taguchi method, we optimized the potential solubility of nanopolymer sample from bacterial nanocellulose into deep eutectic solvents (choline chloride:imidazole) with the presence of tannic acid as a source of polyphenols.

11:45 AM SB08.08.04
Lignin/PBS Filaments for 3D Fused Deposition Modeling of Medical Orthoses AdnanMemic; King AbdulAziz University, Saudi Arabia

There is a technological need for materials with improved functionalities to propel new biomedical applications. Some of the outstanding challenges could be solved using three dimensional (3D) printing. However, there is a pressing need for new generation of biomaterials that have unique properties. Combining nanomaterials with bio-based and synthetic polymers could yield biomaterials with improved properties. We developed filaments using bio-based waste polymer (lignin) and synthetic polymer (polybutylene succinate (PBS)). Next we coated these scaffolds that could provide antioxidant and antifouling properties while improving the rheological and physical properties of the composites filaments and easy of extrusion and 3D printing. Taken together these nanocoated filaments could propel several biomedical applications including aiding design of medical orthoses and bracing materials.

12:00 PM SB08.08.05
Mussel Byssus as a Green Fiber Manufacturing Platform DavidU. Zamora Cisneros, AlejandroD. Rey, Noemie-ManuelleDorval Courchesne and MatthewJ. Harrington; McGill University, Canada

Biological materials and Nature's manufacturing processes offer inspiration to move towards more green manufacturing of structural and functional materials. Functionality in Natures' materials is strongly correlated with structure, such as chirality, orientation, and layering. In this Ph.D. thesis, I will focus on the mussel byssus, a thread fabricated by marine mussels from a pretransition liquid crystal organization within vesicles, which offers rich store principles and mechanisms to create green tough functional materials and composites used to remain attached to surfaces under continuous flowing states. The material organization of the mussel byssus precursor is a smectic liquid layered semisolid with oriented elements between layers.

This work is divided into three sequential stages: (i) thermodynamic-geometric modeling to ascertain the energy landscape and the stable, unstable, and metastable states of this material under changing thermodynamic driving forces, (ii) colloidal organization including the shape, size, and structural organization to attain for the vesicle-vesicle interactions during the transitional state, and (iii) fiber formation under flow conditions. In this work, I will focus on the progress so far in the area of thermodynamic-geometric model and will shed light on how geometric tools are powerful and useful to detect, control, and optimize equilibrium states of smectic liquid crystals, their organization, and thus, its application for the tunning of material properties.

In particular, we use level set lines of steepest decent, bifurcation methods, lines of curvature and geodesic to provide a multidimensional view of the evolution of stable, unstable states that appear when decreasing the phase transition parameter, here taken as temperature. Overall, it is found that the emergence of smectic order favors the increase of the orientational alignment, yielding in the enhancement of the elasticity modulus of the solid state. Understanding the evolution and behavior of the hierarchical organization will provide a pathway for the development of green engineering principles, storage technologies, biocompatible materials such as tissue scaffolds, and advances in the processing of such materials involving scalable biomedical and technical applications like extrusion molding, and injection molding to address crucial public health and environmental concerns.

12:05 PM SB08.08.06
Feasibility of Hot-Melt Extrusion of Simvastatin-Based Amorphous Solid Dispersions with PVP-VA and HPMC-AS CharinaLampa[1], ScottSmith[2], XiaolingLi[1] and BhaskaraJasti[1]; [1]University of the Pacific, United States; [2]Gilead Sciences, United States

Purpose:
Poor aqueous solubility is among the primary causes of low or variable oral bioavailability in pharmaceutical development, with ~45% of new drugs considered very slightly soluble or practically insoluble. Preparation of amorphous solid dispersions (ASDs) is one approach to address the challenge. An ASD is composed of an amorphous drug stabilized in a polymeric excipient matrix. Amorphous forms have higher free energy and thus, higher aqueous solubility and/or faster dissolution compared to crystalline forms. However, its thermodynamic instability means it has a propensity to degrade or crystallize during processing and storage. Hot-melt extrusion (HME) is an emerging technology for ASDs due to its advantages as a scalable and efficient process. It is also attractive due to its sustainability as it does not require the use of solvents as other manufacturing practices like spray-drying. Key challenges with HME are poor physical stability of the amorphous drug and thermal degradation during processing. Simvastatin (SIM), which belongs to an important class of lipid-lowering drugs, was selected as a model drug. Poly(vinylpyrrolidone) vinyl acetate (PVP-VA), a neutral, aprotic polymer, and hydroxypropyl methylcellulose acetate succinate (HPMC-AS), an anionic, protic polymer were selected as the excipients. The objective of this study is to prepare and characterize HME ASDs with varying SIM/polymer ratios.

Methods:
ASD Preparation. ASDs of SIM/PVP-VA and SIM/HPMC-AS were prepared at varying ratios of 0/100, 25/75, 50/50, 75/25, 100/0 % w/w SIM/polymer using twin-screw hot melt extrusion. Physical blends of SIM and polymer were prepared by a 1-min trituration, followed by a 10-min blending step. Each blend was fed into the hot-melt extruder with a thin-slit die at 150°C. The extrudate was collected and milled to a powder using a tube mill at 15,000 RPM for 1 min.
Physical form characterization. The physical form of SIM in the ASDs was identified using powder X-ray diffraction (PXRD). Samples were scanned in reflection mode over a 2.0000 – 39.9990 °2θ range with a Cu Kα1 radiation source and a detector at 45 kV and 40 mA. Step size was 0.0131 °2θ and scan rate was 0.08 sec/step. Modulated differential scanning calorimetry (mDSC) was used to determine the glass transition temperature Tg, with a nitrogen purge flow of 50 mL/min and a 3°C/min ramp rate and a modulation cycle of ±1°C every 60 sec.
Water content. Thermogravimetric analysis (TGA) was performed on the ASDs, with a nitrogen purge flow of 50 mL/min and a 10°C/min ramp rate from 25°C to 150°C. Weight loss was attributed to water content.
Chemical purity. Chemical purity was evaluated using ultra performance liquid chromatography (UPLC). A gradient method using water with 0.1% trifluoroacetic acid (TFA) and acetonitrile with 0.1% TFA was employed for separation, and the chromatogram at 236 nm was used for analysis.

Results
This study determined the suitability of preparing SIM/polymer ASDs with HME. All extrudates passed through the extruder with a residence time of 5-10 minutes. Subsequent milling of the ribbons yielded free-flowing powders that can be used for further processing. All ASDs demonstrated the amorphous nature of the drug, indicated by an amorphous halo using PXRD. A single glass transition temperature was observed, indicating a homogenous solid solution. The composite Tg of the ASDs decreased as the SIM-loading was increased. Weight loss by TGA was relatively low across all ASDs, indicating moisture content ranging from 0.3% to 3.8%. Thermal degradation was minimal, with purity >97% across all ASDs relative to starting SIM purity, although purity seemed slightly higher with PVP-VA.

Conclusions
ASDs of simvastatin/PVP-VA and simvastatin/HPMC-AS were successfully prepared by hot melt extrusion. Simvastatin was demonstrated to be in an amorphous form with both polymeric excipients, and exhibited good chemical stability during the hot melt extrusion process.

12:10 PM SB08.08.07
Naturally Derived Photoluminescent Composite Inks for Advanced Applications DanielaCorreia[1], BárbaraCruz[1,1,1], RitaPolícia[1], NelsonPereira[1], PauloNunes[2], MarianaFernandes[2], CarmenR. Tubio[3], GabrielaBotelho[1], Veronicade Zea-Bermudez[2,4] and SenentxuLanceros-Mendez[3,5]; [1]University of Minho, Portugal; [2]University of Tras-os-Montes e Alto Douro, Portugal; [3]Basque Center on Materials, Applications and Nanostructures, Spain; [4]University of Trás-os-Montes e Alto Douro, Portugal; [5]Ikerbasque, Basque Foundation for Science, Spain

Naturally derived polymers have been increasingly explored by different fields of knowledge to be applied in different areas. The high interest devoted to natural polymers mainly relies on their natural abundance, unique properties, and sustainability attributes.
The interesting advantages of this type of polymer allow the development of smart and multifunctional materials with a strong potential for sensors and actuators, biomedicine, and environmental remediation applications [1], among others.
Particularly, photoluminescent materials are of high interest for sensors in anti-counterfeiting systems and actuators [2]. This type of material can be obtained by incorporating different luminescent compounds, such as rare-earth elements, quantum dots, fluorescent compounds, and inorganic phosphors.
Lanthanide ions (Ln^{3+}), have gained a special interest in recent times due to their fine emission bands, wide diversity of colours, large pseudo-Stokes shifts, long luminescence lifetimes, and difficult replication of the fingerprint emission profiles [3].
The present work presents the development of photoluminescent materials based on the natural polymer sodium alginate (SA), a linear polysaccharide derivative of alginic acid comprised of 1,4-β-d-mannuronic (M) and α-l-guluronic (G) acids [1], incorporating different contents of the compounds sodium tetra(2-thenoyltrifluoroacetonate) europate (III) ($Na[Eu(tta)_4]$) (5, 10 and 20% wt.) and 1-butyl-3-methylimidazolium tetra(2-thenoyltrifluoroacetonate) europate (III) $[Bmim][Eu(tta)_4]$ (20% wt.) have been developed by a solvent casting method [4].
The influence of both compounds in the morphology of all the developed materials were evaluated by SEM and their physical-chemical properties by FTIR-ATR and DSC analysis.
Independently of the luminescent compound, a non-porous material was obtained, however, a surface roughness increase was observed. Both $Na[Eu(tta)_4]$ and $[Bmim][Eu(tta)_4]$ induce a

thermal stability behavior on SA and an improvement of the mechanical properties.
The highest luminescence was observed for SA/[Bmim][Eu(tta)$_4$] films, exhibiting an intense red/orange emission when irradiated with ultraviolet (UV) light at 388 nm, and in this context a strong potential to be applied in anticounterfeiting applications. The developed materials are also suitable to be applied as electromechanical actuators.

Silk Proteins as Functional Biomaterials for Regenerative Medicine DavidL. Kaplan; Tufts University, United States

Biomaterials that provide versatility in terms of control of structure, chemistry, morphology, mechanics, degradation lifetime, and material form factor, while biocompatibile, are useful in meeting regenerative medicine goals. Silk, as one of the oldest biomaterials utilized as sutures for centuries, is undergoing a rebirth into new biomaterial formats and applications for regenerative engineering for the medical field. Key to this emergence has been fundamental insight into mechanisms of self-assembly and control or tunability of material features achievable with silk. As a unique, high molecular weight, amphiphilic protein, new modes to modify the native protein using processing methods, chemistries and bioengineering approaches are emerging from the laboratory. Some of these recent strategies will be discussed related to fundamental aspects of controlling biomaterial structure and function, leading to new silk-based biomaterials for regenerative medicine.

9:00 AM SB09.01.02
Unconventional Biomaterials for Regenerative Engineering GuldenCamci-Unal; University of Massachusetts Lowell, United States

Across different areas of regenerative engineering, there are limitations with controlling cell adhesion, viability, growth, differentiation, biocompatibility. Conversion of simple and abundant items to advanced cell culture substrates addresses some of the limitations in regenerative engineering. Departure from complex fabrication processes to the applications of unusual materials provides another dimension to the engineering of viable multifunctional tissue constructs and regenerative can increase access to regenerative engineering technologies on a global scale. In this work, we used unconventional biomaterials such as eggshells and paper for tissue regeneration.

We fabricated eggshell micro/nanoparticle (ESP) reinforced protein-based scaffolds to produce mechanically stable and biologically active three-dimensional (3D) scaffolds that can differentiate stem cells into osteoblasts. The ESP-reinforced constructs were then implanted in a rat model to determine their biocompatibility and degradation behaviors. In addition, these composite scaffolds were used to regenerate critical sized cranial defects in a rat model. We also used mineralized paper scaffolds with hydrogels through an origami-inspired approach to test their osteoinductivity and potential for tissue repair in *in vitro* and *in vivo* studies.[1-6]

The ESP-reinforced scaffolds enabled the differentiation of stem cells into osteogenic lineage. The constructs showed significant enhancement in mineralization by the cells. The ESP composites demonstrated superior mechanical properties and showed favorable *in vivo* responses by subcutaneous implantation in a rat model. The scaffolds were responsive to cells and did not elicit inflammatory responses *in vivo*. The implants were easily accepted by the host, allowed for cellular infiltration and migration in 3D, and highly vascularized. Implantation of ESP-reinforced scaffolds into critical sized cranial defects in a rat model resulted in significant bone regeneration in 12 weeks. The resulting bone volume and bone density were as high as the native bone using these composite scaffolds as determined by micro-computed tomography assessment.

We also fabricated origami-inspired paper-based scaffolds for biomineralization. Material properties of the paper-based mineralized scaffolds were highly tunable. The tensile modulus of the scaffolds increased significantly after the mineralization process. Gene expression results for the osteogenic differentiation markers revealed the osteoinductivity of the mineralized paper scaffolds. Subcutaneous implantation of the samples in rats demonstrated biocompatibility, vascularization, and integration *in vivo*.

Unconventional scaffolds that are readily available and adapted from nature demonstrated biomimetic characteristics including porosity, structure, and bioactivity resulting in physiologically relevant constructs. The use of existing naturally derived materials in combination with hydrogels for regenerative engineering provides an inexpensive and sustainable approach that benefits the economy and environment while providing unique solutions to unmet clinical needs. Many of the unconventional biomaterials are overlooked and under-studied for biomedical applications, partly for their simplicity as mundane items.

Development of Tissue-Safe, Shape Memory Polymer Scaffolds CourteneyRoberts, SarahK. Beck, CaitlynM. Prejean and MelissaGrunlan; Texas A&M University, United States

Thermoresponsive shape memory polymers (SMPs) were developed as self-fitting scaffolds to heal cranial bone defects. Exposure to temperatures above the melt transition temperature (T_m) causes scaffolds to undergo shape recovery, driving its expansion to the tissue perimeter for improved osseointegration and healing. SMP scaffolds were originally prepared from semi-crystalline, biodegradable *linear*-poly(ε-caprolactone)-diacrylate (PCL-DA; 10k g mol^{-1}). However, a major limitation of scaffolds based on *linear*-PCL-DA is a T_m of ~55 °C. Such a scaffold could be submerged into saline at this temperature and pressed into a bone defect for self-fitting. However, to extend the working time, post-implantation irrigation with ~55 °C saline would induce thermal damage to the surrounding tissues. Ideally, a SMP self-fitting bone scaffold would have a reduced T_m, but still be > 37 °C in order to ultimately return to its rigid state for mechanical support. Other devices prepared from SMP scaffolds could also be envisioned if the T_m was reduced to 37 °C, affording shape recovery (expansion) upon implantation. For instance, this would enable the development of self-expanding gynecological stents. Thus, in this work, a T_m of ~39 - 45 °C (bone scaffolds) and ~37 °C (stents) was targeted for tissue safety and functionality. We sought to lower the T_m of PCL by altering the architecture, creating *star*-PCL-tetracrylate (*star*-PCL-TA), and by also decreasing molecular weight (M_n). This yielded scaffolds with T_m of ~45 °C (10k g mol^{-1}), ~40 °C (7.5k g mol^{-1}), and ~29 °C (5k g mol^{-1}). Owing to reduced crystallinity, scaffolds based on *star*-PCL-TA degraded faster than *linear*-PCL-DA of the same M_n, and also exhibited decreased compressive moduli. Scaffold degradation rates increased as the M_n of *star*-PCL-TA was decreased. Overall, by altering the architecture of the PCL macromer from a *linear* to a *star* architecture and reducing the M_n, more tissue-safe SMP scaffolds were created. Specifically, scaffolds with T_m values ideal for self-fitting bone scaffolds and self-expanding stents were obtained.

9:30 AM SB09.01.04
Oncological Engineering: The Development of 3D Printed Metamaterial Implants for Patients with Bone Tumours in End-Of-Life-Care AliMohammed, BorutLampret and ConnorMyant; Imperial College London, United Kingdom

Cancer in bone presents a formidable challenge, particularly for terminally ill patients. Addressing this issue, our research focuses on the development of a pipeline for ultra-high-resolution 3D printed metamaterial-based bone replacements. Unlike traditional implants or conventional 3D printed bone scaffolds, our approach aims to improve patients' quality of life during end-of-life care by offering biocompatible, bioinert implants with sophisticated functionality that closely match the mechanical behaviour of native bone. The challenge arises in meeting the custom requirements of patient specific implants such as size, shape and native mechanical properties, along with the fabrication technology required to 3D print them.

The presentation introduces the fabrication process and material for a Metamaterial implant, where the mechanical properties are not derived from the properties of the base material but from its smartly designed architecture. The chosen technology is vat-polymerisation 3D printing which offers the opportunity to produce complex, multiscale, geometries from a suitable biocompatible material at the required specifications. The final implant will be a computationally derived hierarchical lattice with an intricate multiscale structure. It will need to span several orders of length scale (cm > mm > µm) to create the desired properties. However, commercially available 3D printers face limitations with delivering the required high-resolution and small build size print specifications for such designs. These limitations stem from resolution constraints, curing inconsistencies, and challenges in balancing speed and precision. Therefore, a challenge remains in the development of a printer capable of producing biocompatible photopolymer objects with the desired feature resolution at the required build size.
To overcome the limitations faced by commercial 3D printers at the macro scale, we developed an in-house projection micro-stereolithography (Pµ-SL) 3D printer capable of achieving ultra-high resolutions. This achievement is essential for fabricating implants with intricate designs that exhibit metamaterial properties at resolutions of 1-5 µm. Further, we successfully developed a photoresin suitable for 3D printing our desired implants. An integral challenge lies in formulating a biocompatible photoresin that can achieve the desired feature resolution when printing at small build volumes. This was achieved by optimising photoresin chemistry, rheological properties, and light penetration depth. Ultimately, a base formulation suited for ultra-high-resolution 3D printing was produced and iteratively tailored to meet the application requirements. Our study identifies a range of photoreactive monomers and cross-linkers that demonstrate biocompatibility and compatibility with sterilization protocols.
In conclusion, our work focuses on developing an in-house Pµ-SL 3D printer and compatible ultra-high-resolution photoresin to address the micro-to-macro scale challenge in 3D printing. Achieving close to 1µm print resolutions, our printer enables the fabrication of novel implant bone replacements. Leveraging metamaterial design and computational frameworks, we aim to produce biocompatible implants emulating native bone properties, advancing additive manufacturing for patient-specific solutions and improving quality of life for individuals with bone cancer.

Artifical Intelligence (AI) for Improved Biomaterial Design and Healthcare: From *In Vitro* Experimentation to Real Human Clinical UseTomWebster; Hebei University of Technology, United States

Artificial intelligence (AI) has already revolutionized numerous industries, yet, its use in biomaterials and healthcare is almost non-existent. This presentation will provide a summary of how AI can be used to design better biomaterials for various biomedical applications. In particular, AI is being used in biomaterial implantable sensor design to prevent, diagnose, and treat various diseases from cancer to infection. Specifically, AI is being used to predict tissue growth and/or bacteria colonization onto biomaterials based on patient data. Such results can be used to help select a successful biomaterial for that patient. Moreover, AI has been used to predict what types of drug delivery vehicles will be most effective for that particular patient based on prior patient health data and real time response to therapies. Further, AI has been incorporated into digital health where hand held devices can detect patient local temperature, oxygen levels, heart rate, and other critical health parameters comparing such data to patient history to predict whether that patient has cancer, an infection, or is even about to have a heart attack. It is well known that due to variations in immune systems from patient to patient, patients will respond differently to the same biomaterials and drug treatment, thus, personalized or tailored treatments are necessary and can result from AI. Specifically, in this study, cell phones were modified to collect patient data (N = 12) after hip implant surgeries as a means to detect temperature changes at the implant site (on the skin surface as well as internally). Temperature (as just one of many health indicators) was measured surrounding the implant and was able to determine extensive inflammation, infection, and/or proper healing. Then, AI was used to predict if such temperature changes would require surgical intervention to salvage a failed implant. Results showed that AI is an effective means to predict patient outcomes and as such can be used to identify and improve biomaterials for a wide range of medical applications. This abstract presents a positive view on the implementation of AI into medicine showing how it can be used to improve implant surgery and disease treatment.

Polymer Strategies in Musculoskeletal Tissue Engineering ElizabethCosgriff-Hernandez; The University of Texas at Austin, United States

Over one million surgical procedures are performed each year to treat bone defects with an associated medical cost over 5 billion dollars. Current procedures are fraught with problems that limit clinical success from fixation challenges in osteoporotic bone to replicating form factor in craniomaxillofacial reconstruction to infection control in traumatic injuries. Each indication requires a tailored strategy to restore function and guide regeneration. Our laboratory specializes in the development of polymeric biomaterials that meet the design criteria of each regeneration strategy. One particular area of interest is the treatment of fractures using an injectable, bone void filler. Current bone cements do not adequately support bone healing and lead to poor clinical outcomes. Our laboratory has developed a novel emulsion templating methodology to generate injectable, high porosity bone void fillers that cure to rigid foams at body temperature with compressive properties in the range of trabecular bone. We have enhanced the regenerative capacity of these synthetic grafts by mixing the emulsion with autograft particles. Recently, we have utilized this biomaterial platform to develop emulsion inks for 3D printing. Emulsions inks are rapidly cured after deposition by constant UV irradiation to form rigid constructs with interconnected porosity in a method we term Cure-on-Dispense printing. 3D printed constructs benefit from the tunable pore structure of emulsion-templated materials and the fine control over complex geometries of 3D printing that is not possible with traditional manufacturing techniques. A cell-releasing hydrogel was then developed to provide osteogenic potential and enhance the regeneration of these 3D printed scaffolds. Finally, we have utilized advanced electrospinning techniques to create bone wraps that eradicate infection and enhance vascularization. Collectively, this work highlights the versatility of polymer engineering to design tissue engineering scaffolds to meet clinical needs.

11:00 AM SB09.01.07
Injectable Colloidal Hydrogels of N-Vinylformamide Microgels Dispersed in Covalently Interlinked pH-Responsive Methacrylic Acid-Based Microgels BrianSaunders; University of Manchester, United Kingdom

Injectable hydrogels offer great potential to augment damaged or degenerated soft tissue. A key criterion for such gels is that their modulus is as close as possible to that of the target tissue. The majority of synthetic hydrogels have used low molecular weight polymer chains which may cause problems if they diffuse away from the injection site and/or increase the local osmotic pressure. We previously introduced a different approach of injecting preformed ultra-high molecular weight pH-responsive microgels (MGs) that interlink to form hydrogels. MGs are crosslinked polymer colloid particles that swell when the pH approaches the particle pK_a. These colloidal hydrogels are termed doubly crosslinked microgels (DX MGs). The gel moduli of previous DX MGs were much greater than that reported for human nucleus pulposus (NP) tissue of the spinal intervertebral disk. Here, we replace some of the pH-responsive

poly(ethylacrylate-*co*-methacrylic acid) (PEA-MAA) MGs with hydrophilic non-ionic MGs based on poly(*N*-vinylformamide) (NVF). We investigate the morphology and mechanical properties of these new injectable DX MG composite gels and show that the mechanical properties can be tuned by systematically varying the NVF MG content. Using this approach, gel moduli close to that for NP tissue are achieved. These injectable new pH-responsive gels exhibit low cytoxicity. Our work provides a potential new system for minimally-invasive intervertebral disk augmentation[1].

11:15 AM *SB09.01.08
Regenerative Engineering Through Biomaterial Design BrendanA. Harley; University of Illinois-Urbana-Champ, United States

Advances in the field regenerative medicine require biomaterials that instruct, rather than simply permit, a desired cellular response. A major contemporary motivator in biomaterial design is the complex organization of the tissues in our bodies, which are hierarchical, vary in space and time, and can differ person-to person. However, the future success of regenerative medicine requires more deeply considering aspects of human variation and heterogeneity. For example, considering the role of sex-specific differences in tissue engineering technologies motivates innovative lines of investigation that will become central dogma in the future.

Defects in craniofacial bones of the skull occur congenitally, after high-energy impacts, and during the course of treatment for stroke and cancer. They affect a broad segment of the US population, are large and irregularly shaped, and heal poorly. Contemporary tissue engineering efforts that combine exogenous mesenchymal stem cells (MSCs), morphogens, and biomaterials face challenges due to the cost and time for in vitro MSC expansion and MSC-biomaterial culture as well as the need for supraphysiological morphogen doses. We are developing porous biomaterials that can be shaped precisely and quickly like an alloplastic implant but that work in a regenerative fashion like autologous bone. Specifically, I will describe a class of mineralized collagen scaffold that promotes MSC recruitment and osteogenicity in the absence of osteogenic supplements. We have refined these materials to study MSC-macrophage crosstalk and to promote MSC-osteoprogenitors to secrete osteoprotegerin, a soluble glycoprotein and endogenous inhibitor of osteoclast activity. We showed polymeric meshes can be integrated into the scaffold, à la rebar in concrete, to create composites that can be shaped intraoperatively to aid surgical-practicality and accelerate regeneration. I will also describe scaffold processing approaches to create spatially-graded collagen biomaterials that direct MSC differentiation down multiple musculoskeletal lineages in a spatially-selective manner, along with methods to develop continuous hydrogel zones that link dissimilar musculoskeletal tissue zones (e.g., tendon and bone) to provide mechanical and trophic advantages to accelerate regenerative healing. I will conclude by describing recent efforts to address barriers preventing regeneration, notably the role of sex-differences in regenerative activity. These initiatives demonstrate that understanding sex-specific differences in cell activity is essential in the design of biomaterial system to improve regenerative potential as well as to study disease progression and therapy.

11:45 AM SB09.01.09
Injectable and Biodegradable Piezoelectric Hydrogel for Medical Applications ThanhD. Nguyen and TraVinikoor; University of Connecticut, United States

Osteoarthritis (OA), a painful joint disease manifested by cartilage damage, affects 654 million people worldwide every year. Currently, there is no cure for OA; available medicines only alleviate the disease symptoms (e.g. pain and inflammation) while surgical approaches including the use of replacement auto- or allo- graft cartilages suffer from the problems of donor-site morbidity, infection, immune-rejection, and especially, limited tissue supply. Herein, we present a novel injectable and biodegradable piezoelectric hydrogel with ultrasound (US) activation to offer a minimally invasive regenerative engineering approach for OA treatment. The piezoelectric hydrogel can be injected into the joints and self-produce localized electrical cues under US activation to drive cartilage healing. *In vitro* data shows the hydrogel with US activation attracts host cells, enhances cell migration, and induces stem cells to secrete endogenous growth factors like TGF-β1 which facilitates *COL2A1*, *ACAN*, and *SOX9* expression to promote chondrogenesis and extracellular matrix (ECM) deposition. Significantly, the piezoelectric hydrogel enables the healing of hyaline cartilage in rabbits with critical size osteochondral defects. After two months of the piezoelectric hydrogel and US treatment, the animals had more subchondral bone formation, well-organized hyaline cartilage structure, and improved mechanical properties, close to those of healthy native cartilages and superior to the other control/sham groups either without US activation or piezoelectricity. This injectable piezoelectric hydrogel is not only applicable for cartilage healing but potentially other tissue regeneration and could serve as a minimally-invasive material platform for important medical devices such as injectable piezoelectric pressure sensors, actuators, energy-harvesters, and transducers, thus offering a significant impact on medicine.

SESSION SB09.02: Polymeric Biomaterials for Regenerative Engineering II

Hynes, Level 1, Room 104

1:30 PM *SB09.02.01
Cells and Biomaterials as Building Blocks for Tissue Engineering and Regenerative Medicine KentLeach, JeremyLowen and DavidRamos-Rodriguez; University of California-Davis, United States

Biomaterials are an integral component of tissue engineering and regenerative medicine. The selection and biophysical properties oof the materials are instrumental in guiding the behavior of transplanted or invading host cells. I will highlight our recent work in two areas to create building blocks for tissue engineering: 1) manufacturing cellular spheroids with instructive cues to guide cell fate; and 2) production of instructive microgel scaffolds to dictate macrophage phenotype, instruct cell differentiation, and promote tissue formation.

Our group has developed key advances in generating and guiding cell spheroids as building blocks for tissue formation. The bioactivity and function of spheroids is dictated by the selected cell population(s) (both homotypic and heterotypic), culture conditions such as local oxygen tension or inflammatory stimuli, and the association of spheroids with instructive biomaterials. Our group engineered a decellularized extracellular matrix (ECM) secreted by bone marrow-derived mesenchymal stromal cells (MSCs). After characterizing its composition, we demonstrated that MSC spheroids loaded with cell-secreted ECM exhibited markedly increased osteogenic potential and survival in harsh conditions. We have iterated on this ECM to retain endogenous growth factors more effectively. We examined the composition and bioactivity of ECM produced by MSCs differentiated from induced pluripotent stem cells as an alternative cell population that addresses shortcomings of MSCs. Finally, we identified key biophysical properties of hydrogels that regulate cell migration, proangiogenic potential, and tissue formation by MSC spheroids.

Tunable scaffolds that direct cell fate are desirable in many tissue engineering applications such as wound healing, organoid systems, and drug delivery. As our understanding of tissue complexity increases, so does the demand for heterogeneous biomaterials. Microgels are an emerging tool that fulfill this role given their modularity, injectability, and range of fabrication techniques. Unlike bulk hydrogels, microparticle-based scaffolds possess tunable void space which inherently exists between the particles. Such void space permits cells to migrate and proliferate readily without first remodeling their surrounding environment. While the effects of pore size on cell penetration and proliferation have been studied in bulk hydrogels, it has yet to be thoroughly investigated in a microgel platform.

We employed the ability to readily alter porosity in photoanneable microgel scaffolds to influence macrophage polarization, alter cell spreading and aggregation, and influence cell function. We generated microgels with compressive moduli ranging from ~ 10-80 kPa, which demonstrates their ability to match a range of tissue stiffnesses. The compressive modulus and bioactivity of the microgels remained constant after cryopreservation at -20°C, which facilitates high-throughput production, storage, off-the-shelf availability, and expands their potential for clinical translation. Void volume was a key stimulus to instruct macrophage polarization toward a pre-regenerative M2 phenotype.

In another example, we created bilayer constructs of microgels with distinct compressive moduli and pro-osteogenic and chondrogenic peptides. Using light to anneal the gels, we produced constructs that did not delaminate, as is common for many bilayer materials. When cultured in mixed media, we observed upregulation of osteogenic and chondrogenic markers that were primarily restricted to the designated layer. The ease of loading cells, cryopreservability, and short annealing time make this a promising platform for translation to the clinic.

2:00 PM SB09.02.02
A Resurfacing-Regenerative Approach to Repair Osteochondral Defects using a Bioprosthetic Device MelissaGrunlan, ConnorJ. Demott, LaurenK. Davis, WilliamB. Saunders and OliviaF. Dingus; Texas A&M University, United States

Osteochondral defects (OCDs), areas of localized joint damage to articular cartilage and underlying subchondral bone, often lead to pain, loss of joint function, and osteoarthritis. Clinical repair is focused on biological grafting procedures, which are innately limited by graft availability and donor site morbidity. We have developed a bioprosthetic implant, combining articular

cartilage resurfacing and osseous tissue regeneration, as a new method for OCD repair. These implants – “cartilage-capped, regenerative osteochondral plugs (CC-ROPs)” - combine a multi-network hydrogel (cartilage cap) and osseous scaffold (base). The cartilage cap is prepared from a multi-network, electrostatic hydrogel that gives rise to articular cartilage-like mechanical, hydration, and tribological properties. The osseous scaffold base is prepared from a semi-interpenetrating polymer network (semi-IPN) of poly(ε-caprolactone)-diacrylate (PCL-DA) and poly(L-lactic acid) (PLLA). The scaffold is intrinsically osteoinductive and has a trabecular bone-like modulus as well as robust degradation rates to facilitate bone ingrowth. Formed as cylindrical plugs, CC-ROPs are able to be implanted using existing grafting techniques and be fabricated at a wide range of sizes. CC-ROPs were successfully implanted into rabbit OCDs using an osteochondral graft delivery device with a custom tip to help alignment on the small rabbit condyles. At 10 days, MRI images illustrated the cartilage cap remained intact with the osseous scaffold (i.e., no delamination). It was also confirmed that CC-ROPs did not become displaced post implantation. Formation of new tissue around the periphery of the osseous scaffold was illustrated in microCT and histological analyses. At 12 weeks post-implantation, there were likewise no signs of delamination or fracture of the CC-ROP. Furthermore, no migration of the implant was seen (e.g., cartilage cap surface congruent with surrounding cartilage). Extensive bone tissue formation was seen around the edges and throughout the pores of the osseous scaffold. Performance in rabbit OCDs illustrated the ability of CC-ROPs to immediately provide an articulating surface as well as promote regeneration of osseous tissue, exemplifying the potential to improve the treatment of OCDs.

2:15 PM SB09.02.03
A Dynamic Hydrogel Platform to Model Cardiac Tissue Development and Disease AndrewHouse and MuratGuvendiren; New Jersey Institute of Technology, United States

Heart disease is currently the leading cause of death in the United States, and is most often caused by myocardial infarction (MI). There is a desire to create novel therapies and treatments. However, due to a lack of fundamental understanding of the heart’s inflammatory response to infarction, the development of new therapies is both time consuming and costly. In this work, we report a novel biomaterial platform to mimic dynamic changes in the heart tissue during MI. We believe that our platform enables dynamic control of cardiac cell alignment and matrix stiffness (from healthy to fibrotic tissue) to investigate cardiac tissue development and disease.

In this study, we report a novel dynamic hydrogel platform enabling spatiotemporal control of cellular alignment and matrix stiffness (from healthy to fibrotic tissue stiffness). Our approach involves: (i) fabrication of polydimethylsiloxane (PDMS) based elastomeric film displaying lamellar wrinkling patterns with user defined and spatiotemporally controlled pattern amplitude and wavelength, and (ii) chemically grafting a hydrogel film allowing light-induced stiffening from healthy to fibrotic stiffness, matching values reported in the literature. In our approach, methacrylated alginate (MeAlg) hydrogel films are first fabricated using Michael-type addition crosslinking using dithiothreitol (DTT) to form hydrogels with healthy stiffness (~15 kPa), during which it is also chemically tethered to the PDMS substrate. When needed, hydrogels can be stiffened in situ when exposed to UV or blue light in the presence of a photo initiator to reach to fibrotic stiffness (~55 kPa). Using this platform, we first investigate the effect of pattern size (amplitude and wavelength) on cardiac cell alignment. We then report the effect of matrix stiffness on cardiac cell function. Human cardiac fibroblasts (hCFs, Normal Human Ventricular Cardiac Fibroblasts, NHCF-V, CC-2904, Lonza, United States), human cardiomyocytes (hCMs, AC16 Human Cardiomyocyte Cell, and human induced pluripotent stem cell-derived cardiomyocytes (iPSC-CMs) (iCell Cardiomyocytes 01434, FUJIFILM Cellular Dynamics, Inc.) were used in this study.

In the first part, we show that the degree of cellular alignment for hCMs and hCFs is controlled by the pattern dimensions, such that higher degree of alignment is obtained for higher pattern amplitudes or smaller wavelengths. Spatial control of lamellar patterns allows us to create distinct regions with tunable patterns or continuous patterns with gradient dimensions. In the second part, we show that hydrogels are capable of being stiffened dynamically during the culture (confirmed by AFM and rheology), and gel integrity can be maintained for up to 21 days of culture. In addition, iPSC-CMs cultured for up to 21 days show distinct changes in their sarcomere expression and beating frequency in response to changes in stiffness and alignment. We plan to conclude with our approach to use this platform to mimic the dynamic changes in the ECM post-MI to develop a drug screening platform.

Engineered Biomaterials for *In Situ* Tissue RegenerationAkhileshK. Gaharwar; Texas A&M University, United States

Engineered biomaterials have emerged as powerful tools for a range of biomedical applications, including tissue engineering, drug delivery, and additive manufacturing (3D bioprinting). These biomaterials possess tunable biophysical properties, specific biochemical cues, and complex architecture, enabling precise control over cellular behavior. In this talk, I will outline three biomaterials-based approaches developed in our lab for biomedical applications. Firstly, I will highlight how engineered biomaterials can harness the body's regenerative potential to control and direct cell functions for in situ tissue regeneration. Our work has resulted in a new class of biomaterials for bone regeneration, osteoarthritis treatment, angiogenesis, hemostasis, and wound healing. The second approach focuses on designing nanoengineered biomaterials for sustained and controlled release of therapeutics. We have developed a range of nano-tool kits for the delivery of small molecules drugs and large proteins, which have high loading efficacy and tunable delivery properties. These approaches can be used for targeted delivery of cancer therapeutics. Lastly, I will demonstrate the design of a new class of bioinks for 3D printing anatomical-size tissue constructs. These tissue structures can be used to develop physiologically relevant tissue models, mimicking disease conditions such as vascular pathophysiology and vascularized glioblastoma models.

Peptides with Polyproline II Helix Secondary Structure and Their Potential Role in Biomaterials Engineering JulieRenner; Case Western Reserve University, United States

Bound peptide monolayers are a promising way to control surface properties because peptides are biocompatible, easily tunable, and can be designed to have, or not have, interactions with cells. Our lab is especially interested in establishing new engineering models and assembly techniques to control and understand the behavior of surface-bound peptides for use as biomaterials. Peptides with a polyproline II helix secondary structure (PPII helix peptides) have recently emerged as promising tools for biomaterials due to their unique antifouling properties and ability to form dense monolayers. Using a variety of characterization techniques, we uncover new details about the assembly mechanisms of PPII helix peptides and explore their antifouling capacity. In addition, we explore the interactions of these peptdies with human mesenchymal stem cells and 3T3 cells with and without bioactive peptides attached. Collectively, these results reveal greater understanding of the mechanisms behind PPII helix peptide assembly and antifouling and provide insight into their potential use as biomaterials for regenerative engineering.

4:00 PM *SB09.02.06
Designing Biocompatible Hydrogel Nanoparticle Emulsions for Regenerative Engineering GeorgiaPapavasiliou, ShadiMotamed, FernandoBorges and FouadTeymour; Illinois Institute of Technology, United States

Polymeric nanoparticle (NP) emulsions have shown significant promise for regenerative engineering applications as they can be designed as topical and/or injectable formulations for *in vivo* administration of therapeutic compounds. Hydrophilic therapeutic delivery often requires water-in-oil-in-water (w/o/w) double emulsions which are difficult to produce and have limited storage life because of their inherent instability. Inverse, water-in-oil (w/o) emulsions for encapsulation of hydrophilic therapeutics are far less common as they involve use of organic solvents. Highly biocompatible and biodegradable crosslinked hydrogel NP are perfectly suited for controlled and sustained diffusive-based release of therapeutics, enhanced tissue-targeted delivery and bioavailability of hydrophilic drugs. Hydrogel NP, however, come in contact with cytotoxic organic solvents and surfactants during emulsion polymerization requiring subsequent purification and isolation before being administered directly *in vivo*. This leads to limitations, including significant drug loss, dosage uncertainty, compromised drug release kinetics, and loss of particle stability, thereby minimizing *in vivo* therapeutic efficacy. To address these limitations, we have developed novel biocompatible NP emulsions (BCNE) consisting of stable poly(ethylene) glycol (PEG) crosslinked hydrogel NP dispersed in a naturally-derived consumable organic phase that can be formulated as a liquid (or as an ointment) and administered *en masse*, directly to target tissues. BCNE are synthesized with biocompatible components including PEG diacrylate (PEGDA) crosslinking macromer, N-vinyl pyrrolidone or ethylene glycol comonomers, polyphosphate (PPi) or NaCl as the lipophobe, soybean oil (SO), as the organic phase, with PolyGlycerol PolyRicinoleate (PGPR) emulsifier (FDA recognized as safe for human consumption) and with V50 initiator using inverse phase miniemulsion polymerization. We synthesized BCNE with varying mesh dimensions to accommodate the encapsulation and sustained release of hydrophilic therapeutics of varying size and conformation including PPi (PPi-BCNE), NaCl (NaCl-BCNE) and the α-helical pro-angiogenic peptide QK (QK-BCNE). BCNE NP size measurements (Nanosight LM10, Malvern) yielded mean NP diameters of 111±7.2nm and 96±3.9nm for PPi-BCNE and NaCl-BCNE, respectively. To define mesh dimensions suitable for encapsulation and release of PPi and QK, experimental measurements of hydrogel mass swelling ratio were coupled with theoretical kinetic and thermodynamic interpretations we recently developed to characterize the network architecture of hydrogel networks comprised of macromeric crosslinkers. Our approach accounts for crosslinker size, and its behavior under swelling, both neglected by the Flory-Rehner theory. This allows for quantification of two new hydrogel mesh dimension variables that establish bounds on the maximum size and aspect ratio of therapeutics that can be encapsulated and released from crosslinked hydrogel NP networks. Using this approach to guide our experimental design, QK-BCNE were designed to release QK for 46 days whereby 90% of the encapsulated peptide was retained for 36 days *in vitro*. *In vitro* findings indicate that PPi-BCNE completely disperse PAO1 *P. aeruginosa* biofilms compared to blank BCNE and no treatment controls. Preliminary experiments conducted with e*n masse* topical application of BCNE in a *Staphylococcus aureus* C57BL/6 mouse model of burn injury and impaired healing demonstrated incontrovertible evidence that PPi-BCNE improves wound healing compared to blank BCNE treatment. These results highly suggest that BCNE provide a versatile platform whereby hydrogel nanoparticle mesh dimensions can be precisely tuned for enacpsulation of hydrophilic therapeutics of varying size and complex conformation (peptides, growth factors and iRNA) to enable sustained tissue-targeted delivery *in vivo* for regenerative medicine applications.

Stiffness Assisted Cell-Matrix Remodeling to Induce Stem Cell Differentiation AkhileshK. Gaharwar; Texas A&M University, United States

Engineered matrices provide a valuable platform to understand the impact of biophysical factors on cellular behavior such as migration, proliferation, differentiation, and tissue remodeling, through mechanotransduction. While recent studies have identified some mechanisms of 3D mechanotransduction, there is still a critical knowledge gap in comprehending the interplay between 3D confinement, ECM properties, and cell behavior. Specifically, the role of matrix stiffness in directing cellular fate in 3D microenvironment, independent of viscoelasticity, microstructure, and ligand density remains poorly understood. To address this gap, we designed a nanoparticle crosslinker to reinforce collagen-based hydrogels without altering their chemical composition, microstructure, viscoelasticity, and density of cell-adhesion ligand and utilized it to understand cellular response. This crosslinking mechanism utilizes nanoparticles as crosslink epicenter, resulting in 10-fold increase in mechanical stiffness, without other changes. Human mesenchymal stem cells (hMSCs) encapsulated in 3D responded to mechanical stiffness by displaying circular morphology on soft hydrogels (5kPa) and elongated morphology on stiff hydrogels (30kPa). Stiff hydrogels facilitated the production and remodeling of nascent extracellular matrix (ECM) and activated mechanotransduction cascade. These changes were driven through intracellular PI3AKT signaling, regulation of epigenetic modifiers and activation of YAP/TAZ signaling. Overall, our study introduces a unique biomaterials platform to understand cell–ECM mechanotransduction in 3D.

4:45 PM SB09.02.08
Development of an iPSC Loaded Biomimetic Biomaterial Scaffold for Spinal Cord Repair Applications CianO'Connor[1,2,1], IanWoods[1,2,1], SarahF. McComish[2], MaeveA. Caldwell[2], AdrianG. Dervan[1,2,1] and FergalJ. O'Brien[1,2,1]; [1]Royal College of Surgeons in Ireland, Ireland; [2]Trinity College Dublin, The University of Dublin, Ireland

Introduction: Following spinal cord injury, a lesion cavity develops preventing axonal regrowth. Biomaterial implants that bridge the cavity and encourage axonal growth while delivering trophic cells to restore lost tissue may have potential for repair. Therefore, by identifying neurotrophic extracellular-matrix proteins to incorporate into biomimetic hyaluronic acid biomaterial scaffolds and by tuning the biomaterial stiffness, we aimed to develop a novel platform for spinal cord repair. Furthermore, we wished to determine if the developed biomimetic biomaterial scaffolds were capable of delivering and modulating the trophic capacity of induced pluripotent stem cell (iPSC)-derived progenitors for spinal cord repair applications.

Methods: Spinal cord astrocytes and neurons were cultured on a range of extracellular matrix-proteins to identify the optimal neurotrophic substrate combination. Following the incorporation of the neurotrophic substrate into freeze-dried 3D hyaluronic acid scaffolds of varying stiffnesses, scaffold properties were characterized. Next, spinal cord astrocytes, neurons, dorsal root ganglia (DRG) and iPSC-derived astrocyte progenitors were cultured in the scaffolds for up to 21 days and the effect of scaffold physicochemical properties was assessed. Thereafter, the impact of scaffold properties on the trophic capacity of iPSC-derived progenitors was assessed *in vitro* and *ex vivo* using neurons, DRG and spinal cord explants.

Results: A combination of collagen-IV (CIV) and fibronectin (FN) synergistically enhanced neurite outgrowth by 203% while also promoting astrocyte process extension. Subsequently, hyaluronic acid biomaterial scaffolds functionalized with CIV/FN were successfully manufactured with different stiffnesses ranging from soft/biomimetic to stiff/supraphysiological (0.8-3.5 kPa). Spinal cord astrocytes cultured in soft-CIV/FN functionalized biomaterial scaffolds matching cord stiffness, displayed positive stellate morphologies and increased pro-regenerative IL-10 release. Furthermore, soft scaffolds significantly enhanced neurite outgrowth from neurons and adult mouse DRG explant cultures compared to stiffer scaffolds. Soft-CIV/FN scaffolds also enhanced iPSC-progenitor neurotrophic and functional capacity while encouraging the growth of iPSC-derived spheroids that subsequently formed extensive neuronal/astrocytic cellular tracts, colonizing the biomaterial scaffold. Conditioned media from soft-CIV/FN but not other, iPSC-loaded scaffolds, and applied to growing neurons enhanced neurite outgrowth by over 280%. Super-resolution microscopy also confirmed similar neurite enhancement (170%) in mouse primary spinal cord neurons treated with media from soft-CIV/FN scaffolds only without eliciting negative inflammatory and/or reactive responses from healthy and injured astrocytes. Furthermore, analysis of media from stiffer or non-CIV/FN-containing scaffolds showed increased pro-inflammatory IL-1β release compared to soft CIV/FN scaffolds. Finally, when *ex vivo* DRGs or spinal cord explants were cultured directly on CIV/FN iPSC-loaded biomaterial scaffolds up to 21 days, only soft biomaterials enhanced cellular infiltration, astrocytic process extension and directed axonal outgrowth between DRG and iPSC-spheroids.

Conclusion: Overall, this research describes the development and utilization of a novel, biomimetic biomaterial scaffold-based platform for spinal cord repair and demonstrates that biomimetically inspired biomaterials can enhance the growth of cord resident neurons and astrocytes and promote the neurotrophic potential of implanted progenitor cells to act as a novel, therapeutic platform for spinal cord injury repair applications.

5:00 PM SB09.02.09
Protein-Derived Jammed Microgels as Inks for Extrusion 3D Printing of Bioactive Scaffolds LucasRibeiro[1,2], RitaSobreiro-Almeida[2], VítorGaspar[2], EmersonCamargo[1] and JoãoMano[2]; [1]Federal University of São Carlos, Brazil; [2]University of Aveiro, Portugal

Extrusion 3D printing has emerged as a promising technique in tissue engineering, enabling the creation of personalized scaffolds for individual patients. Typically, natural hydrogels are utilized as inks due to their resemblance to the extracellular matrix (ECM), as well as their biodegradability and biocompatibility, making them ideal for tissue engineering applications. One such biomaterial is human platelet lysates (PL) derived from whole blood, which contains a rich assortment of growth factors, cytokines, and proteins that can stimulate cell proliferation and differentiation, and tissue regeneration. However, the use of PL as ink for printing scaffolds is limited by its liquid nature even at high concentrations, preventing the formation of a solid and stable filament upon deposition.
To address this challenge, granular hydrogels of methacrylated PL (PLMA) were developed through chemical coupling. These granular hydrogels consist of jammed microgels that exhibit viscoelastic solid properties at low levels of strain while flowing under high levels of strain. This unique characteristic enables filament formation and facilitates their application as injectable biomaterials. Additionally, a granular ink of methacrylated bovine serum albumin (BSAMA) was prepared for comparison, leveraging the high albumin content of PL. The microgels were generated by extruding bulk hydrogels through a series of nozzles with progressively higher gauges (18G, 21G, and 23G), followed by centrifugation to remove excess liquid phase and obtain granular hydrogels. Both materials displayed irregular microgels and a wide size distribution. Moreover, the process resulted in albumin microgels with a larger average size, leading to increased porosity compared to the PLMA hydrogel.
Rheological analysis revealed that both inks exhibited shear-thinning, yield-strain, and self-healing properties—essential characteristics for materials used in 3D printing. Additionally, a time sweep test utilizing UV light demonstrated a rapid increase in the storage modulus of the hydrogels due to photo-crosslinking, indicating rapid stabilization of the printed scaffolds. The study of filament formation using different nozzles allowed an evaluation of the printing fidelity of BSAMA and PLMA inks. In all cases, the filament diameter closely matched the internal diameter of the needles, and thus the smallest nozzle tested (22G) was selected for printing the scaffolds. Due to its larger microgels, the printing of the BSAMA presented some clogging, requiring higher pressure for constant extrusion compared to the PLMA ink. Nevertheless, stable scaffolds with varying geometries and layer numbers were successfully printed, confirming the efficacy of this strategy in producing protein inks with the necessary printing properties.
Finally, the bioactivity of the granular hydrogels was assessed by seeding human adipose-derived stem cells (hASCs) for a period of 7 days. Metabolic activity increased at each time point, being consistently higher in PLMA hydrogels. This can be attributed to cell proliferation in the spaces between the microgels, with cells adhering around them from the first day, as indicated by the Live/Dead assay. Furthermore, only a small number of dead cells were detected, indicating the non-cytotoxic nature and biocompatibility of the inks. The DAPI/Phalloidin assay confirmed a higher cell count in the PLMA scaffolds from day 1, highlighting the superior bioactivity of this material. In summary, bioactive granular hydrogels of protein sources with microporosity were successfully created, demonstrating their potential for 3D printing stable scaffolds with excellent resolution for use in tissue engineering applications.

Enhanced Therapeutic and Immunomodulatory Effect of Stem Cell Spheroid with Transition Metal-Based Nanoparticles in Rat Myocardial Infarction Model Yeong HwanKim and Suk HoBhang; Sungkyunkwan University, Korea (the Republic of)

Myocardial infarction (MI) which accompanies decrease in myocardium function and destruction of millions of cardiomyocytes is a leading cause of mortality worldwide. In this study, we demonstrated advanced stem cell therapy to treat cardiovascular disease with enhanced therapeutic efficacy of stem cell spheroids by upregulating angiogenesis-related paracrine factors secretion and inducing immunomodulatory ability with transition metal based nanoparticles (TMNs). Stem cell spheroids treated with TMNs (spheroids-TMNs) had widen hypoxia inducible factor (HIF) expression area in core with mild reactive oxygen species (ROS) generation. According to increased HIF expression of spheroids-TMNs, the secretion of angiogenesis-related paracrine factors was enhanced compared to untreated spheroids. Immunomodulatory effect of spheroids-TMNs was verified with Raw cell; suppression of pro-inflammatory responses and promotion of anti-inflammatory responses. Enhanced therapeutic effect and immunomodulatory effect of spheroids-TMNs were verified in vivo rat MI model. An advanced stem cell therapy we provided can be a promising therapeutic strategy for cardiovascular disease treatment.

SESSION SB09.03: Poster Session I: Biomaterials for Regenerative Engineering I
Session Chairs: Guillermo Ameer, Gulden Camci-Unal, Melissa Grunlan and Carolyn Schutt Ibsen

8:00 PM SB09.03.01
Injectable Hydrogel Formulations with Controlled-Release of Curcumin and Vitamin E for Dental Tissue Engineering DenizAtila[1], Ali DenizDalgic[2], AgnieszkaKrzeminska[1], JoannaPietrasik[1], EdytaGendaszewska-Darmach[1], FouadLaoutid[3], PiotrPaneth[1] and VigneshKumaravel[1]; [1]Lodz University of Technology, Poland; [2]Istanbul Bilgi University, Turkey; [3]University of Mons, Belgium

Dental infections affect millions of people globally with a burden of $298 billion annually associated with direct costs to treat oral diseases. Injectable hydrogels incorporated with antimicrobial and antioxidant agents can be used to treat dental pulp infections. Herein, injectable hydrogels of chitosan (CH) and liposomes loaded with curcumin and α-tocopherol have been developed to provide antimicrobial and antioxidant action for dental pulp regeneration. Hydrogels are prepared with high (HCH), and low (LCH) molecular weight chitosan to investigate the impact of molecular weight on injectability, biodegradability, controlled release, and antimicrobial activity. The diameters of liposomes are mostly uniform, in the range of 152 - 162 nm, making them suitable for controlled release and injectability. Zeta potential values of hydrogels are negative, which could lead to a homogenous distribution of liposomes in the positively charged hydrogels. Approximately 80 % of curcumin and α-tocopherol are released from liposomes within 21 days in a controlled manner. Therefore, the antimicrobial and antioxidant activity of the hydrogels could be sustained during the healing process. TGA results showed that the thermal stability of the hydrogels decreased with respect to the solution volume and the sonication time while preparing the hydrogels (*i.e.*, the mass loss values of LCH and HCH at 500 ºC increased from 79 to 96 % and 90 to 95 %, respectively). DSC findings are consistent with the TGA results for LCH groups, where a shift in Tc from a higher (347 ºC) to a lower (326 ºC) temperature is observed in response to the increase in volume and sonication time. Nevertheless, the Tc values of HCH are not influenced (366 ºC). Rheological analysis revealed that the viscosity of hydrogels decreases as the shear rate increases, signifying the shear-thinning behaviour and injectability of the hydrogels. *In vitro* biocompatibility and antimicrobial features are investigated using dental pulp stem cells and gram-negative as well as gram-positive bacteria. Finally, the antimicrobial mechanism of LCH and HCH on *Escherichia coli* and *Staphylococcus aureus* is evaluated theoretically by density functional theory.

8:00 PM SB09.03.02
Novel Bioink for 3D Bioprinting of Complex Structures with Tunable Stiffness MrinalGanash; University of New Hampshire, United States

The field of tissue engineering is rapidly adopting the principles of additive manufacturing (i.e. 3D bioprinting), which provides a means to generate complex functional tissue constructs in a programmable manner within micron-scale precision. However, the low mechanical stiffness and strength of 3D printed hydrogels significantly limits the application of 3D bioprinting in tissue engineering. Here, we propose the use of a novel bioink consisting of Gelatin, Methacrylated methacrylated gelatin (GelMA) and a\Alginate. Once printed, this bioink is crosslinked by (i) photopolymerization of GelMA by UV radiation, (ii) enzymatic crosslinking of gelatin by microbial transglutaminase (mTG) and (iii) ionic crosslinking of alginate by calcium ions, to form an interconnected polymer network (IPN), which exhibits much improved mechanical properties. Enhanced mechanical properties of the IPN hydrogels are demonstrated by rheology and mechanical testing. Biocompatibility of the bioink and the subsequent crosslinking process was demonstrated by cytotoxicity and proliferation assays. Cell morphologies in the 3D structures were monitored by live/dead assay in conjunction with confocal microscopy. Cell viability was measured by calculating the live cell count/total cell count.

8:00 PM SB09.03.03
Microfluidics-Assisted Fabrication of Human Natural Killer Cell Encaplsulated Increases the Therapeutic Efficacy for Cancer Immunotherapy DongjinLee[1], SeokminKim[2], DahongKim[3], SuaPark[1] and Tae-DonKim[2]; [1]Korea Institute of Machinery & Materials, Korea (the Republic of); [2]Korea Research Institute of Bioscience and Biotechnology (KRIBB), Korea (the Republic of); [3]Seoul National University, Korea (the Republic of)

Tumors are a global human health issue, and various anti-cancer therapies such as surgical-, chemo-, radiation-, and immunotherapy have been used to treat it. Among these therapies, the therapeutic strategy using immune cells capable of recognizing and killing tumor cells is of interest as a next-generation anti-cancer therapy. In recent years, many studies on the chimeric antigen receptor (CAR) have focused on T cells. However, it takes a long time to modify donated T cells to proliferate them, and it is too expensive to use. CAR-T therapy is generally limited to blood tumors. Additionally, further clinical trials may be limited because cytokine release syndrome (CRS) or other side effects may occur from the off-target.

Unlike T cells, NK cells can distinguish tumor sites in an antigen-independent manner, and have no memory function or clonal expansion, resulting in fewer side effects like CRS. Since allogeneic cell transfer therapy is possible it offers the advantage of being available as an off-the-shelf product. Through preclinical and clinical studies, the safety and efficacy of allotransplantable NK cells for assorted types of hematological and solid cancers have been indicated, and various clinical trials are currently in progress. However, the disadvantages of NK cells include a low proliferation rate and the inability to be cultured for a long period of time. In addition, maintaining the cytotoxic activity of NK cells is important in cell therapy, but it is difficult to maintain it in general two-dimensional cultures and cell proliferation is not easy in in-vivo systems. Microgels were fabricated to contain immune cells in an emulsion method, and solid cancer disease models were demonstrated through in-vitro experiments. However, the NK cell-laden microgel researches for anticancer immunotherapy has not yet been studies. Furthermore, an in-vivo experiment was performed in which cancer cells were killed through intravenous injection of a NK cell-laden microgels which would be degraded.

Double flow-focusing microfluidics was used to create cell-containing photo-crosslinkable methacrylic gelatin (MGel) monodisperse droplets, while cell-containing microgels with high viability were produced through cross-linking. Microgels have the advantage of being able to easily control the modulus of elasticity by controlling the concentration of biopolymers. It can be applied efficiently to produce monodisperse droplets containing a large number of biomolecules and enable high-throughput examination and injectability. The generated droplets can be transformed into microgels through crosslinking and applied in multiple ways depending on the characteristics of the material. However, no study has reported the use of a uniform microgel containing NK92 cells using a microfluidic chip yet.

MGel is one of the materials because it is highly biocompatible and its physical properties can be controlled by regulating its concentration. GelMa is composed of arginine, glycine, and aspartic acid, which are present in large amounts in the molecule, and is designed to be decomposed by the matrix metalloproteinase. There is also growing interest in three-dimensional (3D) cell culture models to enable more multiple and physiologically appropriate biological assays compared to traditional two-dimensional (2D) monolayer cell cultures.

In this study, we encapsulated NK92 cells in the microgels (3D) using a microfluidic chip, and their activity was compared with that of the 2D cultured NK92 cells. We observed that NK92 cell-laden microgels (3D) increased cell proliferation, mRNA expression levels, cytokine release, and anti-tumor efficacy, compared to the 2D cultures. We have shown that microgels have no diffusion limit because of their size (approximately 100 μm). These results suggest that microgels containing NK92 cells can be used to provide a new platform for anticancer immunotherapy.

8:00 PM SB09.03.04
Development of a Sprayable Multifunctional Hydrogel Wound Dressing MineAltunbek[1], MertGezek[1,1] and GuldenCamci-Unal[1,2]; [1]University of Massachusetts Lowell, United States; [2]University of Massachusetts Medical School, United States

Hydrogel-based wound dressings are widely used for the treatment of wounds due to their advantages. Their high-water content allows for maintaining tissue homeostasis in the wound area. In addition, they provide a favorable three-dimensional (3D) matrix during migration and proliferation of fibroblasts, and re-epithelialization, neovascularization, and wound remodeling processes. The convenient and rapid application to irregular surfaces and deep wounds renders hydrogels dressings useful in wound healing. The chemistry of hydrogel-based wound dressings can be modified to improve their functionality for the treatment of specific types of wounds. In this work, we developed sprayable hydrogel-based wound dressings that are self-oxygenating and have anti-microbial and anti-inflammatory functions. We used naturally-derived biomaterials: gelatin (hydrolyzed collagen) and hyaluronic acid for the development of the sprayable hydrogels. The starting materials were modified with methacrylate groups (GelMA and HAMA) to obtain photocrosslinkable gel precursors. The bioactive GelMA component was evaluated at 5-15% w/v while HAMA was used as the anti-inflammatory component at 1% w/v. Solid calcium peroxide microparticles were incorporated into the hydrogel precursor solution at 0-12 mg/mL concentrations to protect the dressing from microbial invasion. The rapid and easy application of *in situ* photocrosslinkable hydrogels were demonstrated by spraying the composite gel precursor on the surface of the *ex vivo* pig skin model. The physical properties of the composite hydrogel dressings were analyzed by measuring the mechanical strength, swelling, degradation, and porosity characteristics at the macro scale. The antimicrobial properties of the composite hydrogels were evaluated against the growth of two major pathogens that typically grow during wound healing: *Staphylococcus aureus* and *Pseudomonas aeruginosa*. The oxygenation kinetics was measured using an oxygen sensing probe under hypoxic condition (2-5% O_2). The cytocompatibility of the composite hydrogels were assessed by testing their effects on metabolic activity and viability of the primary human dermal fibroblasts. We successfully demonstrated the practical and convenient application of our sprayable composite hydrogels on *ex vivo* pig skin tissue by an *in situ* crosslinking strategy. The optimum sprayable concentration for GelMA was found to be 10% w/v in the dressing. The gelatin, hyaluronic acid, and peroxide containing composite hydrogels showed high tunability in their physical and biological properties. The peroxide microparticles provided antimicrobial properties in this sprayable wound dressing. The composite hydrogels were able to provide oxygen for up to two weeks in the *in vitro* cell culture. The metabolic stress from human dermal fibroblast cells was relieved by the release of oxygen from the peroxide microparticles.

High-Throughput Mass Spectrometry Imaging of Biomaterials for Regenerative Medicine using Three-Dimensional Biomimetic Models (Spheroids and Organoids) SoheeYoon; Korea Research Institute of Standards and Science, Korea (the Republic of)

Three-dimensional spheroids and organoids are the next generation of biomimetic models that can mimic tissues and organs, as well as diseases and cellular microenvironments such as microtumors. This biomimetic model can be used to elucidate the mechanisms of various biomaterial changes or to rapidly screen cellular responses to drug treatments, and is therefore actively being applied in disease treatment and regenerative medicine. Imaging-based assays are important for a holistic understanding of tumor cell formation and behavior based on organ mimics. Cell viability in three-dimensional biomimetic models is primarily characterized by fluorescence-based imaging techniques. While fluorescence analysis can confirm cell viability, it is difficult to quickly identify chemical changes occurring in high-throughput cells simultaneously. Mass spectrometry imaging is a label-free, high-throughput imaging technique that can simultaneously obtain spatial and chemical information about analytes. We applied mass spectrometry imaging techniques to a three-dimensional biomimetic model to investigate changes in the cellular microenvironment and drug penetration upon drug application.
To this end, we applied drugs and nanoparticles to three-dimensional colon cancer spheroids and liver organoids to investigate chemical changes in the cellular environment by mass spectrometry imaging. In the case of three-dimensional spheroids, the extent of drug penetration into each proliferating, quiescent, and necrotic layer within the spheroid and the accompanying metabolites were investigated, confirming its potential for expansion as a nanomedicine that can be applied to regenerative medicine. To investigate the environmental changes following nanoparticle-based drug delivery in the liver organoid model, we developed and optimized a high-throughput chemical imaging assay that provides a global view of chemical changes within the organoid.

8:00 PM SB09.03.06

Disulfiram-Encapsulated PLGA Nanoparticles for Liver Injury Treatment WeiXu[1], WaliulIslam[1], HisaakiHirose[2], ShirohFutaki[2], YukioFujiwara[1], YoshihiroKomohara[1] and TakuroNiidome[1]; [1]Kumamoto University, Japan; [2]Kyoto University, Japan

Liver macrophages, Kupffer cells, the most abundant immune cells in the liver, play important roles in innate immunity and contribute to many liver diseases. Disulfiram (DSF), a drug used to treat alcohol abuse, has attracted much attention because it has anti-cancer and anti-inflammatory activities. However, DSF distribute in several cell types, and few studies have examined its utility as a potential treatment for liver injury. In this study, we prepared DSF-encapsulated PLGA nanoparticles (DSF@PLGA NPs) and examined anti-inflammatory effect in vitro and in vivo experiments. Size of DSF@PLGA NPs was about 250 nm and zeta-potential was negative. The encapsulated DSF was slowly released from the nanoparticles over a couple of weeks. DSF@PLGA NPs had low cytotoxicity, were selectively taken up by the human macrophage cell line THP-1 via macropinocytosis, and inhibited lipopolysaccharide-induced proinflammatory cytokine production by THP-1 cells. Intravenously administered PLGA NPs predominantly localized to the liver, specifically CD68-positive Kupffer cells, and DSF@PLGA NPs significantly ameliorated thioacetamide-induced proinflammatory cytokine production and liver injury. These results indicate that encapsulation in PLGA NPs promotes specific delivery of DSF to Kupffer cells and reduces liver injury and inflammation, suggesting that DSF@PLGA NPs may be a promising treatment for liver disease.

8:00 PM SB09.03.07

Drug-Loaded Decellularized Tissue for Suppression of Anastomotic Stenosis after Artificial Vascular Grafting KaitoShimizu[1,2], YoshiakiHirano[2,3], TetsujiYamaoka[1,4] and AtsushiMahara[1]; [1]The National Cerebral, and Cardiovascular Center Research Institute, Japan; [2]The Kansai Univercity, Japan; [3]The Kansai University Medical Polymer-Research Center, Japan; [4]The Komatsu University, Japan

[Introduction] The suppression of thrombus formation and anastomotic stenosis is required for long-term patency of small-diameter vascular grafts [1]. Surface modification technics for an anti-thrombus surface are reported [2], while no effective strategy has been developed to prevent anastomotic stenosis. It is well known that anastomotic stenosis causes to the hyperproliferation of transformed smooth muscle cells (SMCs) [3]. SMC phenotype is altered from contractile to synthetic type, resulting in hyperproliferation. Drug eluted stent is a famous device in the clinical site, and the stent is coated with a biodegradable polymer loaded with rapamycin. The drug is released over a month after application to the arteriosclerosis site. If this concept can be applied to artificial blood grafting, we assumed that stable graft patency would be achieved over the medium to long term the by local releasing of the drug at the anastomotic site. In this study, we focused on cilostazol as the anti-proliferative drug for SMC and developed a cilostazol-loaded acellular tissue (CLZ-Graft). After grafting the vessel, CLZ-Graft was implanted into the periarterial anastomotic site. When the tissue was degraded during the tissue regeneration, anastomotic stenosis would be suppressed by releasing CLZ. Here, we developed the CLZ-loaded acellular tissue, and inhibition of in vitro SMC growth and in vivo stenosis would be discussed.
[Experiment] The decellularized carotid artery was freeze-dried, and the artery was immersed in 100 mg/ml of CLZ/DMSO solution for 1 hour. As the control, the artery immersed with only DMSO were also prepared (FD-Graft). After that, the sample was washed with water to remove the solvent. The cilostazol loading in the CLZ-Graft was evaluated by FT-IR. The total amount of cilostazol in CLZ-Graft was quantified by using collagenase digestion. Enzymatically degraded CLZ-Graft was added to SMCs, and suppression of the SMCs proliferation was evaluated. In in vivo experiments, CLZ-Graft was implanted into the periarterial area of the carotid artery in a stenosis model rat. The vascular stenosis was evaluated after 4 weeks by histostaining.
[Result and Discussion] IR spectrum derived from CLZ was detected in CLZ-Graft by FT-IR analysis, and approximately 110 μg of CLZ was loaded in 10 mg of the graft. When the graft was incubated with the collagenase solution, the weight of the CLZ-Graft was reduced to 19 % for 8 hrs, and 82% of the loaded CLZ was gradually released during this time. When the lysate was added to the SMCs, the cell number was decreased, suggesting that the SMCs proliferation was suppressed by the degradation of the CLZ-Graft. In vivo experiment, the carotid artery with abraded lumen was wrapped with the grafts. As the result of this, the lumen area in the case of CLZ-Graft was maintained to 60% after 4 weeks while the area was largely reduced to 35% in the case of FD-Graft. These results suggest that CLZ-Graft would suppress anastomotic stenosis by CLZ release.

Prevention of Adverse Ventricular Remodeling Post-Myocardial Infarction by Sorbitol-Responsive *In-Situ* Gelling MaterialHueT. Le[1], AtsushiMahara[1], TakeshiNagasaki[2] and TetsujiYamaoka[1,3]; [1]The National Cerebral and Cardiovascular Center Research Institute, Japan; [2]The Osaka Metropolitan University, Japan; [3]The Komatsu University, Japan

Introduction: The loss of myocardium after myocardium infarction (MI) leads to a thinned left ventricular (LV) wall and the exacerbated dilation of the LV cavity, eventually leading to heart failure[1]. Intramyocardial hydrogel injection has gained attention as a therapeutic approach in MI treatment. Various materials have been tested in preclinical and clinical studies[2]; however, the difficulties in control of their gelation cause inadequate distribution and retention of the hydrogel within the myocardium. We recently developed a sorbitol-responsive *in-situ* gelling material composed of poly (3-acrylamidophenylboronic acid-co-acrylamide) (BAAm), poly(vinyl alcohol) (PVA), and sorbitol. This mixture exists in a sol state because the phenylboronic acid group of BAAm is bound to the sorbitol. The BAAm and PVA are quickly conjugated by a non-covalent bond to form a gel when the sorbitol is released from the BAAm. We previously reported the proof-of-concept for the sol-gel transition of sorbitol-containing BAAm/PVA (S-BAVA) solution in the heart tissue by diffusing the sorbitol out of the sol. In this study, we investigated the distribution and retention of the injected S-BAVA in the infarct myocardium and its therapeutic effect on post-infarct adverse LV remodeling in a rat model.
Method: S-BAVA solution was prepared from 25 mg/ml BAAm, 10 mg/mL PVA, and 10 mg/mL sorbitol. To examine S-BAVA hydrogel formation in vivo, 1 mL of the S-BAVA containing 100 mg/mL of iopamidol was intramyocardially injected in the porcine heart and tracked by computer tomography (CT) 30 min after injection. A rat subacute MI model was prepared by surgically ligating the left anterior descending (LAD) artery. The LV wall motion of MI rats was acquired from an MRI scan. To investigate the distribution and retention of S-BAVA solution in the MI heart, 200μL of rhodamine (rho)-labeled S-BAVA solution was injected into the infarct myocardium and observed by fluorescent microscopy up to 21d after injection. Finally, 200μL of the S-BAVA or calcium-crosslinked alginate (ALG) containing 24 mg/mL alginate and 4 mg/mL $CaCl_2$ or saline solution was intramyocardially injected into the MI hearts (four to six rats per each group). Fraction shortening (FS), and LV internal diameter (LIVD) index were measured by echocardiography, and the LV morphology was assessed by histological staining at 21d after administration. The saline was set as a negative control.
Result: The CT images showed the presence of the iopamidol–containing S-BAVA in the porcine myocardium 30min after injection, suggesting the occurrence of its hydrogel formation. The rho-labeled S-BAVA was fully distributed in the infarct myocardium and stably remained up to 21d after injection. The MRI images showed the dyskinetic wall motion and thickness in all rats operated with LAD ligation. A gradual reduction of the LV function indicated by a declining FS was observed in the saline-injected MI rats. Even with the ALG injection, the reduction of FS still occurred although it was less severe than in the cases with saline injection. However, the FS in the S-BAVA group was not reduced for 21d. In addition, the increase of systolic LVID caused by MI was suppressed by the S-BAVA injection whereas the saline or ALG injection did not. The histological assessment showed that the infarction area in the S-BAVA group was lower than that in the ALG and saline groups after 21d of administration.
Conclusion: Our results proved that the S-BAVA could be widely distributed and retained for 21d in the myocardium. Intramyocardial injection of the S-BAVA solution effectively suppressed adverse LV remodeling, resulting in maintaining cardiac function up to 21d.

3D Printed Polymer Scaffolds for Bone Regeneration ShreyaMadhavarapu and JosephFreeman; Rutgers, The State University of New Jersey, United States

Significant bone loss can occur due to trauma or disease, resulting in large bone defects. Typically, autografts and allografts are used as bone grafts but these are associated with disadvantages

like limited availability, and the risk of disease transmission with allografts. In recent time, synthetic bone graft substitutes have come up as alternatives, but they fall short in one or more aspects as well. Tissue engineered bone grafts are viable alternatives. In order for these to be successful, we must first address two important issues - lack of cell infiltration throughout their structure and a lack of vasculature formation. We have developed a 3D printed polylactic acid (PLA) scaffold with distinct cortical and trabecular geometries. These are highly porous structures promoting capillary inflow of blood and bone marrow. They are also mineralized and prevascularized to promote regeneration of both bone and it's vasculature. These scaffolds are evaluated in a load-bearing, rabbit critical-sized radial defect model and show promise.

Scaffolds were designed using Solidworks and 3D printed using the Ultimaker 2+/S3 3D printers. They were tested under compression and their mechanical properties were compared to the previous iterations of scaffolds developed in our lab. The new design displayed superior mechanical properties when compared to the previous design. Our previous design displayed Ultimate Compressive Stress and Compressive Modulus which fall within the limits for trabecular bone (0.2-10MPa and 7-200MPa) but fall short of those required for native whole bone i.e. 200 MPa and 1 GPa respectively. With our new design, we have been able to achieve a mean Ultimate Compressive Stress of approximately 40 MPa and a mean Compressive Modulus of approximately 600 MPa. Glycerol-water mixtures were used to mimic the viscosities of blood and bone marrow and study scaffolds' ability to promote capillary inflow. Slow capillary rise of fluids mimicking viscosities of blood and bone marrow was observed in the 3D printed scaffolds. In order to improve their ability to wick up these fluids, polymer surface was pretreated with oxygen plasma prior to mineralization using concentrated simulated body fluid. Presence of mineral resulted in them quickly wicking up fluid followed by a more gradual rise. Scaffolds were prevascularized by allowing vascular endothelial cells to grow within the cortical structure. They were decellularized after 2 weeks leaving behind a pro-angiogenic matrix. Scaffolds with and without autologous bone marrow were implanted in a rabbit critical-sized radial defect model, with allografts serving as controls. X-Ray and CT imaging was used to track bone regeneration over the course of 20 weeks. X-ray images showed progressive bone regeneration from 2 to 10 weeks, originating first from the ulna ridge just below where the radius was removed and from the two ends where the radius meets the implant. The CT images taken at 12 weeks post-op showed significant bone regeneration. At the end of the study, histology will be performed to analyze regenerated bone and vasculature.

We have developed load bearing scaffolds that promote infiltration of bone marrow into and throughout the scaffold, reducing the need to add stem cells prior to implantation in vivo. Using endothelial cells to prevascularize our scaffolds, we have created decellularized lumens within our cortical geometry to promote growth of vasculature upon implantation. Our ongoing in vivo evaluation has shown that our scaffolds can maintain their structural integrity while promoting bone remodeling and show promise as bone graft alternatives.

Control of Notch Signalling Timing and Strength Through Bead-Tethered Ligands for T Cell Differentiation from Induced Pluripotent Stem Cells AlessiaPallaoro, RichardCarpenedo, YuanHe, Manu ThomasKalathottukaren, HiofanHoi, ColeZmurchok, DanKirouac, StevenWoodside and EmilyTitus; Notch Therapeutics, Canada

Human induced pluripotent stem cells (iPSCs) provide a highly consistent cell source for the ex-vivo production of therapeutic T cells. Of the different T cell subtypes, the CD8αβ+ T cell has the strongest clinical precedence in autologous and healthy-donor derived CAR-T cell products yet has historically been challenging to generate from iPSCs. Notch signaling is required to drive T-lineage differentiation, and in conventional culture, protocols are delivered by Delta-Like 4 (DLL4)-expressing feeder cells or DLL4 protein-coated culture vessels. Unfortunately, these methods have not yielded efficient production of CD8αβ+ T cells from iPSCs and lack control of ligand dose and timing.
We have developed the Engineered Thymic Niche (ETN), a fully defined custom reagent consisting of magnetic beads coated with DLL4 and vascular cell adhesion molecule 1 (VCAM-1). The ETN allows temporal and intensity modulation of Notch signaling by adding or removing beads from culture vessels and increasing or decreasing the surface concentration of DLL4 and VCAM-1.
ETN was manufactured with beads sterilized by gamma irradiation before aseptic coating with DLL4 and VCAM-1. Gamma-irradiation sterilized the base beads without impacting the bead's physicochemical properties. To characterize the ETN, we developed assays for bead size, concentration, protein content, and function. On-bead DLL4 content was quantified using an immunofluorescence-based Notch-1 binding assay, while the bead function was assessed by measuring Notch-responsive gene expression and cell phenotype in response to ETN dose during differentiation of iPSC-derived CD34+ cells. ETN storage stability was improved through a storage buffer formulation study. Results suggest that ETN can be stored at 4 °C and potentially at room temperature, simplifying cell manufacturing and ETN reagent handling and storage procedures.
We applied ETN to T cell manufacturing from iPSC cultures in microplates and stirred tank reactors (STR). In microplates, we demonstrated that increasing both bead concentration and protein density (10-fold range) in cultures initiated with CD34+ HSPC cells modulates the expression of Notch-responsive genes (*Notch1, TCF7, DTX1, BCL11B, HES1*) and higher gene expression correlated to increased expression of progenitor T (ProT) markers (20 to 60%) after 14 days. In both microplates and STR, we show that medium to high bead dose and high cell seeding density yield the highest ProT population (CD7+/CD5+). Further differentiation of ProTs using a high bead dose yielded a higher proportion of CD8+ SP cells than lower bead doses. In both culture formats, gene expression dynamics for CD8A (T cell), IL7R (lymphoid), CD4 (T cell), and BCL11A (hematopoietic progenitor) show similar trends with CD8A and IL7R increasing and CD4 and BCL11A decreasing over time. Differentiation to CD8+ SP with ETN in STR is highly reproducible (n=8) and comparable to that in microplates. Furthermore, the iPSC-derived CD8+ cells produced in STR demonstrate comparable function as primary CD8+ cells in serial killing assays and similar proliferation (57,000-fold over 4 rounds of antigen exposure, 2:1 E:T ratio), and have a majority central/stem cell memory phenotype while being less prone to exhaustion than primary CD8 CAR-Ts. Finally, we show that ETN is remarkably stable in the custom-formulated storage buffer, with ongoing shelf-life studies showing > 9 months of stability at 4 °C and for 35 days at 37 °C. Looking ahead, the aseptic, scalable ETN manufacturing process will incorporate qualified raw materials, including GMP-level DLL4 and VCAM. Our advances in ETN bead design and characterization demonstrate that we have a stable reagent that enables the in-vitro control of Notch signaling required for consistent differentiation of iPSC-derived CD34+ cells to mature T cells, opening a path to clinical translation of ETN for cell production.

Eggshell Reinforced Scaffolds for Bone Repair MertGezek[1,1] and GuldenCamci-Unal[1,2]; [1]University of Massachusetts Lowell, United States; [2]University of Massachusetts Medical School, United States

More than two million bone graft procedures are performed to treat patient defects annually.[1,2] The main drawbacks of some of the existing bone graft materials are their complex fabrication steps, inflexibility, lack of porosity and biofunctionality, and requirement of costly reagents. Bone regeneration can be achieved using mineral-based materials, such as calcium carbonate, which is a major component of eggshells. Global waste of discarded eggshells typically amounts to millions of tons annually from household and commercial cooking. Innovative repurposing of eggshells can impact the economy and environment while providing unique solutions to unmet clinical needs. Due to the superior biophysical properties of calcium carbonate over other calcium-based minerals, the incorporation of chicken eggshell microparticles (ESP) into polymers can enhance osteogenic differentiation and bone regeneration.

In this work, we developed ESP-reinforced polymeric scaffolds to obtain mechanically stable and biologically active three-dimensional (3D) scaffolds that can differentiate stem cells or preosteoblasts into osteoblasts.[1] We generated ESP-reinforced 5-50% (w/v) polymeric scaffolds. The concentrations of the ESP were 5, 15, 30, and 50% (w/v) in the scaffolds. We characterized the mechanical properties, porosity, swelling, and degradation of these biomaterials. The cellular response was then evaluated against the ESP-reinforced scaffolds via, cytotoxicity, growth, and proliferation assays as well as gene expression analyses. Implantation of ESP-reinforced scaffolds was performed *in vivo* using a rat model and histology was carried out to evaluate the inflammatory response. In addition, near full regeneration of critical-sized calvaria defects was achieved using our ESP-reinforced scaffolds *in vivo*.[2] These composite materials demonstrated significant bone formation as well as bone remodeling.

This work demonstrates that eggshell microparticles can be used in a composite 3D polymeric construct for bone regenerative engineering. We successfully fabricated ESP microparticle-reinforced biomaterials and evaluated their suitability for osteogenic cell cultures *in vitro*, and biocompatibility and bone regeneration *in vivo*. Pre-osteoblasts were encapsulated within the ESP-reinforced scaffolds at 5 million cells/mL density which underwent osteogenesis as determined by RT-qPCR for osteocalcin and BMP-7. The ESP-reinforced composite scaffolds were osteoinductive and enabled the differentiation of stem cells without the use of a specialized osteogenic growth medium. The ESP-reinforced constructs were then subcutaneously implanted in Wistar rats and found to be biocompatible without inflammatory response and they were biodegradable. The implants were easily accepted by the host, allowed for cellular migration and infiltration in 3D, and were highly vascularized. To study the regenerative capability of the ESP-reinforced scaffolds, they were implanted into critical-size calvaria defects. The *in vivo* model demonstrated a near full regeneration of the critical-size defects in 12 weeks. The newly formed bone had similar bone density compared to the native bone and it was capable of producing bone marrow. Furthermore, in addition to vascularized bone formation, bone remodeling also took place as determined by immunohistochemistry for TRAP. We anticipate that the ESP-reinforced scaffolds will serve as promising implants for the treatment of bone defects in the body.

Simultaneous Antifouling and Selective Adsorption in a Poly(dimethyl siloxane) (PDMS) Based Microfluidic Device using a Functional Surface Segregating Zwitterionic Copolymer Additive RyanO'Hara[1], LucaMazzaferro[1], AslihanGokaltun[2,3], BerkUsta[2,3] and AyseAsatekin[1]; [1]Tufts University, United States; [2]Harvard Medical School, United States; [3]Massachusetts

General Hospital, United States

Nonspecific protein adsorption and small molecule absorption have been a persistent challenge in the use of poly (dimethyl siloxane) (PDMS)-based microfluidic devices due to PDMS's hydrophobicity. This issue has led to the development of various post-processing techniques to make the surface fouling resistant, such as plasma treatment and surface grafting of hydrophilic polymers. However, these approaches often have limited stability, with the surface becoming hydrophobic again within days. Additionally, for many applications, it is of interest to selectively adsorb only specific analytes while preventing the adhesion of others, specifically for use in protein capture for diagnostics, biochemical assays, and cell capture for organ-on-a-chip models. Achieving both selective adsorption and fouling resistance is particularly challenging. To address these challenges, we have synthesized a surface spontaneously segregating copolymer additive to create a hydrophilic, antifouling zwitterionic surface interspersed with functionalizable groups that can be easily blended into pre-cured PDMS during the traditional manufacturing method of microfluidic devices. Using this approach, we have been able to decrease the nonspecific adsorption of Bovine Serum Albumin (BSA) on PDMS surfaces by at least 95%. We have also shown that we can utilize the functionality of this polymer additive to attach desired functional groups to mediate the adsorption of specific analytes using isocyanate or EDC/NHS coupling chemistry. We expect this novel method for simultaneous fouling prevention and surface functionalization of PDMS surfaces to enable the development of better-performing biomicrofluidic devices.

8:00 PM SB09.03.13

Synergistic Effects of Extrinsic Photobiomodulation and Specific Collagen Micropatterns to Promote Mesenchymal Stem Cell Differentiation Guan YingTsai[1,2], Meng-JiyWang[1], Szu-YuanChen[2], SaitongMuneekaew[1] and ThipwadeeKlom-In[1]; [1]National Taiwan University of Science and Technology, Taiwan; [2]Academia Sinica, Taiwan

The design of functional biomaterials relates closely to the chemical, and physical cues between cells and scaffolds. Among the important factors, topographic cues such as micro-patterns of different size and shape were reported to specifically impact cell functions, including cell attachment, proliferation, and differentiation. For example, the precise control of mesenchymal stem cells (MSCs) differentiation was modulated through the underneath micro-patterns such that a rectangular micropattern with an aspect ratio of 1 favored MSCs to differentiate toward adipogenic differentiation.
Moreover, photobiomodulation (EPM) was recently reported to promote differentiation of MSCs that MSCs exposed under light with wavelength of 660 nm can facilitate differentiation into adipocytes. Based on the previous studies, it is speculated that the effective control of cell phenotypes to guide MSCs differentiation toward specific lineages while EPM can be used to induce stem cell differentiation. Even more, combination of EPM with micropatterns might be further enhance MSCs differentiation, with the benchmark of chemical induction.
Therefore, this study proposes to prepare collagen micro-patterns with different aspect ratios, areas, and symmetries by photolithography method to guide Wharton's Jelly mesenchymal stem cells (WJ-MSCs) behavior. The application of EPM was achieved by using verteporfin as the photosensitizer, which targeted endoplasmic reticulum, and light irradiation with a laser of 690 nm wavelength to induce differentiation of stem cell toward adipogenic, neural, osteogenic cells.
In this dtudy, the preparation of collagen micropatterns, the glasses were firstly treated by oxygen plasma to activate glasses (O_2/glass), followed by immersing in 1% of 3-(trimethoxysilyl) propyl methacrylate (TMA) solution to silanize the glasses (TMA/O_2/glass). After that, the photomasks of rectangular or stellate arrays were applied on the PEGDA solution dropped on silanized glass. Then UVA light of 365 nm wavelength with a light fluence of 500 mJ/cm^2 was shined to solidify PEGDA patterns to form PEGDA/TMA/O_2/glass. The collagen microislands were finally prepared by covering collagen solution on PEGDA/TMA/O_2/glass to eventually obtain col/PEGDA/TMA/O_2/glass microislands.
WJ-MSCs were cultured on collagen microislands for 5 days to guide cells adhesion, follow by EPM treatment twice to regulate stem cell differentiation. For the positive control groups with chemical inducing factors, the medium was replaced by differentiation medium on day 0 and again on day 3. The characteristics of the differentiated cells were observed by confocal microscope, and the number of differentiated cells were identified by flow cytometry analyses.
To reveal how collagen micropattern and EPM work synergistically to induce cell differentiation, WJ-MSCs were cultured on square, rectangluar and stellate micropatterns, with or without EPM. In absence of EPM, WJ-MSCs were cultured on various micropatterns in maintance medium (MM). The sqaure micropatterns can direct WJ-MSCs toward adipogenic differenitaion, the rectangluar micropatterns guided neurogenic differentaion, and the stellate micropatterns led MSCs to osteogenic differentiation. Additionally, by combining with EPM treatment, the differentiated WJ-MSCs on micropatterns can be further promoted. Meanwhile, it was found that adipogenic and neurogenic differentiation were signifcantly influenced by the aspect ratio (AR) of micropatterns, while the symmetry of stellate micropatterns impacted on osteogenic differentiation
In conclusion, this study proposde that the combination of collagen micropattern and EPM can effectively replace chemical induction medium to induce WJ-MSCs differentiation. The synergetic effects of unique micropattern and EPM could direct the differentiation route for WJ-MSCs which confirm the great potential of the proposed technique for the applications in tissue engineering and regenerative medicine.

8:00 PM SB09.03.14

Decoupling of Adhesive and Repulsive Domains of Microstructured Stimuli-Responsive Polymer Film for the Refining of Particulates and the Non-Enzymatic Harvesting of Cells YongwookKim[1,2], UmmayM. Jahan[3,2], AlexanderP. Deltchev[2], NickolayLavrik[4], VladimirReukov[2] and SergiyMinko[2]; [1]Lawrence Livermore National Laboratory, United States; [2]University of Georgia, United States; [3]North Carolina State University, United States; [4]Oak Ridge National Laboratory, United States

Sorting colloidal particles such as protein complexes, cells, and viruses presents a challenge due to their strong and quasi-irreversible adsorption to interfaces, which hampers their efficient separation. To overcome this limitation, a microstructured stimuli-responsive polymer interface has been developed to generate a controlled local oscillating repulsive mechanical force. This force facilitates the transition between particle adsorption and facilitated desorption, allowing for the separation of colloidal mixtures based on their affinity to the particle-polymer interface. The microstructured films consist of adhesive domains and disjoining thermoresponsive poly(N-isopropylacrylamide) brush domains. This dynamic regime holds significant potential for various applications in research, diagnostics, and large-scale label-free sorting of highly asymmetric mixtures of colloids and cells. Furthermore, this novel polymeric interface can be applied to non-enzymatic cell harvesting. By utilizing microstructured patterns, the areas responsible for solid cell adhesion serve as cell growing scaffolds, while the repulsive areas are employed to collect proliferated cells from the surface. This surface design effectively addresses the limitations associated with thermoresponsive coatings, such as the need for precise coating thickness, grafting or cross-linking density, and specific substrate materials. This innovative architecture enables efficient cell harvesting and selective sorting of particulates by separating the adhesion and detachment processes.
Part of this research was conducted as a user project at the Center for Nanophase Materials Sciences (CNMS), which is a US Department of Energy, Office of Science User Facility at Oak Ridge National Laboratory.

8:00 PM SB09.03.15

O-Carboxymethyl Chitosan-Based Nanostructured Surface using Poly(Ethylene Glycol) for Multi-Functionalization of Vascular Catheters Min YeongJeong[1], Se KyePark[2], KibeomNam[1] and Dong YunLee[1]; [1]Kyungpook National University, Korea (the Republic of); [2]Korea Institute of Industrial Technology, Korea (the Republic of)

Vascular catheters (VCs) are essential medical devices used for diagnostic purposes, drug administration, and surgical interventions. However, using VCs can lead to severe complications, including bloodstream infections, thrombosis, and blood vessel damage, posing a risk to patient safety. To address these critical issues, it is crucial to incorporate antimicrobial, antithrombotic, and low-friction properties into the surface of ICs. One approach for achieving multifunctionality in ICs involves coating them with a hydrogel that embeds antimicrobial and antithrombotic agents. Although catheters with such hydrogel coatings have effectively prevented these issues, they can have unwanted side effects such as cytotoxicity and tolerance. Additionally, the performance of hydrogel-coated ICs tends to degrade over time due to the leaching of functional agents from the coating layer. O-carboxymethyl chitosan (O-CMC) is a promising material for multi-functionalizing VCs due to its exceptional material properties, including biocompatibility, biodegradability, antimicrobial activity, and hemocompatibility. However, the antithrombotic activity of O-CMC remains uncertain due to incomplete thrombosis reduction and limited clinical use cases [5]. Although O-CMC has sufficient hemocompatibility, the antithrombotic activity is questionable due to its incomplete performance of thrombosis reduction and lack of clinical use cases[5]. Furthermore, there is a lack of studies on the multifunctionalization of VCs using chitosan derivatives like O-CMC. Consequently, the verification of multi-functional performance, including antithrombotic activity, remains a challenge in the application of actual VCs. In this study, we introduce a novel strategy to achieve surface multi-functionalization of ICs using O-CMC. To enhance the inherent performance of O-CMC, we fabricated a nanoscale rough surface for the coating layer. This is accomplished by fabricating a nanoscale porous O-CMC coating layer on pre-treated ICs through the selective leaching of water-soluble polyethylene glycol (PEG) from a heterogeneous O-CMC/PEG composite. The resulting coated layer exhibits superhydrophilicity due to increased surface roughness. Notably, the antifouling effect by superhydrophilicity of the coating layer effectively prevented the adhesion of bacteria and platelets, synergizing with the inherent properties of O-CMC. Additionally, the porous O-CMC coating layer exhibits sufficient low-friction properties even with its rough surface. Moreover, we have successfully demonstrated that the practical VC with the proposed coating method exhibits excellent trackability in a curved artificial blood vessel. This proposed coating strategy shows great potential not only for VCs but also for a wide range of polymer-based vascular devices, including vascular filters, grafts, pacemakers, and soft robots.

8:00 PM SB09.03.16

Cationic Material-Free mRNA Delivery Carrier NaokiTaguchi[1,2], AkihisaOtaka[1], YoshiakiHirano[2,2] and TetsujiYamaoka[1,3]; [1]The National Cerebral and Cardiovascular Center Research Institute, Japan; [2]The Kansai University, Japan; [3]The Komatsu University, Japan

[Introduction] Since mRNA is easily degraded in our body, it requires a delivery carrier to be delivered to target cells. Cationic carriers are often used for mRNA delivery because it electrostatically interacts with the phosphate groups of mRNA. However, cationic feature often causes cytotoxicity and nonspecific protein adsorption in the blood, thus decreasing the

therapeutic efficiency. To solve this problem, we focused on zwitterionic arginine methacrylamide (ArgMA), in which the alpha-amino group of arginine is conjugated with methacrylic acid as a carrier component. The guanidyl group of arginine has affinity to nucleic acid[1] and retains mRNA despite its zwitterionic and nonionic structure. Furthermore, previous papers have reported several attractive features of ArgMA as a delivery career, such as lower cytotoxicity than cationic arginine[2] and antifouling properties[3]. In this study, ArgMA-containing polymers were synthesized and verified whether the polymer can retain and protect mRNA and induce protein expression.
[Synthesis and Method] ArgMA was synthesized according to a previous report [4]. Since ArgMA homopolymer was insoluble in water, ArgMA was copolymerized with 2-methacryloyloxyethyl phosphorylcholine (PMR) at the ArgMA composition ranging from 0 to 70 mol%. Free radical polymerization and reversible addition-cleavage chain transfer (RAFT) polymerization were performed using 2,2'-azobis(isobutyronitrile) as initiator and water/ethanol as solvent. PMR was mixed with mRNA, encoding a near-infrared red fluorescent protein (iRFP), with a guanidyl/phosphate group ratio from 0 to 200, and the polyplex formation was confirmed by an agarose gel electrophoresis. The mRNA protection by PMR was evaluated after incubation with 10% fetal bovine serum (FBS) at 37°C for 10 min. The transfection efficiency of fibroblast cells (HEK293) was evaluated using flow cytometry analysis.
