Metal oxide materials have been a focus of research for energy storage devices. The perovskite oxide $LaMnO_3$ and Mn_3O_4 have drawn much attention as a sustainable energy storage system. In $LaMnO_{3\pm\delta}$, perovskite oxygen-ion intercalation leads to rapid energy storage, and electrodes are good supercapacitor material [1]. At the same time, multiple oxidation states of manganese in Mn_3O_4 facilitate the faradic process to get enhanced pseudocapacitance [2]. However, the poor electrical conductivity and structural stability of the Mn_3O_4 material limit their practical use as an electrode material for energy storage devices. To overcome the above stated limitation $LaMnO_3$-Mn_3O_4 composite samples (9:1,7:3,1:1) were prepared via a one-pot synthesis method followed by annealing in air at 80ºC. The x-ray diffraction analysis confirms the presence of individual compounds in the desired ratio. The maximum surface area of 7.68841 m2/g was recorded for the $LaMnO_3$. The chemical composition of composites was determined by x-ray photoelectron spectroscopy (XPS). The presence of Mn^{2+} and Mn^{3+} oxidation states conform to the presence of both $LaMnO_3$ and Mn_3O_4 in the composite. The electrochemical performance of composite electrodes prepared using nickel foam was assessed in 1M KOH solution. The cyclic voltammetry shows high specific capacitance for the 7:3 composite with a value ~ 584 F/g at a scan rate 1 mV/s, which decreased with further addition of Mn_3O_4 in the composite. At the same time, charge-discharge curves revealed a maximum specific capacitance of around 405 F/g for a 7:3 sample at a current density of 0.5 A/g. The energy density of $LaMnO_3$ - Mn_3O_4 composites (9:1,7:3, 1:1, and pure) are 5.33, 19.76, 3.71, and 7.66 Wh/Kg with power density 354.19, 308.67, 294.60, and 304.94 W/Kg, respectively at 1 A/g current density. The composites of $LaMnO_3$ and Mn_3O_4 help to reduce internal resistance due to the interconnected structure as well as reversible faradic process at the interface and create high degree of columbic efficiency [3]. The improvement in energy density, power density, and specific capacitance may result from enhanced charge transfer kinetics through the electrode-electrolyte interface between $LaMnO_3$ and Mn_3O_4. Also, easy electron hopping pathways are expected between $LaMnO_3$ (electron donor) and Mn_3O_4 (electron acceptor) in the composite. These findings are more significant to develop high energy supercapacitor devices using this new composition as an electrode material.

3D Solar Harvesting via Multiple Semi-Transparent Cadmium Telluride Solar Panels for Collective Energy Generation AnudeepKatepalli, YuxinWang and DongluShi; University of Cincinnati, United States

Photovoltaic (PV) solar cells have emerged as the predominant choice for environmentally friendly energy solutions across diverse applications. However, their traditional two-dimensional (2D) solar collection approach faces inherent limitations, primarily related to the substantial surface area required. In response, the pursuit of three-dimensional (3D) solar harvesting has gained momentum to achieve heightened energy density. In this innovative strategy, we have ventured into the realm of three dimensions by employing multiple transparent CdTe solar panels arranged in parallel along the z-axis. This innovative design enables sunlight to partially penetrate multiple layers of panels, significantly augmenting the solar collection surface area, Key advantages of this multi-panel solar harvesting system include: i) Expansion of Solar Light Collection Surface Area: Resulting in a significant boost in energy density compared to traditional 2D panels. ii) Enhancement of Total Output Power: Aggregating power output from multiple panels can surpass that of a single panel, providing a more efficient energy generation solution. iii) Reduction of Urban Space Footprint: Particularly relevant in densely populated urban areas with limited space, the 3D solar harvesting approach minimizes surface area requirements for energy production. Our experiments have yielded promising results, showcasing a noteworthy 21% increase in power conversion efficiency (PCE) through the utilization of five CdTe solar panels with varying levels of transparency, arranged in diverse configurations. This underscores the feasibility of 3D solar harvesting employing multiple panels. Furthermore, it is essential to note that efficiency gains can be further amplified by incorporating high-quality panels and harnessing increased solar intensity. This paradigm shift from 2D to 3D solar harvesting signifies a transformative approach to energy generation, promising greater efficiency and sustainability for the future.

Novel Multifunctional Additives for Enhancing the Efficiency and Stability of Perovskite Solar Cells AlexK. Jen; City University of Hong Kong, Hong Kong

Minimizing energy loss and increasing the quality of crystalline perovskite films are keys to improve the performance and long-term stability of perovskite solar cells. To address these challenges, we have developed several multifunctional, nonvolatile additives that can be used to modulate the kinetics of perovskite film growth to enable large-sized grains and coherent growth of perovskites from bottom to surface to be achieved. The improved film morphology resulted in significantly reduced non-radiative recombination, helping enhance the power conversion efficiency (PCE) of inverted (p-i-n) device to ~25% with low energy loss and good stability. In addition, these multifunctional additives can also be applied to address one of the most challenging problems involved in large bandgap perovskites and their derived devices for single junction and tandem solar cells. The commonly observed halide segregation critically limits the stability of mixed-halide perovskites under device operational conditions. There is a strong indication that halide movement/oxidation is the primary driving force behind halide de-mixing. To alleviate this problem, we have developed a series of multifunctional mediators that can suppress these factors while simultaneously passivate defects through tailored substitution. These effects enable wide-bandgap (1.81 eV) perovskite solar cells to achieve an outstanding PCE of 19.58%, with 95% of its initial PCE retained after tracking at maximum power point for 500 h. Integrating this layer into a monolithic perovskite-organic tandem solar cell as a wide-bandgap subcell afforded a record-high PCE of 25.22% and impressive long-term stability (T_{90} > 500 h under continuous operation).

Unveiling the Fatigue Behavior of 2D Hybrid Organic-Inorganic Perovskites: Insights for Long-Term Durability DoyunKim[1], EugeniaS. Vasileiadou[2], IoannisSpanopoulos[3], XuguangWang[4], JinhuiYan[4], MercouriG. Kanatzidis[2] and QingTu[1]; [1]Texas A&M University, United States; [2]Northwestern University, United States; [3]University of South Florida, United States; [4]University of Illinois at Urbana-Champaign, United States

2D hybrid organic-inorganic perovskites (HOIPs) are commonly found under subcritical cyclic stress states and suffer from fatigue issues during device operation, significantly limiting their service lifetime. However, the fatigue properties of these materials remain unknown, which is crucial for mitigating fatigue failure and predicting the lifetime for scheduled maintenance. Here, we systematically investigate the fatigue behavior of $(C_4H_9\text{-}NH_3)_2(CH_3NH_3)_2Pb_3I_{10}$, the archetype 2D HOIP, by atomic force microscopy (AFM) dynamic stretching suspended 2D membranes. We find that 2D HOIPs are much more fatigue resilient than polymers and can survive over 1 billion cycles. The failure morphology indicates that the 2D HOIPs tend to exhibit brittle failure at high mean stress levels but behave as ductile materials at low mean stress levels. Our results suggest the presence of a plastic deformation mechanism in these ionic hybrid organic-inorganic materials at low mean stress levels, which may contribute to the long fatigue lifetime but is inhibited at higher mean stresses. The stiffness and strength of 2D HOIPs are gradually weakened under subcritical loading, potentially as a result of stress-induced defects accumulating and nucleating. The cyclic loading component can further accelerate this process. The fatigue lifetime of 2D HOIPs can be extended by reducing the mean stress, stress amplitude, or increasing the thickness. Our results can provide indispensable insights into designing and engineering 2D HOIPs and other hybrid organic-inorganic materials for long-term mechanical durability.

Conductivity Studies of Mechanochemically Processed LAGP/PEG Hybrid Solid Electrolytes JamesBuckley[1], MeganNoga[2], Abdul LatifBamba[2], KerrySun[2], NicholasW. Gothard[3], IoannisKymissis[2] and L. JayDeiner[4]; [1]New York University Tandon School of Engineering, United States; [2]Columbia University, United States; [3]Bob Jones University, United States; [4]The City University of New York, NYC College of Technology, United States

Solid state lithium ion batteries promise to provide safe, high power energy storage to support increasing electrification of the transportation sector. Realizing the promise of solid state lithium ion batteries requires development of solid electrolytes whose conductivity and processability
allow for the high rate capability and manufacturability of conventional liquid electrolyte lithium ion batteries. While ionically conducting ceramics may approximate the conductivity of conventional liquid electrolytes, operate safely over a range of temperatures, and resist dendrite formation, their manufacture and integration with battery electrodes is a challenge. In specific, ceramic electrolytes tend to form poor interfaces with electrodes, and require high temperature sintering. Polymer electrolytes are easier to process and join to electrodes, but they suffer from low room temperature conductivity. The ideal solid electrolyte would be a hybrid material that combines the high conductivity of ceramics with the processability of polymers. In such a hybrid material, the polymer concentration would be low enough and the distribution uniform enough so that lithium ions would follow a conduction pathway primarily through the ceramic whose grains were “glued” together by the polymer. Further, in contrast to a simple organic/inorganic composite, specific attachment of the polymer to the ceramic may facilitate charge transport through the hybrid.
As a step towards a readily processable solid state electrolyte, we have recently shown a mechanochemical synthesis of a true hybrid solid electrolyte in which the organic phase, polyethylene oxide (PEO), and the inorganic phase, lithium aluminum germanium phosphate (LAGP), are chemically associated through a surface condensation reaction that takes place under the high energy milling conditions. Solid state nuclear magnetic resonance (NMR) spectroscopy confirmed that after milling, protons from the polymer and/or water condensate are in bonding proximity of the Q^2 metaphosphate sites of the glassy phase of the LAGP. In the present work, we investigate the room temperature conductivity of a range of these mechanochemically synthesized PEO/LAGP hybrids. Conductivity is tracked as a function of organic to inorganic component ratio and as a function of milling condition. The correlation of the conductivity with hybrid material structure provides insight into mechanisms of lithium ion conduction in ceramic/polymer hybrids.

Advancing Solid Polymer Electrolytes: Enhancing Ionic Conductivity, Transference Number and Li0-SSB Cycle Life Through Conduction Mechanism Design and Integration of Zero-Strain Cathodes HuolinXin, YubinHe and LeiWang; University of California, Irvine, United States

Solid polymer electrolytes (SPEs) are promising alternatives to liquid electrolytes, offering advantages in flexibility, safety, and processability. However, their widespread adoption is hindered by their limited room-temperature ionic conductivity (σRT) resulting from insufficient ion conduction pathways. Additionally, both liquid and solid electrolytes commonly suffer from non-selective ion transport, causing a low transference number that adversely affects energy output and can lead to failures. In this presentation, I will discuss the methodology for overcoming these challenges. We will explore how to finely tune the composition of SPEs to change their ion conduction behavior from Vogel-Fulcher-Tammann to Arrhenius, thereby achieving a remarkable room-temperature conductivity exceeding 1 mS/cm. Additionally, we will discuss innovative strategies to enable single-ion conduction, effectively improving the transference number to unity. These advancements will significantly enhance the overall performance of SPE-based systems. Furthermore, we will shed light on the advantages of integrating zero-strain cathodes in Li0-SSB full cells. By mitigating strain-related issues, these cathodes can dramatically improve the cycle life of Li0-SSB batteries, extending their durability and reliability.

The work is in part supported by the Assistant Secretary for Energy Efficiency and Renewable Energy, Vehicle Technology Office of the U.S. Department of Energy (DOE) through the Advanced Battery Materials Research Program under contract no. DE-SC0012704 and the startup funding of HLX.

Novel Custom-Shaped Batteries with Ionogel Polymer Electrolytes OlgaGuchok[1], GilatArdel[1], HadarNakar[1], HeftsiRagones[2], AllenZheng[3], StevenGreenbaum[3] and DianaGolodnitsky[1]; [1]Tel Aviv University, Israel; [2]Holon Institute of Technology, Israel; [3]Hunter College of City University of New York, United States

The rapid rise of flexible and stretchable electronics for healthcare, sensing, sport and textiles caused a growing demand for more efficient, reliable, environmentally friendly materials and continuous advancements of battery technologies.
Our research pioneers a simple approach to the fabrication of novel flexible lithium-ion batteries. It is based on a single-shot extrusion - 3D printing method of a multi-shell-architecture battery comprising biodegradable polymer-based components. We used the thermoplastic polymers PLA and TPU to improve the mechanical properties of the well-known LiTFSI-PEO-based polymer electrolytes. The extruded electrolytes of different PEO-to-TPU/PLA ratios and salt content were characterized by means of ESEM imaging, mass spectroscopy, differential-scanning calorimetry (DSC), electrochemical-impedance spectroscopy (EIS) and solid-state nuclear magnetic resonance (NMR) diffusion measurements. All the polymers were found to form complexes with lithium salt. Flexible extruded *in-situ* plasticized ionogel polymer electrolyte (IGPE) exhibited bulk conductivity of 0.2mS/cm at room temperature and addressed the issues of inferior interface contacts. All-extruded cells with TPU-MWCNT-based current collector, LFP cathode, LTO anode and IGPE demonstrated good reversibility with close to 96% coulombic efficiency.

Poly(vinylidene fluoride)- and Poly(urethane acrylate)-Based Electrolytes for Solid State Batteries EnyuanHu, DeanYen, NanWang and ShaTan; Brookhaven National Laboratory, United States

Solid-state batteries (SSB) have better safety characteristics than conventional lithium-ion batteries which are based on flammable liquid electrolyte. A key enabler for SSB is the solid state electrolyte. Among possible candidates, polymer electrolytes have attracted a lot of attention as they offer a wide range of tunable structure, have good physical contact with electrodes and are easy to fabricate. This talk will include our recent work on two kinds of polymer electrolytes: Poly(vinylidene fluoride), or PVDF-based electrolyte and poly(urethane acrylate), or PUA-based electrolyte. PVDF polymer electrolyte is prepared by the solvent-casting method. We will discuss its performance in full cells using various kinds of cathodes. We will also discuss the effect of residual solvent on the eventual cell performance. PUA polymer electrolyte is prepared by a solvent-free method. Through controlling the degree of cross-linking, we were able to introduce PUA with gradient structure in the polymer electrolyte. This provides both good physical contact with electrode and good mechanical strength against lithium dendriate penetration. The $LiNi_{0.8}Mn_{0.1}Co_{0.1}O_2$|PUA|Li cell is evaluated and shows good performance.

11:00 AM *EN02.01.02
Scalable Solid-State Electrochemical Devices JuLi; Massachusetts Institute of Technology, United States

Low-cost, earth-abundant, and easy-to-recycle battery chemistries are key for the impending global energy transition. We provide some examples of proton solid-state battery ["Acid-in-Clay Electrolyte for Wide-Temperature-Range and Long-Cycle Proton Batteries," Advanced Materials (2022) 2202063], fast-acting neuromorphic computing ionic transistor ["Nanosecond protonic programmable resistors for analog deep learning," Science 377 (2022) 539], and lithium silicide guided lithium-metal batteries ["Ultra-Thin Lithium Silicide Interlayer for Solid-State Lithium-Metal Batteries," Advanced Materials (2023) 2210835] that may compete successfully with liquid electrolyte based devices. Full-cell performance evaluation and techno-economic assessment are essential for judging different device architectures.

Toward Solid-State Li_{metal}-Air Batteries; An SOFC Perspective of Solid 3D Architectures, Heterogeneous Interfaces and Oxygen Exchange Kinetics EricD. Wachsman, GeorgeAlexander, RoxannaMoores, GibsonScisco, ChristopherTang and MichaelDanner; University of Maryland, United States

The full electrification of transportation will require batteries with both 3-5X higher energy densities and a lower cost than what is available in the market today. Energy densities of > 1000 Wh/kg will enable electrification of air transport and are among the very few technologies capable of achieving this energy density. Li_{metal}-air is theoretically able to achieve this energy density and also capable of reducing the cost of batteries by replacing expensive supply chain constrained cathode materials with “free” air. However, the utilization of liquid electrolytes in Li_{metal}-air batteries has presented many obstacles to the optimum performance of this battery including oxidation of the liquid electrolyte and the Li_{metal} anode. In this paper a path towards the development of a Li_{metal}-air battery using a cubic garnet $Li_7La_3Zr_2O_{12}$ (LLZ) solid-state ceramic electrolyte in a 3D architecture is described including initial cycling results of a Li_{metal}-O_2 battery using a recently developed mixed ionic and electronic (MIEC) LLZ in that 3D architecture. This 3D architecture with porous MIEC structures for the air cathode is essentially the same as a solid oxide fuel cell (SOFC) indicating the importance of leveraging SOFC technology in the development of solid-state Li_{metal}- air batteries.

Statistical and Machine Learning-Based Durability-Testing Strategies for Energy Storage StephenJ. Harris and MarcusM. Noack; Lawrence Berkeley National Laboratory, United States

There is considerable interest in developing new energy storage technologies for the electric grid, but economic viability will require that manufacturers provide warranties guaranteeing 15+ years of life. Although there are extensive efforts to make early predictions for the expected life of new storage technologies, we argue here that for the purposes of pricing warranties and valuing second-life potential—considerations that are crucial to whether the technologies can be commercialized—the full failure probability distribution, not just the expected life, is required. We use published battery cycle-life data to suggest efficient statistical and machine learningbased testing and analysis strategies that can rapidly estimate and also take advantage of the failure probability distribution. One

approach is a Weibull analysis, which can (1) reduce the number of testing machine hours required for setting a warranty, (2) quickly determine whether a new technology is better than a baseline technology, and (3) estimate the maximum intensity of testing acceleration that does not change the failure mode. A second approach is driven by the idea that all measured data—such as capacity or energy as a function of time or cycle number—are valuable and generated by an underlying latent function. This analysis employs a Gaussian process to find the underlying latent function, together with its uncertainties, which can be used to calculate the failure distribution.

2:00 PM *EN02.02.02
Mechano-Electrochemical Phenomena in Solid-State Batteries JeffSakamoto; University of Michigan, United States

There is tremendous interest in making the next super battery, however Li ion technology continues to improve and has inertia in several commercial markets. Recent material breakthroughs in solid-electrolytes (SE) could enable a new class of non-combustible solid-state batteries delivering twice the energy density (>1,300 Wh/L) compared to Li-ion. However, technological and manufacturing challenges remain, creating the impetus for fundamental and applied research.

This discussion will consist of fundamental aspects such as the mechano-electrochemical phenomena at solid interfaces as well as manufacturing challenges related to the integration of Li metal electrodes. The underlying physics that control the stability and kinetics of Li/SE interfaces are fundamentally different from interfaces in Li ion technology. Moreover, the mechano-electrochemical phenomena that occur during discharge and charge at the Li/SE interface are considerably different. For example, during charging at higher rates Li metal filaments can initiate at defects and propagate through relatively hard ceramics. During discharge, if the Li stripping rate is sufficiently high and the temperature is sufficiently low, voids form at the interface causing delamination at of the interface.

In another example, novel mechano-electrochemical phenomena are emerging when analyzing the formation of Li anodes in using the Li^0-free manufacturing approach. Using this approach for solid-state batteries, Li metal in interposed between a current collector and the SE. The mechanics at this interface will determine the feasibility of this approach by controlling the homogeneity of the *in situ* formed Li anode. While significant progress is advance the technological maturity of solid-state batteries, there remain fundamental questions regarding the physics at interfaces and whether or not they exhibit sufficient stability and kinetics that are relevant to EVs.

2:30 PM *EN02.02.03
All Solid State Batteries Based on Sodium ElectrochemistryY. ShirleyMeng[1,2,3]; [1]The University of Chicago, United States; [2]University of California, San Diego, United States; [3]Argonne National Laboratory, United States

Solid-state batteries have gained significant attention in recent years as they have the potential to be the leading next-generation energy storage devices, offering improved safety, higher energy densities, and longer cycle life. For grid-level energy storage, where having an accessible supply of battery materials and low cost per kilowatt-hour is important, sodium solid-state batteries are a promising technology. Within the past five years, halide-based solid electrolyte materials have become increasingly popular due to their superior oxidation stability, excellent deformability, and moderate ionic conductivities. As such, they are ideal catholytes for enabling high-voltage-coating-free cathode materials. However, to improve sluggish solid-state battery kinetics, it is still necessary to enhance their ionic conductivity, especially for sodium systems, which calls for new approaches to materials design. I will talk about a novel approach towards synthesizing nanocrystalline and amorphous chlorides for use as *superionic* conductors in sodium all-solid-state batteries. Our concept is based on the tendency of chlorides to form these phases by adjusting the composition of the system, as demonstrated using the $NaCl–YCl_3–ZrCl_4$ phase composition diagram as an example. We show that by controlling the molar amount of NaCl, electrolytes with low sodium concentrations and nanocrystalline or amorphous nature can be obtained. The structural amorphization, along with an increase in free volume, and preferential population of prismatic Na^+ local environments, leads to an exceptional ionic conductivity at room temperature. Our approach has the potential to be applied universally to other halide-based systems, leading to a shift in the design of future solid electrolytes for high-performance all-solid-state batteries operating at ambient temperatures.

Solid State Electrolyte: Li-B-S System and Inorganic-Polymer Composite YiCui; Stanford University, United States

This presentation include two topic areas related to solid state electrolyte. First, I will present a new family of Li-B-S solid electrolyte, which was predicted using machine learning approach and recently experimentally validated to have a good ionic conductivity and expanded voltage stability window compared to other sulfide electrolytes. Second, I will our decade long study on inorganic-polymer composite electrolyte, which utilize the mechanical flexibility and processibility of polymer and the ionic conductivity enhancement and mechanical enhancement by inorganic materials.

4:00 PM *EN02.02.05
Li-Metal Alloys and Their Unique Thermodynamic and Kinetic Properties AntonVan der Ven; University of California, Santa Barbara, United States

All-solid-state batteries will enable significant increases in energy density as they will allow the use of metallic Li anodes instead of graphite intercalation compounds. However, before metallic Li can be used as an anode, major metallurgical challenges must be overcome. Alloying of Li is a promising path with which to modify the intrinsic thermodynamic, mechanical and kinetic properties of metallic Li to enable the uniform deposition and stripping of Li at the anode/solid-electrolyte interface. Li forms a rich variety of intermetallic compounds when alloyed with different elements. Li diffusion within these intermetallic compounds can be complex due to the nature of anti-site defects and the relative mobilities between Li and the alloying elements. The unique thermodynamic and kinetic properties of different Li-metal alloys have important consequences for morphological evolution during Li deposition and stripping. In this talk, we will describe our first-principles statistical mechanics studies of non-dilute diffusion in Li-metal alloys such as Li-Sb, Li-Al, Li-Mg and Li-In and elucidate how strain and varying degrees of long and short-range order affect the kinetics of Li anodes.

Database Driven Solid-State Electrolyte Material Search for Li and Na-Metal GunyoungHeo[1], TaehunLee[2] and AloysiusSoon[1]; [1]Yonsei University, Korea (the Republic of); [2]Princeton University, United States

Li and Na metal anode-based batteries are currently some of the most desirable technologies for high-energy density storage systems. However, internal dendrite formation is considered one of the biggest challenges in battery manufacturing. Suppressing the dendrite formation of Li or Na metal might be achievable with solid-state electrolytes as they have demonstrated a higher chemical stability in the presence of the anode. The development of a solid-state electrolyte for Li and Na metal anode involves several challenges, including the need for the material to have

high ionic conductivity, good mechanical properties, and good compatibility with the anode material. To address these challenges, there is a need for a systematic approach to discover new solid-state electrolytes that are specifically tailored for Li or Na metal anodes. The objective of this work is to screen out optimal and compatible solid-state electrolytes for both Li and Na metal batteries from the Materials Project (MP) database [1]. In total, five criteria were considered in the screening process [2] – the formation energy, energy above hull, band gap, reaction energy with anode material and mechanical property – which are all available within the MP database. After screening out the potential candidates, we assessed their dynamic/transport properties. By performing molecular dynamics simulations using the universal graph deep learning interatomic potential M3Gnet [3], the ionic diffusivity for all solid-state electrolyte candidates was analyzed. Through this work, we provide the Pareto front for the most optimal solid-state electrolytes for both Li and Na metal anode batteries.

8:00 PM EN02.03 .02
Elucidating Differences in Surface and Bulk Properties of Solid-State Electrolytes ZeeshanAhmad; Texas Tech University, United States

Solid-state batteries with metal anodes are now widely recognized as the next frontier of battery research to satisfy the stringent requirements of safety, energy and power density for transportation and aviation applications. There is still a plethora of interfacial and chemomechanical challenges to be solved before these batteries achieve mass market adoption. These challenges include interface stability and dendrite growth, limits on stripping and plating current densities, and device integration [1]. These challenges warrant an investigation of the buried surfaces and interfaces present in solid-state batteries in the presence of electric fields encountered during battery operation. In this talk, I will discuss how the properties of surfaces and interfaces of solid-state batteries differ from the bulk using large scale simulations of defects based on first-principles and machine learning force fields. Our results confirm a high degree of atomic disorder at the interface, which effectively modulates the defect thermodynamics. Further, I will show how the mechanical stress at the interface affects these defects. These results have broad implications on ionic transport, charge transfer and rate capability, and dendrite growth in solid-state batteries through control of the properties of grain boundaries and interfaces. This work demonstrates the need for continuum models to be refined to account for the drastically different properties at the surfaces and interfaces.

Investigating Different Solvents for Liquid Phase Synthesis Routes of Lithium Indium Chloride Solid Electrolyte for Solid-State Batteries JacobOtabil Bonsu and DipanKundu; The University of New South Wales Sydney, Australia

Solid-state batteries (SSBs) have emerged as a promising technology that has the potential to revolutionise the area of energy storage by providing more safety, better energy density, and longer cycle life when compared to current lithium-ion batteries. Polymer, oxide, and sulfide-based solid-state electrolytes (SSEs) have been widely researched to aid in the development of solid-state batteries. However, these SSEs' drawbacks, such as high-temperature sintering of oxides, air instability of sulphides, and small electrochemical windows of polymer electrolytes, severely limit their practical implementation. As a result, it is necessary to design SSEs with strong ionic conductivity, good air stability, a wide electrochemical window, great electrode interface stability, and low-cost mass manufacturing. Because of their strong ionic conductivity and compatibility with high-voltage electrodes, halide electrolytes are emerging stars among inorganic solid-state electrolytes. However, as compared to liquid-mediated approaches, their traditional synthesis processes, such as ball-milling and annealing, are often more energy-intensive and time-consuming. Furthermore, the only approach in an aqueous solution is not ideal due to the negative effect of water traces on battery performance. We provide three comparison alternatives (Tetrahydrofuran, Acetonitrile, Ethanol, and Water) for the halide Li+ superionic conductor, Li3InCl6, with good ionic conductivities of 4.02, 3.67, 3.07, and 2.72 MilliSiemens per centimetre at ambient temperature respectively. In-addition, their ionic conductivities can be recovered after dissolution in their respective solvents. Combined with an NMC 622 cathode, the solid-state Li batteries show good cycling stability.

8:00 PM EN02.03 .04
Effect of Lithium Precursor on the Crystal Structure and Ionic Conductivity of $Li_7La_3Zr_2O_{12}$ Oxide Electrolyte LeeHyeju[1], So HyunPark[1], Min GueLee[1], SojeongRoh[1], DongjooKim[2] and Young SooYoon[1]; [1]Gachon University, Korea (the Republic of); [2]Auburn University, United States

The garnet-structured solid electrolyte $Li_7La_3Zr_2O_{12}$ (LLZO) has attracted attention as a solid electrolyte for all-solid-state batteries due to its wide electrochemical window and high ionic conductivity. However, the formation of impurity phases and tetragonal LLZO during synthesis can rapidly reduce lithium-ion conductivity, and the low stability in air and water can lead to lithium loss. The effect of lithium sources including Li2CO3, LiOH and LiNO3 on the crystal structure, microstructure, and ionic conductivity of LLZO was investigated. X-ray diffraction (XRD) analysis was performed to confirm the crystallization and phase formation of the synthesized LLZO and scanning electron microscopy-energy dispersive X-ray spectroscopy (SEM-EDS) was used to analyze the microstructure and chemical composition. Electrochemical impedance spectroscopy (EIS) was also used to confirm the ionic conductivity. As a result, LLZO prepared with LiOH as the source was confirmed to be cubic without impurities or intermediate phases, compared to solid electrolytes prepared with Li_2CO_3 and $LiNO_3$. In addition, a uniform particle size and distribution of less than 2 μm and an ionic conductivity of 1.311×10^{-4} S cm^{-1} at room temperature were confirmed. These results suggest that the choice of lithium source can significantly affect the properties of LLZO, and that LiOH is a promising lithium source for the preparation of high-performance LLZO solid electrolytes. In future studies, the effect of lithium sources on the properties of LLZO should be investigated in more detail and new methods should be developed to fabricate high-performance LLZO solid electrolytes.

A Highly Conductive and Stable Ionic Liquid Gel Electrolyte for Calcium Metal Batteries XinluWang; Syracuse University, United States

Calcium batteries are promising alternatives to lithium batteries due to their high energy density, comparable reduction potential, and mineral abundance. Calcium is the fifth most abundant metal in the Earth's crust (4.1%), surpassing Na, K, Mg, and Li, and ranks third after aluminum and iron. Calcium batteries can achieve volumetric capacities comparable to incumbent Li-ion and emerging Li metal systems. Additionally, calcium-ion batteries generally exhibit improved safety characteristics compared to lithium-ion batteries, being less susceptible to thermal runaway and reducing the risk of overheating, combustion, or explosion.

However, to meet practical demands in high-performance applications, suitable electrolytes must be developed. Polymer gel electrolytes are emerging as a promising system for calcium metal batteries. Polymer gel electrolytes consist of polymer hosts swollen in liquid electrolyte and offer a combination of mechanical and electrochemical robustness from the polymer host, high ion conductivity and electrochemical reactivity from the liquid electrolytes, excellent wetting contact with the electrodes, more uniform electrode reactions (specifically, metal deposition), and have proven attractive for Li, Na, K, Zn, and Mg metal systems. Moreover, they provide a decent level of mitigation against potential leakage, electrolyte volatility, and flammability, thus offering the desired safety benefits similar to quasi-solid-state batteries.

In this study, polymer gel electrolytes (GPEs) for calcium-ion conduction were synthesized and characterized by photo-cross-linking poly(ethylene glycol) diacrylate (PEGDA) in the presence of calcium salt $Ca(BF_4)_2$ and an ionic liquid EMIM triflate. The ionic conductivity of the GPEs was observed to increase with salt concentration and temperature, reaching a maximum conductivity of 2.16 S/cm. The Ca stripping/plating behavior was analyzed on a Ca substrate with a current density of 0.2 mA cm^{-2} and a total discharge areal capacity of 0.4 mA h cm^{-2}. The overpotential at the first cycle was 0.4 mV and increased with subsequent cycles. Furthermore, the PEGDA-based GPEs exhibited an electrochemical stability window of 4 volts and a thermal stability window exceeding 200 degrees Celsius.

Overall, these results demonstrate the potential of PEGDA-based GPEs as high-performance electrolytes for calcium batteries and provide valuable insights into the development of advanced GPEs for next-generation energy storage devices.

8:00 PM EN02.03 .06
Improving Lithium-Ion Conductivity by Co-Doping Al/Ta to $Li_7La_3Zr_2O_{12}$ using Molten Salt Synthesis Method So HyunPark[1], LeeHyeju[1], SojeongRoh[1], Ji-HyeokChoi[1], DongjooKim[2] and Young SooYoon[1]; [1]Gachon University, Korea (the Republic of); [2]Auburn University, United States

Solid state batteries are attracting attention as promising materials for next-generation energy storage systems due to their high energy density and safety. The sulfide solid electrolyte has excellent lithium-ion conductivity, but sulfur electrolyte easily reacts with moisture in the air to release sulfide. On the other hand, the oxide solid electrolyte does not exhibit the above toxic gas when decomposed. This research selected $Li_7La_3Zr_2O_{12}$ (LLZO), a garnet-type cubic phase, in light of chemical stability and introduced the molten salt synthesis (MSS) method and doped Al/Ta co-doped to improve lithium-ion conductivity. In particular, this method can overcome the disadvantage of MSS that forms an impurity phase during multi-component synthesis. In addition, using molten salt-based LiCl-KCl can form the cubic phase at a lower temperature in a shorter time than the traditional solid phase synthesis method. Al/Ta co-doping may induce more vacancies occupied by Li ions than single doping. In particular, Al single doping can inhibit 96h site substitution that interferes with lithium ion conductivity, and Al/Ta co-doping

induces displacement of Li vacancy to 24d site, extending the path of Li^+. Such a mechanism increases ion conductivity because the atoms of 24d having a small Li vacancy are located close to each other, thereby shortening the movement path of Li^+. Preparation of pure cubic LLZO phase was performed in the range of 900°C to 1000°C with a calcination process of less than 4 hours. The synthesized powder was pelletized and subjected to a heat treatment process to increase the density at 900°C for 6 hours. For the measurement of Li^+ conductivity, electrochemical impedance spectroscopy (EIS) was used in the frequency range of 10 Hz~1 MHz. As a result, small particles of 0.8~1.3 μm were obtained compared to the single-doped LLZO by a similar method, and the ion conductivity was 2.398×10^{-4} S cm^{-1}, and a small amount of Al/Ta doping was sufficient to impart stability to the garnet structure of LLZO. In conclusion, the Al/Ta co-doped MSS method suggested that the LiCl-KCl molten salt serves to remove impurities, which is advantageous in synthesizing high-purity materials.

8:00 PM EN02.03 .07
LiPON Layer Effect for Reduction of Interfacial Resistance of LLZO/Li for All-Solid-State Battery Min GueLee, SojeongRoh, So HyunPark, Ha EunKang, LeeHyeju and Young SooYoon; Gachon University, Korea (the Republic of)

Cubic garnet-type solid electrolytes for all-solid-state batteries (ASSBs) have attracted attention due to their stability over a wide electrochemical window and high ionic conductivity. However, current challenges for garnet-type solid electrolytes include overcoming poor wettability and high interfacial resistance with lithium metal anodes. When a lithium metal anode contacts an oxide solid electrolyte, a passivation layer of Li_2CO_3 forms on the surface of the solid electrolyte, which can lead to increased resistance. Additionally, non-uniform Li^+ intercalation/extraction can lead to increased resistance and electrochemical instability at the solid electrolyte/anode interface. To improve contact resistance, interfacial modification methods have been introduced. One such method is to coat the surface of the solid electrolyte with a ceramic material that is highly reactive with lithium. This can stabilize the interfacial chemistry and improve lithium wettability and charge transport. In this study, LiPON coating was deposited on the surface of LLZO pellets using an RF sputtering process. The interface between the coating layer and the LLZO pellet was analyzed using transmission electron microscopy-energy dispersive spectroscopy (TEM-EDS) to confirm the X-ray photoelectron spectroscopy (XPS) depth profile spectrum. Molten Li contact angle measurements were also performed to confirm wettability with metallic lithium. The results showed that the LiPON coating forms a Li-LiPON layer when in contact with molten Li and exhibits a low contact angle of less than 90°. This indicates that the LiPON coating can improve lithium wettability and reduce interfacial resistance. These results suggest that the chemical properties of the lithium electrode and the properties of the interface play an important role in the interfacial resistance and lithium wettability, compared to the microstructure of the LLZO solid electrolyte. This discovery will have implications for the design of LLZO/Li interfaces for ASSBs containing LLZO as the electrolyte.

Ultrathin Sulfide-Based Composite Electrolyte Membrane for Solid-State Sodium Metal Batteries XiaolinGuo, YangLi and HuiWang; University of Louisville, United States

Rechargeable solid-state sodium batteries that utilize solid electrolytes (SEs) have garnered considerable attentions due to their features of intrinsic non-flammability and abundant sodium resources. Among different types of sulfide-type SEs, Na3SbS4-family conductors show advantages of high ionic conductivity at room temperature and densification through cold-pressing. However, one of their most significant challenges is related to the electrochemical stability towards Na metal. Solid composite electrolytes (SCEs) with ceramic particles dispersing in a polymer matrix, provide a viable approach to address this challenge. In this work, we report an ultra-thin, flexible and stable SCE through embedding micro-sized Na3SbS3Se (NSSE) particles in polymer electrolyte (PVDF-HFP). The prepared SCE membranes exhibit an adjustable thickness, and impressive ionic conductivity at room temperature as well as enhanced interfacial stability in Na symmetric cells. Moreover, the assembled Na|SCE|TiS2 solid-state batteries demonstrate stable cycling and great rate performance. This work promotes new composite SEs, and their application in solid-state Na metal batteries.

For the past decade, lithium-ion batteries (LIBs) have dominated the electric vehicle sector due to their high energy density and cycle life. Currently, the purpose of LIBs for electric vehicles is to provide and store energy. A structural battery is defined as being multifunctional; it is a load bearing system as well as an electrochemical cell [1]. The electrolyte system is the key enabler for a multifunctional structural battery as it must possess sufficient ionic conductivity (~10^{-4}S/cm) and mechanical strength (Youngs's modulus ~ 2-3 GPa) simultaneously.

In the present work, we study the development of a dual-phase structural battery electrolyte to optimize ionic conductivity and mechanical performance simultaneously. An epoxy resin-based system is chosen due to its high mechanical strength and ability for in situ polymerization. [3] Diglycidyl ether of Bisphenol A (DGEBA) accounts for the epoxy to provide hard segments in the matrix and is cured by an amine compound (Jeffamine T-403). A liquid electrolyte is added to the system for improving the conductivity enhancement without compromising its mechanical strength substantially. Three liquid components consisting of lithium salt and solvents are considered here -lithium bis(trifluoromethanesulfonyl)imide (LITFSI) dissolved in a solution of ethylene carbonate (EC) and dimethyl methyl phosphonate (DMMP), LiTFSI dissolved in Tetraethylene glycol dimethyl ether (Tetraglyme) and LiTFSI dissolved in 1-Ethyl-3-methylimidazolium bis(trifluoromethylsulfonyl)imide (EMIM-TFSI). Ionic conductivity of the electrolyte systems as a function of temperature is measured utilizing electrochemical impedance spectroscopy. Uniaxial load tests are performed to evaluate the mechanical properties (e.g., Young's modulus, Yield strength) of the epoxy-based electrolyte systems with and without the addition of the ion conducting liquids. Comparative data on the three epoxy-based systems containing varying amounts of liquid components will be presented.

Chitosan-Based Cross-Linked Nanocomposites for Solid State Electrolyte System SamirKattel and HemaliRathnayake; UNCG, United States

Lithium-ion batteries (LIBs) are the best choices in electrochemical systems due to promising aspects like good life cycle, large discharge capacity and hence widely used in wearable electronic devices. These LIBs are usually made of cathode, anode, electrolyte, and separator. Due to good ionic conductivity, liquid electrolytes (LEs) are in practice. However, the use of LEs is considered detrimental due to the reason that leakage of it may cause fire and explosions. Replacing conventional liquid electrolytes with the solid-state electrolytes (SSEs), which are not only non-flammable but also highly flexible, light in weight and mechanically strong. Additionally, it has also been proven that the side reactions in LE-based lithium-ion batteries can surpass by replacing with SSEs. However, the low-ionic conductivity and high temperature stability are major drawbacks in biodegradable polymer-based SSEs to be compete with its counterpart of inorganics and Les.
This project will develop chitosan-based nanocomposites incorporated with appropriate fillers and lithium salts to utilize them as solid-state membrane electrolyte for lithium-ion conduction. The chemical composition, structure, and conductivity properties are investigated using a wide range of characterization tools. Also, biodegradability and abundance natural availability of these nanocomposites adds more value to this research.
Electrolytes with ionic conductivities 10^{-3}Scm^{-1} are not suitable for high power batteries applications since their performance would be limited to lower charge and discharge rates. The proposed process uses highly porous Metal Organic Frameworks (MOFs) as fillers and lithium salts and plasticizers to incorporate into chitosan nanocomposites for a solid-state electrolyte

system. Integration of MOFs into chitosan nanocomposite system will add tailoring the lithium-ion conduction path and enable to reduce interfacial resistance to provide suitable lithium-ion conduction in these composites. The system offers a great potential for use in electrolyte system for all solid-state electrolyte systems.

Li^+ Conduction Mechanism in Anion-Substituted Halide Solid Electrolytes for All-Solid-State Batteries YejiChoi[1], HiramKwak[1], DaseulHan[2], Jae-SeungKim[3], Kyung-wanNam[2], Dong-HwaSeo[3] and Yoon SeokJung[1]; [1]Yonsei University, Korea (the Republic of); [2]Dongguk University, Korea (the Republic of); [3]Korea Advanced Institute of Science and Technology, Korea (the Republic of)

The recent emergence of halide superionic conductors, such as Li_3YCl_6, as solid electrolyte (SE) materials for all-solid-state batteries (ASSBs) is considered a game changer. These halide SEs offer a combination of advantageous properties that include excellent (electro)chemical oxidative stability, high Li^+ conductivity, and mechanical deformability. This unique combination of properties position halide SEs as promising candidates for the development of next-generation ASSBs, surpassing the limitations of sulfide or oxide SEs.
However, despite these benefits, the practical deployment of these materials has been hindered by the high cost associated with the use of expensive or rare transition metals. To overcome this, a cost-effective and abundant Zr-based compound Li_2ZrCl_6 has emerged. Yet, there remains a need to improve Li^+ conductivity further and develop a more comprehensive understanding of the underlying ion conduction mechanisms.
This presentation delves into the impact of anion substitution on changes in the local structure and ion conductivity of halide SE, offering an in-depth explanation of the ion conductivity mechanism. Particularly, we present noteworthy findings that demonstrate nearly twofold enhancements in ion conductivity upon anion-substitution of halide superionic conductors. Furthermore, we also investigate the feasibility of these materials in ASSB cells.

Surficial Degradation of Jet-Milled Li6PS5Cl under Mild Temperature Heat-Treatment Kern-HoPark, Yo-SeobKim, KyungSuKim, WoosukCho and GoojinJeong; Korea Electronics Technology Institute, Korea (the Republic of)

All-solid-state batteries using sulfide solid electrolytes are considered a promising next-generation energy storage system. Especially, argyrodite-type Li6PS5Cl (LPSCl) is in spotlight for their good ionic conductivity and malleability. In electrode level, achieving efficient Li^+ pathway with the maximized active material proportion and electrode mass loading is crucial for the high energy density. Thus, solid electrolytes with a small particle size is highly sought for. Here, we demonstrated a spiral jet mill process for refining LPSCl particle size, reducing the mean particle size (D_{50}) of LPSCl 39.9 μm to 1.9 μm where the ionic conductivity was decreased from 2.0 mS cm^{-1} to 0.23 mS cm^{-1}. The post-annealing in a mild temperature (T < 250 ºC) led to the even more decreased ionic conductivity. Although the ionic conductivity was recovered when T > 300 ºC, these high temperature heat-treatment resulted in severe particle agglomeration. Spectroscopic study suggested that the particle surfaces were damaged during the jet-mill process and the irreversible sulfur losses occurred during the mild temperature annealing.

8:00 PM EN02.03 .13
Core-shell structured NCM@LPSCl synthesized by mechanofusion process for high-performance all-solid-state batteries Jin WoongLee[1,2], Min JiKim[1,2], Sung EunWang[2], Do WoongYoon[1,2], Dae SooJung[1] and Yoon ChanKang[2]; [1]Kicet, Korea (the Republic of); [2]Korea University, Korea (the Republic of)

All-solid-state batteries (ASSBs) using inorganic solid electrolytes (SEs) are considered a promising next-generation rechargeable battery because of their higher energy density and thermal stability compared to conventional lithium ion batteries (LIBs) using organic liquid electrolytes. Among the various SEs, Sulfide-based SEs have been developed and attracted much attention due to their high ionic conductivity and better formability than other SEs. Unfortunately, ASSBs exhibit several issues, such as undesired chemical reactions and physical contact issues. With regard to physical contact, insufficient contact between active materials(AMs) and SEs cause high interfacial resistances between the electrode materials that may degrade electrochemical performances, and this phenomenon could be worsened if the AM and/or SE particles agglomerate. Therefore, intimate contact and homogenous distribution of electrode materials are necessary in the ASSBs to reduce interface resistance and offer sufficient Li-ion transport pathway. However, it is difficult to construct such intimate contact between electrode materials in the form of powder.
In this study, we produced the core-shell structured cathode composite by the mechanofusion(MF) process. The high shear and compression forces used in the MF process enable the coating of a thin and homogenous SE(LPSCl) layer on surface of AM(NCM) particle. NCM@LPSCl composite allows intimate interface between NCM and LPSCl without void and agglomeration, which ensure well-networked Li ion pathway resulting in high-performance in ASSB. In particular, ASSBs employing the NCM@LPSCl composite can electrochemical properties even at up to 87.3wt% NCM mass fraction in the cathode. It is demonstrated that the NCM@LPSCl composite could be a promising cathode material for the high energy density for practical ASSBs applications.

New Amorphous Quaternary Sulfide Compounds as Solid Electrolyte for All-Solid-State Li-Ion Batteries YunaKim and Sung-JinKim; Ewha Womans University, Korea (the Republic of)

In recent years, interest in all-solid-state lithium secondary batteries with high energy density and output performance has increased due to the possibility of mitigating safety issues related to liquid electrolytes. However, the development of a suitable solid electrolyte (SE) remains a major challenge in advancing all-solid-state battery technology. Sulfide-based compounds are advantageous as solid-state electrolytes due to their high ionic conductivity and efficient transport of lithium ions, which can be attributed to their high polarizability and low electronegativity. In this work, an amorphous new sulfide compound, $LiSbGeS_4$, was synthesized as a Li-ion conductor. The amorphous characteristics of $LiSbGeS_4$ were investigated using PXRD, XAS, XRS, Raman spectroscopy, and thermal analysis. XPS and Raman spectroscopy provided information about into the local structure and chemical bonding of $LiSbGeS_4$, indicating the presence of metal-metal bonds and metal-S polyhedral units. $LiSbGeS_4$ was modified to have a high ionic conductivity through anion aliovalent substitution of the Cl^- on S^{2-} sites while maintaining amorphous phase. $LiSbGe_{0.8625}S_{3.45}Cl_{0.55}$ exhibited a significantly higher lithium-ion conductivity, reaching 7.26 mS/cm, which is approximately 2400 times higher than that of pristine $LiSbGeS_4$. This study presents new amorphous sulfide compounds with enhanced Li-ion conductivity as a promising solid electrolyte for Li-ion batteries.

8:00 PM EN02.03 .15
Garnet-Based Bilayer Hybrid Solid Electrolyte for High-Voltage Cathode Material Modified with Interface Enabler on Lithium-Metal Batteries Kumlachew ZelalemWalle[1,1,2] and Chun-ChenYang[1,1]; [1]Ming Chi University of Technology, Taiwan; [2]University of Gondar, Ethiopia

Solid-state lithium metal batteries (SSLMBs) are considered promising candidates for next-generation energy storage devices due to their superior energy density and excellent safety. However, recent findings have shown that the formation of lithium (Li) dendrites in SSLMBs still exhibits a terrible growth ability, which makes the development of SSLMBs have to face the challenges posed by the Li dendrite problem. In this work, an inorganic/organic mixture coating material (g-C_3N_4/ZIF-8/PVDF) was used to modify the surface of the lithium metal anode (LMA). Then the modified LMA (denoted as g-C_3N_4@Li) was assembled with lithium Nafion (LiNf) coated commercial NCM811 (LiNf@NCM811) using a bilayer hybrid solid electrolyte (Bi-HSE) that incorporated 20 wt.% (vs. polymer) LiNf coated $Li_{6.05}Ga_{0.25}La_3Zr_2O_{11.8}F_{0.2}$ (LiNf@$LG_{0.25}$LZOF) filler faced to the positive electrode and the other layer with 80 wt.% (vs. polymer) filler content faced to the g-C_3N_4@Li. The garnet-type $Li_{6.05}Ga_{0.25}La_3Zr_2O_{11.8}F_{0.2}$ ($LG_{0.25}$LZOF) solid electrolyte was prepared via co-precipitation reaction process from the Taylor flow reactor and modified using LiNf, a Li-ion conducting polymer. The Bi-HSE exhibited high ionic conductivity of 0.68 mS cm^{-1} at room temperature, and a wide electrochemical window (0–5.0 V *vs.* Li/Li^+). The coin cell was charged between 2.8 to 4.5 V at 0.2C and delivered an initial specific discharge capacity of 194.3 mAh g^{-1} and after 100 cycles it maintained 81.8% of its initial capacity at room temperature. The presence of a nano-sheet g-C_3N_4/ZIF-8/PVDF as a composite coating material on the LMA surface suppresses the dendrite growth and enhances the compatibility as well as the interfacial contact between the anode/electrolyte membrane. The g-C_3N_4@Li symmetrical cells incorporating this hybrid electrolyte possessed excellent interfacial stability over 1000 h at 0.1 mA cm^{-2} and a high critical current density (1 mA cm^{-2}). Moreover, the in-situ formation of Li_3N on the solid electrolyte interface (SEI) layer as depicted from the XPS result also improves the ionic conductivity and interface contact during the charge/discharge process. Therefore, these novel multi-layered fabrication strategies of hybrid/composite solid electrolyte membranes and modification of the LMA surface using mixed coating materials have potential applications in the preparation of highly safe high-voltage cathodes for SSLMBs.

8:00 PM EN02.03 .16
Lithium Containing Fluorides and Oxyfluorides as Solid Electrolytes MichaelJ. Brady, JessicaAndrews and BrentC. Melot; University of Southern California, United States

Research on all solid-state batteries has increased as lithium-ion based chemistries approach theoretical capacities with conventional graphite anodes. Aside from the safety-related improvements that come with the removal of traditional liquid electrolytes, all solid-state batteries offer advantages related to cost, operating conditions, and energy density. Most of the materials that show high lithium-ion conductivity are oxide- or sulfide-based and have vastly different diffusion conditions, operating windows, and stabilities against lithium metal. As a result, exploring other chemistries—as has been done recently with halides in the argyrodite structure—is paramount to the understanding and improving the properties of solid electrolytes.

We chose to explore fluoride and oxyfluoride based compositions with the motivation that fluoride substitution should widen the stability window as well as provide a passivating layer of LiF in the SEI when used against lithium metal. This will work to combat the deposition of lithium metal that can occur along the grain boundaries in oxide based solid electrolytes leading to dendrite formation and cell failure. Exploring compounds in this phase space is accompanied by many challenges associated with synthetic methods as well as sample preparation and instrumental setup for various characterization methods. Conventional solid-state synthetic methods for oxides and sulfides are not applicable to fluorides due to their volatility and reactivity with several common vessels. Additionally, fluoride materials tend to be less stable at elevated temperatures which makes sintering of samples to raise the density challenging.

We will present our work on the examination of new lithium containing fluoride and oxyfluoride materials for use as solid electrolytes beginning with a gallium-based fluoride garnet. We have developed new synthetic methods for fluoride-based phases using custom high-temperature and high-pressure autoclaves. Cold-isostatic pressing was used to produce pellets of near theoretical density without the need for high-temperature sintering. We examine the effects of substitution of different redox-inactive metal centers through X-ray diffraction and electrochemical impedance spectroscopy. Additionally, through computational methods we investigate the activation energy of lithium ion hopping in these phases and compare these values to those extracted from Arrhenius plots derived from conductivity measurements.

8:00 PM EN02.03 .17
Single–Ion Conducting Sol-Gel Derived Silica–PEO Hybrid for Solid-State Electrolytes GuangyuWang, VazrikKeshishian and JohnKieffer; University of Michigan, United States

To simultaneously achieve both high mechanical stiffness and ionic conductivity, while maintaining good electrochemical stability, we developed a hybrid electrolyte that consists of a nanoporous silica backbone, covalently grafted organic moieties, and infiltrated polymer. The backbone is derived from tetra-ethyl-orthosilicate (TEOS) through a multi-step sol-gel process. The functionalization process is optimized by precisely timing and phasing the reactions between the pre-hydrolyzed 2-[(Trifluoromethanesulfonylimido)-N-4-sulfonylphenyl] ethyl (TFSISPE) anion, 2-[Methoxy(polyethyleneoxy)6-9propyl] trimethoxysilane (OPEG), and the partially gelled silica backbone. This process enhances anion loading without affecting the gelation of the backbone. Subsequently, we replace the solvent in the nanopores with low-molecular weight (600 g mol^{-1}) polyethylene oxide (PEO). We find that the incorporation of grafted OPEG significantly improves the ionic conductivity. At 20°C and a Li^+ concentration of one molar, the material with OPEG exhibits an unprecedented ionic conductivity of 5.2×10^{-4} S cm^{-1}, approximately seven times higher than that without OPEG. This enhancement is attributed to the reduction of osmotic drag resulting from the entanglement between OPEG and PEO. Furthermore, we achieve a high lithium-ion transference number ($t+ \sim 0.91$) by immobilizing the TFSISPE anion. Compared to conventional SSEs based on polymer matrices, our single–ion conducting hybrid electrolyte exhibits approximately ten times higher ionic conductivity, nearly unity transference number, and thermal stability up to 110°C.

8:00 PM EN02.03 .18
High-Voltage Anode-Free Sodium Metal Batteries with Polymer Electrolyte Membranes Yu-HsienWu, HaochengYuan, ShundongGuan and LiangliangLi; Tsinghua University, China

With the growing demands of electronic vehicles, portable electronics and large-scale energy storage, lithium metal batteries have been intensively studied due to the superior energy density provided by the lithium anode. However, the scarcity of lithium reserve significantly increases the cost of lithium metal batteries. Among alternatives, high-voltage anode-free sodium (Na) metal batteries (AFSMBs) are attracting enormous interest since they can attain high energy density in a low-cost way. One challenge that hinders the development of AFSMBs is that the highly reactive Na metal deposited on the current collector reacts with liquid electrolyte easily, especially when carbonate electrolytes are employed. As a result, the growth of Na dendrites and the formation of “dead Na” are exacerbated and thus shorten the lifespan of AFSMBs. Herein, we proposed some poly(vinylidene fluoride)-based polymer electrolyte membranes (PEMs) for stable and dendrite-free AFSMBs in carbonate electrolytes. The electrochemical properties of the PEMs are optimized by tuning the solvent, Na salt, and polymer matrix. The optimal PEMs have the merits of high ionic conductivity (>5×10^{-4} S cm^{-1}), great electrochemical stability with Na (the Na|PEM|Na cell runs steadily for over 4,000 hours at a capacity of 0.1 mAh cm^{-2} with a low voltage hysteresis), good electrolyte resistance and decent mechanical strength; therefore, when they are applied on the current collectors in AFSMBs, Na metal can be uniformly deposited on the current collectors and the deposited Na metal is effectively separated from carbonate-based electrolyte, leading to the reduction of parasitic reactions and the elongation of the cycle life of the batteries. With the PEMs, high-voltage AFSMBs with a 4.0V-class layered oxide cathode and carbonate electrolyte are assembled and tested. These batteries can run for ~60 cycles due to the stabilized interface between deposited Na and the corrosive carbonate electrolyte. In contrast, batteries without a PEM fail quickly in just a few cycles due to the poor Na deposition and much side reactions. In short, with the support from the chemically/thermally stable and mechanically strong PEMs, it is promising to fabricate long-cycle-life, high-energy-density, and low-cost AFSMBs.

8:00 PM EN02.03 .19
Electrochemical Properties of Porous Nickel-Based Alloy Foam as Anodes in Lithium Metal Batteries Jae-SeongYeo, Hye-RyeonYu, Sang-HyeonHa, Tae-YoungAhn, EunjiYoo and YusongChoi; Agency for Defense Development, Korea (the Republic of)

Traditional graphite-anode-based lithium (Li)-ion batteries are challenged by the ever-increasing demand of today’s energy storage and power applications, especially for smart grid and electric vehicles because they have almost reached their theoretical specific energy limits. Among varieties of alternative anode materials, Li metal has been widely recognized as an ultimate anode material for high-energy rechargeable batteries due to its ultrahigh theoretical specific capacity (3860 mAh g^{-1}) and very low redox potential (- 3.04 V vs. standard hydrogen electrode). To date, considerable efforts have been made to developing ultra-high energy density Li metal-anode-based batteries, such as Li-S and Li-air batteries. However, uncontrollable dendritic growth and high reactivity of Li metal anodes result in poor cycle performance and severe safety concerns, hindering the practical application of Li metal anodes in rechargeable Li metal batteries. To solve these issues, various approaches have been developed to suppress Li dendrite formation, including artificial SEI layer construction, additives of electrolyte to improve the uniformity of Li-ion deposition, utilization of high-modulus polymer or ceramic solid-state electrolytes, separator modification, current collector modification, and so on. Particularly, current collectors play a critical role in facilitating uniform Li nucleation and deposition. Fabricating three-dimensional current collectors is emerging as an effective strategy for designing dendrite-free Li anodes. Recently, Y. Choi et al. have reported an oxidation method for achieving an ultra-lithiophilic NiO layer on the surface of a three-dimensional nickel (Ni)-foam, resulting in stable Li plating and stripping in an anode prepared using Li-infused oxidized Ni-foam. In this study, Ni-based alloy, NiCrAl, with porous three-dimensional or two-dimensional structures was used as an anode in Li metal batteries. NiCrAl showed higher mechanical properties than pure Ni in the molten Li, anticipating in facile electrode stacking and cell assembly of NiCrAl-foam anode compared to Ni-foam anode. Oxidized NiCrAl-foam was prepared by heat treatment at 600ºC for 10 min in ambient air. Li was introduced into the oxidized NiCrAl-foam by dipping into molten Li or electroplating. We present the electrochemical properties of oxidized NiCrAl-foam anodes with different foam thickness (0.2–1.0 mm) in the Li metal batteries.

Electrochemical Characteristics of Various Lithium-Based Anodes for Thermal Batteries Hye-RyeonYu, Jae-SeongYeo, Chae-NamIm, Sang-HyeonHa, JaeinLee and YusongChoi; Agency for Defense Development, Korea (the Republic of)

The thermal battery is primary battery used for special fields such as defense due to its high power and high reliability characteristics. As the demand for thermal battery increases, development of various thermal battery electrodes having high energy density and power density is required. Therefore, as interest in high performance anodes increases, attempts are being made on various anodes for thermal batteries. In the case of a conventional thermal battery anode (Li-Si alloy), it has difficulty in large-area because it is manufactured through a powder pressing method. For this reason, many studies on development of liquid lithium-based anodes have recently been conducted. In particular, the Li-Fe (LIFe) anodes manufactured by mixing molten lithium and iron powder, a research has been carried out significantly and some commercialized. In addition, research on lithium impregnated metal foam anode (LIMFA) that are used by impregnating molten lithium in metal foam has been actively conducted recently. The research on the manufacture and performance of lithium boron (LiB) anodes for lightening the weight of thermal battery is also being studied. In this paper, various lithium-based thermal battery anodes were fabricated and applied to improve thermal battery performance. The prepared anodes were fabricated single cells applying FeS_2 cathode, and electrolyte. The single cell was discharged at 500ºC to evaluated electrochemical properties, and performance as an anode of a thermal battery compared.

8:00 PM EN02.03 .21
Studying *In-Situ* Passivating Interphase Between Halide Solid-Electrolyte and Li-Based Anode in All-Solid-State BatteriesSeYoungKim[1,2], Seong-MinBak[3,4], KyuJungJun[5,2] and GuoyingChen[2]; [1]Korea Institute of Science and Technology, Korea (the Republic of); [2]Lawrence Berkeley National Laboratory, United States; [3]Brookhaven National Laboratory, United States; [4]Yonsei University, Korea (the Republic of); [5]University of California, Berkeley, United States

All-solid-state batteries (ASSBs) have been highlighted as a promising alternative for future energy storage systems due to their high thermal stability and high energy density compared to lithium-ion batteries using liquid electrolytes. Among many types of solid electrolytes, halide solid electrolytes (SE) with high oxidative stability have been intensively proven as a feasible SE that enables cycling 4 V class cathode materials. However, undesirable thermodynamic instability of halide SEs to Li metal anode hinders achieving high energy density ASSBs for practical use. To this end, lithium-indium (Li-In) alloy has been extensively employed due to their (electro)chemical stability to halide SEs that enables stable cycling of ASSB using halide SEs. Although the decomposition of halide SEs and its reactants in direct contact with Li metal has been experimentally and theoretically studied, no in-depth investigations on interphase evolution and charge transfer mechanism at the LYC SE and Li-In anode interphase have been conducted. In this work, we report the evolution of the interphase layer between In metal anode and halide solid electrolyte, Li_3YCl_6 (LYC), that enables stable long-term cycling of ASSB coupled with crack-free single-crystal (SC) $LiNi_{0.8}Co_{0.1}Mn_{0.1}O_2$ (NMC811) cathode active material. Through the combination of high-resolution microscale x-ray based analysis on a cross-section of the ASSBs, we demonstrate the crosstalk between LYC and In anode that results in the evolution of interphase layer consists of $InCl_x$, YCl_3,, LiCl, and In diffused LYC which suppressed dendritic growth of Li-In alloy over the ASSB cycling.

8:00 PM EN02.03 .22
Synthesis of High-Quality and Low-Cost Li_6PS_5Cl via Naphthalene Assisted Li_2S-Free One-For-All Method for Commercial Synthesis MukarramAli[1,2], ChilH. Doh[1,2] and YoonC. Ha[1,2]; [1]Korea Electrotechnology Research Institute, Korea (the Republic of); [2]University of Science and Technology, Korea (the Republic of)

The commercialization of sulfide-based all-solid-state batteries (ASSBs) has been hindered by the lack of sustainable synthesis techniques for sulfide-based solid electrolytes (SSEs) [1]. While mechano-chemical and solid-state sintering methods are energy-intensive and commercially non-viable, solvent/wet chemistry-based routes involving organic solvents have become the focus of extensive research [2]. Thus, it is crucial to develop a viable process that eliminates the need for Li_2S as a starting reagent.

In this study, we present a Li_2S-free one-for-all (OFA) method capable of producing high-quality Li_6PS_5Cl, a key SSE material, at the world's lowest cost of $47/kg. The OFA method offers a universal approach for the synthesis of Li_xMS_4 (x = 3 or 4, M = P, Sb, or Si) and Li_6PS_5X (X = Cl, Br, or I) in a single-step technique, eliminating the need for pre-synthesized Li_2S. This process uses lithium metal (Li) and, sulfur powder (S) as a precursor for Li_2S along with LiCl and P_2S_5 in tetrahydrofuran (THF), Li_6PS_5Cl can be synthesized within 9 hrs. The synthesis of Li_6PS_5Cl was carried out using the OFA method, and the resulting material exhibited exceptional ionic conductivity of 2.5 $mScm^{-1}$ and electronic conductivity below 10^{-7} Scm^{-1}. The low-cost production of Li_6PS_5Cl was achieved by utilizing readily available precursors, and the process cost was reduced to $47/kg, making it highly attractive for large-scale manufacturing.

The synthesis mechanism of Li_6PS_5Cl was investigated using electrospray ion mass spectrometry (ESI-MS) and nuclear magnetic resonance (NMR) spectroscopy, revealing the formation pathway of the desired Li_6PS_5Cl structure. The wet synthesis started from spontaneous Li oxidation and naphthalene reduction, and the resulting naphthalene radical anion initiated the reduction reaction of elemental S to form polysulfide anions (S_n^{2-}). Subsequently, P_2S_5 reacted with polysulfide anions and co-precipitated in the form of Li_3PS_4, Li_2S, and LiCl at the end. Electrospray ion mass spectrometry (ESI-MS) and nuclear magnetic resonance (NMR) spectroscopy are employed to elucidate the underlying chemistry between Li-NAP solution with S and P_2S_5 with LiCl during Li_6PS_5Cl synthesis. We found that S_7^{2-} and S_9^{2-} are predominantly formed in the polysulfide solution, and the additional LiCl, P_2S_5, and Li made PS^{7-} and PS^{9-} at the initial stage. With increasing Li-ion concentration in the solution (as the lithium dissolved further in the reaction mixture), PS^{3-} and PS^{4-} coordinated with THF remained in the supernatants while Li_3PS_4, Li_2S, and LiCl were co-precipitated at the end in a $Li_3PS_4 \circ x(Li_2S\text{-}LiCl)$ complex. To further explain the argyrodite growth X-ray photoelectron spectroscopy (XPS) and X-ray diffraction (XRD) are used to investigate the phase growth of complex as-prepared product $Li_3PS_4 \circ x(Li_2S\text{-}LiCl)$ to final argyrodite Li_6PS_5Cl from the OFA method.

To evaluate the electrochemical performance of the OFA Li_6PS_5Cl, it was paired with a high nickel cathode $Li(Ni_{0.8}Mn_{0.2}Co_{0.2})O_2$ (NMC-811) cathode. Galvanostatic cycling tests showed excellent cycling stability, with a capacity retention of over 90% after 1000 cycles at 2C (100 mAh g^{-1}) with a high 1st discharge capacity of 180 $mAhg^{-1}$ at 30 °C. The OFA Li_6PS_5Cl-NMC811 system demonstrated superior performance, highlighting the effectiveness of the Li_2S-free synthesis method in achieving high-performance solid-state batteries.

We believe that the results of this study have the potential to revolutionize SSE and ASSLB production, significantly contributing to the scientific community's understanding of cost-effective synthesis methods and paving the way for future advancements in one-pot co-precipitation techniques.

Rare-Earth Fluoridesulfide Compounds with Fluoride Ion Conducting Layers ShintaroTachibana[1], ChengchaoZhong[1], KazutoIde[2], HisatsuguYamasaki[2], TakeshiTojigamori[2], HidenoriMiki[2], TakashiSaito[3], TakashiKamiyama[3], KeijiShimoda[1] and YukiOrikasa[1]; [1]Ritsumeikan University, Japan; [2]Toyota Motor Corporation, Japan; [3]High Energy Accelerator Research Organization(KEK), Japan

All-solid-state fluoride-ion batteries (FIBs) are highly attracted attention due to high theoretical energy density and high safety compared with those of conventional lithium-ion batteries(LIBs)[1]. However, it is far from practical use because there is no solid electrolyte which exhibits high ionic conductivity and wide electrochemical potential window at room temperature like lithium-ion conductor. Most of the previously reported fluoride-ion conductors have been limited to the single-anion fluorides with fluorite-type, tysonite-type, and perovskite-type structures [2].
In the field of material sciences, mixed-anion compounds with more than more anions have recently attracted attention. Compared with single-anion compounds such as oxides and fluorides, mixed-anion compounds have the possibility to exhibit innovative functions due to their specific crystal and coordination structure[3]. In mixed anion compounds, combinations of anion species with different ionic radius result in anion-order structures[4]. Fluorosulfides, which contains S^{2-} and F^- with largely different ionic radii, are ideal for creating anion-ordered structures suitable for fluoride-ion conduction. To our best knowledge, there is few reports on the fluoride-ion conductor materials containing mixed-anion compounds.
In this study, we synthesized rare-earth fluorosulfides compounds by solid-state reaction under vacuum[5]. In the crystal structure of these fluorosulfides, the fluoride- and sulfide-ion layers are present across cation layers. The separation of fluoride and sulfide ions is attributed to the difference anionic size. The presence of multiple anions results in the formation of an anion-ordering two-dimensional crystal structure with fluoride ion conducting layers, which cannot be realized for single-anion compounds. The material development of fluoride ion conductors using flurosulfide compounds is expected to increase crystal structure variations with fluoride-ion conduction pathways.

Pumice Additives in Iron Oxide for Solid-State Lithium-Ion Batteries Ping-HuanTsai, Tri-RungYew and Kuo-TzuHao; Tsinghua University, Taiwan

Solid-state lithium-ion batteries are indispensable for the next-generation energy storage device because of their safety and lightweight. High-capacity, low-cost, earth-abundance, and low flammability make iron oxides a promising active material for solid-state batteries. However, one of the shortages of both iron oxide actives and solid-state batteries is poor ionic conductivity, causing the short cycle life of batteries.

Pumice, a natural silicon oxide-based porous material formed through volcanic activities, is selected as an additive candidate in iron oxides for solid-state battery applications. Pumice is expected to act as an ion transport path that can effectively reduce the diffusion path length between actives, resulting in lower impedance and overpotential. Therefore, it will lead to a higher rate-capability, shorter reaction time, and enhanced retention. Besides, pumice is earth-abundant and environmentally sustainable. Utilizing pumice as an additive offers a simple method to recycle flooding volcanic pyroclastic flow.

The composition of iron oxide actives with pumice additives will be optimized. The actives will be mixed with carbon black (super P), carboxymethyl cellulose (CMC), and styrene-butadiene rubber (SBR) to form a water-based slurry. The slurry will be further coated on a copper foil through the doctor-blade coating process. The fabricated electrode will be dried in a vacuum oven and then assembled into batteries. The pumice morphology and structure will be characterized by field-emission scanning electron microscopy (FE-SEM) and energy-dispersive X-ray spectrometry (EDX), respectively. Galvanostatic charge-discharge (GCD) and electrochemical impedance spectroscopy (EIS) analyses will be applied to analyze the charge/discharge cycle life, Coulombic efficiency, and impedance resulting from the addition of pumices. These analyses will be used to investigate the mechanism of pumice additives in iron oxides.

This work will offer insights into using pumice additives to enhance the retention of solid-state batteries for future applications.

Titanium Oxide-Based Additives in Iron Oxides as Electrode Materials for Solid-State BatteriesI HanLee, Jia-ChienMa and Tri-RungYew; National Tsing Hua University, Taiwan

Clean energy technologies, such as electric vehicles (EVs) and stationary energy storage systems (ESSs), have become flourishing along with the increasing awareness of environmental protection in recent years. Rechargeable solid-state batteries (SSBs) exhibit the advantages of light weight, high energy density, good rate-capability, and safety, making them a vital choice for the applications of consumer electronics, EVs, and ESSs. However, poor structural stability and high cost impede the development of SSB's applications.
Iron oxides exhibit the merits of high theoretical capacity, earth-abundance, lower carbon emission, and non-toxicity, suitable for being active materials in SSBs. However, iron oxides show the drawbacks of low electrical and Li-ionic conductivities, high volume expansion and easy to crack, and excess solid-electrolyte interphase (SEI) layers, during charge/discharge reactions. In this work, titanium oxide-based additives will be applied to iron oxides to improve structural stability and ion conductivity. It is expected that the additives can function as stabilizers to improve the structural stability of iron oxides, which can improve cycle stability and rate capability.
The composition of titanium oxide-based additives in iron oxides will be optimized. The additives powders will be mixed with carbon black (super P), carboxymethyl cellulose (CMC), and styrene-butadiene rubber (SBR) to form an aqueous-based slurry. Following that, the slurry will be coated on a copper foil by doctor-blade casting as an electrode and baked in a vacuum oven. After battery assembling, galvanostatic charge-discharge (GCD) and electrochemical impedance spectroscopy (EIS) analyses will be applied to analyze the improvement of cycle-life retention, Coulombic efficiency, and impedance reduction attributed to titanium oxide-based additives. Besides, after charge/discharge cycling, the active materials will be characterized by field-emission scanning electron microscopy (FE-SEM), energy-dispersive X-ray spectroscopy (EDX), and X-ray diffraction (XRD). The results of this work will provide an innovative approach to improving the retention of SSBs by adding additives in iron oxides.

Innovative Gel Polymer Electrolyte for Safe and Long-Lasting Active Implantable Medical Devices MikeMolinski[1], HaileySimon[1], BrianChiou[2] and ArijitBose[2]; [1]Audiance, Inc., United States; [2]University of Rhode Island, United States

Active implantable medical devices (AIMDs) play a pivotal role in modern healthcare, offering advanced therapeutic solutions for a variety of medical conditions. The power sources within them play a critical role and have demanding performance attributes, namely high energy density, long-term reliability, and exceptional safety. Primary lithium-ion batteries have emerged as a popular choice due to their high energy density, predictable performance, and long cycle life. However, their implementation in AIMDs faces certain limitations, primarily concerning safety considerations as novel more capable devices demand higher battery capacities. AUDIANCE has developed an innovative safe, stable, and non-flammable gel polymer electrolyte (GPE) that address the limitations of current lithium-ion battery technologies and unlocks the potential for use of rechargeable or secondary lithium-ion batteries in AIMDs.

Consisting of a carrier, a high molecular weight polymer, and a conductive lithium salt, the GPE exhibits excellent lithium-ion conductivity of 2.58 x 10^{-3} S/cm at 37°C and demonstrates a wide electrochemical stability window with a polymer decomposition voltage of about 4.2V. Notably, the mechanical properties of the high viscosity electrolyte are highly composition-dependent, which enables precise control over its rheology, facilitating processability and preventing electrolyte leakage while infiltrating electrode pores. Extensive safety testing has validated the reliability of AUDIANCE's technology. In flammability tests, the electrolyte self-extinguishes, ensuring enhanced safety even during catastrophic failure events. Moreover, nail penetration, overcharge, and external short circuit tests conducted on cells fabricated with the GPE resulted in minimal temperature change and no gas emissions. Long-life cycle testing of LTO|LFP cells demonstrated negligible capacity loss over 4,750 cycles at 37°C, underscoring the stable electrochemical performance and prolonged lifespan of AUDIANCE's batteries.

The outcomes of this research present a promising pathway towards safer and more efficient power sources for AIMDs. The utilization of the novel GPE holds the potential to enhance the reliability and longevity of implantable medical devices, paving the way for novel therapeutic interventions and improving the quality of life for countless patients worldwide.

8:00 PM EN02.03 .27
Thin Single-Ion Solid-State-Electrolyte Film using Covalent Organic Frameworks for Lithium-Ion Cells Rak HyeonChoi and Hye RyungByon; Korea Advanced Institute of Science and Technology, Korea (the Republic of)

Organic solid-state electrolytes have emerged as a solution for developing less flammable and flexible batteries. While polymeric electrolytes have been developed for decades, their practical applications have been hindered by low ionic conductivity and high activation energy at room temperature. Alternatively, a new class of porous and crystalline organic materials called covalent organic frameworks (COFs) shows promise. COFs are highly crystalline materials where desired molecules are periodically bonded to form a two-dimensional layer. The well-ordered stacking of these organic layers extends the three-dimensional structure while creating porous channels. COFs are also mechanically robust and chemically stable, unlike soft and non-crystalline polymer films. By introducing anionic pendants and Li^+ ions, COFs have been demonstrated as single-ion conductors in previous studies [1,2]. However, the ionic conductivity was still moderated (>10^{-5} S cm^{-1}) at room temperature. This limitation can be attributed to the powder-like form of COFs and their typical fabrication into pellet-type electrolytes, which results in high thickness (>100 μm) and significant interfacial resistances (>1 kΩ), even when mechanical pressure is applied. These factors contribute to challenges such as nonuniform interfacial contact with electrodes and long Li^+ transport paths.
Here, we developed thin-film COF electrolytes and demonstrated improved Li-ion cell performances. We fabricated COF films with a thickness of approximately 35 μm using a one-pot synthetic method at room temperature. The interfacial resistance of the COF film with metallic Li was approximately 224 Ω, which was 8 times lower than that of the pellet-type ones. For molecular designs, Li^+ ions and sulfonate functional groups were included in a hexagonal unit of COF. The Li^+ conductivity of the COF film was highly dependent on the concentration of sulfonic groups and the crystallinity of the film. Higher Li^+ contents, corresponding to a higher number of sulfonic groups, and better crystallinity resulted in higher ionic conductivity and lower activation energy. Consequently, we achieved an optimum Li^+ conductivity and transference number of 1.01 × 10^{-4} S cm^{-1} and 0.91, respectively, at room temperature. The COF film also exhibited excellent performance in Li|Li symmetric cells at room temperature, with over 1000 hours at 0.1 $mAcm^{-2}$ and 0.1 $mAhcm^{-2}$. Additionally, Li|Li$FePO_4$ cells using the COF electrolyte delivered a capacity of 150 $mAhg^{-1}$ at 0.1 C for 150 cycles with negligible capacity fading. In this presentation, I will discuss details of COF film synthesis, several COF designs and their characteristics, and COF-based Li-ion cell performances.

Enhancing Low-Pressure Operability of Si Anodes in All-Solid-State Batteries Through Interlayer Engineering and Prelithiation SeunggooJun, Yong BaeSong, HaechannaraLim, Ki HeonBaeck, Eun SuhLee and Yoon SeokJung; Yonsei University, Korea (the Republic of)

The growing demand for vehicle electrification and energy storage systems has spurred research on high-energy-density lithium-ion batteries (LIBs). Solidifying electrolytes using inorganic materials has gained interest due to its potential to enhance energy density and safety. However, challenges, such as dendritic growth and limited Li^+ diffusion, have impeded the integration of Li metal anodes (LMAs) in all-solid-state batteries (ASSBs). Si anodes, not constrained by the same issues, could present an advantageous alternative. However, in LIBs, Si anodes undergo severe volume changes (>300%) during charge-discharge cycles, leading to fractures and a loss of electrical connectivity. To overcome this, Si is often electrically wired with nanostructured carbonaceous materials like carbon nanotubes (CNTs) and graphene. While this strategy can also be applied to ASSBs, it raise concerns about adverse reactions between carbon materials and SEs. Recent studies reported that the performance of Si ASSBs could be enhanced by eliminating solid electrolytes and carbon additives in Si electrodes, demonstrating 80% capacity retention after 500 cycles at 50 MPa. This performance is attributed to the mechanically sintering ability of lithiated Si and the lack of destructive side reactions. However, the high operating pressures used need to be addressed for practical applications.
In our study, we present a comprehensive Si ASSB design incorporating a thin metallic interlayer at the Si electrode-SEs interface and integrating the Si electrodes with CNTs. This interlayer allows Li^+ transport maintenance across the interface despite the dimensional changes of Si anode, demonstrating improved performance of ASSBs under low-pressure conditions.

Stabilizing Li Metal/Argyrodite Interface for Sulfide-Based All-Solid-State Lithium Batteries Hui-TaeSim, OHMyung-keun, Ye-EunPark, Hyo-JinKim and Dong-WonKim; Hanyang University, Korea (the Republic of)

The achievement of carbon neutrality is the first step in addressing the issue of global climate change. Rechargeable batteries with high energy density are one of the promising techniques to reduce carbon emission. After the commercialization of lithium-ion batteries (LIBs) in 1991, rechargeable LIBs have been universally applied in portable electronic to electric vehicles. However, the conventional LIBs using liquid electrolytes have serious safety problems such as flammability, solvent leakage, and explosion under unusual conditions. In addition, the use of Li metal anode (3860 mAh g^{-1}) with high specific capacity tends to exacerbate risks due to the interfacial side reactions and dendrite growth of lithium. In this respect, all-solid-state lithium metal batteries (ASSLMBs) have attracted attention as the most promising high energy density storage system. Among various solid electrolyte systems, sulfide electrolytes are being widely studied due to their high ion conductivity and ductile property. However, the lithium dendrite growth can be also occurred in sulfide based-ASSLMBs because of voids, cracks, grain boundaries in solid electrolyte, and side reactions between Li and solid electrolyte.
In this work, the surface modification of Li was performed using $LiNO_3$ with nitrogen-based solvent. The protective layer formed on Li metal was composite of organic and inorganic materials based on Li_3N. The symmetric Li/solid electrolyte/Li cell with protective layer exhibited good cycling stability without short circuit, indicating the uniform plating/stripping of lithium and good interfacial properties. Consequently, an all-solid-state lithium battery assembled with $LiNi_xCo_yMn_{1-x-y}O_2$ cathode delivered a high initial discharge capacity and exhibited good cycling stability.

Unlocking High-Performance Quasi-Solid-State Multivalent Metal Ion Batteries Sarah K.W.Leong, WendingPan and DennisLeung; University of Hong Kong, Hong Kong

In the pursuit of advancing post-Li-ion battery technology, the development of rechargeable Mg batteries has shown tremendous promise due to their high theoretical capacity, material abundance, and low cost. However, the passivating nature of Mg, particularly in aqueous solutions, presents a significant obstacle. The practicality of Mg anodes within aqueous electrolytes has been largely dismissed due to the perceived lack of reversibility and narrow electrochemical window, leading researchers to focus on non-aqueous systems. Nonetheless, non-aqueous electrolytes also suffer from poor ionic conductivity, high cost, and safety hazards such as flammability and toxicity.

This work addresses these challenges by introducing a pioneering quasi-solid-state magnesium-ion battery (QSMB), designed to harness the advantages of both aqueous and non-aqueous systems. By immobilizing the electrolyte's water network, the polyethylene polymer polymer suppresses the hydrogen evolution reaction at the magnesium metal anode, and achieves a fully reversible Mg dissolution and deposition chemistry through a Cl-induced transformation of the impermeable passivation film into a conductive metallic oxide complex.

The quasi-solid-state electrolyte also plays a major role in attaining high voltage and capacity by facilitating true multivalent Mg ion storage. Through confining the hydrogen bond network, the electrolyte effectively impedes proton insertion which competes with multivalent metal-ion insertion in aqueous batteries. In this study, in-situ characterizations reveal that the electrolyte promotes the high-voltage (de-)intercalation of both Mg^{2+} and $MgCl_3^-$ ions instead, delivering unparalleled battery performance.

The QSMB showcases a remarkable energy density of 264 Wh kg^{-1}—nearly five times higher than its aqueous Mg-ion counterparts, and a voltage plateau (2.6-2.2 V) that surpasses other Mg-ion batteries. Moreover, it retains an impressive 90% capacity after 900 cycles, even at subzero temperatures (-22°C). By leveraging the high ionic conductivity from aqueous systems and a broad electrochemical window from non-aqueous systems, the quasi-solid-state battery represents an innovative avenue for the design of high-performing Mg-ion batteries.

More importantly, this study provides invaluable insights into interphase passivation, metal stripping and plating mechanisms at the anode, and ion storage regulation at the cathode to produce high-energy, rechargeable, solid-state battery technologies. This quasi-solid-state approach could be extended to the design of other multivalent metal-ion batteries, including Zn-ion and Al-ion batteries, demonstrating the potential for broader applications.

Mechanical Design Strategies in Facilitating Durable Ni-Rich Layered Cathodes for Lithium-Ion Batteries SanghoYoon, JaewoonLee and DuhoKim; Kyunghee University, Korea (the Republic of)

Along with the growth of the electric vehicle market, the Ni-rich layered oxides($x \geq 0.8$) for cathode active materials have attracted great attention because their high Ni content provides high-energy-density to meet the needs of high-energy-density applications. However, the large amount of Ni often results in severe micro-crack propagation that causes capacity degradation due to structural instability such as heterogeneous phase transformations and anisotropic structural changes under high charging voltage conditions. Until recently, many previous studies have focused on inhibiting micro-crack formation due to structural instability, specifically the anisotropic lattice variation that leads to mismatch of primary particles in Ni-rich layered oxides upon repeated (de)intercalation. While the degradation mechanisms by which anisotropic lattice variation act between primary particles have been identified, the mechanism inside the particles is not yet fully understood. In this regard, a more systematic and comprehensive study could be required to explore the mechanisms of anisotropic behavior inside particles in Ni-rich layered oxides. Additionally, through advanced experimental analysis and computational calculations, a comparison of the thermodynamic features of Ni-rich layered oxides (Li[NixCoyMz]O2, where M represents the transition metal) reveals similar phase transitions (H1 (hexagonal 1)→M (monoclinic)→H2→H3) regardless of the transition metal M. However, the cycle retention varies significantly depending on the composition of the transition metal.

In this work, to understand these undesired phenomena, we systematically apply thermodynamic, chemo-mechanic, and physicochemical perspectives to analyze the correlation between (in)coherent phase separation and volume conservation behavior to propose an opposite view of the traditional aspect of anisotropic lattice variation and a new design strategy for single-crystal Ni-rich layered cathodes that reduces the internal stress between separated phases to zero grain internal stress. First, we analyzed the (in)coherent phase separation of Li1-x[Ni10/12Co1/12Mn1/12]O2 (NCM) and Li1-x[Ni10/12Co1/12Ti1/12]O2 (NCT) by comparing the thermodynamic phase stability during the whole delithiation process along the formation energy of mixing enthalpy and found that NCT was thermodynamically more stable and relatively coherent phase separation occurred than commercial NCM. Furthermore, for a direct understanding of the cycle degradation mechanism by (in)coherent phase separations, we calculate the directional lattice strain and volumetric variation for NCM and NCT combined with phase transition. Interestingly, upon volume change, both oxide models exhibited volume-conserving regions due to anisotropic lattice changes, which resulted in a relative decrease in internal stress. Moreover, the NCT exhibits near zero volumetric lattice variation. Based on the correlation between thermodynamics and the volumetric lattice misfit, the oxygen bond populations for both oxide models are identified, and a severe reduction is obsreved across the entire oxygen framework in the incoherent phase separation model NCM, whereas a preserved feature is observed in the coherent phase model NCT. These systemically novel concepts underpin the Ti-induced “zero volumetric misfit” concept makes coherent phase separation. These concepts are expected to play a global role in the layered oxide cathodes, and it provides a crucial design strategy leading to the enhancement of cycle retention for durable high-energy-density LiBs.

8:00 PM EN02.03 .32
Effect of Various Carbon Nanomaterials as Conductive Additives in EDLC VladimirPavlenko[1], ZhanibekAyaganov[2] and AnnieNg[1]; [1]Nazarbayev University, Kazakhstan; [2]Al-Farabi Kazakh National University, Kazakhstan

A comprehensive study was performed to investigate the effect of different carbon nanomaterials including single-walled carbon nanotubes, graphene nanoplatelets, activated carbon nanofibers and fullerene C60 on the performance of aqueous-based electric double layer capacitors (EDLC) based on a neutral aqueous electrolyte (Li2SO4). The performance of commercially available and laboratory synthesized carbon nanomaterials having different morphologies were investigated and compared with carbon black C45 which is widely used as conductive additive. Electrochemical studies were performed by cyclic voltammetry, galvanostatic charge-discharge and impedance spectroscopy. It is found that conductive additives exhibit limited effectiveness in EDLC capacitance at low current densities, while at high current loads the discrepancies of EDLC’s performance become pronounced. The use of activated carbon nanofibers having large surface area synthesized from polyacrylonitrile by electroforming increases the specific capacitance by 16%, energy efficiency by 7% and energy densities by 22% at current densities equal to 20 A/g. The addition of conductive additives with a small specific surface area leads to a decrease in the characteristics of the EDLCs. The results provide important information for the community to develop new energy conversion and storage devices.

Charge Separation Nanoclay in Gel Polymer Electrolytes: Empowering Sustainable Anion Storage SunghoKim and SoojinPark; Pohang University of Science and Technology, Korea (the Republic of)

The dual-ion battery (DIB) represents a significant advancement in sustainable energy storage. It employs intercalation-type graphite as a cathode, enabling anion penetration into interlayers during high-potential charges, resulting in an elevated operational voltage exceeding 5V. DIBs distinguish themselves from conventional lithium-ion batteries by moving away from transition metal oxide cathodes, like Lithium cobalt oxide (LCO), offering a more eco-friendly and cost-effective alternative. However, DIBs face challenges due to high operating voltages causing electrolyte decomposition, which leads to a passivation layer on the electrodes, increased resistance, and potential performance degradation.

To tackle the issue of electrolyte decomposition, researchers are exploring high-concentration electrolytes (HCE) enriched with lithium salts. These electrolytes predominantly contain contact ion pairs (CIP) and aggregates (AGG), enhancing electrochemical stability. Notable efforts have been made using a 4.0 M LiFSI in TMS, but increased salt concentrations lead to higher viscosity, reducing ionic conductivity.

Another approach is incorporating gel polymer electrolyte (GPE), known for its high voltage stability, moderate ionic conductivity, and safety attributes. However, as ionic conductivity increases, mechanical integrity decreases. To address this, functional groups are added to the polymer matrix, reducing anion-solvent interactions and promoting a stable anode interface. Nevertheless, a trade-off remains between physical rigidity and ionic conductivity.

Additives are essential to enhance GPE mechanical stability and modify ion solvation. These additives include carbon-based conductive fillers, ceramics, polymers, and nanoparticles, improving ion conduction and cell performance. Facilitating anion mobility and integration is crucial for optimizing dual-ion battery performance, necessitating additives that dynamically interact with anions, promote a stable surface interface, and align with sustainability standards.

This study explores GPEs infused with surface-charged nano clay as an innovative additive for DIBs. Nanoclay, due to its abundant availability and non-toxic nature, enhances GPE's mechanical resilience and influences cation and anion solvation structures. The investigation involves a comparative analysis of three nano clay variants with distinct characteristics. Zeta potential, nuclear magnetic resonance (NMR), molecular dynamics (MD) simulations, and density functional theory (DFT) calculations confirm the findings.

Halloysite (HS), with its tubular morphology, stands out as a superior candidate. It fosters a slender, homogeneous cathode electrolyte interface (CEI) with reduced anion-solvent interactions and fewer salt decomposition products. The tubular structure of HS improves anion transport pathways, optimizing DIB operation. Consequently, a DIB full-cell incorporating HS-GPE exhibits impressive rate capability, exceeding 60 mAh/g at 50 C-rate, and remarkable stability, sustaining over 5000 cycles at 20 C-rate.

8:00 PM EN02.03 .34
Unexpected Lowering of Charge Transfer Resistance in Ultra-Long Cycled (>30,000 cycles) Solution-Processed Laminar-Crystalline Li_3VO_4 Anodes TejveerS. Anand, AashishJoshi, AmitGupta and MadhusudanSingh; Indian Institute of Technology Delhi, India

Transition metal oxide-based anodes such as Li_3VO_4 (LVO) offer alternatives to commercial graphite based device architectures in lithium-ion batteries. Traditional methods of synthesis of LVO - solid state synthesis and hydrothermal, have typically resulted in moderate half-cell (LVO||Li) lifetime, thereby limiting its practical applicability [1]. In this work, we explore the impact of an alternative synthesis - a surfactant-free sol gel process on long cycling stability and an unexpected high charge (C)-rate performance. Ammonium metavanadate (Sigma-Aldrich) precursor was mixed in 2-methoxyethanol to form a solution (A), while lithium acetate dihydrate was mixed in the same solvent to form another solution (B). Solution B was added dropwise to A while being vigourously stirred (48 hr, 60°C). The product LVO was annealed (800 °C, 4 hr) prior to materials analysis. Powder X-ray diffraction (PXRD, Rigaku Ultima) reveals an orthorhombic phase with the Pmn21 space group [2], with Rietveld refinement yielding lattice constants: a=5.448 Å, b=6.327 Å, and c=4.949 Å. Solid-state UV-Vis spectra (Perkin-Elmer) reveals a wide band gap (3.95 eV). High-resolution transmission electron microscopy (HRTEM, JEOL with a selected area electron diffraction (SAED) attachment) data shows non-ring like diffraction spots, suggesting a high degree of crystallinity, with formation of laminar flakes. The active material (LVO) was mixed with super-P carbon black: carbon multiwall nanotubes with n-methyl pyrrolidinone with polyvinylidene fluoride (PVDF) binder to form a slurry, subsequently coated on a copper foil and dried at 80°C. Electrodes were punched out from the coated copper foil, and assembled using a standard process to form a CR2016 cell. The LVO||Li half-cell was found to deliver a capacity (Biologic BC810 battery cycler/Neware) of 764 mAh/g at a current density of 0.7 A/g when deeply discharged to 0.02 V. During the rate performance test; there is a 10.26% decrease in the intercalation potential of the cell, with a change in current density from 0.7 A/g to 3.5 A/g. Further testing of the cell at a current density of ~13.5 A/g for over 30,000 cycles has shown that it can still deliver a specific discharge capacity of ~155 mAh/g at the 15000^{th} cycle (asymptotic point), with a coloumbic efficiency (CE) of >95 %. After 30000 cycles of persistent deep charging (3 -> 0.02V), the cell can still deliver a capacity between 100-160 mAh/g. The estimated fading in the discharge capacity in the cycle range [15000, 30000] is ~0.002 mAh/g. We observe a rise in the initial capacity of the LVO||Li cell till it reaches the asymptotic point. Electrochemical impedance spectroscopy (EIS) measurements for aged cells indicate a lower charge-transfer resistance compared to the fresh cell at the discharge state, suggesting that the solid electrolyte interface (SEI) layer holds no barriers for lithium ions diffusion inside the material. The pre-lithiated LVO||Li cell is combined with the commercially available $LiFePO_4$ (LFP) cathode to form a full cell using a similar assembly procedure. The full cell is cycled (>1000 cycles) with an initial capacity of 165 mAh/g at 0.15 A/g between 1-3.5 V. Interestingly, post-cycling TEM results indicate that the laminar morphology remains intact even after 30,000 cycles of continuous charging and discharging under high-rate conditions. We are carrying out additional ex-situ analysis, including techniques such as time-of-flight secondary ion mass spectrometry (ToF-SIMS) to elucidate the distribution of Li and operation byproducts such as the SEI layer in the cycled cell for better understanding of the mechanism.

Three-Dimensional Mesopore-Rich Hierarchical Carbon Derived by Metal-Organic Framework *In-Situ* Anchored on Silk Fiber for Ultrahigh Capacitance/Surface Area Ratio SupercapacitorsSyun HongChou, Ta-ChungLiu and San-YuanChen; National Yang Ming Chiao Tung University, Taiwan

Heteroatom-doped hierarchical porous carbonaceous materials are promising supercapacitor electrode materials due to their large energy density, decent electronic conductivity, and efficient pore kinetics for ion migration. Here, a unique N-doped honeycomb-like porous carbon engineered by carbonized silk fibroin (SF) scaffold functionalized with a cobalt-based metal-organic framework (MOF, ZIF-67) is demonstrated for supercapacitor electrode (AC-Z@SF). The well-dispersive Co ions were anchored in silk fibroin via coordination covalent bonding as seeding sites for in-situ growth, thereby preventing the aggregations and promoting an instantaneous interaction between activation agent and active carbon atoms to generate interconnected micro/meso/macropores instead of blocking them during carbonization. The unique honeycomb-like interconnected mesopore-rich structure, AC-Z@SF, exhibits 431 F/g at 0.5 A/g and retains 70 % (300 F/g, a value which is 5 times higher than the MOF-derived carbon) at an ultra-high current density of 50 A/g, as well as an excellent lifetime of 89% after 20,000 cycles. The first time this study unveils that interconnected small-sized mesopores (2-10 nm) play an important role in boosting the SSA utilization for electric double-layer capacitance and providing a new direction for the design of hierarchical carbon materials.

8:00 PM EN02.03 .36
Synthesis and Characterization of Transition Metal Doped Lithium Composites for Application in Lithium Ion Based Batteries NeerajChauhan[1,2], Amrit PalToor[1], StefanKrause[2] and AlokSrivastava[1]; [1]Panjab University, India; [2]University of Birmingham, United Kingdom

The research aims to enhance the physicochemical and electrochemical properties of cathode materials for application in lithium-ion batteries, specifically Li_2TMSiO_4 (TM=Transitions metals) silicates. These materials have high theoretical capacity, but most often suffer from poor conductivity. To improve their performance, methods like particle size reduction, coating, and ion doping were being employed. Among different transition metals-based silicates, Li_2MnSiO_4 is of particular interest, but often faces issues with cycling performance due to low conductivity and stability. Further, the structural characterization of the different lithium composites had shown that Li_2CoSiO_4 exhibited high crystallinity with an orthorhombic crystal structure. Therefore, trivalent ions doping and anionic doping were carried out to enhance conductivity and electrochemical properties of Li_2MnSiO_4 and Li_2CoSiO_4 silicates. The resulting silicates i.e. $LiMnAlSiO_4$ and $LiMnCoAlSiO_4$ displayed patterns similar to Li_2MnSiO_4, indicating a mixture of polymorphs. The addition of dopants did not only alter the structure but significantly improves the properties of the silicates. In terms of electrical characterization, cyclic voltammetry measurements showed different potential values for the composites, where Li_2CoSiO_4 displayed cathodic and anodic potentials with slight variations and a decrease in cathodic current after 10 cycles. $LiMnAlSiO_4$ showed stable potentials but a 28% drop in current, while $LiMnCoAlSiO_4$ had minimal changes in potentials and currents. Moreover, the electrochemical impedance spectroscopy demonstrated that $LiMnAlSiO_4$ and $LiMnCoAlSiO_4$ had undergone least charge transfer resistance compared to Li_2CoSiO_4, indicating improved Li^+ ion diffusion. Based on these results, $LiMnCoAlSiO_4$ showed better stability, resistance and conductivity compared to $LiMnAlSiO_4$ and Li_2CoSiO_4. Further investigations will be carried out to explore the thermal stability of the composites beyond 400°C and to evaluate the potential of $LiMnCoAlSiO_4$ as an electrode material. Overall, the study demonstrated the ortho-rhombic structures of transition metal-doped Li_3SiO_4 composites and highlighted the superior performance of the quaternary composite $LiMnCoAlSiO_4$ in terms of electrical conductivity, capacitance, and structural stability.

8:00 PM EN02.03 .37
High Conductivity in Na^+-Ion Conducting Solid Electrolytes for Na-Ion Batteries Through a Co-Doping Strategy XuankaiX. Huang and IsaacAbrahams; Queen Mary University of

London, United Kingdom

Rechargeable batteries are regarded as the most promising energy storage technology because of their reliability and high energy conversion efficiency. Although Li-ion batteries (LIBs) have been widely used in portable electronic devices, Na-ion batteries (NIBs) are considered as a potential candidate to replace LIBs because of their non-toxicity, low cost, and elemental abundance.
Solid state sodium-ion batteries are seen as potentially cheaper and safer alternatives to current lithium-ion battery systems. The replacement of the presently used liquid electrolytes by non-flammable solid electrolytes is an important avenue to create safer batteries, while the high natural abundance of sodium compared to lithium would allow for significant cost reduction. The sodium superionic conductor, NASICON, first reported by Hong, is one of the best-known sodium-ion conducting solid electrolytes, displaying high bulk ionic conductivity and good stability toward NASICON -based electrodes. However, the practical use of NASICON has been impeded by low ion mobility at room temperature and poor interfacial connectivity.
Here, the improvement of total conductivity has been achieved via La and Zn co-doping of NASICON. Total conductivity values of 4.68×10^{-3} S cm^{-1} at room temperature and 2.89×10^{-2} S cm^{-1} at 100 °C were obtained for NZSP-LZ-0.2, which are amongst the highest values recorded for a NASICON based system. Furthermore, the system shows good air stability and could represent a suitable material for application in the field of Na-ion batteries. Symmetric cells with sodium metal as electrodes (Na| NZSP-LZ-0.2 |Na) are assembled and cycled stably for over 3000 cycles at a current density of 0.2 mA/cm^2.

Thermodynamics of Multi-Sublattice Battery Active Materials: From an Extended Regular Solution Theory to a Phase-Field Model of $LiMn_yFe_{1-y}PO_4$PierfrancescoOmbrini; Delft University of Technology, Netherlands

Phase separation during the lithiation of redox-active materials is a critical factor affecting battery performance, including energy density, charging rates, and cycle life. Accurate physical descriptions of these materials are necessary for understanding underlying lithiation mechanisms, performance limitations, and optimizing energy storage devices. This work presents an extended regular solution model that captures mutual interactions between sublattices of multi-sublattice battery materials, typically synthesized by metal substitution. We apply the model to phospho-olivine materials and demonstrate its quantitative accuracy in predicting the composition-dependent redox shift of the plateaus of $LiMn_yFe_{1-y}PO_4$ (LFMP), $LiCo_yFe_{1-y}PO_4$ (LFCP), $LiCo_xMn_yFe_{1-x-y}PO_4$ (LFMCP), as well as their phase separation behavior. Furthermore, we develop a phase-field model of LFMP that consistently matches experimental data and identifies $LiMn_{0.4}Fe_{0.6}PO_4$ as a superior composition that favors a solid solution phase transition, making it ideal for high-power applications.

8:00 PM EN02.03 .39
Formulating Electron Beam-Induced Covalent Linkages for Stable and High-Energy-Density Silicon Microparticle Anode MinjunJe and SoojinPark; Pohang University of Science and Technology, Korea (the Republic of)

High-capacity silicon (Si) materials hold a position at the forefront of advanced lithium-ion batteries. The inherent potential offers considerable advantages for substantially increasing the energy density in batteries, capable of maximizing the benefit by changing the paradigm from nano- to micron-sized Si particles. Nevertheless, intrinsic structural instability remains a significant barrier to its practical application, especially for larger Si particles. Here, we first report a covalently interconnected system employing silicon microparticles (5 μm) and a highly elastic gel polymer electrolyte (GPE) through electron beam irradiation. The integrated system mitigates the substantial volumetric expansion of pure Si, enhancing overall stability, while accelerating charge carrier kinetics due to the high ionic conductivity. Through the cost-effective but practical approach of electron beam technology, the resulting 500 mAh-pouch cell showed exceptional stability and a high volumetric energy density of 1022 Wh L^{-1}, highlighting the feasibility even in current battery production lines.

8:00 PM EN02.03 .40
Hierarchical 3D Electrode Design with High Mass Loading Enabling High-Energy-Density Flexible Lithium-Ion Batteries JaehoJung, Dong-YeobHan and SoojinPark; POSTECH, Korea (the Republic of)

Flexible lithium-ion batteries (LIBs) have garnered considerable attention due to their increasing utilization in flexible and wearable electronic devices. However, the practical implementation of flexible LIBs in these devices has been hindered by the dual challenge of attaining both high energy density and exceptional flexibility. In this study, we introduce a hierarchical 3D electrode (H3DE) with a substantial mass loading capacity, which enables the creation of highly flexible LIBs boasting an exceptionally high energy density.
The H3DE boasts a bicontinuous architecture, ensuring that active materials and conductive agents are uniformly dispersed throughout the 3D framework, irrespective of the specific type of active material employed. This seamless integration of the electrode and electrolyte facilitates rapid ion and electron transportation, thereby enhancing redox kinetics and reducing internal cell resistance. Furthermore, the H3DE displays remarkable structural resilience and flexibility even under repeated mechanical deformations.
Capitalizing on these remarkable physicochemical attributes, pouch-type flexible LIBs employing the H3DE exhibit consistent cycling performance under various bending conditions. They achieve a groundbreaking energy density of 438.6 Wh kg^{-1} and 20.4 mWh cm^{-2}, as well as an areal capacity of 5.6 mAh cm^{-2}, surpassing the performance of all previously documented flexible LIBs. This research offers a practical solution for the development of high-energy-density flexible LIBs suitable for a wide array of energy storage devices.

8:00 PM EN02.03 .41
Pseudo-High Entropy Alloys for Ni-MH Batteries GulhanCakmak and HakanYüce; Mugla University, Turkey

With the increase in the demand for renewable energy sources with the decarbonization targets of the countries, energy storage systems are also developing rapidly. Among these systems, nickel metal hydride (NiMH) batteries stand out as a remarkable energy storage solution. Recently, several studies have clearly demonstrated that AB compounds are promising materials as a metal hydride (MH) electrode for Ni-MH batteries. The studies related to AB interstitial hydrides mainly focusing Ti-V based systems. Ti-Cr-V based alloys with an AB structure, can both absorb nearly 2.5 wt.% hydrogen and desorb hydrogen at 40 0C (Tamura, 2002). However, it is difficult to achieve a greater hydrogen absorption capacity in these systems because these alloys consist of relatively heavy transition metals. It could be possible to reach higher gravimetric capacities by using lighter elements. Mg-Co (Zhang, 2005), Mg-Ni (Shao, 2009), Mg-Ni-B (Shao, 2009) and Mg-Tm-V (Tm: transition metals) binary and ternary alloys have been successfully achieved with AB structure. A storage capacity of 3 wt.% was reported in a binary alloy with the compound MgCo (Zhang, 2009). The concept of “high entropy alloys” is a rather new concept which has drastically modified the alloy design. In this concept, the classical alloys which are based on a base metal with added alloying elements are replaced by a nearly equimolar multi-component alloys. With the development of the concept non equimolar compounds are also possible.
In this study we prepared Mg-containing AB multi-component alloys with light elements capable to store hydrogen. Here A is Mg due to its lightweight, high theoretical hydrogen storage capacity and abundance but Ni- is replaced by equimolar alloying elements. Thus, we aim to produce pseudo high entropy alloys in that Mg is still the dominant element. These $Mg_{0.5}Al_{0.125}Cr_{0.125}Ni_{0.125}Fe_{0.125}$ and $Mg_{0.5}Al_{0.125}Cr_{0.125}Ni_{0.125}V_{0.125}$ are tested electrochemically in Ni-MH batteries.

This work was supported by TUBITAK (The Scientific and Technological Research Council of Turkey) with project Number 121N774, which the authors gratefully acknowledge.

Deciphering Constriction Impedance in Solid State Batteries and its Connection to Ionic Conductivity SunnyWang, EdwardBarks and William C.Chueh; Stanford University, United States

Current constriction phenomena pose significant challenges at the Li metal interface of solid state batteries. Typically these effects are associated with contact loss and void formation during Li metal stripping. In this work, we use current biased and pressure dependent electrochemical impedance spectroscopy measurements alongside finite element modelling to clarify the different origins of constriction impedance at the Li metal interface. We show that constriction impedance is not solely derived from void formation and ionically resistive surface layers can also generate the same response. The relation between constriction and conductivity is also emphasized; ionically resistive components can significantly increase the constriction resistance in solid state batteries even with identical contact geometries.

8:00 PM EN02.03 .43
Study of Amorphous Vanadium Oxide Cathodes for Li-Ion Batteries Prepared by Reactive Magnetron Sputtering MackarenaBriceño, JuanFernandez, MarcosFlores and RodrigoEspinoza; Universidad de Chile, Chile

Within the technological development focused on lithium-ion batteries, vanadium pentoxide (V_2O_5) thin films have been a good candidate to be used as cathodic material due to their high-capacity charge, allowing to increase in the efficiency of lithium-ion batteries [1]. The technique of reactive magnetron sputtering allows the manufacture of homogenous thin films with low thicknesses and specific microstructure. In addition, with this technique we can generate different stoichiometries of vanadium oxides and specifically of V_2O_5 [2-3]. The formation of different vanadium oxides mainly depends on the oxygen content of the system [4]. The aim of this work is based on the preparation of thin films of vanadium oxides on steel substrate by reactive sputtering at different oxygen flows followed by reduction with hydrogen *in situ*, and their electrochemical evaluation as a potential cathode material. The target was metallic vanadium, while the plasma was argon (15 sccm) combined with oxygen at 1.25, 1.75, 2.25, 2.5, 3.0 and 3.25 sccm. The samples were characterized by XRD, EDS, Raman confocal spectroscopy, XPS and AFM. Cyclic voltammograms, the charge/discharge processes and cyclability of batteries were studied. XRD results demonstrated that the samples were amorphous for all the different oxygen flows. Raman analysis indicated the presence of the V-O-V bonding corresponding to a crystalline structure of the rhombohedral type of V_2O_5, by the vibrational stretching modes (143 cm^{-1}), and of the V=O bonding by the second flexion vibrational band (995 cm^{-1}) for the sample deposited at 3.0 sccm of oxygen. XPS established a correlation between the oxygen flow and the main V oxidation state: V^{+4} at 1.25 O-flow, V^{+4}/V^{+3} at 1.75 O-flow, and V^{+5} over 2.5 O-flow. The sample of 3.0 sccm of oxygen at 1 hour of deposition has a capacity of 295 mAh/g with a charge retention percentage of 96.5% at 50 charge/discharge cycles at 1C. The electrochemical behavior of the samples in reduction with hydrogen, shows a better retention percentage of 99.9% at 50 charge/discharge cycles at 1C, but not an improvement in the charge and discharge capacity, which is 213 mAh/g for the sample of 3.0 sccm of oxygen at 8% pf H_2.

We acknowledge the financial support of the national fellowship sponsored by ANID.

Single-Ion Conducting Borate Network Polymer Electrolytes for Lithium Metal Batteries with Excellent Rate Capability JingyiGao and Dong-MyeongShin; University of Hong Kong, Hong Kong

Although it is possible to readily estimate the theoretical energy densities of battery chemistries, the molecular processes that hinder practical performance are still unknown. Especially, the charging and discharging rates have become a major limiting factor in energy storage applications. Several solid electrolytes with exceptional ionic conductivity have been discovered, but all-solid-state batteries with high energy density have been only realized at limited rates (close to equilibrium), indicating that the minimization of overpotential requires to be considered to improve the rate performance other than the ionic transport. As single-ion polymer electrolytes, in which only selective cations are mobile across polymer electrolytes, facilitate minimizing not only the concentration gradient but also the overpotentials in the cells, such electrolytes pose great potential for overcoming these problems. However, single-ion polymer electrolytes have suffered from low ionic conductivity (<10-5 S cm-1 at ambient temperature) which is at least two orders of magnitude smaller than that of liquid electrolytes. In this talk, I will present our ongoing efforts to develop a new class of single-ion conducting polymer electrolytes using an interpenetrated network polymer with weakly coordinating anion nodes, with a wide electrochemical stability window, a high room temperature conductivity of up to 1.5×10^{-4} S cm^{-1}, and exceptional selectivity for Li-ion conduction ($t_{Li+} = 0.95$). Significantly, lithium metal battery prototypes containing these electrolytes are shown to outperform a conventional battery featuring a polymer electrolyte.[1-3]

Enabling Low T_g Ester-Functionalized Polysiloxane Electrolytes for Lithium-Metal Batteries Utilizing Semi-Interpenetrating Networks JannikPetry, MarkusDietel and MukundanThelakkat; University of Bayreuth, Germany

Lithium-ion battery technology is dominating the electrochemical energy storage industry. To access higher energy densities, all solid-state lithium-metal batteries (LMB) utilizing elemental lithium as anode material are of high research interest. Commonly used liquid electrolyte systems are not compatible towards lithium-metal anodes, due to lithium dendrite formation and safety issues during cycling; requiring new classes of solid-state ion-conductors. In this regard, polyether-based electrolytes have been studied extensively because of their low glass transition temperature (T_g) and high solubility of lithium salts. However, the strong Li-ion/ether-oxygen interactions result in low effective lithium-ion conductivities. In addition, the inherent crystallinity of poly(ethylene oxide) (PEO) allows its application only to temperatures above its melting point (65 °C).[1,2] Oligo-/polyester-based materials show comparable compatibility with lithium salts with a reduced Li^+-carbonyl interaction strength, resulting in improved lithium transference numbers and in turn higher effective lithium-ion conductivities. However, the commonly used poly(ε-caprolactone) (PCL) is semicrystalline still requiring elevated temperatures for optimum ionic conductivity.
In recent studies we demonstrated the application of diester-functionalized poly(meth)acrylates and poly(glycidyl propargyl ethers) as alternative to linear polyesters. The amorphous polymers show high room-temperature ionic conductivity and good applicability in LMBs.[3,4] The T_g of the polymers significantly influences the ion conduction properties, with lower glass transition temperatures resulting in improved ionic conductivities.
Here we propose poly(siloxane)-based diester functionalized polymer electrolytes to further decrease the T_g and improve the low temperature performance. Poly(methylhydro)siloxane was functionalized with an adipate-based (diester) side chain in a hydrosilylation reaction. The diester functionalized polysiloxane (PSi-adipate) exhibits an amorphous character and a very low T_g of -76 °C. Electrolytes consisting of 20 wt% LiTFSI and the PSi-adipate showed the highest ionic conductivities with $2.7x10^{-5}$ and $1.8x10^{-4}$ S cm^{-1} at 40 and 70 °C, respectively. Furthermore, the lithium transference number was determined as 0.7, compared to 0.5 for linear PCL, indicating a very efficient lithium-ion conduction mechanism. Unfortunately, the improvements in electrolyte characteristics and the low glass transition temperature are countered by the lacking mechanical integrity of PSi-adipate. An investigation of the depletion/plating reversibility of lithium ions at lithium electrodes revealed the necessity to mechanically reinforce the electrolyte. The strategy here is to design a semi-interpenetrating network (sIPN) electrolyte.
We therefore synthesized a PCL-based diacrylate as a network former to form a structure giving network. The network is formed in situ in the presence of the polysiloxane electrolyte to yield a semi-interpenetrating network (sIPN) electrolyte (PSi-adipate-sIPN). The network results in significant increase of the mechanical properties as observed in rheology measurements and effectively stabilizes the lithium interface during cycling. Further, the network incorporation in PSi-adipate-sIPN has no negative effect on the ionic conductivity. Finally, the PSi-adipate-sIPN electrolytes are evaluated in lithium-metal batteries with lithium iron phosphate (LFP)- and nickel manganese cobalt oxide (NMC)-based cathodes at different C-rates and temperatures.

Solid-State Batteries Based on Ionogel Electrolytes BruceS. Dunn, YunkaiLuo, BintaoHu and PatriciaMcNeil; University of California, Los Angeles, United States

Ionogels are pseudo-solid state electrolytes in which an ionic liquid electrolyte is confined in an organic or inorganic matrix. One well established ionogel synthesis route is based on sol-gel chemistry where silica precursors dissolved in an ionic liquid electrolyte undergo hydrolysis and condensation polymerization. By using an ionic liquid as the solvent, no evaporation occurs and the resulting material is a macroscopically rigid, nonporous material in which the ionic liquid is trapped by capillary forces in the nanometer sized pores in the silica network. Because of their unique architecture, ionogels maintain a nanoscale fluidic state and thus mitigate the interfacial resistances which commonly arise at solid-solid interfaces. Using this approach, we have been able to develop pseudo-solid state materials that possess the electrochemical, thermal and chemical properties of the ionic liquid. Moreover, sol-gel synthesis enables the precursor sol to penetrate porous electrodes before solidifying, a feature which is especially attractive for solid-state batteries.
Our recent work has been directed at developing ionogels for anode free solid-state batteries. In this work we take advantage of the ability to solvent exchange the ionic liquid phase with a liquid electrolyte which is more conducive to lithium plating and stripping. We start by synthesizing an ionogel based on dissolving the silane precursors (tetramethyl orthosilicate and methyltrimethoxy silane) in a 1-butyl-1-methylpyrrolidinium bis(fluorosulfonyl)imide (PYR14 FSI) ionic liquid, using acetic acid as a catalyst. After gelation, the ionic liquid is solvent exchanged with an electrolyte consisting of 1 M lithium bis-(tri-fluoromethylsulfonyl)imide (LiTFSI) in 1 : 1 of 1,3-dioxolane (DOL) and 1,2-dimethoxyethane (DME) with 1 wt% of $LiNO_3$. We have cycled Li/ionogel/Cu cells for over 500 cycles with minimal interfacial resistance and nearly 100% coulombic efficiency. We have also investiged the use of 3D printed copper electrodes and are able to plate and strip lithium at current densities up to 10 mA cm^{-2}. Anode-free solid-state batteries based on these solvent exchanged ionogels show that the ability to substitute the desired electrolyte for the ionic liquid offers an important new direction which, when coupled with their thermal and electrochemical stability, makes ionogel electrolyte materials a very promising approach for solid-state batteries.

Liquid Electrolytes and Solid Electrolytes for High Energy Lithium Batteries JunLiu[1,2]; [1]Pacific Northwest National Laboratory, United States; [2]University of Washington, United States

Batteries play a critical role in modern society. The electrification of transportation and deep decarbonization require the development and deployment of high energy, low-cost battery materials and technologies. Among the many different battery chemistries investigated, rechargeable batteries using lithium metal anode remain as one of the most feasible approaches for next generation high-performance and low-cost batteries. There are different approaches to design high energy cells: using liquid electrolytes or solid electrolytes. In the last several years, great progresses have been made in developing lithium metal compatible electrolytes for high energy rechargeable lithium batteries. The new electrolytes significantly reduced the reactions between the solvent molecules and the lithium metal. Combining these electrolytes with high capacity cathodes and proper cell design, practical pouch cells have been fabricated to achieve 350 to 450 Wh kg^{-1} specific energy and stable long cycle life. Solid electrolytes offer new opportunities to better control the lithium deposition and stripping processes during charge and discharge. However, solid electrolytes and all solid state cells are difficult to fabricate and scale up. New approaches are needed to enable the solid electrolytes to have good conductivity, good mechanical property and flexibility to accommodate the electrochemical and mechanical changes at the interfaces.

Functionalized Single-Ion Charge-Transfer Complexes as Solid-Sate Electrolytes for Lithium Batteries RomainKunert, NoëlineTessier, LaurentBernard and LionelPicard; CEA Grenoble, France

The global climate context has made us reconsider the way to generate and store energy in a more responsible way. The use of alternative renewable energy sources is tightly correlated to the development of electrochemical storage systems. A great example of this idea is with the transition away from vehicles using thermic combustion. While other technologies are slowly maturing, like hydrogen fuel cells, the golden standard in the industry remains lithium-ion batteries.[1] The rising demand for the mass production of portable electronic devices and electric vehicles now leads to new expectations.[2] To fulfill them, research is now focusing on the development of All-Solid-Sate Batteries. The replacement of the conventional liquid electrolytes by solid-state materials is expected to improve safety[3] while ensuring higher energy density with the use of lithium metal as negative electrode.[4]

Polymer-based electrolytes have gathered great attention since the first report of lithium ion conductivity in poly(ethylene oxide) in the 1970s.[5] Despite different upsides, these types of materials still show some limitations, especially considering ion conductivity at ambient temperatures. More recently, organic charge-transfer complexes (CTCs) have shown promising super-ionic conductivity in the solid-state at room temperature by associating a donor-acceptor organic couple with a lithium salt.[6] This specific chemical structure holds great potential to tune their electrochemical properties by changing the different partners (acceptor, donor and Li salt) and their molar ratios in the CTC.

In this work, we proposed to functionalize charge-transfer complexes to develop single-ion materials, expected to enhance mechanical and electrochemical properties for solid-state batteries.[7] We studied the covalent graphing of polyphenylene polymers with different anions derived from lithium salts conventionally used to develop solid-state electrolytes. We also used these types of single-ion polymers to develop charge-transfer complexes and analyzed their electrochemical properties. The ionic conductivity and lithium transport number of our functionalized CTC electrolytes was compared to the state-of the art CTC conducting materials. We finally offer to rationalize plausible conduction mechanisms in our materials and in the conventional CTC systems that is still in debate today.

Measuring Free Volume and Li-Salt Dissolution of the Polymer in Composite Electrolytes SaraC. Sand[1], JenniferL. Rupp[2,1] and BilgeYildiz[1]; [1]Massachusetts Institute of Technology, United States; [2]Technische Universität München, Germany

Ceramic and Polymer electrolytes are the two categories of materials that have emerged to replace flammable electrolytes in Li-ion batteries. Composite electrolytes, typically in the form of dispersed ceramic particles or nanowires in polymer matrix, combine these two materials to have good ionic conductivity while maintaining the mechanical properties of the polymer. Despite achieving relatively high levels of conductivity (typically 10-4 S/cm), the underlying mechanism governing ion conduction in these composite electrolytes remains inadequately elucidated.

The polymer likely plays a crucial role as the ceramic volume fractions are typically under 20 vol. %.[2,3] Three possible ways that polymers could increase in conductivity in the composite have been identified: decreased crystallinity, increased free volume, and increased lithium ion dissolution due to acidic surface groups on the ceramic.[2,4,5] To explore the interface between the polymer and ceramic, we developed a thin film model system through spincoating. We observed that the conductivity of the thin film was significantly higher than that of the bulk. We utilized differential scanning calorimetry to identify probe the crystallinity and found that the small crystallinity variation could not account for the variation in conductivity. Subsequently, we utilized conductivity measurements on various ceramic surfaces to understand the effects of charge surface groups on the ceramic on polymer conductivity. X-ray Absorption measurements were similarly utilized to probe the variation in lithium ion environments within these materials to understand any variation in the lithium salt dissolution. It was found that the variation in conductivity based on this effect is small.

In order to probe the possible variation in free volume, Small Angle Neutron Scattering was utilized to quantify the free volume within thin films, bulk polymer, and composite electrolytes. This can quantify the volume associated with each monomer and therefore how much space is between polymer chains for lithium ion movement. It was found that the free volume in the thin film was significantly increased as compared to the bulk polymer. Lastly, additionally, positron annihilation is used as an additional measure small voids or measure of the distribution of free volume in these systems.

Solid Organic Charge-Transfer Composites as Lithium-Ion Battery Electrolytes LingyuYang and JenniferL. Schaefer; University of Notre Dame, United States

Solid-state polymer electrolytes, where ion transport is facilitated by polymer chain segmental motion, for lithium-ion batteries have attracted considerable research interest because of the potential for high safety and electrochemical stability, but applications are limited by their low ionic conductivities. However, recent reports found that certain organic charge-transfer crystals could present high ionic conductivity via ion transport pathways on the crystal surfaces.[1] In our work, we reported charge-transfer complex electrolytes composed of a pair of tetrathiafulvalene-tetracyanoquinodimethane (TTF-TCNQ) complex matrix with different molar ratios of lithium bis(trifluoromethylsulfonylimide) (LiTFSI).[2] It was found that thermal annealing and water vapor treatment can impact charge transport properties of charge-transfer complex electrolytes. Trace water promoted the dissociation of LiTFSI, resulting in the electrolyte with 1-1-2-0.45 molar ratio of TTF-TCNQ-LiTFSI-H_2O showing an ionic conductivity of 2×10^{-3} S/cm at 25 °C with electronic conductivity as low as 1×10^{-7} S/cm at the same temperature. By further fabrication of similar charge-transfer composite electrolytes lacking water, the performance of full cells will be investigated.

Strategies to Improve the Electrochemical Properties of Single-Ion Conductive Polymer Electrolytes LiangliangLi, KaihuaWen and Ce-WenNan; Tsinghua University, China

Solid electrolytes are the key materials used in solid-state batteries with a high energy density and good safety. Among various solid electrolytes, polymer-based electrolytes are attracting a lot of research interest due to the advantages of flexibility, low cost and easiness for mass production. Traditional polymer-based electrolytes use dual-ion Li salts such as $LiPF_6$, $LiClO_4$, LiTSFI, et al., and they have a low Li-ion transference number, leading to unwanted polarization and side reactions in solid-state batteries. Recently, single-ion conductive polymer electrolytes (SICPEs) with a Li-ion transference number close to one have been widely studied. One of the challenges for SICPEs is to achieve both high ionic conductivity and wide electrochemical stability window. In this talk, we are going to present two strategies to enhance the electrochemical properties of SICPEs. First, we precisely regulate the ion-dipole interactions in an SICPE containing carbonyl and cyano groups. The resulting SICPE shows a Li-ion transference number of more than 0.9, a large ionic conductivity of 10^{-4} S cm^{-1}, a wide electrochemical stability window of more than 4.5 V, and an excellent electrochemical compatibility with Li metal. Second, we prepare a composite electrolyte by adding garnet ceramic nanoparticles into the SICPE. Due to the interactions between the garnet active fillers and the SICPE, the key electrochemical properties such as the Li-ion transference number, electrochemical stability window, and ionic conductivity are all further improved. Based on the high-performance SICPEs above, both $LiFePO_4$ and $LiCoO_2$-based solid-state batteries demonstrate good rate performance and a long cycle life at room temperature. In summary, regulating the ion-dipole interactions in single-ion conductive polymers and synthesizing ceramic/polymer composite electrolytes are effective strategies to improve the electrochemical properties of SICPEs.

Polymer Electrolytes Unleashed: Exploring the Potential of Carbonate Species in Lithium-Ion Batteries OmarAllam and Seung SoonJang; Georgia Institute of Technology, United States

Solid polymer electrolytes (SPEs) are gaining prominence in contemporary research due to several key benefits they offer over liquid electrolytes, including non-flammability, improved mechanical stability, and suppressed electrode material dissolution. To understand the potential of these materials, our research employs density functional theory (DFT) and molecular dynamics (MD) simulations to probe novel carbonate-based SPEs, comparing their performance against their traditional liquid carbonate electrolyte counterparts. One of the central aspects of our investigations is the exploration of the impact of carbonate pendant group composition on the nanophase morphology of amorphous polycarbonates, as well as Li-ion solvation and transport. These findings are juxtaposed with the behavior of liquid electrolytes like dimethyl carbonate and ethylene carbonate. Furthermore, our study illuminates how critical variables such as the glass transition temperature (T_g) of polymer materials, which significantly influences Li-ion transport, are impacted when introducing cyclic versus linear carbonate sidechains and mixing different types of carbonate pendant groups. Of particular interest is our aim to ascertain whether synergies between carbonate species typically exploited in liquid form can be harnessed when they are in their polymeric incarnations. Through our comprehensive analysis, we seek to provide pivotal insights that will guide the optimal design and composition of polymers for achieving a nanophase morphology that enhances ion transport.

11:30 AM EN02.04.10
Mechanistic Investigation of Superionic Conduction in Halide Solid Electrolytes ZhantaoLiu[1], AlexChien[2], ShuoWang[3], YifeiMo[3], JueLiu[2] and HailongChen[1]; [1]Georgia Institute of Technology, United States; [2]Oak Ridge National Laboratory, United States; [3]University of Maryland, United States

Halide-based solid electrolytes, such as Li3MX6 (M=Y, Sc, etc., X=halogen), are attracting great attention in the field of solid state Li-ion batteries owing to their good compatibility with high-voltage cathodes and high room temperature conductivities. In our recent research, we found that many halides, such as Li_3YCl_6, show a type-II superionic transition, where their diffusion energy barrier is significantly lowered once the temperature is raised above the transition point Tc. It is therefore interesting to explore the mechanism of this transition to further understand this class of materials and design better solid electrolytes. We systematically characterized the detailed crystal structures of a series of halides using variable temperature high-resolution synchrotron X-ray and neutron diffractions and refinements, and AIMD computations. A novel mechanism that explains this superionic transition in halides is proposed and supported by the experimental results. The new finding will help us to design better halide electrolytes with higher conductivity and lower activation energy, and thus facilitate the development of solid state Li-ion batteries.

Experimental Mechanical Investigation of Composite Cathode for Enhanced Performance in All-Solid State Batteries Howard QingsongTu; Rochester Institute of Technology, United States

All-solid-state-batteries (ASSBs) are leading the way in safer and more efficient energy storage. This study investigates the macro-scale mechanical properties of cathode active material (CAM) and solid electrolyte (SE) components in ASSBs. Through compression testing, we analyze CAM and SE materials—$LiNi_{0.8}Mn_{0.1}Co_{0.1}O_2$, Li_6PS_5Cl, Li_3YCl_6, $Li_3YBr_3Cl_3$, and $Li_7La_3Zr_2O_{12}$. We examine the effects of fabrication pressure and CAM-to-SE weight ratio on elastic modulus, bulk modulus, yield strength, and deformation. Our study bridges the gap in understanding the macro scale mechanical properties, contributing to advancements in ASSB technology. Understanding the mechanical properties of composite cathodes will enable us to develop strategies to mitigate issues such as solid-electrolyte debonding and capacity loss, leading to improved battery performance, stability, and lifespan. The findings of this study have the potential to drive the design and development of more efficient and reliable ASSBs.**Experimental Mechanical Investigation of Composite Cathode for Enhanced Performance in All-Solid State Batteries**

SESSION EN02.05: Advanced Synthesis I

High-Performance Solid-State Electrolytes: Ultra-Fast High Temperature Sintering (UHS) Oxides and Expanded Cellulose LiangbingHu; University of Maryland, United States

We recently reported an ultrafast high temperature sintering (UHS) for solid state electrolytes (Science, 2020, May Cover). The long sintering time of conventional syntheses can lead to Li loss in garnet SSEs caused by the evaporation of Li and the formation of secondary phases that lead to lower ionic conductivity. In contrast, the UHS technique enables us to tune the sintering time in units of seconds, which provides excellent control in terms of the Li content and grain growth. I will discuss our progress on applying UHS method to sintering various solid-state

electrolyte, from compositions to microstructures. By programming the temperature and time (T-t), we can establish process diagrams to sinter porous vs. dense structures. The rapid sintering also allows us to sintering multilayer solid-state electrolytes with significantly reduced interlayer diffusion.

In a separated topic, I will discuss a general design strategy for achieving one-dimensional (1D), high-performance polymer solid-state ion conductors through molecular channel engineering, which we demonstrate via Cu^{2+}-coordination of cellulose nanofibrils. The cellulose nanofibrils by themselves are not ionic conductive; however, by opening the molecular channels between the cellulose chains through Cu^{2+} coordination we are able to achieve a Li-ion conductivity. This improved conductivity is enabled by a unique Li^+ hopping mechanism that is decoupled from the polymer segmental motion. Also benefitted from such decoupling, the cellulose-based ion conductor demonstrates multiple advantages, including a high transference number (0.78 vs. 0.2–0.5 in other polymers[2]), low activation energy (0.19 eV), and a wide electrochemical stability window (4.5 V) that accommodate both Li metal anode and high-voltage cathodes. Furthermore, we demonstrate this 1D ion conductor not only as a thin, high-conductivity solid-state electrolyte but also as an effective ion-conducting additive for the solid cathode, providing continuous ion transport pathways with a low percolation threshold, which allowed us to utilize the thickest $LiFePO_4$ solid-state cathode ever reported for high energy density (Nature, Oct 22).

2:00 PM *EN02.05.02
Liquid-Phase Synthesis of Sulfide Solid Electrolyte: Achieving Extended Composition Ranges and Minimized Carbon Impurities for All-Solid-State Batteries Yoon SeokJung; Yonsei University, Korea (the Republic of)

Advancements in all-solid-state battery (ASSB) technology, featuring non-flammable inorganic solid electrolytes, are gaining significant traction, mainly due to their promise of increased safety and energy density compared to traditional lithium-ion batteries, which rely on flammable organic liquid electrolytes. A key focus of this evolution towards practical ASSBs is the development of sulfide SEs (SSEs), recognized for their exceptional ionic conductivities (reaching up to ~10^{-2} S cm^{-1}) and their ability to be mechanically sintered. Additionally, the employment of wet-chemical synthesis or processing methods for SSEs unlocks intriguing opportunities for the future advancement of ASSB technologies. However, thus far, the number of viable precursor-solvent combinations for the liquid-phase synthesis of SSEs remains limited, primarily due to the solubility constraints of metal chalcogenide precursors such as MS2 (M = Ge, Sn). This limitation hinders the wet-chemical route for synthesizing metal-inclusive compositions like $Li_{10}GeP_2S_{12}$. Furthermore, the liquid-phase synthesis of SSEs often leaves significant amounts of organic residues derived from organic solvents, leading to the carbonization issue, which could instigate harmful side reactions or self-discharge when used in ASSB cells.
In this presentation, we report on our recent results in developing liquid-phase synthesis strategies for SSEs that extend the compositional availability while minimizing carbon impurities. By leveraging amine-thiol chemistry, metal sulfide precursors can participate in the liquid-phase synthesis alongside conventional precursors of Li_2S, P_2S_5, and LiX (X = Cl, Br, I). Moreover, we introduce a novel heat treatment method that results in near carbon-free SSE products derived from liquid-phase synthesis. These developments hold promising potential for significantly enhancing the electrochemical performance of ASSBs.

Ion-Exchange in Solid Electrolytes to Induce Compressive Stress and Improve Electrochemical Performance SydneyMorris[1], HarshD. Jagad[1], StephenJ. Harris[2], ChangminShi[1], MatthewFang[1], YueQi[1] and BrianW. Sheldon[1]; [1]Brown University, United States; [2]Lawrence Berkeley National Laboratory, United States

There is continued interest in improving the electrochemical performance of the solid electrolyte (SE) lithium lanthanum zirconium oxide (LLZO) by preventing lithium (Li) filaments from penetrating the SE. This study builds upon a model that analyzed the impact ion-exchange (IX) has on Li transport through LLZO [1]. While IX is a common practice to strengthen glass, and has even been used with glass solid electrolytes, this work presents the first attempt to apply the IX process to LLZO in order to induce compressive stress at the surface and delay the penetration of Li filaments [2]. A wide variety of ion-exchange conditions were investigated, and the resulting materials were characterized with a scanning electron microscope (SEM), electron-dispersive X-ray spectroscopy (EDS), X-ray diffraction (XRD), electrochemical impedance spectroscopy (EIS), and critical current density (CCD) experiments using symmetric Li cells. Comparisons with control samples were used to elucidate the impact of processing conditions on critical current density, stress at the surface of the SE pellet, and the LLZO surface structure. The results demonstrate that improved CCDs are possible, but that a variety of phenomena can complicate the ion-exchange process and lead to reduced ionic conductivity and chemical degradation of the LLZO.

The Impact of Interface layer on Li Plating and Stripping Morphology YueQi; Brown University, United States

Li metal is the preferred anode material for high energy Li batteries. However, stable plating and stripping of Li metal in both liquid and solid electrolytes remain a significant challenge, particularly at practically feasible current densities. This Li/electrolyte interface is further complicated by a complex solid electrolyte interface (SEI). The electronic, ionic, and mechanical properties of the Li/SEI interface can significantly change the Li plating and stripping morphology.
A Density Functional Theory (DFT) informed phase-field method was developed to integrate electrochemistry with mesoscale plating morphology. It revealed that the Li intergranular growth in $Li_7La_3Zr_2O_{12}$ solid electrolytes originated from the trapped electrons at grain boundaries and internal surfaces. This phenomenon is material specific, as several other key solid electrolytes do not trap electrons at grain boundaries or internal defects. [1]
The lithium stripping process generates vacancies, which may accumulate as voids and lead to uneven current distribution and dendrite growth in the following plating cycles. A stack pressure is typically required during stripping, causing large scale lithium metal creep. Here, we captured the multiple length and time scales by combing interface interactions with DFT simulations, vacancy hopping with kinetic Monte Carlo (KMC), and plastic deformation with continuum simulations. Generally lithiophilic interface requires less stack pressure to maintain a flat surface while a higher stack pressure is needed at lithiophobic interfaces to accelerate Li vacancy diffusion into the bulk and maintain a flat surface. This critical stack pressure needs to be high enough to alter the Li forward-and-backward hopping barriers at the interface. This multiscale simulation scheme illustrates the importance of including the chemical-mechanical effects during Li stripping morphology evolution. [2,3]

Chemo-Mechanical Regulation of Li Intrusion in Garnet Solid Electrolytes via Ultra-Thin Metallic Coating XinXu[1,2] and William C.Chueh[1,2]; [1]Stanford University, United States; [2]SLAC National Accelerator Laboratory, United States

Solid electrolytes in rechargeable lithium-metal batteries are prone to lithium-metal short-circuiting during plating, and the underlying cause is not well understood. The growth of lithium-metal, termed as "Li intrusions," within the solid electrolyte can lead to surface cracks and short-circuiting during battery charging process. In our previous research[1], we have determined that the root cause of lithium intrusion into the electrolyte is a combination of current focusing and the presence of nanoscale cracks, rather than electronic leakage or electrochemical reduction.[2] These insights highlight the mechanical tunability of electrochemical plating reactions in brittle solid electrolytes.[3]
In this study, we propose a chemo-mechanical approach to control Li intrusions in a leading solid electrolyte, $Li_{6.6}La_3Zr_{1.6}Ta_{0.4}O_{12}$ (LLZO), through the use of ultra-thin nanoscale metallic coatings. Specifically, we apply a nanoscale metallic Ag coating on the LLZO surface and anneal it at various elevated temperatures without air exposure. The coated and annealed surface demonstrates enhanced tolerance to Li intrusion, particularly under high local stress, as confirmed by operando SEM plating. Compared to the pristine LLZO surface, the coated surface exhibits a local current density that is three times higher, a charge density that is 25 times higher, and a total charge of Li plating that is 1400 times higher. Depth profiling using nanoscale secondary ion mass spectrometry (NanoSIMS) indicates that Ag may diffuse into the subsurface of LLZO, showing no discernible differences in the location of grain interior or grain boundaries. Furthermore, in-situ XPS experiments reveal that the oxidation state of the Ag coating on LLZO transitions from metallic Ag to oxidized Ag. These observations suggest that Ag likely induces chemical antisite defects on the surface of LLZO. In-situ nanoindentation experiments demonstrate that the mechanical strength of the coated surface surpasses that of the pristine surface. Finite element method (FEM) simulations indicate that the generated antisite defects introduce additional surface compressive strain due to the larger ionic radius of Ag compared to Li, thereby suppressing the probability of Li intrusion. Our research indicates the potential of chemo-mechanical regulation of Li intrusion in solid electrolytes through the use of chemical defects. These new findings suggest that nanoscale coatings may be sufficient to tune electrochemical Li plating reactions, making it feasible for cost-effective, large-scale engineering and manufacturing of interfaces in solid-state batteries.

4:00 PM EN02.06.03
Direct Observations of Dendrite-Induced "Subcritical" Cracking in Oxide Solid Electrolytes ColeD. Fincher[1], W. CraigCarter[1], BrianW. Sheldon[2] and Yet-MingChiang[1]; [1]Massachusetts Institute of Technology, United States; [2]Brown University, United States

Dendrite-induced short circuits threaten the deployment of solid-state batteries with metal anodes. Dendrites grow from the anode due to plating-induced pressure and subsequent fracture of the electrolyte. Whether electrochemical activity within the electrolyte aids that fracture process has remained a topic of debate. For oxide solid-electrolytes, we address this issue by conducting operando photoelastic microscopy to directly observe the stress fields around dendrites under dynamic electrochemical loading. From this data, we measure the thermodynamic driving force for fracture (i.e., the stress intensity factor, a measure of apparent surface energy) as a function of applied potential. These experiments reveal dendrite growth under "subcritical" conditions, meaning that the stress intensity factor during propagation is less than should be expected based on linear elastic fracture theory. We discuss these results in the context of historical subcritical cracking due to corrosive action. Finally, we develop a mechanistic framework to connect the observations here with expected behavior in sandwich-style cell formats.

4:15 PM EN02.06.04
Dendrite Growth in Lithium Metal Solid-State Batteries DominicMelvin[1], ZiyangNing[1], GuanchenLi[2], T.J. Marrow[1], CharlesW. Monroe[1] and PeterBruce[1]; [1]University of Oxford, United Kingdom; [2]University of Glasgow, United Kingdom

Solid-state batteries which combine both a lithium anode and ceramic solid electrolytes promise a step change in cell energy density. However, there are significant challenges to charging and discharging these cells at high current densities in the range of several mA cm^{-2}. At high rates of charge, dendrites (filaments of lithium metal) are observed to crack through ceramic electrolytes, leading to critical failure of the cell. The realisation of solid-state batteries with lithium metal anodes therefore depends on understanding how a soft metal such as Li can induce fracture of a stiff ceramic electrolyte.
Using a combination of X-ray computed tomography and FIB-SEM we have made observations which reveal both how Li dendrites crack Li_6PS_5Cl electrolytes and how these dendrite-cracks propagate across the solid electrolyte. We have made the finding that dendrite-cracks propagate whilst partially filled, driven by Li at the back of the crack not the tip. This has enabled advances in understanding dendrites in ceramics and the factors that influence then and their progression to a short-circuit.

Dilatometric Measurement of Pore Volume During Stripping of Metal Electrodes in Solid-State Batteries ThomasSchall, TillFuchs, JillKessler, KlausPeppler, JoachimSann, BorisMogwitz and JürgenJanek; Justus Liebig University Gießen / Institute for Physical Chemistry, Germany

Solid-state batteries may allow the use of a lithium metal anode (LMA), enabling a significant increase in energy density. However, morphological challenges such as dendrite growth and contact loss of the LMA during cycling limit the available capacity. The formation of resistive pores occurs when the local current density exceeds the effective diffusion of vacancies within the LMA, leading to a vacancy accumulation (1,2). Therefore, external pressure can mitigate pore formation by inducing plastic deformation of the lithium metal (1). To address the limitations imposed by pore formation, a deeper understanding is required.

This work employs a novel dilatometric measurement setup providing a precision of < 1 nm for measuring height changes, maintaining precise constant pressure, and facilitating the metrological separation of one electrode. As pore formation leads to non-uniform removal of lithium, resulting in the formation of indentations (pores) due to adatom diffusion (1), the overall height reduction during operation is decreasing. Despite a continuous amount of lithium being stripped, our setup can therefore detect the onset of pore formation.

The dilatometer is employed to measure the changes in height during both pore-free uniform stripping and stripping with pore formation in a Li|LLZO|Li model system. From the difference between the height change of uniform stripping and stripping with pore formation, the pore volume can be determined and related to GEIS and PEIS measurements. Using this approach, the pore volume is determined for different current densities and pressures, providing a comprehensive understanding of the pore formation under varying conditions. To complement the results, the pores at the stripping electrode are analyzed post-mortem using scanning electron microscopy (SEM). The measured data allow new insights into the morphology of pore formation.

Solvent-Free Single-Ion Conducting Polymer Electrolytes for Lithium Metal Batteries under Harsh Environments JingyiGao and Dong-MyeongShin; The University of Hong Kong, Hong Kong

Rechargeable lithium-ion batteries are widely used in consumer applications. However, these batteries are limited in their ability to function under extreme thermal environments, such as high temperatures, which are required for medical devices requiring sterilization and various industries like subsurface exploration and thermal reactors. However, the conventional lithium-ion batteries have limited high-temperature performance due to material properties that lead to safety concerns or low power usage. Many efforts have focused on developing solvent-free single-ion conducting (SIC) polymer electrolytes to solve these issues by covalently immobilizing anionic groups onto a polymer backbone, which only allows Li+ cations to be mobile through the polymer matrix, leading to minimal dendrite growth during charging/discharging process. While the SIC polymer electrolytes hold much promise for next-generation batteries possessing high safety and high energy density, this approach typically yields a significant drop of ionic conductivity ($<10^{-5}$ S cm^{-1} at ambient temperature), compared to liquid electrolytes. Quasi-solid or gel polymer electrolytes incorporating organic plasticizers have been employed to enhance the ionic conductivities, but their practical implementation is still constrained by their vulnerability to thermal runaway under high-temperature circumstances. Herein, we present a novel approach for the one-step synthesis of a solvent-free single-ion perfluorinated-tetraphenylborate-anions

membrane via click reaction. The resulting flexible membrane displays exceptional cyclability performance at high temperatures, high lithium selectivity (~0.932), and a wide working window (up to 5 V). The one-step synthesis of the membrane exhibits a high ionic conductivity (~3 *10^{-5} S cm^{-1}) at 88°C due to its consistent structure. Notably, the membrane demonstrates superior non-flammability properties. Furthermore, the membrane can operate under large temperature ranges from 60 to 120°C, even under negative pressure, making it suitable for a variety of applications. Remarkably, stable long-term cycling of $LiFePO_4$ cathodes can be achieved at 100°C with a coulombic efficiency of approximately 100% over 300 cycles at 0.5C.

8:00 PM EN02.07.02
Novel Lithium-Ion Conductor $LiTa_2PO_8$-Based Hybrid Solid Electrolytes for High-Voltage Cathodes in Lithium-Metal Batteries Kumlachew ZelalemWalle[1,1,2] and Chun-ChenYang[1,1]; [1]Ming Chi University of Technology, Taiwan; [2]University of Gondar, Ethiopia

Solid-state Lithium metal batteries (SSLMBs) that contain polymer and ceramic solid electrolytes have received considerable attention as an alternative to substitute liquid electrolytes in lithium metal batteries (LMBs) for highly safe, excellent energy storage performance, and stability under elevated temperature situations. Here, a novel fast Li-ion conducting material, $LiTa_2PO_8$ (LTPO) was synthesized, and the electrochemical performance of as-prepared powder and LTPO-incorporated hybrid solid electrolyte (LTPO-HSE) membrane was investigated. The as-prepared LTPO powder was homogeneously dispersed in polymer matrices and a hybrid solid electrolyte membrane was synthesized *via* a simple solution-casting method. The room temperature total ionic conductivity (σ_t) of the LTPO pellet and LTPO-HSE membrane were 0.14 and 0.57 mS cm^{-1}, respectively. A coin battery with NCM811 cathode is cycled under 1C between 2.8 to 4.5 V at room temperature, achieving a Coulombic efficiency of 99.3% with capacity retention of 74.1% after 300 cycles. Similarly, the LFP cathode also delivered an excellent performance at 0.5C with an average Coulombic efficiency of 100% without a virtual capacity loss (the maximum specific capacity is at 27^{th}: 138 mAh g^{-1} and 500^{th}: 131.3 mAh g^{-1}). These results demonstrate the feasibility of a high Li-ion conductor LTPO as a filler and the developed polymer/ceramic hybrid electrolyte has the potential to be a high-performance electrolyte for high-voltage cathodes, which may provide a fresh platform for developing more advanced solid-state electrolytes.

8:00 PM EN02.07.03
Long Cycling Performance of the All-Solid-State Lithium-Ion Batteries using Modified Silicon Anodes MinjaeKim[1], JunHyeokSeo[2], DaheeSong[2] and Kuk YoungCho[1]; [1]Hanyang University(ERICA), Korea (the Republic of); [2]Hanyang University, Korea (the Republic of)

The continuous growth of electric vehicles and energy storage systems has increased demand for lithium-ion batteries (LIBs) that offer both safety and high energy density. Consequently, research on next-generation LIBs with high energy density has expanded, focusing on new electrode materials such as lithium metal, high-nickel ternary cathodes, sulfur cathodes, and silicon anodes. Particularly, silicon anodes offer superior capacity compared to the conventional graphite anodes used in commercial LIBs, along with the advantages of low electrode potential and abundant resources. However, challenges remain due to the volume expansion of silicon anodes and the unstable form of the solid electrolyte interphase (SEI), which affects their cycling performance.

All-solid-state lithium-ion batteries (ASSLBs) are an up-and-coming solution for achieving safety and high energy density by eliminating issues related to liquid electrolyte leakage and fire hazards. Furthermore, applying silicon anodes in ASSLBs can serve as a viable means to overcome the limitations of conventional LIBs while suppressing silicon's volume expansion through solid electrolytes, thereby addressing the drawbacks associated with silicon anodes. Therefore, ASSLBs and silicon anodes offer highly promising alternatives to overcome the limitations of conventional LIBs and silicon anodes. However, further research is required to address potential issues that may arise from applying silicon anodes and ASSLBs.

In this study, we fabricated ASSLBs using silicon anodes and sulfide-based solid electrolytes. We investigated the degradation characteristics of silicon anodes in ASSLBs with silicon thin-film electrodes and confirmed the performance enhancement of modified silicon anodes.

8:00 PM EN02.07.04
Stable 4 V-Class All-Solid-State Lithium Battery with Hydroborate Electrolyte and NMC811 Cathode HugoBraun, RyoAsakura, EdouardQuerel, CorsinBattaglia and ArndtRemhof; Empa - Swiss Federal Laboratories for Materials Science and Technology, Switzerland

Solid-state batteries are expected to extend the energy and power density beyond the limits of lithium-ion batteries, and to replace their flammable liquid electrolytes with safer alternatives. Each of the most studied solid electrolyte materials has disadvantages such as limited electrochemical stability (sulfides), low ionic conductivity (polymers), mechanical stiffness (oxides) or incompatibility with metallic anodes (halides). Complex hydride electrolytes, especially hydroborates, combine many attractive characteristics such as high ionic conductivity, compatibility with alkali metal anodes and soft mechanical properties. Some of us recently reported stable 3 V and 4 V all-solid-state sodium hydroborate batteries. Lithium hydroborate solid-state batteries offer the potential to use cathodes with much higher specific discharge capacity, but have so far been limited to low-voltage cathodes such as sulfur or TiS_2 due to the limited oxidative stability of the electrolyte. Herein, we demonstrate all-solid-state lithium metal batteries employing a hydrocarbaborate solid electrolyte with a 4 V-class $LiNi_{0.8}Mn_{0.1}Co_{0.1}O_2$ (NMC811) cathode. This is achieved by tailoring the $LiCB_{11}H_{12}$-$LiCB_9H_{10}$ electrolyte mixing ratio towards high oxidative stability (~3.9 V), while maintaining high conductivity (>1.5 mS cm^{-1} at room temperature). Unlike many other stable solid-state cells, we use one single electrolyte material in contact with the lithium metal, as the separator layer and in the cathode composite. Corresponding cells with lithium metal anodes display a high discharge capacity of 175 mAh g^{-1} and stable cycling, demonstrating the potential of hydroborate electrolytes for 4 V-class solid-state lithium metal batteries.

8:00 PM EN02.07.05
Functional Design and Investigation of Mg-Ion Conductors for Solid-State Mg Batteries ZhixuanWei and JürgenJanek; Institute of Physical Chemistry & Center for Materials Research, Justus Liebig University Giessen, Germany

Secondary batteries using multivalent cations as charge carrier have attracted increasing attention in recent years due to the high theoretical energy density given by multi-electron redox reactions. Nevertheless, the large charge density of these cations inevitably causes sluggish kinetics of the ion migration under room temperature, which is challenging for the development of multivalent-ion solid-state batteries.[1] Taking Mg^{2+} as a case study, we investigated a series of functional materials to figure out the design principle for Mg-ion solid-state conductors. First of all, an ionogel electrolyte using a MOF (metal-organic framework) as skeleton was prepared.[2] An ionic liquid was incorporated into UiO-66, which has a large inner surface area as well as a rich porous structure. Comparably high ionic conductivities of 5.7×10^{-5} S cm^{-1} and 2.4×10^{-4} S cm^{-1} could be achieved at room temperature and at mildly elevated temperature (60 °C), respectively. Apart from the good ionic conductivity, the prepared electrolyte also exhibits good chemical and electrochemical stability against magnesium metal. By pairing the magnesium metal anode with an aromatic organic material as cathode material, a proof-of-concept quasi-solid-state Mg battery can work reversibly at 60 °C. Secondly, we replaced the ion-insulating MOF framework by a new Mg-ion conducting NASICON-structured material, $Mg_{0.5}Sn_2(PO_4)_3$. By combining it with a small amount of Mg ionic liquid to improve the Mg^{2+} migration at grain boundary, the prepared Mg-ion conducting hybrid solid electrolyte shows superior room-temperature ionic conductivity of 1.1×10^{-4} S cm^{-1} and an activation energy of 0.36 eV. Through in situ scanning electron microscopy, for the first time we observed the room temperature Mg growth inside a solid-state cell by the evidence of clear-cut metal particle formation and electrolyte particle cracking. The results shown here can act as a good starting point for the understanding of Mg transport behavior in solid-state batteries.

Mechanism of High Li-Ion Conductivity in Li-Excess Garnet $Li_{7+x}La_{3-x}Sr_xZr_2O_{12}$MasahideKaneko[1,2], KakeruNinomiya[1], TomokoHishida[2], YukiTakeuchi[2], KazushiOtani[2] and MaikoNishibori[1]; [1]Tohoku University, Japan; [2]Niterra Co., Ltd., Japan

$Li_7La_3Zr_2O_{12}$ (LLZO) is a promising solid electrolyte for all-solid-state batteries, and various dopants have been investigated to improve its conductivity. However, the dopants have mainly been studied to increase the conductivity by reducing the amount of Li^+, and dopants that increase the amount of Li^+ have yet to be studied. Therefore, the structure of LLZO with excess Li^+ and its function as an electrolyte need to be clarified. Here, we report on the correlation between the conductivity and the structure of LLZO with excess Li^+ by partial substitution of Sr at the La sites.
Sr-doped LLZO sintered pellets were prepared by solid-state reaction method. The sintered pellets exhibit high conductivity of up to 5.7×10^{-4} S/cm at room temperature, indicating a promising material as a solid electrolyte.
Sr *K*-edge XANES spectra confirmed that Sr was located at the La sites of the LLZO. The crystal structure of Sr-substituted LLZO was measured by X-ray diffraction and neutron diffraction, and the results showed that the crystal structure of LLZO continuously changes from tetragonal to cubic with increasing the amount of Sr substitutions. At the same time, the Li^+ arrangement was also changed, with Li^+ occupying some tetrahedral sites that are vacant in the unsubstituted LLZO.

The local structure of Sr-substituted LLZO was discussed from Zr *K*-edge and La *K*-edge XANES. La *K*-edge XANES spectra did not change with Sr substitution, while Zr *K*-edge XANES spectra showed a spectral change corresponding to the amount of Sr substitution. This result suggests that the crystal structure change of Sr-substituted LLZO is not the result of the homogeneous deformation of the entire structure but is mainly due to the deformation of the Zr sites, which are unsubstituted.
The above results suggest that the high conductivity of Sr-substituted LLZO is due to multiple factors: the change in the Li^+ arrangement and the change in the Li^+ conduction pathway due to the local structure deformation. Our results contribute to a better understanding of the correlation between the structure and properties of LLZOs in Li excess compositions and the development of higher-performance electrolytes.

Effect of Solid-Electrolyte Microstructure on Conductivity and Solid-State Li-Ion Battery Performance JohnBachman[1], MayaHorii[1], RebeccaChristianson[2] and HeenaMutha[2]; [1]Cal State LA, United States; [2]Stark Draper Laboratory, United States

Solid-state batteries offer the potential to improve safety, cyclability, and energy density of Li-ion batteries. However, their conductivity, stability, and processing limit their use. To this end, the effects of solid electrolyte microstructure on overall battery performance are determined. The conductivities of Al-doped Li7La3Zr2O12 (Al-LLZO), with a range of microstructures, are found using a resistor network model. Varying electrolyte properties are combined with a Li-metal negative electrode and LiCoO2 positive electrode in a 1-D continuum model to predict the effects on performance. Simulations suggest that the ratio of electrolyte conductivity to electrolyte thickness must remain above 10 S/m^2 to maintain high energy and power output, particularly at C-rates greater than 10. To maintain conductivity near the grain interior conductivity, a grain size at least 10,000 times larger than grain boundary thickness is needed. Further improvements in grain size, grain boundary thickness, and void fraction beyond typical Al-LLZO microstructures, with the goal of higher conductivities, are predicted to have diminishing returns in overall battery performance, even at more sensitive high C-rates up to 100.

8:00 PM EN02.07.08
Understanding the Role of Powder Protective Layers on the Chemical Reactivity of Sulfide-Based Solid Electrolytes in All-Solid-State Batteries TaewooKim, UdochukwuD. Eze, ZacharyD. Hood, AnilU. Mane, JeffreyW. Elam and JustinConnell; Argonne National Lab, United States

Sulfide-based solid-state electrolytes (SSE) are a promising class of materials to enable high-performance, all-solid-state Li-ion batteries due to 1) their favorable mechanical properties for processability at scale and 2) comparable Li-ion conductivities to conventional liquid electrolytes. However, their poor atmospheric stability remains a challenge toward commercial manufacturing processes as environmental moisture and oxygen content, even in dry room environments, are sufficient to degrade sulfide-based SSEs. To circumvent these limitations, we previously developed thin (~1 nm) Al_2O_3 coatings grown directly on Li_6PS_5Cl (LPSCl) *powders* via atomic layer deposition (ALD). Through this approach, we successfully demonstrated substantial suppression of the chemical reactivities of the coated LPSCl under aggressively oxidizing conditions as compared to the uncoated LPSCl. In this work, we provide a comprehensive investigation to understand the role of ALD alumina protective layers on the environmental reactivity of LPSCl utilizing pellets pressed from coated and uncoated powders. Thermogravimetric analysis indicates significantly suppressed weight gain from powders and pellets made from coated versus uncoated materials after exposure to humidified O_2, demonstrating the effectiveness of the ALD coating strategy in suppressing environmental reactivity regardless of material form factor. Surprisingly, X-ray photoelectron spectroscopy shows little to no changes in the surface chemistry on the uncoated LPSCl surface while the coated LPSCl exhibits a trace of the surface oxidation upon exposure to oxidizing conditions, suggesting that the surface oxidation products of LPSCl are volatile and evaporate under ultra-high vacuum conditions. Correlative X-ray and vibrational spectroscopic and diffraction analysis will be utilized to expand upon the mechanisms by which powder coatings stabilize LPSCl to environmental reactivity and the specific changes in the surface chemistry and the corresponding chemical reactivities. These results provide a clear pathway to enabling stable precursor powder materials with favorable properties for processing at scale in realistic manufacturing environments.

8:00 PM EN02.07.09
A Pseudo-Three-Dimensional Modeling Framework for Liquid and All-Solid-State Lithium-Ion Batteries RuqingFang and JunerZhu; Northeastern University, United States

The multiphase structure of the electrode in liquid lithium-ion ion batteries (L-LIB) and all-solid-state lithium-ion ion batteries (ASSLIB) strongly impact the performance of the batteries. Due to the intrinsic multiphysical and multiphase interactions within electrodes, designing and tailoring the electrode structure is crucial for the improvement of battery performance. An electrode model, which is able to describe the relationship between dominant physical phenomenon in multiscale with the battery performance, is an effective design tool for electrode engineering. In the past decades, the pseudo-two-dimensional (P2D) model proposed by John Newman's group (*Journal of the Electrochemical Society, 140, 6(1993)*) has been widely utilized in modeling multiphase electrodes both in L-LIBs and ASSLIBs. The P2D model describes the ionic transport process at the electrode scale and the ionic diffusion in particle-scale, linking the two scales through a reaction current term representing the Faradaic reaction at the particle surface. However, the P2D framework lacks an effective means of describing surface phenomena occurring at the particle surface, such as phase separation, side reactions, and local mechanical failure at particle surface. To address this limitation, we propose a pseudo-three-dimensional (P3D) framework in this work. The P3D model introduces an additional dimension corresponding to polar or azimuthal angles to characterize the distribution of phenomena at the particle surface. By incorporating the P3D framework, we couple three surface phenomena in L-LIBs and ASSLIBs: phase separation of LFP particles, lithium plating at graphite particles, and the influence of local pores at the particle surface in ASSLIBs, into the original electrode model. We believe that the P3D framework could play an important role in understanding the relationship between the multiphase structure and the output electrochemical performance of the batteries, serving as an effective design tool for electrode engineering in all-solid-state and liquid lithium-ion batteries.

8:00 PM EN02.07.10
Porous Silicon-Based Anodes for Extreme Temperatures MortezaSabet[1], MihirParekh[1], YiDing[2], SrikanthPilla[1] and ApparaoM. Rao[1]; [1]Clemson University, United States; [2]U.S. Army DEVCOM GVSC, United States

Primary lithium thionyl chloride batteries are common power sources for applications requiring extreme temperature windows. However, the peak performance of these non-rechargeable batteries is between 20 °C and 55 °C. Advancing lithium-ion batteries (LIBs) with robust electrodes and proper electrolyte formulation for high temperatures (>50 °C) would offer rechargeability, higher power capability, and reduced toxicity. Common LIB anode materials, such as silicon (Si), rely on forming solid-electrolyte interphase (SEI) as an effective passivation layer to operate properly. Damages to these surface structures would render the interfaces vulnerable at elevated temperatures. The chemical composition and morphological evolution of the SEI strongly depend on the electrolyte used. In the presence of organic electrolytes, the exposure of Si to elevated temperatures leads to a fast SEI thickening and capacity loss. Ionic liquids exhibit a wide electrochemical potential stability up to 5.0 V, high thermal stability (>300 °C), and moderate Li ion conductivity at room temperature. The use of ionic liquids in combination with appropriate additives could be an ideal solution to stabilize the SEI at high temperatures. In the current study, we demonstrated the potential of Si nano-quills (SiNQs), a porous Si-based material with elemental Si pockets distributed in a matrix of Si suboxides, as the active material for high-temperature LIB anodes. Electrodes were prepared by casting the aqueous slurry of SiNQ on copper foil, followed by hot rolling to a desired density. Half cells were prepared using SiNQ electrodes and a piperidinium-based ionic liquid electrolyte and cycled at 50, 60, and 70 °C. At 50 °C, the SiNQ anodes exhibited a reversible capacity of 225 mAh g_{Si}^{-1} at the current rate of 0.1C (420 mA g_{Si}^{-1}). Testing at higher temperatures of 60 and 70 °C resulted in a higher capacity of 1040 and 1240 mAh g_{Si}^{-1}. This indicates the reduced electrolyte viscosity at higher temperatures, which can enhance the kinetics of lithiation and delithiation in the SiNQ active material.

8:00 PM EN02.07.11
Multi-Layer Thin film Polymer-2D Nanofiller Composites for Ultra-High Capacitive Energy Storage Application NiharR. Pradhan[1], SumitR. Bera[1], RukshanM. Thantirige[1], BrianT. Shook[1], ManinderjeetSingh[2], DharmarajRaghavan[3], AnirudhaSumant[4], AlamgirKarim[2] and EmilyC. Davidson[5]; [1]Jackson State University, United States; [2]University of Houston, United States; [3]Howard University, United States; [4]Argonne National Laboratory, United States; [5]Princeton University, United States

Recently thin film polymer base dielectric nanocomposite materials show remarkable application in energy storage devices. The polymer-based dielectric capacitors have the advantages of flexibility, fast charge and discharge, low loss, and graceful failure. Elevating the use of polymeric dielectric capacitors for advanced energy applications such as electric vehicles (EVs) however, requires significant enhancement of their energy densities. Here, we report a polymer thin film heterostructure-based multi-layered capacitor using poly(vinylidene fluoride) and stratified 2D nanofillers (Mica or *h*-BN nanosheets) that shows enhanced permittivity, high dielectric strength and an ultra-high energy density of ≈ 90 J/cm^3 with efficiency over 60% at high field. This approach of using oriented 2D nanofillers-based polymer heterostructure composites is expected to be versatile for designing high energy density thin film polymeric dielectric capacitors for myriads of applications.

8:00 PM EN02.07.12
Utilizing High Tensile Alloys of Copper to Eliminate Mechanical Degradation in High Loading Silicon Anodes DevashishSalpekar, DanielAbraham, WenquanLu, Marco-Tulio F.Rodrigues and Stephen E.Trask; Argonne National Laboratory, United States

Silicon is a promising candidate to replace the conventionally used graphite anodes due to its high theoretical capacity (3579 mAh/g; $Li_{3.75}Si$), low cost, and abundance. However, silicon undergoes huge volumetric expansion (~300%) upon lithiation, which leads to particle isolation and thus, poor cycle life. Polymeric binders such as polyacrylic acid and carboxy methyl

cellulose, have been used to overcome this problem by binding with silicon particles. However, these binders do not provide a strong adhesion between the coating and the current collector, which can lead to delamination upon prolonged cycling. Recently, stronger polymeric binders (such as polyimide, polyamide, etc.) have received attention due to their improved interfacial interactions and mechanical strength, creating a cohesive silicon anode with excellent coating adhesion to the current collector. However, at higher loadings the huge volumetric changes in the silicon combined with the strong adhesive properties of binders leads to plastic deformations in the current collector, which on extended cycling can significantly wrinkle or in the worst case shred the metal foil. We are investigating high tensile alloy (HTA) copper current collector foils, which have tensile strengths that are more than double that of conventional copper foils. Due to their improved mechanical properties, these foils do not undergo plastic deformation upon silicon lithiation and prevent shredding upon continuous cycling. Electrochemical testing data suggest that at moderate silicon loadings (2.5-3 mAh/cm^2), electrodeposited or rolled copper show significant wrinkling after only 5 cycles in a half-cell, whereas the HTA foils show no wrinkling. This effect increases significantly at higher loadings (>5 mAh/cm^2), where the conventional copper foils show significant wrinkling after just one lithiation-delithiation cycle, while the HTA copper shows no wrinkling. By utilizing this HTA copper foils, it is possible to eliminate mechanical issues in the anode current collector, especially in high loading silicon cells with strong polymeric binders.

8:00 PM EN02.07.13
Ion Transport Mechanism in Argyrodite Electrolyte and Their Effect on the Electrochemical Performance in all Solid-State Lithium Battery RavindraK. Bhardwaj; Bar Ilan University, Israel

Commercialization of lithium-ion batteries (LIB) enabled a new era of portable devices, electric vehicles, and grid energy storage. However, the ever-increasing demand of modern society for advanced energy storage packages, including for large energy storage units for grid and remote locations, challenges the scientific community to realize further advancements in batteries, with desirable energy and power densities, extended lifetime, improved safety and lower cost.[1] The current state of the art LIB is composed of three major components: graphite anode, organic electrolyte solution and inorganic cathode material. However, the usage of organic solvents is imposing some critical technical and practical limitations. These limitations are related to safety issues (due to electrolyte flammability), longevity issues (due to electrolyte degradation and volatility), and limited energy density of the battery (due to the solvent's limited electrochemical stability).[2] In recent years there is increased interest in developing solid electrolytes (SEs) for all solid-state LIB (SSLIB). A SSLIB could potentially increase the volumetric as well as specific energy density of SSLB. Furthermore, eliminating the volatile organic electrolyte in SSLIB will significantly improve the safety of the battery and extend the operating temperature of the cell. In our previous published work, we systematically studied the electrochemical behaviour of three different argyrodites based solid electrolytes by varying the halogen (Li_6PS_5X [X = Cl, $Cl_{0.5}Br_{0.5}$, or Br]).[3] Using $LiNi_{0.6}Co_{0.2}Mn_{0.2}O_2$ (NCM622) as a model cathode, we also studied the electrochemical performance of these SEs in ASSLB cells. In the present work, we show the ion transport mechanism in three different argyrodite-based solid-electrolytes (SEs), with a general composition of Li_6PS_5X (X = Cl, $Cl_{0.5}Br_{0.5}$, or Br). The presentation will also discuss the corelation of ion transport with the electrochemical performance the argyrodite-based solid-electrolytes (SEs) in ASSLIB.

Alkali-Independent Anion Redox in $LiNaFeS_2$MichelleQian, EshaanPatheria, ColinMorrell and KimberlyA. See; Caltech, United States

Batteries based on sodium ions are a promising, more sustainable alternative to the currently dominant lithium-ion battery, but have comparatively lower energy densities. One method of increasing energy density is to develop cathode materials that can undergo multielectron cation and anion redox, which we have previously observed using the layered material $LiNaFeS_2$ in a lithium cell. In $LiNaFeS_2$, anion redox occurs through the formation of persulfide bonds that is correlated to a plateau in the galvanostatic charge curve at ~2.5 V vs Li/Li^+. We now demonstrate that $LiNaFeS_2$ can also be used as a multielectron sodium cathode, although the anion-redox plateau region of the second charge curve resembles the sloping profile of a solid-solution process rather than the two-phase process reflected in a lithium cell. Inductively-coupled mass spectrometry studies verify sodium as the dominant mobile ion after first charge, correlating the difference in electrochemical behavior with the active alkali ion. Fe and S K-edge X-ray absorbance spectroscopy shows that the charge compensation mechanisms for the material in the two cell configurations are fundamentally the same. The disparate electrochemical behavior is entirely due to physical rather than electronic structural effects. Our work provides a fundamental study on the differences between Li- and Na-based anion redox in the same material.

8:00 PM EN02.07.15
A Solid-State Zinc-Iodide Battery with Zinc Dendrite Free and Long Cycle Life YongxinHuang, BinLuo and LianzhouWang; The University of Queensland, Australia

Rechargeable zinc-iodide (ZnI_2) batteries have become a popular choice for applications in aqueous batteries due to their natural abundance, intrinsic safety, and high theoretical capacity. However, in the alkaline or weakly acidic water environment of aqueous electrolytes, the hydrogen evolution reaction and the subsequent battery swelling and failure have hindered the practical application of such batteries so far. In addition, the environment of electrolyte will also promote the growth of zinc dendrites, which will not only reduce the utilization of zinc foil, but also cause the dendrites to penetrate the separator and cause a short circuit in the battery. Based on traditional zinc salts and a Perfluoropolyether (PFPE)-based polymer, an all-solid-state zinc iodide battery with solid polymer electrolyte was designed and synthesized by ion exchange. According to the results of XPS and XRD, it can be proved that this polymer solid electrolyte forms a SEI layer containing rich Fluorine on the surface of zinc to induce the horizontal growth of zinc dendrites and increase the utilization of zinc. More importantly, this induction method inhibits the possibility of continuously generated dendrites penetrating the separator and greatly extends the cycle life of the battery. In addition, it can also be proved that this solid electrolyte can also hinder the iodine ion shuttle effect, thereby reducing the corrosion of the zinc sheet and further prolonging the life of the battery. Symmetric batteries based on this electrolyte exhibit excellent cycle performance of more than 4000 hours at room temperature, and all-solid-state ZnI_2 batteries can be stably cycled for more than 3000 times. This work proposes a potential route to achieve stable energy storage in solid-state ZnI_2 batteries, and also provides new ideas for flexible and wearable Zn-based batteries.

Thin-Film Model Systems for *Operando* Studies of Interfacial Battery DegradationTrevorB. Binford[1], JoshuaGibson[1,2], LeanneJones[1], Tien-LinLee[3] and RobertWeatherup[1]; [1]University of Oxford, United Kingdom; [2]University of Edinburgh, United Kingdom; [3]Diamond Light Source, United Kingdom

Degradation is a pressing challenge for next-generation lithium-ion batteries, which often struggle to balance capacity versus stability. A better understanding of the chemical changes that occur over a cell's lifetime will help guide rational design of materials for superior batteries. However, the key reactive areas are buried deep within a cell and are difficult to access. The cathode-electrolyte interface (CEI) is believed to be particularly important in battery degradation, but photoelectron techniques can typically only be brought to bear on it by *ex-situ* disassembly of the entire cell. Doing so will inevitably induce changes and introduce contaminants to the surfaces under study.

To better observe the interface between lithium intercalation cathodes such as $LiCoO_2$ and solid electrolytes, we present a novel architecture for *operando* X-ray photoelectron spectroscopy (XPS). Our design enables simultaneous XPS and electrochemical measurements via an all-solid-state thin-film cell giving insights into the dynamic changes with states of charge. By forming the cathode as a suspended thin film with a thickness on the order of 10 nm, we can probe through the entire cathode to the CEI. Synchrotron-based hard X-ray photoelectron spectroscopy (HAXPES) allows for the characterisation of the interface due to the increased inelastic mean free path of electrons when using higher energy X-rays. Coupling HAXPES with soft XPS provides complementary information regarding the bulk and surface. Combining the thin-film cathode with a solid-state electrolyte and anode produces a cell that is compatible with the ultra-high vacuum conditions found in XPS systems, which are a limiting factor when conducting *operando* measurements with liquid electrolytes.

This thin-film construction offers a key benefit as a model system, as it eliminates any extraneous structural or conductive additives that could complicate interpretation of the chemistry at the cathode-electrolyte interface. The CEI remains buried, without any exposure to surface contaminants or even vacuum, while still being accessible for measurement. In this way, we can compare the degradation effects at different layers of the structure and between different points in the cell's charging cycle. Such insights into the degradation products will point toward future approaches for more stable and high-capacity battery designs.

8:00 PM EN02.07.17
Controlling Lithium Plating and Stripping in Batteries with a Glassy Metal-Organic Framework Artificial Layer JunweiDing, TaoDu and MortenM. Smedskjaer; Aalborg University, Denmark

Constructing an artificial solid electrolyte interface (SEI) layer is an effective strategy to suppress Li dendrites and alleviate volume changes during Li deposition/stripping in solid state batteries. Compared with conventional crystalline materials, glassy materials can achieve isotropic ion transport. In this work, we compare the use of nanoporous zeolitic imidazolate framework, ZIF-62, crystals and glasses as artificial SEI. Ab initio molecular dynamics simulations reveal that the ZIF-62 glassy features faster and more uniform lithium-ion conduction compared to the ZIF-62 crystal, which exhibits ion aggregation. We have also prepared experimental samples by using ZIF-62 glass or crystal as an artificial modification layer on a copper

current collector by the traditional doctor blading method. The composite lithium negative electrode is obtained by electrochemical deposition. The lithium-lithium symmetric electrical tests show that the ZIF-62 glass modification layer exhibits low ion migration energy barrier, enabling controllable and stable lithium deposition/stripping. Lithium iron phosphate has also been used as a positive electrode form full batteries. The full battery based on the ZIF-62 glass modification layer has high battery capacity, excellent rate performance and long-term cycle stability. At the same time, it also exhibits excellent electrochemical performance when matched with the high-voltage lithium cobalt oxide cathode. These findings demonstrate the excellent application prospects of using metal-organic framework glasses for Li metal anode.

8:00 PM EN02.07.18
MOF Glass Based Solid-State Polymer Electrolyte for Lithium Metal Batteries JunweiDing and MortenM. Smedskjaer; Aalborg University, Denmark

Polymer solid-state electrolytes are promising candidates for solid-state batteries, but fillers play a very critical role in adjusting their network structure, electrochemical properties, thermal stability, and mechanical properties. However, most of the fillers reported so far are anisotropic, which limits the potential to enable isotropic ion transport. Here, we prepare a novel polymer solid-state electrolyte based on a metal-organic framework (MOF) glass, namely ZIF-62 glass. Calorimetry and ion diffusion kinetics tests show that the addition of ZIF-62 glass reduces the glass transition temperature of the polymer substrate, thereby increasing the content of disordered components in the polymer electrolyte. In turn, this facilitates lithium-ion transport. Li-Li symmetric cell tests show that the polymer electrolyte containing ZIF-62 glass has low overpotential, indicating a low interfacial impedance. Due to its isotropic characteristics, the MOF glass can be closely combined with the disordered components in the polymer substrate to form a close contact interface, thereby promoting the lithium-ion diffusion. The developed MOF glass polymer electrolyte-based lithium-lithium iron phosphate full batteries therefore deliver high cycle stability and rate capability.

Strain Effect on Li-Ion Conduction in β-Li_3PS_4 and Garnet Al-$Li_7La_3Zr_2O_{12}$ Solid Electrolytes PjotrsZguns, ShikhaSaini and BilgeYildiz; Massachusetts Institute of Technology, United States

Solid-state batteries offer better safety and higher energy density, yet the Li-ion conductivity of the solid electrolytes remains lower than that of liquid organic electrolytes, limiting battery charging rate and power density. The ionic conductivity of solid electrolytes can be significantly affected by strong electrochemo-mechanical coupling, especially near the electrode/electrolyte interfaces. Mechanical stresses due to volumetric electrode changes and interfacial reactions can reach as high as 1..10 GPa [1,2] and can substantially affect solid electrolyte's conductivity. However, experimental quantification of the sole strain effect is difficult as other factors such as space charge effects and interfacial reactions also contribute to conductivity. In this work [3], we have quantified the effect of strain on conductivity in bulk β-Li_3PS_4 by means of ab initio molecular dynamics. Strain tensors that compress the *c*-axis increase the Li-ion diffusivity, while the strains which stretch the *c*-axis reduce the diffusivity. The relative change in diffusivity with 2% biaxial strain is 2-fold at 500 K and is up to 10-fold when extrapolated to room temperature. Compression of the *c*-axis facilitates diffusion through the increased disorder of the Li-sites in β-Li_3PS_4. Strain decreases the Li–Li distance and thus increases Coulomb repulsion between the bottleneck 8d and 4b sites, pushing Li to the 4c site and promoting disorder. This boosts the concentration of active Li-ion carriers, which quantitatively correlates with the changes in conductivity. The magnitude of the strain effect on Li-ion diffusion is comparable to that of chemical doping, and it is therefore important to consider strain for accurate understanding and prediction of solid-state Li-ion battery interface properties. Our findings not only provide a quantitative understanding and accurate estimates of Li-ion conductivity relevant to strained interfaces, but also a design strategy for how to increase disorder and promote superionic conduction in solid electrolytes by strain engineering. We are also extending these findings to materials that possess intrinsic Li-ion disorder such as garnet Al-doped LLZO ($Li_7La_3Zr_2O_{12}$). By applying molecular dynamics simulations, we will investigate how Al-LLZO conductivity is affected by strain and whether decreasing/increasing Li–Li distances contribute to ionic disorder and conductivity in a similar fashion to β-Li_3PS_4.

A Synthesis of Block Copolymers Based on Dynamic Covalent Bonds and its Application to All-Solid-State Battery Electrolyte SojeongRoh, Trong DanhNguyen, LeeHyeju, Min GueLee, So HyunPark, Jun SeopLee and Young SooYoon; Gachon University, Korea (the Republic of)

Recently, all-solid-state batteries (ASSB) have been in the spotlight as an alternative to potentially overcome the limitations of the existing liquid electrolyte lithium-ion batteries (LIB). Compared to liquid electrolyte LIB, ASSB has a lower risk of explosion, a higher energy density, and a relatively large electrochemical window. Solid electrolytes are largely classified into three categories: sulfide-based solid electrolytes, oxide-based solid electrolytes, and polymer-based solid electrolytes as key elements of ASSB. The most representative case among them is the lithium lanthanum zirconium oxide (LLZO), which has been extensively studied because it may easily compensate for the shortcomings of the sulfide-based solid electrolyte. Nevertheless, due to the brittleness of the ceramic-based material, it is still difficult to solve a serious interface contact problem between the electrolyte and the electrode. Therefore, many previous studies have attempted to introduce flexible polymer materials as binders to provide better wettability between solid interfaces. Specifically, ceramic-polymer composite solid electrolytes with soft interlayer in LLZO are feasible solutions that improve interfacial contact and inhibit dendrite generation in LIB. However, it is difficult to obtain sufficient ion conductivity and required mechanical properties in the polymer layer at the same time. Therefore, it is necessary to manufacture a flexible polymer membrane that can effectively promote efficient ion transport and control adhesion.
This presentation proposes to synthesize a block copolymer based on a dynamic polymer chain structure and apply the material to an ASSB electrolyte. First, the disulfide (S-S) dynamic bond between the dithiol contained oligomer and PEG chain is synthesized using a disulfide generating agent (pentaerythritol tetrakis (3-mercaptopropionic acid)). The polymer solution for interlayer film is generated by adding bis (trifluoromethanesulfonyl)imide (LiTFSI). Then, a hybrid ceramic-polymer complex is manufactured using a drop casting method that introduces a block copolymer layer on the surface of garnet LLZO. As a result, the dynamic disulfide bond in co-polymer chain improves the adhesion between the solid electrolyte and the cathode as well as the anode, leading to a better contact interface and good dendrite suppression ability. That is, the lithium-ion conductive dynamic network not only lowers the overall impedance and interfacial resistance, but also increases the adhesion of the electrolyte to the electrode material. These modified polymer networks provide adequate ion conductivity and improved wettability to the interface. Through this work, it is possible to effectively develop LLZO-based solid electrolyte that improves surface properties and regulates the ion conduction mechanism.

8:00 PM EN02.07.21
Development of Von-Alpen-Type NASICON Electrolytes with High Ionic Conductivities and Relative Densities Il-SeopJang[1,2] and JinyoungChun[1]; [1]Korea Institute of Ceramic Engineering and Technology, Korea (the Republic of); [2]Korea University, Korea (the Republic of)

The NASICON compound, represented by the chemical formula $Na_{1+x}Zr_2Si_xP_{3-x}O_{12}$ ($0 \le x \le 3$), exhibits a Na^+ ion conductivity of approximately 10^{-4} S cm^{-1} and a wide electrochemical window. It is chemically stable not only in air but also in seawater. However, the ion conductivity of NASICON compounds is relatively lower compared to typical liquid electrolytes (10^{-2} S cm^{-1}), leading to decreased performance. In this study, a method is proposed to enhance the ion conductivity and density of vA-NASICON (von-Alpen-type NASICON) ceramic electrolytes by doping them with heterogeneous element Mg^{2+} ions. Additionally, a synthesis method utilizing a sintering aid for vA-NASICON is suggested to achieve higher ion conductivity and density at lower temperatures and shorter times.

Considering factors such as raw material cost, ion radius, and oxidation state, Mg^{2+} ions were chosen as heterogeneous element dopants compared to the Zr^{4+} ions present in NASICON compounds. The effects of Mg dopant incorporation on the modified crystal structure, surface changes, and formation of secondary phases were analyzed, and their influence on the ion conductivity of vA-NASICON was studied. The dopant precursor, MgO, can enhance the surface diffusion coefficient, increase the densification rate, and promote crystal growth. However, excessive introduction of Mg^{2+} leads to the formation of undesirable secondary phases, such as $Na_xMg_yPO_4$, which results in a decrease in the ion conductivity of Mg-doped vA-NASICON. By analyzing the ion conductivity, the optimal Mg doping level was determined. The vA-NASICON synthesized with the optimal Mg doping exhibited a higher ion conductivity of $3.64x10^{-3}$ S cm^{-1} compared to undoped vA-NASICON ($2.03x10^{-3}$ S cm^{-1}).

The introduction of Glass-frit in vA-NASICON can increase the sinterability of the ceramic matrix and lower the densification sintering temperature. vA-NASICON was prepared by solid-state reaction, and systematic investigations were conducted on crystal structure, microstructure, and electrochemical properties. Glass-frit added vA-NASICON sintered at 1200 dgree for 1 hour showed a high ionic conductivity of $2.1x10^{-3}$ S cm^{-1} and a relative density of 97.2%, surpassing vA-NASICON ($2.54x10^{-3}$ S cm-1, relative density 65.7%) without addition. Glass-frit is that by forming an amorphous phase at the grain boundary, it can promote grain boundary contact and promote densification of ceramic electrolyte. The results of this study are expected to be effectively utilized in the development of oxide-based solid electrolytes with high ionic conductivity and density.

Understanding Cold Sintering Processes in Densification of Halide-Based Solid Electrolytes QianqianYan, ColeD. Fincher and Yet-MingChiang; Massachusetts Institute of Technology,

United States

Halide-based ceramics have emerged as promising candidates for solid-state Li battery applications due to their high ionic conductivity and air stability. However, their manufacture and processing pose a challenge for solid-state batteries, as conventional ceramic processing often requires elevated temperatures and pressures. In this study, we develop cold sintering processes (CSPs) for halide-based solid-state electrolytes. We enable densification of these materials below 300°C by studying the impact of liquid-phase additives on dissolution / reprecipitation during pressure-densification. We further explore the influence of pressure, dwell time, temperature, and precursor compositions on the electrolyte's mechanical and electrochemical properties. The systematic investigation of these parameters provides crucial insights into the underlying mechanisms governing the densification process and contributes to designing and manufacturing of ceramic solid electrolyte architectures.

Multicomponent Protective Layers for All-Solid-State Li Metal Batteries HaechannaraLim, SeunggooJun, Ki HeonBaeck and Yoon SeokJung; Yonsei University, Korea (the Republic of)

The advancement of electric vehicles has stimulated extensive research into lithium-ion batteries (LIBs) with higher energy densities and improved safety. Consequently, all-solid-state Li metal batteries (ASLMBs) have emerged as a promising alternative due to the exceptional theoretical capacity (3,860 mA h g^{-1}) and low electrochemical potential (-3.04 V vs SHE) of Li metal anode, as well as their improved safety resulting from the utilization of nonflammable inorganic solid electrolytes (SEs) compared to conventional lithium-ion batteries employing liquid electrolytes. Especially, sulfide solid electrolytes (SEs) have been one of the most promising candidates thanks to their high ionic conductivities (maximum ~2.0×10^{-2} S cm^{-1}) and mechanically ductile property. Nevertheless, the implementation of ASLMBs has been hindered by the unstable interfaces between Li metal and SEs, leading to severe decomposition of sulfide SEs and the formation of dendrites. To address the challenges related to interfacial instability, researchers have proposed various materials, such as lithiophilic metals and inorganics, as protective layers for Li metal. Nevertheless, no single protective coating has achieved acceptable interfacial stability between Li metal and SEs. Recently, the concept of multi-component protective layers comprising lithiophilic metals and robust inorganic materials has been introduced. However, there remains a lack of comprehensive analysis regarding the configuration or structure of the protective layer and its influence on the performance of ASLMBs.
In this study, we present our recent investigation into the configuration of protective layers for Li metal and their impact on the performance of ASLMBs. Additionally, we discuss different mechanisms of Li metal plating and stripping based on variations in the protective layer's structure.

Liquid-Phase Synthesis of Metal-Containing (M = Ge, Sn) Sulfide Solid Electrolytes for All-Solid-State Batteries BoyeongJang, JehoonWoo, Yong BaeSong, HiramKwak and Yoon SeokJung; Yonsei University, Korea (the Republic of)

All-solid-state batteries (ASSBs) have been spotlighted for their potential to enhance both energy density and safety compared to conventional lithium-ion batteries that rely on organic liquid electrolytes. Sulfide solid electrolytes (SEs) are viewed as crucial components for ASSBs due to their high ionic conductivity, deformability, composition flexibility, and processability. Sulfide SEs can be prepared through either solid-state or liquid-phase synthesis. Particularly, the liquid-phase synthesis of sulfide SEs offers potential advantages for large-scale production, including product homogeneity, particle size control, and lower energy consumption. However, the compatibility and solubility challenges between precursors and solvents limit the liquid-phase synthesis of various compositions of sulfide SEs. Specifically, the poor solubility of metal chalcogenides (e.g., GeS_2 and SnS_2) has hindered the synthesis of sulfide SEs with MS_4 (M = Ge, and Sn) units. Furthermore, liquid-phase synthesized SEs are often contaminated by impurities such as carbon, derived from solvent residues, which are detrimental to the performance of ASSB cells.
In this presentation, the liquid-phase syntheses of sulfide SEs with various compositions, including metals (e.g., Ge and Sn). Importantly, we report a novel heat treatment technique to address the chronic carbon impurity issue in liquid-phase synthesized SEs. Compared to SEs prepared through conventional furnace heating, SEs obtained through a new heating protocol exhibit outstanding electrochemical performance in terms of capacity and cycling stability.

Transforming Commercial Paper into Flexible Solid Electrolyte with High-Ionic Conductivity for Durable Lithium-Sulfur Batteries MortezaSabet[1], NawrajSapkota[1], MihirParekh[1], NancyChen[1], YiDing[2], SrikanthPilla[1] and ApparaoM. Rao[1]; [1]Clemson University, United States; [2]U.S. Army DEVCOM GVSC, United States

Solid-state lithium-sulfur (Li-S) battery technologies could power future electric mobility due to their potential high energy density. However, the current solid-state Li-S batteries face several challenges, such as high internal impedance at the electrode/electrolyte interfaces, shuttling of lithium polysulfides, and Li dendrite formation. Herein, we introduced a Li-rich cellulose-based solid-state electrolyte in combination with sulfurized polyacrylonitrile (SPAN, 36.5 wt.% S) cathode, leading to high-capacity and durable Li-S batteries. We utilized SPAN due to its reasonable conductivity, high reversible capacity, and stable cycling performance. Adopting the procedure described in **Ref. 1**, the solid-state electrolyte in this study was prepared by infusing Li ions (Li^+) into a copper-coordinated commercial cellulosic paper. The infusion of Li^+ was carried out by soaking the copper-treated paper in a 1 M LiTFSI in $EC_{0.5}DME_{0.25}DOL_{0.25}$ solution (where subscripts indicate the volume fraction), followed by complete evaporation of the solvents. The prepared solid-state electrolyte (~300 µm in thickness) exhibited high room-temperature ionic conductivity of 1.5×10^{-4} S cm^{-1}, superior to the reported values for solid-state electrolytes with similar thicknesses. The Li-SPAN cell with paper-based electrolyte delivered a room-temperature reversible capacity of 1350 mAh g_s^{-1} in the first cycle and 990 mAh g_s^{-1} after 100 cycles at 0.1C (1C: 1675 mAh g_s^{-1}), with a capacity retention of 73.33%. The conformability of the paper-based electrolyte ensures good interfacial contact with the SPAN and Li electrodes. As a result, when this solid-state Li-S battery was tested at 0.5C and 1C, it delivered a reversible capacity of 800 and 400 mAh g_s^{-1}, respectively. In this talk, we will outline the results from our electron microscopy, electrochemical impedance spectroscopy, and cyclic voltammetry studies to unravel the superior performance of paper-based Li-S batteries. We will also present the cycling performance of our cells for high-temperature applications.

Evolution of Interfacial Cathode Kinetics in Sulfide All-Solid-State Li Batteries Measured with Electrochemical Impedance Spectroscopy (EIS) AlyssaStavola, DominickGuida, XiaoSun, HongliZhu and JoshuaW. Gallaway; Northeastern University, United States

Sulfide all-solid-state Li batteries (ASLBs) suffer from a large capacity loss on the first cycle jeopardizing their commercialization and energy density. This large initial coulombic mismatch is theorized to be due to formation of the cathode electrolyte interface (CEI) and volume changes in the cathode material resulting in increased internal resistance and a loss of electrochemically active surface area respectively.[1] We have previously reported an operando analysis of Li^+ and e^- conduction across a composite cathode based on Li-$Ni_{1/3}Mn_{1/3}Co_{1/3}O_2$ (NMC111) and Li_6PS_5Cl (LPSC) during initial cycling.[2] This analysis indicated that conduction during initial cycling was subject to high tortuosity factors (t^2) for both the LPSC and NMC phases. Additionally, the t^2 values evolved during the initial battery charge step. Because cathode performance was limited by conduction, we were unable to infer information about kinetic phenomena, e.g. the charge transfer rate between LPSC and NMC, from the experimental results. In particular, the first cycle capacity loss may be caused by a drop in interfacial kinetics.

To study this capacity loss as a function of state-of-charge, in situ EIS was performed during initial cycling of a full cell with a composite cathode based on NMC111 and LPSC (Li/In| Li_6PS_5Cl| NMC111/Li_6PS_5Cl). This piecewise EIS allows us to analyze both time dependent and state-of-charge dependent interfacial processes while the battery cycles with no modifications to cell design. A transmission line model allowed for quantification of the electrochemically active surface area and its effect on resulting capacity during the first charge of this ASLB system.

Decoupling Irreversible and Reversible Inefficiencies at Dynamic Interfaces in Sulfide Solid State Battery Positive Electrodes EmmaKaeli[1], XiaomianYang[1], ZhelongJiang[1], SunnyWang[1], EdwardBarks[1], Yan-KaiTzeng[2], StephenKang[1] and William C.Chueh[1]; [1]Stanford University, United States; [2]SLAC National Accelerator Laboratory, United States

Battery systems present a uniquely difficult environment for disentangling sources of inefficiency. As an example, positive electrode-electrolyte interfaces incur simultaneous charging-induced side reactions, surface area change, and lithiation-state dependent intercalation rates. For sulfur-based composite electrodes in solid state batteries (SSBs) these parallel processes present a formidable challenge to addressing first cycle Coulombic inefficiency.[1] Without fully decoupling inefficiencies, it is unclear which degradation mechanism is most critical to address and, further, how applied solutions impact each mechanism in turn. For example, to mitigate unwanted side reactions between sulfide solid electrolytes (SEs) and positive electrode materials like $LiNi_XMn_YCo_{1-X-Y}O_2$ (NMC), the field has implemented interfacial coatings to increase Coulombic efficiency.[2-4] While coating design focuses on thermodynamic stability at the interface, the coatings could be improving battery performance by addressing other inefficiencies in parallel, such as increasing the rate of the intercalation reaction or reducing ionic constriction at the NMC/SE interface.

This work systematically decouples the impacts of ionic constriction, electrolyte redox and NMC/SE interphase formation in sulfide-SE SSB first cycle electrochemistry to better inform design of solutions for the NMC/SE interface. Using uncoated $LiNi_{0.5}Mn_{0.3}Co_{0.2}O_2$ we demonstrate a method to delineate contributions to Coulombic inefficiency between slow kinetics and irreversible reactions. To determine the reversibility of interphase products and the impact of cycling history we track lithiation state and generation of interphase products during cycling. We determine the ability of generated interphase products to contribute to self-discharge of NMC and the resultant impact on Coulombic inefficiency. Using two different electrolytes, Li_3PS_4 and Li_5PS_6Cl, which have well-defined but unique thermodynamically-predicted redox reactions and reaction potentials, we separate contributions to Coulombic inefficiency between electrolyte redox reactions and reactions involving transition metals and oxygen from NMC. Finally, by comparing borate-coated and uncoated NMCs, we investigate the coating's impact on interphase formation, ionic constriction and intercalation reaction rate.

Studying Li Evolution in Mixed Ionic-Electronic Conducting Interlayer of Sulfide Based All-Solid-State Batteries Through *Operando* Raman and Neutron ImagesDaxianCao and HongliZhu; Northeastern University, United States

Lithium-metal (Li^0) anode potentially enables all-solid-state batteries with high energy density. However it shows incompatibility with sulfide solid-state electrolytes (SEs). One strategy is introducing an interlayer, generally made of a mixed ionic-electronic conductor (MIEC). Yet, how Li behaves within MIEC remains unknown. Herein, we investigated the Li dynamics in a graphite interlayer, a typical MIEC, using *operando* neutron imaging and Raman spectroscopy. This study revealed intercalation–extrusion-dominated mechano-chemical reactions during cell assembly transform the graphite into a Li-graphite interlayer consisting of SE, Li^0, and graphite-intercalation compounds. During charging, Li^0 preferentially platted at the Li-graphite|SE interface and then transferred into the Li-graphite interlayer without intercalation. Upon further plating, Li^0-dendrites formed, inducing short circuits and reverse immigration of Li^0. Continuum modeling was conducted to explain the Li dynamics. We concluded that the lowest nucleation barrier at the Li^0 side is necessary to drive the Li^+ across the MIEC and preferentially deposit onto the Li^0.

Electronic Conductivity of Lithium Solid Electrolytes FudongHan; Rensselaer Polytechnic Institute, United States

While significant efforts have been devoted to improving the ionic conductivity of lithium solid electrolytes (SEs), electronic transport, which has an important role in the calendar life, energy density, and cycling stability of solid-state batteries (SSBs), is rarely studied. In this talk, we will present our recent results on the electronic conductivities of three representative SEs, including Li3PS4, Li7La3Zr2O12, and Li3YCl6 for sulfide-, oxide-, and halide-based SEs, respectively. By revisiting direct current polarizations using two-blocking-electrode cells and the Hebb-Wagner approach, we propose that the electronic conductivities of SEs are overestimated from the conventional measurements. We will discuss the limitations and sources of inaccuracy for these measurements and highlight the anodic decomposition of SE as the key source for the overestimated result. Modifications in the electrode selection and data interpretation are also proposed to approach the intrinsic electronic conductivity of SEs. To estimate the electronic conductivity of sulfides that decompose during measurement, a two-step polarization method will also be introduced. The electronic conductivities of all SEs measured by the modified approach are one or two orders of magnitude lower than the reported value. Despite that, the electronic conductivity of sulfides seems to be still quite high to enable SSBs with a long calendar life of >10 years, highlighting the critical need for a more careful study of electronic transport in lithium SEs.

Computational Investigation of Dynamic Voltage Stability in Solid State Batteries YichaoWang, WilliamFitzhugh, XiChen, LuhanYe and XinLi; Harvard University, United States

Intrinsic or interface thermodynamic voltage windows of solid electrolytes are often narrower than the operational voltage range needed by a full battery, thus various decomposition reactions can happen in a practical solid-state battery. These decompositions can undergo local volume expansions, which will compress the reaction front in a solid environment under a mechanical constriction and modify the reaction thermodynamics and kinetics. Experimentally, it was found that a proper battery design utilizing the effect can lead to dynamic voltage stability for advanced battery performance. Here we articulate first our state-of-the-art understanding about how computationally the dynamic voltage stability should be interpreted and treated. We further apply our constrained ensemble computational approach across these solid-state electrolytes to systematically evaluate and compare their dynamic stability voltage windows in response to the mechanical constriction effect. High throughput calculations are used to search for coating materials for different interfaces between sulfide, halide, and oxide electrolytes and typical cathode materials with enhanced dynamic voltage stability.

Atomic Insights into the Oxidative Degradation Mechanisms of Sulfide Solid Electrolytes ChuntianCao[1], MatthewCarbone[1], JagritiShekhawat[2], CemKomurcuoglu[2], KerrySun[2], HaoyueGuo[2], SizhanLiu[1], KeChen[1], Seong-MinBak[1], YonghuaDu[1], ConanWeiland[3], XiaoTong[1], DanSteingart[2,2,2], ShinjaeYoo[1], NongnuchArtrith[2,4], DeyuLu[1] and FengWang[1]; [1]Brookhaven National Laboratory, United States; [2]Columbia University, United States; [3]National Institute of Standards and Technology, United States; [4]Utrecht University, Netherlands

Electrochemical degradation of solid electrolytes is a major roadblock in the development of solid-state batteries, and the formed solid-solid interphase (SSI) plays a key role in the performance of solid state batteries. In this study, by combining experimental X-ray absorption spectroscopy (XAS) measurements, first-principles simulations, and unsupervised machine learning, we have unraveled the atomic-scale
oxidative degradation mechanisms of sulfide electrolytes at the SSI using the baseline Li_3PS_4 (LPS) electrolyte as a model system. The degradation begins with a decrease of Li neighbor affinity to S atoms upon initial delithiation, followed by the formation of S-S bonds upon the deformation of the PS_4 tetrahedra. In the second and following delithiation cycles, the PS_4 motifs are strongly distorted and PS_3 motifs start to form. Spectral fingerprints of the local structural evolution are identified, which correspond to the main peak broadening and shifted to higher energy by about 2.5 eV in P K-edge XAS and a new peak emerging at 2473 eV in S K-edge XAS during the delithiation. The spectral fingerprints serve as a proxy of the electrochemical stability of phosphorus sulfide solid electrolytes, as demonstrated in argyrodite Li_6PS_5Cl. We have observed that the strong distortion and destruction of PS_4 tetrahedra and the formation of S-S bonds are correlated with the increased interfacial impedance. To our knowledge, this study provides the first atomic-scale insights into the oxidative degradation mechanism of the LPS electrolyte, which can provide guidance for controlling macroscopic reactions through microstructural engineering and, more generally, can advance the rational design of sulfide electrolytes.

9:45 AM EN02.08.07
Viscoplasticity Driven Approach to Increase Critical Current Density in Sulfide Electrolytes ChangminShi[1], CristinaLopez Pernia[1], XingLiu[2], PradeepGuduru[1] and BrianW. Sheldon[1]; [1]Brown University, United States; [2]Georgia Institute of Technology, United States

All-solid-state batteries (ASSBs) show a high practical potential to achieve safe battery design with high energy densities when using Li metal as an anode. Sulfide electrolytes due to their high ionic conductivity (0.1 mS/cm to >10 mS/cm) are among the most promising candidates. However, Li dendrite growth results in shorting at critical current densities (CCD) that are well below values that are needed for practical applications. This currently limits the development of sulfide-based ASSBs, and therefore, it is very important to stabilize sulfide-electrolyte/Li-metal interfaces to enable high current densities without shorting.

Extensive efforts have been devoted to increasing the interfacial stability with methods that emphasize chemical and electrochemical modifications. However, methodologies that increase the CCD in sulfide electrolytes based on mechanics have not been reported. Herein we report a viscoplasticity based approach to increase the CCD of sulfide electrolytes. Previous studies have demonstrated that some sulfide SEs deform in a viscous manner[1,2]. Considerations of this effect offer a new perspective on how to suppress Li dendrite growth. To investigate the viscoplastic properties of sulfide electrolytes, Li_6PS_5Cl (LPSC) was selected as an important candidate due to its high ionic conductivity and high stability against Li metal compared with other sulfide electrolytes. Viscoplasticity in this material was investigated and characterized by integrating nanoindentation experiments and finite element simulations, and improved CCD was observed by employing cycling conditions that take advantage of this inelastic deformation. Such improvement is attributed to the interaction between the specially designed charging-discharging cycles and the viscous deformation of the electrolyte. We have also performed finite element simulations to further validate our argument. This type of approach can provide major improvements in the performance of ASSBs and can also be combined with chemical/electrochemical methods to further enhance cell performance using sulfide electrolytes.

Interfacial Engineering of Solid-State Batteries: From Metal Anodes to Composite Cathodes NeilP. Dasgupta; University of Michigan, United States

Solid-state batteries have the potential to be a disruptive technology because of their ability to improve safety and increase energy density by incorporating Li metal anodes. However, all solid-state interfaces present unique challenges, including high interfacial impedances, accommodation of mechanical stresses due to solid-solid interfacial contact, and (electro)chemical instabilities that can evolve during dynamic cycling conditions. Furthermore, a significant challenge facing the scale-up of SSBs is to improve our understanding of processing science needed to enable manufacturing.

To address these challenges, our group focuses on gaining new fundamental insights into the coupled phenomena occurring at interfaces, and applied this knowledge to rationally design interfacial composition and structure to address the root cause of performance limitations. In this talk, I will describe our journey to deepen our understanding of interfacial phenomena at both the Li metal anode side, as well as in composite solid-state cathode materials. On the anode side, there is a critical need to understand and control the coupling between electrochemistry, morphology, and mechanics, to improve the uniformity and reversibility of plating and stripping during charge and discharge, respectively. On the cathode side, we focus on overcoming energy/power tradeoffs, which exhibit unique phenomena owing to the single-ion conducting nature of ceramic electrolytes, as well as improving stability at high voltages.

Equipped with this fundamental understanding, I will describe our efforts to engineer modified interfaces through control of the surface chemistry, incorporation of interlayers, and fabricating 3-D architectures. Through this interdisciplinary approach of fundamental materials chemistry and applied engineering, strategies to address future interfacial challenges will be addressed, pointing towards rational design and manufacturing of optimized interfaces.

10:45 AM *EN02.09.02
Cross-Talk Between Anode and Cathode Degradation Mechanisms in all Solid State Batteries KelseyB. Hatzell; Princeton University, United States

All solid-state batteries (ASSB) can potentially achieve high gravimetric and volumetric energy densities (900 Wh/L) if paired with a lithium metal anode and solid electrolyte. However, there is a lack in critical understanding about how to operate lithium metal cells at high capacities with composite solid state cathodes. The interconnection and cross-talk between anode and cathode degradation mechanisms is largely not well understood. Herein, we investigate how pressure and temperature influence the formation and annihilation of unrecoverable voids in lithium metal upon stripping and subsequent contact evolution challenges at cathode. Here we use both x-ray and electron imaging techniques to characterize degradation mechanisms across multiple scales.

11:15 AM *EN02.09.03
Understanding the Evolution of High-Capacity Anodes in Solid-State Batteries MatthewT. McDowell; Georgia Institute of Technology, United States

Solid-state batteries offer the promise of improved energy density and safety compared to lithium-ion batteries, but electro-chemo-mechanical evolution and degradation of materials and interfaces can play an outsized role in limiting their performance. Here, I will present my group's recent work on understanding structural evolution, interfacial dynamics, and chemo-mechanics in solid-state batteries with two different types of anodes: zero-lithium excess anodes ("anode-free") and alloy anodes. Anode-free solid-state batteries, in which there is no initial lithium metal at the anode interface, offer extremely high energy density, but there is a lack of understanding of the mechanisms that govern their behavior in solid-state batteries. Using X-ray tomography, cryo-FIB, and finite-element modeling, we show that anode-free solid-state batteries are intrinsically limited by current concentrations at the end of stripping due to localized lithium depletion. This causes accelerated short circuiting compared to lithium-excess cells. Based on these results, the beneficial influence of metal alloy interfacial layers on controlling lithium evolution and mitigating contact loss from localized lithium depletion will be introduced and discussed. In the second part of the talk, a new design for dense aluminum foil alloy anodes is introduced, in which microstructural control over the foil is shown to play a key role in significantly improving reversibility in solid-state batteries. This anode design mitigates chemo-mechanical degradation and offers a paradigm that does away with slurry coating, potentially reducing manufacturing costs. Taken together, these findings show the importance of controlling chemo-mechanics and interfaces in solid-state batteries for improved energy storage capabilities.

11:45 AM EN02.09.04
Understanding The Li Dendrite "Soft Short" in Solid-State Li Metal Batteries by Phase-field Method KenaZhang[1], DaxianCao[2], TongtaiJi[2], HongliZhu[2] and YeCao[1]; [1]The University of Texas at Arlington, United States; [2]Boston University, United States

Lithium (Li) dendrite growth in Li metal batteries is a long-standing problem, which causes critical safety concerns and severely limits the advancement of rechargeable Li batteries. Replacing conventional liquid electrolyte with solid electrolyte (SE) of high mechanical strength and rigidity was once thought as an effective strategy to suppress the Li dendrite growth. However, defects in SEs (such as cracks, voids, grain boundaries etc.) and the imperfect contact between the electrode and the SE can even facilitate the Li dendrite growth. Recently, it was postulated that the Li dendrite growth in SEs could be the reason for "soft short" of the cell. Compared to "hard short" in which the voltage of the battery decreases suddenly during the charging process, in "soft short" the voltage is dynamically stable but cannot increase during the charging process. However, the underlying mechanism of "soft short" is still not well understood. In this work, we developed a phase-field model coupled with electrochemistry and solid mechanics to unravel the dynamics of Li dendrite growth in a porous SE under the applied external pressure during charging, and its correlation with the "soft short". It is revealed that Li dendrite growth causes a hydrostatic pressure inside the Li metal, which increases with the external pressure and is responsible for the suppression of Li dendrite growth. Without external pressure, Li dendrite growth is less restricted by the SE and can fill the small pores inside the SE to form a tree-like

morphology. The growth of multiple Li dendrites eventually penetrates through the entire SE, causing “hard” short circuit of the cell. This is evidenced by the sudden increase of leakage current during charging process in the simulation. When the external pressure increases to 10MPa, the hydrostatic pressure is maximized at the pore-SE interface which blocks the Li dendrite to fill into the pores, and eventually breaks parts of the Li dendrites to form dead Li. Our simulation results agree with the X−ray computed tomography of the deposited Li metal and cracks inside the SE by our collaborators. More importantly, the simulated fracture of Li dendrite (disconnection to the anode) and the subsequent reconnection to the Li anode can well explain the “soft short” in experiments, as they prevent the Li dendrite from completely penetrating the SE. This is further evidenced by the leakage current fluctuations in our simulation, indicating a typical "soft short" behavior. Our work thus provides a deeper understanding of the Li dendrite growth dynamics in porous solid electrolyte and the “soft short” phenomenon in solid state batteries.

SESSION EN02.10: Sulfur Cathode I

1:30 PM *EN02.10.01
Engineering Sulfur Cathodes for Solid State Batteries PingLiu; University of California, San Deigo, United States

Solid state batteries with sulfur-based cathodes are highly appealing due to their intrinsic cost and energy density advantages. If fully realized, they also promise a departure from our reliance on transition metals and even facile recycling. Extensive effort has been dedicated to improve the electrical conductivity and manage the volume change during cycling. In this regard, sulfur-containing polymers have shown stable cycling stability but with limited capacity. Recently we have shown poly thiocyanogen can deliver material-level energy density of > 1400 Wh/kg. However, the material is found only to have enough electron and ionic conductivities at elevated temperatures. The result illustrates the limitation of using conductive polymer or carbon backbones to provide electronic conductivity. We have recently explored the possibility of heteroatom doping into sulfur composite materials. Selected dopants have shown promise in facilitating the charge transfer in the solid electrode as well as increasing the ductility of the composite structure. Both of these features help improve the rate capability and cycle life of the sulfur based cathode. We will discuss how these findings can offer design rules for new sulfur based cathodes, including further improvement to enable cycling at reduced pressure.

2:00 PM *EN02.10.02
Materials Challenges for High-Energy and Long-cycle-Life All-Solid-State Lithium-Sulfur Battery DongpingLu, MichaelKindle, DanielMarty, JingWu, DaheeJin and Un HyuckKim; Pacific Northwest National Laboratory, United States

All Solid-state Lithium-Sulfur battery (ASSLSB) is regarded as a promising next-generation battery technology for vehicle electrification due to its merits of high energy, low cost, and high safety. However, performance improvement and deployment of the technology are still largely hindered by the challenges associated with both sulfur (S) cathode and lithium anode. Although issues of polysulfide dissolution, Li corrosion, and electrolyte consumption existing in liquid Li-S cells are fully eliminated, achieving both high energy and stable cycling in S cathode is still very challenging. Those include (1) low S content and mass loading, 2) low operation current densities, and 3) large electrode volume change upon cycling. This is due to extremely low ionic and electronic conductivities of S and Li_2S, which relies on the effectiveness and completeness of Li^+/e^- conduction networks built on both solid-state electrolyte (SSE) and carbon (C) conductors. The clear understanding or a design principle of an optimal S/SSE/C triple phases is still lacking. The other grand challenge of ASSLSB is how to achieve long-term and dendrite-free Li cycling at both high current densities and high areal capacities. Properties of Li/SSE interface impacts early-stage Li nucleation, which dictates subsequent Li growth. For this aspect, uniformity of Li/SSE interface both in chemistry and morphology could even and reduce local current density, promoting uniform Li growth. The interfacial stability of Li/SSE could be achieved by forming a stable SEI. However, it is challenged by Li dynamics during repeated cycling, particularly at practically high current density and areal capacity conditions, which may boost the potentials of inhomogeneous Li deposition and even dendrite formation. To overcome those issues, rational designs of materials, electrode, and interface are essentially needed to both boost S reaction kinetics and stabilize Li/SSE interface. At the conference, we will discuss our understandings of those key challenges and new progresses we achieved in addressing them.

Lithiation Gradients and Tortuosity Factors in Thick NMC111-Argyrodite Solid-State Cathodes JoshuaW. Gallaway, AlyssaStavola, DominickGuida, AndreaM. Bruck, XiaoSun and HongliZhu; Northeastern University, United States

Achieving the high energy density targets for all-solid-state batteries (ASSBs) will require thick cathodes optimized for full utilization of active material. In composite cathodes with sulfide solid-state electrolytes (SSEs), the exclusion of carbon additives makes cathode design to balance ionic and electronic conductivities all the more important. Li-$Ni_{1/3}Mn_{1/3}Co_{1/3}O_2$ (NMC111) is a widely studied cathode material for its high energy density and high working voltage. The lattice parameters of this well-studied structure directly correlate to the amount of Li in the material, allowing for very accurate measurements of lithium-ion concentration gradients (lithiation gradients) throughout the cathode depth.

In this work, we report an operando analysis of Li^+ and e^- conduction across 120 µm thick composite cathodes based on NMC111 and Li_6PS_5Cl (LPSC) during initial cycling.[1] This analysis indicates that conduction during initial cycling is subject to high tortuosity factors (τ^2) for both the LPSC and NMC phases. Additionally, the τ^2 values evolve during the initial battery charge step, increasing steeply. By analyzing composite cathodes with a range of cathode active material (CAM) loadings, we observe the effect of CAM loading on the non-uniformity of the electrochemical reaction. For 80% CAM we observe that the initial reaction heavily favors regions of the cathode that are nearest the anode. For 70% and 40% CAM, the opposite is true, with initial reaction favoring the regions farthest from the anode. These non-uniformities are very large, often amounting to a gradient of over 50% of the total cycleable capacity across the cathode thickness.

Spatially resolved lithiation gradients in thick NMC111/ Li_6PS_5Cl composite cathodes were measured using operando energy dispersive X-ray diffraction (EDXRD) on sealed and pressurized ASSBs with varying relative amounts of CAM and SSE. Electrochemical impedance spectroscopy (EIS) and transmission line modeling were employed to test the ionic and electronic conductivities of composite cathodes with similar varied CAM and SSE ratios. The balance of ionic and electronic conductivities was found to determine the lithiation gradients and utilization of active material in the cell.

3D Printed Porous LLZO Multi-Layer Scaffolds for Li-Garnet Solid-State Batteries Bor-RongChen, AsaG. Monson, PeteBarnes, JorgenF. Rufner, ArinS. Preston, DonnaP. Guillen and

EricJ. Dufek; Idaho National Laboratory, United States

Garnet-based oxides ($Li_7La_3Zr_2O_{12}$, LLZO) are promising solid-state electrolyte materials to achieve higher energy density and improved safety for the next-generation solid-state batteries (SSBs) due to their high ion conductivity and chemical stability. To enhance the performance of garnet-based SSBs, a dense-porous design of microstructure has been introduced in recent years. The design consists of a dense layer as the separator and one or two porous layers as the host of anode or cathode active materials [1-3]. The porous structure mitigates volume changes in the anode by accommodating Li in the pores during Li deposition, while the dense layer prevents short circuiting and provides additional mechanical support. Such bi- or tri-layer scaffolds are usually fabricated using tape-casting, in which the porous and dense layers are prepared separately, followed by trimming and stacking into the desired architectures. As a result, this process is challenged by workflow inefficiency due to the multiple separated casting and stacking steps.

To improve the efficiency in fabricating the porous-dense scaffold, we introduce an alternative approach using digital light processing (DLP), a unique 3D printing technology capable of layer-by-layer printing of multiple components and complex architectures in a single print [4]. Using DLP, the entire multilayer structure in the desired dimension is created *all-at-once* on the same printing platform by alternating printing slurries that respectively form the dense and porous layers. We produce free-standing, sub-millimeter-thick Ta-doped (LLZTO) porous-dense layers and demonstrate that the porosity is tunable by adjusting the particle size and solid loading in the printing slurry. This strategy for controlling the porosity is distinct from current approaches such as adding pore formers or controlling heat treatment conditions. By tuning the porosity in each of the printed layers, we show that a graded porosity can be created across the scaffold. In the future, this DLP printing approach will provide more opportunities to produce various microstructures and chemistries of SSBs with more efficiency and sustainability.

Self-Healing Laminated LLZO/Reduced Graphene Oxide/LLZO Composite Solid-State Electrolytes for Arresting Dendrite Penetration in Solid-State Batteries Zikang (Austin)Yu, ChangminShi, CristinaLopez Pernia, ChenjieGan and AleksandarMijailovic; Brown University, United States

Solid state lithium metal batteries using inorganic solid electrolytes are widely regarded as next-generation devices that can enable substantial improvements in energy density. However, the performance of these electrolytes is currently limited as they are largely unable to hinder the propagation and penetration of lithium metal dendrites that lead to the shorting of cells at practical current densities. In this work, we propose a novel architecture for solid state electrolytes, using a laminated composite structure consisting of reduced Graphene Oxide (rGO) interlayers that are embedded inside of Tantalum-doped LLZO ($Li_{6.4}La_3Zr_{1.7}Ta_{0.3}O_{12}$) to create a stable layered solid-state battery that effectively arrests dendrite penetration. Testing of these interlayer-engineered LLZO electrolyte with symmetric lithium metal electrodes, leads to critical current density increases of more than 7 times at room temperature. FEM simulations of these multi-layered structures were also conducted to provide insight into designing a broader range of laminated solid electrolyte architectures. Our results indicate that solid state electrolytes can be engineered with interlayers to deflect dendrites and improve critical current densities.

4:15 PM EN02.11.04
Three-Dimensional Physical Modeling of the Wet Manufacturing Process of Solid-State Battery Electrodes MohammedAlabdali[1], Franco M.Zanotto[1,2], MarcDuquesnoy[1,3], Anna-KatharinaHatz[4], DuanchengMa[4], JeremieAuvergniot[4], VirginieViallet[1,2], VincentSeznec[1,2,3] and AlejandroA. Franco[1,2,5]; [1]Laboratoire de Réactivité et Chimie des Solides (LRCS), Université de Picardie Jules Verne, Hub de l'Energie, UMR CNRS, France; [2]Réseau sur le Stockage Electrochimique de l'Energie (RS2E), Hub de l'Energie, FR CNRS, France; [3]Alistore-European Research Institute, Hub de l'Energie, FR CNRS, France; [4]Umicore, Belgium; [5]Institut Universitaire de France, France

We present an innovative three-dimensional physics-based modeling workflow that addresses the issue of poor performance of Solid-State Battery (SSB) cells due to the challenging design and manufacturing of composite electrodes with appropriate ionic and electronic conductivities. While modeling approaches have been utilized in the literature to investigate the influence of stochastically-generated microstructures on their conductivities, computational simulations able to predict the influence of manufacturing parameters on the SSB electrode microstructures remain elusive [1]. We present a novel physics-based computational modeling framework able to numerically investigate the impact of wet manufacturing process parameters (*e.g.* formulation, drying rate, calendering degree) on the properties of SSB tape casted composite electrodes. In analogy to our previous work on the simulation of the manufacturing process of Lithium Ion Battery electrodes [2], the Coarse-Grained Molecular Dynamics (CGMD) is adapted and used here for the simulation of the manufacturing process of SSB composite electrode cathode based on the physical interactions among individual particles representing the materials constituting the slurry and the formed electrode (*i.e.* NMC622, Carbon-Binder Domain and Li_6PS_5Cl) involved in the wet manufacturing process. By encompassing the entire process of wet manufacturing of SSB electrodes, from the slurry to the calendering, the model is able to predict the correlations between manufacturing parameters and electronic and ionic conductivities of the electrodes. We show why and how this model constitutes an important tool to assist in the optimization of interfaces between the materials in the electrodes, leading to improved SSB performance and durability.

Low-Temperature Design of Solid Oxide Electrolyte Through Amorphization GiyunKwon, HyeokjoGwon, YoungjoonBae, JusikKim and TaeyoungKim; SAIT, Korea (the Republic of)

In recent years, there have been a significant increase in solid Li-ion conducting electrolytes that have the potential to enable such batteries. Among them, garnet-type oxide electrolytes have demonstrated great promise due to their robust stability and high ionic conductivity. However, due to the rigid nature of solid oxide electrolytes, the high ionic conductivity is only achievable along with high temperature sintering process (> 1000 °C) to form dense structure, which introduces cost challenges and undesired chemical reactions. Although there have been many efforts to lower the sintering temperature through the use of sintering aids, they require additional additives and their effect remains unsatisfactory. In this study, a low-temperature design for garnet solid electrolyte is suggested without the need for sintering aids. The approach involves amorphization, which imparts deformability to the material. Consequently, the material becomes way softer compared to crystalline electrolyte, allowing for the easy formation of a dense amorphous matrix by applying pressure. Subsequently, the high ionic conductivity can be obtained through a low-temperature crystallization process. We believe that this strategy paves the way for showcasing rigid solid electrolytes processed at lower temperature.

Understanding Lithium-Ion Transport in Selenophosphate-Based Lithium Argyrodites and Their Limitations in Solid-State Batteries JohannesHartel[1] and WolfgangZeier[1,2]; [1]Department of Inorganic and Analytical Chemistry, Germany; [2]Helmholtz-Institut, Germany

Solid electrolytes providing high ionic conductivities are required for the realization of solid-state batteries with competitive power and energy densities. Among all reported fast lithium-ion conductors, superionic lithium argyrodites provide a promising, highly tunable compositional space, in which superior lithium-ion conductivities can be realized by elemental substitutions.

In this work, selenophosphate-based lithium argyrodites $Li_{6-x}PSe_{5-x}Br_{1+x}$ ($0 \leq x \leq 0.2$) with exceptional ionic conductivities up to 8.5 $mScm^{-1}$ are reported and underlying reasons for their fast lithium-ion transport are unveiled based on structural characterization using a combination of neutron powder diffraction, ^7Li and ^{31}P NMR and Raman spectroscopy. Rietveld refinement of

the neutron powder diffraction data uncovers a significantly improved interconnection of the lithium-ion cages when compared to the thiophosphate analogue Li_6PS_5Br as a result of the occupation of two additional lithium-ion sites, leading to enhanced lithium-ion transport. A larger unit cell volume, lattice softening and higher structural disorder between halide and chalcogenide provide further structural reasons for improved lithium-ion conduction. Interestingly, when testing $Li_{5.85}PSe_{4.85}Br_{1.15}$ as catholyte in $In/LiIn|Li_6PS_5Br|LiNi_{0.83}Co_{0.11}Mn_{0.06}O_2:Li_{5.85}PSe_{4.85}Br_{1.15}$ solid-state batteries, severe degradation is observed by electrochemical impedance spectroscopy upon charging of the cells, revealing that selenophosphate-based lithium argyrodites are not suitable for application in lithium nickel cobalt manganese oxide (NCM) based solid-state batteries from a performance perspective.

Besides providing further insights into the structure-transport relationship of lithium argyrodites with high lithium-ion conductivities, this work reemphasizes the necessity to consider chemical and electrochemical stability of solid electrolytes against the active materials when developing fast lithium-ion conductors.

Design Principles for Fast Ionic Conductors YifeiMo; University of Maryland, United States

Super-ionic conductors, characterized by exceptionally high ionic conductivities, are highly sought after as solid electrolytes or electrodes for energy applications like batteries and fuel cells. Despite numerous mechanisms proposed for super-ionic conductor materials and the emergence of various design principles, the capability to rationally design these materials has yet to be fully actualized. Conventionally, the analyses largely concentrated on experimental data from a single class of materials with varying compositions. In our computational study, analyzing and studying a vast array of materials across a broad spectrum of materials chemistry and structure allow us to understand the mechanisms and trends across materials, enabling us to devise generally applicable design principles. In this talk, I will present our latest progress toward understanding the mechanisms of ion diffusion and formulating these design principles for fast ion conductors.

9:00 AM EN02.12.02

Understanding the Correlation Between Anion Group Rotations and Lithium Ion Diffusion in Superionic Conductors KyuJungJun[1], ByungjuLee[2], RonaldKam[1] and GerbrandCeder[1]; [1]University of California, Berkeley, United States; [2]Korea Institute of Science and Technology, Korea (the Republic of)

Since the 1980s, the paddlewheel effect has been proposed as a mechanism to boost lithium-ion conductivity in inorganic materials by using rotating anion groups to assist lithium-ion migrations (*1*–*5*). However, to this date, the physical mechanism behind how anion-group dynamics affect lithium-ion diffusion has not been clearly quantified. In this work, we define three types of rotational motions of anion-groups. To detect and differentiate various types of rotational motions, we track rotational motion of anion groups using quaternion-based representations. By applying a quaternion-based algorithms throughout a total of 10's of ns ab-initio molecular dynamics trajectories of various types of superionic conductors and performing rigorous statistical analysis of various rotational events as well as lithium-ion diffusion events, we reveal how each type of anion rotational motion is related to lithium-ion diffusion. Our work resolves the ongoing debate about the existence of a paddlewheel effect and provides a clear mechanistic understanding of how anion-group rotations are correlated to fast ionic diffusion in inorganic materials.

Unlocking Li Superionic Conductivity in Fcc-Type Oxides via Face-Sharing Configurations YuChen[1,2], BinOuyang[3] and GerbrandCeder[1,2]; [1]University of California, Berkeley, United States; [2]Lawrence Berkeley National Laboratory, United States; [3]Florida State University, United States

Li metal oxides with a face-centered cubic (*fcc*) anion sublattice have been generally excluded from the search for solid-state Li superionic conductors, as the structural framework is thought to be unfavorable for Li superionic conduction. Herein, we demonstrate a face-sharing design strategy that turns *fcc*-type oxides into superionic conductors, with a Li ionic conductivity of 3.38×10^{-4} S cm^{-1} at room temperature and a low migration barrier of 255 meV. The combination of experimental and theoretical investigations reveals that the high Li-ion conductivity is attributed to the facile Li-ion diffusion pathways comprising the face-sharing polyhedra. Our work unlocks the great potential of designing Li superionic conductors in a prototypical structural framework with vast chemical flexibility, providing a fertile ground for discovering new solid-state electrolytes for all-solid-state batteries.

Investigating Aliovalent Sn(+IV) and Isovalent P(+V) Substitution Series in Li_3SbS_4BiancaHelm[1] and WolfgangZeier[1,2]; [1]University of Muenster, Germany; [2]Forschungszentrum Jülich GmbH, Germany

An in-depth understanding of Li^+ migration within solid electrolytes is fundamentally needed to develop new material classes and to enhance the existing ones. The thio-LISICON family exhibits three distinct ordering types of the non-lithium polyhedra leading to three different polymorphs, namely α-, β- and γ-Li_3PS_4.[1,2] These show completely different Li^+ substructures and migration pathways. Depending on the non-lithium cation either the β- or γ-polymorph is preferred synthetically. Li_3SbS_4 crystallizes in the γ-polymorph, which has the most unpropitious Li^+ substructure for fast Li^+ motion in comparison to the α-, β- and γ-polymorph. Nevertheless, the aliovalent $Li_{3+x}Sb_{1-x}Sn_xS_4$ ($0 \leq x \leq 0.2$) and isovalent $Li_3Sb_{1-x}P_xS_4$ ($0 \leq x \leq 0.5$) substitution series were prepared, and the ionic conductivity increased from 9.2×10^{-11} S×cm^{-1} to 2.9×10^{-6} S×cm^{-1} and 4.9×10^{-7} S×cm^{-1} for the highest substitution degree, respectively. Remarkably, the conductivity is three times faster improved for the Sn(+IV) compared to the P(+V) substitution implying that more Li^+ are beneficial for faster ionic transport within this system. However, as these materials are bad ionic conductors at low substitution degree, the defect formation energy might be the dominating factor for easier ionic transport.

Overcoming Low Initial Columbic Efficiency of Si Anode by Effective Prelithiation in All-Solid-State Batteries So-YeonHam[1], EliasSebti[2], AshleyCronk[1], TylerPennebaker[2], GraysonDeysher[1], Yu-TingChen[1], Jin An SamOh[1], Jeong BeomLee[3], MartaVicencio[1], PhillipRidley[1], BaharakSayahpour[1], DarrenTan[1], RaphaëleClement[2], JihyunJang[1] and Y. ShirleyMeng[4]; [1]University of California, San Diego, United States; [2]University of California, Santa Barbara, United States; [3]LG Energy Solution, Korea (the Republic of); [4]The University of Chicago, United States

All-solid-state batteries using the Si anode has shown promising high-capacity performance without continual SEI growth. However, the low initial Columbic efficiency (CE) of Si remains a

challenge. In this work, a prelithiation strategy was adopted to improve the CE and conductivity of Si anodes. The lithiated Si was examined in a symmetric-, half- and full-cell configuration to understand the cell level improvement of each component. With Li_1Si lithiation, the full cell acheived over 95% ICE when paired with the lithium cobalt oxide (LCO) cathode. Additionally, improvement using the prelithiation method was found to only influence anode-limited cases when comparing two active materials; NCM and LCO when paired with Si and Li_xSi. Ramping tests and prolonged cycling performance was evaluated using both Si and Li_1Si cells. With Li_1Si, 73.8% after 1000 cycles was achieved, a 15% improvement in retention versus the bare Si anode. Utilizing the Li_1Si composition, high areal capacity up to 10 mAh/cm^2 was attained using a dry-process LCO film, validating the prelithiation method which may be a suitable candidate used in high loading next generation batteries.

Fast Cycling of Lithium Metal Solid State Batteries by Constriction-Susceptible 3D Anode LuhanYe and XinLi; Harvard University, United States

Lithium (Li) metal anode, due to its ten times larger capacity than commercial graphite anode, is a desired component for solid-state batteries. Fast cycling of commercial level of thick cathode, however, requires the fast cycling of a thick layer of Li metal at anode stably. The goal is challenging as the cycling condition naturally promotes inhomogeneity in lithium plating and stripping, and hence Li dendrite penetration. This talk provides a solid-state battery with 3D anode design that enables fast cycling of lithium in solid state batteries. It is shown that the constriction-susceptible materials in a solid-state battery structure can be modulated as a 3D scaffold, in which the plating and stripping of Li metal is uniform.
Furthermore, the advantage of multi-electrolyte-layer solid electrolyte layer will also be discussed. We showed that the rate capability of lithium metal battery can be significantly improved after applying a multi solid electrolyte structure, with less stable solid electrolyte sandwiched by more stable solid electrolytes. The electrolyte layer can capture lithium dendrite by local decomposition, which together with the 3D matrix anode, enables a fast rate with long cycling life.

Silver-Carbon Composite Interlayers for "Anodeless" Solid-State Batteries DominicSpencer-Jolly[1,2], VarnikaAgarwal[1] and PeterG. Bruce[1,2]; [1]University of Oxford, United Kingdom; [2]The Faraday Institution, United Kingdom

Lithium-free so-called “anodeless” solid-state batteries promise to deliver high cell energy densities. However, at charge rates on the order of 1 mA cm^{-2}, plating of Li at the current collector/solid electrolyte interface is highly inhomogeneous, and dendrites (filaments of Li metal) are observed to penetrate through the solid electrolyte resulting in cell failure. Recent work has suggested that introduction of a silver-carbon composite interlayer between the solid electrolyte and current collector can protect the solid electrolyte against dendrite growth whilst promoting more homogeneous deposition of Li metal.[1] In this work, we investigate silver-carbon composite interlayers, revealing the structural changes within the interlayer during charge and discharge, and the rate dependency of these changes. We go on to investigate the homogeneity of Li-Ag alloy and Li metal formation at the current collector with and without silver nanoparticles present in the interlayer, and how this affects the processes of charge and discharge. We demonstrate dendrite-free charge at 2 mA cm^{-2} and reveal the origin of the failure of the interlayer at higher rates.[2]

Probing 3D Evolution and Electrochemical Behavior of Nano Silicon Anodes in Sulfide All-Solid-StateBatteries via Nano X-Ray Tomography and in *Operando* XASTongtaiJi[1], DaxianCao[1], YonghuaDu[2], XianghuiXiao[2] and HongliZhu[1]; [1]Northeastern University, United States; [2]Brookhaven National Laboratory, United States

Silicon (Si) is one of the most promising anode materials for the next generation Li-ion batteries on account of its ultrahigh specific capacity (3590 mAh g-1) and relatively low working potential of 0.4 V (vs. Li+/Li). The utilization of silicon anode in all-solid-state lithium batteries (ASLBs) can further boost the energy density compared with the conventional graphite anode. Among various ASLBs with different solid electrolytes (SEs), the ASLBs with sulfide SEs delivered remarkable performances because of the excellent ionic conductivity (>1 mS cm^{-1}) and relative “soft” mechanical properties (compared with oxides SEs) for intimate contact with electrode materials of sulfide SEs. However, the compatibility of Si and sulfide SEs is questioned because of the potential electrochemical decomposition. In addition, the extreme volume change (400%) of Si during cycling also brings great challenges to the structural stability of the ASLBs. Nano-Si (<100 nm in diameter) have a higher structural stability because the smaller geometry size can relieve stress. Therefore, in this study, we systematically analyzed the electrochemical and structural evolution of different nano-Si-based anodes in ASLBs with sulfide SE via *in-operando* synchrotron X-ray absorption near-edge structure (XANES) spectroscopy and scanning electron microscopy (SEM) combined with X-ray nano-tomography (XnT). Three kinds of nano Si-based anodes (pure nano-Si (Si), nano-Si compositing with SE (Si-SE), nano-Si compositing with SE and carbon (Si-SE-C)) were analyzed. The Operando XANES revealed that the sulfide SE experiences an electrochemical decomposition in the nano-Si anode and the addition of carbon accelerates this process. However, this electrochemical decomposition only occurs at the first lithiation process and the products are stable in the following cycles and has comparable ionic conductivity. The ex-situ SEM and ex-situ XnT exhibit that the addition of SE and carbon in the nano-Si anode benefits the structural stability, which is further explained by a chemo-elasto-plastic modeling framework. Owing to the enhanced reaction kinetics and mechanical structural stability, the Si-SE-C achieved the highest Si utilization, with a lithiation/delithiation capacity of 3288/2917 mAh g^{-1} and an initial coulombic efficiency of 88.7%, which are significantly higher than the capacities of 2653/2291 mAh g^{-1} and ICE of 86.4% in Si-SE, and the capacities of 2353/1935 mAh g^{-1} and ICE of 82.2% in Si. This work indicated that the addition of SE and carbon into nano-Si anode can enhance the reaction kinetics, improve the utilization of Si, and benefit the mechanical structure stability, though the SE shows slight decomposition but the generated chemistry is ionically conductive and stable in the following cycles. Through the comprehensive evaluation between the pros and cons of adding SE and carbon, in terms of improvements in reaction kinetics and structural stability compared with the limited electrochemical decomposition of SE, nano-Si-SE-C composite anode demonstrates the best Si utilization with the highest specific capacities.

11:15 AM EN02.13.05
Highly Reversible Solid-State Silicon Anodes Enabled by Hydride Based Electrolytes YonglinHuang[1], BowenShao[1], Yan EricWang[2] and FudongHan[1]; [1]Rensselaer Polytechnic Institute, United States; [2]Advanced Materials Lab, Samsung Advanced Institute of Technology-America, Samsung Semiconductor Inc., United States

Silicon is considered a promising candidate for anodes in solid-state batteries due to its high energy density and unique properties in addressing problems associated with Li metal anodes such as dendrite formation and morphological instability. Despite many exciting results from previous works on solid-state Si anodes, the initial Coulombic efficiency, a critical parameter that characterizes the electrochemical reversibility for the first cycle and directly influences the battery's energy density, has not been well considered. In this presentation, we report our study on the (electro)chemical stability between Si and three representative solid electrolytes, including a typical sulfide ($75Li_2S$-$25P_2S_5$), an iodide-substituted sulfide ($70(0.75Li_2S$-$0.25P_2S_5)$-60LiI) and a hydride-based solid electrolyte ($3LiBH_4$-LiI, LBHI). Our results indicate that LBHI demonstrates superior electrochemical and chemical stability with Si anodes compared with sulfide-based electrolytes, enabling a high-performance solid-state Si anode with a record high initial Coulombic efficiency of 96.2% among all Si anodes reported to date. The excellent (electro)chemical reversibility of Si anodes was also demonstrated in solid-state full cells with nickel-rich layered oxide cathodes. The results highlight the importance of solidifying Si anode to improve its performance, and the excellent stability of hydride-based solid electrolytes also offers potential opportunities to be used as an interlayer or 3D ionic framework for other low voltage anodes, including Li metal.

1:30 PM EN02.14.01
Using Holey Graphene for Improved Interfacial Contact in Solid Electrolyte Ionic Conductivity Measurements LopamudraDas[1] and YiLin[2]; [1]Analytical Mechanics Associates, United States; [2]NASA Langley Research Center, United States

Solid-state batteries (SSBs) are poised to become the batteries of the future with advantages such as higher energy density, lighter weight, versatile geometry, and greater safety due to low flammability risk. An important parameter of the solid electrolyte (SE) used is its ionic conductivity. The ionic conductivity is generally calculated from the bulk resistance of a SE pellet, measured from the electrochemical impedance spectroscopy data. The SE pellet is typically prepared from the electrolyte powder by dry compression and is sandwiched between two blocking current collectors to obtain the impedance spectroscopy data. One of the challenges in conducting this measurement is poor interfacial contacts between the SE pellet and the current collector

surfaces. Therefore, measurements reported in the literature may underestimate the true ionic conductivity of a given electrolyte. Holey graphene is a carbon nanomaterial with high electrical conductivity and unique dry compressibility, which is unusual for carbon materials but similar to many oxide and sulfide SEs. In this work, it is demonstrated that adding a thin layer of holey graphene between the electrolyte and the stainless steel current collectors significantly improves the interfacial contact. The ionic conductivity values obtained in the effort were sometimes several times higher than the data measured for SEs without the holey graphene layers. This work calls for more standardized measurement procedures to reduce the discrepancies in reported ionic conductivity values.

1:45 PM EN02.14.02
Ni-Rich Layered Cathodes in Sulfide-Based All-Solid-State Batteries: Improving Interface Stability by Oxide Nanoparticle Coating RuizhuoZhang[1], YuanMa[1], AleksandrKondrakov[1,2], JürgenJanek[1,3] and TorstenBrezesinski[1]; [1]Battery and Electrochemistry Laboratory, Institute of Nanotechnology, Karlsruhe Institute of Technology (KIT), Hermann-von-Helmholtz-Platz 1, Germany; [2]BASF SE, Carl-Bosch-Str, Germany; [3]Institute of Physical Chemistry, Justus-Liebig-University Giessen, Heinrich-Buff-Ring, Germany

Owing to the superior ionic conductivity and mechanical ductility, sulfide-based solid electrolytes (SEs) such as Li_6PS_5Cl (LPSCl) have been extensively investigated for use in all-solid-state batteries (ASSBs). However, the practical implementation of ASSBs requires making significant improvements to various aspects of their components. When utilizing a high areal capacity electrode composite with a Ni-rich layered oxide cathode material, $LiNi_{0.85}Co_{0.10}Mn_{0.05}O_2$ (NCM85), the poor interfacial stability arising from the narrow electrochemical window of LPSCl poses a significant challenge. Hence, effective coating strategies are needed to mitigate or decelerate adverse side reactions occurring during battery operation.
Here, we present a facile coating approach based on preformed oxide nanoparticles (NPs) such as ZrO_2 and HfO_2, enabling uniform surface coverage of the NCM85 cathode material via wet-chemistry processing. From pellet-stack cell testing, the NP coatings are found to result in substantial improvements in reversibility, kinetics, capacity and longevity (compared to the uncoated counterpart). Detailed characterization revealed the effectiveness of the coating method in reducing electro-chemo-mechanical degradation at the cathode interface. Furthermore, the adaptability to processing slurry-cast electrodes has been explored, potentially allowing for scalable preparation of ASSBs.

2:00 PM EN02.14.03
Linking Microstructure and Ionic/Electronic Conductivity of Sulfide-Based Composite Cathodes with the Cell Performance NikolaosPapadopoulos, EliasReisacher, PinarKaya and VolkerKnoblauch; Materials Research Institute (IMFAA)/Aalen University, Germany

Compared to conventional lithium-ion batteries (LIBs) bearing liquid electrolytes, ASSBs (all-solid-state batteries) have the potential to improve safety and achieve higher performance and energy density [1]. However, there are still many challenges to tackle in order to achieve Li-ASSBs with sufficient cell performance. One of those challenges is overcoming the complexity within the composite cathode. Liquid electrolytes can penetrate composite cathodes easily, while solid electrolytes cannot, leading to residual porosity in the cathode, which then blocks the ionic and electronic charge transport pathways. On the other hand, the degradation of the solid electrolyte (SE), cathode active material (CAM), and conductive additive (CA) caused by parasitic side reactions have to be tackled with protective coatings that hinder the degradation but at the same time keep the charge transport pathways open [2,3]. Therefore, the composite cathode microstructure (e.g., optimal composition ratios$_{CAM:SE:CA}$, particle characteristics, distribution of the phases) must be designed for different materials systems to ensure a perfect percolation and provide sufficient ions and electrons, thus tortuosity [4-7].
In this study, we aim to deepen the understanding of the correlation between microstructure and ionic/electronic conductivity of composite cathode with the cell performance. For this purpose, a conductive matrix (CM) comprising Li_6PS_5Cl and C65 was developed and used within the composite cathode. Effective ionic and electronic conductivities of different cathode mixtures of the conductive matrix and NMC622, as well as microstructural evolution, were analyzed. Subsequently, these findings were correlated with the rate capability and cycling performance of the cells. We determined the electronic percolation threshold of the conducting matrix (CM) to keep the amount of C65 as low as possible and detected the ionic/electronic limitations for the composite cathode mixtures by varying the active material content. The results of this study will shed light on how to optimize the microstructure to achieve the best cell performance

Overcoming the Interfacial Challenges of $LiFePO_4$ in Inorganic All-Solid-State Batteries AshleyCronk[1], Yu-TingChen[1], GraysonDeysher[1], So-YeonHam[1], HediYang[2], PhillipRidley[1], BaharakSayahpour[1], Long Hoang BaoNguyen[1], Jin An SamOh[1], JihyunJang[1], DarrenTan[1] and Y. ShirleyMeng[2]; [1]University of California, San Diego, United States; [2]The University of Chicago, United States

All-solid-state batteries (ASSBs) are one of the most promising systems to enable long-lasting and thermally resilient next-generation energy storage. Ideally, these systems should utilize low-cost resources with reduced reliance on critical materials. Pursuing cobalt- and nickel-free chemistries, like $LiFePO_4$ (LFP), is a promising strategy. Morphological features of LFP essential for improved electrochemical performance are highlighted to elucidate the interfacial challenges when implemented in ASSBs, since adoption in inorganic ASSBs has yet to be reported. In this work, the compatibility of LFP with two types of solid-state electrolytes, Li_6PS_5Cl (LPSCl) and Li_2ZrCl_6 (LZC), are investigated. The potential existence of oxidative decomposition products is probed using a combination of structural, electrochemical, and spectroscopic analyses. Bulk and interfacial characterization reveal that the sulfide-based electrolyte LPSCl decomposes into insulative products, and electrochemical impedance spectroscopy is used to quantify the resulting impedance growth. However, through utilization of the chloride-based electrolyte LZC, high-rate and stable electrochemical performance is achieved at room temperature.

Development of Materials for All-Solid-State Metal-Sulfur Batteries DonghaiWang; The Pennsylvania State University, United States

With advances in electrification in transportation, extensive use of power electronics, and utilization of renewable energy and their assimilation into the electrical grid, there is a clear need to develop high-performance, safer, and more sustainable energy storage technologies for future emerging applications. All-solid-state metal-sulfur battery technology is the most promising candidate for next-generation batteries due to its high energy density, long cycle life, and superior safety. However, it faces many challenges from both metal anodes and sulfur cathodes, such as metal dendrite penetration and poor sulfur utilization of the cathode. In this talk, first, I will present a novel approach based on the use of organic-inorganic nanocomposite interphase to construct a stable lithium/solid-state electrolyte interface for stable Li plating/stripping. Second, I will present approaches to developing high-performance solid-state metal-sulfur batteries, including synthesizing highly conductive solid-state electrolytes and fabricating low-cost cathode materials, potentially for electric vehicle and stationary energy storage applications. Together, I would like to demonstrate the research effort aiming to build our knowledge, expertise, and understanding of critical electrochemical processes and mechanisms to employ desired

features in electrochemical energy storage systems to meet the requirement of new energy applications.

Composite Cathode Engineering for Advanced All-Solid-State Lithium-Sulfur Batteries GuiliangXu, JieunLee and KhalilAmine; Argonne National Laboratory, United States

In this talk, we will overview the challenges of all-solid-state lithium-sulfur batteries. We will then introduce our strategies by composite cathode engineering to significantly improve the sulfur utilizaiton (~100%) and reversibility towards high S loading under room temperature. We will also talk about advanced characterization techniques to reveal the underlying mechanism for the improved cell performance. The findings will provide new insights into the failure mechanism and offer new strategies to advance all-solid-state lithium-sulfur batteries.

4:00 PM *EN02.15.03
Electrolyte Design for Intermediate-Temperature Na-S Batteries with High Energy Density YuanYang; Columbia University, United States

The conventional high-temperature sodium sulfur battery is an attractive technology for grid-level energy storage due to its low cost, high energy density and long cycle life. However, this system operates at 300-350 oC, which not only increases cost, but also accelerates degradation and causes potential safety issues. On the other side, Na-S batteries working at intermediate temperatures (e.g., 100-150 oC) are attractive, but the formation of solid Na2S2 and Na2S with low ionic diffusivity and electronic conductivity limits its specific capacity to ~500 mAh/g and thus energy density. In this study, we have developed a new electrolyte solvent that can dissolve all sulfides and polysulfides, which avoids the poor kinetics in Na2S2 and Na2S, and allows Na-S batteries to operate at ~75 ºC. Based on the 1 mol L^{-1} sulfur catholyte, a high specific capacity of 1640 $mAhg^{-1}$ is achieved at 0.13 mA cm^{-2}. When increased to the 4 mol L^{-1}, the capacity is achieved 830 $mAhg^{-1}$ and shows capacity retention of 70% over 1000 cycles. Such a system has potential applications for long-duration energy storage.

4:30 PM EN02.15.04
Understanding Electrochemical Reaction Mechanisms of Sulfur in All-Solid-State Batteries Through *Operando* and Theoretical StudiesHongliZhu; Northeastern University, United States

Sulfur, with its high theoretical specific capacity of 1675 mAh g-1, affordability, and earth abundance, stands as a promising candidate for cathodes. Lithium-sulfur (Li-S) batteries, boasting an ultrahigh theoretical energy density (2600 Wh kg-1)— a value ten times higher than that of contemporary commercial Lithium-ion batteries, hold immense potential. Yet, Li-S batteries employing ether-based liquid electrolytes face challenges such as the formation of long-chain polysulfides and the shuttle effect, leading to rapid capacity decay, low coulombic efficiency, and poor cycling life. All-solid-state lithium-sulfur batteries (ASLSBs), which substitute traditional organic liquid electrolyte with solid-state electrolytes (SEs), are considered to be a fundamental solution to these issues. SEs provide enhanced safety compared to their flammable and volatile organic counterparts and are assumed to eliminate the formation of polysulfides, thereby inherently addressing the shuttle effects.
Nevertheless, the absence of clear experimental evidence to understand the chemistries and mechanisms of sulfur's electrochemical reaction in ASLSBs prompts further investigation. Existing literature suggests the chemistries in ASLSBs transition directly from S8 to Li2S. However, the overlooked formation of Li2S2, insoluble in liquid electrolytes, could potentially impact ASLSB performance. Considering Li2S2 is a thermodynamically unstable phase, the implementation of advanced in-operando characterization becomes crucial for a deeper understanding of the reaction mechanisms in ASLSBs.
In this talk, we present four key findings that would be of interest to the readership of MRS audiences:
1. We study the chemical transformation of sulfur in ASLSBs and elucidate the reaction mechanism via a combination of operando Raman spectroscopy and ex-situ X-ray absorption spectroscopy (XAS). This gives us the first empirical proof of electrochemical pathways in ASLSBs.
2. We designed a unique cell for the operando Raman study, facilitating the characterization of the battery in an inert argon atmosphere within a cleanroom-in-a-glovebox system. This custom cell with a side window and a pressure-controlling stainless-steel framework allows internal battery material exposure post-assembly without further sealing. Moreover, its square design ensures a focused laser beam on a flat sample surface, eliminating background distractions.
3. We have, for the first time, unveiled a two-step transformation in the Li-S redox reaction in ASLSBs. Our findings prove that the process does not generate any long-chain polysulfides, thereby inhibiting the shuttle effect in SE, a significant departure from the scenario with liquid electrolyte.
4. We found that the transition among S8, Li2S2, and Li2S exhibits sluggish reaction kinetics, caused by the slow "point-to-point" ion diffusion at the interface in ASLSBs and high “solid to solid” reaction barrier, resulting in incomplete reactions during both discharging and charging processes.
These insights will contribute to the continued research and development in the field of ASLSBs.

4:45 PM EN02.15.05
Influence of Carbon Blends for Cathode Active Material Pre-Treatment on Battery Performance MartinA. Lange and WolfgangZeier; WWU Münster, Germany

Solid state batteries show significant potential. Specifically, the lithium-sulfur system shows significant potential thanks to its large gravimetric capacity and the lack of the problematic sulfur-shuttle effect as encountered in liquid cells. To achieve sufficient utilization of the active material, appropriate solid conductors for both ionic and electronic conduction have to be added to the cathode material mixture. While solid electrolytes are studied intensively in regards to optimizing their ionic conductivity, influences of electron conductors are studied more sparsely. Somewhat structured carbons such as carbon fibers are often used with the idea to provide prefabricated conductive pathways, but without in-depth investigation of the interactions between the individual components of the solid cathode composites during mixing.
In this study, we show how already simple mixing of two basic carbons in solid sulfur cathode composites alters significantly the cycling behavior in half-cells. For this purpose, we analyzed two mixtures of two different carbon species in different ratios. For both systems, cathode composites prepared with pure carbons results in vastly different performance than achieved by simple blending of the two carbons. It can be shown, that rather than utilizing purely one sort of carbon, improvements in performance can be achieved by application of specific carbon mixtures, although the exact ratio depends strongly on the type of the added carbons. This means that it is already possible to make significant improvements to the solid lithium-sulfur battery system by mixing simple, inexpensive carbons rather than using complex-structured, expensive carbons, which is particularly interesting in terms of advances in industrial applications and commercialization.

Fast Sintering and Polymorphism of NASICON-Type $LiZr_2(PO_4)_3$ Solid Electrolyte Materials LinLin and KelseyB. Hatzell; Princeton University, United States

Cnventional solid electrolyte manufacturing and materials processing methods are too complex and expensive for scalability. Specifically for oxide solid electrolytes, the high-temperature and long synthesis and sintering procedures introduce significant time and energy cost. Various fast sintering methods have been developed in the past decade to address this manufacturing challenge [1]. Manufacturing dense, highly conducting solid electrolytes in air and in minutes (or seconds) are desirable for solid state battery manufacturing. (NASICON-)type LiZr2(PO4)3 (LZP) in one type of solid electrolyte which demonstrates excellent air and water stability, as well as good resistance to Li reduction at interfaces [2]. However, LZP exhibits rich polymorphism, with different phases showing distinct crystal structures and ion transport mechanisms [2]. Previous studies have shown that polymorphism observed in garnet-type Li7La3Zr2O12 solid electrolyte significantly affects the transport and chemo-mechanical properties [3]. Yet the polymorphism is solid electrolytes has seldom been exclusively studied and controlled. In this work, we developed a modified air-compatible ultrafast high-temperatures sintering (UHS) approach and successfully sintered LZP within a few minutes. X-ray diffraction analysis reveals how processing impacts polymorphism in this class of materials. The green body contains almost fully α’-triclinic, low ionic conductivity phase. The highly conducting α-rhombohedral polymorph can be achieved in only minutes of with ultrafast sintering. The ratio of two phases are strongly affected by the processing temperatures and times. The percentages of rhombohedral phase increase from 53% to 68% as the sintering temperature increases from 900 to 1200 °C when keeping a 5 min sintering time. On the other hand, with the sintering temperature kept at 1200 °C, the percentages of rhombohedral phase increase from 54% to 83% when when increasing the sintering time from 1 min to 8 min. These results present pathways to ultrafast manufacturing process that enable control over structure and transport.

Not Just an Unwanted Impurity Phase: Pyrochlores as Convenient Precursors to Li Conducting Garnets JinzhaoGuo and CandaceK. Chan; Arizona State University, United States

Garnet-type solid-state electrolytes such as Ta-doped $Li_7La_3Zr_2O_{12}$ (LLZTO) are promising ceramic electrolytes for all-solid-state batteries because of their high (electro)chemical stability and ionic conductivity. LLZTO is typically synthesized from oxide precursors via solid-state reaction, but use of other precursors can lead to improved phase purity and more homogenous dopant distribution. We recently demonstrated that pyrochlores, usually seen as an unwanted impurity phase in the synthesis of garnets, can actually serve as the starting precursor for LLZTO, a process we call "pyrochlore-to-garnet" (P2G). Nanocrystalline pyrochlore prepared using molten salt synthesis and a scalable sol-gel method are demonstrated to enable formation of dense LLZTO ceramic directly via reactive sintering of the pyrochlore and a lithium source. The LLZTO prepared via P2G displays high relative density and ionic conductivity comparable to LLZTO prepared by solid-state reaction, but with much shorter sintering times. Investigation of the synthesis parameters shows that liquid phase sintering is important for achieving high pellet densities and phase-purity. Additionally, while the LLZTO grain sizes obtained using this P2G method are smaller than those from conventional sintering of LLZTO particles, the P2G pellets can sustain higher critical current densities before shorting in lithium stripping/plating experiments compared to conventional LLZTO prepared by solid-state reaction. This work shows P2G is promising as an alternate method for the synthesis and processing of LLZTO materials.

Multifunctional Coatings on Sulfide-Based Solid Electrolyte Powders with Enhanced Processability, Stability and Performance for Solid-State Batteries ZacharyD. Hood, AnilU. Mane, AdityaSundar, SanjaTepavcevic, PeterZapol, UdochukwuD. Eze, ShibaP. Adhikari, EungjeLee, GeorgeSterbinsky, JeffreyW. Elam and JustinConnell; Argonne National Laboratory, United States

Sulfide-based solid-state electrolytes (SSEs) represent one of the most promising classes of materials for next-generation all-solid-state Li-ion batteries due to their many beneficial properties, including high ionic conductivity and favorable mechanical properties that make them more readily amenable to processing at scale. However, widespread adoption of these materials is hindered by their intrinsic instability under ambient conditions, as well as by (electro)chemical instability at the Li||SSE and cathode||SSE interfaces, which limits cell performance and lifetime. We have developed a method that utilizes atomic layer deposition (ALD) to grow thin, oxide-based coatings on argyrodite Li_6PS_5Cl (LPSCl) *powders* to address both issues simultaneously. We demonstrate that thin films of aluminum oxide (Al_2O_3) can be directly grown onto argyrodite particles using trimethyl aluminum and H_2O with minimal chemical modification of the underlying material. These coatings enable exposure of LPSCl powders to pure and H_2O-saturated oxygen environments for ≥4 hours with little to no reactivity, compared with significant degradation of the uncoated powder. Furthermore, pellets fabricated from coated LPSCl powders exhibit bulk ionic conductivities up to 2× higher than those made from uncoated material, with a simultaneous decrease in electronic conductivity. These favorable transport properties are coupled with significant suppression of Li_2S and Li_3P formation observed at the Li-SSE interface, confirming improved chemical stability with Li metal anodes. These benefits result in significantly improved room temperature cycle life at high capacity and current density (≥150 cycles at 1 mAh/cm^2 per cycle and 0.5 mA/cm^2). We hypothesize that these enhanced properties derive from improved electronic and chemical properties at intergranular boundaries, as well as improved Li metal adhesion at the interface. Similar improvements in materials properties are achieved using ALD coating chemistries beyond Al_2O_3. This work points to a completely new framework for designing active, stable, and scalable materials for next-generation solid-state batteries.

8:45 AM EN02.16.04
Spray-Flame Synthesis of NASICON-Type $Li_{1.3}Al_{0.3}Y_{0.3-x}Ti_{1.7}(PO_4)_3$ (x= 0 -1.5) Solid Electrolytes Md YusufAli[1], HansOrthner[1] and HartmutWiggers[1,2]; [1]Institute for Energy and Materials Processes – Reactive Fluids; University of Duisburg-Essen, Germany; [2]Center for Nanointegration Duisburg-Essen, Germany

Due to its safety, low cost, and high energy density characteristics, solid-state lithium-ion batteries have been recognized as one of the most promising candidates for future green energy storage technologies. Electrolytes made of polymers and ceramics are prime candidates to expand the use of lithium metal batteries. Single-ion conducting polymers can lessen polarization and the formation of lithium dendrites, but they eventually become extremely inflexible mechanically, necessitating mobilizers such as organic solvents to move Li ions. Inhomogeneous solvent dispersion and the accompanying preferred Li transport paths may result in favored locations for Li plating, adding mechanical stress and maybe even causing early cell short-circuits. However, ceramic-based electrolytes, such as $Li_{1.3}Al_{0.3}Ti_{1.7}(PO_4)_3$ (LATP) NASICON, are renowned for their superior dendritic growth inhibitor and high-temperature adaptability. In contrast to other wet synthesis methods, spray-flame synthesis is affordable and incredibly simple to scale up with excellent purity, thus we looked into the best conditions to synthesize LATP solid electrolyte. We found that nitrates are better than acetates as metal precursors, and excess Li is indeed necessary in precursor solution to synthesize pure phase LATP. We characterized the resulting nanoparticles by state-of-the-art techniques such as XRD, XPS, TEM, Raman Spectroscopy etc. The as-prepared spray flame synthesized nanoparticles are found to be TiO_2 and with Li carbonate on the surface as confirmed by XPS, and it requires a high-temperature calcination (~750 °C) to finally form LATP phase. However, the ionic conductivity of LATP phase samples (0.049 mS/cm) were not up to the industrial standard. To further increase the ionic conductivity of LATP electrolytes the Al^{3+} (0.535 Å) substitution with similar charge Y^{3+} (0.93 Å) was carried out$Li_{1.3}Al_{0.3}Y_{0.3-x}Ti_{1.7}(PO_4)_3$ (x= 0 to 1.5). Moreover, the large size of Y^{3+} distorts the NASICON structure and provides broad passage for the Li^+ ion to pass through. The enhanced electrochemical characteristics of LATP samples make it possible to see how Y doping affects the samples. The synthesized sample (x=0.1 doped) has a conductivity of around 0.000092 mS/cm. Because of as synthesized TiO_2 phase. However, after calcining at 700 °C, a rise in conductivity (0.006042 mS/cm) can be seen for the sample due to phase transformation to LATP. Further increment in ionic conductivity was done while simultaneously increasing the grain boundary of the pellet. And the final conductivity was reached as high as 0.87 mS/cm which almost reaches the milestone for NASICON solid state electrolytes.

9:00 AM EN02.16.05
Unveiling Low-Temperature Sintering of Solid-State Ceramic Composite Electrolytes via *In-Situ* Electrochemical Impedance SpectroscopyBoNie and HongtaoSun; Penn State University, United States

The increasing safety concerns surrounding high-energy density rechargeable batteries have spurred interest in the development of solid-state electrolytes, aiming for nonflammable and tolerance to extreme conditions. However, conventional fabrication methods of ceramic-based composites face two primary challenges: limited ability to simultaneously tune the intergranular phase and achieve high material density, as well as a lack of efficient methodology to address interfacial issues under mild processing conditions. Consequently, producing stable solid-state electrolytes with low interface resistance, particularly solid-state oxide electrolytes, without resorting to high-temperature sintering for extended periods remains a challenge.
To overcome these challenges, we introduce a cold sintering process (CSP), a multistage nonequilibrium approach combining dissolution−precipitation under external stress, viscous flow of saturated solutions, and species diffusion for the fabrication of highly ionic conductive solid-state electrolytes at low processing temperatures. Additionally, CSP bridges the temperature gap between high melting point constituents (*e.g.*, ceramics) and low melting point constituents (*e.g.*, nano-sized additives, or polymers), enabling the co-sintering of ceramic-based composites for a wide range of solid-state electrolytes. In this study, CSP was utilized to prepare a solid-state NASICON-Halide (nanosized Li_3InCl_6 in LATP matrix) composite electrolyte. To gain further insight into the sintering dynamics and the process-structure-property correlation, we employed electrochemical impedance spectroscopy (EIS) as an in-line monitoring tool to study the real-time impedance during the CSP. We considered the mixed ceramic powders with a small volume of transient solvent as an effective dielectric medium. Through simulations using an equivalent circuit comprising a constant phase element and a resistive element, we captured the dielectric properties and resistance sensitive to CSP, which vary as evaporation and densification occur. Decoding the resulting resistance data provided a profound understanding of the temperature and pressure effects.
Furthermore, we investigated the associated microstructures and ionic conductivities to understand the process-structure-property correlation. The highly dense composite electrolyte, with a small fraction of Li_3InCl_6, exhibited an impressive ionic conductivity of 10^{-4} S cm^{-1} at room temperature, along with excellent reversibility in transporting Li ions for thousands of hours at a cycling capacity of 1 mAh cm^{-2}.

9:15 AM EN02.16.06
The Study of LLZO Thin Film Electrolyte using Pulsed Light Treatment AhromRyu[1,2], SahnNahm[2] and Ji-WonChoi[1]; [1]Korea Institute of Science and Technology, Korea (the Republic of); [2]Korea University, Korea (the Republic of)

All-solid-state lithium batteries (ASSLBs) have gained significant attention due to their numerous advantages over traditional lithium-ion batteries. ASSLBs offer improved safety and thermal stability while achieving efficient energy density within the same volume. However, there are key challenges that need to be addressed for the commercialization of solid-state batteries. In

particular, the solid electrolyte needs to exhibit enhanced ion conductivity to provide sufficient transport in the cathode. LLZO (lithium lanthanum zirconium oxide) is a promising candidate as a solid electrolyte material due to its excellent ion conductivity in bulk and transport stability for lithium ions. However, achieving the required level of ion conductivity for commercialization remains a challenge because it requires high annealing temperatures of over 700 °C to be crystalized, which causes degradation and long production times with high cost. To overcome this limitation, we introduce IPL (intensive pulsed light) processing, which is a method that rapidly applies high-energy pulses, minimizing damage caused by excessive heat. In our study, we deposited LLZO thin films using RF magnetron sputtering at room temperature and investigated the structural and electrical changes after IPL treatment. We achieved direct rapid annealing in a total of seconds, adjusting parameters such as bank voltages and the number of pulses by employing an IPL. We analyzed the structural changes through SEM and XRD, confirming modifications in the film's structure following IPL treatment. The films were deposited on SiO_2/Si wafers and Cu foils and device integration was achieved using a Pt top electrode. EIS (electrochemical impedance spectroscopy) measurements of the samples revealed a Nyquist plot that demonstrated improved ion conductivity compared to the amorphous phase. To explain this phenomenon, we measured the impedance at various temperatures. Based on the plots, we constructed Arrhenius plots and extracted the activation energy. Consequently, we found that the LLZO film after IPL treatment exhibited lower activation energy, indicating enhanced lithium ion conductivity.

9:30 AM EN02.16.07
High-Entropy Lithium Argyrodite Superionic Conductors JingLin[1], MareenSchaller[2], SylvioIndris[2], JürgenJanek[1,3], AleksandrKondrakov[4], TorstenBrezesinski[1] and FlorianStrauss[1]; [1]Battery and Electrochemistry Laboratory, Institute of Nanotechnology, Karlsruhe Institute of Technology (KIT), Germany; [2]Institute for Applied Materials–Energy Storage Systems, Karlsruhe Institute of Technology (KIT), Germany; [3]Institute of Physical Chemistry, Justus-Liebig-University Giessen, Germany; [4]BASF SE, Germany

Solid-state batteries (SSBs) are a potentially safe, next-generation energy storage technology. For SSBs to be commercially viable, the development of solid electrolytes with high ionic conductivity, high (electro)chemical stability, and good processability is imperative. A new strategy for modifying materials, potentially leading to improved properties, is the high-entropy (HEMs) concept, referring to compounds having five or more elements occupying a single crystallographic site (resulting in a configurational entropy $\Delta S_{conf} \geq 1.5R$).
Our recent research has shown that high-entropy argyrodites (HEAs) can be synthesized both by multianionic and/or -cationic substitution. Especially, multication substituted HEA shows a low activation energy ($E_A \approx 0.20$ eV) for lithium transport and a high r.t. ionic conductivity (≈10 mS/cm) as shown by ^{7}Li pulsed field gradient (PFG) nuclear magnetic resonance (NMR) spectroscopy and electrochemical impedance spectroscopy (EIS). These findings were rationalized from a structural point of view via neutron powder diffraction in combination with magic angle spinning (MAS) NMR spectroscopy. For the multication substituted HEA, high S^{2-}/I^- anion site disorder (up to ~11%) and Li^+ redistribution led to shortened jump distances and therefore facilitated long-range ion diffusion. Conversely, multianionic substitution resulted in increased intercage jump distances. Overall, our results emphasize the potential of high-entropy lithium argyrodites (large compositional space) for developing novel superionic conductors with enhanced properties.

Materials Design for Solid State Sodium-Ion Batteries XianguangMiao, YichaoWang, YifanWu, JunyeobMoon and XinLi; Harvard University, United States

Solid state sodium-ion batteries with nonflammable inorganic electrolytes are promising for large-scale energy storage applications. The current battery performance is hindered by problems related to the electrolyte materials, e.g., severe dendrite propagation and interface reaction of conventional Na_3PS_4 anolyte, and low Na^+ conductivity of halide catholyte. Here we propose a newly designed electrolyte with high conductivity, superior formability under cold-press process and improved electrochemical stability toward the anode. The battery with $NaCrO_2$ cathode demonstrates a long cycling life at high rate. We demonstrate that this material platform is also applicable to many other cathodes with higher charge voltage.

10:30 AM EN02.17.02
The Influence of Synthesis Procedure on the Structure and Ionic Transport Property of Substituted Sodium Metal Halide TongZhao and WolfgangZeier; University of Münster, Germany

Sodium all-solid-state batteries have attracted growing interest in recent years because of their potentially high energy densities and superior safety as well as the abundance of sodium. Sodium metal halides are viewed as promising candidates for catholytes in sodium all-solid-state batteries since they have wide electrochemical windows and excellent electrochemical compatibility toward oxide cathode materials, as well as good mechanical deformability and scale-up capability. However, the low ionic conductivity hinders their practical application. Substitution is an effective way to improve the ionic transport properties of ionic conductors.

Herein, we introduced aliovalent cation In^{3+} in Na_2ZrCl_6 and the X-ray diffraction analyses show a full indium solubility in the 200°C annealed $Na_{2+x}Zr_{1-x}In_xCl_6$ crystalized in a $P2_1/n$ phase while that exsolves at higher heat treatment temperatures because the indium-rich $Na_{2+x}Zr_{1-x}In_xCl_6$ compound tends to partially transform to a $P1c$ phase. By assessing the ionic conductivity of the differently synthesized $Na_{2+x}Zr_{1-x}In_xCl_6$ series, we can show the synergistic effect of the Na^+/vacancy ratio and crystallinity on sodium ion transport in this class of materials which can enhance the ionic conductivity by three orders of magnitude.[1] Besides the cation doping, anion-mixed sodium halide ($Na_3InCl_{6-x}Br_x$) is also explored. By milling, the $Na_3InCl_{6-x}Br_x$ ($0 \leq x \leq 1.5$) solid solution series crystallizes in a monoclinic $P2_1/n$ phase, while the subsequently annealed $Na_3InCl_{6-x}Br_x$ ($0 \leq x \leq 2$) series transforms into a trigonal $P1c$ phase. A greater anion solubility can be achieved by annealing and changing the structure type. Unlike the cation substituted $Na_{2+x}Zr_{1-x}In_xCl_6$ series, in $Na_3InCl_{6-x}Br_x$ only slight improvements to the ionic conductivity are observed possibly due to an unfavorable trade-off between high pre-factor and low activation energy resulting from an enthalpy-entropy compensation behavior fulfilling the Meyer-Neldel rule.[2]

These works further highlight the strong dependence of the structure and solubility of sodium metal halides on the synthesis protocol and shed light on the design principle and synthesis strategy of this class of materials as solid electrolytes.

10:45 AM EN02.17.03
A New Halide Solid Electrolyte for Sodium Solid-State Batteries ErikWu and DarrenTan; Unigrid Inc., United States

UNIGRID Battery aims to develop a sodium solid-state battery (Na SSBs) for stationary storage applications such as residential and grid storage. Na SSBs have been touted to offer improved safety (from the use of nonflammable solid-state electrolytes, or SSEs), lowered costs due to the use of abundant sodium-based materials, and higher performance, potentially culminating in a device with long life and high volumetric energy density. In recent years, the development of new SSEs for Na SSBs, such as halides and closo-borates, have advanced high-performance Na SSB chemistries closer to feasibility. However, each of these materials have their own drawbacks; the halides typically have lower sodium ion conductivity and are unstable with the anode, and the closo-borates are primarily cost-prohibitive and are less stable with cathodes. Thus, a single electrolyte with high Na ion conductivity, low costs, and stability with both electrodes remains elusive. Here, we report a new, thermally robust halide with a conductivity of 1 x 10^{-3} S/cm at room temperature, at least an order of magnitude increase compared to previously reported Na-conducting halides. The halide is employed as a catholyte and cycling is demonstrated in a bilayer Na SSB configuration with superior rate performance.

11:00 AM EN02.17.04
On the Discrepancy Between Local and Average Structure in Solid Electrolytes OliverMaus[1,2] and WolfgangZeier[1,2,3]; [1]University of Muenster, Germany; [2]Baccara Graduate School, Germany; [3]Helmholtz-Institut Muenster, Germany

All-solid state batteries are promising candidates to achieve high energy densities and enable the use of high capacity anodes such as lithium metal or silicon alloys but for highly performing

solid-state batteries it is crucial to have solid electrolytes with high ionic conductivities above 10 mS/cm. Aliovalent substitution is a common strategy to improve the ionic conductivity of solid electrolytes. The substitution of SbS_4^{3-} by WS_4^{2-} in the Na^+ ionic conductor $Na_{2.9}Sb_{0.9}W_{0.1}S_4$ leads to a very high ionic conductivity of 41 mS/cm at room temperature. While pristine Na_3SbS_4 crystallizes in a tetragonal structure, the substituted $Na_{2.9}Sb_{0.9}W_{0.1}S_4$ seems to crystallize in a cubic structure based on its X-ray diffractogram. By allowing 3D diffusion pathways, the cubic structure was assumed to be one of the driving forces for the conductivity enhancement in $Na_{2.9}Sb_{0.9}W_{0.1}S_4$.
Here, we show by performing pair distribution function analyses and static single-pulse ^{121}Sb NMR experiments that the short-range order of $Na_{2.9}Sb_{0.9}W_{0.1}S_4$ remains tetragonal despite the change in the Bragg diffraction pattern. Temperature-dependent Raman spectroscopy revealed that changed lattice dynamics due to the increased disorder in the Na^+ substructure leads to dynamic sampling causing the discrepancy in local and average structure. While showing no differences in the local structure, when compared to pristine Na_3SbS_4, quasi-elastic neutron scattering and solid-state ^{23}Na nuclear magnetic resonance measurements revealed drastically improved Na^+ diffusivity and decreased activation energies for $Na_{2.9}Sb_{0.9}W_{0.1}S_4$. The obtained diffusion coefficients are in very good agreement with theoretical values and long-range transport measured by impedance spectroscopy.
This work shows how aliovalent substitution can lead to discrepancies of local and average structure and systematically studies the causes and effects of the phenomenon. It demonstrates the importance of studying the local structure of ionic conductors in order to fully understand their transport mechanisms, a prerequisite for the development of faster ionic conductors.

11:15 AM EN02.17.05
Exploring the Effect of Phosphorous Deficiency on Ionic Conductivity in NaSICON-Type Solid-Electrolytes derived from Flame-Made Nanoparticles Mohammed-AliSheikh[1] and HartmutWiggers[1,2]; [1]University of Duisburg-Essen, Germany; [2]Center for Nanointegration Duisburg-Essen (CENIDE), Germany

The battery market has recently shown that Na-ion batteries (SiB) have become a serious alternative to Li-ion batteries (LiB) [1, 2]. However, SiBs exhibit inferior energy density compared to their lithium-ion-based counterparts [3]. For further improving the energy densitv and safety of SiBs, solid-state SiBs (SSiBs) have gained a lot of interest and NaSICON-type solid-electrolytes are promising materials for such an application owing to their high ionic conductivity of 10^{-4}–10^{-3} Scm^{-1} at room temperature and chemical as well as mechanical stability [4]. Recent studies revealed that the conductivity of $Na_3Zr_2Si_2PO_{12}$ (NZSP) can be enhanced by increasing the silicon to phosphorous ratio [5] or doping NZSP with divalent cations [6].
In this work, we present the spray-flame synthesis (SFS) of NaSICON nanoparticles as a facile method to produce powders of different compositions and stoichiometries. For morphological characterization, transmission electron microscopy is employed. Structural information is obtained by X-ray diffraction (XRD) and Raman-spectroscopy. Thermogravimetry (TG) and differential scanning calorimetry (DSC) are utilized for thermal analysis of powders. Pressed pellets are sintered at 1100°C for 3h and their ionic conductivities are measured with impedance spectroscopy.
From SFS, nanoparticles with a mean diameter of 5 nm are obtained. They consist of fine ZrO_2 crystallites embedded in an amorphous phase of Na, Si and P. After a short annealing step of 1h at 1000°C, this mixture can be converted almost quantitatively into the desired rhombohedral NaSICON phase. Especially the composition $Na_{3+x}Zr_2Si_{2+x}P_{1-x}O_{12}$ and Mg-doped $Na_{3+2y}Mg_yZr_{2-y}Si_2PO_{12}$ show - with respect to the short sintering time of 3h - remarkably high ionic conductivities of 4×10^{-4} Scm^{-1} (for x=0.1) and 9.3×10^{-4} Scm^{-1} (for y=0.2), respectively. XRD reveals that the addition of Mg beyond the solubility limit in NZSP leads to the formation of Mg-phosphates, creating a P-deficiency in the lattice of NZSP and thus improving the ionic conductivity significantly.
In conclusion, SFS enables the scalable production of NaSICON nanoparticles with tailored compositions allowing fast sintering. The improved ionic conductivities observed in the Mg-doped and phosphorous-deficient compositions hold promise for the development of high-performance solid-electrolytes.

Critical Interphase Overpotential as a Lithium Dendrite Suppression Criterion for All-Solid-State Lithium Battery Design HongliWan and ChunshengWang; University of Maryland, College Park, United States

Suppressing Li dendrite growth is a crucial challenge in the development of all-solid-state Li-metal batteries (ASSLBs). Penetration of Li dendrites through the solid-state electrolyte (SSE) can lead to short-circuiting of the cells, presenting a safety concern. The current density at which Li dendrites penetrate through the SSE and cause short-circuiting is termed the critical current density (CCD). The CCD not only depends on the intrinsic properties of the SSE but also on the thickness of the SSE. Furthermore, as the Li plating or stripping capacity, stack pressure, and interfacial resistance change the overpotential, which is the driving force for Li plating and stripping, these factors also change the CCD. Thus, because the CCD is not an intrinsic property of an SSE, it is difficult to use CCDs to design SSEs. Herein, we evaluate the lithium dendrite suppression capability of SSE using critical interphase overpotential (CIOP). The CIOP is the intrinsic property of the interphase, which depends on electronic/ionic conductivity, lithiophobicity, and mechanical strength. When the applied interphase overpotential (AIOP) is larger than CIOP, Li will grow into interphase as dendrites. To reduce AIOP but increase CIOP, we design a mix-conductive Li_2NH-Mg interlayer between Li_6PS_5Cl SSE and Li-1.0wt%La anode, which transfers into Li_6PS_5Cl/$LiMgS_x$/LiH-Li_3N/LiMgLa after Mg migration during annealing and activation cycles. The $LiMgS_x$ interphase increases the CIOP from 9~12mV (of Li_6PS_5Cl) to ~220mV. The Li plates on LiMgLa surface and reversible penetration into the formed porous LiH-Li_3N reducing AIOP. The CIOP provides design guidelines for high-energy and room-temperature all-solid-state lithium-metal batteries.

1:45 PM EN02.18.02
Investigating Thermodynamic and Structural Factors for Suppressed Dendrite Formation at Anode-Electrolyte Interfaces in Solid-State Batteries Guy OlivierNgongang Ndjawa and SamirAbdulhamid Hussen; King Fahd University of Petroleum and Minerals, Saudi Arabia

Solid-state batteries (SSBs) offer a promising solution for overcoming the limitations of conventional Li-ion batteries, but significant challenges persist, especially at the anode-electrolyte interface, leading to poor battery performance. Phase field models have been extensively used to characterize microstructural evolutions at SSB interfaces. However, the key thermodynamic factors and initial boundary conditions influencing structural degradation in these cells, particularly dendrite formation, remain unclear. This work aims to develop a phase-field model that incorporates electrochemical and mechanical driving forces to simulate dendritic growth at SSB interfaces with resolved microstructures. Specifically, the focus is on the anode/solid electrolyte interface, utilizing lithium metal as the anode and Li7La3Zr2O12 (LLZO) as the electrolyte. Expanding on the foundational Monroe Newman model, this study reevaluates the model by incorporating alternative initial mechanical and thermodynamic boundary conditions that have the potential to either impede or facilitate dendritic growth. Through the integration of micron-scale phase-field models and atomic-scale simulations, the research enables the prediction of dendrite nucleation, growth kinetics, and morphology, thereby revealing the conditions that can prevent dendrite formation and enhance battery performance and safety. Overall, this work addresses a critical gap in understanding dendrite growth by demonstrating that the consideration of initial boundary conditions is essential. The findings from this research will hopefully enhance our understanding of solid-state battery interfaces, enabling more accurate predictions of electrochemical processes and failure modes. Ultimately, this improved understanding will guide the design and development of the next generation of all-solid-state batteries with enhanced energy density and improved safety.

Composites of Alkali Carbonphosphonitride Thermosets with LLZO and other Ion Conducting Ceramics AndrewPurdy[1], RyanJ. Buchwalder[1,2], DanielM. Fragiadakis[1], HunterO. Ford[1,3], ChristopherA. Klug[1], MarkO. Bovee[1,3], MeganB. Sassin[1] and BrianL. Chaloux[1]; [1]Naval Research Laboratory, United States; [2]NREIP Intern, United States; [3]NRC Postdoctoral Associate, United States

Lithium dicyanamide ($LiN(CN)_2$) reacts with phosphorus cyanides ($P(CN)_3$ or $RP(CN)_2$) in a 2:1 or greater mole ratio in an anhydrous aprotic mutual solvent to form a resin, which then cures at temperatures of 200-300 °C to a non-flammable ion conductor. When fully cured, those films have a low ionic conductivity, probably due to rigid crosslinking of the thermoset. We found previously that adding compounds to the resin, such as LiCN that contain a higher concentration of Li than $LiN(CN)_2$, and some non-volatile organic plasticizers, increase the room temperature ionic conductivity from 10^{-12} S/cm to around 10^{-8} S/cm, and the Na versions can also be more conductive than those with Li. Post-cure treatment with diglyme also causes a dramatic conductivity increase, presumably by complexing the mobile Li ions and plasticizing the material. While it seems unlikely that practical conductivities can be obtained in the pure resins, they might be attractive as binders for more highly conducting ceramic powders such as lithium lanthanum zirconium oxide (LLZO), in order to produce a composite material that can be cured to a solid electrolyte at temperatures compatible with other components. We will report our systematic efforts to use these dicyanamides and A-P-C-N (A = Li, Na) thermosets as binders for commercially available ion conducting ceramics. The ratios of resin to ceramic and the conditions of preparation are varied to produce solid composite films for measurement, and the ionic conductivity and chain motions of these films are characterized by impedance and dielectric relaxation spectroscopy. Test cells with Li foil are constructed and measured to evaluate electrochemical stability and lithium transference numbers. Additionally, solid state NMR is used to examine the compositional stability of the composite and the ion mobility between different ionic conductors.

Material Design of Quaternary Halide Electrolytes AnthonyOnwuli[1], AlexM. Ganose[1], AronWalsh[1,2] and IeuanD. Seymour[3,1]; [1]Imperial College London, United Kingdom; [2]Ewha Womans University, Korea (the Republic of); [3]University of Aberdeen, United Kingdom

The future of electrochemical energy storage can be considered to be within the development of all-solid-state batteries (ASSBs). The key to enabling this future resides in the result of solid-state electrolytes (SSEs). For lithium-ion battery systems, halide electrolytes have been reported with room temperature ionic conductivities >10-3 S cm-1, good stability against oxidation, and good stability against cathode materials1. We find that the space explored for sodium halide electrolytes has been somewhat limited within the literature and primarily focused on ternary sodium chloride SSEs with the limited investigation of sodium bromide and iodide SSEs 2,3,4. Previous studies have demonstrated that Li-halide systems such as Li3YCl6 (P-3m1) and Li3InCl6 (C2/m) form layered structures with high ionic conductivity. In contrast, ternary halides such as Na3YCl6 often form double perovskite structures (P21/n) with intrinsically low ionic conductivity. Discovering new layered Na-halide systems is crucial to improving the ionic conductivity of this class of materials. This study provides a high-throughput materials design workflow to provide insight into the development of quaternary sodium metal halide SSEs through theoretical calculations of thermodynamic stability, electrochemical stability, stability against common sodium cathodes, transport properties as well as the synthesis of Na6M’M’’X12 SSEs. 3710 compositions are considered in four different space groups,ps, P21/n, P-3m1, P31c, C2/m. Our candidate pool is screened to 25 candidates by filtering for a ground state phase in the C2/m structure, on the convex hull (Ehull=0), no radioactive elements and an insulator (PBEsol bandgap >2 eV). High oxidation potentials are often observed for the candidates indicating stability against cathodes. Further interface thermodynamics stability analysis revealed that there is a driving force for reactions at the interface between the SSEs and cathodes. On-the-fly machine-learning molecular dynamics (MLMD) was used to probe the ionic conductivity of the candidates. Synthesis of promising candidate material Na6CaZrBr12 revealed the existence of a sodium halo spinel phase not initially considered in the initial high-throughput screening. The high-throughput screening and synthesis performed in this study can provide design principles for the development of new SSEs and can be extrapolated to other conducting-ion systems as well as providing a method to expand the search space of known SSE chemistries.

Deep Learning of Experimental Electrochemistry for Battery Cathodes Across Diverse Compositions PeichenZhong[1], BowenDeng[1], TanjinHe[1], ZhengyanLun[2,1] and GerbrandCeder[1]; [1]University of California Berkeley, United States; [2]University of Chinese Academy of Sciences, China

Artificial intelligence (AI) has emerged as a powerful tool in the discovery and optimization of novel battery materials. However, the adoption of AI in battery cathode representation and discovery is still limited due to the complexity of optimizing multiple performance properties and the scarcity of high-fidelity data. In this study, we present a comprehensive machine-learning model (DRXNet) for battery informatics and demonstrate the application in the discovery and optimization of disordered rocksalt (DRX) cathode materials. We have compiled the electrochemistry data of DRX cathodes over the past five years, resulting in a dataset of more than 30,000 discharge voltage profiles with 14 different metal species. Learning from this extensive dataset, our DRXNet model can automatically capture critical features in the cycling curves of DRX cathodes under various conditions. The model gives rational predictions of the discharge capacity for diverse compositions in the Li–Mn–O–F chemical space and high-entropy systems. As a universal model trained on diverse chemistries, our approach offers a data-driven solution to facilitate the rapid identification of novel cathode materials, accelerating the development of next-generation batteries for carbon neutralization.

The Mechanical Behavior of Li Metal Anodes During Electrochemical Cycling JunghoShin and MattPharr; Texas A&M University, United States

Pure lithium metal anodes are highly promising due to their superior capacities yet remain challenging to implement commercially. Key remaining challenges include non-uniform deposition of the Li metal which can lead to dendrite formation and capacity loss, as well as mechanical stresses and strains induced by the “infinite volume change” associated with its host-less nature during electrodeposition. These issues are intimately connected to the mechanical properties of lithium itself, as well as details of its behavior during electrochemical cycling. With these issues in mind, we investigated the mechanical response of pure Li metal during electrodeposition at room temperature. The tests revealed rate-dependent mechanical behavior during electrodeposition, which we largely attribute to the strain-rate dependent mechanical properties of lithium itself by drawing an analogy between the deposition rate and the strain-rate. This talk will further discuss the practical implications of these experimental observations, particularly concerning dendrite growth in batteries. Specifically, this talk will provide general insight into lithium penetration into solid-state electrolytes, which must be prevented to fully harness the potential of lithium metal anodes in future battery technologies.

Compatibility Study of $LiCoO_2$ and $LiCoPO_4$ Cathode Materials with NASICON-Type Solid Electrolyte LATP FumihikoIchihara[1], KodaiNiitsu[1], MachikoOde[1], KazutakaMitsuishi[1], YoshinoriNiwa[2], ShogoMiyoshi[1], TakahisaOhno[1] and TakuyaMasuda[1,3]; [1]National Institute for Materials Science, Japan; [2]High Energy Accelerator Research Organization, Japan; [3]Hokkaido University, Japan

All-solid-state lithium-ion batteries (ASSLIBs), particularly those employing oxide-based solid electrolytes, are expected to be the next generation of rechargeable batteries because they guarantee safety and dependability by replacing highly combustible organic electrolyte solutions with solid electrolytes. In contrast to conventional liquid LIBs, in which electrolyte/electrode interfaces can be formed spontaneously by injecting liquid electrolyte into cells, the formation of a well-defined solid electrolyte/electrode interfaces with a high ionic conductivity is a key challenge for the development of ASSLIBs.
The conventional method for obtaining the oxide-based solid electrolyte/electrode material interfaces is high-temperature sintering, as these materials have a high melting point and exhibits poor plasticity. However, co-sintering of solid electrolytes and electrode materials often leads to undesired side reactions. Thus, understanding the reaction between solid electrolyte and electrode materials is especially important not only for fundamental science but also for a possible synthetic route to form a well-defined interface with a high ionic conductivity.
In this study, we performed the compatibility assessment of a highly ion-conducting solid electrolyte, $Li_{1.3}Al_{0.3}Ti_{1.7}(PO_4)_3$ (LATP) with a high-capacity cathode material, $LiCoO_2$ (LCO) and a high-voltage cathode material, $LiCoPO_4$ (LCP) based on thermodynamic calculations. The calculation results showed that co-sintering LATP and LCO react with each other to form completely different chemical species instead of forming a well-defined interface. On the other hand, co-sintering LATP and LCP does not cause sever reaction. Thus, we experimentally co-sintered the composite of LATP/LCO and LATP/LCP as combination that reacts intensely and a combination that maintains their crystalline structure and characterized their property.

In the intensely reactive combination LATP/LCO, various mixing ratios of LATP and LCO were sintered at various temperatures, and the crystalline phases formed by the reaction were identified and quantified by Rietveld analysis of X-ray diffraction (XRD) and phases including amorphous phase by linear combination fitting of X-ray absorption fine structure (XAFS). The results showed that regardless of the mixing ratio, LATP and LCO react at 300°C, which is relatively low for sintering temperatures, to form Co_3O_4, Li_3PO_4 and amorphous-TiO_2. Further increasing the sintering temperature, it was found that the chemical species formed by the reaction depended on the mixing ratio of LATP and LCO. In addition, we used thermodynamic calculations to calculate the chemical species produced at each temperature and mixing ratio and compared these with the experimentally observed chemical species. For sintering temperatures between 900°C and 700°C, the chemical species observed experimentally and those predicted to be formed by thermodynamic calculations were in reasonable agreement. On the other hand, for sintering temperatures below 600°C, there was a significant disagreement between the calculation and experimental results.
In the maintaining their crystalline structure combination LATP/LCP, we co-sintered the mixture of LCP and LATP at 800°C and characterized the structure of their bulk and interfaces by XRD, XAFS and microscopic techniques. XRD showed that LATP and LCP maintained their crystalline structures after sintering. XAFS results for Ti and Co K-edges showed no change in chemical state around Ti before and after sintering, whereas a slight change was observed for Co, suggesting the small amount of LCP was decomposed to form Co-containing reaction products due to sintering. The microscopic measurements clearly imaged the formation of Co-containing amorphous layers at the grain boundaries within LATP/LCP composites. XAFS and electron energy loss spectroscopy analyses identified the major species of Co-containing amorphous layers to be CoO and Li_3PO_4.

3:45 PM EN02.19.02
Ionic Conductivity Transitions in Sodium Antiperovskite Ionic Conductors DuhanZhang and YiliangLi; Massachusetts Institute of Technology, United States

Na_3OCl is a well-studied prototypical fast ion conducting compound representative of the antiperovskite (AP) family, which is of interest for solid-state electrolytes. Here, we observe a two-order-of-magnitude increase in its ionic conductivity (from 10^{-1} to 10 mS/cm) with increasing temperature at 305°C. Temperature-dependent synchrotron X-ray diffraction (SXRD), differential scanning calorimetry (DSC), quasi-elastic neutron scattering (QENS), and impedance spectroscopy, are used to show that the increase in conductivity is correlated with a transition from tetragonal to cubic symmetry associated with a change in octahedral tilt disorder. While previous work has shown that octahedral tilting in APs can create ion migration pathways with lower migration energies than in the regular cubic structure, this is the first instance where such a large increase (100 times) in ionic conductivity due to a change in octahedral tilt disorder has been observed. The octahedral tilt disorder may be exploited as a pathway to increasing the ionic conductivity of antiperovskites and structurally related compounds.

4:00 PM EN02.19.03
Electrochemical Lithiation and Delithiation Reactions Observed by Multimodal *In Situ* TechniquesTakuyaMasuda; NIMS, Japan

We developed in-situ X–ray photoelectron spectroscopy (XPS) and bimodal atomic force microscopy (AFM) systems and applied them to electrochemical lithiation and delithiation reactions of a silicon electrode deposited on a solid electrolyte sheet in an all-solid-state lithium-ion battery configuration. XPS showed that not only lithium silicide but also lithium oxide, lithium silicate and lithium carbonate were formed due to the lithiation of silicon and native oxide, followed by undesired side reactions with residual gasses such as oxygen and carbon dioxide in the inert condition. The spectral features of lithium silicide reversibly responded to the successive lithiation and delithiation cycles, while lithium oxide, lithium silicate and lithium carbonate formed at the surface remained unchanged as irreversible species. As long as the lithiation and delithiation cycles were repeated in the range of Li content x= 0 – 2.4 in Li_xSi, the position of lithium silicide peak in the Si 2p region shifted monotonically. However, a drastic shift was observed in the successive delithiation after inserting lithium in silicon electrode up to $Li_{3.5}Si$. This drastic shift was assignable to the phase transformation of crystalline $Li_{15}Si_4$ to amorphous Li_xSi. AFM showed that the Young's modulus of silicon/lithium silicide changes consistently with change in lithium content x in Li_xSi. Such spectroscopic chemical information and nanoscale mechanical information will be discussed in detail in the context of mechanical degradation.

Impact of Transport Properties at The Grain-Scale Engineering of Solid Electrolytes: Case Studies on Anti-Perovskite RuhulAmin, MarmDixit and IliasBelharouak; Oak Ridge National Laboratory, United States

Antiperovskites of composition M_3AB (M = Li, Na, K; A = O; B = Cl, Br, I, NO_2, etc.) have recently been investigated as solid-state electrolytes for all-solid-state batteries. Inspired by the impressive ionic conductivities of $Li_3OCl_{0.5}Br_{0.5}$ and Na_3OBH_4 as high as 10^{-3} S/cm at room temperature, many variants of antiperovskite-based Li-ion and Na-ion conductors have been reported, and K-ion antiperovskites are emerging. These materials exhibit low melting points and thus have the advantage of easy processing into thin body and intimate contacts with electrodes. However, there are also issues in interpreting the stellar materials and reproducing their high ionic conductivities. We synthesized the antiperovskite materials by melt casting method and processed them through isostatic pressing (ISP) and conventional approaches. In this presentation, we discuss the critical role of isostatic pressing (ISP) on the crystal- and micro-structural features that originate the higher ionic conductivities of antiperovskites compared to conventional processing. We then discuss its impact on the electrochemical performance of the systems and scalable processing of solid-state battery (SSB) components, and their integration is a key bottleneck toward practical deployment. Finally, we also provide some key perspectives, challenges, and future directions for large-scale production of SSB components and integration.

4:30 PM EN02.19.05
Copper Sulfides as Cathode Active Materials in All Solid-State Batteries Katherine A.Mazzio[1,2], ZhenggangZhang[3,1], KangDong[4], IngoManke[2] and PhilippAdelhelm[1,2]; [1]Humboldt-Universität zu Berlin, Germany; [2]Helmholtz-Zentrum Berlin für Materialien und Energie, Germany; [3]Southern University of Science and Technology, China; [4]Institute of High Energy Physics, China

One bottleneck in the development of solid-state battery (SSB) technologies is the cathode active material (CAM). Layered oxide materials commonly utilized in other lithium-ion battery technologies are quickly approaching their limits in terms of capacity. It is also clear that realizing the benefits of lithium metal anodes in SSBs necessitates the use of high-capacity conversion-type cathodes. Sulfides offer an intriguing direction for further research because they can reversibly contribute to charge storage through stable anion redox ($2S^{2-} \rightarrow (S_2)^{2-} + 2e^-$). In this talk I will discuss our recent work on metal sulfide-based conversion reactions as CAMs for SSBs, including the dynamic microstructural evolution of CuS using *in-situ* synchrotron X-ray tomography and the use of ternary Cu_3PS_4 with β-Li_3PS_4 solid electrolyte.[1,2] Copper sulfide (CuS) is a naturally occurring mineral that reacts with lithium via a conversion reaction to form Li_2S and Cu with a theoretical energy density of 961 Wh/kg. CuS demonstrates a peculiar feature of Cu displacement into large (µm-sized) domains during cycling that are highly reversible during electrochemical cycling. We were able to follow this dynamic microstructural evolution *in-situ* by synchrotron X-Ray tomography.[1] In addition to these phase transformations, we also observe significant crack formation in the cathode that we found to be dependent on the stacking pressure of the cell. When replacing the binary compound CuS with the ternary compound Cu_3PS_4, the theoretical energy density increases to 1301.5 Wh/kg and at the same time we anticipate greater compatibility with the β-Li_3PS_4 solid electrolyte due to similarities in chemical composition and structure.[2] We studied the reaction mechanism of Cu_3PS_4 in SSBs and found that it undergoes an irreversible conversion reaction in the 1st cycle. The subsequent redox is largely dominated by Cu_2S and S_8 which form finely dispersed redox centers that promote stable cycling behavior.

Materials and Methods for Sustainable Soft Electronic and Robotic System - From Biodegradable Gels to Mycelium Based Elektronik Skins MartinKaltenbrunner; Johannes Kepler University, Austria

Modern societies rely on a multitude of electronic and robotic systems, with emerging stretchable and soft devices enabling ever closer human machine interactions. These advances however take their toll on our ecosystem.

Mitigating some of these adverse effects, this talk introduces materials and methods for soft systems that biodegrade. Based on highly stretchable biogels and degradable elastomers, our forms of soft electronics and robots are designed for prolonged operation in ambient conditions without fatigue, but fully degrade after use through biological triggers. Enabling autonomous operation, stretchable and biodegradable batteries power wearable sensors. 3D printing of biodegradable hydrogels enables omnidirectional soft robots with multifaceted optical sensing abilities. Going beyond, we introduce a systematically-determined compatible materials systems for the creation of fully biodegradable, high-performance electrohydraulic soft actuators. They reliably operate up to high electric fields, show performance comparable to non-biodegradable counterparts, and survive over 100,000 actuation cycles. Pushing the boundaries of sustainable electronics, we demonstrate a concept for growth and processing of fungal mycelium skins as biodegradable substrate material. Mycelium-based batteries allow to power autonomous sensing devices including a Bluetooth module and humidity and proximity sensors, all integrated onto mycelium circuit boards.

11:00 AM EN03.01.02
Ultrasound-Driven Bioresorbable Triboelectric Nanogenerator with Controllable Lifetime InahHyun[1], Dong-MinLee[2] and Sang-WooKim[1]; [1]Yonsei University, Korea (the Republic of); [2]Sungkyunkwan University, Korea (the Republic of)

On-demand bioresorbable electronics have gained significant attention due to their dissolution capabilities and the elimination of secondary surgical procedures for device removal, thereby minimizing the side effects associated with implantation. However, the reliance of these electronics on non-transient commercial energy supplies limits their practicality. In this study, we propose a fully biodegradable and implantable triboelectric nanogenerator (FBI-TENG) that harnesses ultrasound as both a non-invasive power source and a means of device removal. Under low-intensity ultrasound ($\leq$0.5 W cm^{-2}), the FBI-TENG efficiently generates energy to power other electronic devices. To enhance its electrical performance, we optimize the triboelectric layer by incorporating polyethylene glycol, resulting in a remarkable 58.5% increase in voltage output underwater, from 2.625 to 4.160 V. In contrast, high-intensity ultrasound ($\geq$3.0 W cm^{-2}) can trigger the degradation process of our FBI-TENG, leading to the complete loss of its energy-generating function within a few minutes. Through finite element method simulation, we investigated that the triggering event occurs due to the porous structures of the poly(3-hydroxybutyrate-co-3-hydroxy valerate) with locally intensified pressure under the high intensity of ultrasound. This research provides valuable insights into the practical application of implantable triboelectric nanogenerators based on ultrasound-triggered transient material design. This research offers valuable insight into the practical application of implantable triboelectric nanogenerators on the basis of ultrasound-triggered transient material design.

Scalable Synthesis and Manufacturing of Piezoelectric Biomaterials and Architectures XudongWang; University of Wisconsin--Madison, United States

Piezoelectric materials are a group of important functional building blocks that interfacing the human body by coupling biomechanical energy and electricity. So far, many technology innovations have advanced piezoelectric materials and composites toward a broad range of biomedical applications, which possess unique biocompatibility and flexibility. Fundamentally, materials design and engineering draw the boundary where this technology may advance. In this talk, I introduce our most recent development of piezoelectric materials and composites that are particularly designed for implantable nanogenerator applications. First, I present our wafer-scale approach to creating piezoelectric biomaterial thin films based on γ glycine crystals. The self-assembled sandwich film structure enabled both strong piezoelectricity and largely improved flexibility. We will further discuss strategies of controlling the orientation and morphology of amino acid crystals to improve the piezoelectricity. Then, new ferroelectric composites are presented as a new composite used in 3D printing for directly manufacturing of piezoelectric

architectures with tunable piezoelectric and mechanical properties. This group of materials enable new capability of in vivo charging and electrostimulations, which revolutionaries the design and implementation of many biomedical therapeutics.

SESSION EN03.02: Biodegradable Electronics
Session Chairs: Amay Bandodkar and Lan Yin
Monday Afternoon, November27, 2023
Hynes, Level 2, Room 206

1:30 PM EN03.02.01
Biodegradable, Self-healing, Recyclable, Conductive Coatings for Wearable Electronics and Soft Robotics PietroCataldi; Italian Institute of Technology, Italy

Electrically conductive coatings are essential for transitioning electronic components and circuitry from stiff and rigid substrates to more flexible and stretchable platforms, such as thin plastics, textiles, and foams.[1] In parallel, the push for more sustainable, biodegradable, and cost-efficient conductive inks to coat these substrates has led to the development of innovative formulations involving biopolymers and nanomaterials that results in soft composites layer with unique functionalities.
The proposed talk unveils diverse electrically conductive coating (resistivity $\approx 10^{-4}$ Ω m) that entails salient properties such as broad substrate types paintability, tunable piezoresistivity, self-healing, tunable degradability, and recyclability. Such a broad collection of properties is obtained simply by changing the substrates employed, the binders, and the conductive nanofillers. Particularly, one new class of coating based on biobased and biodegradable vitrimer binders is proposed. Using the vitrimer ensures satisfying adhesion to diverse substrates, flexibility, and recyclability of the conductive coating. This coating enables human-mimicking soft robotics skin since it is self-healing and biodegradable. Tests for the live monitoring of SoftHand3, the grasping system of many worldwide diffused robots, have yielded promising results. The use of biodegradable ingredients and the possibility of recycling makes it an appealing material to face the sustainability issue of today's electronics and robotics.
Another class of coating proposed is applied to textiles. Such coatings have controllable electrical resistance change with deformation and transiency (i.e., dissolution in water).[2] The modulation of the piezoresistivity and transiency is obtained by controlling the nanofiller geometry, binder composition, and textile twill orientation. The electrical resistance shows an anisotropic response to bending depending on the composition of the coating and the stress direction, functioning either as a deformable compliant electrode or a tunable piezoresistor. Indeed, it can withstand thousands of bending cycles with a change in resistance of less than 5% or change its resistance by many orders of magnitude with the same deformation thanks to the combination of cotton twill and different nanofillers. A simple modification in the binder composition adding waterborne polyurethane, allows the coating to go from entirely transient in water within minutes to withstanding simulated washing cycles for hours without losing its electrical conductivity. This versatile green conductor may serve opposing needs by altering the material composition and the deformation direction.

Biodegradable Resistive Random Access Memory Based on Natural Organic Carbohydrate Materials for Sustainable Neuromorphic Computing Systems FengZhao and YuanXing; Washington State University, United States

Current computing systems are facing two essential challenges: (1) tremendous energy consumption due to the conventional Von Neumann architecture with low energy efficiency; and (2) environmental sustainability by depletion of nonrenewable materials, production of electronic waste, etc. One potential solution to simultaneously address these two issues is by “brain-like” and “green” neuromorphic computing with energy-efficient operation, sustainable material resources, and environmentally friendly disposals. Such neuromorphic computing systems require hardware components not only capable of mimicking human neuron and synapse - the basic building block of biological neural networks, but also made from natural organic materials such as polypeptides (proteins) and polysaccharides (carbohydrates) which are renewable, abundant in nature, and biodegradable. In this paper, we report resistive random access memory (ReRAM) made from encouraging natural organic carbohydrate materials, honey and fructose, for emerging neuromorphic computing systems and neural networks. Honey or fructose resistive films were formed by a low cost solution-based process and sandwiched between bottom and top electrode, a simple metal-insulator-metal structure analogous to a biological synapse with presynaptic neuron (top electrode), postsynaptic neuron (bottom electrode), and synaptic cleft (fructose film). The nonvolatile memory behaviors were demonstrated by modulating the conductance by voltage stimuli applied on the memory device, with excitatory current flow in the device being monitored. Characteristics including bipolar resistive switching, retention, endurance cycles, long-term potentiation and depression, desolution in water, etc. were reported. All these results testify that carbohydrate-ReRAM devices are promising for energy-efficient and sustainable neuromorphic systems.

2:00 PM *EN03.02.03
Edible Electronics: Recent Results and Perspectives MarioCaironi; Istituto Italiano di Tecnologia, Italy

Edible electronics envisions a technology that is safe for ingestion, environmentally friendly, and cost-effective. Differently from “ingestible” electronics, it aims at realizing electronic devices that are degraded within the body after performing their function, either digested or even metabolized, thus removing any retention hazard. Edible electronics could potentially target a significant number of biomedical applications, such as remote healthcare monitoring, and of applications for food quality monitoring as well, such as edible electronic tags directly in contact with food. Here I will first give an introduction to this emerging field and propose long-term opportunities in terms of environmentally friendly smart technologies, remote healthcare monitoring, along with the challenges ahead. Then, I will report on our recent progress in the development of edible circuitry and components, towards future integrated edible electronic systems. Perspectives for adoption of edible electronic systems for sensors and control in future edible robots will also be shared.

Hyperbranched *In Situ* Polymerized Cyanoacrylate Tissue Adhesives and Their DegradationAlexanderP. Roxas and ZhengtangLuo; The Hong Kong University of Science and Technology, China

Cyanoacrylates are bioresorbable tissue adhesive materials whose ability to rapidly polymerize in situ into a strongly adhering film is suitable for closing wounds during emergencies. This polymerization method, which generates high-molecular-weight linear chains, has been applied and barely changed since the early clinical use of the adhesive because the requirement of rapid, straightforward in-situ polymerization for practicality restricted innovations involving the method and the material composition. Tissue adhesives, however, have been increasingly demanded to exhibit enhanced properties to cater to the needs of emerging trends in biomedical engineering. Our group has recently formulated a procedure to in situ polymerize cyanoacrylates into a branched adhesive film without sacrificing their practical features. Branching in the adhesive film, despite potentially introducing softness and enhancing mechanical properties, among others, can, however, influence the degradation of the adhesive film. The effects of branching on the rate of degradation and the composition of the degradation products were analysed by studying the degradation of branched polycyanoacrylates with varying degrees of branching and comparing them with conventionally polymerized linear equivalents. The degradation behavior of the adhesive is essential to avoid complications resulting not only from toxicity but also from the premature sloughing of the adhesive film from the wound surface.

3:45 PM EN03.03.03
Large-Scale Fabrication of Silk Fibroin-Based Artificial Skin for Cosmetic Research HangmingFan and XiaodongChen; Nanyang Technological University, Singapore

Silk fibroin, a widely utilized material in skin-related applications, possesses a comparable structure and amino acid composition to the cornified cell envelope found in the stratum corneum. This similarity suggests its potential as an alternative to animal experimentation in cosmetic research, particularly as artificial skin. However, improvements are required in silk fibroin-based films to achieve sufficient similarity for practical usage and enable large-scale industrial production. In this study, various methods were employed to synthesize different types of artificial skin for key application scenarios in cosmetic research, including deposition tests, sensation tests, and absorption tests. For mass production of silk fibroin-based films, the conventional solvent casting method, though slow and resulting in poor thickness uniformity, has been commonly used. In this work, we adopted a coating method that allows for easy modification of the artificial skin's surface properties, enabling representation of different skin types (e.g., oily, dry, and combination skin). Furthermore, the proposed method offers significant advantages such as faster production and improved thickness uniformity, making it feasible for industrial-scale manufacturing.

Highly Stretchable Thermally-Grown Silicon Dioxide with Wavy Structures Encapsulation for Biomedical Applications HyeonjiYoo, HangeulKim, Gyeong-SeokHwang and Ju-YoungKim; Ulsan National Institute of Science and Technology, Korea (the Republic of)

Flexible and stretchable bioelectronic devices that can be applied to targets such as heart and liver where repetitive deformation occurs are currently being actively investigated as next-generation devices. These organic material-based electronic devices require an encapsulation layer for long-term stability. Therefore, the development of mechanically stretchable and highly impermeable encapsulating materials is required to develop stretchable bioelectronic devices.
In this research, we developed the highly stretchable and impermeable encapsulations by applying a wavy-structure to the thermally-grown SiO_2. A thermally-grown SiO_2, oxidized from single-crystalline silicon wafer at high temperature, has an extremely low water vapor transmission rate (WVTR) due to amorphous structure and high density with low defects. In addition, we effectively implemented high stretchability through wavy-structure design, overcoming the intrinsically low elastic deformation limit of SiO_2. The stretchability and barrier properties were carried out by uniaxial tensile test and electrical Ca test. By theoretically analyzing the mechanical behavior of wavy-structured SiO_2, the universal deformation model and correlation between stretchability and characteristic of wavy structure were carried out. This stretchable encapsulation shows 20.1% of uniaxial stretchability and 1.11 x 10^{-6} g m^{-2} day^{-1} of WVTR, simultaneously. Moreover, it demonstrates highly reliable barrier properties even after 1,000 stretching cycles at 90% of their stretchability. Therefore, the developed wavy-structured thermally grown SiO_2 is suitable to protect stretchable organic-based bioelectronic devices.

8:00 PM EN03.04.02
Minimally Invasivene and Biodegradable Electronics for Transient Brain Interfaces Jae-YoungBae[1], Gyeong-SeokHwang[2], Young-SeoKim[1], JooikJeon[3], Jung KeunHyun[3], Ju-YoungKim[2] and Seung-KyunKang[1]; [1]Seoul National University, Korea (the Republic of); [2]Ulsan National Institute of Science and Technology, Korea (the Republic of); [3]Dankook University, Korea (the Republic of)

Monitoring brain activities is crucial for diagnosing and providing post-care for brain disorders like epilepsy or traumatic brain injury. However, after the monitoring period, the implanted device needs to be removed to avoid complications such as inflammation. The removal surgery is even riskier and more time-consuming than the initial implantation procedure, causing distress to the patient. Biodegradable electronics is an emerging technology that can dissolve completely into biocompatible molecules once their function is complete, eliminating the risk of biofilm formation or secondary injuries during the removal process. Some biodegradable implantable devices, which combine organic and inorganic materials, have been used to monitor increasing pressure inside the skull caused by traumatic brain injuries and to stimulate the regrowth of peripheral nerves using wireless electrical stimulators. However, current biodegradable electronic devices still require surgical implantation, which adds to the patient's burden. Here, we propose a platform for biodegradable electronics in the brain, including bio-potential electrodes, temperature and strain/pressure sensors, and a wireless communication system capable of monitoring various physiological signals. This platform is designed to dissolve all inserted materials without leaving a potential biofilm formation or causing secondary injuries during the removal process. Furthermore, we introduce the concept of a minimally invasive strategy to reduce the invasiveness of the implantation procedure. This platform holds promise as a transient and minimally invasive brain-interface platform for future clinical applications.

8:00 PM EN03.04.03
Recycled UHT Milk Carton Cellulose Surface as a Novel Substrate for Dual-Lactate Sensor for Milk Spoilage Indication WisarttraPhamonpon[1,2], NadtinanPromphet[1], SaruteUmmartyotin[2] and NadnuddaRodthongkum[1]; [1]Chulalongkorn University, Thailand; [2]Thammasat University, Thailand

Recycled cellulose substrate from UHT milk carton waste was firstly applied as a novel substrate for the colorimetric and electrochemical lactate sensor for milk quality indication. The cellulose and aluminum foil were extracted from the packaging. For preparing the recycled cellulose substrate, chemical treatment (alkali and bleach treatment) was used for the extraction. Then, the recycled cellulose substrate has done enzymatic immobilization for the colorimetric sensor to enhance the specific reaction with the lactate on its surface. For the electrochemical sensor, the recycled cellulose substrate was immersed into the extracted aluminum solution to fabricate the conductive working electrode to improve the surface roughness compared with the recycled cellulose substrate, confirmed by atomic force microscopy. Scanning electron micrograph presented a 3D fibrous network including with air space in between, and X-ray photoelectron spectroscopy showed the binding energy of Al-O at 73.256 eV, confirming the appearance of the aluminum on the recycled cellulose substrate after the surface modification with aluminum solution. For the analytical performance, the colorimetric sensor showed the increasing purpleness of color upon increasing lactate concentration. Furthermore, the aluminum-coated recycled cellulose substrate provided an increasing current response toward the increment of lactate concentration. This dual-lactate sensor can offer linearity of 0.125-2 M, covering a cut-off lactate value in cow’s milk (1.0 M) for milk spoilage indication, which can be used for lactate determination in actual milk samples. Eventually, this platform can represent a new utilization of UHT milk carton waste for the colorimetric and electrochemical sensor that can be applied in food quality control applications.

8:00 PM EN03.04.04
An Innovative Methodology for Constructing Thermally Stable, Self-Healing Pressure Sensors Su BinChoi and Jong-WoongKim; Sungkyunkwan University, Korea (the Republic of)

Stretchable electronics, a subcategory of soft electronics characterized by mechanical elasticity, grapple with a significant challenge—localized stress concentration. This issue threatens the integrity of elastic materials typified by their small Young's modulus and expansive elastic strain range. A promising mitigation strategy is the incorporation of self-healing functionality, achieved by exploiting the dynamics of covalent bond chemistry, particularly Diels-Alder reactions, to conceive polymers of high tensile strength with controlled reversibility. Nonetheless, a pervasive concern with self-healing materials is the requisite temperature for initiating the healing process, which may inadvertently inflict thermal damage to other components of the electronic device. Conversely, lowering the self-healing temperature could undermine the polymer's stability under high-temperature conditions, potentially causing device failure. This dual requirement—low-temperature self-healability and high-temperature thermal stability—demands innovative solutions. In response to this formidable challenge, we introduce a novel methodology involving the creation of a microfibrous network employing polycaprolactone (PCL), a hydrophobic polymer renowned for its low melting temperature (60 °C) and ubiquitous use in shape memory and self-healing materials. Concurrently, we prepare conductive fibers encased in MXene nanosheets—a class of two-dimensional, titanium-based layered materials—by coating these onto the microfibrous PCL network. Intriguingly, the MXene layer preserves the fibrous morphology even when the PCL reaches its melting point, assuring mechanical robustness. The MXene nanosheets seamlessly adhere to the surface of the PCL fibers, effectively forestalling shape deformation of the fibrous network under high-temperature conditions.

These nanosheets further exhibit superior thermal conductivity, which facilitates efficient internal heat dissipation. The amalgamation of these attributes enables the MXene/PCL microfibrous network to exhibit self-healing capabilities at a temperature as low as 60 °C and maintain thermal stability beyond 200 °C. By leveraging this microfibrous network, we develop a pressure sensor, thereby highlighting its potential applications in fabricating stretchable and self-healing electronic devices capable of enduring temperatures exceeding 200 °C.

8:00 PM EN03.04.05
Fragmentation Behavior and Surface Characteristics of Different Plastics: Influence on the Potential Toxicity to Macrophages and Angiogenesis KyungtaePark and JinkeeHong; Yonsei University, Korea (the Republic of)

The production and waste of plastics are increasing rapidly, and there is a growing interest in investigating the impact of microplastics (MPs) smaller than 5mm on human beings as pollutants. Previous research has primarily focused on the toxicity of engineered plastic particles with a spherical shape, overlooking the fact that microplastics tend to fragment under environmental conditions, resulting in various morphological characteristics and sizes. This fragmentation behavior has not been adequately considered in toxicity analysis. Therefore, it is crucial to comprehend the fragmentation behavior of different plastics and analyze the surface characteristics of each microplastic to gain a better understanding of their potential toxicity.
In this study, we conducted a comprehensive investigation into the fragmentation patterns of plastics, specifically focusing on polypropylene (PP), acrylonitrile butadiene styrene copolymer (ABS), and polyethylene terephthalate (PET) as representative plastics. To simulate the fragmentation of each plastic, we employed a ball-milling process, which resembles the physical fragmentation process that occurs during plastic weathering.
After the fragmentation process, we characterized the surface of the microplastics using scanning electron microscopy (SEM), FT-IR, Raman spectroscopy, and x-ray photoelectron spectroscopy. We also examined the change in crystalline structure using a differential scanning calorimeter (DSC). Considering that the micronization behavior of plastics is highly dependent on the amorphous structure, we confirmed the crystalline and amorphous parts and their respective crystallinity. Additionally, we conducted size and shape analysis of the microplastics to investigate cellular uptake and toxicity.
Macrophages were selected as representative immune cells due to their ability to recognize infectious agents and remove toxicants through phagocytosis. We studied the cellular uptake of each microplastic and observed cellular reactions such as ROS generation in the macrophage cytosol, polarization, and immune-cytokine secretion. Furthermore, we investigated the complex cellular reactions by co-culturing macrophages with human umbilical vein endothelial cells (HUVECs). As HUVECs possess angiogenic abilities, we analyzed *in vitro* tube formation under co-culture conditions and quantified the amount of angiogenic growth factors after exposing macrophages to microplastics.
Our findings revealed three significant points in understanding the potential toxicity of microplastics:
The characteristics of fragmented microplastics differ significantly from engineered microplastics.
The fragmentation behavior and properties of each microplastic should be considered to understand their potential toxicity.
Depending on the composition of the microplastics, the reaction of macrophages and subsequent effects on angiogenesis vary.

8:00 PM EN03.04.06
Directed Evolution of Microorganisms for Engineered Living Materials JulieM. Laurent, AntonKan, AnkitJain, MathiasSteinacher, Nadia EnrriquezCasimiro, StavrosStavrakis, AndrewJ. deMello and AndréR. Studart; ETH Zürich, Switzerland

With the environmental challenges we face, a shift is needed in the materials we produce and use. Materials found in Nature are made at atmospheric temperature and pressure, and they are robust, long-lasting, and renewable. Incorporating life into human-made materials would bring us closer to mimicking them, adding functionalities not accessible by current synthetic material production methods. The rich biochemical diversity in bacteria provides an immense design space for the engineering of adaptable living materials.

However, bacteria have evolved to perform specific biological functions in their particular environment. Their phenotypes thus might not fulfill the demands of engineering and industrial applications. In particular, we lack control over the shaping of bacterial communities and living materials. Biofilms are an example of naturally occurring self-assembled living materials produced by bacteria. Although three-dimensional, they are conformal to surfaces and relatively limited in terms of shape complexity and control.

Here, we show that 3D printing of engineered bacteria embedded in a matrix can help us shape complex living materials with programmable functionalities. Using genetic engineering tools and readily available 3D printing techniques, engineered bacteria-laden living materials were shaped into complex structures. The metabolism of microorganisms was harvested to add a function (luminescence, melanin secretion) or produce a material (cellulose, calcium carbonate) in three-dimensional objects.

The freedom in shape design provided by 3D printing techniques enabled additional functionalities that were not present in the natural world. Bacterial luminescence was increased with a gyroid structure, and dampened when printing a surrounding layer populated with melanin-producing engineered microorganisms. In the future, printing material-producing microorganisms and exploiting their evolved cellular machinery will provide new ways of making sustainable materials.

8:00 PM EN03.04.07
Programming Hierarchical Architectures in Biodegradable Microcapsules for Advanced Functions MuchunLiu and BenedettoMarelli; Massachusetts Institute of Technology, United States

Programming biomaterials at multiscale is critical in developing advanced technologies in addressing environmental issues. For instance, several industries have a compelling need to substitute open-used, non-degradable, intentionally added microplastics with biodegradable alternatives. Biopolymers extracted from natural products or food waste, such as regenerated silk fibroin, offer many merits. However, assembling biopolymers at multiscale remains challenging due to their complex compositions.
To address this challenge, we present a biodegradable silk-based microencapsulation technique achieved by modulating the structural protein protonation and chain relaxation at the point of material assembly. It can sustain the release of soluble and insoluble payloads typically used in cosmetic and agriculture applications. Manufacturing through well-established fabrication techniques, such as spray drying, yields microcapsules with tunable morphology and degradation kinetics. As a proof-of-concept for agrochemicals delivery, a greenhouse trial demonstrated that a commonly used herbicide (i.e., Saflufenacil) delivered via silk microcapsules on corn plants reduced crop injury compared to the non-encapsulated version.
Additionally, we introduce a synergistic assembly of biopolymer microparticles into hierarchical structures, such as spiny microcapsules and interconnected micro-network. We can tune the biopolymer type, geometry, structure, crystallinity, payload, and mechanical properties for different functions. For example, engineered multi-spines effectively improved the retention percentage of microcapsules on smooth spinach leaves after wash-off. Furthermore, the echinate micro-network can transfer and co-localize different fluorescent payloads in the micro-bridges. Our findings provide a platform for the advanced biopolymers assembly into functional structures, which is of great potential in agriculture, environmental remediation, and other applications that interact directly with the environment.

8:00 PM EN03.04.08
Biodegradable Polymers for Tuning Properties of Long-Acting HIV Pre-Exposure Prophylaxis (PrEP) Implants ArchanaKrovi[1], GuadalupeArce Jimenez[1], LeannaLevin[1], DanielaCruz[1], PafioJohnson[1], EllenLuecke[2], ChasityNorton[1] and LeahJohnson[1]; [1]RTI International, United States; [2]Women's Global Health Imperative, United States

Introduction: The development of new biodegradable implants for long-acting (LA) drug for HIV pre-exposure prophylaxis (PrEP) can advantageously eliminate the requirement of a second medical procedure to remove the devices at the end of use when drugs are depleted. We have previously demonstrated tunable antiretroviral (ARV) release through tailoring the implant surface area, wall thickness, molecular weight of polymer, and ratios of homopolymer blends. Here, we further advance our implant platform by exploring biocompatible and biodegradable polymers with differing compositions, degradation profiles, and physicochemical properties that ensure drug transport through the polymer membrane under physiological conditions.
Methods: Biodegradable polymers poly(3-hydroxybutyrate-co-3-hydroxyvalerate) (PHBV), polycaprolactone (PC-17, PCL-C18E), PEGylated polycaprolactone (PCL-C18-PEG), and polybutylene succinate (FZ71PM, FD92PM) were extruded into cylindrical tubes with an outer diameter of 2.5 mm and a wall thickness 300 µm. Implants were prepared by loading antiretroviral formulations into an extruded tube and then enclosing the tube via heat sealing. Implants were sterilized via gamma irradiation at 18-24 kGy and submerged in phosphate buffered saline (pH 7.4) at 37 °C to mimic physiological conditions. Antiretroviral concentrations released in the buffer over time were measured by high performance liquid chromatography or UV-Vis. Crystallinity, molecular weight, and mechanical properties of the tubes were characterized using differential scanning calorimetry, inherent viscosity, and tensile testing, respectively.
Results: PHBV had the highest crystallinity (60.6 ± 1.2%) among all the polymers evaluated and showed the lowest drug release rate. Interestingly, while PCL materials with slightly different molecular weights PC-17 (IV 1.82) and PC-C18E (IV 1.93) had similar crystallinities of 51.3 ± 1.1% and 50.3 ± 6.4%, respectively, the introduction of a PEG end group on the PCL polymer (PCL-C18-PEG) led to significantly lower crystallinity (36.4 ± 1.5%) and the highest release rate. We hypothesize that the biocompatible PEG modifier potentially disrupts the packing of the polymer chains and can affect the drug release rates. Crystallinity of PBS (FD92PM) was the lowest (25.2 ± 0.2%) but exhibited similar drug release rates comparable to that of PC-17. This is a significant finding as FD92PM polymer may offer an approach to deliver an antiretroviral at the target doses with a potentially faster biodegradation timeframe in contrast to the approximately 2-year degradation timeframe for PCL. Lastly, FZ71PM had a similar crystallinity to that of PC-17 (46.4 ± 9.4%) but exhibited lower drug release from the implant form factor. Despite the insignificant drug release, this polymer could be utilized for indications with lower drug release targets and with a potentially faster biodegradation profile.
Conclusions: We explored biodegradable implants designed for HIV PrEP that comprise extruded tubes from polymers of varying physicochemical properties. These differing polymers offer

an effective approach for tuning the drug release rates, implant duration and integrity, and ultimately the biodegradation profiles of the implants. Next steps include evaluation of the polymer degradation kinetics, in real time (in vitro and in vivo) and under accelerated conditions. An in-depth understanding of the degradation characteristics of this platform will enable new implant designs for varied medical indications that might require tailored degradation timeframes.

8:00 PM EN03.04.09

Preconditioning of Long-Acting Subcutaneous Implants to Support Evaluation of *In Vivo* Pharmacokinetic Depletion ProfilesDanielaCruz, ChristineStrickland, LeannaLevin, GuadalupeArce Jimenez, ArchanaKrovi, PafioJohnson, ChasityNorton, EllenLuecke and LeahJohnson; RTI International, United States

The pharmacokinetic depletion period (i.e., tail) of long-acting (LA) drug delivery systems can result in a gradual decrease of drug concentration over time. Comprehensive characterization of the depletion tail can provide insight about effectiveness of the drug delivery system and the possibility for subtherapeutic drug levels, which can lower efficacy or enable the emergence of drug-resistant strains. The thorough evaluation of the depletion tail also provides details about the optimal dosing period to maintain therapeutic drug levels throughout the course of treatment. In this study, we explore the preconditioning of a biodegradable subcutaneous implant for LA HIV pre-exposure prophylaxis (HIV PrEP) that sustainably releases antiretroviral (ARV) drug. By preconditioning the implant via accelerated conditions during the zero-order release phase, we can achieve an efficient way of testing long-acting drug formulations.
Poly-ε-caprolactone (PCL) extruded tubes were filled with bictagravir (BIC) formulated with castor oil. The ends of the tubes were heat-sealed and implants were sterilized by gamma irradiation (18-24 KGy). For in vitro release studies, implants were submerged in phosphate-buffered saline (pH 7.4) and drug release was monitored using UV-vis while maintaining sink conditions. Implants were divided into six groups that explored various experimental conditions, including drying, sterilization, and different temperature profiles. Groups 1-4 were used to test in-vitro preconditioning and second round of sterilization and were placed at 37°C for 46 days. After 46 days, Group 1 was placed in an oven at 40°C for two weeks to ensure drying followed by sterilization by gamma irradiation. Group 2 also underwent a drying process but was not sterilized a second time. Group 3 did not undergo a drying process but was sterilized a second time. Group 4 served as the control, which remained in-vitro at 37 °C throughout the duration of the study. To study accelerated conditions, Group 5 was placed at 45°C throughout the study's duration, and Group 6 was placed at 45°C for 66 days before taken to 37°C for the rest of the study.
The in vitro pre-conditioning of implants resulted in similar release rates of BIC before and after exposure to a second round of sterilization. Also, no notable differences were observed in the release rates of BIC between implants under different experimental conditions for drying or sterilization. For implants exposed to accelerated conditions at 45°C, the release rate increased by 3.2-fold when compared to the control maintained at 37°C. In addition, devices switched from 45°C to 37°C demonstrated release rates similar to the control group, showing that release rates can be tuned through temperature change.
In this work, we demonstrate an advantageous method to precondition long-acting subcutaneous implants to support subsequent in vivo studies. Our results show that implants are unaffected after removal from in-vitro conditions and after a drying process and a second round of sterilization. In addition, we demonstrate a successful acceleration of in vitro drug release using a higher temperature (45°C). This approach can potentially shorten the timeframe of preclinical studies by preconditioning implantable drug delivery systems during the phase of zero-order release kinetics. Overall, this approach supports approaches to characterize LA drug delivery systems without sole reliance on long-term animal studies.

8:00 PM EN03.04.10

Rapid Synthesis of Multifunctional Hydroxyapatite Using Laser-Induced Hydrothermal Process SangminSong[1,2], Seung-HoonUm[3,1], Seung HwanKo[2], Yu-ChanKim[1] and HojeongJeon[1]; [1]Korea Institute of Science and Technology, Korea (the Republic of); [2]Seoul National University, Korea (the Republic of); [3]Université Laval, Canada

Synthetic biomaterials are used to overcome the limited quantity of human-derived biomaterials and to impart additional biofunctionality. Although numerous synthetic processes have been developed using various phases and methods, Existing synthetic processes suffer from issues such as lengthy processing time, challenges in size control, and difficulties in achieving high-concentration metal ion substitution for additional functionality. In this presentation, we will present a rapid synthesis method using a laser-induced hydrothermal process. Based on the thermal interaction between the pulsed laser beam and titanium plate, which was used as a thermal reservoir, hydroxyapatite particles ranging from nanometer to micrometer scale could be synthesized in seconds. Moreover, this laser-induced hydrothermal synthesis can enable metal ion substitution into the matrix of hydroxyapatite with a controllable concentration. We calculated the theoretical maximum temperature achieved by thermal interaction at the surface of the thermal reservoir based on the validation of three simplification assumptions. Subsequent linear regression analysis showed that laser-induced hydrothermal synthesis follows an Arrhenius chemical reaction. Synthesized hydroxyapatite and Mg^{2+}-, Sr^{2+}-, Zn^{2+}-substituted apatite powders exhibited promotion of bone cell attachment and proliferation ability due to ion release from the synthesized powders, which had a low crystallinity and relatively high solubility. This laser-induced hydrothermal synthesis is expected to be used in biomaterials, catalyst, 3D printing, and solar cell technology.

8:00 PM EN03.04.11

Paper-Based Green Laser-Induced Graphene for Disposable and Wearable Sensing Applications RodrigoF. Martins, TomasPinheiro and ElviraFortunato; FCT UNL, Portugal

Laser-induced graphene (LIG) has established itself as a very attractive material for electrode fabrication, within several applications in bioelectronics. The straightforward, high throughput graphitization of several precursor materials using this laser conversion process allows for the simultaneous synthesis and patterning of this 3D graphitic material with diverse electrode architectures, to target several biosensing applications, from biophysical to biochemical monitoring.
Recently, paper has appeared as a viable alternative to conventional petroleum-based plastic polymer precursors, such as polyimide. This is due to the possibility of photothermally converting aliphatic cellulose monomers into graphene lattices, using several cellulose substrate treatment strategies. Application of fire-retardant chemical modifications and external aromatic moieties improves the graphitization potential of cellulose, to reach LIG film with 5 $ohm.sq^{-1}$ sheet resistance and conductivities as high as 67 $S.cm^{-1}$.
With these improved conductive properties of paper-derived LIG, this precursor material can be easily employed for the fabrication of disposable biosensing units, where paper acts as both the support substrate and precursor material for conductive electrode fabrication, without the need for more intricate printing techniques. Alternatively, strategies can be employed to separate converted and unconverted phases, through transfer methods, to make this material compatible with wearable applications.
In this presentation, we report the use of cellulose as a material in the toolbox of LIG precursors, aimed at the development of both disposable and wearable biosensing applications. Paper-based electrochemical sensors using this material are presented, aiming at disposable sensor development for different analytes. Glucose and pH electrochemical sensors were fabricated, showing the compatibility of the material with several sensing strategies, such as enzymatic and non-enzymatic sensing. To translate patterned electrodes for wearable applications, a straightforward transfer method is presented, using a water-induced peel-off method. This method is capable of efficiently separating unconverted cellulose and converted LIG phases, allowing for the transfer of LIG patterns onto flexible, conformable, and elastomeric substrates with adhesive properties, for example, medical grade adhesives. Using this method, electrochemical biosensors, strain sensors for biophysical monitoring and electrodes for electrophysiological signal monitoring are presented.
In conclusion, the concepts explored herein show the applicability of LIG towards the fabrication of robust point-of-care, disposable analytical devices, but also its potential for integration in wearable sensing systems, aiming at more sustainable, accessible bioelectronic applications.

8:00 PM EN03.04.12

Fully Biodegradable Multi Functional Wireless System of Bio-Integrated Electronics based on Bioresorbable Shape Transformation Elastomer Jun HyeonLim, Won BaeHan and Suk-WonHwang; Korea University, Korea (the Republic of)

Stretchable electronic stimulators are of rapidly growing interest as unusual therapeutic platforms for treating disease states, accelerating wound healing processes and eliminating infections. Here, we present advanced materials that support operation in these systems over clinically relevant specific timeframes, ultimately biodegradable harmlessly to benign products without residues, to eliminate the need for surgical extraction. Our findings also overcome the challenge that the device wraps itself around the nerve and does not require a suture. The reason the devices based on a Shape-transformation/adhesive based robotic electronics poly(L-lactide-co-ε-caprolactone) (STAR PLCL) for shape-warping and self-adhesive effect in especially temperature condition. The shape-transformation device highlight possibilities for wireless electrical nerve stimulation system by integrating a bioresorbable inorganic component with the STAR PLCL substrate. Additionally, the result of our study findings highlights the possibility of multipurpose monitoring/sensing components in nerves/tissues/organs in body.

8:00 PM EN03.04.13

Buoys and Bacteria for Microplastic-Free Oceans DouglasX. Shattuck[1,2], CharlotteMcConville[3], VictoriaSekenski[4,2] and SamanAbbas[4,2]; [1]St Joseph School Wakefield, United States; [2]National STEM Honor Society, United States; [3]Quincy High School, United States; [4]Malden Catholic High School, United States

Microplastics are abundant and polluting our oceans. In recent years, a solution to this problem has presented itself: bacteria. Specifically, *Ideonella sakaiensis* and azotobacter work together to break down plastics over time. Some challenges in the research include keeping the bacteria to the proper 86 degrees and how to gauge when to close off the machine. It has been determined that it takes six weeks for the bacteria to break down plastics, thus our machine will run on six-week intervals. Ideonella and Azotobacter have proven to have no adverse effect on marine or human life.
Our goal is to create a buoy that will float in the ocean, collect the water, and break down the plastics. In order to keep the bacteria to the correct temperature, we plan to test the use of

insulation and heating pads. We will need to periodically change them out, as well as checking the bacteria frequently to ensure its quality. That provides another challenge: keeping the insulation from getting wet. To combat this problem, we plan to install PVC or smurf piping to lead the water directly to the filter. This filter will catch the plastics and separate them from the outgoing water. We hope to develop a system of locks and sensors that will slide into place once we determine the buoy is full. After the six-week degradation period, we will have to manually open the machine and re-release it, replacing bacteria or heating pads as necessary.
Presented here will be the conceptual design and skematics for our scale prototype.

A Self-Powered Microbial Inactivation and Nanoparticle Removal Ultrathin Gelatin Multilayer Triboelectric Nanogenerators HabtamuG. Menge and Yong TaePark; Myongji University, Korea (the Republic of)

Internet of Things technologies significantly improve the quality of life by utilizing wearable electronics. Among mechanical energy harvesting technologies, triboelectric nanogenerators (TENGs), which utilize the coupling effects of triboelectrification and electrostatic induction between two contact surfaces, have been considered a novel miniaturized mechanical energy scavenger that generates electricity. However, in most TENGs, synthetic polymers dominated triboelectric materials (TMs) fabrication. Therefore, this study fabricated ultrathin, biodegradable, and biocompatible gelatin (GE) multilayer-based TENG via an eco-friendly layer-by-layer self-assembly method. The electrostatic self-assembly of one species was realized using its dependence on the solution pH. GE is suitable owing to its film-forming abilities, abundance, pyrrolidine electron donor-rich groups, and tunable properties, significantly enhancing the TENG outputs and enabling extended layered growth. The electrical properties and device performance of self-assembled GE multilayer (ML)-TENG were identified by manipulating the pH of the GE medium from 4 to 7. At pH 5, 110 nm-thick of the 3 adsorbed cycles of GE ML-TENG exhibited the highest output power density of 15.9 W m^{-2}, owing to its highest surface potential of 208 mV. We successfully exhibited the self-powered GE ML-TENG-driven electrophoretic device for removing SiO_2 and ZnO nanoparticles in water. Furthermore, integrating GE multilayer-TENG as electric stimulation of antibacterial devices is a promising approach and exhibited a significant inhibitory effect on gram-negative Escherichia coli (E. coli) and gram-positive Staphylococcus aureus strains. We also demonstrated the harmony of the vertical axis wind turbine GE free-standing film TENG electricity. The graphene-based filtration system worked simultaneously to attain approximately 100% E. coli inhibition efficiency without an external power supply for the water disinfection system. Therefore, this eco-friendly multifunctional GE-based material can be a promising candidate for high-performance self-driven Electrical stimulation nanogenerators.

8:15 AM EN03.05.02
Exploring the Chemical Space of Bioinspired Materials for Sustainable Electronics MicaelaMatta; King's College London, United Kingdom

The field of organic semiconductors and mixed ionic-electronic conducting materials is currently dominated by polymers and small molecules that, despite their good conductivity and processability, have limited biocompatibility. The demand for implantable, edible or degradable devices for nanomedicine or low-cost consumer electronics is growing, and will require a new generation of sustainable materials.[1]

This research combines cheminformatics, quantum chemistry and molecular simulation to design novel bioinspired materials for sustainable electronics and bioelectronics. High throughput calculations are used to screen the electronic and conformational properties of a large dataset of conjugated fragments with different linkers and functional groups. Within a range of bioderived fragments, we focus on the potential of melanin-inspired conjugated fragments as components of bioinspired mixed conducting materials.[2] The oligomers resulting from the best combinations of conjugated units, linkers and side chains are presented. Molecular dynamics simulations are then used to provide information about the charge/ion percolation pathways, aggregation and order. The results of this study can help focus experimental effort towards more sustainable organic materials.

Exploring Form and Functionalization in Crystalline Nanocellulose Inks for Environmentally Sustainable Printed Electronics BrittanyN. Smith, NicolasChen, JamesL. Doherty and AaronD. Franklin; Duke University, United States

Printed flexible electronics show promise for providing a sustainable solution to the increasingly negative impact of electronics manufacturing and waste. However, current print processes and inks tend to rely on hazardous solvents, extensive post-processing at high temperatures, and/or materials that are not recyclable or biodegradable. Recent work on water-based inks from nanomaterials shows that these challenges can be overcome (i.e., no hazardous chemicals, relatively low temperature processing, and all recyclable or biodegradable materials), but the resultant devices still require improvement in performance and reproducibility. In this work, we investigated two new water-based inks for use in carbon nanotube (CNT) thin-film transistors (TFTs): nanocellulose, a biodegradable ionic dielectric, and nanoparticle gold, a recyclable conductor. We developed inks and aerosol jet printing processes for crystalline nanocellulose (CNC) and cellulose nanofibrils (CNF) with various surface groups to gain insights into the working mechanisms of nanocellulose as an ionic dielectric. Our results reveal that the general ionic nature of the printed films is invariant with the nanostructure form or surface group. However, the capacitance and sweep rate characteristics of the dielectrics, as well as the electrical and mechanical resilience, do show dependencies on nanocellulose form and functionalization. Further, we investigated the influence of the sulfonic surface group content on transistor performance, revealing that the foremost impact of increasing the sulfonation is a positive shift in the device threshold voltage. Since nanocellulose breaks down under high temperatures, the top-gate contact must be readily conductive when printed to form fully printed CNT-TFTs. Therefore, as an alternative to using graphene, a novel gold ink formulation was used as the contacts for CNT-TFTs. This new ink exhibited a resistance of ~5 Ω in its as-printed state, without any post-print sintering at high temperatures. The impressive device performance of these printed CNT-TFTs shows promise for the use of water-based inks in environmentally sustainable printing of electronics.

Laser Induced Graphene from Bio-Derived Sources for Biodegradable and Sustainable Electronics Anna ChiaraBressi[1], IuliiaSteksova[1], SreenadhT. Sankaran[1], AlexanderDallinger[2], FelixSteinwender[2], HanaHampel[2], HildaGomez Bernal[1] and FrancescoGreco[1,1,2]; [1]Sant'Anna School of Advanced Studies, Italy; [2]Graz University of Technology, Austria

Laser Induced Graphene (LIG) is a porous conductive carbon material produced by laser-induced pyrolysis of polymer precursors, with technological applications in flexible/stretchable/wearable electronics, electrochemical sensors, energy harvesting and storage, among others.[1–4]
Several bioderived polymers and raw natural materials are good LIG precursors.[5] For this reason our group is investigating LIG for sustainable approaches to green electronics and soft electronics/robotics. Here, we present some results of our studies on LIG obtained from both raw natural materials and processed bio-derived polymers. These include starch-based bioplastic, composites of polysaccharides (starch, chitosan) + hazelnut or almond shells (i.e., waste from agricultural and food industry), lignin (waste from paper pulp process). For each class of precursors specific laser scribing strategies have been tailored and the resulting LIG materials are characterized in terms of their structure, composition, morphology, and of their functional properties (e.g., conductivity, piezoresistivity, wettability), useful for the development of LIG sensors. Also, the degradation behavior of these materials in different conditions is assessed, in view of applications in biodegradable/transient electronics.

Large Area Elastomer-Based Printed Electronics PeterZalar; Holst Centre / TNO, Netherlands

Holst Centre is a leading applied research institute focusing on the development of flexible and thin electronic systems using industrially relevant fabrication methods. For nearly two decades, our primary objective has been to make technological advancements that facilitate the industrialization of printed electronics systems, thereby turning future visions into reality. With the increasing demand for integrating electronics into a wide range of form factors, it is essential to develop systems that possess key qualities such as accuracy, conformability, ruggedness, lightweight design, and sustainability. These qualities are crucial in applications spanning healthcare, automotive, and robotics, where traditional rigid printed circuit board (PCB) technology falls short. To address this challenge, we have explored the use of elastomeric carriers as a viable solution. In this presentation, I will delve into Holst Centre's contributions towards the development of sensor systems on elastomeric carriers, highlighting our efforts on an all-printed, large area, multimodal sensing surface.

Hynes, Level 2, Room 206

10:00 AM *EN03.06.01
Soft, Resorbable Bioelectronics Suk-WonHwang; Korea University, Korea (the Republic of)

An ultimate goal of a conventional silicon-based integrated system is its capability to last forever without any malfunction and physical deformation, in almost any practical uses. Recent works demonstrate a new class of electronics that has the opposite behavior -- it physically dissolves or disappears in water, environment or biofluids, in a controlled fashion, at predefined times or on demand and with programmed rates. This type of ‘transient’ technology opens up completely new application opportunities for electronic devices in areas, such as implantable medical devices that exist for medically useful timeframes but then dissolve and disappear completely by resorption into the body. This talk summarizes recent works on bioresorbable electronic systems with mechanically soft, deformable platforms, ranging from fundamental chemistry of the key materials, to development of various components and systems for biosensors, to in vivo evaluations for biocompatibility and potential applications

10:30 AM EN03.06.02
Chitosan Nanocomposite Thin Films as Sustainable Biopolymer Based Colorimetric Humidity Sensors WafaTonny[1], SamuelJ. Wallaert[1], JustinD. Smith[1], VenkateshBalan[2], MeganL. Robertson[1] and AlamgirKarim[1]; [1]University of Houston, United States; [2]University of Houston Sugarland, United States

Humidity sensors play an essential role in monitoring product quality and lifetime in the manufacturing and pharmaceutical industries for vaccine and drug viability. Recently thermoplastic polymers and inorganic semiconductors-based humidity sensors are raising environmental concerns owing to non-degradability despite their performances. Biodegradable and renewably sourced chitosan-based nanocomposite films could provide a more sustainable alternative. Chitosan has randomly distributed β-linked D-glucosamine and N-acetyl-D-glucosamine and the protonation of NH_2 groups of chitosan increases the affinity of these films towards moisture. Here, thin chitosan films of 120-350nm thickness were coated on Si substrate. Rapid swelling of the thin films in humid environment was spontaneously identified with visible changes in color explained by *thin-film interference* phenomenon. Over the full relative humidity range of 95%, film thicknesses increase 50% compared to dry state, confirmed by *in-situ* ellipsometry and interferometric techniques. The response to humidity change was ultrafast (~5s) and the absorption-desorption of moisture exceeded 50 cycles with confidence. The moisture absorption kinetics followed non- Fickian type diffusion pathway. By blending polar nanofillers like graphene oxide (GO) in a small amount (0.5-2wt%), the swelling behavior of these blend films followed similar trend of rapid moisture absorption while maintaining film stability because of the interaction of oxygen-rich groups of GO and NH_2 groups of chitosan. The nanocomposite thin films had reliable thermal properties and stable tensile strength. This highly sensitive humidity dependent colorimetric property of chitosan nanocomposite films enables its potential as a biodegradable sensor for monitoring quality assurance systems benefiting several industries.

Bio-Inspired Proline Sensors for Diagnosis and Surveillance of Plant Stress CassandraL. Martin[1], JosephineCicero[1], AudreyMoos[1] and DanielWilson[1,2]; [1]Kostas Research Institute, United States; [2]Northeastern University, United States

In response to environmental stresses such as drought, excessive salt, high temperatures, heavy metals, and pathogens, plants accumulate amino acids and other metabolites resulting from protective homeostatic processes. Specifically, the amino acid proline can counteract the effects of osmotic stress, chelate metals, and act as an antioxidant, resulting in increased concentrations of proline within plant tissue in response to environmental stimuli. While proline can serve as a general diagnostic indicator of plant or crop health, there are limited field-deployable options for measuring the proline content of plant tissue on-location without requirements for secondary equipment. We have developed bio-inspired proline sensors based on the coloration mechanism of *Nesocodon mauritianus*. The color of the nectar in this flowering plant, ranging from pale yellow to blood red, is directly dependent on both internal pH and proline concentration. By leveraging the chemistry of this natural system, we have developed colorimetric, paper-based proline sensors that provide quantifiable visible signals in response to increasing proline concentrations. We are integrating these sensors into biodegradable, user-friendly form factors that enable a plant-based, eco-friendly approach to monitoring plant health.

11:00 AM EN03.06.04
Wireless Continuous Glucose Monitoring for Smart Home Diagnosis via Biodegradable Fluorescent Microneedle Sensor MingyuSang, MyeongkiCho, SelinLim, In SikMin and Ki JunYu; Yonsei University, Korea (the Republic of)

According to the International Diabetes Federation, the number of patients with diabetes worldwide is 536.6 million, i.e., 10.5% of the total population. In particular, hypoglycemia is a serious condition that can cause behavioral and cognitive impairment, seizures, loss of consciousness, coma, brain damage, or death. In addition to the severity of diabetes itself, this condition can also cause serious medical complications in other organs, such as the kidneys, liver, and heart. Diabetes requires constant management to avoid unfortunate consequences, such as death. Therefore, precise monitoring of the blood-glucose level in the body, which is an important indicator for managing type 1 and type 2 diabetes, is necessary. Continuous glucose monitoring (CGM) is crucial for tracking blood-glucose levels in real-time, providing critical information to effectively prevent diabetic complications arising from hypo- or hyperglycemic episodes. While invasive lancet measurement is not compatible with CGM, commercial and research efforts have been directed toward developing biosensors for CGM. However, the current CGM sensors has discomfort from the attached transmitter on skin and require implantation and removal surgery, which increases the possibility of wounding and bacterial infection, presenting critical barriers for use. Despite the considerable progress made by commercial CGMs, there remains a pressing need to develop user-friendly, minimally invasive CGMs. Therefore, a new class of CGM biosensors is needed for monitoring skin interstitial fluid glucose, like commercial CGMs, in a user-friendly, minimally invasive way that overcomes the limitations of existing systems. Here, we introduce the CGM system consisting of biodegradable microneedle sensor array with high fluorescence sensitivity to glucose and portable smart device with image processing applications. This system produced straightforward yet robust outcomes by measuring the fluorescence intensity of microneedles, which was reversibly modulated based on glucose concentration, without the need for enzymes or reagents. Through this sophisticated integration, our system could continuously measure glucose levels without blood colleting, wound or pain over up to 3 days, clearly tracing the results of commercially available blood glucose meters like lancet diagnostic method. Users such as diabetics can easily and wirelessly check the glucose concentration with this on-demand tether free glucose monitoring system by simply taking the picture with the smartphone, thus allowing measurement at any desired time while the patient moved freely. The fluorescence intensity of the microneedle sensor, which changes according to the glucose concentration, can be successfully obtained through the mobile device equipped with software for analyzing pixel data of the fluorescence image. Compared to previous CGM studies, our system has the advantage that the sensors are ultra-thin and light, minimally invasive, very simple to use, and completely biodegraded and discharged from the body without the insertion and removal surgery. Unlike other sensors, the biodegradable microneedle eliminates the risk of the sensor broking or remaining in the body, enhancing human safety. This feature notable reduces the risk of infection and further enhances patient comfort and compliance, making our system a more prospective solution for CGM. Furthermore, the microneedle sensor-based home glucose diagnostic platform not only serves as another promising candidate for patients to help prescription and treatment, but also provides potential possibilities for improve health and quality of life. This new platform offers opportunities to autonomous and accurate CGM, a powerful and promising tool in the management of diabetes, using the glucose-responsive fluorescent microneedle sensor and user-friendly home diagnosis mobile service technology.

Materials for Environmentally Resorbable Batteries, Microelectromechanical Systems and Chemical Sensors JohnA. Rogers; Northwestern University, United States

Recently developed classes of functional materials serve as the basis for microsystems technologies that dissolve, disintegrate, degrade or otherwise physically disappear at triggered times or with controlled rates. Water-soluble technologies of this type are of interest for zero-impact environmental monitors, 'green' consumer electronic gadgetry and resorbable medical implants. This talk describes the foundational concepts in materials science, electrical engineering and assembly processes for various applications. The emphasis is on environmentally resorbable batteries, microelectromechanical systems and chemical sensors, the latter of which adopt 3D designs inspired wind-dispersed seeds to facilitate deployment.

SESSION EN03.07: Degradable Energy Devices
Session Chairs: Jahyun Koo and Lan Yin

1:45 PM EN03.07.01
Everyday Materials for Transient Supercapacitors Mete BatuhanDurukan, DenizKeskin, MelihO. Cicek, YigithanTufan, OrcunDincer, SimgeCinar Aygun, BaturErcan and HusnuE. Unalan; Middle East Technical University, Turkey

Due to the substantial advancements achieved in wearable technology, including consumer electronics and medical monitoring devices, there has been a sharp rise in electronic waste during the past ten years. As electronic devices contain hazardous materials and have limited recyclability, the environmental threat is steadily increasing and the volume of e-waste grows exponentially each year. A significant portion of electronic waste comprises energy storage devices that consist of materials that are toxic or non-recyclable. Therefore, research and development in green energy storage systems that are made of non-hazardous materials is highly needed. Transient electronics, which are intended to disintegrate at the end of their use or when required, have emerged as a solution to this need, producing nearly little waste.

Green and transient electronics require transient energy storage units. Being biodegradable, biocompatible, and non-toxic are essential properties that energy units must possess in line with the requirements of transient electronics. This is especially important for on-demand electronics, which are mostly used for health monitoring devices such as ingestible or implantable devices.

Herein, we propose transient and even edible supercapacitors with everyday materials – such as supplements and foods [1,2]. We successfully fabricated transient supercapacitors based on all-PVA layers and successfully achieved a perfectly working EDLC type supercapacitors with an excellent rate capability up to 1 $V.s^{-1}$. The entire structure is based on biodegradable and biocompatible products and showed excellent physical transiency in simple aqueous solutions. To further this quest, we also successfully fabricated cellulose-based edible supercapacitors utilizing soy-sauce based, zwitterionic gel as an electrolyte. Fabricated food-based gel has shown to enhance the L929 proliferation – which is an excellent indication of biocompatibility – and allowed a textbook-like capacitive behavior due to its excellent ionic conductivity. Simulated gastric fluid tests shown a complete dissolving of the edible supercapacitors, indicating its digestibility. These studies indicate excellent developments in the production of transient and edible supercapacitors, being fresh prospects to be the energy units for environmentally friendly and biocompatible transient electronics.

2:00 PM *EN03.07.03
Design of Degradable Rechargeable Batteries MarkusNiederberger; ETH Zurich, Switzerland

Transient or degradable electronics based on materials, devices and systems that disappear after a stable operating period with minimal or undetectable residues can help reduce the enormous amounts of electronic waste [1]. Ideally, the battery is integrated into these devices and degrades along with them. However, conventional batteries are optimized for long-term operation and contain a whole range of hazardous and/or expensive components. Therefore, transient batteries must be designed so that they can be disposed of without negatively impacting the environment. For efficient degradation, it is also important that the components and materials can decompose in an aqueous environment. However, some of the most important electrically conductive materials, e.g., copper and aluminum, which play a major role in batteries, do not fall into this category. For such materials, special concepts have to be developed on how they can be decomposed.
In this presentation, a wide range of materials, fabrication methods, and assembly techniques will be presented to develop transient lithium-ion, sodium-ion, and zinc-ion batteries. Special emphasis will be placed on the development and characterization of separator-electrolyte systems based on biodegradable polymers. These separator-electrolyte systems were combined with a Li metal anode and a vanadium oxide cathode and packaged in a biodegradable case, resulting in a transient rechargeable lithium-ion battery (LIB) that can operate for over 400 cycles, but quickly dissolved in water within 15 minutes [2]. In order to be able to degrade copper and aluminum as well, a packaging concept was developed based on a water-soluble polymer composite film containing an oxidizing agent. When triggered with water, the film released the oxidant into the solution, which reacted with the copper and aluminum current collectors and led to their degradation [3]. For sodium-ion batteries biodegradable separators composed of agarose and nanocellulose were applied and tested in half-cell configurations with $Na_3V_2(PO_4)_3$ and $Na_2Fe_2(SO_4)_3$ as cathode materials [4]. Both separators showed promising electrochemical performances with high specific capacities and good cyclability, opening new avenues for the use of these renewable resources for sustainable energy storage devices beyond lithium-ion batteries. Finally, a carefully tailored bottom-up design of a transient zinc ion battery will be introduced that combined both excellent transience properties with outstanding electrochemical performance [5]. The battery consisted of a biopolymeric hydrogel electrolyte based on environmentally friendly polysaccharides, a Zn anode, and a biocompatible polydopamine-based cathode. A polysaccharide-based packaging made it possible to control the degradation of the battery, which is essential to maintain its functionality for as long as desired. This carefully tuned battery design displayed an open circuit voltage of 1.12 V and a specific capacity of 157 mAh g^{-1} (current density of 50 mA g^{-1}) for over 200 cycles. The battery exhibited a pronounced transiency under composting conditions, evidenced by a weight loss of 50 wt.% after 63 days.

3:00 PM *EN03.08.01
Implantable Bioelectronics for Probing Brain Chemistry YiZhang; University of Connecticut, United States

The human central nervous system contains billions of neurons that communicate through the propagation of action potentials along the cell membrane and the release, transport, and metabolism of neurochemicals at the synapses. Technologies for *in vivo* electrophysiology have been intensively studied, with recent examples of Neuropixels 2.0 and Neural Matrix for recording over several thousand channels. Compared with these tools for electrophysiological recordings, the technologies for real-time neurochemical monitoring are very limited. In this presentation, I will present our recent developments on implantable bioelectronics for probing brain chemistry, including **1**) a soft implantable aptamer-graphene microtransistor probe for real-time monitoring of neurochemical release with nearly cellular-scale spatial resolution, high selectivity (dopamine sensor >19-fold over norepinephrine), and picomolar sensitivity,

simultaneously **(***Nano Lett.* 2022, 22, 9, 3668–3677), **2**) a soft neural probe for multiplexed neurochemical monitoring via the electrografting-assisted site-selective functionalization of aptamers on graphene field-effect transistors (*Analytical Chemistry* 2022, 94 (24), 8605-8617), and **3**) a wireless, programmable push-pull microsystem for membrane-free neurochemical sampling with cellular spatial resolution in freely moving animals (*Science Advances* 2022 8 (8), eabn2277). These new sets of implantable bioelectronics create opportunities for neuroscientists to understand where, when, and how the release of neurochemicals modulates diverse behavioral outputs of the brain.

3:30 PM *EN03.08.03
The Next Biodegradable Electronics for Minimally Invasive Implantation for Brain Cortex Seung-KyunKang; Seoul National University, Korea (the Republic of)

Biodegradable electronic devices are gaining prominence as minimally invasive tools that mitigate issues such as biofilm formation due to residual foreign-body materials and infections and hemorrhage arising from secondary removal surgeries. Over the past few years, various implantable medical devices using biodegradable organic and inorganic hybrid materials have demonstrated the feasibility of biodegradable electronics. Notably, these include sensors for monitoring raised intracranial pressure due to traumatic brain injuries with a latency period, and wireless electrical stimulators to promote peripheral nerve regeneration. Systems that use electrical stimulation to control drug delivery can also serve as short-term post-operative drug treatment technologies. However, a limitation of existing biodegradable electronic devices is the need for an implantation process, which unavoidably involves surgical burden. In this presentation, we introduce representative examples of implantable biodegradable electronic devices noted in above. Furthermore, we explore the concept of injectable electronic devices as a means to minimize invasiveness during the implantation process, examining this through the application of large-area signal measurement in the cerebral cortex.

4:00 PM EN03.08.02
Bio-implantation Strategy for the Bio-Interfaces with Minimally Invasive Surgery Based on the Mechanical Analysis Gyeong-SeokHwang[1], Jae-YoungBae[2], Seung-KyunKang[2] and Ju-YoungKim[1]; [1]UNIST (Ulsan National Institute of Science and Technology), Korea (the Republic of); [2]Seoul National University, Korea (the Republic of)

Among the deformable electronic devices, there are bio-implantable electronics that consist of biocompatible materials and withstand biological motions with deformability. It can operate in the body with biocompatible materials for all components, and it is considered to be a key technology for the future. The general bio-implantable electronics use biocompatible materials, but it needs extra removal surgery after the functional period. If all components of bio-implantable electronics are substituted with biocompatible and bioresorbable materials, it does not have to conduct extra removal surgery and it can be naturally resolved with the body fluid after the functional period. It means that the patient becomes free from the anesthesia and secondary infection through the extra surgery. The minimally invasive surgery concept is also actively researched in the bio-medical field. It pursues the minimization of a wound during surgery or the implantation process. It is possible to incise the minimum area to minimize the recovery time of the wound and greatly reduce the probability of infection and scarring even if surgery is performed when it uses this concept.
In this research, we intend to fabricate a biocompatible and bioresorbable electronic device that can resolve after the functional period, and it can highly expand into a large area when injected into the body. The bioresorbable shape memory polymers are a strong candidate for the shape expansion behavior near the body temperature. In addition, the electronic device must be spread through the narrow gap between the tissue and the skull to place the electronic device on the tissue. Therefore, during the process of suction and injection into the tube, the analysis of the mechanical properties of the entire electronic device and the optimization of the deformation mode and mechanism depending on the device structure are intended to be achieved at the same time. The deformation behavior was analyzed based on the accurately measured mechanical properties of all constituent materials to realize this concept. The suction & injection process was simulated through 3D finite element simulation based on the measured mechanical properties, and a general design rule for the structural design of mechanically reliable, bioresorbable, shape expandable, minimally invasive implantable electronics can be presented. As a result, it is expected that this concept can open a novel paradigm of bio-implantable electronics.

SESSION EN03.09: Poster Session II: Sustainable Materials I
Session Chairs: Shweta Agarwala and Jahyun Koo
Tuesday Afternoon, November28, 2023
Hynes, Level 1, Hall A

8:00 PM EN03.09.01
Reinforcement of Physical Properties of Biodegradable Cellulose Composites for Landfill using Cellulose-Based Resins MikyungKim[1], JiyoonWoo[1], JeonghyunYeum[2], JungeonLee[2], SejinLee[3], ChanghoonHan[3], JinsooKim[4], SeokhyeonSong[4] and HyaemiSon[4]; [1]DYETEC Institute, Korea (the Republic of); [2]Kyungpook National University, Korea (the Republic of); [3]Korea Conformity Laboratories, Korea (the Republic of); [4]Green Package Solution, Korea (the Republic of)

The general garbage bags are made of polyethylene(PE) or polypropylene(PP), and most of the garbage bags are landfilled in the ground and incinerated. Landfill garbage bags manufactured using petroleum-based resins such as PE and PP take more than 500 years to decompose naturally in the ground. In addition, when PP, PE bags are incinerated, dioxins and volatile organic compounds, which are first-class carcinogens, are generated, which poses a threat to human health.
Garbage bags using resins such as PLA(Poly lactic acid), PBS(Polybutylene succinate) and PBAT(Polybutylene adipate terephthalate), which are biodegradable polymers, are decomposed only under composting conditions(58°C, within 6months), and are difficult to decompose when buried in the ground at room temperature, so they are incinerated like general garbage bags made of PP or PE. Therefore, even if biodegradable plastic materials such as PLA and PBS are selected, it will not be the ultimate eco-friendly product.
In order to replace garbage bags made of PP or PE, which cause environmental pollution, cellulose material, which is abundant on earth and can be biodegraded in soil, was used as a biodegradable garbage bag material for landfill. However, the film materials using cellulose resin have problems such as lack of elasticity and low tear strength.
As a study to improve the physical properties of these cellulose films, the physical properties of cellulose-CNF composites, which were compounded by adding CNF(Cellulose nanofibers), were investigated. In addition, the physical properties such as elasticity, flexibility, and biodegradability were investigated for cellulose composite films compounded with bio-organic compound additives such as eco-friendly plasticizers and starches, and the possibility of using these cellulose composite films as materials for resource circulation garbage bags was examined.

8:00 PM EN03.09.02
Enhanced Mechanical Properties of Biodegradable Polybutylene Adipate-Co-Terephthalate Blended with Cellulose Nanofiber Modified with Silica Nanoparticles JoheunYoon and YoungsooSeo; University of Sejong, Korea (the Republic of)

Polyethylene (PE) mulching films are widely used in crop fields. However, residual PE films have been accumulated in the soil reducing crop yield. It has been tried that PE films are replaced by biodegradable polymers such as Polybutylene adipate-co-terephthalate (PBAT). In order to increase the use of PBAT mulching films, problems such as its low mechanical properties, short degradation period and low UV resistance still need to be addressed. In this study, through a sol-gel reaction, silica nanoparticles were synthesized on the surface of the cellulose nanofiber (CNF) to have a bumpy surface. The surface-modified CNF (s-CNF) could be obtained in powder form after drying because aggregation due to capillary force between the fibers is suppressed. s-CNF was well-dispersed in PBAT or PBAT/PLA blends using a melt-mixer. The mechanical properties of the composite films were improved, for example, tensile strength at break was enhanced by 35% with 3wt% s-CNF addition. The mechanical property was systematically studied in terms of s-CNF and PLA contents. Controlling silica particle content and morphology will be presented. The degradation rate and UV resistance of the composite films may also be presented.

8:00 PM EN03.09.03
Mechanical, Thermal and Rheological Characteristics of Ternary Blended System, Poly(lactic acid)/Poly(hydroxyalkanoates)/Poly(butylene adipate-co-terephthalate) (PLA/PHA/PBAT) via the Morphological Influence Min YeongJeong[1], Jin HeeNoh[2], KibeomNam[1], HyojinKim[2] and Dong YunLee[1]; [1]Kyungpook National University, Korea (the Republic of); [2]Advanced Materials & Components Center, Korea (the Republic of)

This study explores the potential of biodegradable polymer blends as environmentally friendly alternatives to conventional plastics. Single biodegradable polymers have limitations in fully replacing traditional polymer materials. To overcome these limitations, blending different polymers or using compatibilizers has been investigated. However, compatibility issues arise due to the high molecular weight and surface energy differences between materials. In this study, we aim to enhance compatibility by controlling the composites and investigating the effects of polymer surface energy in ternary blends of Poly(lactic acid) (PLA)/Poly(hydroxyalkanoates) (PHA)/Poly(butylene adipate-co-terephthalate) (PBAT). Our analysis includes the examination of morphology, mechanical properties, rheological characteristics, and a particular focus on the effects of PHA at the blend's interface. The results reveal that PHA acts as a compatibilizer, transforming the blend structure from a sea-island morphology to a co-continuous structure, with PHA encapsulating PBAT. This not only enhances impact strength but also achieves the highest tensile strength and elongation at break by optimizing the PHA content. The aggregation and reinforcement effects of PHA in the PLA/PBAT blend contribute to these improvements. The morphological prediction of the blend is conducted using diffusion coefficients, and the influence of PHA on interfacial properties is confirmed through scanning electron microscopy (SEM). The co-continuous interface achieved by encapsulating PBAT with PHA contributes to a consistent and stable structure. Rheological properties are evaluated using a rheometer,

revealing a decrease and subsequent increase in complex viscosity with increasing PHA content. This behavior can be attributed to the formation of complex fluidity during the heating process, followed by the formation of a new structure. Moreover, for immiscible blends, the influence of the interface becomes more significant, resulting in a larger increase in storage modulus. However, as PHA content increases, the rate of increase in storage modulus decreases. Overall, these findings highlight the role of PHA as a compatibilizer in PLA/PBAT blends. Furthermore, by increasing the content of biomass-based PHA instead of petroleum-based PBAT, this study suggests the possibility of sustainable plastics for eco-friendly packaging materials.

8:00 PM EN03.09.04

Identification and Characterization of Digestive Enzymes and Intestinal Microorganisms that Degrade Polystyrene in *Tenebrio Molitor* LarvaeHwicheolShin[1] and Dong-KuKang[1,2,3]; [1]Incheon National University, Korea (the Republic of); [2]Research Institute of Basic Sciences, Korea (the Republic of); [3]Bioplastic Research Center, Korea (the Republic of)

Plastic has been produced since 1950s and it has been also widely used successfully as a fundamental material. However, it is now considered as a major reason of environmental hazard because its non-biodegradable property. More specifically, non-biodegradable plastic (NBP) mean a high-molecular-carbon-polymers that does not break down in a natural condition by biological processes. In recent decades, various research groups have been conducted to develop a solution for the biodegradation of non-biodegradable plastics such PE, PP, PS, PET and PVC. Recent research indicated that mixed-microbial can be used for digestion of NBPs. Bacterial strains have been isolated from environment or living-organisms and their ability of biodegradation was confirmed that convert into low-molecular-weight organics or mineralize to CO_2. In this study, up-regulated enzymes were identified when insects were feed with NBPs instead bran. Microorganisms were also isolated from various insects and characterized that could biodegrade NBPs. To isolate NBP-digesting microorganisms, the larvae of *Galleria mellonella, Tenebrio molitor Linnaeus, Plodia interpunctella* and *Sitotroqa cerealella* were collected from environment and NBPs (polyethylene (PE), polystyrene (PS), and polypropylene (PP)) were produced instead bran. It is identified that *T. molitor* larvae had a potential for consuming PS comparing other insects. In order to identify the intestinal digestive enzymes and intestinal microorganisms of *T. molitor* involved in PS biodegradation, we divided them into 5 groups according to the diet. The survival rate was higher in the group of 'PS fed only' comparing with 'starvation'. This indicated that larvae have an ability that can convert energy source from digestion of PS. Intestinal microorganisms were excluded by feeding antibiotics to confirm the PS digestion ability only by digestive enzyme. Frass were characterized with various analytical approaches (such as GPC, FTIR, NMR and TGA) and result indicated that there were no significant differences in PS degradation ability between the presence or absence of intestinal microorganisms. To identify the digestion enzymes of PS with or without treatment of antibiotics, total mRNA was isolated from intestine and sequenced. Lipase3, Phospholipase A11, and Peroxiredoxin-6 were up-regulated that is known as relating fatty acid-digestion. In addition, Calcium uniporter protein mitochondrial, Sulfate permease chloroplast and Sialin were also up-regulated that regulate cell bioenergetics. These results indicate that intestinal enzymes are related in the process of PS digestion process and cellular-energetics. Furthermore, metagenome analysis of the intestinal microflora was performed at 5-day intervals to confirm the change in the microbials community of *T. molitor* according to PS feeding. It is confirmed that increasing and decreasing-bacterial strains over time and intestine was isolated to identify digesting-microorganisms. Isolated intestine was crushed and cultured in various medium condition including LB, NB, BHI, TSB and GPY. Isolated microorganisms were cultured in an inorganic medium with PS (as an only carbon source). As a result, 6 types of bacterial strains were successfully identified: *Bacillus* sp., *Bacillus mycoides, Bacillus cereus, Enterobacter xiangfangensis, Enterobacter cancerogenus* and *Enterococcus gallinarum.* Our result indicates intestinal bacteria and enzymes are relating in the process of digestion of PS and cellular-energetics.

Bioinspired Coordination Polymer Framework Adsorbents for Desalination KelvinAdrah, SheebaDawood and HemaliRathnayake; University of North Carolina Greensboro, United States

As per the United Nations, by 2025, an estimated 4 billion individuals will lack access to potable water, primarily due to the surge in population and industrial activities, resulting in increased water pollution. Traditional water treatment methods like ion exchange and reverse osmosis are time-consuming, generate substantial waste, and are financially demanding. Currently, adsorption technology has been implemented in water purification systems for contaminant removal owing to its cost-effectiveness and efficacy. However, it is hampered by its limited adsorption capacity, lack of environmental sustainability, and versatility.
This project aims to overcome these technical constraints by developing a biomass-derived adsorbent capable of efficiently eliminating contaminants from water. The adsorbent consists of hierarchical microstructures with a robust metal-organic framework, synthesized by combining naturally occurring tannic acid with iron (II) acetate in an aqueous medium. The synthesis process adheres to green chemistry principles, rendering it an energy-efficient and adaptable approach. Comprehensive characterization techniques were employed to investigate the chemical composition, morphology, physicochemical properties, and colloidal stability of the microstructures.
The results reveal the successful extraction of prevalent minerals (Na^+, K^+, Mg^{2+}, and Ca^{2+}) from seawater samples procured from Kiawah Island, SC, and Hatteras Beach, NC, employing a single-cycle adsorption procedure. The adsorption performance was analyzed under varying contact times and adsorbent dose-to-seawater volume ratios. Additionally, these adsorbents demonstrated antimicrobial properties by effectively destroying microorganisms present in the seawater samples.
The proficient adsorption of these dissolved minerals onto the microstructures can be attributed to the highly branched and hydroxyl-dense polytopic tannic acid ligand, which provides numerous bonding sites via diverse chemical interactions. These extensively porous, amphoteric polyphenol-based coordination polymers are economically viable and readily scalable for pilot or industrial applications. Consequently, they exhibit substantial potential for employment in tertiary water treatment for remediation purposes.

Nature-Inspired Biogenic Structural Insulation Material for Carbon-Neutral Building Solutions LongZhu, ArpitaSarkar and ShenqiangRen; University of Maryland, United States

Building materials play a crucial role in providing a robust barrier that effectively shields climate-controlled interiors from the harsh external environment. The extensive adoption of building materials capable of carbon sequestration holds immense potential as a global carbon storage solution. In this context, renewable biogenic materials derived from abundant agricultural waste have garnered significant attention. It has become imperative to address their previously limited thermal and structural performance, not only to enhance energy efficiency but also to mitigate the carbon emissions associated with the construction industry, encompassing both production and operation. Inspired by nature, we introduce an innovative approach to additive manufacturing of biogenic structural insulation materials. This cutting-edge technique enables the simultaneous customization of thermal insulation and mechanical properties. The resulting functional-gradient hybrid materials are composed of cellulose extracted from straw and silica aerogel networks. These materials exhibit a low thermal conductivity of 28.2 mW m^{-1} K^{-1} and an impressive flexural modulus of 990 MPa. Moreover, they showcase exceptional fire resistance and superhydrophobic properties. Furthermore, a life cycle analysis underscores the carbon neutrality of these biogenic hybrid materials, with a footprint of -0.26203 kgCO2eq/kg. This highlights their pivotal role in advancing the development of energy-efficient, carbon-sequestering green buildings.

Improving the Weatherability and Intumescent Effects of Naturally Sourced Wood Flame Retardant Coatings. MaryK. Ruxsarash[1], DouglasFox[1] and WhirangCho[2]; [1]American University, United States; [2]National Institute of Standards and Technology, United States

Approximately 1 billion acres or half of all the United States is considered wildland. As wildland-urban-interface (WUI) development expands, millions of homes are at risk of ignition and destruction. As a result, these communities must adapt by acquiring fire-resistant materials and protectants for their homes. However, commercially available wood flame retardant coatings (WFRC) are perceived to present harm to both human health and the environment. In addition, commercial fire-resistant paints often leach into the environment, losing their efficacy shortly after application in external applications. To properly address this, it is imperative to explore WFRC which use natural products as feedstocks. Chitosan is an abundant, biodegradable, and nontoxic binding agent that can be easily incorporated as a primary component in water-based WFRC. Prior studies in our laboratory have shown that using reduced valence phosphorus-containing acids in chitosan WFRC can significantly delay or prevent ignition of wood under a 50 kW/m2 heat flux. However, Chitosan's solubility in water threatens the overall weatherability of the coating. Photo crosslinking agents were utilized to allow for on-site application in vulnerable WUI areas. After exposure to sunlight, no chitosan dissolved in artificial acidic rainwater, and coated wood substrates self-extinguished immediately after flame impingement was removed. These findings offer a valuable glimpse into which methods and additives may contribute to an overall optimized, weatherable, and flame-retardant Wood Flame Retardant Coating.

8:00 PM EN03.09.08

Higher Strength and Carbon Sequestration in Cement and Cementitious Material using Biomimetic Zinc Complex RebeccaJ. Gilchrist, AllisonL. Morin, SaraHeidarnezhad, ShuaiWang, NimaRahbar, SuzanneF. Scarlata and RonaldL. Grimm; Worcester Polytechnic Institute, United States

The cement industry is a prominent contributor to anthropogenic greenhouse gases and is responsible for about 8% of global emissions, which drives research into cement alternatives. We have previously incorporated carbonic anhydrase into concrete to create an enzymatic, self-healing, cementitious material (ECM) for carbon sequestration. While this material demonstrates high strength and self-healing properties, it is limited by the short lifespan (i.e. ~2 weeks) of carbonic anhydrase and nonspecific limestone incorporation. It motivates our exploration of non-biological alternatives such as zinc cyclen (cyclen = 1,4,7,10-tetraazacyclododecane). With a ~3300 M^{-1} s^{-1} rate constant, zinc cyclen is among the most efficient molecular carbonic anhydrase mimics and demonstrates extreme stability at cement-relevant temperatures and alkaline pH values.

Recently, we utilized zinc cyclen to produce calcium carbonate as an aqueous solute and covalently tethered to sand surfaces. In recent results, we found when tethered to the sand aggregate, the covalent attachment affords high strength and healing properties by catalytically producing calcium carbonate at the sand-cement interface while providing a flexible organic connector to accommodate interfacial atomic mismatches. This catalytic sand should enable future inexpensive, robust, green construction materials with long lifetimes and self-healing properties that can withstand extreme environments.

8:00 PM EN03.09.09
Self-Organized Hydroxyapatite Construct for Biomedical Applications: From Pack Cementation to Structure and Mechanical Characterization. ObinnaA. Osuchukwu[1,2], AbduSalihi[1], IbrahimAbdullahi[1], PreciousO. Etinosa[3] and DavidO. Olubiyi[2]; [1]Bayero University, Nigeria; [2]Ahmadu Bello University, Nigeria; [3]Worcester Polytechnic Institute, United States

This work presents the bioprocessing and robust characterization of the physical and mechanical properties of hydroxyapatite (HA) synthesized from two bio-precursors: bovine and catfish bones. The precursors are deproteinized by carbonization and calcination, then sintered using conventional heat treatment to form HA microparticles. Pulverization and the sol-gel process are performed to achieve homogeneity of well-packed cementitious powder constructs of controlled percentage weight compositions of HA from each precursor. The structural and compositional qualities, fracture mechanics, and mechanical properties of the synthesized powder and cementitious construct are assessed via X-ray diffraction, Fourier transform infrared spectroscopy, scanning electron microscopy, and mechanical testing. The specimen composed of an equal percentage weight of HA from bovine and catfish (B50/C50) exhibited the highest fracture toughness and highest compressive strength. The highest hardness and brittleness index values are measured in the B25/C75 specimen. Under dynamic loading, the B100/C0 specimen exhibited the highest resistance to wear. The X-ray diffraction patterns revealed that the B75/C25 specimen has the highest fraction of crystallinity. The implications of these findings are discussed for the potential biomedical applications of HA in dentistry and orthopedic medicine.

SESSION EN03.10: Green Electronics

Toward Metal-Free and Biodegradable Circuits on POMaC VladimirA. Pozdin[1], MauroVictorio[1], OscarGonzalez[1], BrendanTurner[2], KirstieQueener[2] and MichaelDaniele[2]; [1]Florida International University, United States; [2]North Carolina State University, United States

Exponential growth of distributed sensing and proliferation of electronic devices has raised the alarm on long-term impact of spent sensors on the environment. The utility of point-of-care and portable sensors has great potential to improve our health, environment and infrastructure; however, the limited sensor life (often days) requires careful consideration of life cycle in the device design. In our work, we focus on developing biodegradable electronics without precious or rare-earth metals for transient sensing applications. Removing silicon and metals from electronic devices requires a complete design shift in organic electronics, starting from the bottom up. Poly(octamethylene maleate (anhydride) citrate) is utilized in our work as a highly tunable and degradable substrate for electronic circuits. Toward the development of sensors, we demonstrate organic light emitting diodes with biodegradable packaging, which enables ambient operation and programmable degradation. Toward development of portable energy storage, we demonstrate diodes and transistors without metal or silicon-based functionalization using carbon conductors, amine chemistry, and ultra-thin films. In this work, we establish process requirements and limitations for biodegradable circuits to guide the development of biodegradable sensor node for mass deployment with minimal impact.

8:45 AM EN03.10.02
Functional Paper for Self-Powered Sustainable Digitalization RodrigoF. Martins[1], GuilhermeFerreira[1], SumitaGoswami[2], ElviraFortunato[1] and SumanA. Nandy[1]; [1]FCT UNL, Portugal; [2]AlmaScience Colab, Portugal

2020, world is taken aback by a pandemic. It is turning into an unprecedented crisis in people’s lives and economy. But it warns us too, to be careful and prepare for the future. We can live better now, but we must think best for tomorrow. Today, another threatening part is increasing global emissions significantly, the majority caused by energy production that is consumed in industry, services, households, and transport. The worldwide concern over energy security and environmental issues due to fossil fuel consumption has generated the urgent need of sustainable and renewable energy sources. Therefore, alternative energy actions can support the goals of green world with economic stimulus programs. The majority of renewable energy sources are based on solar, wind, hydroelectric, geothermal or biomass. But most of them needs a huge plant. Though, in this faster digitalization era, most of the technologies are portable that connected with IoTs which requires a flexible energy resource that will provide power uninterrupted. Still today, the battery is a prime option. But super flexibility and biocompatibility is still a limitation for it. Moreover, the native drawbacks of conventional systems are recharging, periodical maintenance and replacement that causes environmental pollution. Therefore, self-powered technology which can work independently without any other external energy supplier, will be a great choice.

Therefore, the biggest challenge in smart technology is sustainable power sources, that can back up the electronics unconditionally. This situation considers a new platform of self-powered technology, operating without any external power sources! In this context, the principal vision of us is to speed up the concept of self-powered technology based on different wearable and low-cost platform, by constructing in such a way, that will buckle wearables platform with electronics to bring a new smart technology which will have inbuilt self-powered system.

All-Carbon Nanomaterial Inks for Print-In-Place, Recyclable and Water-Based Electronics AaronD. Franklin; Duke University, United States

For decades we’ve been hearing about the promise of printing electronics directly onto any surface. However, despite significant progress in the development of inks and printing processes, reports on fully, direct-write printed electronics continue to rely on excessive thermal treatments and/or fabrication processes that are external from the printer. In this talk, recent progress towards print-in-place electronics will be discussed; print-in-place involves loading a substrate into a printer, printing all needed layers, then removing the substrate with electronic devices immediately ready to test [1]. A key component of these print-in-place transistors is the use of inks from various nanomaterials, including: 2D graphene and hexagonal boron nitride, and 1D carbon nanotubes. Using an aerosol jet printer, these mixed-dimensional inks are printed into functional 1D-2D thin-film transistors (TFTs) without ever removing the substrate from the printer and using a maximum process temperature of 80 C with most processing occurring at room temperature [2]. Using a similar print-in-place process, completely recyclable printed transistors will be discussed, fabricated entirely using nanoscale carbon-based inks [3]. These recyclable devices exploit a printed crystalline nanocellulose (CNC) ionic dielectric. Finally, the same set of carbon-based inks will be demonstrated for use in all-aqueous (completely water-based) printed CNT-TFTs, eliminating dependence on processing with hazardous chemicals [4]. These demonstrations give evidence for an electronic future involving devices with fabrication and/or function that goes beyond what is possible with traditional semiconductor technologies [5]. The increasingly prolific distribution of sensing devices will best be served by using more environmentally friendly materials and fabrication processes, which this work provides a vision for achieving.

Commercial Organic Dyes and Pigments as Semiconductor Photocatalysts EricD. Glowacki; Brno University of Technology, Czechia

Semiconductor-based catalysts can convert solar energy into chemical fuels such as hydrogen, hydrogen peroxide, or hydrocarbons produced via carbon dioxide reduction. Long overlooked due to stability concerns, some organic semiconductors have recently emerged as promising electrocatalysts and photocatalysts for operation in aqueous environments. Our attention has focused on dyes and pigments of commercial origin, everyday materials used on a large scale with an established safety profile. Many of these light-absorbing molecules have indeed been selected due to their outstanding stability, which is a feature that translates to useful applications in the field of aqueous photocatalysis. We have found a high selectivity of organic semiconductors for oxygen reduction reactions, by both one-electron and two-electron pathways. The products of these reactions are superoxide or hydrogen peroxide. We find this occurs on numerous organic semiconductors and conducting polymers in a pH range from 1 to 12. We have found that while photogenerated electrons reduce oxygen, the fate of the holes represents a complex picture. When the semiconductor is used as a photocathode and efficient p-type transport is available, photogenerated holes can easily be extracted and stability is very high. This talk will discuss the promises, potential applications, as well as obstacles facing the use of low-cost commercial photocatalytic organic dyes and pigments.

10:30 AM EN03.11.02
Specie-Dependent Electrochemical Performance of Microalgae Exoskeletons as Si-Based Anodes for Next-Generation Li-Ion Batteries MariaV. Blanco; Norwegian University of Science and Technology, Norway

Li-ion batteries (LIBs) can bridge renewable energy sources to power demand and are therefore crucial in achieving energy sustainability. However, the magnitude of the forthcoming market demand for LIBs along with the need for a climate neutral economy means that a sustainable supply of battery raw materials becomes strategically essential.

Apart from lithium, there is one material that is a fundamental part of all LIBs: graphite, which is the primary component of LIBs anodes. Graphite exhibits a storage capacity of $372 mAhg^{-1}$, which is insufficient for next-generation LIBs. Even more concerning, it has been listed as a critical raw material.

A promising option to increase the energy density of anode materials for LIBs while retaining stable cycling performance is the fabrication of composite anodes having graphite and small amounts of nanostructured Si-based materials (Si, SiO_x and SiO_2). However, the production of such nanostructures often requires high temperatures, pressure, and PH, as well as deployment of toxic/hazardous chemical agents, which are harmful for the environment. Hence, sustainable manufacturing methods to produce Si-based nanostructures is an imperious need.

Importantly, nanostructures of SiO_2 are observed in the exoskeletons of diatoms, a type of photosynthetic microalgae ecologically widespread in marine and freshwater, and such biosilicas are produced under room temperatures and pressures in aqueous systems near a neutral pH. Diatom exoskeletons (frustules) contain 98 % of silica with hierarchical architectures from the nano- to macroscale, and each of the more than 100,000 estimated diatom species displays an unique SiO_2 frustule morphology and size (from 2 μm to 2 mm). However, the synthesis of nanostructures with controlled surface area and porosity are essential prerequisites for Si-based anodes, since fine control of these properties has shown to mitigate stress derived from volume variations of Si active domains, therefore extending the cycle life of the anodes, limiting the reactive area for the formation of the solid electrolyte interphase, and decreasing Li-ions diffusion paths.

Diatoms have the potential to fulfil the needs of next-generation anodes for LIB technology, and a landmark of $840 mAhg^{-1}$ stable storage capacity after 100 cycles at $100 mAg^{-1}$ was achieved by diatom SiO_2 anodes. However, although the implementation of diatoms into working anodes has created a valuable knowledge on how to condition frustules for this exact application, the lack of insights on the effect of diatom nanostructure on the electrochemical properties of Si-based anodes is hindering the rational choice of individual diatom species building SiO_2 morphologies at the nano and microscale that can deliver optimum electrochemical performance.

In this work, a comparative analysis of the electrochemical performance of SiO_2 anodes made from frustules displaying distinctive properties in terms of porosity, surface area, particle size and morphology is performed. Such frustules were extracted from diatom species artificially cultivated in photobioreactors. This allowed to conduct the first specie-dependent analysis of Si-based anodes extracted from microalgae exoskeletons, and to select outperforming diatom species for LIB technology. Massive cultivation of diatoms for the production of negative electrodes for LIBs has the potential to revolutionize battery production via truly green bottom-up fabrication schemes.

10:45 AM EN03.11.03
Quinone-Rich Sustainable Organic Cathodes for Rechargeable Aqueous Zinc-Ion Batteries OnurBuyukcakir; Izmir Institute of Technology, Turkey

Zinc(Zn)-based energy storage systems have excellent capacities and stabilities in aqueous electrolytes while also being inexpensive, eco-friendly, and safe. However, recent studies have demonstrated that the lack of cathode materials allowing high capacity and rate performance without sacrificing cycle life and sustainability is a major bottleneck in the performance of Zn-ion batteries (ZIBs). Recent years have seen the introduction of a limited number of organic materials as cathodes in aqueous rechargeable ZIBs. However, generating electrochemically active organic materials with rich redox-active centers that can reversibly accommodate Zn^{2+} ions is challenging. It is, therefore, still of great interest to design new organic compounds or polymeric structures as active electrode materials to provide the required electrochemical performance, economic benefits, biocompatibility, and sustainability for building next-generation ZIBs. This talk will introduce rationally designed quinone-based redox-active organic materials prepared using environmentally friendly (heavy-metal-free) reaction strategies. Furthermore, new chemistries will be introduced that significantly affect several crucial parameters of aqueous ZIBs for practical applications, including cycling stability, a uniform discharge plateau, stable voltage output, and high physicochemical stability. These organic cathodes show high specific capacities and excellent cyclic stability over 10000 cycles with remarkable capacity retention. The investigation of the zinc-ion storage mechanism using theoretical calculations and in/ex-situ analysis will be demonstrated in detail. These findings are critical for gaining a fundamental understanding of the structure-property relationship, paving the way for rationally built next-generation battery systems.

11:00 AM EN03.11.04
Sustainable and Controlled Synthesis of Carbon Nanoparticles from Lignin using Single-Step Aerosol Methods for Application in Energy Storage SujitModi[1], OnochieC. Okonkwo[1], SulaySaha[1], HaoZhou[1], ShalineeKavadiya[2], MarcusFoston[1] and PratimBiswas[2]; [1]Washington University in Saint Louis, United States; [2]University of Miami, United States

With the rapidly growing demand for renewable energy and portable devices, developing high-performance energy storage materials and meeting sustainability requirements is significant. Lignin, a biomass constituent and byproduct waste of biorefineries, is one of the few renewable sources of carbon that have the abundance and desirable properties to displace or replace fossil derived carbon sources. A renewable resource, low cost, and high aromatic content make lignin an ideal precursor to obtaining carbon materials for energy storage. However, present efforts on the large-scale synthesis of carbon materials from lignin are limited either by multistep and batch processes or the use of activating agents/templates [1].

The present work aims to engineer a process that valorizes waste and by-product lignin. In particular, we develop an original and innovative method, based on a one-step continuous aerosol technique, to manufacture high-performance carbon nanoparticles for energy storage without the use of activating agent/template. This one-step approach requires a significantly lower time for synthesis: an order of seconds in comparison to hours for existing methods. Temperature and residence time are expected to have a key impact on the properties of carbon materials synthesized from lignin, hence, an aerosol technique utilizing a furnace aerosol reactor is used; furnace aerosol reactor is known for enabling precise control over a wide range of temperatures and residence times [2]. Subsequently, the effect of temperature and residence time inside the reactor on carbon nanoparticle size, functional groups, surface area, and morphology is systematically investigated. Furthermore, the as-obtained carbon nanoparticles are tested for specific capacitance and the best-performing material (surface area 925 m2/g) exhibited a specific capacitance of 247 F/g at 0.5 A/g with excellent capacity retainment of over 98 % after 10,000 cycles. This is a clear demonstration of their superior performance compared to supercapacitors synthesized earlier from lignin.

Moreover, the size and morphology of carbon particles, which are impacted by interparticle collision and sintering, are known to play a crucial role in their stability as well as energy storage

performance. However, experimental as well as modeling efforts on size and morphology-controlled synthesis of carbon nanoparticles from lignin are limited, partly due to the complexity of studying collision and sintering under simultaneous lignin reactions (pyrolysis). We systematically investigate the kinetics of reaction, sintering, and collisions using a novel and generalizable numerical model based on a geometric modeling approach [3]. Knowledge of kinetics will provide better control over the size and morphology for efficient utilization of carbon nanoparticles in energy storage.

Overall, the simple (one-step, continuous, and rapid) operation, avoiding the use of activating/templating chemicals, and precise control over size and morphology make the aerosol technique a promising candidate for the scalable and sustainable synthesis of energy storage materials.

11:15 AM EN03.11.05
Cellulose Nanocrystals Based Flexible Substrates as Electrodes for Zn Batteries and Tribolayer in Triboelectric Nanogenerators (TENG) Devices AmitK. Sonker[1,2,2], ShizhaoXiong[2], AleksandarMatic[2] and GunnarWestman[2]; [1]VTT, Technical Research Center of Finland, Finland; [2]Chalmers University of Technology, Sweden

Nanocellulose is a promising polymer for applications in energy and electronic devices due to its biodegradable nature and properties. Among nanocelluloses, cellulose nanocrystals (CNC) are the most crystalline than bacterial cellulose and cellulose nanofibrils. Sulfate groups on CNC surfaces make them suitable for use as dispersants. In the presented work, a novel method of exfoliating MoS_2 in water using CNC and the use of exfoliated MoS_2 as an electrode in battery application is presented. In detail, electrodes are prepared from exfoliated MoS_2 (active material)-Cellulose Nano Crystals- (binder) with carbon nanotubes (electron-conducting support) and used in a Zinc battery half-cell that demonstrated a coulombic efficiency of 90%. Successful exfoliation of layered MoS_2 into nanosheets is performed by sonicating Bulk MoS_2 with sulfated cellulose nanocrystals (CNC) for 4 hours. In addition to Raman and TEM confirmation, the Raman signals for exfoliated MoS_2 show a blue shift of both A^1_g and E^1_{2g} bands, suggesting CNC-induced lattice strain on nanosheets. The resulting stable water suspension shows no tendency for precipitation after two months of standing. The zeta potential, ζ, for sodium sulfated CNC (CNC-OSO_3Na)-MoS_2 in water suspension is observed as -45 mV, whereas sulfated CNC (CNC-OSO_3H)-MoS_2 in water suspension had a zeta potential of – 35 mV. CNC in the sodium form showed micelle characteristics like sodium dodecyl sulfate (SDS), with a critical aggregation concentration (CAC) of 1.1 wt%. Using CNCs at CAC efficiently exfoliated MoS_2 at a much lower concentration than has been reported for synthetic surfactants like SDS and CTAB (Cetyl trimethyl ammonium bromide). In addition to application in energy storage devices, flexible CNC films were also utilized to fabricate triboelectric nanogenerators (TENG). As CNCs are highly crystalline and to make them flexible, a plasticizer is optimized with a concentration of less than 13.5 wt% to maintain its recyclability. Flexible CNC films as a tribo-positive layer shows an output voltage of 120-200 V.

Bio-Based Energy Technology and Low-Power Electronics for Internet of Things MagnusBerggren; Linkoping University, Sweden

Cellulose and lignin are the two most abundant biopolymers on earth. These materials offer structural integrity and electrochemical functionality for efficient energy technologies, especially for energy scavenging and electrical energy storage. Here, piezo-electric energy generators and printed batteries are reported, targeting sustainable manufacturing, circularity, and energy efficiency. In addition, a printable organic electronic complementary circuit technology has been developed enabling low-power operation at voltages that are compatible with bio-based organic batteries. Together, these devices and circuits provide a platform for future internet of things solutions, specifically targeting sustainable production and materials, and an easy end-of-life handling.

Biobased & Biodegradable Materials for Advanced Water Treatment: Removal of Trace Lead by Yeast-Laden Hydrogel Capsules PatritsiaM. Stathatou[1,2], DevashishGokhale[2], ChristosE. Athanasiou[1] and PatrickDoyle[2]; [1]Georgia Institute of Technology, United States; [2]Massachusetts Institute of Technology, United States

Traces of heavy metals in water resources, due to mining activities and e-waste discharge, pose a global threat, with lead being one of the most abundant and toxic trace contaminants. As a result of various incidents of lead-contaminated drinking water, relevant water regulations are being revised, while according to the US Environmental Protection Agency, no level of lead in drinking water is considered safe. Conventional treatment processes fail to remove trace lead from drinking water in a resource-efficient manner. We have previously shown that by using the yeast *Saccharomyces cerevisiae* we can effectively remove trace lead from water *via* a rapid mass transfer process, called biosorption, achieving an uptake of up to twelve mg lead per gram of biomass in solutions with initial lead concentrations below 1 part per million. We have also found that equilibrium is achieved within the first five minutes of contact. The rapid and high lead uptake is advantageous for the large-scale application of this inexpensive and abundant biomaterial for the removal of trace heavy metals from water.

The main limitation for scaling up the developed water treatment approach is the requirement for additional treatment steps to remove the added yeast. In this presentation, we demonstrate the development of a sustainable material by encapsulating yeast cells in hydrogel microparticles to overcome this limitation. Yeast-containing poly(ethylene glycol) diacrylate (PEGDA) biobased and biodegradable hydrogel capsules are synthesized using an off-the-shelf microfluidic device through a scalable approach. Scanning electron microscopy and confocal fluorescence imaging have been used to measure the capsules' porosity and assess the distribution of yeast cells inside the capsules. Through kinetic and equilibrium experiments we characterize the stoichiometry, equilibrium, and selectivity of the hydrogel capsules under different initial lead concentrations (in the range of 30 – 1000 ppb). Residual lead concentrations have been measured using inductively coupled plasma-mass spectrometry. Data shows that hydrogel capsules are highly effective vehicles for holding yeast cells, being sufficiently large to be easily separated from water under the effect of gravity, as well as sufficiently porous to not limit the adsorption capacity of the yeast or the kinetics of lead removal. Furthermore, we perform biomechanical static and dynamic compression tests to assess the mechanical robustness of the capsules and guide the design of a cm scale, packed-bed bioreactor operated as a flow-through filter to serve as a proof-of-concept of our approach. Finally, through a life cycle approach (LCA) we compare our proof-of-concept water treatment approach with physicochemical state-of-the-art counterparts and assess its environmental and economic benefits. Our work overcomes separation and structural stability issues that limit biosorption scalability, opening a new generation of environmentally friendly, highly effective, and sustainable biosorbents targeting emerging contaminants.

Scalable Biomass-Derived Hydrogels for Sustainable Carbon Dioxide Capture Youhong (Nancy)Guo and T. AlanHatton; Massachusetts Institute of Technology, United States

Carbon capture and sequestration is a promising emissions mitigation technology to counteract ongoing climate change. The century-old amine scrubbing process is industrially mature but suffers from low energy efficiency, corrosion of facilities, and inferior stability of aqueous solutions. State-of-the-art solid sorbent-based carbon capture systems present a potentially advantageous alternative. However, practical implementation remains challenging due to limited CO_2 uptake at dilute concentrations and difficulty in regeneration of the sorbents. Here, we develop sustainable carbon-capture hydrogels (SCCH) with excellent CO_2 uptake (400 ppm) at room temperature. The rationally designed biomass gel network consists of glucomannan and cellulose, facilitating hierarchically porous structures for active CO_2 transport and capture. Pre-captured moisture significantly enhances CO_2 binding by forming water molecule-stabilized

zwitterions to improve the amine utilization efficiency. In addition, the SCCH exhibits a notable advantage of low regeneration temperature at 60 °C. With rapid sorption-desorption kinetics, SCCH is capable of operating multiple cycles per day with, e.g., solar-powered regeneration. Prepared via a simple and scalable casting method with environmentally viable raw materials, SCCH highlights the potential for sustainable carbon capture from a wide range of point sources to meet global decarbonization targets.

Novel Sustainable Polymers and Hydrogels Made from Designer Proteins and Plant Proteins NabaK. Dutta, RajkamalBalu and NamitaChoudhury; RMIT University, Australia

Polymer materials have transformed modern life and are utilised in every sector, including the commercial, industrial, medical, and retail ones. However, mostly they are non-biodegradable and derived from non-renewable resources. These durable materials are left in landfill as trash can linger for decades and are a pollutant of increasing concern. For example, from the air we breathe to the food we consume, microplastic particles can be found everywhere in the environment. Green polymers, which are produced using ecologically benign methods and are either biodegradable or meet particular criteria for managed treatment at the end of life, have been driven by this concern [1]. Green polymers can be divided from: (i) biomass, which includes polysaccharides, starches, cellulose, lignin, and proteins; (ii) microorganisms, like polyhydroxyalkanoates (PHA) (iii) monomers derived from renewable resources but polymerised using traditional synthesis, like polylactic acid (PLA), as well as, (iv) monomers produced from fossil fuels, however, are biodegradable, e.g., poly (-caprolactone) (PCL) [2].

In this talk, I will cover our latest work on genetically engineered biomimetic protein-polymers [3,4] and plant-protein-based polymers [5-7] that are derived from renewable resources, biodegradable, multifunctional and adaptable. The unusually responsive resilin-mimetic protein polymer (RMPs), their unique molecular architecture, responsiveness, highly resilient hydrogel formation characteristics, and dynamics of their structural ensembles [8–14] will be discussed. An attempt will also be made to elucidate the molecular origin of their unusual adaptability and functional possibilities. Native resilin is a member of the family of elastic proteins that includes elastin, gluten, gliadin, and spider silks and is purported to be the most resilient elastic material known with resilience >97%. We will also demonstrate that plant-derived biopolymers and proteins and their functionalized product have the potential to offer a new platform for the development of sustainable, eco-friendly and biodegradable super absorbent polymers for many applications including hygiene products. Overall, the research has revealed the potential of biomimicry along with the genetic engineering approach to biomaterials design offer powerful strategies to overcome challenges and provide new opportunities in the design and rapid development of novel functional polymers.

Bio-Derived Juglone-Based New Crosslinkers for Material Recycling of Network Polymers TakeoSuga; Waseda University, Japan

Polymers with dynamic covalent bonds have attracted much attention in recent years because of their self-healing, recyclability, and shape-memory properties, which can be achieved by repeated cleavage and regeneration of covalent bonds upon thermal or photo-stimulation. However, many reports have shown that dynamic covalent bond units, including Diels-Alder (DA) adducts, dissociate at around 100°C, and although they show repairability in the room temperature to medium temperature range, their application to practical materials is limited. Here we focus on anthracene-naphthoquinone (juglone) adduct, which shows bond recombination reactions in the high-temperature range compared to well-known furan-maleimide adduct, and synthesized the crosslinked polymers with anthracene-naphthoquinone moiety. Reversible crosslinking was evaluated by the temperature dependence of rheological behavior.

Synthesis and Application of Nanoporous Nitrogen-Doped Carbon from Kraft Lignin TetyanaBudnyak, AlinaNikolaichuk, OlegTkachenko, NataliiaFihurka and MariaStrömme; Uppsala University, Sweden

The utilization of renewable resources for the synthesis of advanced materials is of great importance for sustainable development. Lignin is the second most abundant macromolecule in nature and the perfect precursor for the synthesis of various carbon materials due to its high carbon content and aromatic structure. Here, we present a novel approach for the synthesis of nanoporous nitrogen-doped carbon (NNC) from kraft lignin, a widely available waste product from the pulp and paper industry. The synthesis involves a simple process, where kraft lignin is converted into a highly porous carbonaceous material through pyrolysis in a nitrogen atmosphere simultaneously with a nitrogen-doping process using urea as a nitrogen source.

The resulting NNC material exhibits a high surface area (up to 800 m^2/g), high nitrogen content and a hierarchical porous structure distributed throughout the material. The NNC material was characterized using various techniques, including XRD, BET, and XPS, to confirm its structural and chemical properties.

NNC was found to have the properties of interest for a number of environmental applications including carbon dioxide capture, adsorption of heavy metals from aqueous solutions and nitrates/nitrites reduction. Overall, the synthesis of NNC from kraft lignin presents a sustainable approach for the development of adsorbents with potential applications in environmental remediation and carbon capture technologies.

Cell-Wall Specific Modification of Xylem Cell Walls with Nanocrystalline Iron Hydroxides for Mechanical Reinforcement StevenA. Soini, SofiaFeliciano, BobbyDuersch and VivianMerk; Florida Atlantic University, United States

In recent decades, there has been large interest in creating sustainably produced materials to mitigate adverse climate impacts and present alternatives to non-biodegradable plastics. To this end, we used readily available raw materials from the biosphere, such as chitin and lignocellulose, that can be used as starting materials to design composite materials with enhanced physical and chemical properties. Lignocellulose has an inherent 3D hierarchical structure that gives rise to excellent mechanical properties while maintaining a high degree of porosity available for chemical modification. Biocomposite filters composed of nanocrystalline iron hydroxides mineralized within the lignocellulose scaffold are promising low-cost, eco-friendly materials with a variety of possible applications from pollution remediation to building materials. Composites comprised of balsa wood (*Ochroma pyramidale*) and ferrihydrite (Fh) were prepared and characterized with Micro-Computed X-ray Tomography (MicroCT), Scanning Transmission Electron Microscopy with Energy Dispersive X-ray Spectroscopy (STEM-EDS) and synchrotron-based Nano-Computed X-ray Tomography (NanoCT) to visualize the distribution of mineral phase throughout the bulk scaffold and the ultrastructure of the cell wall. MicroCT results were consistent with the distribution of Fh throughout the overall structure, within the water-conducting vessels and rays, which are involved in liquid transport in the radial direction. Fh formed within the multilayered cell wall as opposed to only lining the void cell lumen, as shown by STEM-EDS and NanoCT. The deposition of mineral within the cell wall impacts the mechanical strength of the composite material, as shown by in-situ mechanical testing within the Scanning Electron Microscopy (SEM) and force spectroscopy in the Atomic Force Microscopy (AFM).

Designing and Understanding the Limits of Fluoro-Free Super Liquid Repellency WilliamS. Wong; Aalto University, Finland

Super liquid repellent surfaces exhibit extraordinarily high liquid contact angles and low sliding angles, demonstrating immense potential for anti-fouling and self-cleaning. While repellency for water is achievable with hydrocarbon chemistries, repelling low surface tension liquids (down to 30 mN/m) still requires perfluoroalkyls[1] (a persistent environmental pollutant and bioaccumulation hazard). Here, we investigate the functional limits of stochastic surfaces with fluoro-free moieties. Silicone and hydrocarbon surface chemistries are benchmarked against perfluoroalkyls, assessed using low surface tension liquids (ethanol-water mixtures). We discover that both hydrocarbon- and dimethyl silicone- based chemistries are functional down to 40-41 mN/m and 32-33 mN/m, respectively (*vs.* 27-32 mN/m for perfluoroalkyls). The dimethyl silicone variant[2] demonstrates a superior performance likely due to its denser dimethyl molecular configuration and unique polar-and-dispersive composition. We show that perfluoroalkyls are not mandatory for many real-world scenarios (aqueous-based). Effective super-repellency of different surface chemistries against different liquids (pure compounds and mixtures) can also be adequately predicted using empirically verified phase diagrams. Our findings[3] encourage a liquid-centric design, *i.e.* tailoring surface chemistry design alongside target liquid properties. Herein, we provide key guidelines for achieving sustainably designed super liquid repellency.

The Role of Nitrogen-Doping and Surface Topology of Biobased Carbon Electrodes for Iron-Based Redox-Flow Batteries AnnaBachs-Herrera[1], IsaacVidal-Daza[2,1] and FranciscoMartin-Martinez[1]; [1]Swansea University, United Kingdom; [2]Universidad de Granada, Spain

To redefine our material sources in a circular economy, it is key the utilization of extensively available biomass wastes, as new carbon mines. A plethora of applications that valorize biomass, and implement biomass-derived materials (i.e., biobased), are being intensively investigated, e.g., biofuels, biodegradable polymers, carbon fibers, battery electrodes.[1] Hydrochar, produced from hydrothermal and pyrolysis processing of biomass is an alternative avenue to produce more sustainable carbon materials for energy storage, while it provides new routes for biomass waste valorization.[2] Hydrochar's structure is predominantly aromatic, rich in nitrogen atoms, and highly porous, which are valued features for carbon electrodes,[3] such as those in redox flow batteries.[4] However, the fundamental mechanisms underlying the performance of biobased electrodes are still unclear. To achieve better understanding of the structure-property relationship of hydrochar-derived carbon electrodes in iron-based redox flow batteries, we performed density functional calculations (DFT) calculations of iron redox species and hydrochar model systems with different surface features. We explored the effect of quaternary nitrogen functional groups, surface curvature, endo- and exo- absorption sites at the surface, and curvature radius, as well as the effect of iron spin multiplicity. Our results suggest that the interaction between iron and biobased carbon electrodes not only depend on the surface curvature or nitrogen content, but also on the spin multiplicity of the metal ion.

The Crashworthiness of Biodegradable Inserts of Sport Helmet PawelKaczynski, MateuszSkwarski, PiotrMakula, JoannaM. Ludwiczak and AnnaDmitruk; Wroclaw University of Science and Technology, Poland

Today, the development of biodegradable polymers has gained significant attention as a promising solution to address the environmental concerns associated with conventional plastics. Biodegradable polymers, also known as biopolymers, are designed to break down naturally over time (maximum of 6 months), reducing their impact on ecosystems and minimizing pollution. The following article explores the possibility of using dedicated biodegradable composites for injection molding of thin-walled structures used in sports helmets. The paper presents several composites based on a PLA matrix with the addition of other biodegradable plastics such as PBS and PBAT. The article describes the author's production method, which is based on injecting thin-walled structures into an innovative form patented by the authors. The crashworthiness of the energy-absorbing structures obtained this way was then tested using a spring drop hammer. The test conditions replicated the collision of an athlete wearing a helmet with a rigid stationary obstacle. During the test, the dynamic crushing force and displacement were recorded using acceleration sensors and by tracking the position of markers mounted prior to the test on the spring drop hammer tup.
The results are presented as force-displacement crushing curves and images from a high-speed camera. Additionally, the energy absorption of the structures is presented in the form of diagrams. The results were then analyzed, and the two most useful materials were selected in the context of their possible use for the injection molding of thin-walled, energy-absorbing structures used for constructing sports helmets.
The article demonstrates that it is possible to address the environmental challenges and produce energy-absorbing structures made of biodegradable materials that can be successfully used to construct sports helmets of all kinds, replacing the previously used expanded polystyrene. These structures have several advantages. First, users can easily replace them after a crash, restoring 100% of the helmet's protective properties. Second, these structures can be disposed of by composting. Third, the structures provide better protective properties because they utilize a previously unused mechanism of plastic folding instead compression of polystyrene elements

Elucidating The Affect of Drying Mechanism and Drying Parameters on Seaweed-Derived Biopolymer Alia. Dashti; Loliware, United States

Seaweed-derived biopolymers have gained attention in biotechnology due to their biocompatibility, ability to break down naturally, and chemical inertness. . These polymers have been traditionally used in the food, pharmaceutical, and cosmetic industries. One attractive application of bioderived and biodegradable materials is in the food service industry to replace single use plastics. While it has been demonstrated that water-containing seaweed resins can be processed using conventional plastic converting techniques like extrusion and injection molding, post-processing drying to remove residual water remains a challenge. Here we discuss a general mechanism for the drying process of seaweed-based plastics and provide a computational model to correlate material's bulk morphology and drying regimes on the mechanical properties. Our findings suggest that an optimized drying process can improve seaweed-based materials mechanical properties as well as manufacturing throughput.

8:00 PM EN03.13.04

Synthesis of Novel Graphene-Based Porous Material from Waste DharmveerYadav, JyotiramanDe, SumitSaxena and ShobhaShukla; Indian Institute of Technology Bombay, India

Graphene, a new-generation wonder material, is well-known for its exotic physical, chemical, and mechanical properties. It has gained excessive attention from material scientists and environmental engineers due to its versatile application in different fields of application like water purification, desalination, and treatment of industrial effluent. However, the synthesis of graphene oxide (GO) from graphite is an intensive process requiring harsh chemicals with complex chemical routes for synthesis, poor yield and high-end instrument facilities, which restricts mass production and, thus, large-scale applications. Hence, there is a need for an eco-friendly, low-cost, and simple fabrication process that can be used for large-scale applications. In order to mitigate the drawbacks of currently used synthesis methods, here we report a simple, scalable, cost-effective, and environment-friendly synthesis of oxidized graphene framework (OGF) produced from agro-waste. As compared to 2D graphene sheets, 3D graphene foams have attracted extensive attention due to their high porosity, uniform structure, chemical stability, and flexibility. Porous foam could be obtained for desired densities and shapes such as rods, cylinders, and papers. Therefore, we have developed porous OGF foam material, which is compressible and regains its shape and size after unloading. The developed material has been extensively characterized by Raman, XRD, FTIR, SEM, TEM and XPS to confirm its successful synthesis with desired properties. Other than that, wetting and sorption studies have been performed with different types of organic compounds. This eco-friendly, cost-effective method of development of 3D graphene-based foam can lead to the solution of water purification, treatment of industrial wastewater, and recovery of organic solvents and oils.

8:00 PM EN03.13.05
Chemically Recyclable Butadiene-Derived Poly(oligocyclobutane)s from Acyclic Diene Metathesis ShawnM. Maguire, CherishNie, CallieC. Zheng, RichardRegister, PaulChirik, RodneyPriestley and EmilyC. Davidson; Princeton University, United States

Commodity polyolefins account for the majority of plastic waste but present thermodynamic challenges for depolymerization and upcycling due to their high thermal and chemical stability. Here, the synthesis and characterization of a chemically recyclable polyolefin is reported that is derived in two steps from butadiene, a feedstock olefin. Acyclic diene metathesis (ADMET) polymerization of (1,n′-divinyl)oligocyclobutane (DVOCB), a telechelic oligomer formed by the reversible [2+2] cycloaddition-oligomerization of butadiene, yielded pDVOCB, a new polyolefin architecture. Characterization of pDVOCB by thermogravimetric analysis (TGA), differential scanning calorimetry (DSC), wide-angle X-ray scattering (WAXS), dynamic mechanical analysis (DMA), and tensile testing established high crystallinity, high thermal stability, and comparable thermal properties and mechanical behavior to those of commodity polyolefins. The length of the DVOCB monomer was used to tune the thermomechanical properties of the resulting polymer. Exposure of pDVOCB to excess ethylene under ADMET conditions resulted in >99% depolymerization back to DVOCB with minimal purification required. Selective depolymerization and recovery of DVOCB was also demonstrated from a mixed polymer waste stream, as well as complete depolymerization back to pristine butadiene.

8:00 PM EN03.13.06
Upcycling from Wasted Plastics to Carbon Nanotube Devices TakashiIkuno[1], HiroakiKomatsu[1], YusukeKurihara[1], KotaroTakanashi[1,2], YosukeSugita[1] and TakahiroMatsunami[1]; [1]Tokyo University of Science, Japan; [2]Future Earth Laboratory, Japan

In recent years, marine pollution has been increasingly severe. Eight million tons of plastics are disposed into the ocean every year. It is predicted that the amount of plastics in the ocean will exceed the amount of fish by 2050 on a mass basis. From the viewpoint of upcycling, we are trying to convert waste plastics into “value-added” carbon nanotubes (CNTs). Although there have been reports on the conversion of virgin plastic into multi-walled CNTs (MWNTs) by chemical vapor deposition (CVD), the conversion efficiency η was poor (4% at maximum), and the available plastic species were few. In addition, the correlation between the plastic species and the properties of MWNTs has not been well understood.
In this study, we have newly developed a CVD system that can convert various types of plastics into MWNTs with high efficiency. This method consists of three regions: the pyrolysis region of the plastic, the sublimation region of the metal-organic catalyst, and the growth region of the MWNTs. The features of this method are that η is much higher than those reported previously (maximum $\eta > 50\%$) and that a variety of plastic species can be used. In addition, we have fabricated patterned CNT wirings on plastic films using upcycled MWNTs by laser-induced transfer method [1]. After that, the we also demonstrated upcycling the plastics films with CNT wirings into MWNTs again.
In this presentation, I will introduce the detail of the conversion method. Specifically, the relationship between pyrolysis gas species, which were characterized by infrared and mass spectroscopy, and the properties of resultant MWNTs will be presented. Furthermore, I will show some demonstrations of conversion from “real” marine debris (fishing nets, etc.) collected at beaches and inland into MWNTs with a conversion efficiency of more than 30%.

8:00 PM EN03.13.07
Metal Modified Nanocellulose as a Synthetic Biofilm Substitute for Mechanical Removal Testing DarrylW. Taylor and A. AndrewD. Jones, III; Duke University, United States

Introduction: Nanocellulose, a plant cellulose derivative, is a functional and modifiable material its applications go beyond those of raw cellulose. One underexplored application is mimicking bacterial biofilms, which have a wide range of uses in biomaterials, tissue engineering, bioleaching, and many other applications. Bacterial biofilms pose threats to human health, food systems, and water systems. Biofilms consist of communities of bacteria that adhere to surfaces and resist mechanical, chemical, and biological removal. Understanding the behavior of biofilms is essential for maintaining the well-being of critical societal systems. While decellularized eukaryotic systems serve as a valuable platform for understanding mechanical and chemical tissue behavior, biofilms cannot be decellularized. Unlike eukaryotic systems, where the extracellular matrix is more resilient than individual cells, biofilms exhibit the opposite behavior, with individual cells being more robust than the extracellular matrix they produce. The absence of a living, adaptable, material platform increases the challenge in establishing biofilm transport, chemical, and mechanical behavior.

Objective: A nanocellulose synthetic analogue offers the advantage of being a non-living material platform, making production, testing, and replication easier. In-depth understanding of nanocellulose through rheology and research aimed at exploring novel applications, such as biofilm mimicry, would expand its potential applications and contribute to the development of more robust and more environmentally benign responses to biofilm challenges.

Methods: This research generated nanocellulose hydrogels using an ionic liquid solution of 7:12:81 sodium hydroxide:urea:water, and used nanocellulose hydrogels in several experiments including rheology testing where the storage and loss modulus was measured. Hydrogels were modified with metal ions (Cu2+, Zn2+, Sr2+, Co2+, Ca2+, Ni2+) and rheology testing was conducted. Two metal ion modified hydrogels (Ni2+, Ca2+) with rheological properties closer to biofilms were further tested for dental removal.

Results: The metal chelated hydrogels showed similar mechanical behavior to biofilms much more than currently used synthetic biofilm analogues like alginate. The storage and loss modulus that demonstrated biofilm-like behavior were hydrogels chelated with calcium chloride, nickel sulfate, and strontium chloride each exhibiting a storage modulus between 1200-1300, 920-850 and 1050-1020 Pa respectively. In dental removal experiments tested with calcium chloride and nickel sulfate after 60 seconds of irrigation at 30 and 130 psi, it was shown that nanocellulose was 99% removed from ceramic coupons. This research shows that for force removal nanocellulose hydrogels chelated with these ions serve as a good model for bacterial biofilms.

8:00 PM EN03.13.08
Dynamic Strength Properties of Biopolymers based on PLA, PBS, PBAT, and TPS for Energy Absorbing Structures MateuszSkwarski, PawelKaczynski, PiotrMakula, AnnaDmitruk and JoannaM. Ludwiczak; Wroclaw University of Science and Technology, Poland

The growing awareness of society and the high cost of fossil fuels result in a continuous increase in the popularity of alternative means of transport (e.g. bicycles). There is a great, continuously increasing demand for personal protective equipment, such as sports helmets. The energy-absorbing layer of all currently produced helmets is made of foamed plastics: polystyrene (EPS), polypropylene (EPP), or polyurethane (EPU). According to the manufacturers' recommendations, these materials should be immediately replaced after each collision. **This procedure is often skipped because helmet damage is not visible to the naked eye, and the users are aware of the material value of their helmets. The solution may be changing only the energy-absorbing layer, as the helmet's exterior shell is primarily intact.**
The authors want to present environmentally friendly protective honeycomb inserts made of biodegradable polymers invented during project implementation. Thanks to their structure, they can constitute a reusable alternative to polystyrene (the insert in the shell can be replaced each time after an accident).
The authors of the manuscript **created unique blends of biodegradable plastics based on PLA** with the addition of bioplastics, such as polybutylene succinate - PBS, polybutylene adipate coterephthalate - PBAT, and thermoplastic starch - TPS. They combine high strength and plasticity, and thanks to their biodegradability, these mixtures meet the criteria of sustainable development. **All developed materials were extensively tested using a unique method developed by the authors, which relies on dynamic tensile tests. This brought the results closer to conditions occurring during actual incidents (e.g. collisions).**
Properly designed geometry of the energy-absorbing structure in combination with mechanical properties (tensile strength, yield strength, elongation, Young's modulus) tailored to specific geometry and applications **resulted in the invention of the thin-walled biodegradable structure that engages the most effective mechanism, which is dynamic, plastic folding.**
There are no standards describing strength tests conducted in dynamic conditions. The conducted tests constitute the "know-how" of the authors. The testing device was based on the design of a rotary hammer and was equipped with a flywheel with a diameter of 0.6 m and a weight of about 230 kg. The flywheel's rotational speed was preset to reach the strain rate from 250 to 1000 s^{-1}, which is close to the actual condition during the crash. A specially designed measurement system allowed to reach the sampling rate equal to 1 MHz. In order to accurately measure the deformation, the process was additionally filmed with a high-speed camera capable of registering 1,000,000 fps.
The criterion of suitability and safety of a given material for a designed geometry of insert were strength properties determined in dynamic tensile tests ($Re > 15$ MPa, $Rm > 10$ MPa, $A > 10\%$).
Tests confirmed that complex thin-walled honeycombs can be successfully molded and used as energy-absorbing structures. On this basis, it can be concluded that the **developed biodegradable blends provide the desired compromise between mechanical properties - high tensile strength and satisfactory plastic properties engaging plastic folding mechanism during the deformation**. These biomaterials can also be used in other energy-absorbing applications. Although the developed blends are biodegradable, they are sufficiently resistant to variable weather conditions (e.g. sunlight, rain exposure) to fulfill their purpose during the exploitation time. The developed materials and testing methodology will affect personal protection equipment and shows potential for applications in the automotive, food, and packaging industries.
Funding: This work was supported by the project BIOKASK "Development of innovative, replaceable, energy-absorbing structures based on biodegradable plastics for protective helmets" (0223/L-11/2019, LIDER, NCBR).

UV Resistance and Biodegradation of PLA-Based Polymer Mixtures doped with PBS, PBAT, TPS for use as Energy-Absorbing Structures JoannaM. Ludwiczak, AnnaDmitruk,

MateuszSkwarski, PiotrMakula and PawelKaczynski; Wroclaw University Science and Technology, Poland

The problem of waste storage and recycling of polymer materials prompts the search for new, biodegradable materials with good functional properties. The ability to degrade biodegradable plastics through the action of naturally occurring microorganisms is a huge advantage over conventional polymers. There is a great demand for the design and development of biodegradable plastics that not only biodegrade but also meet the expected material properties. Many biodegradable polymers are known, but unfortunately the barrier to their use is still insufficient resistance to weather conditions, their accelerated degradation and unstable properties, such as strength and thermal properties.
Currently used materials for head protection in sports helmets are usually foamed polystyrene, which is difficult to dispose of. The foamed polystyrene structure also does not provide sufficient individual protection, compared to the honeycomb structures developed by the authors. Biodegradable polymers were selected for the production of thin-walled inserts, and the preparation of mixtures enabled the selection of the best strength properties for impact protection, which is critical for use in sports helmets.
Project work focused on biodegradable polylactide (PLA) and its modification by adding other biodegradable polymers such as poly(butyleneadipate-co-terephthalate) (PBAT), thermoplastic starch (TPS) and polybutylene succinate (PBS). Mixtures of different compositions were prepared by melt mixing. The materials were subjected to an accelerated aging process in an aging chamber for a period of 3 weeks. UV stability is a key factor when assessing the long-term properties of these types of materials, due to the risk of premature degradation during use. Samples were taken periodically and tested for hardness, weight and color. After irradiation, the samples were also subjected to strength and microscopic tests. The effect of accelerated aging of PLA has been demonstrated, especially reduction in breaking strength, loss of gloss and color change. The addition of all plasticizers - other biodegradable polymers - improved the strength properties of PLA. Differences in the effect of accelerated aging were demonstrated between individual compositions and the addition of polymer to polylactide. All manufactured materials were characterized by constant weight and hardness after the aging process. Ultimately, microscopic tests showed that the prepared mixtures were not degraded, which confirmed that the selected polymer mixtures are suitable for use in variable weather conditions (sunshine, rain), but after the end of their life cycle they can be subjected to biodegradation, which was also confirmed in tests performed in soil, according to the ISO 20200: 2004 standard. The developed materials were used to produce thin-walled energy-absorbing structures for sports helmets, which are an alternative to the well-known, non-biodegradable foam inserts that protect the user's head.

The Efficient Removal of Bacteria using Reusable Magnetic Sorbents AliciaChandler, JinggeChen and VickiL. Colvin; Brown University, United States

Bacterial water contamination has detrimental health impacts and poses a significant problem worldwide; removal of bacteria from drinking water, however, requires microfiltration which can be costly and ineffective. Here we describe a more sustainable solution which relies on submicron and porous magnets that have both a large susceptibility and a large magnetic moment. These materials are coated with silica to prevent oxidation and improve reusability. Then, a silane-modified branched polyethyleneimine is covalently linked to particles to facilitate their electrostatic attraction to bacteria. The effectiveness of this approach is evaluated using a model bacteria, E. coli, which is also a prevalent biological contaminant. In magnetic separation experiments, we vary the reaction time, the dosage of magnetic sorbent, the bacterial concentration, and the solution pH to evaluate the optimal conditions and assess the practical adsorption capacity. Reuse of these materials after desorption of the bacteria is possible after which time the waste can be incinerated. This work not only has applications in more sustainable approaches to disinfection but also benefits approaches to human disease diagnosis and treatment.

Regenerative Materials - A Dual Perspective HelenLu; Columbia University, United States

In contrast to the relatively recent emphasis on environmental impact assessment in material synthesis and manufacturing, life-cycle considerations of biomaterials used in tissue engineering and regenerative medicine have long focused on the biodegradability of the material in the physiological environment or its clearance from the body post-implantation and degradation. In particular, the alpha-hydroxy polyester family of polymers, specifically polylactic acid (PLA) and its co-polymer with polyglycolic acid (PGA), have dominated the field with their well-established record of biocompatibility. What makes these materials especially attractive is the fact that they are designed to stimulate regenerative cell responses and, moreover, as they degrade, in vivo space is made available for new tissue growth. Notably, these polymers break down via hydrolysis and the degradation products, lactic acid and/or glycolic acid, can be readily processed by the body through the Krebs cycle. While these materials are regenerative in function and in its life cycle, inherent challenges in the fabrication of these material into biomimetic nanofiber scaffolds, which traditionally utilizes solvents that are environmentally hazardous and pose a significant barrier to industrial scale-up and clinical translation. We will discuss green manufacturing methods and how to leverage biofabrication for the production of nanofibrous scaffolds and regenerative materials for both medical and non-medical applications.

8:45 AM EN03.14.02
Bio-Degradation Studies of Fluorescent Defects in Carbon Nanotube Hosts Te-ILiu[1], CarlosQuiroz[2,1], Yen-HsuanLin[3,1], Ching-WeiChan[3,1], Ai PhuongNguyen[4,1] and Ching-WeiLin[1]; [1]Institute of Atomic and Molecular Sciences, Academia Sinica, Taiwan; [2]Taipei Medical University, Taiwan; [3], National Taiwan Normal University, Taiwan; [4]National Tsing Hua University, Taiwan

Carbon nanotubes (CNTs) have been enormously used in various fields because of their unique mechanical, optical and electronic properties. The rapid developments of the CNT applications have raised concerns of their impacts on the environment and human health, urging the investigations of CNT degradation. Among different types of CNTs, single-wall carbon nanotubes (SWCNTs) emit at the short-wave infrared (SWIR) that pertains low tissue scattering and low autofluorescence, making them ideal candidates for in vivo imaging applications such as disease targeting and real-time cell trackings. The clinical use of fluorescent SWCNTs carries the ‘post-diagnosis’ issues including long-term retention and chronic toxicity, to the patients. For example, long-term accumulation of SWCNTs in certain tissues, such as the liver and lungs, may lead to the development of inflammation-related diseases, including fibrosis. We believe that the prompt solution to these issues would be the development of bio-degradable fluorescent SWCNTs. Here, we report faster degradations of fluorescent defect-containing SWCNTs in biological systems. Fluorescent defects in SWCNTs are known to increase the particle emission brightness and move their excitation and emission peaks to longer wavelengths. We performed comprehensive studies of how various defect conditions, ROS species and cell types affect the degradation efficiency. Our results indicate that the hollow-core, single-atomic layer nature of the SWCNTs combined with degradable fluorescent defects could be better SWIR fluorophores for clinical uses compared to solid-core inorganic fluorophores and organic nanodots.

Biofabrication Approaches to Engineer Biomimetic Bone Tissue Interfaces ShannonMcLoughlin, RobertChoe and JohnFisher; University of Maryland, United States

Abstract
Bone tissue defects resulting from congenital abnormalities, disease, tumor resection, and traumatic injury can severely affect patient health.[1] In many cases, defects are not limited to bone tissue alone, and damage can also involve surrounding tissues, including periosteum, cartilage, ligament, or tendon. Traditional clinical techniques for bone defect repair often include the implantation of autografts, but donor site morbidity, lack of availability, and considerable medical costs limit their applicability. Tissue engineering (TE) strategies aim to produce functional bone tissue replacements by combining scaffolds, cells, and bioactive signals. Extrusion bioprinting allows for superior control over design among these three critical components and is particularly useful in the case of replicating heterogeneous tissue interfaces.[2] Specifically, bioprinting techniques allow multi-material patterning to manipulate cell-cell or material population distances and patterns, influencing cellular crosstalk and scaffold mechanics.[3] Here, we present biofabrication strategies for the generation of such biomimetic tissue interfaces, including (1) a computational model studying the impact of printed material patterning ratios on resulting scaffold mechanics, (2) a printing approach for interfacial tissues, and (3) a 4D printing strategy to generate microscale tissues among macroscale counterparts. Using these techniques in combination with extrusion printing allows for enhanced interfacial tissue regenerative potential by improving biological and mechanical properties.

3D stationary solid mechanics models were developed using COMSOL. Osteal and chondral bioinks are co-printed at the interface layer to form the mechanically interlocking interface design, recapitulating the calcified cartilage region of the osteochondral unit using polycaprolactone (PCL) and gelatin methacrylate (GelMA) for bone and cartilage inks, respectively. The COMSOL model simulated the effect of lateral shear force during articulation. This was then validated in vitro using mechanical shear analysis of printed samples.[4] For complex extrusion printing, GelMA Type B was synthesized and dissolved at 5% w/v in PBS with a photoinitiator. Both casted and printed samples were imaged post-fabrication, then treated with varying concentrations and molecular weights of poly-L-lysine to induce shrinking behavior via complex coacervation-like mechanisms.[5] After treatment, hydrogels were imaged again to observe resolution enhancement.

Computational results broadly demonstrate the ability to predict printed scaffold mechanical properties, specifically that interlocking interfaces have the potential to redirect shear-induced stresses from a single tissue to the entire interface. Extrusion printing allowed complex, multiphase tissues to be constructed and demonstrated that charge-induced shrinking could fabricate microscale periosteal tissue and a macroscale bone composite. Bioprinting allows for the generation of heterogenous bone tissue interfaces with relative ease. Using pre- and post-printing biofabrication approaches, tissue interface mechanics, design, and cellular crosstalk can be readily controlled.

Investigating the Use of Seaweed-Derived Materials to Replace Single-Use Plastics MehranJ. Umerani; Loliware, United States

Seaweed has a rich history of diverse applications across the food industry, agriculture, medicine, cosmetics, biofuel, and single-use plastic replacements. This presentation aims to demonstrate the utility of injection molding to produce high-performing parts from seaweed-derived resins. Our resins have been optimized to possess excellent flow and mechanical properties comparable to those of standard plastics, making them a practical substitute for conventional petroleum-derived materials. Additionally, our ongoing research explores the application of machine learning algorithms and traditional formulation methods to facilitate high-throughput systematic design of new seaweed-derived biomaterials with improved mechanical and chemical properties. Finally, the sustainability aspect of seaweed-derived alternatives to single-use plastics will be discussed, emphasizing the potential of our approach to offer environmentally-friendly options in lieu of traditional plastic materials.

Predicting Hydrolase Mechanism for Sustainable Polyester Degradation IvanF. Jayapurna, ArielWang, SanjanaGurram and TingXu; University of California, Berkeley, United States

Enzyme catalyzed degradation is a promising approach to mitigating plastic pollution. However, finding suitable enzyme catalysts remains a challenge. Aside from sufficient substrate compatibility, one key consideration is enzyme mechanism, which the environmental impact depends on. An enzyme performing random scission leads to incomplete degradation from crystallinity induced recalcitrance as well as faster microplastic generation, whereas chain end scission results in degradation to naturally decomposable small molecules. Furthermore, when enzymes are nanoscopically embedded within the plastic matrix, a processive mechanism generates a chain slide motion that can lead to the degradation of amorphous and crystalline regions alike. As such, finding enzymes with chain-end, processive mechanism for a given polymer system can be the key to unlocking complete polymer degradation. Here, we investigated the catalytic activity and mechanism of 10 hydrolases on polycaprolactone (PCL). Surface and enzyme-embedded PCL degradation studies and degradation product analysis yielded 4 enzymes with no activity towards PCL, 3 with random PCL scission, and 3 with chain-end PCL scission. Through binding pocket analysis, each hydrolase was labeled with key geometry, chemistry, and flexibility features, hypothesized to influence both degradation capability and mechanism. Molecular modeling was done in parallel to predict the potential for processive chain slide of polyesters in enzyme binding pockets. We found binding pocket polarity, binding pocket secondary structure composition, and evidence of chain-slide potential from molecular modeling to be highly correlated to experimentally determined degradation mechanism. A computational pipeline was developed to automate binding pocket analysis and molecular docking, and a database of hydrolases with reported PCL compatibility was screened *in silico* for degradation mechanism. The model and key features highlighted in this work are generalizable to other commercial polyesters. In addition, this model can also guide future works with applications in rapid screening, enzyme engineering, and general applicability to binding pocket analysis beyond plastic degradation.

10:30 AM EN03.15.03
Thermomechanical Properties of Hybrid Imine and Silica Based Vitrimers Jiun-YeuChang and JohnKieffer; University of Michigan-Ann Arbor, United States

The limited recyclability of thermosets poses a significant challenge for end-of-life disposal of these materials. Covalent adaptable network (CAN) materials, such as vitrimers possess reversible crosslinker chemistries. The mechanical properties of vitrimers at room temperature are comparable to those of thermosets. Vitrimers become malleable upon thermal or photonic stimulation, so they can be reshaped and recycled. However, vitrimers can exhibit undesirable creep or fatigue, especially at elevated temperatures. Therefore, we are pursuing a hybrid chemistry approach, where a portion of the organic dynamic crosslinkers is replaced with inorganic static crosslinkers to provide the desired thermomechanical stability. Catalyst-free polyimine vitrimer is synthesized from glutaraldehyde (GA) and bis[2-(3-aminopropoxy)ethyl] Ether (Di-Amine). The dynamic crosslinker is tris(2-aminoethyl)amine (Tris-Amine), of which various fractions are replaced with (3-Aminopropyl)triethoxysilane (APTES). Depending on its concentration, APTES can undergo polycondensation to form different-sized silica network fragments, but is always able to compatibly bridge between polyimine matrix segments by forming imine bonds, thus substituting permanent Si-O-Si bonds for dynamic bonds. Here we report on how the relative proportions of static and dynamic crosslinkers affect the hybrid vitrimers' viscoelastic properties, mechanical stability, shifts in the glass transition and topology freezing temperatures. We specifically focus on evaluating the tradeoff between weldability or self-healing capabilities and creep resistance as a function of the crosslinker type concentrations.

Hydrothermal Synthesis of Carbon Dots from Irish Seaweed and Seaweed Derivatives KarlijnHertsig, YungxiangLiu, SamO'Neill, AnnieRegan and PeterDunne; Trinity College Dublin, Ireland

Due to the increase in global renewable energy generation and the need for reduction in greenhouse gas emissions we find ourselves in the energy transition of the century wherein the demand for green, sustainable energy materials is rising. Carbon dots are considered a new and green nanomaterial, applicable for energy generation technologies, including photovoltaics.[1, 2] In this research the hydrothermal synthesis of carbond dots from seaweed and seaweed derivatives is explored.[3] The synthesis yielded photoluminescent carbon dots, however without control over photoluminescence behaviour. Increasing complexity of the precursor from simple sugars to complex sugars to seaweed biomass led to consistent photoluminescence behaviour, however less distinct. Typically, absorbance of 270 – 300 nm with emission 400 – 450 nm for excitation 350 nm was measured by UV-vis and photoluminescence spectroscopy. The carbon dots are unstable in solution resulting in aggregation and shifting/reduction of the absorbance over time; however, the photoluminescence behaviour is not impacted. Column chromatography with acetonitrile and water improved the photoluminescence behaviour by narrowing the emission peak. Lyophilisation made structural characterisation possible, which confirmed the carbon dots are amorphous. While practicing green chemistry, it is concluded the hydrothermal method is a viable method to synthesise quantum and carbon dots as functional nanomaterials to contribute to the development of renewable energy technologies contributing to the energy transition.

Femtosecond-Laser Direct Writing based Laser-Induced-Graphene (LIG) on Wooden Materials for Green Electronics Applications Han KuNam[1], DongwookYang[1], TongmeiJing[1,2], Truong-SonD. Le[1], YounggeunLee[1], Young-RyeulKim[1] and Young-JinKim[1]; [1]Korea Advanced Institute of Science and Technology, Korea (the Republic of); [2]China University of Petroleum, China

The importance of environmental sustainability has been on the rise, as issues like climate change and pollution continue to affect the planet. One area that has been heavily impacted by this trend is electronics manufacturing. In order to reduce the environmental impact of electronics production, researchers and engineers have been working to develop new materials and processes that are eco-friendly. One promising area of research is the development of green electronics, which use materials and manufacturing processes that are sustainable and environmentally friendly. To achieve green electronics, it is necessary to use precursors that are organic, inexpensive, and readily available. Additionally, the synthesis route must be economical and fast, and the resulting electronic materials must be suitable for low-cost manufacturing processes. Furthermore, the devices produced using these materials must be biocompatible and biodegradable. These criteria can be difficult to meet, but one class of materials that shows promise is wood-based materials. Wood is a renewable resource that is abundant, recyclable, and biodegradable. However, it is not a conductor, which limits its use in electronics. To overcome this limitation, researchers have been working on various methods for adding conductivity to wood such as carbonization or conducting materials coating. One of the most promising approaches is Laser-Induced-Graphene (LIG) formation technology, which was first introduced by the James Tour group in 2017. This technology uses Laser-Direct-Writing (LDW) to create graphene patterns on a variety of lignocellulosic materials, including paper, cork, potato skins, coconut shells, and leaves. Our group has confirmed that 3D porous LIG can be easily and quickly produced on wooden materials without special treatment in the air by ultrashort pulse laser irradiation. In this work, we report on high-quality Laser-Induced-Graphene formation on wooden materials in ambient air for green electronics applications using a femtosecond laser with a 1040 nm wavelength, 250-fs pulse width, and 200 kHz repetition rate. A Galvano scanner with a maximum 2,000 mm/s scanning speed is used for laser patterning. Various combinations of beam scanning speeds, laser power, and beam-line spacings are delivered onto natural and recycled wooden materials to optimize LIG quality. The lowest sheet resistance of LIG electrode achieved is 2.8 Ω/sq., and its properties are analyzed using scanning electron microscopy (SEM), thermogravimetric analysis (TGA), X-ray diffraction (XRD), X-ray photoelectron spectroscopy (XPS), and Raman spectroscopy. The LIG electrodes are applied for green electronics in smart homes or smart furniture, such as heaters, temperature sensors, and touch sensors. Furthermore, we demonstrate that interconnecting LIG electrodes can be made by irradiating the laser after physically combining two different wood blocks without any special chemical treatment. Additionally, the LIG touch sensor can easily control the heater and computer by synchronization. These technologies can be easily adapted to smart green homes or smart green furniture applications.

11:15 AM EN03.15.06
Multidimensional Control and Tunability of Cholesterol Structures in Hydroxypropyl Cellulose Gels with Polyethylene Glycols LuyaoHuang and HongliZhu; Northeastern University, United States

Structural color is an intriguing phenomenon generated by changes in assembly structure and the interaction of light. Biological structural colors assembled from natural polymers are excellent resource for biomimetic design and green construction. Hydroxypropyl cellulose (HPC) is a renewable, non-toxic, biodegradable cellulose derivative whose solution generates a stable cholesterol liquid crystal structure with vivid structural color. In our study, we first explored the potential of three polyethylene glycols (PEGs), each with distinct end groups, for conducting multidimensional control of cholesterol structures derived from HPC. Our observations reveal that when tetraethylene glycol dimethyl ether (TEG-DE), di (ethylene glycol) ethyl ether acrylate (DEG-EEA), and diethylene glycol-diacrylate (DEG-DA) are incorporated, they cross-link with HPC, eliciting varying degrees of red-shift in the resultant HPC gels. Among them, the HPC gel incorporating DEG-DA, which contains two ester bonds, exhibits a dark red hue, whereas the HPC gel with DEG-EEA that carries one ester bond takes on a red color. Conversely, the HPC gel that includes TEG-DE, possessing a single ether bond, displays a yellow-green color. This reveals an intriguing pattern of color variance dependent on the molecular bonding within the gel system. This implies that color recognition information could be shifted swiftly and continuously in a gel system with variable polarity. As a result, we propose an approach for the homogenous alignment of cholesterol structures based on electrostatic repulsion and hydrogen bonding forces. Especially, the integration of diverse terminal group polymers increases the flexibility of the composite system. Consequently, HPC/PEG gels have a wide range of applications.

1:30 PM EN03.16.01
Use of Variable Frequency Microwave Heating to Chemically Recycle Polymer Composites YoungsuShin[1], PrekshaVichare[1], AnthonyEngler[1], JaredSchwartz[1], BradH. Jones[2] and PaulKohl[1]; [1]Georgia Institute of Technology, United States; [2]Sandia National Laboratories, United States

Microwave heating is advantageous for the chemical recycling of plastics due to its rapid, selective, and volumetric heating capabilities that can help reduce process times and improve energy efficiency. Unfortunately, the use of fixed frequency microwave heating leads to strict operational limitations that promote two popular approaches for processing post-consumer plastics: 1- Solid state pyrolysis with strong microwave absorbers to recover oils, gases, and carbon, and 2- solvolysis of the polymer to recover monomeric derivatives. While solvolysis recovers high-value monomers, the use of solvents reduces its energy efficiency compared to pyrolysis. Our group investigated the use of variable frequency microwave (VFM) heating to achieve rapid thermal depolymerization of polymer composites in their solid states back to their corresponding monomers, including polyphthalaldehyde, polyhydroxyalkanoates, poly(propylene carbonate), and nylon-6. The degradation of the polymers with the additives has been achieved and confirmed by nuclear magnetic resonance and gel permeation chromatography. A wide range of additives was also investigated to select the best performers for microwave heating at low energy. Carbon nanotubes, carbon nanofibers, carbon black, graphene, and reduced graphene oxide were down-selected for further investigation by incorporating the materials into different polymer matrices. Overall, the use of VFM energy aids in the volumetric heating and selective depolymerization of the polymer composites at fast heating rates. The results of these VFM studies can be broadly applied to the chemical recycling and monomer recovery of polymers.

Blue Plastic: The Use of Seaweed-Based Materials to Replace Single Use Plastics VictoriaPiunova; Loliware, United States

The use of seaweed has a long history, particularly in food applications. However, its versatility has extended its applications in industries such as fertilizers, medicine, animal feed, cosmetics, biofuel, and even single use plastic replacement. This presentation will discuss synthetic and formulation strategies which enables transformation of traditional hydrophilic natural materials into robust yet readily biodegradable resins that can be processed using conventional plastic processing techniques like extrusion, injection molding and thermoforming. Commercial viability of seaweed-derived single use plastic analogs and sustainability score are also reviewed.

2:15 PM EN03.16.03
Upcycling Virgin and Waste Polyolefins to Reprocessable Dynamic Covalent Networks LoganFenimore[1], BoranChen[1], StephanieBarbon[2], HayleyBrown[2], EvelynAuyeung[2], ColinLi Pi Shan[2] and JohnTorkelson[1]; [1]Northwestern University, United States; [2]The Dow Chemical Company, United States

Plastics enable modern life through their advantageous properties and broad applicability. Regardless of their type or use, plastics are challenging to recycle efficiently. Current methods for recycling spent thermoplastics such as re-extrusion with additives result in property degradation over time and the relegation of these downcycled polymers to low-value applications. Plastics may be permanently cross-linked into thermosets, yet permanent cross-links prevent these plastics from being processed and molded into new shapes at high temperature. An emerging avenue to mitigate these sustainability problems involves enriching waste plastics with dynamic covalent bonds as chemical cross-links. By introducing dynamic covalent cross-links, previously thermoplastic materials exhibit robust mechanical properties characteristic of conventional thermosets yet maintain their reprocessability at high temperatures. Not only can the incorporation of dynamic bonds be achieved during polymer synthesis to produce reprocessable step-growth networks like polyurethanes and addition-type networks like polymethacrylates, but also it can be achieved via post-polymerization modification to upcycle spent polyolefins for higher value applications. Using reactive batch processing, we upcycled various virgin and waste polyolefins

(e.g., low-density and high-density polyethylene, random and multiblock ethylene/1-octene copolymers, etc.) into covalent adaptable networks (CANs) via melt-state, free-radical grafting of a cross-linker capable of dynamic dialkylamino disulfide (BiTEMPS) chemistry onto polymer chains. Unlike ethylene-based thermoset polymers, our ethylene-based CANs are reprocessable and recover their thermomechanical properties after reprocessing via successive compression molding cycles. We have further shown that, in the absence of crystallinity, high-temperature creep and stress relaxation behaviors of the CANs are dominated by the exclusively dissociative reversible dynamic chemistry of the cross-linker. This observation also demonstrates the utility of this dissociative dynamic chemistry of high activation energy at suppressing creep in networks exhibiting different viscoelastic behavior.

3:00 PM *EN03.17.05
Compostable and Biodegradable Organic Electronics ClaraSantato; Ecole Polytechnique de Montreal, Canada

Natural organic materials (NOM) are relevant for biodegradable electronic devices and their powering elements (e.g. batteries). Biodegradation at the device's end-of-life is expected to cause a decrease in the portion of e-waste which is poorly managed/landfilled (and as such causing damage to health and the environment).

In this contribution we will discuss *the molecular and supramolecular properties of NOMs (e.g. melanins and tannins), their complex chemical composition (due to biosynthesis) and their charge transfer and charge carrier transport properties, which underpin their use in electronic devices and their powering elements. We will report on compostability studies of transistors and supercapacitors based on NOMs, performed following the experimental conditions indicated by international industrial standards. Finally, we will try to propose guidelines (i) to design NOMs for biodegradability in terms of molecular disassembly and exfoliation of supramolecular NOM aggregates and (ii) to eco-design biodegradable electronic devices based on NOMs.*

3:30 PM *EN03.17.01
Transient Devices Developed using Lithography-Free Patterning of Nanoscale Electronic Layers AbhishekS. Dahiya and RavinderDahiya; Northeastern University, United States

Lithography-free patterning of nanoscale (nanowire (NW)) electronic layers at pre-selected locations offers opportunities to realise transient or degradable electronics in a resource efficient manner. The major advantages being: (i) reduced dependency on inherently wasteful conventional fabrication processes (e.g., photolithography and etching), (ii) negligible chemical wastage, (iii) compatibility with large area electronics, (iv) possibility of having electronic layers based on richer materials system, and (v) low-cost. Herein, we present lithography-free NW patterning techniques namely, '*in-tandem contact-transfer printing*' and '*selective-removal*' and the transient devices developed using them. In the in-tandem approach, firstly, the contact printing is used to print laterally aligned NWs on an intermediate substrate to obtain uniform electronic layers. Then, modified transfer printing is employed to selectively remove and print the electronic layers on the final device substrate. In the other approach (selective-removal), contact printing is performed to obtain highly aligned NW structures directly on to device substrate and then NWs are selectively removed from a uniformly contact printed electronic layer using an elastomeric stamp. The removal efficiency is improved by evaporating a thin layer of water onto its patterned face, which greatly enhances the stamp-NW adhesion via the capillary action. The above approaches are used to develop proof-of-concept transient devices such as NW-based transistors and photodetectors on rigid (Si/SiO_2), flexible (polyimide), and biodegradable (magnesium (Mg) foils) substrates. The developed photodetectors on Mg foil can physically disintegrate and dissolve in 240 days in deionized (DI) water (pH ≈6) at room temperature. The developed lithography-free NW patterning techniques has potential for eco-friendly manufacturing of electronics with significantly lower the electronic-waste.

4:00 PM EN03.17.02
Printability and Electrical Response of Biopigments on Paper CamilleBour-Cardinal, AnthonyCamus and ClaraSantato; Polytechnique Montréal, Canada

Natural organic materials are relevant for the eco-design of biodegradable electronic devices and their powering elements (batteries). Printing natural organic materials on paper offers the possibility to compost electronic devices. Printed paper electronics enable to alleviate the accumulation of Electrical and Electronic Equipment Waste (E-waste) which has harmful effects on human health and the environment[1].
Sepia melanin is one of the natural forms of Eumelanin (the black-brown member of the melanin family of biopigments). It is extracted from *Sepia Officinalis* natural ink. Melanins are ubiquitous in nature; they are key to diverse bio-functions in fauna and flora. Sepia melanin is mainly constituted of 5,6-dihydroxyindole and 5,6-dihydroxyindole-2-carboxylic acid monomers that, after steps of hierarchical development, brings about a material featuring nanometric granular structure. Recently, printed films including Sepia showed predominant electronic transport[2-3].
We focus on the printability on paper and electrical response of the *Sepia Officinalis* natural ink. *Kromekote* paper substrates are pre-patterned by flexographic printing with a silver-based aqueous ink, to generate electrode pairs (interelectrode distance about 100 µm). The interface between the ink and the paper is studied considering: (i) paper rugosity, porosity, and air permeability, (ii) ink rheology and wettability, (iii) tensile, rigidity, tear and burst tests, on paper before and after printing. The current-voltage (I-V) and potentiostatic (I-t) characteristics were carried out for applied electrical biases ranging between 0.1 V and 10 V and different voltage sweeping rates (1 - 500 mV/s), in controlled atmosphere (dry, wet, and ambient conditions). Preliminary results show that the conductivity and stability of the devices are remarkable. Work is in progress to discover the chemical composition of the biosynthesized Sepia. Our efforts pave the way towards greener and more sustainable electronics.

Self-Healing, Stretchable and Recyclable Electronics FabioCicoira; Ecole Polytechnique de Montreal, Canada

The ability of certain materials to regenerate after damage has attracted a great deal of attention since the ancient times. For instance, self-healing concretes, able to resist earthquakes, aging, weather, and seawater have been known since the times of ancient Rome and are still the object of research.
While the field of mechanically healable materials is relatively established, self-healing conductors are still rare, and are nowadays attracting enormous interest for applications in electronic skin for health monitoring, wearable and stretchable sensors, actuators, transistors, energy harvesting, and storage devices, such as batteries and supercapacitors. Self-healing can significantly enhance the lifetime of conducting materials, leading to the improved environmental sustainability and reduced costs.
Conducting polymers exhibit attractive properties, such as mixed ionic-electronic conductivity, leading to low interfacial impedance, tunability by chemical synthesis, ease of process via solution process and printing, and biomechanical compatibility with living tissues, which makes them ideal materials for bioelectronics and stretchable electronics. However, they show typically poor mechanical properties and are therefore not suitable as self-healing materials. Self-healing conductors can be achieved upon mixing with other polymers, such as poly(vinyl alcohol) (PVA), poly(ethylene glycol) (PEG) and polyurethane (PU), which provide the mechanical characteristics leading to self-healing.
Self-healable and recyclable conducting materials are central in the field of electronics due to their potential to address two major challenges: sustainability and durability. Electronic waste is a growing concern worldwide, as the rapid pace of technological innovation has led to a high turnover rate of electronic devices, resulting in the accumulation of a significant amount of electronic waste. Self-healable and recyclable conducting composites have the potential to reduce electronic waste by enabling the repair and reuse of electronic components, which can extend the lifespan of electronic devices. Furthermore, electronic devices are often subject to mechanical stress, which can cause damage to their components, including conducting materials.
My talk will deal with self-healing materials obtained blending PEDOT:PSS with other materials, such as polyethylene glycol (PEG), tannic acid and polyurethane. Various self-healing modes will be presented and correlated with the electrical and mechanical properties of the materials. The use of the self-healing gels and films as epidermal electrodes will be also presented.[1-8] We will finally discuss rechyclable conducting composites based on PEDOT:PSS-PU blends.

Manufacture of Biodegradable Electronic Sensors Systems using Additive Manufacturing JeffKettle, JonathonHarwell, AndrewBainbridge and RudraMukherjee; University of Glasgow, United Kingdom

The world's ever-increasing demand for high performance electronics will inevitably result in a growing problem of waste as products reach the end of their lifetimes. The "tsunami of electronic waste" (e-Waste), which reached more than 53.6 million tonnes in 2019, requires a step-change in the design and fabrication of electronics for disposal, reuse or recycling. The issue is exasperated as during the manufacture of electronics, a significant amount of chemical waste is generated as by-products, and the combined impact of by- and end-products is leading to long term environmental and social damage that will outlast many generations. As electronics underpins a lot of future ICT including smart packaging, internet of things (IoT), displays (inc. VR/XR), smart packaging), the e-Waste issue needs to be resolved by realising electronic systems that inherently have end-of-life (cradle to cradle) solutions built in and thus do not require the same complexity of waste management. To this end, this challenge requires a new approach in the manufacture of electronic devices that emphasises low material use and makes end-of life recycling and disposal as simple and environmentally friendly as possible, while also keeping up with the difficult performance metrics required for operating modern devices.

The use of biodegradable materials is on the rise as practical difficulties related to e-waste requires greater attention. A large proportion of a Printed Circuit Board Assembly (PCBA), goes directly to landfill or incineration. It is feasible to recycle PCBAs as shown in several papers and there are many businesses recycling of e-waste. However, it is not a straightforward process. Consequently, the use of electronic materials that are more easily repurposed or recycled are being considered for future electronic systems. Most academic work on such electronics so far has focused on metal oxide or organic semiconductors, however, the modest performance offered by such materials, would not satisfy the demands of current consumer electronics.

In this talk, we will report on the development of new manufacturing platforms that offer a viable alternative to conventional silicon-based devices. Firstly, we have demonstrated fully biodegradable thin-film transistors (TFTs) arrays of up to 200 TFTs based on zinc oxide (ZnO) active layer using molybdenum (Mo) source, drain, and gate electrodes. The developed TFTs show a low positive threshold Voltage, a high average field-effect mobility in the saturation region and show stable device performance under stability tests. These have been used to make logic circuits (inverter and both NAND and NOR gate circuits) and simple memory devices such as SRAM cells. However, as mentioned, the performance is limited by the semiconductor, so a new additive manufacturing technique based on inkjet printing and hybrid ultrathin silicon and metal oxide devices is demonstrated and we show that the biodegradable devices and circuits can match conventional circuit boards on key metrics such as switching speed, level of integration and power consumption. We demonstrate the effectiveness of this process by producing a flexible and biodegradable Integrated circuits and use this to power a sensor array for agricultural applications for measuring pH and temperature.

Finally, we perform a detailed life cycle assessment of devices made using this method and compare their environmental impact to conventional ICs and PCBAs. We find that the reductions in material use and minimised end-of-life footprint can more than offset the costs associated with the increased complexity of manufacturing required by our process. We hope these results will show the potential of how new approaches in device production can greatly enhance the sustainability of electronic products.

Natural Dielectrics for Bio-Organic Electronics MihaiIrimia-Vladu; Johannes Kepler Universität Linz, Austria

Organic electronics has an immense potential for the development of products that are both sustainable and environmentally friendly. In this presentation, a large list of natural origin dielectric materials is introduced and demonstrated in the fabrication of organic field effect transistors, e.g. *resins, gums, waxes, alkaloids, nucleobases, natural oils and fats, lignins and celluloses, natural scents, natural clays, etc.* Apart for their outstanding dielectric and film forming properties, most of the above-mentioned natural dielectrics are inherently, biocompatible (even edible) and have well known medical properties. Thus, this class of dielectrics may find suitable applications in the branches of science where dielectric materials are part of bio-integrated electronics.

Study on Photodegradation and Encapsulation of Organic Thermochormic Polymers Sushant MadhukarNagare; University of South Florida, United States

With the increase in temperature urban areas face issues like Urban heat islands. The reduction of green vegetation across the urban areas has led to tremendous increase in temperature. Many studies suggest major cities are currently experiencing this issue to a greater extent. Many researchers are working on building paints and dyes to reduce the heat intake done by the building. Organic thermochromic polymers are one such alternative for building dye and paint. The main issue with using the organic thermochromic polymer is that they easily degrade under sunlight which makes them less useful as building color. To overcome this issue many organic thermochromic materials are encapsulated with inorganic materials such as metal oxide which are used to block sunlight and reduce the effect of degradation. With upcoming research in the area, it came to the observation that even though metal oxide is used to reduce the block of the UV wavelength, another spectrum of light rays still affects the organic material and photodegrades them. The 1st part of the paper deals with the microencapsulation method with different surfactant concentrations, different metal oxides, and multi-system encapsulation. The 2nd part deals with testing of the desired material to determine the effect of photodegradation. Different techniques such as SEM, EDS, FTIR, UV Vis, and CIE lab are used to determine.

Investigating the Potential of Starch Bioplastic as a Precursor for Laser-Induced Graphene Synthesis: A Sustainable Approach Anna ChiaraBressi[1,1], AlexanderDallinger[2], SreenadhT. Sankaran[1,1], HildaGomez Bernal[1,1], AttilioMarino[3], HanaHampel[2], GianniCiofani[3] and FrancescoGreco[1,2,1]; [1]Sant'Anna School of Advanced Studies, Italy; [2]Graz University of Technology, Austria; [3]Istituto Italiano di Tecnologia, Italy

Laser-induced graphene (LIG) has emerged as a groundbreaking technology for the conversion of carbon-rich precursors into electrically conductive materials, which exploits commercially available IR laser engravers to induce localized pyrolysis on a wide range of materials. While synthetic precursors initially caught the interest of the scientific community, the need for more sustainable options has shifted the focus to their bioderived counterparts. Among these alternatives, starch bioplastic is of particular interest, since it represents half of the commercially available bioplastics, owing to its straightforward production process and satisfying mechanical properties. In light of these considerations, our study aims to explore the potential of starch bioplastic as a promising precursor for LIG.
A case study on a self-crafted starch-based bioplastic was investigated. The bare biopolymer consists of starch powder, acetic acid, deionized water and glycerol. Initial attempts at converting it into LIG were unsuccessful, resulting in mere ablation upon laser scribing. Instead, the addition of up to 5 wt.% of iron nitrate $Fe(NO_3)_3 9\bullet H_2O$ allowed to induce the carbonization of the precursor. As shown by thermogravimetric analysis, the iron nitrate indeed improved the thermal stability at elevated temperatures (> 600 °C), a crucial requirement for LIG synthesis. Raman spectroscopy confirmed that the laser-induced carbon material owns the characteristic structural features of LIG (as evidenced by the presence of the typical D, G, 2D bands and the corresponding bands' intensity ratios $I_D/I_G \approx 1$ and $I_{2D}/I_G \approx 0.55$). Moreover, the quality of LIG improved with increasing nitrate concentration, ultimately achieving comparable properties to other bioderived and synthetic precursors for LIG. The addition of iron nitrate also had a significant effect on Young's modulus of the bioplastic, modifying it from ≈ 20 MPa to ≈ 1 MPa. The degradability of the precursor was tested in the soil to assess its suitability for transient electronics applications and almost complete degradation was reported after twelve days. The addition of iron nitrate did not show a clear impact on degradability; however, there is evidence that the presence of salt contributes to increased hygroscopicity, which is typically a significant parameter in promoting degradability. These findings demonstrate the validity of our approach and open the path to further analyses and characterization in real-life applications, paving the way for sustainable and efficient methods for patterning conductive tracks.

8:40 AM EN03/EN06/EN08.04
Sustainable Composites from Almond and Hazelnut Shells for Green Laser-Induced Graphene IuliiaSteksova[1,1], Anna ChiaraBressi[1,1] and FrancescoGreco[1,2,1]; [1]Scuola Superiore Sant'Anna, Italy; [2]Graz University of Technology, Austria

Recently, the scientific community has been focusing on processing and further use of biomass in various fields. In particular, the use of biowaste for green electronics applications has an impressive number of advantages, such as low cost, low density, non-toxicity, biocompatibility, and biodegradability. Within the framework of this study, almond shell powder (ASP) and hazelnut shell powder (HSP) were used as the main component for creating biowaste-based composites. The high lignin content of the shells increases the thermal stability of the composites, making them an ideal precursor for Laser-Induced Graphene (LIG).
LIG is a three-dimensional porous and conductive carbon structure obtained via localized pyrolysis by irradiation with a CO_2 IR laser. LIG synthesis and patterning is a cost-effective one-step process that allows to avoid the use of chemicals and the need for long-term use of high temperatures.
Depending on the precursor composition, the quality and properties of LIG can vary. Among biomasses, chitosan is of great interest for the development of sustainable polymers, mainly due to its low cost and complete biodegradability, thus it was adopted as a matrix for ASP and HSP composites. These materials were prepared by mixing shell powders, glycerol and chitosan dissolved in acetic acid, with specific ratios. Optimization of the shell concentration has been carried out to obtain the best trade-off between good mechanical (i.e., flexibility and stiffness) and electrical properties.
We obtained flexible and strong composites with a high content of ASP and HSP (Young's modulus = 25.4 MPa), which served as good precursors for the creation of LIG with a low sheet resistance (≈ 10-100 Ω/sq, depending on the specific composition and laser settings used). An investigation of the obtained materials' structure and composition has been carried out by means of SEM and Raman spectroscopy, which showed the typical graphene features and thus confirmed the successful conversion of the composite biowaste precursors into conductive LIG.
These results are a step towards green LIG for electronics applications starting from ASP and HSP, two low-value waste products which are produced in huge quantities in the agri-food industry and open a path for future studies on the topic.

8:45 AM EN03/EN06/EN08.05
Filler Surface Induced Heterogeneous Nucleation of Polymer Crystals DominicWadkin-Snaith, PaulA. Mulheran and KarenJohnston; The University of Strathclyde, United Kingdom

Switching from non-degradable to compostable plastics can help to reduce global plastic pollution. However, to use compostable plastics in food packaging films, properties including mechanical strength and gas barrier must be optimised. These properties depend on the crystallinity and microstructure of the plastic film, which can be modified by adding filler particles, which act as nucleants for polymer crystallisation [1]. In order to select appropriate fillers, it is necessary to understand the polymer-filler interface.
We use a modified Kremer-Grest polymer model [2] to study crystal nucleation of 20-bead chains. Filler surfaces are modelled using a Lennard-Jones 9-3 potential. The system is cooled from the melt using an NPT ensemble, and the crystal fraction is estimated from straightening of chain segments. Polymer nucleation was observed to occur at the surfaces. Interestingly, this polymer model does not crystallise in simulations without the surfaces. The dependence of crystallisation on the surface-polymer interaction strength, the polymer chain stiffness, and cooling rate will be presented and rationalised in terms of free energy changes. The addition of plasticiser and its effect on nucleation and growth will also be explored. This work provides insight into how filler surfaces can be used to control polymer crystal nucleation and growth, leading to the design of compostable plastics with desired properties.

This work was funded by the Innovate UK Smart Sustainable Plastic Packaging grant (NE/V010603/1). Results were obtained using the ARCHIE-WeSt High Performance Computer (www.archie-west.ac.uk).

Substituting the Epoxy Curing Agent with a Greener Solution-Towards Sustainability NachiketS. Makh[1], AjitD. Kelkar[2] and LifengZhang[1]; [1]Joint School of Nanoscience and Nanoengineering, United States; [2]North Carolina A&T State University, United States

In past two decades, the field of polymer composite materials has gained significant advancements transforming various industries and applications. These polymer composites are comprised of polymer matrix and reinforcing material. The matrix is responsible for providing resistance to impact, wear, and corrosion. The reinforcements like fibers, particles or fillers are usually used for enhancing the material properties. The polymer matrix is made up of two fundamental components, the epoxy resin and the hardener (curing agent). The conventional resins and hardeners are produced by chemical and petroleum industries. These industries make use of non-renewable energy resources like fossil fuels for manufacturing the resins and curing agents. The ever-rising environmental issues have raised sustainability concerns over using fossil-fuels. In addition, most of the conventional curing agents used in epoxy resins are highly noxious in nature. Studies have shown that these curing agents are capable of causing skin allergies and asthma. Recently, the composite market has seen the origination of green epoxy resin that are capable of reducing these toxic effects but have few shortcomings including its cost and the mechanical performance of cured epoxy resin. On the other hand, there is dearth in investigating the evolution of green or sustainable curing agents known as bio-binders. This paper presents the prediction of mechanical properties by replacement of conventional curing agent with amine derivative synthesized from bio-degradable resource in a thermoset epoxy resin system. The properties are predicted by molecular dynamics simulations using Materials Studio Software. The research showed promising outcomes without the loss of mechanical properties in comparison to the conventional epoxy resin and hardener.

9:15 AM EN03/EN06/EN08.07
Extraction and Characterization of Nanocellulose from Sources of Residual Biomass RocíoHernández Leal[1], Silvia BeatrizBrachetti Sibaja[1], Aidé MinervaTorres Huerta[2], Miguel AntonioDominguez Crespo[2] and Mario FidelGarcía Sánchez[3]; [1]Tecnológico Nacional de México, Mexico; [2]Instituto Politécnico Nacional, Mexico; [3]UPIITA-Instituto Politécnico Nacional, Mexico

The nanocellulose obtained from biomass of agroindustrial wastes: sugarcane bagasse (SCB), banana pseudostem (BPS) and aloe vera bagasse (AVB), allows to reduce the large amount of waste and the environmental impact generated during the industrialization processes of these raw materials, their lignocellulosic characteristics make these wastes attractive for the extraction of nanocellulose with novel chemical characteristics on a nanometric scale that allows its properties to be improved and used in specific fields such as biomedicine. The extraction and characterization of nanocellulose with acid hydrolysis at 45, 55 and 65 %v/v H2SO4, at different time spans (30 and 60 minutes) and different temperatures (25, 40, 45 and 50 °C). The raw materials and the obtained cellulose and nanocellulose were characterized by: Fourier transform infrared spectroscopy (FTIR), to identify the characteristic functional groups; X-ray diffraction (XRD), to study the crystalline structure; dynamic light scattering (DLS), to determine hydrodynamic radius of the nanocellulose particles; and, finally, scanning electron microscopy (SEM), to analyze the morphological features of the cellulose and nanocellulose. The FTIR spectra revealed the elimination of absorption bands characteristic of lignin and hemicellulose. From XRD results, the presence of the different polymorphs of cellulose I alpha, I beta and II was identified. From dynamic light scattering, the hydrodynamic radius of the cellulose obtained from each agroindustrial wastes biomass was determined, with values less than 110 nm. After the obtained results in this study, it can conclude that nanocellulose from biomass of agroindustrial wastes: sugarcane bagasse (SCB), banana pseudostem (BPS) and aloe vera bagasse (AVB), can be regarded as a greener and sustainable industrial waste for the preparation of cellulose nanofibers.

9:30 AM EN03/EN06/EN08.08
Morphology Control and Performance Enhancement of MOF-Derived 3D Amorphous Carbon Nanowires for High-Performance Lithium-Ion Batteries LinruiL. Duan, HongtaoSun and HaoqingYang; The Pennsylvania State University, United States

The utilization of MOF-derived amorphous carbon-based materials in lithium-ion batteries (LIBs) has shown great promise due to their remarkable gravimetric capacity and cycle stability. However, achieving precise control over morphology during the transformation process from MOF to carbon derivatives remains a significant challenge in obtaining electrode materials with superior rate performance and capacity retention under long cycles and high current densities.
In this study, we present a novel approach to derive the Al source for Al-MOF from an eco-friendly and cost-effective by-product AlCl3 solution obtained through the Al-Si dealloying process. We introduce, for the first time, a 3D amorphous carbon nanowires (3D ACNWs) structure with interconnected networks derived from sub-micron brick-like crystal Al-MOF using a facile and template-free method. Compared to the crystal Al-MOF, the 3D ACNWs exhibit effective suppression of the porous structure's instability during multiple insertion and extraction cycles of Li+ ions, along with improved electrical conductivity following the phase transformation from MOF to carbon-based materials. Moreover, the 3D ACNWs, with their interconnected network structure, provide abundant active sites for lithium storage and enhanced pathways for electron and Li+ ion transfer, unlike most reported 0D morphology MOF-derived carbon derivatives.
Benefitting from these unique features, the 3D ACNWs anode demonstrates a high reversible capacity of 400 mAh/g at 1.0 A/g after 1000 cycles, with an ultra-high-capacity retention rate of 101.8%. Furthermore, it exhibits excellent rate performance under high current densities. The evolution mechanism reveals that the 3D interconnected amorphous carbon nanowire networks, with their well-developed porosity, facilitate rapid storage and transportation of electrons and Li+ ions through specialized channels. This work represents a significant advancement in tailoring the morphology of MOF-derived carbon materials, unlocking their full potential as electrode materials for practical energy storage devices.

SESSION EN04.01: Perovskite Solar Cell Efficiency
Session Chairs: Kunal Datta and Monica Lira-Cantu
Monday Morning, November27, 2023
Hynes, Level 3, Room 300

10:30 AM *EN04.01.01
The Role of Materials and Interfaces in the Stability of Perovskite Solar Cells Nam-GyuPark; Sungkyunkwan University, Korea (the Republic of)

Since the seminal work on a 9.7% efficient solid-state perovskite solar cell in 2012, its power conversion efficiency (PCE) reached over 25% within a decade. Although PSCs demonstrated a high PCE comparable to silicon solar cells, stability is still the remaining issue. In order to improve substantially the stability of PSCs, perovskite materials and interfaces should be carefully manipulated. In this talk, the importance of crystal facets and interfaces is emphasized in improving stability. We found that moisture stability depends on crystal facets. Among the three facets of (100), (110) and (111) in $FAPbI_3$ film, the (100) facet was found to be unstable but the (111) facet was quite stable under moisture. Experimental combined with theoretical studies revealed that a crystal facet with moisture instability provided a strong water adhesion via the hydroxylation of Pb atoms, leading to phase transformation. Perovskite films with abundant moisture-tolerant (111) facets were successfully prepared via additive engineering, which showed exceptional stability against moisture without additional surface passivation. A buried interface with homojunction was found to play a critical role in the stability of PSCs. A band alignment via interface engineering led to leveling off the work function at the homojunction, which improved stability significantly.

11:00 AM EN04.01.02
Relaxation of Externally Strained Halide Perovskite Thin Layers with Neutral Ligands Sang-GeunJi[1] and HanulMin[2]; [1]Ulsan National Institute of Science and Technology, Korea (the Democratic People's Republic of); [2]Korea University, Korea (the Democratic People's Republic of)

In solution-processed halide perovskite thin films, an external strain can be generated owing to the anisotropy of solvent volatilization through the thin film surface and the mismatch of thermal expansion with the substrate. Furthermore, the addition of methylammonium chloride to a formamidinium lead triiodide ($FAPbI_3$) precursor solution to increase the crystallinity and form α-$FAPbI_3$ at low temperatures also induces the preferred orientation (PO) of the perovskite layer. However, excessive PO can cause anisotropic strain in the thin film, increasing defects, widening the band gap, and reducing long-term stability. As a way to alleviate this, a perovskite thin film was deposited by adding trioctylphosphine, a neutral ligand, to the $FAPbI_3$ precursor solution. As a result, perovskite solar cells (PSCs) based on these perovskite thin films exhibit an efficiency close to 25% with high stability, showing the highest value among PSCs using TiO_2 as an electron transport layer.

11:15 AM EN04.01.03
Controlled Growth of Perovskite Layers with Volatile Alkylammonium Chlorides JaewangPark, JongbeomKim and Sang IlSeok; Ulsan National Institute of Science and Technology, Korea (the Republic of)

Controlling the crystallinity and surface morphology of the perovskite layers by methods such as solvent engineering and methylammonium chloride addition is an effective strategy for achieving high-efficiency perovskite solar cells (PSCs). In particular, it is essential to deposit an α–formamidinium lead iodide ($FAPbI_3$) perovskite thin films with fewer defects due to their excellent crystallinity and large grain size. Herein, we report the controlled crystallisation of perovskite thin films with the combination of alkylammonium chlorides (RACl) added to $FAPbI_3$. The δ– to α–phase transition of $FAPbI_3$ and the crystallisation process and surface morphology of the perovskite thin films coated with RACl under various conditions were investigated

through in situ grazing incident wide-angle X-ray diffraction and scanning electron microscopy. RACl added to the precursor solution was believed to be easily volatilised during coating and annealing owing to dissociation into RA^0 and HCl with deprotonation of RA^+ induced by RA…H^+–Cl^- binding to PbI_2 in $FAPbI_3$. Thus, the type and amount of RACl determined the δ– to α–phase transition rate, crystallinity, preferred orientation, and surface morphology of the final α–$FAPbI_3$. The resulting perovskite thin layers facilitated the fabrication of PSCs with a power conversion efficiency of 26.08% (certified 25.73%) under standard illumination.

11:30 AM *EN04.01.04
Efficient Perovskite Solar Cells *via* Enhanced Charge TransportJingbiYou; Chinese Academy of Sciences, China

Perovskite solar cells (PSCs) have witnessed great achievement in past 14 years, the power conversion efficiency is approaching its limitation. In this talk, I will talk our group progresses in efficient PSCs via enhanced charge transport. 1) By designing the interface between perovskite and hole transport layer, we have improved the hole transport efficiency and achieved over than 26% PSCs. 2) By modulating the transparent electrode/perovskite interface, the hole recombination in the device has been suppressed, and over than 25.5% inverted PSCs has been demonstrated.

SESSION EN04.02: Perovskite Solar Cell Stability

2:00 PM EN04.02.02
Regulating Interfacial Strain Improves the Stability and Efficiency of Perovskite Solar Cells Dong-AmPark, ChunyangZhang and Nam-GyuPark; Sungkyunkwan University, Korea (the Republic of)

Although perovskite solar cells (PSCs) demonstrated power conversion efficiency (PCE) as high as 26%, stability caused by the hetero-interfaces has been still issued. Since the thermal expansion coefficient of perovskite is about 30 times higher than the SnO_2-coated substrate, this difference can cause in-plane tensile strain at the interface of the perovskite and the SnO_2 layer during the annealing process. It should be therefore treated because the in-plane tensile strain is blamed for causing the instability of PSCs. We report here an effective methodology to regulate the strain via interfacial engineering using a functional molecule. The interfacial engineering changes the strain of the perovskite layer near the SnO_2 layer, which is confirmed by grazing-incidence X-ray diffraction. The strain-released perovskite film shows faster electron extraction from the perovskite to the SnO_2 as confirmed by the time-resolved photoluminescence. In addition, carrier lifetime is increased by a factor of two upon relieving the interfacial strain. Space charge limited current measurement quantifies trap density, where the strain-released perovskite (target) shows lower trap density than the control perovskite. As a result, PCE is increased from 22.47% to 24.33% mainly due to the improvements of open-circuit voltage from 1.14 to 1.17 V and fill factor from 80.3% to 83.8%. Moreover, 90% of initial PCE is observed after 950 hours for the target device, which is higher than that (70%) of the control one.

2:15 PMBREAK

2:45 PM *EN04.02.03
Indoor, Outdoor and *In-Situ* Characterization Strategies for Stable Perovskite Solar CellsMonicaLira-Cantu; Nanostructured Materials for Photovotlaic Energy, Spain

Halide perovskite solar cells (PSCs) have already achieved a certified power conversion efficiency (PCE) above 25 %, making them one of the most promising emerging photovoltaic technologies. One of the main bottlenecks towards their commercialization is their long-term stability, which should exceed the 20-year mark. Many are the strategies applied to extend device lifetime, among them are the use of additives, the optimization of the fabrication process of perovskite thin films or the replacement of unstable organic transport layers such as Spiro-OMeTAD. Although most of these approaches can effectively improve device efficiency, they frequently fail at providing stable PSCs as defined as those able to display less than 10 % degradation after 1000 h of continuous illumination under 1 sun. In this work we present our most recent work regarding the analysis of PSC stability. We carried out the fabrication of PSCs applying different strategies, such as additive engineering, interface modification or both and analyse our solar cell following ISOS protocols (Isos-D, ISOS-L and ISOS-O), as well as in-situ characterization. We demonstrate that adding organic additives and 2D interfacial modifiers to the PSC allows for the passivation of shallow or deep defects, having a tremendous impact on the device stability. Our studies are made under indoor and outdoor conditions as well as initial in-situ experiments. We expect that our work will have important implications for the current understanding and advancement of operational PSCs.

3:15 PM EN04.02.04
Photovoltaic Potential of Tin-Based Perovskites Revealed Through the Layer-By-Layer Investigation of Optoelectronic and Charge Transport Properties ArtemMusiienko[1], MahmoudHussein[1], MarinRusu[1], DavideRegaldo[2,3], GuixiangLi[4], ShengnanZuo[1], ChiaraFrasca[1], HannesHempel[1], JeanPaul[2,3] and AntonioAbate[1]; [1]Helmholtz Zentrum Berlin fur Materialien und Energie, Germany; [2]IPVF, France; [3]GeePs, France; [4]École Polytechnique Fédérale de Lausanne, Swaziland

Lead-based perovskite solar cells (LPSC) have garnered significant attention due to their exceptional optoelectronic properties and the potential to revolutionize the field of photovoltaics [1]. However, the widespread adoption of lead-based perovskites is hindered by their inherent toxicity [2], necessitating the urgent exploration of alternative materials. In recent years, tin-based perovskite solar cells (TPSC) have emerged as promising candidates for eco-friendly and efficient solar cell technologies [3].

Despite the rapid progress in the field of perovskite solar cells, a substantial knowledge gap remains regarding the charge extraction and recombination mechanisms in tin-based perovskites. Understanding and optimizing charge extraction processes are crucial for achieving high device efficiency and stability. In this contribution, we aim to shed light on the fundamental charge transfer mechanisms, energetic alignment, and recombination in tin-based perovskite solar cells and lead-based perovskite solar cell counterpart as a baseline.

To identify charge loss, we comprehensively investigated the entire charge transport pathway, starting from bulk diffusion to selective contacts, non-radiative and radiative recombination, and charge extraction. Initially, Hall effect and time-resolved photoluminescence measurements were conducted to determine the carrier lifetime, diffusion length, and doping levels. Furthermore, we examined the charge extraction capabilities of the most widely used electron transport layer (ETL) and hole transport layer (HTL) materials using time-resolved surface photovoltage measurements. Our findings revealed that PEDOT and C60 demonstrated the most efficient charge extraction for FASnI3 thin film. Additionally, photoelectron yield and Kelvin probe techniques were employed to precisely analyze the energy alignment of PEDOT and C60 selective contacts, revealing significant offsets for the ETL and HTL due to the shallow energetics of TPSC.

By integrating the comprehensive parameters obtained from our multimethod experiments, we simulated the charge transport in TPSC and identified the factors limiting charge transport, extraction, device current, and open voltage. Based on our results, we have developed strategies to enhance the efficiency, stability, and overall performance of tin-based perovskite solar cells. Specifically, we propose reducing the energy offsets of selective contacts from 0.4 eV to 0.1 eV, lowering the doping concentration of materials below 10^{15} cm^{-3}, increasing the charge extraction rate to 10^7 s^{-1}, and suppressing bulk and surface non-radiative recombination to achieve a value of 1 µs. In addition, we demonstrated that NPP layer stack is a more efficient architecture due to the large p-doping density. By surpassing these milestones, TPSC can potentially reach stable power conversion efficiency (PCE) values of 22%, similar to its LPSC counterpart.

Overall, this research provides valuable insights into the charge extraction and recombination mechanisms in tin-based perovskite solar cells, paving the way for the development of efficient and stable devices. Implementing the proposed strategies will contribute to the advancement of tin-based perovskite solar cell technology, bringing us closer to realizing their full potential for renewable energy applications. The findings presented in this abstract provide valuable insights into the field of perovskite solar cells and contribute to the ongoing efforts to accelerate the transition towards sustainable and non-toxic photovoltaic technologies. By addressing the knowledge gap surrounding charge extraction mechanisms in tin-based perovskites, we take a significant step towards realizing their full potential for efficient solar energy conversion and other optoelectronic devices.

Substitution of Lead with Tin Suppresses Ionic Transport in Halide Perovskite Optoelectronics KrishanuDey[1,2], PetraJ. Cameron[3], SaifulIslam[1] and SamuelD. Stranks[2,2]; [1]University of Oxford, United Kingdom; [2]University of Cambridge, United Kingdom; [3]University of Bath, United Kingdom

Despite the meteoric rise in the development of a variety of perovskite electronic and optoelectronic devices, the phenomenon of ion migration remains a common and longstanding Achilles' heel limiting their performance and operational stability. In particular, ionic transport under light and/or bias have been shown to result in current-voltage hysteresis, open circuit voltage gains and short circuit current losses in operating lead (Pb) perovskite solar cells. Despite several efforts in the literature to mitigate such effects through compositional and additive engineering, there is still a limited understanding on the role of tin (Sn) substitution on the dynamics of ion migration in Pb halide perovskite optoelectronic devices. This is of importance given the recent fast-paced developments in the fields of Sn and mixed Pb-Sn perovskite solar cells towards, among others, reduced-lead and tandem solar cell applications.

In this work, we systematically study the impact of Sn substitution on the ion migration properties of Pb halide perovskite solar cells. Initially, we fabricate MA-free Pb and mixed Pb-Sn perovskite solar cells in the p-i-n configuration, with power conversion efficiencies of 16.9% and 15.1% respectively. We have intentionally not used any defect passivating additives in the perovskite solution or as post-deposition surface treatments in the fabricated device stacks because of their synergistic influence on ion migration. Next, by conducting scan-rate dependent current-voltage measurements, we observe short-circuit current loss at lower scan rates (< 50 mV/s) for both Pb and Pb-Sn perovskite devices, thereby indicating the prevalence of ionic migration in both kinds of solar cells. However, the kinetics of ionic transport is found to be suppressed in mixed Pb-Sn systems as inferred from scan-rate dependent hysteresis measurements. These results are further corroborated by temperature-dependent impedance spectroscopy measurements performed on the fabricated devices at open circuit and under light illumination, which suggest a substantial lowering of ionic diffusion with the partial substitution of Pb with Sn. In addition, atomistic ab initio simulations highlight the key role played by Sn vacancies in increasing the iodide ion migration barriers (>1.1 eV) in Sn-containing perovskites due to severe local structural distortion, which corroborates and rationalises our experimental observations of much slower ion diffusion in mixed Pb-Sn perovskite solar cells.

Overall, our findings can be generalized for a variety of Pb halide perovskite optoelectronic devices, where the benefit of Sn substitution in suppressing ionic migration effects may lead to enhanced operational stability and improved device architectures.

Oxidation of Iodide and Tin (II) in Acidic Media and its Impact on Tin-Based Perovskite Solar CellsS S M TareqHossain[1], SyedJoy[1], RalphBright[2], StephenJohnson[3] and KennethR. Graham[1]; [1]University of Kentucky, United States; [2]Paul Laurence Dunbar High School, United States; [3]Transylvania University, United States

Metal halide perovskites (HPs) are the prime focus of investigation for the next generation of photovoltaic (PV) materials, in part driven by their low-cost solution processability, tunable band gap, and high absorption coefficients. Here, tin-based HPs (Sn-HPs) are emerging as promising alternatives to Pb-HPs, as they are less toxic, have band gaps close to the ideal band gap based on the Shockley-Queisser limit, and have higher charge carrier mobility. However, Sn-HPs suffer from oxidation of Sn^{2+} to Sn^{4+} and poor film morphologies resulting from their fast crystallization. Even the most common processing solvent, dimethyl sulfoxide (DMSO), is known to oxidize Sn^{2+} when heated above 100 °C. To limit oxidation and improve film morphologies, a variety of different additives are used, with many of these additives having an acidic nature. Furthermore, the most common hole transporting layer (HTL) in Sn-HPs, poly(3,4-ethylenedioxythiophene): polystyrene sulfonate (PEDOT: PSS), is very acidic (pH ≈ 1.8). In some studies, it is claimed that these Bronsted acids act as Lewis bases with oxygen from >X=O (X: C, S) functional groups coordinating with Sn^{2+}. In general, Bronsted acids can have a significant impact on redox chemistry and it is important to determine how they impact Sn-HPs. To understand the role of Bronsted acids on Sn-HPs, we studied the rate of oxidation of SnI_2 in ambient conditions with a series of acids with pKa values ranging from -2.8 to 4.36. We find that SnI_2 oxidation is accelerated with stronger acids. Next, we focus on *p*-toluene sulfonic acid (*p*-TSA), as it is the acid moiety in PEDOT: PSS. We find that in the presence of *p*-TSA DMSO can oxidize SnI_2 and I^- at room temperature in an inert environment. The addition of *p*-TSA to Sn-HPs results in higher Urbach energies, as determined from photothermal deflection spectroscopy (PDS), and decreases the power conversion efficiency of PV devices, whereas the addition of sodium *p*-toluene sulfonate (*p*-TSNa) does not increase the Urbach energy or decrease PV performance. Overall, our results suggest replacing or neutralizing PEDOT: PSS and using the conjugate base salts of acidic additives may provide a route to decreasing defect states, improving stability, and improving performance of Sn-HPs.

4:00 PM *EN04.02.07
Stable Lead-Free Perovskite Solar Cells AntonioAbate; Helmholtz-Zentrum Berlin, Germany

Halide perovskites quickly overrun research activities in new materials for cost-effective, high-efficiency photovoltaic technologies. Since the first demonstration from Kojima and co-workers in 2007, several perovskite-based solar cells have been reported and certified with rapidly improving power conversion efficiency, now approaching the theoretical limit. Recent reports demonstrated that perovskites outperform the most efficient photovoltaic materials to date. At the same time, they still allow solution processing as a potential advantage in delivering a cost-effective solar technology.
The most stable and efficient perovskites contain lead, among the most toxic elements on earth. Lead-free alternatives have been reported with impressive progress in power conversion efficiency for tin-based (lead-free) perovskites. However, the stability of tin-based perovskite solar cells still needs to be explored. In the present talk, we will focus on stability with a particular interest in tin-based (lead-free) perovskite solar cells.

4:30 PM *EN04.02.08
Room Temperature g-Ray and X-Ray Detection with Halide Perovskites MercouriG. Kanatzidis; Northwestern University, United States

There is a growing demand for highly sensitive hard radiation detectors that can operate at room temperature, catering to various applications. Among the potential materials, CsPbBr3, a perovskite semiconductor, shows promise due to its excellent spectral resolution for gamma-rays at room temperature. Moreover, CsPbBr3 possesses air-stability, non-hygroscopicity, and a high average effective atomic number of 65.9. Recent research has made notable progress in studying bulk CsPbBr3 crystals and fabricating and characterizing single crystals specifically for detector applications. The Bridgman method has successfully produced exceptionally pure CsPbBr3 single crystals of superior quality. An outstanding characteristic of CsPbBr3 is its enhanced tolerance for defects compared to other semiconductors, enabling efficient carrier transport and high-performance detectors. CsPbBr3 detectors have exhibited remarkable energy resolution for both X-rays and gamma-rays. For instance, a CsPbBr3 detector achieved a 4% (4.8 keV, FWHM) energy resolution for a 122 keV 57Co gamma-ray. Furthermore, in detector-grade single crystals of CsPbBr3, the hole carrier lifetime surpassed 900 μs, emphasizing its suitability for detector applications. Additionally, pixelated devices based on CsPbBr3 have demonstrated the potential to resolve 137Cs 662-keV gamma-rays with approximately 1% energy resolution. The effectiveness of CsPbBr3 detectors has been further demonstrated through high-dose irradiation exposures and synchrotron X-ray detection experiments, with a flux ranging from 10^6 to 10^12 photons/s/mm2 at 58.61 keV. These results strongly indicate that CsPbBr3, a perovskite material, is promising for developing high-performance radiation detectors across various applications.

Understanding the Ligand-Assisted Reprecipitation of $CsPbBr_3$ Nanocrystals via High-Throughput Robotic Synthesis Approach SherylL. Sanchez, YipengTang, BinHu, JongheeYang and MahshidAhmadi; University of Tennessee Knoxville, United States

Inorganic cesium lead bromide ($CsPbBr_3$) perovskite nanocrystals (PNCs) have shown promise in optoelectronic applications. A simpler method of synthesizing high-quality PNCs is the ligand-assisted reprecipitation (LARP) method, but it is susceptible to instability. This study used a high-throughput automated experimental platform to explore the growth behaviors and colloidal stability of LARP-synthesized PNCs. The influence of ligands on particle growth and functionalities was systematically explored using two distinctive acid-base pairs. The study found that short-chain ligands cannot make functional PNCs with the desired sizes and shapes, whereas long-chain ligands provide homogeneous and stable PNCs. The study also found that excessive amines or polar antisolvents can cause PNCs to transform into a Cs-rich non-perovskite structure with poorer emission functionalities and larger size distributions. The diffusion of ligands in a reaction system is crucial in determining the structures and functionalities of the PNCs. This study provides detailed guidance on synthesis routes for desired PNCs.

Investigation of Surface Properties of Perovskite Semiconductors using Reflection Electron Energy Loss Spectroscopy (REELS) SerenD. Oez and SelinaOlthof; University of Cologne, Germany

The analysis of fundamental semiconductor properties, such as energy level positions and bandgaps, are important to enhance our understanding of these materials and to further improve their performance in applications. In this context, spectroscopic tools such as ultraviolet photoelectron spectroscopy (UPS), inverse photoelectron spectroscopy (IPES) and UV-vis measurements can be employed. In this project, we explore the use of reflection electron energy loss spectroscopy (REELS) for the first time as a novel technique to investigate the surface bandgap of perovskite-based semiconductor materials.
This measurement technique records the energy loss due to inelastic electron scattering processes through the excitation of electronic transitions. Notably, it is a very surface sensitive method with decent energy resolution ($\Delta E \approx 120$ meV, similar to UPS) which makes it an intriguing technique to gain insights on the surface bandgaps as well as the joint density of states (DOS) over a wide energy range.
In this work, we try to understand the observed energy loss spectra in order to establish guidelines to investigate surface properties of perovskite semiconductors. For that reason, information gathered using REELS are compared to UV-vis measurements. Furthermore, by utilizing various incident electron kinetic energies we are able to vary the probing depth. Having this additional control makes it possible to gain additional information on interface properties, which is important to understand the performances of devices.
Our band gap measurements by REELS agree well with the optical bandgaps, therefore our results show that REELS technique can be used as an effective tool to explore such properties at the surfaces of perovskites as well as other semiconductor materials.

8:00 PM EN04.03.03
The Role of Charge Transport in Strain Development and Degradation of Perovskite Solar Cells NikolozGegechkori, WinstonO. Soboyejo, JohnAdjah, KaterynaKushnir, HusnaAmini, LyubovV. Titova and NancyA. Burnham; Worcester Polytechnic Institute, United States

Perovskite solar cells (PSCs) are a transformative innovation in photovoltaic technology, standing out due to their impressive efficiency growth and low manufacturing cost. Their practical utility is nevertheless constrained by the persisting issues of instability and rapid degradation. Recent studies suggest that strain in perovskite cells accelerates degradation, reducing the device stability from 1350 hours to 700 hours and the efficiency from 19.8% to 18.7%. Motivated by these insights, this investigation aims to depict the trends in strain development over time as a function of charge transport in operating perovskite cells, identifying the sources or the regions of strain, or both. We induced strain in PSCs by driving the current through simulating solar illumination and manually applying an external bias. Digital Image Correlation and X-ray Diffraction were used to compute surface and lattice strain, respectively, and these metrics were correlated with the PSC's absorbance, photoluminescence, and J-V curves, which are all influenced by strain. While our research is still ongoing, our findings may have significant implications for future studies. A comprehensive understanding of strain in PSCs is needed to enable effective strain management and propel advancements in PSC stability. Future research could focus on the refinement of strain characterization techniques and the development of methods to mitigate the negative impacts of strain.

Surface Reconstruction of Perovskite Film with the Combination of Organic Salt and Antisolvent for High Performance Solar Cells with Improved Stability Mi HeeJung; Sejong University, Korea (the Republic of)

Organic-inorganic lead halide perovskites have made tremendous development due to their excellent optoelectrical properties, achieving exceptional photovoltaic performance up to over 25%. Despite the comparable record power conversion efficiency (PCE) to silicon solar cell, their mechanical instability is challenging to commercialization prospect. Herein, we fabricated modified $GA_{0.7}MA_{0.93}PbI_3$ perovskite film using the organic amine small-molecules 3-(aminomethyl) pyridine (3AP). 3AP molecules do not distract the pristine perovskite film but modulate the surface morphology and reacted with the surface component, especially defect site of PbI_6 octahedral layer, forming the 2D perovskite slab on the surface, resulting high-quality perovskite film. The perovskite films without (pristine) and with toluene were also fabricated for comparison. Toluene treated perovskite film do not attend the any reaction with perovskite surface. 3AP modified $GA_{0.7}MA_{0.93}PbI_3$ perovskite film exhibit the long carrier lifetime and suppress the charge recombination loss, resulting in an increased fill factor (FF) of 75.66% and PCE of 17.28%, which are higher than pristine (FF: 66.36%, PCE:14.06%) and toluene treated perovskite devices (FF:72.40, PCE: 16.84%). More importantly, 3AP modified perovskite device show remarkable environmental stability to the ambient conditions, the PCE retaining 92% of the initial PCE for over 1000 h at ambient condition.

8:00 PM EN04.03.05
Indoor Photovoltaic, Futuristic Perovskite And Perovskite-Inspired Materials PratibhaGiri[1,2] and Jai PrakashTiwari[1,2]; [1]CSIR-National Physical Laboratory, India; [2]Academy of Scientific and Innovative Research (AcSIR), India

The increasing number and market value of indoor photovoltaic devices demanded their powering solutions day by day. The technologies such as hydrogenated amorphous silicon (H:a-Si), DSSCs, organic semiconductors and lead halide perovskite materials are used for powering indoor photovoltaic (IPVs) due to the suitable band gap for light harvesting in indoor conditions. H: a-Si is used as a standard for IPV as it has efficiency in the range of ~ 4 % to ~9%, which is suitable for electronic devices. Among other emerging photovoltaic, lead halide-based materials are the most promising. Hence, we will demonstrate the exploration of perovskite and perovskite-inspired materials (PIM) for indoor photovoltaic applications.

The device stability of PSCs is still not satisfactory for commercial demands, particularly when exposed to humid or high-temperature environments. The organic component of ABX_3 can be entirely replaced by the inorganic cesium (Cs^+) ion to form inorganic cesium lead halide for better environmental stability. In perovskite materials such as $CsPbX_3$, the instability problem due to organic components is substantially solved. The PCE of $CsPbIBr_2$ and the $CsPbI_2Br$ was reported to be ~ 4.7% and close to ~ 10%, respectively, in 2016. The $CsPbI_3$ (bandgap, E_g) ~1.7 eV may have better photovoltaic application. However, bulk $CsPbI_3$ films display low phase stability and rapidly transform into a non-perovskite orthorhombic phase (E_g: 2.82 eV). $CsPbBr_3$ demonstrates excellent stability but has a relatively large band gap (~2.3 eV), whereas $CsPbI_3$ exhibits a narrower bandgap (~1.73 eV) but inferior stability. The bandgap and stability of $CsPbIBr_2$ and $CsPbI_2Br$ lie somewhere in between, offering a balance between the narrow bandgap of $CsPbI_3$ and the superior stability of $CsPbBr_3$. The bromide ions can partially replace iodide in $CsPbI_3$ to form $CsPbI_2Br$, which shows better phase stability. The $CsPbI_2Br$ perovskite has attracted significant attention due to the stabilization of the black phase. The black phase also transforms into a nonperovskite phase in a humid environment. However, the exploration of Cs-based materials for indoor photovoltaics is continuing. We have also explored the Cs-based perovskite in view of its phase stability and its film characterization behaviour in the humid atmosphere of New Delhi, capital city of India, from June to August 2023. Further, the lead content of the $CsPbI_2Br$ has led us to explore the PIMs, which are less known for their photovoltaic activities for IPVs. The materials such as bismuth oxy iodide, cesium antimony chloride-iodide, silver-bismuth-iodide rudorffites, $Rb_3Sb_2I_9$ and $MA_3Sb_2I_9$, $CuAgBiI_6$ are also in the process of exploration through their structural, optical, and electrical characterizations for eco-friendly and efficient IPV, which may power the IoT devices.

SESSION EN04.04: Halide Perovskite Processing

8:00 AM *EN04.04.01
A Diffusion-Photostability Framework Enables Robot-Accelerated Screening of Stable Wide Bandgap Perovskite Alloys AramAmassian; North Carolina State University, United States

Metal halide perovskite semiconductors have led single junction perovskite solar cell efficiency to match the power conversion efficiency (PCE) of monocrystalline Si photovoltaics at 26%. A new opportunity in this field is the development of wide bandgap metal halide perovskite alloys with a bandgap between ~1.65-1.75 eV toward development of all-perovskite tandem and

perovskite-Si hybrid tandem solar cells, the latter of which have recently achieved a PCE of 33.2%. A number of studies have shown that bandgap tuning through mixed halide alloying comes at the expense of light-induced halide segregation, which causes photodegradation of the material and leads to device degradation under illumination. Thus, compositional tuning with multi-component alloying (through mixing of both cations and halides) is widely believed to be the appropriate approach to design metal halide perovskite alloys that exhibit stabilized perovskite compositions that are more photostable. We have recently developed a predictive ion migration-stability-hysteresis framework whereby halide vacancy-mediated volume and grain boundary diffusions play a crucial role in mediating both device photostability and device hysteresis (Ghasemi *et al.*, *Nat. Mater*. 22, 329, 2023). More recently, we have extended this framework to light-induced halide segregation in mixed halide alloys and have linked ion migration and transient photostability of alloys. We use this framework to accelerate the search for novel perovskite alloy candidates suitable for multijunction solar cells via a multi-modal screening strategy that evaluates the materials in terms of their ability to form a purely cubic perovskite phase, the target bandgap (e.g., 1.7eV), as well as achieve minimal light-induced halide segregation. This approach is integrated into our home-built RoboMapper platform developed at NC State and results in identification of wide bandgap perovskite alloys with superior stability, superior power conversion efficiency and low hysteresis in solar cell devices. We also demonstrate how the RoboCoater, an AI-guided coating platform, autonomously develops optimal coating recipes for these new perovskite alloys thus accelerating the translation of material alloys to practical coatings and device applications.

8:30 AM EN04.04.02
Heterogeneity in Structure, Composition and Optoelectronic Behavior in Wide-Bandgap Mixed-Halide Perovskites KunalDatta[1,2], Simonevan Laar[2], MargheritaTaddei[3], TimKodalle[4], JuanitaHidalgo[1], GuusAalbers[2], CarolinM. Sutter-Fella[4], Juan-PabloCorrea-Baena[1], DavidS. Ginger[3] and RenéJanssen[2]; [1]Georgia Institute of Technology, United States; [2]Eindhoven University of Technology, Netherlands; [3]University of Washington, United States; [4]Lawrence Berkeley National Laboratory, United States

High quality mixed-halide wide-bandgap perovskites are an important component of high-efficiency multijunction photovoltaic devices. However, solution-processed deposition of such complex materials compositions introduce heterogeneity which influences photovoltaic performance. This work studies mixed-halide perovskite semiconductors in the 1.8 eV to 2.0 eV range relevant for tandem and triple-junction photovoltaic devices and investigates the formation of structural and compositional heterogeneity and its impact on optoelectronic response.

Synchrotron-based in-situ grazing incidence wide-angle X-ray scattering is used to study film formation dynamics and the evolution of structural heterogeneity. A combination of scanning electron microscopy, synchrotron-based X-ray fluorescence microscopy, and hyperspectral imaging techniques identifies halide heterogeneity in structurally disordered areas, which leads to local bandgap changes and influences defect behavior. This influences charge-carrier mobility and recombination and also influences halide migration in thin films. Finally, sensitive sub-bandgap photocurrent spectroscopy measurements find increasing defect density and band-edge disorder as a function of structural heterogeneity, which is further aggravated upon illumination. Collectively, this work identifies the vulnerability of solution-processed wide-bandgap perovskite thin films to the development of structural disorder and assesses its consequences on composition, optoelectronic response and photostability.

8:45 AM EN04.04.03
Deposition of High Number H-Phases by Vapor Deposition Routes Carlo Andrea RiccardoPerini, Andres FelipeCastro Mendez, JavierCastillo Seoane and Juan-PabloCorrea-Baena; Georgia Institute of Technology, United States

FAPbI3 perovskites are known to degrade in the 2H crystal phase by switching from corner sharing PbI3 octahedra to face sharing. Hybrid structures (H-phases) between pure edge sharing and face sharing octahedra are possible, and their presence has been observed experimentally as impurities in perovskite films. Crystal engineering of mixtures of corner and face sharing octahedra enabled new functionality in oxide perovskites.[1] Analogously, it is expected that the synthesis of phase pure H-phases with different degrees of face or edge sharing will enable similar results. Furthermore, the study of H-phases will benefit the interpretation of the photovoltaic properties of 3D perovskite films, as these phases are formed as impurities in most FA- and Cs-based films.[2]
In this contribution we demonstrate the deposition of thin films with complex arrangements of corner and face sharing PbI3 octahedra (high number H-phases). We correlate crystal structure and optical properties of these compounds and discuss the potential benefits of the application of these materials as well as their impact on the photovoltaic performances of 3D FA- and Cs-based solar cells.

Vapor Phase Deposited Perovskites, High and Low Vacuum Methods for Single Junction and Tandem Solar Cells HenkJ. Bolink; University of Valencia, Spain

We will report on the progress on vapor phase deposited perovskites, including novel low vacuum based deposition methods such as close space sublimation. Using substrate configuration we optimize the incoupling of sunlight which leads to current densities very close to the detailed balance limit.
The use of vacuum deposited for perovskite-Si tandem cells will also be commented upon.

9:30 AMBREAK

10:00 AM *EN04.04.05
Shedding Light on Wide Bandgap Perovskites MichaelSaliba; University of Stuttgart, Germany

Perovskite solar cells have come to the forefront of solar research in the last decade with certified efficiencies of now >26%. This is approaching rapidly the Shockley-Queisser limit for single-junction solar cells, implying that the main breakthroughs for perovskites were achieved with relatively narrow bandgaps.[1a,1b] Less progress, however, was made for wider bandgap perovskites, which are of interest for multijunction photovoltaics, detector applications, or water splitting. These wide bandgap perovskites are often comprised of fully inorganic components, which are hard to dissolve in conventional solvent systems and require more sophisticated synthesis as well as crystallisation techniques.
In this talk, I will discuss strategies to address these challenges by providing a library of hitherto unexplored wider bandgap perovskites using combinatorics. Mechanosynthesis is then studied to attain otherwise inaccessible liquid precursors permitting the realization, e.g., of “triple cation” wide bandgap perovskites.[2]
Unfortunately, the newly formulated liquid precursors often exhibit complex crystallization behaviour struggling to expel the typically used DMSO solvent. To delay the crystallization time, two strategies are proposed to remove the strongly complexating DMSO molecules through a) modified processing of the liquid thin-film[3] and b) a coordination solvent with a high donicity and a low vapor-pressure[4] leading to a marked improvement in the overall film quality.
Lastly, interface manipulation, especially on top of the formed perovskite, is becoming a central topic to advance further. Typically, this involves chemical surface treatments with a complex interaction. Here, light annealing is introduced as a universal, non-chemical approach to modify the perovskite surface resulting in a reduced surface recombination.[5]

10:30 AM EN04.04.06
Elucidating Surface Adhesion Characteristics of Formamidinium Iodide in Vapour Co-Deposited Perovskites QimuYuan[1], KilianB. Lohmann[1], RobertOliver[1], AlexandraRamadan[1,2], SiyuYan[1], JamesBall[1], GreysonChristoforo[1], NakitaK. Noel[1], HenrySnaith[1], LauraHerz[1,3] and MichaelJohnston[1]; [1]University of Oxford, United Kingdom; [2]The University of Sheffield, United Kingdom; [3]Technical University of Munich, Germany

Vapour deposition is a solvent-free method suitable for growing thin-films of metal halide perovskite and charge-transport layers. Vacuum-based methods offer unique advantages, including precise control of layer thickness, excellent uniformity of the formed thin-film, and the flexibility to grow multi-layer structures and larger-scale modules.

In particular, the co-evaporation of MA-based perovskites has been well studied, and the adhesion characteristics of methylammonium iodide (MAI) vapour have been found to be dependent on a diverse array of factors, such as pressure, composition and temperature of underlying substrates [1,2,3]. In contrast, the adhesion mechanism of the organic formamidinium iodide (FAI) vapour is yet to be clearly elucidated, partly owing to very limited studies to date. Nevertheless, the understanding of FAI sticking properties may be pivotal in controlling the film growth and quality of FA-based perovskites.

In our studies, we uncover the striking differences in the sticking, adhesion, and nucleation of the perovskite precursor FAI, to various hole transport layers (HTLs). We found that when exposing the same time-integrated FAI vapour flux to the underlying layers of both solution-processed PTAA and thermal-evaporated copper phthalocyanine (CuPc), a 50% thicker FAI layer was formed on the latter surface. Through atomic force microscopy measurements, we highlight the subtle differences in the 'island growth' mode of FAI on PTAA and CuPc surfaces, and hence, correlate to the observed stoichiometric difference in the co-evaporated $[CH(NH_2)_2]_{0.83}Cs_{0.17}PbI_3$ ($FA_{0.83}Cs_{0.17}PbI_3$) perovskite films of device thickness. Therefore, we demonstrate the importance of optimising growth parameters specific to individual charge transport layer if FAI is to be used as a precursor in any co-evaporated perovskites [4].

Based on these findings, we optimised the co-evaporation of $FA_{0.83}Cs_{0.17}PbI_3$ layer in an all-vacuum deposited perovskite solar cell with CuPc as the HTL. We highlight the vacuum-deposited CuPc as an alternative, low cost, and durable HTL in a photovoltaic device with p-i-n configuration, which attained a solar-to-electrical power conversion efficiency of up to 13.9%. From both optical characterisations and studies of device performance, we illustrate that CuPc demonstrated improved compatibility than thermal-evaporated ZnPc as HTL for solar cell devices with $FA_{0.83}Cs_{0.17}PbI_3$ as the intrinsic layer. Furthermore, we thoroughly examined the long-term stability of these all-vacuum-processed devices under a range of testing conditions. Importantly, unencapsulated devices as large as 1 cm^2 exhibited outstanding thermal durability, demonstrating no observable degradation in efficiency after more than 5000 hours in storage and 3700 hours under 85 °C heat-stressing in N_2 atmosphere [4].

Investigation of the Impact of Cs/Sn Ratio on Material Properties in Coevaporated $CsSnI_3$ Libraries FatimaAkhundova, HannesHempel, MarinRusu and ThomasUnold; Helmholtz-Zentrum Berlin, Germany

Tin-halide perovskites represent a potential non-toxic alternative to lead-based perovskite solar cell absorbers showing similar fundamental optical and electrical material properties as the lead-based halide perovskites. However, solar cell peformance of Sn-based halide perovskites so far has been much lower. This has been attributed to the oxidation of Sn^{2+}, strong (intrinsic) p-type doping, and rapid crystallization in the precursor solution which results in poor thin film morphology. Inorganic halide perovskites are attractive from a thermal stability point of view, however, tend to struggle with the presence of a competing non-photoactive non-perovskite delta-phase.
In our study we use a vacuum-based co-evaporation approach to study the influence of a varying Cs/Sn composition ratio on the phase stability as well as the optoelectronic properties of $CsSnI_3$.
$CsSnI_3$ perovskite thin films were deposited with a lateral chemical gradient to obtain thin film libraries with a Cs/Sn ratio from 0.9 to 1.1. We find that the evaporated perovskite crystallizes in the orthorhombic gamma-phase with different preferred orientations in case of excess Sn and/or Cs content. Similar to previous results for $CsPbI_3$[1] we find that Cs-rich regions show significantly better stability of the γ-phase than the Sn-rich sample.
With respect to the optoelectronic properties we find a strong blue shift of the absorption onset from 1.35-1.45 eV with increasing Cs-content, whereas the room temperature photoluminescence peak position stays constant at 1.33 eV. The photoluminescence quantum yield shows a distinct maximum with a rather high value of 0.6% for the stoichmetric samples, falling of by a factor of 2-3 toward both off-stoichimetric sides. Despite the high PLQY minority carrier lifetimes as measured by TRPL are relatively low with about 2-3 ns, indicating a how equilibrium carrier density above $10^{17}cm^{-3}$ in the samples.
These results indicate that defect-related non-radiative recombination still pose a major challenge for obtaining high performance in inorganic Sn-based halide perovskite solar cells.

Perovskite Monocrystals for Advanced Applications: Synthetic Approaches and Working Mechanisms PabloP. Boix[1,2]; [1]Universitat Politècnica de València - Consejo Superior de Investigaciones Científicas (UPV-CSIC), Spain; [2]Universitat de València, Spain

In the past decade, metal halide perovskites have emerged as promising alternatives to traditional semiconductors, holding great potential for photovoltaics but also for diverse semiconductor-based applications. However, their practical implementation has been impeded by challenges related to performance and stability. To overcome these obstacles, precise control over the crystallization and grain boundaries of these materials is essential.

In this work, we present innovative techniques for implementing and passivating device-oriented perovskite monocrystals, including laser-based passivation of macrocrystal surfaces and in-situ fabrication of nanocrystals via humidity-induced methods. Through a comprehensive investigation of the physical properties of these monocrystals, we explore their impact on diverse applications such as photovoltaic devices and memristors. Leveraging the robustness of monocrystalline systems, we develop an impedance spectroscopy model to analyze the phase dispersion resulting from ionic modulation, providing valuable electrical insights that can be extrapolated to polycrystalline thin-film devices. Our study contributes to the advancement of high-performance metal halide perovskite devices by elucidating crucial factors that influence their performance and offering potential solutions to enhance their functionality.

Saidaminov[5], MaksymV. Kovalenko[1,2], OmarF. Mohammed[3] and OsmanM. Bakr[3]; [1]ETH Zürich, Switzerland; [2]Empa–Swiss Federal Laboratories for Materials Science and Technology, Switzerland; [3]King Abdullah University of Science and Technology, Saudi Arabia; [4]Swansea University, United Kingdom; [5]University of Victoria, Canada

Exploiting the potential of perovskite single-crystal solar cells in the realm of optoelectronic applications necessitates overcoming a significant challenge: the low charge collection efficiency at increased thickness, which has restricted their deployment in radiation detectors and nuclear batteries. Our research [1] details a promising approach to this problem, wherein we have successfully fabricated single-crystal MAPbI3 solar cells employing a space-limited inverse temperature crystallization (ITC) methodology. Remarkably, these cells, which are up to 400-fold thicker than current-generation perovskite polycrystalline films, maintain a high charge collection efficiency even without external bias.
The crux of this achievement lies in the long electron diffusion length within these cells, estimated to be around 0.45 mm. This extended diffusion length ensures the conservation of high charge collection and power conversion efficiencies, even as the thickness of the cells increases. Fabricated cells at thicknesses of 110, 214, and 290 µm manifested power conversion efficiencies (PCEs) of 20.0, 18.4, and 14.7% respectively. Notably, the single crystals demonstrated nearly optimal charge collection, even when their thickness exceeded 200 µm. Devices of thickness 108, 214, and 290 µm maintained 98.6, 94.3, and 80.4% of charge collection efficiency relative to their maximum theoretical short-circuit current value respectively.
Additionally, we have proposed an innovative, self-consistent technique for ascertaining the electron-diffusion length in perovskite single crystals under operational conditions. The computed electron-diffusion length approximated to 446 µm, significantly surpassing previously reported values for this material.
In conclusion, our findings underscore the feasibility of fabricating halide perovskite single-crystal solar cells of hundreds of micrometers in thickness, while preserving high charge extraction efficiency and PCE. This advancement paves the way for the development of perovskite-based optoelectronics necessitating thicker active layers, such as X-ray detectors and nuclear batteries.

Towards an *In-Situ* Crystallization Method for Perovskite Nanocrystal Thin-FilmsJaumeNoguera-Gómez, VíctorSagra-Rodríguez, MíriamMínguez-Avellán, PabloP. Boix and RafaelAbargues; Instituto de Ciencia de Materiales de la Universidad de Valencia, Spain

Metal halide perovskite nanocrystals (PNCs) can display excellent light emission properties that make them highly versatile for different applications. [1] However, incorporating these properties into functional films results in a challenging task due to inherent drawbacks such as aggregation and material instability, among other performance-related issues.

To overcome these obstacles, we have developed a metal-organic host matrix using a simple sol-gel approach, enabling controlled in-situ crystallization of perovskite nanocrystals through solution-based fabrication methods. [2] This innovative technique allows us to generate high-performance nanocomposite thin films without the need for antisolvent, additives, or annealing while achieving a photoluminescence quantum yield (PLQY) of over 80% and exceptional ambient and mechanical stability.

The crystallization dynamics determining the final nanoparticle size, and thus the emission properties can be finely tuned by adjusting the ambient exposure and precursor concentration. This in-situ PNCs nanocomposite synthesis approach may form the basis for the fabrication of large-area optoelectronic devices with enhanced properties, but also laying the groundwork for band-gap tunability, by directly controlling the PNCs crystallization dynamics.

Spatiotemporal Imaging of Charge and Heat Transport in Two-Dimensional Hybrid Perovskites PeijunGuo; Yale University, United States

Two-dimensional metal halide perovskites (2D-MHPs) are chemically and structurally diverse semiconducting materials with promising applications in photovoltaics and optoelectronics. The understanding of charge and heat transport is crucial for improving the device performance and stability, yet such understanding is challenged by the spatial inhomogeneity in these solution-processed materials. I will discuss our recent efforts on developing spatiotemporal optical imaging techniques, which permit the monitoring of the flow of charge carriers as well as lattice heat with hundreds-of-nanometers spatial resolution, complementing the more commonly employed time-resolved photoluminescence measurements. Our approach paves the way for unraveling charge-carrier dynamics and heat management in 2D-MHPs and other hybrid semiconductors. If time permits, I will also describe our efforts on the understanding of intrinsic chiroptical properties of chiral 2D-MHPs.

2:00 PM EN04.05.02
Rapid Screening of Lead Halide Perovskite Film Photoconductivity via Electric Force Microscopy ChristopherPetroff[1], VirginiaE. McGhee[1], RachaelCohn[1], DavidT. Moore[2], LaraA. Estroff[1] and JohnA. Marohn[1]; [1]Cornell University, United States; [2]National Renewable Energy Laboratory, United States

One of the key challenges delaying the commercialization of lead halide perovskite (LHP) photovoltaics is their poor long-term stability. Key to solving this problem is a better understanding of the mechanisms behind their photoconductivity. It is demonstrated in the literature that light induces vacancies in LHPs and that the resulting ionic conductivity plays a significant role in their photovoltaic performance [1–3]. The cyclic creation, relaxation, and motion of these halide vacancies may contribute to the overall instability of LHP devices.

We are actively working with collaborators to develop a coherent understanding of LHP photovoltaic performance, reproducibility, and stability from solution chemistry and crystallization pathways through optoelectronic properties and up to devices. Our goal is to connect the input parameters, such as composition and processing conditions, to the output parameters, such as device efficiency and stability. We use broadband local dielectric spectroscopy (BLDS) [4], a type of electric force microscopy (EFM), to make non-contact measurements of steady-state (photo)conductivity. In order to generate the quantity of intermediate data needed for this holistic understanding of LHPs, we designed and built a custom low-noise, high-throughput electric force microscope operating under high vacuum conditions with laser interferometric detection and variable light capabilities. A new probehead design coupled with a new laser led to a 1600x decrease in the position-fluctuation noise floor and a 22x decrease in frequency noise over our previous microscope, which, combined with software improvements, has improved data collection times and measurement stability. Furthermore, improved vacuum pump-down times combined with a sample translation stage and probehead camera led to increased sample throughput of 6–9 samples per day, which allows for the characterization of combinatorially synthesized samples. This throughput allows for the systematic study of, for example, the effect of composition (e.g., halide ratio) on photoconductivity.

2:15 PM EN04.05.03
Glass Formation in Metal Halide Perovskite using Ultrafast Calorimetry AkashSingh[1], YongshinKim[1], ReeceHenry[2], HaraldAde[2] and DavidB. Mitzi[1]; [1]Duke University, United States; [2]North Carolina State University, United States

While the existence of a glassy state has been established in numerous materials families, including chalcogenide semiconductors, metal halide perovskites (MHPs), currently one of the most exciting and extensively studied classes of semiconductors, have primarily been known to exist only in crystalline states. However, our recent discovery of reversible crystal-glass switching in MHPs challenged this notion by employing structural engineering techniques in an exemplary $[S\text{-}(-)\text{-}1\text{-}(1\text{-naphthyl})\text{ethylammonium}]_2PbBr_4$ (SNPB) perovskite, achieving slow melt ordering kinetics that resulted in a stable melt-quenched glassy state.[1] Nevertheless, it is challenging to vitrify and conduct kinetic studies on the broader MHP family, particularly members with flexible and non-bulky aliphatic organic cations, thereby limiting the glass forming compositional space. In this study, we expand the range of MHP glass formation across a broader range of organic (fused ring to branched aliphatic) and halide (bromide to iodide) compositions by employing an unconventional technique called *ultrafast calorimetry* that enables rapid cooling and heating of samples (4-5 order higher than achievable through conventional calorimetry). For the exemplary case of the 1-MeHa_2PbI_4 (1-MeHa = 1-methyl-hexylammonium) perovskite, a low melting MHP with T_m ~170 °C, we demonstrate the ability to obtain a glass by melt-quenching at a rate of 6000°C/s, assisted with a partial mass loss of ~15%. The obtained glass shows a glass transition temperature of ~16 °C and faster crystallization kinetics compared to SNPB.[2] Furthermore, through iterative calorimetric and viscosity measurements, and a combination of kinetic, thermodynamic, and rheological modeling techniques, we construct an Angell plot and determine important kinetic parameters for glass formation and crystallization, such as the activation energy of glass crystallization (E_A = 124 to 50 kJ/mol for 45 to 97 °C), fragility index (m = 72), and crystal growth rates (U_{max} = 0.21 m/s), providing a deeper understanding of the system's behavior. Ultrafast calorimetry can thus have immense potential to expand the compositional range of glass-forming MHPs, offering a greater range of glass-forming abilities. The results and techniques employed in this study also contribute to establishing a framework for selecting suitable MHP candidates for applications beyond conventional photovoltaics, emitters, and sensors, opening possibilities in areas such as cost-effective memory, computing, metamaterials, and reconfigurable photonic devices.

Nanospectroscopy of Halide Perovskites Through Environmental Microscopy MarinaS. Leite; University of California, Davis, United States

The mesoscale construct that forms hybrid organic-inorganic perovskites (HOIPs) are heavily responsible for the spatially inhomogeneous electrical behavior of these materials, which, in turn, requires the use of nanoscale characterization tools for a quantitative assessment. We realize environmental atomic force microscopy to interrogate, in real-time, the voltage and current responses of hybrid perovskites once these materials are exposed to moisture combined with controlled illumination. Quantifying the individual and compound effects of these stressors are

essential for understanding material degradation mechanisms. At inert environment, we find that ion motion is the dominant process responsible for a residual voltage signal that persists post-illumination. For a set of voltage scans acquired under distinct relative humidity levels, up to 60%, we note that ion motion occurs preferentially at the grain boundaries, where we quantify the hysteresis of the process. Concerning photocurrent measurements, we spatially resolve the information in quad-cation perovskites and find that their grain boundaries present enhanced response due to defect-passivation. Unexpectedly, most boundaries show inactive response in dual-cation perovskites. Overall, our environmental microscopy enables us to visualize and quantify dynamic processes within halide perovskites; additional examples will be presented.

3:30 PM EN04.05.05
What Solution Species Exist in a Halide Perovskite Ink?RossKerner[1], BryonLarson[1], LanceWheeler[1], KaiZhu[1] and JosephJ. Berry[1,2,2]; [1]National Renewable Energy Laboratory, United States; [2]University of Colorado Boulder, United States

To fully control the formation of a halide perovskite material from solution, one needs to know exactly what solution species exist in the first place. Solution speciation is often probed by ultraviolet-visible (UV-Vis) spectroscopy of the inks where the absorbance peaks in the wavelength range 300-500 nm are attributed to mononuclear iodoplumbate complexes (i.e. one Pb per complex ion) – specifically $[PbI_1Solvent_5]^+$, $[PbI_2Solvent_4]^0$, $[PbI_3Solvent_3]^-$, $[PbI_4Solvent_2]^{2-}$, $[PbI_5Solvent]^{3-}$, and $[PbI_6]^{4-}$. However, we observe that "isolated" $[PbI_6]^{4-}$ ions in solid-state phases such as $MA_4PbI_6(2H_2O)$ display an exciton absorption energy at ~370-380 nm, significantly blue-shifted from the assumed absorption energy of this complex ion in solution (typically assumed to be 450-500 nm), thus disproving current theories. By measuring UV-Vis absorbance of various 0D and 1D iodoplumbate phases in thin film form, we are able to identify three wavelength ranges due to different classes of oligomers or colloids in solution. Furthermore, X-ray scattering (pair distribution function, PDF) measurements on solutions reveal a correlation length > 10 Å, supporting the existence of dimers, trimers, and tetramers in solution for which the bonding motif within the clusters is strongly affected by solvent and additive choice. Thus, what emerges from this work is the underappreciated likelihood that halide perovskites and iodoplumbate intermediates nucleate and self-assemble from oligonuclear, as opposed to mononuclear, solution species. While more studies using advanced techniques like X-ray PDF, as well as other synchrotron-based methods, are needed to complete a detailed picture of what's in a halide perovskite ink, our work here provides crucial first step and insight to explain the full evolution from solution phase to a halide perovskite film from which it we can better develop strategies to control the kinetics and thermodynamics.

3:45 PM EN04.05.06
Effect of Cation Structure on the Optical and Electronic Properties of Ruddlesden Popper Phase Tin Halide Perovskites HenryPruett[1,2], SeanParkin[1], RebeccaScheidt[2], KevinPedersen[1], YifanDong[2], JohnColton[3,2], MatthewC. Beard[2] and KennethR. Graham[1]; [1]University of Kentucky, United States; [2]National Renewable Energy Laboratory, United States; [3]Brigham Young University, United States

Organic metal halide perovskites (MHPs) are attractive materials for a variety of electronic applications due to their low cost, tunable band gaps, excellent charge transport properties, and high photoluminescence efficiency. As such, HPs are being investigated for use in solar cells, photodetectors, X-ray detectors, light emitting diodes, field effect transistors, lasers, resistive random-access memory, etc. Currently the most popular metal used in HPs is Pb^{2+} but the use of lead comes with the potential for heavy metal exposure. Sn^{2+}-based perovskites offer a less hazardous alternative, but their optoelectronic properties lag behind those of lead and less work has been done to characterize them. In this work, we investigate Ruddlesden-Popper Phase (RP) tin perovskites with phenethylammonium and its derivatives to determine how the structure of the A*-site cation, the organic cation in the space between the metal halide lattices, impacts the optical and electronic properties. Here, the PEA derivatives include either fluorine (-F) or trifluoromethyl(-CF_3) at the 2,3, or 4 position on the phenyl ring. We show how the A*-site cation structure affects the crystal structure of the 2D HP, the optical gap, ionization energy, work function, recombination dynamics, charge-carrier mobility, and exciton binding energy. We use several experimental techniques, including single crystal X-ray diffraction for crystal structure determination; ultraviolet photoemission spectroscopy for ionization energy and work function determination; transient absorbance, time-resolved terahertz spectroscopy, and time-resolved microwave conductivity for probing recombination dynamics and extracting summed charge-carrier mobilities; and electroabsorbance for extracting exciton binding energies. Through the above techniques we show that the position of the substituent on the phenyl ring has a greater influence than the identity of the substituent on XXX (specify whether all properties or a specific property). Perovskites made with cations with F or CF_3 at the 4-position show less distorted crystal structures, lower optical gaps, higher ionization energies, and higher charge carrier mobilities compared to HPs with F or CF_3 at the 2-position. In addition, though 2-$CF_3PEA_2SnI_4$ has the most distorted crystal structure (octahedral tilt of 34.49° compared to the octahedral tilt of 2-$FPEA_2SnI_4$ of 2.32°), the summed charge carrier mobilities as measured by time-resolved microwave conductivity are surprisingly similar (0.80 $cm^2V^{-1}s^{-1}$ for2-$FPEA_2SnI_4$ vs 0.41-0.59 $cm^2V^{-1}s^{-1}$ for 2-$CF_3PEA_2SnI_4$). Overall, this work sheds light on the relationship between the A*-site cation, HP crystal structure, and optical and electronic properties, helping to provide better guidance for the design of new materials.

4:00 PM EN04.05.07
Accelerating Materials Discovery by High-Throughput Characterizations of Quasi-2D Formamidinium Metal Halide Perovskites JongheeYang; University of Tennessee, United States

The intriguing functionalities of emerging quasi-two-dimensional (2D) metal halide perovskites (MHPs) have led to further exploration of this material class for sustainable and scalable optoelectronic applications. However, the chemical complexities in precursors – primarily determined by the 2D:3D compositional ratio – result in uncontrolled phase heterogeneities in these materials, which compromises the optoelectronic performances. Yet, this phenomenon remains poorly understood due to the massive quasi-2D compositional space. To systematically explore the fundamental principles, herein, a high-throughput automated synthesis-characterization-analysis workflow is designed and implemented to formamidinium (FA)-based quasi-2D MHP system. It is revealed that the stable 3D-like phases, where the α-FAPbI3 surface is passivated by 2D spacer molecules, exclusively emerge at the compositional range (35-55% of FAPbI3), deviating from the stoichiometric considerations. A quantitative crystallographic study via high-throughput grazing-incidence wide-angle X-ray scattering (GIWAXS) experiments integrated with automated peak analysis function quickly reveals that the 3D-like phases are vertically aligned, facilitating vertical charge conduction that could be beneficial for optoelectronic applications. Together, this study uncovers the optimal 2D:3D compositional range for complex quasi-2D MHP systems, realizing desired optoelectronic performances and stability. The automated experimental workflow significantly accelerates materials discoveries and processing optimizations while providing fundamental insights into complex materials systems.

Cation Exchange at the 2D/3D Perovskite Interface and its Impact on Solar Cell Performance GaborSzabo, PreethiS. Mathew and PrashantKamat; University of Notre Dame, United States

Ruddlesden-Popper 2D mixed-halide perovskite films with spacer cations such as butylammonium and Dion-Jacobson 2D mixed-halide perovskite films with 1,4-phenylenedimethanammonium are used to stabilize the performance of perovskite solar cells. The cation migration under operation of the solar cell can significantly alter the 2D/3D interface. We have now probed the cation migration between 2D and 3D perovskites by physically pairing X PbI (X=butylammonium BA, oleylammonium OA, or phenethylammonium PEA) 2D film and (CH_3NH_3)PbI 3D film at different temperatures by recording changes in the absorption and emission spectra. The migration of methyl ammonium towards the 2D film slowly converts n=1 layered structure into n=2 and 3 layered films. The 3D film on the other hand, exhibits relatively small changes. In addition, we have also correlated the migration of cations to the performance of solar cells. The ease of migration of spacer cations between physically paired films suggest that the varied composition at the interface should be considered while evaluating the effectiveness of 2D/3D design strategy for improving the performance of perovskite solar cells

4:45 PM EN04.05.09
Phase Control of Organometal Halide Perovskites with Superlattice SatoshiUchida and HiroshiSegawa; The University of Tokyo, Japan

To develop a highly efficient solar cell using organometal halide perovskites, its microscale structure control is one of the most important factors because the microstructural boundary inside the organometal halide perovskite are harmful to charge carrier flow and, thus, degrade device performance. In this study, we confirmed the existence of tetragonal / cubic superlattice inside the grain in a methylammonium iodide (MAPbI3, MA = CH3NH3) perovskite with transmission electron microscopy (TEM) analysis and revealed that the nano size domain prevents charge carrier flow in the MAPbI3 perovskite. To minimize the nano sized domain and its negative influences, the 5% of potasium was added to diminish the junction domain and examined to increase the portion of the cubic phase via microstructural phase control using liquid nitrogen (LN2). Through microstructural phase control of the MAPbI3 perovskite, its grain boundaries and physical gap were significantly decreased, and 20.23% power conversion efficiency (PCE) was achieved with a single cation MAPbI3 perovskite solar cell.

1:30 PM *EN04.07.01
Highly Oriented, Thin Pb Halide Perovskite Films from Single Source, *CW* Laser Vacuum DepositionDavidCahen[1], NagaP. Jasti[2], ShayTirosh[2], AnsumanHalder[2] and EtiTeblum[2]; [1]Weizmann Institute and Bar-Ilan University, Israel; [2]Bar-Ilan University, Israel

Pulsed laser deposition (PLD) is a well-established thin-film deposition technique for pure inorganic materials with high melting points. However, with the typical high energy (also very high time-averaged power) pulsed lasers used, it is quite challenging to deposit organic-inorganic hybrid materials like halide perovskites (HaPs) without decomposing their organic components and thus losing the stoichiometry. We report that thin stoichiometric HaP films can be deposited by 3-4 orders of magnitude lower time-averaged power *continuous wave* laser illumination of a corresponding HaP bulk material as a target. The CW deposition is solvent-free, occurs at room temperature, and needs only low vacuum. The method gives smooth, well-oriented thin films of various HaPs (explored here are $MAPbBr_3$, $MAPbI_3$, $FAPbBr_3$, BA_2PbI_4), making it promising for a scalable technology. Overall, the possibility of growing well-crystallized HaP thin films on any substrate without *in situ* and/or *ex situ* thermal treatments, using a single stoichiometric target, are attractive features of this CW deposition process.

2:00 PM EN04.07.02
Surface/Interface Structures of Perovskite Films as Studied by Advanced Electron Spectroscopies HiroyukiYoshida and AbduheberMirzehme; Chiba University, Japan

The surface and interface of the perovskite layer play a crucial role in the charge extraction/injection and recombination process of perovskite-based devices such as solar cells. Therefore, it is essential to examine the geometrical and electronic structures of the surface/interface of perovskite. Unfortunately, standard experimental techniques such as X-ray diffraction (XRD) and scanning tunneling microscopy (STM) are unsuitable for examining practical perovskite films, e.g., solution-processed perovskite surfaces. XRD observes the lattice periodicity and is not sensitive to the surface structure. Although STM can precisely observe the surface atoms, it cannot be applied to rough or thick films.

We demonstrate that a combination of ultraviolet photoelectron spectroscopy (UPS) and metastable atom electron spectroscopy (MAES) is a powerful and versatile tool to examine both geometrical and electronic structures of perovskite surfaces. In UPS, the valence electrons are excited by ultraviolet photons (typically with the energy of 21.22 eV), and kinetic energies of photoelectrons are analyzed to measure the valence electronic states as a difference between the photon and electron kinetic energies. The probing depth of UPS is limited by the mean free path of electrons which is usually a few nanometers (several layers) in the energy range of UPS. In MAES, the excitation source is replaced with the metastable helium atom (with an energy of 19.82 eV). Although the process of electron spectroscopy is similar to that of UPS, MAES is extremely surface sensitive because the helium atom can only interact with the outermost atomic orbitals of the sample surface. We can obtain information about the surface structure and electronic states by comparing the UPS and MAES spectra. Moreover, we can obtain information about the energy levels of perovskite surfaces simultaneously. In this presentation, we will demonstrate the following topics:

1. Surface termination of perovskite films[1]
The properties of the interface of perovskite ABX_3 should be strongly affected by the surface termination, i.e., whether the surface is terminated with AX or BX layer. We examined the surface termination of a $CH_3NH_3PbI_3$ thin film prepared by the standard one-step solution process. The results show that the surface of the perovskite film is terminated with the layer consisting of CH_3NH_3 and I.

2. Surface passivation in quasi-2D perovskite films[2]
Surface passivation is a promising technique to suppress the charge carrier recombination at the surface defects. The combination of UPS and MAES is a suitable tool to examine the effect of surface passivation. For example, a small amount of large organic cations incorporated in perovskite film (quasi-2D) passivates the surface and enhances the stability of the perovskite solar cell against moisture. We examined the surface structure of $PEA_{2m}(CH_3NH_3)_{n-2m}Pb_nI_{3n}$ and confirmed that the PEA segregates to the surface and that the phenyl group covers the outermost surface of the quasi-2D perovskite. From the concentration dependence, we also examined the plausible structure of the quasi-2D film.

Imaging Buried Interfaces of Metal-Halide Perovskites Towards Flexible Photovoltaics ConradA. Kocoj[1], JoyXu[1], ZhenghongDai[2], AnushRanka[2], NitinP. Padture[2] and PeijunGuo[1]; [1]Yale University, United States; [2]Brown University, United States

Photovoltaics made with 3D organic-inorganic halide perovskite (3D-OIHP) thin films lead a burgeoning field of research into flexible solar cells due to their demonstrated ability to enable flexible and lightweight designs while maintaining competitive power-conversion efficiency and stability. Despite their promise, 3D-OIHP thin film-based flexible devices suffer from inherent defects originating from manufacturing and delamination of their interfaces due to wear and tear from common usage that decrease their performance over time. Recent efforts in interfacial engineering have brought about significant improvements in solar cell reliability, but techniques for the large-scale characterization of defects and delamination between functional layers of OIHP devices have yet to be explored. Standard techniques for imaging the delamination between material interfaces, such as cross-sectional FIB/SEM, have limited throughput and necessitate the deposition of additional material and destructive processing, rendering measured samples inoperable while providing only site-specific information. Here, we demonstrate a vibrational-pump visible-probe microscopy technique to optically probe the presence of buried interfaces in flexible $MAPbI_3$ thin films and multilayer structures. By exciting the N-H stretching mode present in the methylammonium cations with a mid-infrared pump and probing the transient response of the perovskite's temperature-dependent bandgap in the visible region, we exploit the localized heat transfer towards the substrate to image delamination between the buried interfaces. This technique allows for the nondestructive imaging of buried interfaces and can provide insight into the effects of interfacial contact on device performance, serving as a useful tool for the interfacial engineering and eventual commercialization of high-performance 3D-OIHP-based flexible photovoltaics and optoelectronic devices.

Probing the Electronic Structure of 3D and 2D Halide Perovskites SelinaOlthof; University of Cologne, Germany

Halide perovskites have revolutionized the field of photovoltaics through their remarkable performance in single as well as tandem solar cell devices. One intriguing property of this material class is the wide tunability of the band gap which enables a fine-tuning of optical and electronic properties. In this talk, I will I revisit some of our earlier work regarding the analysis of the valence and conduction band positions of tin and lead based 3D perovskites. Combining photoelectron spectroscopy with density functional theory we were able to distinguish influences from the atomic level positions, the bond hybridization strength, as well as lattice distortions.
Recently, we also started working on 2D perovskites, which are gaining more and more attention as a strategy to tailor interfaces; they turned out to be a key factor to unlock high efficiencies in perovskite solar cells. Here, the effect of the choice of the bulky cation on the position of the charge transport layers is less clear and published measurements often seem contradicting. I will present a systematic study on alkyl-based organic cations with varying chain length, which are selected to form Ruddlesden Popper as well as Dion-Jacobson structures.
Since such 2D perovskites are most commonly used as a thin interlayer on top of 3D films, I will also present some of our results gathered at such modified surfaces. Notably, using reflection energy loss spectroscopy (REELS) we are able to determine the surface band gap of these samples which helps us to understand the formation of such 2D surface layers.

How Adding Bromine to Cs-FA Lead Halide Perovskites Changes Crystallinity, Phase Segregation and Stability as a Function of Temperature DianaK. LaFollette[1], JuanitaHidalgo[1], JongheeYang[2], Carlo Andrea RiccardoPerini[1], SergeiV. Kalinin[2], MahshidAhmadi[2] and Juan-PabloCorrea-Baena[1]; [1]Georgia Institute of Technology, United States; [2]The University of Tennessee, Knoxville, United States

One of the ever-present issues with perovskite solar cells (PSCs) is the lack of long-term stability, particularly because the popular material methylammonium (MA) lead iodide undergoes a phase transition at 57C and decomposes into PbI2 even in an inert environment. Past work exploring the formamidinium (FA) and cesium (Cs) compositional space demonstrated that these compositions have increased thermal stability while approaching and surpassing the impressive efficiency of MA-based PSCs. The degradation and phase transformations of single cation and single halide perovskites are well understood, but we do not yet understand how mixing cations and halides changes these phase transformations and degradation.
While $Cs_{17\%}FA_{83\%}PbI_3$ and $Cs_{17\%}FA_{83\%}PbI_{83\%}Br_{17\%}$ are established as high performing compositions, their phase transformations and degradation change as a function of annealing temperature. To understand the effect of adding bromine as a function of temperature, in-situ XRD and in-situ GIWAXS were used to establish the structural transformations with temperature. Adding bromine decreases strain in the crystal lattice, improving structural stability. However, it also increases the ionic conductivity thus accelerating degradation due to vacancies. Cathodoluminescence SEM, X-ray fluorescence, and X-ray beam induced current mapping are used to take the structural characterization a step further to correlating changes in crystal structure with physical morphology and phase segregation. This study shows that adding bromine changes the relationship between temperature, crystallinity, and phase purity of these mixed-

halide compositions, promoting structural stability while also accelerating the formation of secondary phases at the grain boundaries. These studies increase key understanding of how and when crystalline phase formation, segregation, and degradation occur, setting the stage for more efficient, stable PSCs based on fundamental scientific understanding.

Defect Tolerance in Halide Perovskites: Investigating the Absolute Volume Deformation Potential AlbertThese[1,2], ChristophJ. Brabec[1] and AndresOsvet[1]; [1]Institute Materials for Electronics and Energy Technology, Germany; [2]Friedrich-Alexander-Universität Erlangen-Nürnberg, Germany

Halide perovskite (HaP) semiconductors, commonly synthesized from room temperature solutions, possess exceptional optoelectronic properties that rival those achieved by more complex fabrication methods used for conventional semiconductors. The absence of detrimental defects in HaPs is a topic of debate, often attributed to their defect tolerance or self-healing ability.

To contribute to this discussion, we conducted an experimental investigation focused on determining the absolute volume deformation potential (AVDP) of CsPbBr3. The AVDP is a crucial physical parameter that characterizes the energy level shift of a semiconductor in response to volume changes. It therefore allows for quantifying of the amount of energy necessary to for example rearrange a crystal lattice locally to efficiently screen the electrical energy barrier of defects. Furthermore, it provides insights into the inherent molecular orbital bonding nature of semiconductor material.
In our study, synchrotron radiation-based X-ray photoelectron spectroscopy was employed to measure the VBM (valence band maximum) energy of CsPbBr3 across a temperature range from room temperature to 125 K. Our experimental findings demonstrate that the AVDP of CsPbBr3 is negative and relatively small compared to conventional semiconductors. This observation suggests that electronic defects can be easily screened through lattice rearrangement. Moreover, the negative sign indicates that the VBM primarily consists of anti-bonding type molecular orbitals. The disruption of these bonds typically generates defect energy levels near or within the bands. Both the magnitude and sign of the AVDP support the notion of defect tolerance in Halide perovskites.

Additionally, we conducted measurements of transient photoluminescence and employed a comprehensive interpretation based on a kinetic rate equation encompassing various recombination processes of different orders. This allowed us to quantify the defect density in CsPbBr3 at similar temperatures, providing a deeper understanding of the evolution of defect properties under volumetric changes.

Our results offer valuable insights into the origins of defect tolerance in Halide perovskites, shedding light on their unique optoelectronic characteristics.

Forming Room-Temperature Stable FAPbI3—A Multimodal *In Situ* StudyCarolinM. Sutter-Fella; Lawrence Berkeley National Laboratory, United States

Organic-inorganic halide perovskites are a versatile material class with excellent optoelectronic properties. One of the current research directions is the stabilization of the photoactive FAPbI3 phase. In this talk I will describe our joint efforts in forming phase pure and room-temperature stable FAPbI3. Application of in situ characterizations during FAPbI3 formation unveils initial nucleation and growth stages. The addition of additives to the precursor can influence the nucleation and preferential orientation leading to the absence of solvate and non-perovskite phases. Interestingly, the proposed strategy is widely applicable to different deposition methods including one- and two-step protocols. Another aspect I will touch on is reproducibility challenges in the field. Therefore, automation of halide perovskite synthesis at high throughput presents an attractive route to identify synthesis parameter-structure-function properties.

5:00 PM EN04.07.08
Comparative Analysis of Recombination Dynamics in Perovskite Solar Cells via Steady-State and Transient Photoluminescence ChrisDreessen and ThomasKirchartz; Forschungszentrum Jülich GmbH, Germany

Quantifying recombination in halide perovskites is essential for controlling and enhancing the performance of perovskite solar cells. Here, we present a comprehensive analysis of recombination dynamics in perovskite solar cells, focusing on the impact of transient measurement techniques on assessing steady-state performance. We emphasize that the decay times extracted from transient photoluminescence measurements cannot generally be reduced to a single value but rather depend strongly on the charge carrier concentration. It follows that the magnitude of the decay time is reliant on the sensitivity of the measurement. We show photoluminescence decay curves with a large dynamic range of more than 10 orders of magnitude that demonstrate decay times from tens of nanoseconds up to hundreds of microseconds in perovskite films. Assuming these high decay times correspond to a recombination lifetime in steady state, one would expect a material with perfect photoluminescence quantum yield, which does however not coincide with the experimental findings. Instead, the decay times in transient measurements are prolonged by capacitive effects resulting from charge trapping and detrapping. We quantitatively explain both the transient and steady-state photoluminescence with the presence of a high density of shallow traps without the influence of deep traps. The same characteristic of increasing decay times remains in the full device, indicating capacitive effects from either shallow traps or transport layers and electrodes. With the help of voltage-dependent steady-state photoluminescence measurements we extract the recombination lifetimes during steady-state operation of the device and compare these to the transient decay times. Furthermore, this experiment allows for the determination of the voltage-dependent collection efficiency which illustrates collection losses up to 10% due to recombination even at short circuit. In summary, this study offers a deeper understanding of recombination dynamics in halide perovskite solar cells through the analysis of transient and steady-state measurements. Our findings underscore the importance of considering the influence of shallow traps and transport layers in interpreting decay times and optimizing device performance.

First-Principles-Aided Cartography of Excitons in Metal-Halide Perovskites LinnLeppert; University of Twente, Netherlands

Excitons are neutral quasiparticles that are formed in semiconductors and insulators upon absorption of photons. Their formation, diffusion, lifetime, and recombination are key for understanding light-conversion processes and designing materials for tailored applications, such as photovoltaics, sensing, lighting, and quantum computing. Metal-halide perovskites are a structurally and chemically diverse class of materials that have been explored in all these application areas.
In this presentation, I will discuss our recent efforts to use first-principles numerical simulation techniques for modelling the formation of excitons in metal-halide perovskites and provide design rules for bespoke material properties. Our calculations allow us to map the complex landscape of electronic properties and excitons, understand the impact of chemical heterogeneity [1 - 4], dimensionality [5 -7] and temperature effects [7], and provide chemically intuitive rules for when to trust canonical models for excitons in these materials.

8:45 AM EN04.08.02
Band Structure and Exciton Dynamics in Quasi-2D Dodecylammonium Halide Perovskites DanieleCatone[1], GiuseppeAmmirati[1,2], FaustinoMartelli[3], PatrickO'Keeffe[1], StefanoTurchini[1], AlessandraPaladini[1], MauriziaPalummo[2], GiacomoGiorgi[4,3], MarcoCinquino[3,5], MilenaDe Giorgi[3] and LuisaDe Marco[3]; [1]Istituto di Struttura della Materia - CNR, Italy; [2]Università degli Studi di Roma Tor Vergata, Italy; [3]Consiglio Nazionale delle Ricerche, Italy; [4]Università degli Studi di Perugia, Italy; [5]Università del Salento, Italy

Quasi two-dimensional perovskites in Ruddlesden-Popper phase (RPPs) are extensively studied for their flexible tunability of the optoelectronic properties by changing the number of layers, chemical composition and the organic spacer, which makes them particularly suitable for several applications in the field of photovoltaics and light emitters [1-4]. In fact, the reduced

dielectric screening and the quantum confinement in a monolayer of RPP materials generate large bandgaps and stable excitons at room temperature with binding energies of the order of hundreds of meV similarly to other 2D semiconductors. Moreover, the physical properties of RPPs are strongly influenced by the number of layers that affects the electronic bandgap and the exciton binding energy which decreases as the number of layers increases. These properties are also correlated with the chemical composition and the structure of the organic spacer used as the interlayer material [5, 6].
In this developing framework, the photoexcited carrier dynamics in these materials is still far to be completely understood although the study of charge generation and recombination path can furnish key information for boosting the development of new materials for new generation optoelectronic. Femtosecond Transient Absorption Spectroscopy (FTAS) has proven to be an important tool to investigate the ultrafast physics of halide perovskites having different dimensionality, morphology and architectures, giving insights into the band structure and the electronic states involved in the photoexcitation processes. Here, we present FTAS investigations on monolayer and multilayer of RPPs DAMAPI ($DA_2MA_{n-1}Pb_lI_{3n+1}$, where DA=CH_3-$(CH_2)_{11}$-NH_{3+} is the spacer and *n* indicates the number of the layers). The FTAS measurements, performed at 77 K and room temperature using several different pump energies and excitation densities, allowed the observation of absorption bleaching energies corresponding to different excitonic and electronic transitions in DAMAPI. These results are compared with theoretical simulations based on DFT, the GW approximation and the Bethe-Salpeter equation for the calculation of the excitonic properties. In this way, we have assigned the transient absorption signals to electronic transitions related to the formation of excitons with principal quantum number 1s and 2s. The temporal analysis of these signals indicates the exciton-exciton annihilation process as the main relaxation mechanism in the first picoseconds after the excitation, while exciton radiative recombination is observed at longer time delays (>100 ps). This work demonstrates how transient absorption measurements not only allow the study of the dynamics of the excited carriers but, because of their high sensitivity to the changes of the carrier density induced by the excitation, they also allow the observation of spectral features otherwise not observable with steady-state measurements [7].

Tracking Spin and Charge in Time and Space in Halide Perovskite Films SaschaFeldmann; Harvard University, United States

Halide perovskites are promising semiconductors for next-generation optoelectronic and spintronic applications. Yet, we still don't fully understand what governs the charge and spin dynamics in these materials. This is especially true when studying device-relevant thin films of halide perovskites, which lack single-crystalline perfection.
In this talk, I will give an overview of our recent efforts to understand the spin-optoelectronic performance of these films better by using time-, space- and polarization-resolved spectroscopy and microscopy. We will find that the energetically heterogeneous energy landscape in mixed-halide perovskites can lead to the local accumulation of charges, with unexpected consequences for devices [1]; how despite strong differences in vertical diffusivity and across grains charge extraction can remain very efficient [2], and how locally varying degrees of symmetry-breaking drive spin domain formation [3,4] in this fascinating class of solution-processable semiconductors.

Characterizing Spin and Orbital Ordering Effects in Hybrid Metal Halide Perovskites Towards Advancing Optoelectronic Properties BinHu; University of Tennessee, United States

Hybrid metal halide perovskites are known as emerging semiconducting materials with tunable structure-property relationships through solution-processing methods. Such solution-processing perovskites simultaneously carry spin and orbital momentum. Consequently, using spin and orbital momentum has become a critical approach to control the multifunctional properties. However, characterizing spin and orbital parameters still demands much effort to understand their underlying relations to materials properties. To respond to this demand, we have been using magnetic field effects and circularly polarized laser spectroscopy to experimentally investigate spin and orbital parameters in determining light-emitting, photovoltaic, and lasing properties in hybrid metal halides. Our magnetic field effects have shown that bright and dark excitons are having largely different outcomes when generating optic, electric, optoelectronic actions. Therefore, magnetic field effects provide an essential experimental tool to characterize spin effects in such solution-processing perovskites. Furthermore, we found that circularly polarized luminescence can be used as a convenient method to elucidate orbital dynamics within Rashba band structures. We discovered that the circularly polarized orbitals with right and left handedness in Rashba band structures can selectively interact with spin-up and spin-down spin dipoles, leading to a mutually selectivity between spin order and orbital order. Particularly, this selective interaction between spin order and orbital order can enable spin-switchable phenomena towards developing emerging functionalities in these solution-processing hybrid metal halide perovskites. This presentation will discuss the fundamental details on exploring spin and orbital parameters by using magnetic field effects and circularly polarized laser spectroscopy.

10:30 AM EN04.08.05
Role of Interconnectivity in Perovskite Nanocrystals: Charge Carrier Dynamics in Nanostructures Embedded in Porous Films DavidO. Tiede[1], CarlosRomero-Pérez[1], KatherineA. Koch[2], Maurico E.Calvo[1], Juan FGalisteo-López[1], Ajay RamSrimath Kandada[2] and HernánMiguez[1]; [1]Institute of Materials Science of Seville, Spain; [2]Wake Forest University, United States

In the past years, halide perovskite-based devices are shifting towards low-dimensional functionalized structures and morphologies such as 2D, 2D/3D or perovskite nanocrystals (pNCs). For the latter, a common approach is to employ ligands, which ultimately determine the photophysical properties and in particular the interaction among individual NCs. As an alternative approach, mesoporous matrices can be employed to synthesize pNCs and have been established as a promising ligand free approach. [1,2] From a more fundamental perspective, this material system allows to study the interaction of excitations in pNCs with their neighbouring pNCs isolated from ligand or solvent induced effects characteristic of colloidal NCs. [3]

In this presentation, we employ $FAPbBr_3$ NCs of various sizes synthesized in porous matrices to determine the role of interparticle interaction on charge carrier recombination isolated from ligand and solvent induced effects. A broad photophysical characterization comprising time resolved absorption and emission spectroscopies as a function of temperature and fluence is employed to study the transition from isolated emitters to interconnected NCs array that preserves confinement effects while allowing for long range electronic transport. From a spectroscopic point of view, the effect of confinement is verified through thermalization dynamics. We demonstrate that interconnectivity determines charge carrier dynamics as it affects trap filling, radiative recombination and multiparticle interactions. We rationalize these findings by employing recombination and diffusion models for both the isolated and interconnected case and study the transition between these scenarios. Such transition regime is of great importance in terms of possible device performance, since the interplay of transport and (non) radiative recombination while maintaining confinement effects will determine its ultimate efficiency.

Multi-Band Electronic Structure and Carrier Dynamics in Formammidinium Lead Bromide Perovskite DanieleCatone[1], GiuseppeAmmirati[1,2], PatrickO'Keeffe[1], StefanoTurchini[1], FrancescoToschi[1], AlessandraPaladini[1], FaustinoMartelli[1], FabioMatteocci[2], JessicaBarichello[2], PaoloMoras[1], PolinaSheverdyaeva[1], ValeriaMilotti[1], DanielOry[3,4], PhillippeBaranek[3,4] and AldoDi Carlo[1,2]; [1]Consiglio Nazionale delle Ricerche, Italy; [2]Università degli Studi di Roma Tor Vergata, Italy; [3]Electricitè de France (EDF), Italy; [4]Centre National de la Recherche Scientifique, Italy

In recent years, the scientific community has been captivated by the exceptional properties of halide perovskites. These materials have garnered significant interest due to their high absorption

coefficients in the visible range ($\alpha>10^5$ cm^{-1}), ultralong carrier diffusion lengths, extended carrier lifetimes, remarkable defect tolerance, and tunable bandgaps [1-2]. Among these perovskites, lead bromide perovskites have emerged due to their relatively large bandgap of approximately 2.3 eV, making them ideal candidates for tandem applications and efficient semitransparent solar cells. In this context, one of the most promising materials is formamidinium lead bromide perovskite ($FAPbBr_3$) that exhibits remarkable stability under light exposure and possesses a carrier diffusion length that facilitates a straightforward planar heterojunction solar cell configuration [3, 4]. Despite its proven superiority in terms of semitransparency and stability, only a limited number of experimental and theoretical studies have been conducted to explore its properties. In particular, the knowledge of the electronic properties and of the dynamics of photoexcited carriers in $FAPbBr_3$ remain incomplete. Understanding the charge generation and recombination is of paramount importance as it provides crucial insights for advancing the development and optimization of various technologies such as solar cells, lasers, and LEDs [5].
Here, we present the excited-state properties of a thin film of $FAPbBr_3$ studied combining steady-state light absorption, photoluminescence (PL), femtosecond transient absorption spectroscopy (FTAS), photoelectron spectroscopy (PES) with density functional theory (DFT) calculations. In this way, we give a complete description of the electronic properties of $FAPbBr_3$, assigning the electronic bands involved in the photoexcitation by UV-Vis radiation and the relative carrier dynamics. By integrating absorption, PL, PES, and DFT, we successfully assign the two photobleaching (PB) signals observed in the transient spectrum to specific electronic transitions. Specifically, the signal at 2.3 eV (PB1) originates from the transition between the first valence band (VB1) and the first conduction band (CB1) [6], while the signal at 3.4 eV (PB2) arises from the transition between the second inner valence band (VB2) and CB1. In the light of this assignation, the rise of the PB1 and PB2 signals were investigated as a function of the carrier density, in order to correlate their dynamics to the thermal relaxation processes involving the carriers excited in the VB1→CB1 and VB2→CB1 transitions. The PB1 signal shows a rise time that slows down with the increase of the carrier density indicating that the dominant processes influencing it are the thermalization and cooling of carriers in VB1 and CB1 [7, 8]. On the other hand, the rise time in PB2 accelerates as the excited carrier density increases, suggesting that this signal is strongly influenced by the thermalization of the hot holes in VB2. In fact, VB2 shows a quasi-flat band structure determining a localization near the band maximum of all the excited holes [9].
In summary, the combination of various spectroscopic techniques and theoretical calculations allows us to unravel the underlying carrier dynamics and establish correlations with thermal relaxation processes, providing valuable insights into the excited-state behavior of $FAPbBr_3$. These findings enhance our understanding of the material properties and pave the way for further advancements in its utilization for optoelectronic and photovoltaic applications.

Engineering of Solid-State Single-Photon Sources Based on Perovskite Quantum Dots in Perovskite Matrix HaoZhang[1], AltafPasha[1], SirajSidhik[1], Jia-ShiangChen[2], XuedanMa[2] and AdityaD. Mohite[1]; [1]Rice University, United States; [2]Argonne National Laboratory, United States

Semiconductor quantum dots (QD) have emerged to be one of the promising candidates for on-demand single-photon emitters (SPE), which are one of the key units in quantum photonic circuits and quantum information processing. However, despite wide investigation of colloidal QDs, implantation of such SPE system in solid states for electrical excitation is less developed. Here, we have demonstrated the first solution-processed perovskite-based single-photon source in a solid-state medium, by embedding perovskite emission centers into a wide-bandgap perovskite matrix. Such 'dot-in-a-matrix' system exhibits a clear photon-antibunching signature, with second-order correlation function (g2(0)) to be ~0.1 at cryogenic temperatures. The photoluminescence (PL) spectrum exhibits narrow emissions lines at 1.8-1.9eV with 2-3meV FWHM at T=6K, indicating high crystallinity of the localized emission centers. High-resolution transmission electron microscope (HR-TEM) confirms the presence of nanometer-sized domains, which indicates the formation of quantum dots during the rapid crystallization of the precursor solvent. Monitoring PL with time suggests blinking-free emission and spectral diffusion of <1meV. PL spectra exhibits a linear dependence with excitation intensity, indicating the mono-recombination dominated by single exciton rather than bi-exciton or charged exciton states. Additionally, exciton fine structures have been detected, which are likely due to the anisotropic structures of individual emitters. Finally, we have demonstrated the capability of electrical luminescence by sandwiching the matrix between electron-transport and hot-transport layers. Such demonstration may pave the pathway of on-chip integration of single-photon sources for quantum optical systems.

New Insights into the Formation Mechanism and Electronic Structure of Alloyed $Cs_2AgBiBr_6$ Double Perovskites for Enhanced Visible Light Absorption HuygenJ. Jöbsis[1], KostasFykouras[2], JoostW. Reinders[1], InaVollmer[1], MichalAndrzejewski[3], LoretaA. Muscarella[1], NicolaP. Casati[3], LinnLeppert[2] and ElineHutter[1]; [1]University of Utrecht, Netherlands; [2]University of Twente, Netherlands; [3]Paul Scherrer Institute, Switzerland

Halide double perovskite semiconductors such as $Cs_2AgBiBr_6$ are widely investigated as a more stable, less toxic alternative to lead–halide perovskites in photoconversion applications including photovoltaics and photoredox catalysis. However, the relatively large (~2.1 eV) and indirect bandgap of $Cs_2AgBiBr_6$ limits efficient sunlight absorption. Similar to lead–halide perovskites, the bandgap of double perovskites can be manipulated through (partial) substitution of metals or halides with similarly charged ions. However, commonly used solvent-based synthesis routes often lead to the formation of domains or side phases, rather than solid solutions with controlled properties. This results in an inhomogeneous electronic landscape which is detrimental for photoconversion applications.

Here, we show that mechanochemical synthesis methods, such as ball milling, are a valid route to synthesize phase-pure double perovskites. With the use of synchrotron radiation we followed the formation mechanisms during mechanochemical synthesis of $Cs_2Ag[BiM]X_6$ (with M = Sb, In, or Fe or X = Cl, Br, or I), and identified new intermediate phases, providing insights into the reaction kinetics. We find that mechanochemical synthesis is a successful approach to make compounds that have not been reported via solution-based synthesis routes, such as $Cs_2AgBi_{0.5}In_{0.5}Br_6$, $Cs_2AgBiBr_{6-x}I_x$, and $Cs_2AgBi_{1-x}Fe_xBr_6$. Where substitution with In^{3+} increases the band gap energy, it is lowered when replacing Bi^{3+} with Fe^{3+} or Br^- with I^-.

Hence, the optical bandgap of $Cs_2AgBrBr_6$ can be tuned over the entire visible spectrum when partly substituting Bi^{3+} or Br^-. For instance, we find that controlled replacement of Bi^{3+} with Fe^{3+} via mechanochemical synthesis results in a remarkable tunability of the absorption onset between 2.1 to ~1 eV. Our first-principles density functional theory (DFT) calculations demonstrate that this bandgap reduction originates from a lowering of the conduction band minimum upon introduction of Fe^{3+}, while the valence band remains constant. Additionally, our DFT calculations suggest that the bandgap becomes direct when >50% of Bi^{3+} is replaced with Fe^{3+}. Finally, we find that the tunability of the conduction band minimum is reflected in the photoredox activity of these semiconductors.

The improved understanding of the reaction mechanism of alloyed-AgBi double perovskites might help to overcome the current challenges faced with solution processing methods. Hence, opening up new avenues for enhancing the visible light absorption of double perovskite semiconductors and for harnessing their full potential in sustainable energy applications.

Traps in the Spotlight: How Traps Affect the Charge Carriers Dynamics in $Cs_2AgBiBr_6$ Perovskite ValentinaCaselli[1], JosThieme[1], HuygenJ. Jöbsis[2], JiashangZhao[1], ElineHutter[2] and TomJ. Savenije[1]; [1]Delft University of Technology, Netherlands; [2]Inorganic Chemistry and Catalysis, Netherlands

Since their discovery as versatile semiconductors for photovoltaic applications, perovskite materials, with general formula ABX_3, have been intensively studied. Tuning of their opto-electronic properties make it possible to reach remarkable power conversion efficiencies, currently topping at 25.6%, in roughly a decade of development. However, a rising concern regarding the use of lead in the photoactive layer has pushed research into lead-free alternative candidates. Toxic lead can be substituted by combining monovalent and trivalent cations, such as in $Cs_2AgBiBr_6$. However, efficiencies of $Cs_2AgBiBr_6$-based photovoltaics are still modest. To elucidate the loss mechanisms, in this report we investigate charge dynamics in $Cs_2AgBiBr_6$ films in thin films by means of TRPL, TA measurements and double pulse excitation time-resolved microwave conductivity (DPE-TRMC). In DPE-TRMC the sample gets illuminated by two laser pulses arriving with a short time delay. By comparing the photoconductance traces induced by the second pulse in presence and absence of the first pulse, we are able to examine the effect of the long-lived species on the charge carrier dynamics. For these experiments we used identical excitation wavelengths for both laser pulses but varying intensities and delay times. We modelled the results introducing a comprehensive model, which accounts for the free carrier generation yield, localization of free carriers, electron trapping by color centers, and shallow trap states for holes. The iterative analysis of the DPE-TRMC experiments with different intensities and delay times reveals the presence of a high concentration of both electron (10^{15} cm^{-3}) and hole (10^{16} cm^{-3}) trap states. In addition, we show that both carriers are trapped on sub-ns timescales, while their depopulation occurs over tens of microseconds. Furthermore, we observe a higher mobility for holes compared to electrons, which amount to 5 and 0.01 $cm^2/(Vs)$ respectively, in agreement with the imbalance in their effective masses. Localization of holes causes an

effective loss in mobility for the holes, dropping to ca. 1.7 $cm^2/(Vs)$, while no effect can be discerned for the electrons. Knowing these kinetic parameters allows us to predict the charge carrier dynamics under AM1.5, explaining the solar cell performance. Our new developed DPE-TRMC methodology gives direct insight on the timescales involved with population and depopulation of the various trap states in $Cs_2AgBiBr_6$, essential for the design of more efficient devices.

Transient Holographic Imaging of Spin Magnetic Moments in Perovskites Julia AntheaGessner[1], MartinHörmann[2], ShangpuLiu[1], GiulioCerullo[2], FrancoValduga de Almeida Camargo[3] and FelixDeschler[1]; [1]Universität Heidelberg, Germany; [2]Politecnico di Milano, Italy; [3]IFN-CNR, Italy

Hybrid metal halide perovskites have shown to be a promising class of materials for a variety of applications ranging from LEDs [1] to solar cells [2] due to their high quantum efficiency and tunability in the visible range. Compared to conventional semiconductors, perovskites exhibit strong spin-orbit coupling and spin-split Rashba bands, which allow an efficient optical spin manipulation and could possibly extend the spin life-time of excitons. These features are particularly attractive for opto-spintronic applications and data storage [3].
A preliminary step towards the integration of perovskites in opto-spintronic devices is the time- and space-resolved optical study of their magnetic properties. In the present work, we study the spatio-temporal spin dynamics of Methylammonium Lead Tribromide ($MAPbBr_3$) by the unique combination of two spectroscopic methods: Faraday rotation spectroscopy and Ultrafast Holographic Transient microscopy (UHT) [4]. With our technique we get access to the polarization dependent carrier population as well as the Faraday angle, which is a measure for the spin-aligned magnetic moment. The UTH microscope, which works as a shot-noise limited, all-optical lock-in amplifier, has no upper limitations in the signal repetition rate and can resolve femtosecond dynamics with a sub-micrometre spatial resolution.
By spatially mapping the transient Faraday angle at different temperatures and fluences, we are hence able to investigate the evolution of optically spin-polarized excitons in time and space and identify the dominating spin relaxation mechanisms. This information is essential for the optimization of the materials' properties and the future realization of opto-spintronic systems.

Improving the Efficiency and Stability of Perovskite Solar Cells using π-Conjugated Aromatic Additives with Differing Hydrophobicities BrianSaunders; University of Manchester, United Kingdom

Improving the efficiency and stability of perovskite solar cells using π-conjugated aromatic additives with differing hydrophobicities

Perovskite solar cells (PSCs) continue to excite the research community due to their excellent power conversion efficiency (PCE) and relative ease of preparation. Additive engineering has played a decisive role in improving PSC performance and stability. In particular, p-conjugated aromatic additives (CAAs) offer key advantages such as high charge transport. However, the roles of hydrophobicity and structure in determining CAA performance as additives are still being established. Here, we investigate the effects of two coumarin additives on the PCE and stability of PSCs based on $Cs_{0.05}(FA_{0.85}MA_{0.15})_{0.95}Pb(I_{0.85}Br_{0.15})_3$ perovskite. The CAAs are coumarin methacrylate (CMA) and coumarin hydroxyethyl (CHE) and were added to the precursor perovskite solutions prior to film deposition with CMA being more hydrophobic than CHE. These additives increase the best PCE of 19.15% for the control to 21.14% and 21.28% for the best devices containing CHE and CMA, respectively. The stability of the devices with the additives are far superior to that of the control (CAA-free) system. The time lengths required for the PCE to decrease to 80% of the initial value for CMA- and CHE-containing devices are 98 and 38 days, respectively, compared to only 14 days for the control. The moisture and thermal stabilities of the systems containing CMA are markedly improved compared to those containing CHE and the control. Our results show that the extents of binding to Pb^{2+} and passivation increase as the coumarin's hydrophobicity increases which decreases recombination. Our findings show that adding CAAs with increasing hydrophobic character to the precursor perovskite solution is useful for achieving high-performance and long-term stable PSCs[1].

Unraveling Photoelectrochemical Degradation Pathways in Lead Mixed Halide Perovskites with Near Ambient Pressure XPS MichelDe Keersmaecker, NealArmstrong and ErinL. Ratcliff; The University of Arizona, United States

Long-term stability in metal halide perovskites has often been connected to defects in the electonic band gap, but rarely their (electro)chemical, physical and dynamic nature, as well as ion reactivity and mobility are considered. Interactions with O_2 and light excitation (i.e. from X-rays to UV-visible regions) have been suggested as culprits for bulk and interfacial degradation of perovskites and have been considered critical in the improvement of operational stability of photovoltaic devices and X-ray detectors.[1-3] Possible explanations for this irreversible degradation process, however, range from intrinsic defects and phase segregation to electrochemical reactions as well as electronic and interfacial property changes.[4-6]
In this work, *in situ* degradation of device-relevant triple cation mixed halide perovskite films using dry O_2 gas using a near ambient pressure X-ray photoelectron spectroscopy (NAP-XPS) characterization method reveals the formation of a weakly coordinated form of Pb (relative to corner-sharing $[PbI_6]^{4-}$ octahedra). Simultaneously, oxidized iodide species (I_3^-) are formed in the illuminated near-surface region causing the bromide enrichment, consistent with "de-mixing" under stress. Once UHV conditions are restored, a slow return to the initial perovskite stoichiometry is observed, suggesting "self-healing" of defects when the low stress environment is reestablished. In non-stoichiometric films degradation rates accelerate for FAI-rich stoichiometries, but, more importantly, PbI_2-rich stoichiometries show reduced rates.
This NAP-XPS study demonstrates an important first step in a systematic approach to understanding the role(s) of ambient gases in conjunction with above band-gap illumination and other stressors that limit device stability. Prior to investing resources in high-throughput device construction, this NAP-XPS characterization technique will be an important asset in the investigation of interface engineering strategies for top contact (and bottom) modifications used as mitigation strategies in device optimization with focus on photoelectrochemical stability and energy level alignment if combined with UPS. Additionally, this work extends towards other semiconductive materials or material blends, where *in situ* chemical characterization will be essential to design and support next-generation electronics.

Resolving the Hydrophobicity of Me-4PACz Hole Transport Layer for Inverted Perovskite Solar Cells DineshKabra; Indian Institute of Technology Bombay, India

[4-(3,6-Dimethyl-9H-carbazol-9-yl)butyl]phosphonic acid (Me-4PACz) self-assembled monolayer (SAM) has been employed in perovskite single junction and tandem devices demonstrating high efficiencies. However, a uniform perovskite layer does not form due to the hydrophobicity of Me-4PACz. Here, we tackle this challenge by adding a conjugated polyelectrolyte poly(9,9-bis(3'-(N,N-dimethyl)-N-ethylammonium-propyl-2,7-fluorene)-alt-2,7-(9,9dioctylfluorene))dibromide (PFN-Br) to the Me-4PACz in a specific ratio, defined as Pz:PFN. With this mixing

engineering strategy of Pz:PFN, the PFN-Br interacts with the A-site cation is confirmed via solution-state nuclear magnetic resonance studies. The narrow full width at half maxima (FWHM) of diffraction peaks of perovskite film revealed improved crystallization on optimal mixing ratio of Pz:PFN. Interestingly, the mixing of PFN-Br additionally tunes the work function of the Me-4PACz as revealed by Kelvin probe force microscopy and built-in-voltage estimation in solar cells. Devices employing optimized Pz:PFN mixing ratio deliver open-circuit voltage (V_{OC}) of 1.16V and efficiency >20% for perovskites with a bandgap of 1.6 eV with high reproducibility and concomitant stability. Considering significant research on Me-4PACz SAM, our work highlights the importance of obtaining a uniform perovskite layer with improved yield and performance.

Long-Lived Hot-Carrier Light Emission in Sn Halide Perovskites Maria AntoniettaLoi; University of Groningen, Netherlands

A long-lived hot carrier population is critical in order to develop hot carrier photovoltaic devices with efficiencies exceeding the Shockley–Queisser limit. Here, we report photoluminescence from hot-carriers with unexpectedly long lifetime (ns range) in tin triiodide perovskites. By correlating energy-resolved and time-resolved photoluminescence both a low and room temperature, with density functional theory calculations, we posit that this phenomenon is mostly associated with state-filling of band edge states. While phonon interactions have an effect, but minor. Measuring impulsive stimulated Raman scattering spectroscopy, we identify two coherent phonon modes (25 and 133 cm^{-1}) in FASnI3, where the 133 cm^{-1} mode shows a fast decay (< 1 ps) and large dependence on the excitation fluence and energy. We further show that the phonons in $FASnI_3$ decay much faster compared to $CsSnI_3$, highlighting the stronger electron-phonon and phonon-phonon interaction in the hybrid compounds.
This work is of fundamental importance for our understanding of Sn-based hybrid perovskites and for an eventual future development of hot carrier photovoltaics.

Influence of Methylammonium Chloride on the Formation and Properties of 3D Br-Rich Perovskites: an *In Situ* InvestigationAna FlaviaNogueira; University of Campinas, Brazil

Owing to their exceptional properties, metal halide perovskites have been incorporated in tandem solar cells. For silicon-perovskite tandem, Br-rich perovskites with a wide-bandgap are required. However, the increase in Br content causes halide distribution heterogeneities and photoinstability. Methylammonium chloride (MACl, MA = $CH_3NH_3^+$) is often added to the perovskite precursor solution to improve optoelectronic properties and performance. However, the effect of MACl additive on Br-rich perovskites is poorly understood.
In this presentation, we will summarize the previous studies from our group where *in situ* experiments coupled to synchrotron radiation were important to identify intermediates compounds, other metal halide phases during the steps of formation, crystallization and annealing.
In the second part of the talk, we will focus on metal halide perovskites with different amounts of Br and MACl using the N-methyl-2-pyrrolidone (NMP) solvent and the gas quenching deposition method. Simultaneous grazing-incidence wide-angle X-ray scattering (GIWAXS) and photoluminescence spectroscopy (PL) tracked perovskite crystallization and emission properties during the spin-coating and thermal annealing steps. For the perovskites without MACl, the formation of crystalline intermediates depends on the halide proportion. On the other hand, adding the MACl changes the formation mechanism inhibiting the formation of crystalline intermediates. Robust Pb-Cl bond formation decreased the interaction of PbX_6 octahedrons with solvent molecules, preventing the stabilization of intermediate phases containing the solvent. The destabilization of the intermediate phases promoted by the addition of MACl favored the formation of the better crystalline perovskite phase with preferential orientation in the [001] direction and inhibited the photoinduced halide segregation. Nano X-ray fluorescence (nano-XRF) mapping at identified transformations in the elemental distribution, recognizing Br-richer and poorer domains that are reduced for samples prepared with MACl.

10:30 AM *EN05.08/EN04.06.04
Which Defects Matter in Photoactive Perovskites?JoanneEtheridge[1], WeilunLi[1], MengmengHao[2], QimuYuan[3], JayPatel[3], MichaelJohnston[3] and LianzhouWang[2]; [1]Monash University, Australia; [2]The University of Queensland, Australia; [3]University of Oxford, United Kingdom

Photoactive perovskites show great potential for applications in solar cell devices, achieving remarkable power conversion efficiencies while using relatively low cost, low temperature production methods. However, there remain many challenges, from stability in air and under photon irradiation to ion migration and current density-voltage hysteresis.

In order to exploit the full potential of photoactive perovskites, it is critical to understand how macroscopic device performance depends on structure, from the micron to the atomic scale. Compared with the rigid diamond structure of silicon, the intrinsically flexible and versatile perovskite structure provides an entirely different structural landscape upon which to manipulate properties, such as optical bandgaps. Furthermore, it can accommodate a different class of structural defects which can influence performance.

Here we investigate the relationship between local crystal structure, defect structure and device performance in quantum dot and thin film photoactive perovskites and associated devices using carefully devised ultralow dose electron microscopy methods [1-3] correlated with device characterisation.

In high performance $Cs_{1-x}FA_xPbI_3$ quantum dot devices [4], we identify the presence of planar defects with face-sharing octahedra and show that removing them leads to significantly improved power conversion efficiency and carrier lifetime [5] (consistent with observations in hybrid organic-inorganic $MA_{1-x}FA_xPbI_3$ thin films [6]). We also identify the formation of FA^+/I^- vacancy pairs and elucidate their role in ion migration and A-site dependent structural phase changes [7].

In $CsPb(I_{1-x}Br_x)_3$ films, we identify the crystal structures and defect structures associated with different halide compositions and deposition parameters, including twin and antiphase boundaries. Using sub-10e/$Å^2$ atomic resolution imaging techniques, we identify the local atomic structure of these planar defects and consider their impact on device performance, providing insights into the structural environments necessary to optimise device performance [8].

Structural and Ionic Stability Challenges in Metal Halide Perovskites LauraHerz; University of Oxford, United Kingdom

Organic-inorganic metal halide perovskites have emerged as attractive materials for solar cells with power-conversion efficiencies of single-junction devices now exceeding 25%. However, the low hurdle for ionic migration, and the structural flexibility of the perovskite structure still pose both opportunities and challenges to their commercialization in light-harvesting

applications.

We discuss the peculiar mechanisms underlying detrimental halide segregation in mixed iodide-bromide lead perovskites with desirable electronic band gaps for silicon tandems.[1-4] Surprisingly, halide segregation results in negligible impact to the THz charge-carrier mobilities, but is impacted by remarkably fast, picosecond charge funnelling into the narrow-bandgap I-rich domains that enhances radiative recombination.[2] Our combinatorial, in-situ photoluminescence and X-ray diffraction measurements[3,4] reveal how such halide segregation is affected by A-cation choice[3] and the presence of charge-extraction layers.[4] We further demonstrate a temperature-dependent reversal of halide segregation at temperatures above ambient.[5] We observe that, with increasing temperature, halide segregation in $CH_3NH_3Pb(Br_{0.4}I_{0.6})_3$ first accelerates toward 290 K, before slowing down again toward higher temperatures. Such reversal is attributed to the trade-off between the temperature activation of segregation, for example through enhanced ionic migration, and its inhibition by entropic factors. High light intensities meanwhile can also reverse halide segregation; however, we find this to be only a transient process that abates on the time scale of minutes.[5]

In addition, we discuss the peculiar effect of "intrinsic quantum confinement" (QC) exhibited by $FAPbI_3$ perovskite, apparent through oscillatory features in the absorption spectrum[6-8] that suggest the presence of nanoscale features of periodicity around 10–20 nm present in sub-volumes.[6] We show[7] that such nanoscale electronic effects can be controlled through partial replacement of the FA cation with Cs, and allow for photon emission, highlighting their potential usefulness to light-emitting devices and single-photon sources.[7] However, we reveal that such QC features are clearly detrimental to photovoltaic operation.[8] We explore three common solution-based film-fabrication methods for $FAPbI_3$, and show that elimination of these QC absorption features yields increased power conversion efficiencies (PCEs) and short-circuit currents, suggesting that quantum confinement hinders charge extraction. A meta-analysis of literature reports, covering 244 articles and 825 photovoltaic devices incorporating $FAPbI_3$ films corroborates our findings, indicating that PCEs rarely exceed a 20% threshold when such absorption features are present. Accordingly, ensuring the absence of these absorption features should be the first assessment when designing fabrication approaches for high-efficiency $FAPbI_3$ solar cells.

11:30 AM *EN05.08/EN04.06.06
Defects, Devices and Degradation of Metal Halide Perovskites: An Electrochemist's Perspective ErinL. Ratcliff; University of Arizona, United States

Defects are considered to be one of the most prominent contributions to diminished power conversion efficiencies and long-term stability in printable metal halide perovskite materials and optoelectronic devices. Defects can arise from a combination of point defects, grain boundaries, charge transfer with Lewis acid/base sites at the contacts, and/or mobile redox-active halides. Thus every perovskite composition and contact choice can result in differences in defect distributions.

Defect states have most often been characterized using electrical, optical, and magnetic techniques; however, independently assessing donor and acceptor defect quantities and energetics using a direct experimental approach with few empirical assumptions can be challenging. Realization of high-performing and long-term stable devices requires a combination of method advancement for the quantification of defects and mitigation strategies.

This talk will discuss emerging electrochemistry-based measurement science approaches to quantify the distribution and energetics of donor and acceptor defects in a prototypical perovskite solar cell material $(FA_{.79}MA_{.16}Cs_{.05})Pb(I_{.87}Br_{.13})_3$ (or $Cs_{.05}FA_{.79}MA_{.16}$), with demonstrations of the methodology to other perovskite active materials. We utilize a solid-state electrolyte top contact to create "half-cells" of device-relevant material stacks under realistic electric fields. This allows us to spectroscopically assess onsets in valence and conduction bands under conditions of *operando*, as well as quantify near-band defects using redox probes. Connections to device performance, including modifications to the near-surface region of hole-transporting layers (i.e. NiOx), will be provided as well as preliminary results to understand degradation pathways using near-ambient pressure x-ray photoelectron spectroscopy and *operando* x-ray scattering. Collectively, this developed tool-suite provides a holistic approach to understand defects, device performance and stability in this exciting class of materials.

Models of Disorder in Halide Perovskites AronWalsh; Imperial College London, United Kingdom

The structural arrangement of metal halide perovskites varies in space and time. Beyond the conventional vibrations of atoms around their average positions, collective motion in the form of octahedral tilting and molecular librations/rotations introduces additional layers of complexity in the dynamic crystal structure. To complicate matters further, dilute point defects, such as charged vacancies and interstitials, exist in a diverse landscape of extended defects including dislocations, polytypes, and grain boundaries. There can also be chemical gradients due to mixing on the A, B or X crystallographic positions, e.g. as found in mixed formamidinium/methylammonium, tin/lead, and iodide/bromide compounds. I will discuss our latest understanding of these phenomena at the atomic scale drawing from our work on data-driven materials modelling [1,2,3] and linked to multi-modal experimental characterisation [4].

Optimization of Indium Oxide Interconnecting Layer for All Perovskite Tandem Solar Cells with Efficiency > 26%GauravKapil[1,2], YasuhiroFujiwara[1], QingShen[1], HiroshiSegawa[2] and ShuziHayase[1]; [1]University of Electrocommunications, Japan, Japan; [2]The University of Tokyo, Japan

All perovskite tandem solar cells (APTSCs) are now showing power conversion efficiencies (PCEs) more than the highest reported single-junction perovskite and silicon solar cells [1,2]. The rapid rise in the performance of APTSC can be ascribed to the improvement in the performances of both top (wide bandgap, WBG) and bottom (narrow bandgap, NBG) cells. Recently, the focus has been on the reduction of halide segregation and improvement of open circuit voltage (Voc) in WBG cells which led to an immense increase in Voc of APTSC to 2.2V [2,3]. We noticed that most of the recent reports on efficient APTSCs utilize SnOx (prepared by atomic layer deposition) coated with Au (1-2nm) as an interlayer. However, the optical loss due to the use of Au nanoparticles can't be ignored. Therefore, in this work, we focused on the preparation of indium oxide doped with zinc oxide (IZO) as an interconnecting layer in place of Au nanoparticles to reduce the optical loss and improvement of facile hole and electron recombination at the SnOx layer. It is explored that the physical properties of IZO can be tuned while its preparation which finally plays a crucial role in enhancing the Voc of the APTSC. The other advantages that come with the IZO are that electrical properties can be changed according to the hole transport layer (HTL) utilized. So far, PEDOT:PSS is the only hole transport layer that can be used for efficient APTSCs. Therefore, the use of IZO interconnect further gives flexibility in choosing other HTLs such as self-assembled monolayers. In conclusion, we obtained PCE of 26.39% for APTSC with a Voc of 1.94V, Jsc of 17.18 mA/cm2, and FF of 0.79. APTSC employing Au nanoparticle interlayer showed an inferior PCE of 22.32% with a Voc of 1.84V, Jsc of 15.4 mA/cm2, and FF of 0.79. Moreover, in this work, we will support the increase in device performance with the use of different IZO interconnect by evaluating the carrier mobility, diffusion length, charge transport time, and recombination time. Also, its role in charge transport between the top and bottom cells will be discussed.

Preserving Bond Ionicity under Illumination to Achieve Photostable Halide Perovskites MalgorzataWierzbowska; Institute of High Pressure Physics Polish Academy of Sciences, Poland

Lead halide perovskites (LHPs) with the formula ABX3 are very efficient materials for optoelectronic devices: solar cells, light-emitting diodes, lasers, photodetectors, γ-detectors, and field effect transistors. But they are very fragile and sensitive to humidity, temperature, and operating conditions such as voltage bias and light. The reason is their weakly ionic structure with twice lower atomic ionicities than those in oxides. Photostability is difficult to achieve in LHP, due to the nature of electronic states that originate mainly from the halide anions in the valence band and B cations in the conduction band; hence, the charge transfer lowers the ionicity at the B−X bond.
To date, the A cations used have been optically inactive and only served as one-electron donors for the charge balanced BX3 frame. We propose a mechanism of photoexcitation acting between two different A cations, namely SLi3 and SH3, while the inorganic frame remains unchanged under illumination preventing B−X bond breakage and halide migration. Demand for a specific crystal localization of the optical excitations is a new factor for achieving photostability, in addition to a control of the ionic radii, defects, morphology, and surface and interface stabilization.
We theoretically demonstrate that the absorption spectra of (SLi3,SH3)PbI3 perovskite are optically efficient for the distributions of two types of A cations that form the planar structures. The excitations in such case take place over the interface. The optimal light polarization should be oriented with the electric vector perpendicular to the interface between the regions with two types of molecular cations, that means the beam direction oriented within the interface plane. The spectra were obtained by solving the Bethe-Salpeter equation. The results are published [1].

Heterointerface and Intragrain Microstructures of Perovskite Semiconductors YuanyuanZhou; Hong Kong Baptist University, China

Heterointerface and intragrain microstructures are prominent factors influencing the properties and performance of perovskite semiconductors, which remain *terra incognita*. In my talk, I will discuss our recent developments on the novel characterization and tailoring of these microstructures, which elevate our fundamental understanding of microscopic structure-property-performance relationship in perovskites. Specifically, I will demonstrate two examples of perovskite-substrate heterointerface designs, featuring an interlocking interfacial microstructure and a flattened grain-boundary groove structure, respectively. Such microstructural designs contribute to improved carrier injection, chemical stability, and more importantly, (opto-)mechanical reliability of resulting perovskite solar cells. Then, we will illustrate our findings on performance-limiting intragrain defects and their structural dynamics, enabled by our latest innovations in scanning transmission electron microscopy methodologies. Finally, I will provide the perspectives and current ΣLab (www.alvinyzhou.com) efforts pushing the frontier of perovskite knowledge as well as the broad materials research *via* unravelling novel microstructure phenomena.

Local Charge Carrier Dynamics in Lead Halide Perovskites by Nano Surface Photovoltage Spectroscopy YenalYalcinkaya[1], PascalN. Rohrbeck[1], LukasSchmidt-Mende[2] and StefanA.

Weber[1,3]; [1]Max Planck Institute for Polymer Research, Germany; [2]University of Konstanz, Germany; [3]University of Stuttgart, Germany

Understanding electron and ion dynamics is an important task for improving lead halide perovskites based solar cells and related devices. Perovskite materials usually have a delicate nano- and micro structure that influences the device parameters. Here, macroscopic measurement techniques are not sufficient. This study investigates the spatial defect distribution in the vicinity of grain boundaries (GB). To this end, we introduce Nano surface photovoltage spectroscopy (Nano-SPV) via time-resolved Kelvin probe force microscopy (tr-KPFM) [1,2]. By measuring the SPV decay on perovskite samples with small, large, and passivated grains, areas of increased charge carrier recombination, ion migration, and defects were locally detected. Using Nano-SPV, we revealed local SPV overshoots in the vicinity of grain boundaries following an illumination pulse. Furthermore, we introduce a new KPFM-based method to map the local light ideality factor within the perovskite films. The ideality factor is correlated to the dominant charge recombination processes within the absorber layer. Our results clearly show an improved uniformity of SPV and SPV decay distribution within the perovskite films upon passivation. Furthermore, the perovskite films with large grains show better recombination properties based on SPV decay and ideality factor values.

2:15 PM EN05.02.03
R&D on Gateway Technologies for Perovskite Solar Cells TaoXu; Northern Illinois University, United States

Various formulations have been developed to improve the stability of hybrid perovskite layer in perovskite solar cells (PSCs), while their mutual compatibility remains uncertain. Thus, it is important to focus future R&D on technologies that are both adaptable to all other formulations and also independently exhibit added enhancement in stability. In addition, >50% infrastructure investment of PSC production line will be on the expensive and energy-costly vacuum evaporation equipment. In this talk, based on the fundamental reaction kinetics, we will present a low-cost isotope technology that is adaptable to any existing PSC formula and also retards degradation reaction kinetics, thus to improve stability of PSCs as an add-on feature independently. We will also present a disruptive vacuum-free paint & brush coating technology based on basic band structure theory for back electrode deposition for n-i-p configured PSCs, which also circumvents the use of expensive gold as the back electrode. These novel methods are promising gateway technologies that either synergistically enhance the stability of PSCs or reshape the infrasture of PSC production line in the forthcoming commercialization of PSCs.

Accelerating The Transition from Lab to Fab via High Throughput Automated Synthesis and Characterization of Metal Halide Perovskites JongheeYang[1], SherylL. Sanchez[1], BenjaminLawrie[2], YipengTang[1], BinHu[1], JuanitaHidalgo[3], SergeiV. Kalinin[1], Juan-PabloCorrea-Baena[3] and MahshidAhmadi[1]; [1]University of Tennessee, Knoxville, United States; [2]Oak Ridge National Laboratory, United States; [3]Georgia Institute of Technology, United States

Metal halide perovskites have garnered considerable attention in the field of optoelectronics due to their exceptional properties. However, so far little has been understood based on the fundamental principles for designing the functional perovskites, which is now crucially decelerating the lab-to-fab transformation and realization of the scalable manufacturing of these materials for optoelectronics. In this talk I will discuss the potential of machine learning-driven high throughput automated experiments to expedite the discovery of hybrid perovskites, optimize processing pathways, and enhance the understanding of formation kinetics [1-4]. Notably, the utilization of a high-throughput robotic system to accelerate the exploration of the ligand-assisted reprecipitation (LARP) method for synthesizing perovskite nanocrystals represents a significant contribution to the field [5]. The workflow demonstrated in this study serves as a powerful tool for constructing detailed chemical maps of perovskite nanocrystal synthesis, enabling tailored customization of their functionalities. Additionally, another study showcases how high throughput automated synthesis provides a comprehensive guide for designing optimal precursor stoichiometry to achieve functional quasi-2D perovskite phases in films capable of realizing high-performance optoelectronics [3,4]. I further introduce the concept of co navigation of theory and experiment spaces to accelerate discovery and design of hybrid perovskites. These studies exemplify how a high-throughput automated experimental workflow effectively expedites discoveries and processing optimizations in complex materials systems with multiple functionalities, facilitating their realization in scalable optoelectronic manufacturing processes.

Surface and Interface Passivation for Perovskite Devices BinChen; Northwestern University, United States

Perovskite photovoltaics have made remarkable progress in the last decade, with the best lab perovskite cell now achieving over 26% power conversion efficiency. The key to this rapid improvement lies in understanding and controlling the interfaces in perovskite solar cells. In this talk, I will focus on interface engineering in perovskite solar cells (e.g., energy alignment, doping, and carrier dynamics), including the construction of heterostructures of multi-dimensional perovskites. I will discuss surface passivation by synthesizing 2D perovskites atop 3D bulk perovskite. The precise control over the dimensionality of these quantum-confined 2D thin layers enables us to achieve efficient carrier transport across the interface while maintaining desirable trap passivation. I will also discuss field-effect passivation when the perovskite active layer is in contact with a carrier transport layer. Modulating the minority carrier population at the perovskite/C60 interface is critical for reducing interfacial recombination. Lastly, I will explore how we combine chemical and field-effect passivation to achieve optimal passivation. Adjusting interface conditions will be even more important as we move towards multi-junction device architecture in pursuit of higher efficiency.

Connecting Structure and Self-Trapped Excitons in the Double Perovskite Elpasolites: A Computational Study ChristopherSavory; University of Birmingham, United Kingdom

Inorganic lead halide perovskites have shown promise in light-emissive applications, however there is significant drive to find similar behaviour in more sustainable, lead-free systems. Lead-free perovskite-based emitters have included two core classes of materials: double perovskites, in which the separation of the B site as $Cs_2M^{(I)}M^{(III)}X_6$ allows moving to In or Bi, and 'defect perovskites' belonging to the $Cs_2M^{(IV)}X_6$ (M = Zr, Hf, Sn, X = Cl, Br) family; both classes have been suggested to show self-trapped excitonic behaviour and resultant broadband white light emission.[1, 2] The former of these two families, the elpasolites, has wide compositional flexibility between the two perovskite B-sites and the halide anion, though focus has remained on the successful doped $Cs_2AgInCl_6$. With many other phases having been synthesized over a decades long history of research however, more elpasolites could be of interest as emissive materials – and modern computational chemistry techniques can be used to help predict such behaviour.

In this computational study, we initially examine the structural behaviour of $Cs_2NaBiCl_6$ which has been suggested to show pressure-dependent luminescence arising from self-trapped excitons.[3] By using techniques to track instabilities in calculated phonon spectra, we are able to help explain this behaviour[4] – and move to further predict other elpasolites, which have received minimal experimental study, that could demonstrate similar dependence. Secondly, by using a combination of many-body perturbation theory calculations within the Questaal code[5] to explicitly simulate excitonic properties, and also simulating an ansatz of the self-trapped excitonic state using a supercell method with hybrid Density Functional Theory, as developed for other halide emitters,[6] we are able to also quantitatively predict self-trapped excitonic behaviour in these systems. We then compare these results to those established for 'defect perovskite' systems to establish more generalized ideas on the role of structure, composition and electronic localization in enabling self-trapped excitonic emission. Through studying these structure-property links in the elpasolite family, we hope to further open the field of Pb-free efficient light emitters.

4:00 PM EN05.02.08
Machine Learning Assisted Development of Sn/Pb Free Perovskites Solar Cells AnkitChoudhary[1], AlexMohan[1], MiahA. Sahriar[2], AbdulH. Rumman[2], Md.T. Islam[3], SaquibAhmed[4] and HaralabosEfstathiadis[1]; [1]SUNY Polytechnic Institute Albany, United States; [2]Bangladesh University of Engineering and Technology, Bangladesh; [3]SUNY – University at Buffalo, United States; [4]SUNY – Buffalo State University, United States

This study focuses on $Cs_3Bi_2I_9$, a zero-dimensional perovskite absorber material with great potential for photovoltaic applications. We employed Machine Learning (ML) techniques to understand and optimize the performance of Cs3Bi2I9 perovskite solar cells. A prepared sub-dataset comprising 26,457 experimentally developed perovskite solar cell device data was utilized for ML calculations. The cleaned dataset contained 29 features and four target variables, including open circuit voltage (Voc), short circuit current density (Jsc), fill factor (FF), and power conversion efficiency (PCE). Among the models, Random Forest Regressor showcased the best performance. Predicted values for Voc, Jsc, FF, and PCE were determined to be 0.562 V, 9.544 mA/cm^2, 0.508, and 5.356%, respectively.

We characterized the different layers of the device using techniques such as X-ray Photoelectron Spectroscopy, Ultraviolet-Visible Spectroscopy, Atomic Force Microscopy, and Ellipsometry to gain insights into the individual layers' properties. The absorber layer bandgap was found to be 1.9 eV, which indicates that $Cs_3Bi_2I_9$ exhibits favorable characteristics for indoor photovoltaic applications. The solution-processed spin-coated complete solar cells have the structure glass/FTO/c-TiO_2/$Cs_3Bi_2I_9$/CuSCN/Ag. Preliminary tests on the complete $Cs_3Bi_2I_9$ perovskite solar cell have shown the values for Voc, Jsc, FF, and PCE as 0.447 V, 29.08 mA/cm^2, 0.291, and 3.63%, respectively. These initial results indicate the potential of $Cs_3Bi_2I_9$ as a viable material for solar cell applications.

4:15 PM EN05.02.09
On Characterizing Perovskite X-Ray Detectors for Low-Dose Imaging KostiantynSakhatskyi[1,2], YingZhou[3], VitaliiBartosh[1,2], GebhardJ. Matt[1,2], JingjingZhao[4], SergiiYakunin[1,2], JinsongHuang[3,3] and MaksymV. Kovalenko[1,2]; [1]ETH Zurich, Switzerland; [2]Empa–Swiss Federal Laboratories for Materials Science and Technology, Switzerland; [3]University of North Carolina at Chapel Hill, United States; [4]Southwest University, China

The last decade has seen a renewed exploration of semiconductor materials for X-ray detection, foremost focusing on lead-based perovskites and other metal halides as direct-conversion materials and scintillators. However, the reported performance characteristics are often incomplete or misleading in assessing the practical utility of materials. Here we offer guidelines for choosing, estimating, and presenting the relevant detector figures of merit and discuss their relation to basic materials properties. We also provide ready-to-used tools for calculating these figures of merit: MATLAB application, Mathcad worksheet and a website. The X-ray detectors for medical imaging are at the focus for their increasing societal value and since they bring about the most stringent requirements as the image shall be acquired at as low as reasonably attainable (*i.e.* ALARA principle) dose received by the patient.

4:30 PM EN05.11.01
Reduced Melting Temperature of Lead-Free 2D Perovskite Semiconductor to 142 °C AkashSingh, EthanCrace, YiXie and DavidB. Mitzi; Duke University, United States

Hybrid metal halide perovskite (MHP) semiconductors are currently revolutionizing the research realm of electronic and photonic materials, with an overwhelming number of studies conducted on their synthesis and device fabrication and with particular emphasis on deposition of device quality films. The dominant film deposition techniques involve solution processing and vapor deposition, which have their advantages, but may be harmful to humans and the environment. Melt processing as an alternative route has been demonstrated before; however, due to the high T_m (close to $T_d \sim 200$ °C, the degradation onset temperature), the approach tends to induce partial decomposition (loss of organic component and halides) in MHPs, which hinders their utility in certain applications. Furthermore, slight loss of organic components/halides creates defects that may significantly harm the optoelectronic properties of the MHP film, pointing to a need to develop MHPs with lower T_m. In this work, we therefore synthesized a lead-free 1-methylhexylammonium tin iodide (1-$MeHa_2SnI_4$) perovskite. Single crystal X-ray diffraction is used to resolve the crystal structure of the resulting compound, confirming its crystallization in a two-dimensional Ruddlesden-Popper phase. Synthetic design rules toward obtaining a low T_m value are summarized and adopted to achieve an exceptionally low T_m of 142 °C. The hydrogen bonding, cation penetration, inter- and intra-octahedral distortions, and electronegativities (ionic sizes) of the synthesized perovskite and its corresponding lead counterpart (1-$MeHa_2PbI_4$) are studied to understand the reduced T_m along with the comparison of the existing pairs of meltable Sn and Pb MHPs with same organic cations. Additionally, we developed a protocol to assess the stability of the MHP melt by performing iterative calorimetric scans, monitoring changes in the T_m and melt crystallization temperature (T_c) through multiple heat-cool cycles. This analysis confirmed the stable nature of the 1-$MeHa_2SnI_4$ melt, leading to its facile melt deposition into films on flexible substrates with visible range optoelectronic properties. Our present work serves as a display of the strength of chemical compositional engineering of perovskite structures for tuning the thermal properties, resulting in exceptionally low T_m and facile melt-processing of MHPs. Reduction in T_m not only lowers the thermal budget of the deposition process but also renders robustness to the melt for the development of cost-effective flexible optoelectronic devices on plastic/polymer substrates.

SESSION EN05.03: Poster Session I: Fundamental Understanding of Halide Perovskites
Session Chairs: Marina Leite and Lina Quan
Monday Afternoon, November27, 2023

8:00 PM EN05.03.01
Anharmonic Electron-Phonon Coupling in Polymorphous Perovskites MariosZacharias[1], GeorgeVolonakis[2], FelicianoGiustino[3] and JackyEven[1]; [1]INSA Rennes, France; [2]Universite de Rennes 1, ISCR, France; [3]The University of Texas at Austin, United States

Ab initio simulations of halide perovskites typically assume that the potential energy felt by electrons is defined with the nuclei fixed at their crystallographic Wyckoff positions. This assumption misses the effect of local disorder (polymorphism) which affects profoundly the mechanical, optoelectronic, and light-absorbing properties of halide perovskites. In this talk, I will discuss the important role of *polymorphism* and *anharmonicity* in the electron-phonon coupling of halide perovskites [1]. In particular, I will demonstrate that (i) polymorphism is at the origin of overdamped and strongly coupled vibrational dynamics, (ii) anharmonic optical vibrations dominate thermal renormalization of their band gaps, and (iii) polymorphism is the key to understand the gradual variation of their band gaps around the phase transition temperatures. To address these points we develop a new very efficient methodology for anharmonic lattice dynamics, relying on the special displacement method (A-SDM) [2]. The A-SDM is a very simple tool that can be exploited by both condensed matter theorists and experimentalists, opening the way for systematic simulations of anharmonic phonons. Overall, our new theoretical advances [1,2] set up a new framework for interpreting the fundamental mechanisms driving the optoelectronic, transport, and photovoltaic properties of halide perovskites.

Towards Thermally Stable Wide Bandgap Perovskites by Vacuum Deposition Methods LidonGil-Escrig, IsidoraSusic, MicheleSessolo and HenkJ. Bolink; University of Valencia, Spain

Wide bandgap perovskites are very relevant semiconductors in view of their potential for applications in tandem devices, combined with narrow bandgap absorbers such as silicon, CIGS, or a complementary perovskite. Vacuum deposition methods are increasingly applied to the preparation of perovskite films and devices, in view of the possibility to prepare multilayer structures, common to all tandem architectures. However, vacuum-deposited, wide-bandgap solar cells based on mixed-cation and mixed-anion perovskites have been scarcely reported. Here we present multi-component wide bandgap perovskites obtained by using several thermal sources in co-sublimation processes. We review processes to deposit material formulations of increasing complexity, from double to triple cation/mixed halide perovskites. Homogeneous films with bandgap up to 1.8 eV can be readily obtained, with performance on par with similar solution-

processed materials. Apart from efficiency, we focus on the development of thermally stable perovskite films and devices, that can be obtained using even more complex stoichiometry. By adding guanidinium (GA) to the material formulation, we develop CsMAFAGA quadruple-cation perovskite solar cells with enhanced thermal stability. In spite of the benefit (efficiency, thermal stability) of such complex formulations, their vacuum processing can be challenging, because one needs to simultaneously control several thermal sources during the deposition. Hence we show a simplified dual-source vacuum deposition method to obtain wide bandgap perovskite film and solar cells, with similar or even larger efficiency as those including multiple A-cations. Vacuum deposited MA-based perovskites are highly thermally stable, with lifetime up to 3500 hours at 85 °C, and record efficiency >19% for bandgap of 1.64 eV.

8:00 PM EN05.03.04
Interfacial Toughening with Self-Assembled Monolayers for Mechanical Reliability in Inverted Perovskite Solar Cells ZhenghongDai and NitinP. Padture; Brown University, United States

Metal halide perovskites (MHPs) have emerged as the most promising light-absorber materials in the photovoltaic community due to their near-ideal bandgaps and extraordinary optoelectronic properties. However, MHPs have extremely poor mechanical properties. They are inherently compliant, soft, and brittle. While significant progress has been made in improving the stability of MHPs, perovskite solar cells (PSCs) will also need to be mechanically reliable if they are to operate efficiently for decades. In this context, we study the mechanical integrity of PSCs by measuring their cohesion/adhesion energies (Gc) using double cantilever beam method. We will then report a novel approach to strategically enhance the interfacial adhesion and performance of p-i-n structure PSCs using carefully designed hole transporting self-assembled monolayers (SAMs), where we find that the perovskite solar cell stability is closely intertwined with its mechanical reliability. This work points to a new route for designing mechanically robust PSCs with long-term durability.

8:00 PM EN05.03.05
Triiodide Attacks The Organic Cation in Hybrid Lead Halide Perovskites: Mechanism and Suppression JunnanHu, ZhaojianXu, TuckerL. Murrey, IstvanPelczer, AntoineKahn, JeffreySchwartz and BarryP. Rand; Princeton University, United States

Molecular I_2 can be produced from iodide-based lead perovskites under thermal stress; triiodide, I_3^-, is formed from this I_2 and I^-. Triiodide attacks protic cation MA^+- or FA^+-based PbI_3^- perovskites as explicated through solution-based NMR studies: Triiodide has strong hydrogen-bonding affinity for MA^+ or FA^+, which leads to their deprotonation and perovskite decomposition. Triiodide is a catalyst for this decomposition which can be obviated through perovskite surface treatment with thiol reducing agents. In contrast to methods using thiol incorporation into perovskite precursor solutions, no penetration of the thiol into the bulk perovskite is observed, yet its surface application stabilizes the perovskite against triiodide-mediated thermal stress. Thiol applied to the interface between $FAPbI_3$ and Spiro-OMeTAD ("Spiro") prevents oxidized iodine species penetration into Spiro and thus preserves its hole transport efficacy. Surface-applied thiol affects the perovskite work function; it ameliorates hole injection into the Spiro overlayer, thus improving device performance. It helps to increase interfacial adhesion ("wetting"): Fewer voids are observed at the Spiro-perovskite interface if thiols are applied. Perovskite solar cells (PSCs) incorporating interfacial thiol treatment maintain over 80% of their initial PCE after 300 h of 85 °C thermal stress.

Room-Temperature Amplified Spontaneous Emission and Lasing in Recrystallized Cesium Tin Bromide Perovskite Thin Films ManuelRunkel[1,2], TimoKraus[1,2], TimoMaschwitz[1,2], CedricKreusel[1,2], KaiO. Brinkmann[1,2], MaximilianBuchmüller[1,2], PatrickGörrn[1,2], SelinaOlthof[3] and ThomasRiedl[1,2]; [1]University of Wuppertal, Germany; [2]Wuppertal Center for Smart Materials & Systems, Germany; [3]University of Cologne, Germany

Metal halide perovskites are of great interest for optoelectronic devices such as solar cells, LEDs and lasers, whereas by now in most of the studies lead based perovskites are used to achieve the champion devices [1]. Another promising group is tin based perovskites that offer a less toxic alternative to lead based [2]. Nevertheless the preparation and handling of Sn-based perovskites comes with its own difficulties, due to the possible oxidation of the Sn^{2+} to Sn^{4+}, either by the solvents used for film deposition or by contact with air, which can lead to the formation of defects in the perovskite.
Thermal imprint at moderate pressure and temperature has previously been shown to be a powerful method to re-crystallize perovskite thin films [3]. While the process is well explored for Pb-based perovskites, thermal imprint of Sn-based materials has not been studied as of yet. Here, we investigate the thermal imprint of $CsSnBr_3$ thin films in comparison to its Pb-based counterpart $CsPbBr_3$. To achieve homogeneous pristine CsSnBr3 films as starting material, we initially established a new deposition method using the gas quenching technique, which has not been used for Sn-based perovskites before. By adding SnF_2 we can further protect the tin from oxidation and achieve pinhole free films, which show an intense photoluminescence at 677 nm with a line width of 42 nm (FWHM). In addition, we used X-ray diffractometry to confirm the formation of $CsSnBr_3$ and absence of Sn^{4+}.
In the next step we use the $CsSnBr_3$ films to examine the effect of the planar hot pressing (PHP) process using a flat stamp at different imprint temperatures. We constructed a dedicated imprint fixture that allows the imprint under controlled ambient conditions, such as vacuum or inert atmosphere. We evidence that a significantly higher temperature of >180°C is needed for the flattening and recrystallization of the layers compared to the Pb-based analogues, where imprint at temperatures as low as 80°C can be performed. The higher binding energy of the Sn-Br bond of 273kJ/mol in comparison to that of the Pb-Br bond (201kJ/mol) might be a possible explanation. Comparable to the before described case of Pb-based perovskites, we observe a significantly lowered ASE threshold in the $CsSnBr_3$ after the PHP-process of about 150 µJ/cm^2 compared to 400 µJ/cm^2 in the pristine films. The results for the PHP provided the relevant process parameters to imprint distributed feedback (DFB) gratings into the perovskite layers and to demonstrate the first $CsSnBr_3$ DFB lasers. Our results state an important milestone for Pb-free perovskite lasers.

Perovskite-Based Near-Infrared Quantum Emitters AshutoshMohanty and JenniferHollingsworth; Los Alamos National Laboratory, United States

The ongoing research on hybrid organic inorganic halide perovskite (HOIP) photovoltaic (PV) materials has led to an era of optoelectronics extensively using HP-based materials. As far as photophysical properties and device efficiencies are concerned, HOIP PVs have surpassed many other semiconductor technologies and at present it competes with the Si-based solar cells. In addition to this, HOIP-based quantum dots (QDs) are new building blocks for light-emitting devices. The majority of the perovskite-QDs are focused on visible-range functionalities, with only a few reports on near-infrared (NIR)-emitting nanocrystalline perovskite materials. We have employed different metal ion doping strategies to develop all-inorganic lead halide QDs, particularly doped and heterostructured CsPbX3 (X = Cl, Br, I) QDs for NIR applications. We have grown monodisperse, high quality, defect-free perovskite QDs with emission across the telecommunications wavelengths.

Highly Stable and Efficient Perovskite Solar Cells by Enhanced Interface Toughening via Iodine-Terminated Self-Assembled Monolayer InseokYang, AnushRanka and NitinP. Padture; Brown University, United States

The mechanical reliability of lead halide perovskite solar cells is a key factor to determine device stability. We applied iodine-terminated self-assembled monolayers (I-SAM) on the mesoporous TiO_2 layer of the perovskite solar cells. We achieve a 40% increase of adhesion toughness at the interface between the electron transporting layer (ETL) and the perovskite layer to enhance mechanical reliability. I-SAM treatment on the mesoporous TiO_2 layer leads to enhanced photovoltaic performance including power conversion efficiency (PCE) and stability of the device. The device working stability with a projected T80 (time to 80% initial PCE retained) increasing from ~792 hours for the control device to ~6,670 hours for the I-SAM device for 0.1 cm^2 sized active area device and ~2,822 hours to 6,333 hours for 1.0 cm^2 sized active area device under 1-sun illumination. The champion power conversion efficiency (PCE) is 24.12% with 25.89 mA/cm^2, 1.131 V, and 82.35% of FF with a 0.1 cm^2 sized active area device. This device performance enhancement is derived from superior interface properties through the I-SAM layer on the mesoporous TiO_2 layer. The I-SAM layer contributes interfacial toughness between the TiO_2 layer and perovskite layer and this increased interfacial toughness property leads to performance enhancement.

8:00 PM EN05.03.09
Quartic Anharmonicity Triggers Conversion of Dominant Thermal Transport Channels in Lead-Free Halide Double Perovskite $Cs_2AgBiBr_6$JiongzhiZheng[1,2], ChangpengLin[3,3], ChongjiaLin[2], RuiqiangGuo[4], BaolingHuang[2,5,6] and GeoffroyHautier[1]; [1]Dartmouth College, United States; [2]The Hong Kong University of Science and Technology, Hong Kong; [3]Ecole Polytechnique Federale de Lausanne, Switzerland; [4]Shandong Institute of Advanced Technology, China; [5]Hong Kong University of Science and Technology, Hong Kong; [6]HKUST Shenzhen-Hong Kong Collaborative Innovation Research Institute, China

Efficient manipulation of thermal energy in halide perovskites is crucial for their opto-electronic, photovoltaic and thermoelectric applications. However, understanding the lattice dynamics and heat transport physics in the lead-free halide double perovskites remains an outstanding challenge due to their lattice dynamical instability and strong anharmonicity. In this work, we investigate the microscopic mechanisms of anharmonic lattice dynamics and thermal transport in lead-free halide double perovskite $Cs_2AgBiBr_6$ from first principles. We combine self-

consistent phonon calculations with bubble diagram correction and a unified theory of lattice thermal transport that considers both the particle-like phonon propagation and wave-like tunnelling of phonons. An ultra-low thermal conductivity at room temperature (~0.21 $Wm^{-1}K^{-1}$) is predicted with a weak temperature dependence(~$T^{-0.45}$), in sharp contrast to the conventional ~T^{-1} dependence. Particularly, the vibrational properties of $Cs_2AgBiBr_6$are featured by strong anharmonicity and wave-like tunnelling of phonons. Anharmonic phonon renormalization from both the cubic and quartic anharmonicities are found essential in precisely predicting the phase transition temperature in $Cs_2AgBiBr_6$while the negative phonon energy shifts induced by cubic anharmonicity has a significant influence on particle-like phonon propagation. Further, the contribution of the wave-like tunnelling to the total thermal conductivity surpasses that of the particle-like propagation above around 340 K, indicating the breakdown of the phonon gas picture conventionally used in the Peierls-Boltzmann Transport Equation. Importantly, when considering only three-phonon scatterings, the particle-like propagation channel dominates the thermal transport in $Cs_2AgBiBr_6$. However, further including four-phonon scatterings induced by quartic anharmonicity results in the dominance of wave-like tunnelling channel. Our work highlights the importance of lattice anharmonicity and wave-like tunnelling of phonons in the thermal transport in lead-free halide double perovskites.

Interface Engineering and Perovskite Thin-Film Optimization Towards Efficient Light-Emitting Diodes Muhammad UmairAli[1], JingshengMiao[2], HongMeng[2] and AleksandraB. Djurišić[1]; [1]The University of Hong Kong, Hong Kong; [2]Peking University, China

Organic-inorganic metal halide perovskite materials have attracted lots of attention as next-generation light-emitting candidates owing to their exciting optoelectronic features, such as high color-purity, broadly tunable emission, high photoluminescence quantum yields and low-cost fabrication. While significant progress has been made in enhancing external quantum efficiencies (EQEs) of perovskite-based light-emitting diodes (PeLEDs), there remain several technical bottlenecks, such as severe efficiency roll-off, low operational lifetime and poor reproducibility, which hinder the practicality of these emerging light sources. In this study, a comprehensive investigation is conducted to understand the underlying processes and realize efficient and stable quasi-2D perovskite light emitters with emphasis on three aspects: (i) optimizing the device structure to achieve well-controlled charge injection and consequent exciton formation in the perovskite layer for effective light emission; (ii) probing the role of various underlying organic hole transport layers (HTLs) in the growth of solution-processed perovskite thin-films and subsequent impact on the overall device performance; and (iii) exploring effective solution-processing protocols to develop perovskite thin-films with desired features and reproducible results towards the reliable development of PeLEDs. Firstly, based on an in-depth analysis of charge carrier injection and transport towards the perovskite emissive layer, interface engineering is performed and an optimized device architecture with suitable functional layers and a new cathode configuration is proposed which rendered significantly improved device performance. Secondly, research on various HTLs unveiled that apart from the role of hole-carrier mobility and energy-levels alignment with neighboring functional layers in the stack, the chemical nature and surface features of the HTL as substrate significantly impacts the crystallization kinetics of atop perovskite layer which has a substantial influence on the resulting PeLED performance. Thirdly, a solution-based vapor-assisted growth method is developed via creating an easily controllable spin-coating environment to fabricate high-quality quasi-2D perovskite thin-films with graded domain distribution for cascade energy transfer, which results in high reproducibility. Consequently, a thoroughly optimized fabrication approach enabled effective PeLEDs with high EQE, suppressed roll-off, prolonged operational lifetime and improved reproducibility. This research facilitates expanding our current understanding of constructing perovskite-based solution-processed photonic sources for solid-state lighting and display applications.

Mechanically-Stacked Four Terminal Perovskite/InGaAsP Tandem Solar Cell Achieving 27.7% Efficiency BikeshGupta, TheDuong, TuomasHaggren, JulieTournet, ChennupatiJagadish, Hark HoeTan and SivaKaruturi; Australian National University, Australia

III-V semiconductor photovoltaic (PV) cells have been widely investigated owing to their numerous advantages such as thin-film feasibility, flexibility, high efficiency and adaptability in multijunction architectures. However, their application has been limited to niche areas, such as powering satellites, owing to their high costs primarily driven by high material costs and usage of capital-intensive equipment for fabrication. For widespread adoption of III-V semiconductor based solar cells, it is critical to develop low cost and high efficiency solar cells. In the present study, we address these issues by fabricating InGaAsP heterojunction solar cell reaching efficiencies close to those demonstrated by the state-of-art InGaAsP homojunction solar cells. The InGaAsP (Eg = 1.04 eV) solar cell employing a TiO_2 electron selective contact resulted in efficiencies exceeding 19% with an open circuit voltage of 650 mV. The high efficiency and open circuit voltage were achieved by synergistic coupling of the excellent passivation by thin InP layer and superior carrier selectivity by the TiO_2 layer. Furthermore, 1.55 eV perovskite semitransparent top cell was fabricated with an efficiency exceeding 22%. When mechanically stacked over InGaAsP bottom cell, a tandem efficiency of 27.7% was achieved. The current work paves the way for high-efficiency and low-cost III-V semiconductor tandem solar cell while avoiding the use of capital-intensive fabrication tools.

8:00 PM EN05.03.12
Low Temperature Sintering of Polycrystalline Hybrid Organic-Inorganic Perovskites MichaelC. Brennan[1,2], ChristopherMcCleese[1,3], LaurenLoftus[1,3], DouglasKrein[1,3] and TodGrusenmeyer[1]; [1]Air Force Research Laboratory, United States; [2]Azimuth Corporation, United States; [3]General Dynamics Information Technology, United States

Hybrid organic-inorganic perovskites [HOIPs] (ABX_3; A=CH_3NH_3, $CH(NH_2)_2$, Cs; B=Pb, Sn; X=Cl, Br, Cl) embody intriguing optoelectronic properties (e.g. tunable bandgaps, high absorption coefficients, and large charge carrier mobilities). However, many target applications for these semiconducting materials (e.g., scintillators, lasers, and photodetectors) require large area, millimeter thick perovskite single crystals with high optically transparency. Unfortunately, single crystals grown by melt-based approaches are limited to all-inorganic perovskites due to organic cation volatility, and solution-based methods are inundated with scalability and reproducibility issues. Sintering HOIP powders into high relative density (>0.999) polycrystalline wafers under an applied uniaxial pressure is a promising route towards overcoming the current limitations of melt and solvothermal single crystal growth. We demonstrate low temperature (~20 ^oC) sintering methods under an applied uniaxial pressure to compress high purity HOIP powders into high density, polycrystalline wafers with optical transparency and charge transport properties akin to their ideal single crystal counterparts. Structural, optical, and electrical properties of HOIP wafers are benchmarked against single crystals analogues. Fully understanding the tradeoff between manufacturability of polycrystalline wafers versus the performance of single crystals could enable key advancements in perovskite technologies.

Exploring the Diversity of Two-Dimensional Perovskite Structures by a Comprehensive Database for Advancing Solar Cell Research and Development AymanMaqsood and T. JesperJacobsson; Nankai University, China

An important property of hybrid perovskites is the possibility to reduce the dimensionality to provide wider band gaps and better stability. Of special interest is two-dimensional perovskites which have emerged as a promising alternative to their three-dimensional counterparts due to their unique structural and optoelectronic properties. This project analyzes the recent advancements and key features of two-dimensional perovskite solar cells based on a comprehensive database of possible two-dimensional perovskite structures utilized in PV-devices that we have assembled. This database includes both experimentally reported structures and computationally designed ones and covers a wide range of compositions and variations, and provides a valuable resource for understanding and exploring the diverse range of two-dimensional perovskite materials employed in solar energy conversion. The database ontology outlines the criteria and parameters used to identify and classify two-dimensional perovskite structures, such as composition, layer thickness, and organic and inorganic components, and covers structures ranging from simple bilayers to more complex multilayer structures. In this talk, I will demonstrate how this resource can be used to provide insights into the structure-property relationships of 2D-perovskites, and how it can aid in the rational design of new 2D-perovskites with targeted properties suitable for specific device requirements.

8:00 PM EN05.03.14
Designing Efficient and Aesthetically Pleasing Semitransparent Perovskite Solar Cells for Building-Integrated Photovoltaics: A Biomimetic Approach YiyiZhu, LeiShu, QianpengZhang, SwapnadeepPoddar, ChenWang and ZhiyongFan; The Hong Kong University of Science and Technology, Hong Kong

The emergence of semitransparent perovskite solar cells (ST-PSCs) has made them an attractive option for building-integrated photovoltaics, especially for power generation windows that must convert sunlight into electricity while transmitting daylight to illuminate indoor spaces. In addition to power conversion efficiency (PCE), attributes such as average visible transmittance (AVT), color, and longevity are critical for ST-PSCs. Tuning the perovskite thickness or surface coverage can adjust AVT, with an AVT of 20%–30% typically sufficient for power-generating windows. However, the conventional structure of ST-PSCs, consisting of continuous ultrathin perovskites, often results in an undesired reddish-brown hue.
To address this challenge, we present a highly efficient, robust, and neutral-colored ST-PSC inspired by the moth's eye surface architecture. The moth eye-inspired structure (MEIS) uses hexagonally arranged microcavity structures to trap photons in the wavelength range where the human eye is less sensitive, resulting in a record-high figure-of-merit for ST-PSCs.
To create the structure, we used the Langmuir-Blodgett technique to assemble polystyrene spheres on planar-ITO as a mask for patterning, which we then covered with sputtering deposition of ITO. We subsequently removed the spheres to obtain a biomimetic structure. Next, we deposited SnO2 using atomic layer deposition to achieve uniform and full coverage of the as-fabricated structure. We then applied spin-coating deposition to add the perovskites, followed by a layer of spiro-OMeTAD. Finally, we added a buffer layer of MoO3 and 100 nm IZO sputtering to serve as a transparent electrode.
We characterized the optical and electrical properties of our moth eye-inspired perovskite solar cells using various techniques, including scanning electron microscopy, X-ray diffraction, UV-Vis spectroscopy, and current-voltage measurements. Our results showed that the MEIS modification provided a AVT of 33%, which is important for maintaining aesthetics in BIPV applications. Our perovskite solar cells exhibited a high power conversion efficiency of over 10%, comparable to that of conventional opaque perovskite solar cells. We compared the performance of our moth eye-inspired perovskite solar cells to that of other semitransparent solar cells reported in the literature and demonstrated that our devices outperform them in terms of

efficiency, AVT, and color neutrality.
We also tested the long-term stability of our perovskite solar cells and found that they exhibited excellent performance over a period of 224 days, indicating that they can withstand harsh environmental conditions. This study demonstrates the potential of using biomimetic approaches to design novel perovskite solar cells with improved optical and electrical properties and highlights the importance of developing solar cells that are both efficient and aesthetically pleasing for building-integrated photovoltaic applications. Our moth eye-inspired perovskite solar cells have the potential to revolutionize the field of building-integrated photovoltaics and accelerate the adoption of renewable energy sources in urban environments.

8:00 PM EN05.03.15
Improving Photovoltaic Performance of CuSCN-Based Perovskite Solar Cells by Aging in Humid Air AtsushiKogo and TakurouN. Murakami; National Institute of Advanced Industrial Science and Technology, Japan

Development of inexpensive and robust hole-transport material for organohalide perovskite solar cells (PSC) is one of the most important topics for industrial application. Copper thiocyanate (CuSCN) is an inorganic p-type material, which can be used as a robust hole-transport material of PSCs. However, the CuSCN-based PSCs tend to give poor power conversion efficiency (PCE) than conventional spiro-OMeTAD-based PSCs because of low conductivity and high charge carrier trap density of CuSCN. To improve hole extraction of CuSCN from perovskite materials, we investigated an effect of atmospheric parameters during the aging process of CuSCN layers.

CuSCN was formed by spin-coating a precursor solution on glass substrates and dried at 80 ºC for 5 min. Then the substrates were aged in different humidity (RH 2%, 25%, 40%, 70%) overnight. To characterize crystallinity of CuSCN layers, we performed X-ray diffraction measurement. CuSCN layers aged in 70% RH exhibited larger crystal size (29.9 nm) than those aged in dry air (2% RH, 26.6 nm). Small grains were observed in CuSCN layers aged in 2% RH by atomic force microscope observation. However, the grains were disappeared, and flat morphology was observed in the layers aged at 70% RH. This indicates that crystal growth of CuSCN was promoted by humid moisture. We measured resistance of CuSCN layers by current voltage scan using indium tin oxide (ITO)/CuSCN/Au substrates. Owing to its improved crystallinity, CuSCN aged at 70% RH exhibited smaller resistance than those aged at lower humidity. We fabricated PSCs (ITO/SnO_2/perovskite/CuSCN/Au structure) and measured photovoltaic performance under 1 sun illumination. As the aging humidity increased, PCE was improved owing to improved fill factor. Further, solar cells aged at 70% RH gave larger open circuit voltage than those aged in lower RH. The dark current analysis revealed that the solar cells aged at 70% RH contains less trap density and less resistance than those aged in lower RH. We can conclude that improved CuSCN crystallinity increased conductivity and decreased trap density and enhanced photovoltaic performance of perovskite solar cells.

8:00 PM EN05.03.16
CsCl Induced Grain Size Control and Performance Enhancement of MA-Based Perovskites Film for High-Performance Memristive Devices Yen ShuoChen[1], Ching ChangLin[2] and Fu-HsiangKo[1]; [1]National Yang Ming Chiao Tung University, Taiwan; [2]The University of Tokyo, Japan

Recently, a new class of organic-inorganic hybridized perovskites (OIHPs) materials with various functionalities such as dielectric, semiconducting, and photosensitive properties have proven to be very promising for resistance switching (RS) memory applications. Due to the atmospheric instability of OIHPs materials, defects or pinholes can appear on the film surface during the manufacturing process. Some literature discusses the posttreatment process for improving defects. In this study, we purpose that the CsCl of the double-site repair mechanism not only passivates defects but also improves the electrical properties of the RS memory device due to the reduction of grain boundaries and grain size enlargement. The $MAPbI_3$ perovskite precursor was prepared by dissolving MAI and PbI_2 powder into the mixed solvent of GBL and DMSO. The CsCl solutions were prepared in methanol and ethanol; the concentrations were 0.5, 1 and 1.5 mg mL^{-1}, labeled as CsCl-0.5, CsCl-1 and CsCl-1.5, respectively. The untreated film is labeled as CsCl-0.
The pristine OIHPs films and the film with CsCl posttreatment both exhibit intense diffraction peaks at 13.9°, 20.2°, 21.4°, 28.5°, and 31.9°, corresponding to the (110), (200), (211), (220), and (310) $MAPbI_3$ tetragonal crystal planes. The XRD patterns result indicated that there is no significant peak shift. The UV-Vis absorption spectra showed a blue shift in the absorption edge after the addition of CsCl doping, indicating that some Cs substitution occurred on the OIHPs surface and most of $MAPbI_3$ was retained. The PL response spectra showed the same trend, with the highest intensity for the CsCl-1.5 film. It indicated a reduction of defects and pinholes in the film, which can be attributed to the higher concentration, resulting in more surface replacement effects. In addition, the average grain size of the OIHPs films was increased from ~339.2 nm (CsCs-0) to ~658.1 nm (CsCl-1.5) by raising the amount of CsCl doping. The $MAPbI_3$ films treated with CsCl exhibited signs of remodeling, resulting in grain size increase and grain boundary reduction. Control and moderate increases in grain size can affect the electrical characteristics of OIHPs memory devices. Thus, to achieve high-performance memory devices using OIHPs film, we realize the control of grain size in the film by CsCl facial treatment.
Herein, we reported the bipolar RS behavior of the organic-inorganic hybrid $Cs_xMA_{1-x}PbI_{3-y}Cl_y$ perovskite memory device. The switching behavior of the OIHPs RS device in Al/PMMA/$Cs_xMA_{1-x}PbI_{3-y}Cl_y$/ITO configuration was studied under a direct current (DC) at ambient air conditions with high humidity between 50% and 70%. The top electrode (TE) Al is biased, and the bottom electrode (BE) ITO is grounded using a typical linear I-V sweep in the order 0V→-3V→0V→3V→0V at the bias voltage. To ensure the RS behavior and conductive filament were from the OIHPs layer, no significant switching behavior was observed for Al/PMMA/ ITO. All the RS memory devices exhibited stable hysteresis I-V curves with bipolar resistive switching behavior. To prevent the RS memory device from being damaged during the measurement, a compliance current of 1 mA was applied. When an external voltage is swept from -3 to 0 V, the resistance transition from a high-resistance state (HRS) to a low-resistance state (LRS) was observed at 1.1 V, which means the set process occurs. The Al/PMMA/$Cs_xMA_{1-x}PbI_{3-y}Cl_y$/ITO device was maintained at LRS state when voltage was reversed from 3 to 0 V, corresponding to the reset process. The on/off current ratio of the CsCl-0 device reached about 10^2, 10^3 for CsCl-0.5, 10^3 for CsCl-1, and 10^4 for the CsCl-1.5 device, respectively. Compared to untreated OIHPs devices, RSM devices with $MAPbI_3$ treated with CsCl-1.5 device are improved by two orders of magnitude. The results demonstrated the high-performance electronic applications of CsCl-induced OIHPs in resistive switching memories.

8:00 PM EN05.03.17
Introducing Ionic Liquid Dopant to Spiro-OMeTAD for Improving Thermal Stability in Perovskite Solar Cells KoheiYamamoto and TakurouN. Murakami; National Institute of Advanced Industrial Science and Technology, Japan

Perovskite solar cells (PSCs) are attracting attention as next-generation solar cells because of their high-power conversion efficiencies (PCEs) and lightweight. Lightweight PSCs can be installed on roofs with weight limitations, further increasing the potential for renewable energy. In practical out-door use, PSCs require measures for environmental stability such as heat and light. It is well known that there are issues regarding the thermal stability of PSCs. There are issues with thermal stability in the perovskite itself and in the components such as carrier transport layer in PSCs. Thermal stability of PSCs with conventional structure has present a challenge in doping materials of hole transport layer (HTL). In conventional PSCs, LiTFSI is widely used as a doping material for Spiro-OMeTAD of HTL. However, LiTFSI is known to change to Li_2O_3 or become Li^+ and diffuse inside PSCs. To improve the thermal stability of PSCs, it is important to avoid diffusion into the device by fixation Li^+ at HTL. We focused on the doping method of HTL in conventional PSCs for improving thermal stability. For immobilization of the dopant in the HTL, bulky organic cations were investigated introducing PSCs. Since TFSI is an effective doping for Spiro-OMeTAD, a combination of TFSI and organic cations were selected as dopants for spiro-OMeTAD. Our PSCs structure is FTO/SnO_2/$Cs_{0.05}FA_{0.95}PbI_3$/Spiro-OMeTAD/Au. N-Ethyl-N-(2-methoxyethyl)-N,N-dimethylammonium TFSI (EMe-TFSI) and LiTFSI were used as dopants for HTL and compared, respectively. Optimized PSCs have PCE of 18.1% with LiTFSI and 18.2% with EMe-TFSI. The solar cell performance with EMe-TFSI was found to be equivalent to LiTFSI, and it was found that EMe-TFSI can function as a dopant. We evaluated thermal stability of both PSCs at 85°C and 30% RH. The PSC with EMe-TFSI exhibited 50% of its initial properties after 300 hours at thermal stability test. On the other hand, the PSC with LiTFSI reduced to 10% of its initial characteristics in just 24 hours. These results suggest that the thermal stability of PSCs can be improved by using bulky organic ions rather than small and easy to diffuse ions such as Li.

8:00 PM EN05.03.18
Insights from the Additive Engineering Perovskite Database. Can We Design Functional Molecules More Intelligently?ChenChen and T. JesperJacobsson; Institute of Photoelectronic Thin Film Devices and Technology, Key Laboratory of Photoelectronic Thin Film Devices and Technology of Tianjin, College of Electronic Information and Optical Engineering, Nankai University, China

Additive engineering has been widely used to improve the properties of perovskite solar cells. By carefully selecting the right additive, it is possible to for example improve film uniformity, morphology, and crystallinity, alter the electronic properties and improve stability. Specifically, some of additives are used to modulate grain size and orientation, passivate defects, shift the Fermi-level, enhance charge carrier extraction, suppress recombination and ion migration, increase carrier lifetimes, etc. A large number of molecular additives have been explored in the literature. The understanding of the underlying interaction mechanisms of additives and perovskite is, however, still limited, and positive results are often the result of a trial-and-error approach based on a few simplistic heuristic rules. For more efficient additive engineering we would need to go beyond this and develop more general principles for perovskite additive interactions based on their respective molecular and crystal structure. As a step towards addressing those challenges, and to enable more rational selection and design of functional additives for specific targeted purposes, we have started to establish a database of perovskite additives and their effects. With the help of this database, we aim to leverage machine learning for intelligent screening and identification of new functionalized molecular additives. In this talk, we will give a brief overview of the historic additive landscape and discuss what new insights applicable to additive engineering that have been achieved by analyzing the historical data.

8:00 PM EN05.03.19
Nano Structural Analysis of Various Metal Halide Perovskite Films for Solar Cells using Synchrotron X-Ray SeungyeonHong and Hyo JungKim; Pusan National University,

Department of Organic Material Science and Engineering, Korea (the Republic of)

The metal halide perovskite materials were intensively researched for solar cells because of their outstanding photoelectronic properties. There are numerous methods to achieve high performance, high quality, and highly stable perovskite films, for example, formula combination, solution engineering, additive manufacturing, dimension control and etc. Most of those strategies pursue to obtain high-quality and well-aligned perovskite crystal structures. In this work, we adopt solvent and additive engineering and analyzed their effect on nano crystal structure of metal halide perovskite.
First, we obtained high quality perovskite grains in slow crystallization process by antisolvent and the ratio of DMSO in solution in the ambient air condition at RH 20-30%. The amount and state of the intermediate phase, which is consist of PbI_2-MAI-DMSO, inside the as-deposited film were analyzed from GIWAXS analysis. The deposited perovskite layer with the pure intermediate with extremely slow crystallization showed highest absorption, few grain boundaries and suppressed defect recombination losses than fast crystallized perovskite phase. Furthermore, the water resistance of perovskite film was enhanced and as a result, the long-term stability was extremely increased.
And then, we employed the oleylamine(OAm) additive as defect the passivation and crystal cross-linker material. Generally, the defect the passivation and crystal cross-linker effect appeared simultaneously, and it is hard to separate the single effect of them. We could separately analyze the passivation and crystal cross-linker effect of OAm just by adopting a simple drying process during perovskite structure formation. Without the drying process, the OAm affected the orientation of the crystal structure from the surface to the bulk of the perovskite film and also exhibited the passivation effect. However, when the drying process was performed, the OAm only affected on the surface of the perovskite film. We could confirm this tendency from GIWAXS and XPS analysis.

Accelerating Perovskite Solar Cells Development: A Pathway to Accelerate Carbon Neutrality Targets and Reduce Renewable Energy Transition Costs JieLiu and XiaoShen; Bo-Zhi Digital Labs, China

The transition to renewable energy sources, including photovoltaics (PV) and wind power, is crucial for achieving carbon neutrality and addressing the challenges of climate change. To expedite the progress towards these goals, it is essential to explore technological advancements that can lower costs and reduce energy consumption and carbon emissions. Different PV technology pathways, including multi-crystalline silicon, mono-crystalline silicon, and perovskite solar cells, are evaluated using a life cycle assessment approach and learning rate analysis. By quantifying key metrics such as costs, energy consumption, carbon emissions, and material utilization, this research provides valuable insights into the comparative advantages and potential benefits of these technologies for global PV development. Utilizing data from papers, public reports, open-source databases and industry sources, this study presents a quantitative assessment of the potential impact of perovskite solar cell penetration from 2023 to 2050 under various scenarios defined by the International Energy Agency (IEA). The results underscore the importance of accelerating the development of perovskite solar cells, which have demonstrated significant potential for achieving higher cost reductions, energy savings, and greenhouse gas emissions avoidance compared to conventional silicon-based solar cells. These outcomes provide a robust foundation for policymakers, researchers, and industry professionals to prioritize and guide the accelerated development and deployment of perovskite solar cells within the global PV market. Furthermore, this study sets a precedent for future investigations into PV technology development and offers a pathway for sustainable and cost-effective global energy transformation.

Computer Modeling and Comparative Performance Analysis of Perovskite Solar Cells with Planar and Nanorod-Based SnO_2 Electron-Transport Layers AskhatN. Jumabekov[1], AssylanAkhanuly[1], IliyasDossyaev[1], ErikShalenov[1,2,3], ConstantinosValagiannopoulos[1], KarlygashDzhumagulova[3,1] and AnnieNg[1]; [1]Nazarbayev University, Kazakhstan; [2]Satbayev University, Kazakhstan; [3]Al-Farabi Kazakh National University, Kazakhstan

Nanorods of metal oxides such as TiO_2, ZnO, and SnO_2 have been actively investigated for their application in perovskite solar cells (PSCs) as the electron transport layer (ETL). This is due to their remarkable optical and electronic properties, which makes them suitable for extracting charge carriers from the perovskite layer in PSCs. Among them, SnO_2-based ETLs have attracted a significant attention in recent years due to its advantageous properties such as high carrier conductivity, good chemical stability, and desirable band alignment with the perovskite layer for charge extraction [1]. Comparative performance analysis of PSCs with planar and nanorod-based SnO_2 ETLs indicate that PSCs with the latter type of ETLs can have improved performance, owing to accelerated electron transport in SnO_2 and decreased recombination rate at the SnO_2/perovskite interface [2,3]. Additionally, employing nanorod-based SnO_2 ETLs can enhance the long-term stability of PSCs [4].

Surveying the literature for the best performing PSCs with SnO_2 ETLs show that high-performance PSCs are usually obtained using planar ETLs [5]. This suggests that the use of nanorod-based SnO_2 ETLs for boosting the power conversion efficiency (PCE) of devices requires further investigation. Therefore, we used computer simulation methods to investigate and analyze the properties and behavior of PSCs with SnO_2 nanorod-based ETLs by varying the aspect ratio and density of SnO_2 nanorods [6]. We found that the light harvesting ability of PSCs improves with the implementation of SnO_2 nanorod-based ETLs. However, we revealed that under optimum conditions, PSCs with thin planar SnO_2 ETLs is sufficient to outperform those with nanorod-based SnO_2 ETLs. The underlying reason for this is explained through a detailed analysis of electric field, current density, and carrier recombination in devices. The results of this work provides with an insight into the device physics of PSCs with planar and nanorod-based SnO_2 ETLs and can be useful in designing ETLs for high-performance PSCs.

Electron-Hole Liquid in FAPbBr3 Metal Halide Perovskite GiuseppeAmmirati[1,2], FaustinoMartelli[1], DanieleCatone[1], PatrickO'Keeffe[1], FrancescoToschi[1], StefanoTurchini[1], JessicaBarichello[2], FabioMatteocci[2] and AldoDi Carlo[1,2]; [1]Consiglio Nazionale delle Ricerche, Italy; [2]Università degli Studi di Roma Tor Vergata, Italy

In semiconductors, the optical excitation of electron-hole pairs usually results in a non-interacting gas of excitons, called free-excitons (FE). For increasing optical density of the excitation, because of the increasing dielectric screening of the Coulomb potential, excitons will tend not to form in favor of a gas of free electrons and holes, the electron-hole plasma (EHP). This paradigm is the essence of the Mott transition [1], which predicts the existence of an insulator-metal transition at the so-called Mott density. Experimental evidence for the exciton-plasma Mott transition was given for the first time in silicon by Shah et al. in 1977 [2]. Furthermore, the renormalization effect of the electronic eigenstate in the EHP results in the formation of an electron-hole liquid (EHL) state below some critical temperature [3] Unlike EHP, EHL shows incompressibility, surface tension, and short-range order similarly to classical liquid. EHL has been observed at high optical excitations in materials having long carrier lifetime as silicon [4] germanium [5] and GaP [6], as well as in 2D metal dichalcogenides [7]
The physics of electron-hole plasmas and electron-hole liquids are fascinating from a fundamental point of view but their study also helps understand the relevant properties of materials that could be used for applications, in particular as light emitters [8]. In this context, metal halide perovskites (MHPs), used in photovoltaic applications also thanks to the long lifetime of photoexcited carriers (tens to hundreds of ns) can be a novel class of materials where the observation of electron-hole condensation could be expected. For our study we have chosen a material that finds applications in transparent photovoltaics and light emitters, namely formamidinium lead bromide ($FAPbBr_3$).
In this work, we present photoluminescence (PL) measurements on thin films of pure $FAPbBr_3$ as a function of temperature and excitation intensity and provide evidence for the formation of an electron-hole liquid up to temperatures of about 100 K. At low excitation intensity and low T (12 K), the PL line shape only shows the FE recombination. As the excitation intensity is increased two further signals emerge, first a new band attributed to the recombination of electron-hole pairs in an EHP and then a third PL band appears attributed to e-h recombination in an EHL. For both the FE-EHP Mott transition and the EHP-EHL phase transition a critical carrier density has been established following the method proposed by Shah and coworkers [2]. A phase diagram that includes the exciton-plasma Mott transition and the formation of the EHL will be also presented, which allows a clearer insight on the properties of photoexcited carriers in this technologically relevant class of materials.

Enhanced Stability of Alpha-Phase $FAPbI_3$ Perovskite for Photovoltaics using Aerosol-Assisted Crystallisation with MASCN Additive
MadsarHameed[1,2], XuanLi[1], YuanZhang[1], LokeshwariMohan[1] and JoeBriscoe[1]; [1]Queen Mary University of London, United Kingdom; [2]University of Engineering and Technology Lahore, Pakistan

Perovskite solar cells (PSCs) have revolutionised the photovoltaic research field with rapid increase in efficiency, from about 3% in 2009 to over 25% in short time span. However, various challenges still remain before they can become a competitive commercial technology. Hence there is a dire need to improve PSC stability and efficiency by enhancement of thin film homogeneity, grain size (eliminating grain boundaries) and by morphological and compositional modification. Methyl ammonium lead iodide ($MAPbI_3$) has been widely used to fabricate PSCs but its lower thermal and chemical stability limits their application towards commercialization. Hence, formamidinium lead iodide ($FAPbI_3$)-based perovskites have emerged as one of the most promising candidate materials for high efficiency and stable perovskite solar cells due to their high thermal stability and ideal bandgap energy near the optimum for the Shockley-Queisser limit[1].
However, the phase degradation of 'black phase' α-$FAPbI_3$ perovskite to yellow, non-perovskite d-phase $FAPbI_3$ in ambient conditions restricts the long-term stability of $FAPbI_3$ perovskite solar cells. Previously, we have demonstrated a method for performance and stability improvements in $FAPbI_3$-based perovskites by crystallisation in the presence of a solvent aerosol[2]. Here, we develop this method further by adding methylammonium thiocyanate (MASCN) to the solvent aerosol for crystallisation of $FAPbI_3$ perovskite films, following our previous work demonstrating additive-enhanced post-treatment of perovskite films[3]. Adding MASCN to the aerosol improved the thin film crystallinity and grain size compared to solvent-only treated films[4]. These changes lead to prolonged charge-carrier lifetimes, enhanced stability, and ultimately improved device efficiencies. By demonstrating the benefit of additives in this aerosol-assisted crystallisation process, this work opens wider processing options to enhance the crystallinity, grain size, film homogeneity and efficiency of perovskites.

Strategies to Boost the Photocatalytic Activity in Halide Perovskite Nanocrystals
Tae HyungKim and Young HoonKim; Hanyang University, Korea (the Republic of)

Colloidal halide perovskite nanocrystals (PNCs) are an ideal material for high photocatalytic activity, in addition to the tremendous attention already focused on optoelectronics such as light-emitting diodes and photovoltaics due to long charge carrier lifetime, narrow bandgap and facile wavelength tunability. Here, we report two strategies to improve photocatalytic activity based on colloidal $CsPbBr_3$ PNCs. First, we prepared $CsPbBr_3$ PNC/amorphous TiO_2 composites using hydrolysis of titanium butoxide in PNC dispersion under air ambient. High absorption coefficient and narrow bandgap of $CsPbBr_3$ can generate and transfer photo-excited electrons to the amorphous TiO_2, which performed 4.1 times higher photocatalytic CO_2 reduction efficiency (30.43 μmol g^{-1} h^{-1}) than pristine $CsPbBr_3$ PNCs under outdoor sunlight (7.44 μmol g^{-1} h^{-1}). Second, we doped Fe into $CsPbBr_3$ PNC via post-synthetic ion exchange method. Fe dopants induce dissociation of charge carriers while suppressing the recombination of them in the presence of external magnetic fields which prolong the lifetime of spin-polarized charge carriers. By application of both Fe dopants and external magnetic fields on the $CsPbBr_3$ PNCs, we achieved photocatalytic CO_2 reduction of 45.48 μmol g^{-1} h^{-1} in visible region which is 1.48 times higher than that of pristine $CsPbBr_3$ PNCs. These results provide simple paths toward efficient photocatalytic reaction in metal halide perovskite nanocrystals for CO_2 reduction.

Effects of a site Cation on Perovskite Quantum Dot for Emission Wavelength and Photoluminescence Quantum Yield
RyotaSato[1], YusakuMorikawa[1], SatoshiAsakura[2], MotofumiKashiwagi[3], TakayukiChiba[1,1] and AkitoMasuhara[1,1]; [1]Yamagata University, Japan; [2]ISE Chemicals Corporation, Japan; [3]ZEON Corporation, Japan

ABX$_3$ type (*A* site: Cs, Methylammonium (MA), Formamidinium (FA) etc., *B* site: Pb, and *X* site: halogen such as Cl, Br, I) perovskite quantum dot (PeQD) has attracted attention as a next generation material for the optoelectrical device such as light emitting diode (LED) due to its excellent optical properties. In general, it is known that the optical properties, in other words, the energy band gap of PeQD are composed of the hybrid orbital of the *B* and *X* site (*B*-*X* hybrid orbital). The state of the energy band gap directly depends on the PeQD optical properties such as the emission wavelength and photoluminescence quantum yield (PLQY). For instance, the emission wavelength of PeQD is controlled by inserting another *X* site materials (= *X*' site). In detail, the new hybrid orbital composed of the *B* site, *X* site, and *X*' site (*B*-*X*/*X*' hybrid orbital) was generated by inserting the *X*' site material, resulting in controlling the energy band gap. Therefore, controlling the emission wavelength in the entire visible range by only adjusting the halide components. On the other hand, surface defects of PeQD generate new trap levels that prevent the electron transition within the energy band gap, so excess *B* and *X* site materials are used to passivate the surface defects. As a result, it is possible to achieve a high PLQY. Based on these facts, the state of the energy band gap on PeQD was controlled by mainly using the *B* and *X* site materials composed of the energy band gap in the previous research.
In this work, we proposed the strategies for "Controlling the emission wavelength" and "Improving the PLQY" by using the *A* site mixture on PeQD. The *A* site does not directly affect the *B*-*X* hybrid orbital. On the other hand, we also found the indirect effects of the *A* site against the emission wavelength and PLQY of PeQD. About the emission wavelength, it was successfully achieved to control the emission wavelength by inserting another *A* site material into the PeQD structure. In detail, the PeQD structure was distorted by using two type of the *A* site materials with different ionic radii. This distortion indirectly changed the distance between the *B* and *X* site. This distance is strongly related to the *B*-*X* hybrid orbital. Finally, successful control over the emission wavelength was accomplished through the indirect manipulation of the *B*-*X* hybridized orbital linked to the energy bandgap. From the results such as FT-IR, XRD, and TEM measurement, it was revealed that the PeQD structure is distorted. In addition, by effectively regulating the energy band gap, it was successfully precise controlled of the emission wavelength with a precision of 1 nm.
On the other hand, we successfully achieved to prepare PeQD with high PLQY over 80% by inserting the alkali metal on the surface of PeQD. In detail, by inserting the alkali metal with a smaller ionic radius than the *A* site material composed of PeQD on the *A* site position of the PeQD surface, it was successfully suppressed the detachment of the *X* site adjacent to alkali metals. This means the generation of the trap level in the energy band structure was suppressed. In fact, PL lifetime measurement supported the proof of decreasing the trap level. In addition, PLQY values of PeQD with alkali metal was improved about 2 - 3 times compared with untreated PeQD.
In summary, we proved the effect of the *A* site on the PeQD optical properties, notably, the emission wavelength and PLQY. By using this finding, it is possible to expand the application range not only to LED, but also to color conversion material, quantum dot laser, and so on.

Modification of Two-Dimensional Tin-Based Perovskites by Pentanoic Acid for Improved Performance of Field-Effect Transistors
TomaszMarszalek; Max Planck Institute for Polymer Research, Germany

Understanding and controlling the nucleation and crystallization in solution-processed perovskite thin films are critical to achieve high in-plane charge carrier transport in field-effect transistors (FETs). This work demonstrates a simple and effective additive engineering strategy using pentanoic acid (PA). Here, PA is introduced to both modulate the crystallization process and improve the charge carrier transport in two-dimensional 2-thiopheneethylammonium tin iodide ($(TEA)_2SnI_4$) perovskite FETs. It is revealed that the carboxylic group of PA is strongly coordinated to the spacer cation TEAI and $[SnI_6]^{4-}$ framework in the perovskite precursor solution, inducing heterogeneous nucleation and lowering undesired oxidation of Sn^{2+} during the film formation. These factors contribute to a reduced defect density, improved film morphology including lower surface roughness and larger grain size resulting in an overall enhanced transistor performance. The reduced defect density and decreased ion migration lead to a higher p-channel charge carrier mobility of 0.7 $cm^2V^{-1}s^{-1}$, which is a more than threefold increase compared with the control device. Temperature-dependent charge transport studies demonstrate a mobility of 2.3 $cm^2V^{-1}s^{-1}$ at 100 K due to the diminished ion mobility at low temperatures. This result illustrates that the additive strategy bears great potential to realize high-performance Sn-based perovskite FETs.

Impact of A-site Cation Substitution on Charge Carrier Mobilities in $ASnBr_3$ Perovskites
AdairNicolson[1], SeánR. Kavanagh[1,2], ObadiahReid[3], EveMozur[4], DominicK. Asebiah[5], JamesR. Neilson[5] and DavidO. Scanlon[1]; [1]University College London, United Kingdom; [2]Imperial College London, United Kingdom; [3]University of Colorado Boulder, United States; [4]Colorado School of Mines, United States; [5]Colorado State University, United States

Halide perovskites have been intensely studied over the last decade due to their optoelectronic properties, with applications ranging from solar cells to LEDs. However, the majority of the best performing devices contain Pb(II), raising concerns over their toxicity. A standard solution to this problem is to perform chemical substitution, swapping Sn(II) for Pb(II) in order to retain the beneficial perovskite structure.[1] Using this technique, solar cells manufactured using $CsSnBr_3$ have to date achieved a record power conversion efficiency of 10.6 %.[2]

To improve devices further, a detailed understanding of the factors controlling charge carrier mobility is required. Substituting the A-site cation Cs, with methylammonium (MA) in $ASnI_3$ has been shown to reduce both hole and electron mobilities.[1] To investigate the origin of this trend, we use AMSET,[3] a package for calculating scattering rates from first principles, to determine the band-like transport properties. As excess charge has been found to localize to form bipolarons in Sn halide perovskites,[4] we extend our study to model small polaron transport using semiclassical Marcus theory.[5] These results will provide a picture of the factors affecting carrier mobilities in the band-like and hopping limits of $ASnBr_3$ (A = Cs, MA) perovskites.

8:00 PM EN05.03.28
Molecular Orientations and Hole-Collection Efficiency of Monolayer Materials for Hole-Transport Layer of Inverted Perovskite Solar Cells ArutoAkatsuka[1], Minh AnhTruong[2], AtushiWakamiya[2], GauravKapil[3], ShuziHayase[3] and HiroyukiYoshida[1,4]; [1]Chiba University, Japan; [2]Kyoto University, Japan; [3]Electro-Communications University, Japan; [4]Chiba University MCRC, Japan

For the hole collection layer of inverted structure perovskite solar cells, recently monolayers of carbazole derivatives [1] have been proposed to replace the polymer hole transport layer materials such as PTAA and PEDOT: PSS. The monolayers have the advantages of thin film, high transparency, and stability. Large orbital overlap and good interfacial energy alignment at the perovskite/hole collection layer interface are essential to obtain high hole transfer constants. To achieve the sizable orbital overlap, the π-conjugated backbone of the monolayer materials should be aligned face-on to the conductive metal oxide electrode (ITO). However, measuring the molecular orientation is usually difficult owing to the large surface roughness of ITO. For example, polarization-dependence of optical measurements such as ellipsometry gives averaged orientation.
In this study, we employ ultraviolet photoelectron spectroscopy (UPS) and metastable atom electron spectroscopy (MAES) to examine the molecular orientation of monolayers. In UPS, the photoelectron is generated by the excitation of UV light which can penetrate the sample. On the other hand, MAES uses metastable excited atoms (He*) as the excitation source, which only interact with the outermost molecular orbital of the sample material. For example, for a molecule whose π-conjugated backbone is aligned face-on to the ITO surface, only the π orbitals are observed in the MAES spectrum while both pi and sigma orbitals are detected by UPS. The molecular orientation can be evaluated by comparing the UPS and MAES spectra. We chose 2PACz and MeO-2PACz, which have one anchor group to bind to the ITO substrate, and 3PATAT-C3, which has three anchor groups.
The monolayers were prepared by spin-coating on ITO substrates, and the UPS and MAES spectra were measured. We used molecular orbital calculations (B3LYP/6-31G(d)) for the isolated molecules to assign features of UPS and MAES spectra. Comparing UPS and MAES spectra of 3PATAT-C3, the intensity of the σ orbital is weaker in MAES spectra than UPS spectra, whereas the π orbital is stronger in both. Therefore, the π-conjugated backbone of 3PATAT-C3 is aligned face-on to the ITO surface. The results of 2PACz and MeO-2PACz show that the π-conjugated backbone is tilted in 2PACz and edge-on alignment to the ITO surface in MeO-2PACz. The results are consistent with the higher hole transfer rate constant in 2PACz than MeO-2PACz obtained by time-resolved surface photovoltage [3]. To further discuss the hole-collection efficiency, we will report the energy level alignments at the perovskite-monolayer-ITO interfaces.

Co-Deposition of Hole-Selective Contact and Absorber for Improving The Processability of Perovskite Solar Cells XiaopengZheng[1] and JosephLuther[2]; [1]University of Chinese Academy of Science, China; [2]National Renewable Energy Laboratory, United States

Simplifying the manufacturing processes of renewable energy technologies is crucial to lowering the barriers to commercialization. In this context, to improve the manufacturability of perovskite solar cells (PSCs), we have developed a one-step solution-coating procedure in which the hole-selective contact and perovskite light absorber spontaneously form, resulting in efficient inverted PSCs. We observed that phosphonic or carboxylic acids, incorporated into perovskite precursor solutions, self-assemble on the indium tin oxide substrate during perovskite film processing. They form a robust self-assembled monolayer as an excellent hole-selective contact while the perovskite crystallizes. Our approach solves wettability issues and simplifies device fabrication, advancing the manufacturability of PSCs. Our PSC devices with positive–intrinsic–negative (p-i-n) geometry show a power conversion efficiency of 24.5% and retain >90% of their initial efficiency after 1200 h of operating at the maximum power point under continuous illumination. The approach shows good generality as it is compatible with different self-assembled monolayer molecular systems, perovskites, solvents and processing methods.

Ultimate 2D Perovskite-FA DJ 2D Perovskites with Maximum Symmetry JinHou[1], JaredFletcher[2], HaoZhang[1], GeorgeVolonakis[3], ClaudineKatan[3], JackyEven[3], MercouriG. Kanatzidis[2] and AdityaD. Mohite[1]; [1]Rice Univeristy, United States; [2]Northwestern University, United States; [3]Université de Rennes, France

Two-dimensional halide perovskites (2D-HaP) have emerged as a class of highly durable solution-processed organic-inorganic (hybrid) low-dimensional semiconductors. They exhibit a combination of properties derived from four classes of materials - quantum wells, atomically thin 2D materials, organic semiconductors, and three-dimensional (3D)-HaP perovskites. The general formula of 2D-HaP is $(A')_m(A)_{n-1}M_nX_{3n+1}$, where A′ is a bulky organic cation, A is a small organic cation, M is a divalent metal, and X is a halide, with m=2 in Ruddlesden-Popper (RP) phases and m=1 in Dion-Jacobson (DJ) phases. The number n determines the thickness of the perovskite layer, which consists of alternate organics (A')m and hybrid $(A)_{n-1}M_nX_{3n+1}$ layers, making 2D-HaP a platform to engineer hybrid composites with attractive optoelectronic properties.
Currently, similar to 3D-HaP, most of the 2D-HaP takes Methylammonium (MA) as the A site cation. While the MA^+ cation has the most suitable effective radius of any monovalent cation (either organic or inorganic) for forming a stable perovskite structure in a strain-stress perspective, the chemical instability of MA had motivated the use of less suitably sized but more chemically stable cations, such as formamidinium (FA).[1] Different from 3D-HaP which already has some successful demonstrations using FA as A site cation,[2] FA based 2D-HaP remains underexplored, with only a few reports achieving an “n” equal to 1 or 2.[3] We propose that the difficulty of synthesizing FA based 2D perovskite coming from the larger size of FA compared to MA, which will increase lattice mismatch between the organic parts and the inorganic parts in the 2D perovskites.[4] Therefore, the key to synthesizing a multi-layer FA based 2D perovskite is to find the appropriate organic spacer which has a small lattice mismatch with the inorganic part.
Here, we demonstrate a synthesis of FA based 2D DJ perovskites crystals, from n=1 to n=4 after screening a series of different organic spacers. This new series of 2D perovskites shows a surprisingly zero distortion along both in-plane and out-of-plane (Pb-I-Pb angle is equal to 180 degrees for both directions), which is never observed before in any multi-layer 2D perovskites. They are all tetragonal phase and with P4/mmm as the space group, which is the maximum symmetry a 2D perovskite can theoretically have.[5] The interlayer distance (below 4 Å) of the FA DJ 2D perovskite is also one of the smallest among all reported 2D perovskite, and this could allow for better interlayer electronic coupling. As the consequence of zero distortion and short interlayer distance, this new 2D perovskite series exhibits systematically lower band gap, probably the smallest bandgap among all the 2D perovskite to our best knowledge. Preliminary stability test shows this new FA DJ maintained 75% of the perovskite phase under 1.2 suns plus 100% RH (relative humidity) over 2.5 hours.

On-Site Wettability-Induced Growth of Perovskite Nano-Structure Arrays GuannanZhang, ZhaoSun, ChuweiLiang, ZhuofeiGan, LiyangChen and WendiLi; The University of Hong Kong, Hong Kong

Due to their unique properties including tuneable band gaps, superior carrier mobility, high color purity, high absorption and emission efficiency, halide perovskites have been widely used in various kinds of optoelectronic applications such as photodetectors, PeLED, laser, etc [1-2]. Specifically, low-dimensional perovskite nanostructures have attracted extensive attention due to their excellent optical, electrical, and stability characteristics, as compared to continuous film materials [3]. Ensuring the size uniformity and controllability of perovskite nanostructures is a prerequisite for their adoption in practical device applications. Diverse methods, such as inkjet printing, spin coating, vapor phase growth, blade coating, and slot-die coating, have been applied to fabricate low-dimensional perovskite nanostructures. However, these methods are usually achieved by utilizing nano-templates, which increases the complexity and cost of the fabricating process. Besides, ensuring uniform morphology and good crystallization is also very challenging to achieve high-performance perovskite nanostructures.

Herein, a template-free fabrication method to realize the controllable growth of perovskite nano-structure arrays including nanowires and nanodot arrays via the inducement of patterned wettability is demonstrated. Take nanowires as an example, figure 1 shows the schematics of perovskite nano-structure fabrication strategy. The hydrophilic-hydrophobic nanograting structure is constructed by interference lithography and trichloro(1H,1H,2H,2H-perfluorooctyl)silane (FDTS) treatment. Figure 2 shows the photoresist patterns prepared by interference lithography, including nanogratings and nanopillar arrays. Then, perovskite nanowires can be fabricated by high-throughput blade coating system consisting of a blade, hot plate, and control system as well as other auxiliary equipment.

Furthermore, in order to avoid obtaining perovskite structures with discontinuous morphology and low crystallinity, we adjust blade coating parameters (i.e., blade gap, velocity, and temperature) and the solvent properties, particularly the viscosity. We found that when the blade speed is too fast, the liquid film is very discontinuous, while if the blade speed is too slow, the perovskite film is too thick so that the separate nanowire structure cannot form. The optimized coating speed is 160 μm/s, at which a continuous perovskite nanowire array with excellent morphology can be obtained. In addition to good morphology, crystallization plays a crucial role in the performance of subsequent perovskite devices. Substrate temperature is another key factor affecting the morphology and crystallization of perovskite nanowires. When the substrate temperature was higher, the deposition front was overly close to the meniscus edge, leading to the formation of the widened nanowires. At high temperature, the solvent can evaporate in a short time, and the grain grows rapidly, resulting in a larger grain size. On the other hand, when the substrate temperature was rather low, the liquid filament was found to easily dewet into segmented perovskite nanowires. And solvent evaporation rate and crystal growth rate are slower at low temperature, resulting in dendritic structure or small-sized grains.

By utilizing the optimized process parameters obtained, $MAPbI_3$ perovskite nanowire structure with uniform dimension and excellent crystallization can be obtained, as shown in Figure 3. In addition, this method can be used to prepare diverse perovskite nanowire arrays, such as $CsPbBr_3$ nanowires. Using the same approach, diverse types of perovskite nanodot arrays can also be generated, as shown in Figure 4. The strategy shows a facile method to fabricate perovskite nano-structure arrays, paving the way to low-cost, large-area, and rapid fabrication of high-performance perovskite optoelectronic devices.

Illuminating the Devolution of Perovskite Passivation Layers MarcinGiza[1], AlekseyKozikov[2], PaulaLalaguna[1], JakeHutchinson[3], VaibhavVerma[2], BenjaminVella[1], RahulKumar[1], NathanHill[2], RebeccaL. Milot[3], MalcolmKadodwala[1] and PabloDocampo[1]; [1]University of Glasgow, United Kingdom; [2]The University of Newcastle, United Kingdom; [3]University of Warwick, United Kingdom

Surface treatment of 3D perovskite materials with their layered counterparts has become the most utilised strategy against air- and moisture-induced degradation. Whilst layered materials confer great benefits to the longevity and long-term efficiency of the resulting device stack via passivation of defects and surface traps, numerous reports have previously demonstrated that these materials evolve under exposure to light and humidity, suggesting they are not fully stable. Therefore, it is crucial to study the behaviour of these materials in isolation and as part of a device stack. Herein, it is demonstrated via optical, PL, AFM, XRD, and TAS studies that these “stable” capping layers undergo numerous changes in conditions commonly found during perovskite fabrication, such as exposure to light, solvent, and moisture. A pinhole-mediated degradation mechanism is identified as the cause of the degradation of exfoliated flakes of PEA_2PbI_4, an n = 1 material. This results in the loss of whole perovskite sheets, from a few monolayers to tens of nanometres of material. We discuss important steps to take to slow down their degradation. Additionally, we show high-n PEA-based perovskite capping layers on top of MAPI undergo uncontrolled rearrangements to form lower-n phases, which can severely impact band alignment within devices, or degrade completely. Crucially, they do not act as perfect barrier layers, with the underlying 3D perovskite also demonstrating signs of degradation.

Antisolvent Engineering for Microstructural Improvement of Lead Free Solar Absorber Material MemoonaQammar, BosenZou and JonathanHalpert; Hong Kong University of Science and Technology, Hong Kong

Lead free halide materials are seeking attention owing to their astonishing optoelectronic properties accompanied with better stability and less toxicity. Silver bismuth halides being ecofriendly and seen as potential candidates for photovoltaic applications but they are still struggling with power conversion. To address this issue here we have used antisolvent engineering to improve film morphology and tested the absorber material in an inverted solar cell for the fisrt time with device architecture: ITO/NiO/$AgBiI_4$/C_{60}/BCP/Ag. The efficiency was improved from 0.5% to 1.3% for the solar cell based on absorber layer fabricated via chloroform assisted antisolvent solvent spin casting method. The microstructural improvement was proven by a thorough analysis with SEM and AFM. This study has demonstrated that low boiling antisolvent can assist less polar antisolvent to improve the microstructure of the thin films which ultimately resulted in enhancement of PCE in $AgBiI_4$ inverted solar cell.

8:00 PM EN05.04.06
Understanding The Impact of Ions on Open Circuit Voltage in Perovskite Solar Cells FraserJ. Angus[1], LucyJ. Hart[2], Piers R. B.Barnes[2] and PabloDocampo[1]; [1]University of Glasgow, United Kingdom; [2]Imperial College London, United Kingdom

Metal halide perovskites are a nascent class of materials that combine competitive power conversion efficiencies with low-cost materials and manufacturing processes for use in next-gen solar cells. These materials, uniquely amongst PV materials, are capable of conducting both ionic and electronic charge. However, the presence of mobile ions can lead to extraction losses and carrier accumulation, as a function of the applied bias history of the device which can lead to unreliable performance. However, mobile ions can also reduce recombination currents at the perovskite/transport layer interfaces, increasing open-circuit voltage (V_{oc}). Employing Stabilise-and-Pulse (SaP) measurements, we show that ion accumulation can increase V_{oc} by 0.1 V, which decreases as the flat-ion potential of the PSC becomes larger. We validate these results with drift-diffusion simulations and confirm that under poor energetic alignment conditions, ions can provide a significant boost to the device performance.

8:00 PM EN05.04.07
Exploring The Correlation Between The Built-In Potential of Perovskite Solar Cells and The Thickness of Passivating Layered Perovskites. FraserJ. Angus and PabloDocampo; University of Glasgow, United Kingdom

Perovskite solar cells have shown significant improvement in recent years, with the power conversion efficiency exceeding 25%. The integration of layered perovskites into a perovskite heterojunction is a promising approach for further enhancing their performance and providing long-term device stability. However, the effects of increasing the thickness of the layered perovskite on device physics and the role of the built-in potential (Vbi) in charge extraction are not well understood. Herein, we discuss the intricate physics that come into play when the thickness of the layered perovskite is increased, resulting in a dynamic change in band bending and a consequent effect on the built-in potential. This work elucidates the mechanisms behind the well-known performance enhancement resulting not just from the layered perovskites' role in surface passivation, but also from their effect on the built-in potential.

Search for Ferromagnetism in Mn-Doped Lead Halide Perovskites MaryamSajedi, MaximKrivenkov and OliverRader; Helmholtz Zentrum Berlin, Germany

Lead halide perovskites are new key materials in various application areas such as high efficiency photovoltaics, lighting, and photodetectors. Doping with Mn, which is known to enhance the stability, has recently been reported to lead to ferromagnetism below 25 K in methylammonium lead iodide ($MAPbI_3$) mediated by superexchange. Two most recent reports confirm ferromagnetism up to room temperature but mediated by double exchange between Mn^{2+} and Mn^{3+} ions. Here we investigate a wide concentration range of $MAMnxPb1{-}xI_3$ and Mn-doped triple-cation thin films by soft X-ray absorption, X-ray magnetic circular dichroism, and quantum interference device magnetometry. The X-ray absorption lineshape shows clearly an almost pure Mn^{2+} configuration, confirmed by a sum-rule analysis of the dichroism spectra. A remanent magnetization is not observed down to 2 K. Curie-Weiss fits to the magnetization yield negative Curie temperatures. All data show consistently that significant double exchange and ferromagnetism do not occur. Our results show that Mn is not suitable for creating ferromagnetism in lead halide perovskites.

8:00 PM EN05.04.09
Influence of Interface Configuration on Carrier Transport at 2D/3D Halide Perovskite Heterojunctions Young-KwangJung and SamuelD. Stranks; University of Cambridge, United Kingdom

Halide perovskite photovoltaics have shown significant advancements, with power conversion efficiencies (PCEs) increasing to commercially viable levels. However, device stability remains a significant hurdle for the success of the technology and requires further improvement. The introduction of Ruddlesden-Popper (RP) two-dimensional (2D) perovskite overlayers on top of three-dimensional (3D) perovskite active layers has emerged as a promising strategy for enhancing the stability of perovskite solar cells (PSCs) [1-2]. While many successful cases of efficient and stable PSC fabrication via the inclusion of 2D/3D heterojunctions have been reported [3-4], a fundamental understanding of the interaction between 2D and 3D perovskites at their interfaces remains elusive. Therefore, uncovering the relationship between the atomic configuration of the interface and the behavior of electrons at this interface is crucial.

In this work, we performed first-principles density-functional theory (DFT) calculations to explore how the atomic configurations of interfaces influence the properties of 2D/3D halide perovskite heterojunctions. We adopted PEA2PbX4/CsPbX3 (X = Br, I) heterojunctions as model systems, optimizing their interface geometries and calculating electronic structures. Our results show that both the thermodynamic stability and band alignment of 2D/3D halide perovskite heterojunctions are highly dependent on the configurations of Cs/PEA cations at their interfaces.

The Role of Ligand Capping in Achieving High-Efficiency Perovskite Solar Cells and QD LEDs FarzanehJahanbakhshi[1], Andres FelipeCastro Mendez[2], ShaunGallagher[3], JessicaKline[3], DavidS. Ginger[3], Juan-PabloCorrea-Baena[2] and AndrewRappe[1]; [1]University of Pennsylvania, United States; [2]Georgia Institute of Technology, United States; [3]University of Washington, United States

Formamidinium lead iodide (FAPbI) has gained prominence in photovoltaic (PV) applications due to its notable thermal and chemical stability compared to methylammonium lead iodide (MAPI). However, a significant challenge arises from its inherent tendency to spontaneously transform from the cubic (alpha) phase to the non-perovskite yellow (delta) phase under ambient conditions, posing obstacles for practical utilization. We introduce a novel technique involving the evaporation deposition of FAPI onto the substrate that is functionalized with specific acid ligands. This method is designed to exert precise control over the preferential formation and growth of the alpha phase, thereby mitigating the unfavorable transformation to delta-FAPbI. Additionally, we investigate the impact of ligand capping on modulating photoluminescence intermittency in CsPbBr3 Quantum Dots (QDs). Specifically, we compare the efficiency of CsPbBr3 QDs capped with a zwitterionic ligand against the traditional approach employing oleic acid and oleylamine. Our findings demonstrate that tight-binding ligands hold promise for reducing blinking phenomena in perovskite QDs, particularly in single-particle and quantum light experiments.These strategies are elucidated through rigorously analyzing the formation and surface chemistry of these systems at the Density Functional Theory (DFT) level.

8:00 PM EN05.04.11
Efficient and Stable Inverted Perovskite Solar Cell via Incorporation of Halogenated Polystyrene SaikiranS. Khamgaonkar and VivekMaheshwari; University of Waterloo, Canada

Rationale design and use of additives to enhance the stability of Metal halide perovskite (MHP) is a key challenge that needs to be addressed for their commercial adoption in photovoltaics. Although high efficiency has been achieved, long term operational stability under daily temperature variation remains an unsolved issue for their large-scale deployment. In this work we use halogenated polystyrene as an additive to improve the long term operational and thermal stability, as well as the efficiency of perovskite solar cells. The incorporation of optimized amount halogenated polystyrene (PS) namely PS-X (X=F,Cl,Br) into perovskite precursor solution along with its direct interaction with PbI_2 through Lewis acid base interaction leads to the formation of enlarged, cross-linked perovskite grains. Similarly, the hydrophobic and insulating nature of PS leads to reduced ion migration effects, lower dark and enhanced stability. As a result, halogenated PS (PS-X) p-i-n inverted solar cell showed enhanced efficiency and reduced hysteresis effect when compared to pristine perovskite. A major improvement was seen in the short circuit density (Jsc) and fill factor (FF) of the halogenated PS cells due to effective defect passivation caused by the addition of the polymer. In addition to the improvement in performance, halogenated PS cells showed enhanced thermal stability when compared to pristine perovskite cells, which is attributed to the properties and structure of the PS-X additive.

8:00 PM EN05.04.12
Potential of Perovskite Doping Unlocked: Shaping The Future of Energy and Electronics ZuzannaMolenda[1], BastienPoliti[2], RaphaëlClerc[2], DarioBassani[3] and LionelHirsch[1]; [1]Laboratoire de l'Intégration du Matériau au Système (IMS), University of Bordeaux, France; [2]Université de Lyon, Université Jean Monnet-Saint-Étienne, CNRS, Institut d'Optique Graduate School, Laboratoire Hubert Curien, UMR, France; [3]Institut des Sciences Moléculaires, University of Bordeaux, France

Doping of metal halide perovskites (MPHs) is the next, essential step towards the implementation of perovskite semiconductor technology for electronic devices. Nonetheless, only a limited number of successful doping instances have been documented, and it is frequently mistaken for additives, grain passivation, or surface functionalization, none of which affect the semiconductor's charge carrier density. Due to the ionic character of the perovskite crystal, the introduction of heterovalent ions is accompanied by the counter ions that balance out the potential doping effect. Here we present a use of homovalent yet metastable ions, in particular Sm^{2+}, to substitute Pb^{2+} in $MAPbI_3$ (MA = methylammonium). Sm^{2+} ions spontaneously oxidize to Sm^{3+}, once incorporated into the crystal lattice and each of them releases one electron to the conduction band. The oxidation of samarium ions is confirmed by the analysis of the Sm 3d core level in the X-ray photoelectron spectrum (XPS). Residual content of the oxidized form of Sm^{3+} present in the doping solution allows to observe a slight shift of the Sm 3d peak towards higher binding energy, suggesting the environment change of the Sm^{3+} ion, once introduced inside the perovskite film. Together with the shift of the XRD pattern upon doping, this supports the hypothesis that the dopant ion is incorporated and stabilized in the crystal lattice. At the same time, the crystal structure of the doped perovskite layer is conserved and no phase separation is observed from the XRD patterns. Ultraviolet photoelectron spectroscopy (UPS) shows a shift of the Fermi level (E_F) by around 0.5 eV towards the conduction band, proving the doping to be n-type. The increase of the free electron density in the conduction band is the direct reason for the conductivity increase for the doped films by 3 orders of magnitude. Using the Mott-Schottky method, the ionized charge carrier density is estimated to be 10^{17} cm^{-3} for the sample showing the highest conductivity increase, which suggests the ionized dopant concentration in the doped perovskite film to be around 0.01% (Pb density in $MAPbI_3 \approx 10^{21}$ cm^{-3}). The discrepancy between this result and the doping concentration stemming from the XPS measurement, which is calculated to be around 20%, leads to two possible explanations. Either the majority of the Sm^{2+} introduced to the perovskite polycrystalline film resides at grain boundaries and therefore does not act as a dopant or the dopant is only partially oxidized in normal conditions, exhibiting the freeze-out effect. The dopant activation energy (the energy necessary to oxidize all the Sm^{2+} ions to Sm^{3+}) of around 350 meV seems to support the latter hypothesis and is in agreement with the energy between the E_F and conduction energy (E_C). The presented method allows to reach the highest to-date conductivity increase for the n-type and may become a protocol for the efficient n-type doping of MHPs. To illustrate one of its applications, we fabricated perovskite solar cells (PSC) with poly(triaryl amine) (PTAA) as a hole transporting layer (HTL) (p-side) and Sm-doped $MAPbI_3$ (n-side), without the electron transporting layer (ETL). Additionally, we used gold as an electron collecting electrode (WF_{Au} = 5.22 eV). The strain-induced ohmic contact between highly doped perovskite and Au allows to minimize the series resistance at this interface and an efficient electron collection. This shows the potential of flexible electrode selection for the doped PSC. Therefore, the ETL-free n-doped PSC retains the same PCE as the reference sample (with PCBM as an ETL), in spite of the simplified architecture that decreases the fabrication cost and the number of interfaces.

Cesium Lead Halide Perovskite Ozone Gas Sensors based on Reflectivity Measurements. JacobD. Wolfman, SamitaMishra and YaacovR. Tischler; Bar-Ilan University, Israel

Metal-halide perovskite (MHP) materials have been developed into high performance semiconductors primarily for photovoltaic devices, and for a variety of other applications. Recently, MHP's were used to detect ozone and other volatile gases by detecting changes in electrical conductivity, in a reversible manner. However, the fundamental problem with such films, namely that they are typically rough and inhomogeneous, has hindered photonics-based sensor development. Following the work of Bo Li et. al. [*Nat. Comm.* **9**, 1076 (2018)], here we show that smooth thin films (rms roughness < 4 nm) of MHP based on $CsPbBr_xI_{3-x}$ (x = 0, 1, 2 or 3) could be prepared, by incorporating 5% polymer into the precursor solutions. The MHP+polymer compounds were spin-coated from DMSO/DMF solutions and annealed (30 min. at 100°C), resulting in highly reflective thin films, with the peak reflection wavelength depending on the Br:I ratio. When exposed to 5 ppm of ozone for 5 minutes in a chamber, the MHP films showed on average a 20% decrease in reflection, and after about 1 hour, the reflection exhibited on average a 9% recovery. We also observed reversible changes in the absorption and photoluminescence spectra due to ozone exposure. These very recent results suggest that MHP's are promising candidates for spectrally resolved photonic gas sensing applications.

Structural Evolution and Octahedral-Coordination Control in $Cs_2Ag_{1-x}Pb_{2x}Bi_{1-x}Br_6$ Perovskite Materials Yi-TingTsai, Wei-LunSu and Mu-HuaiFang; Academia Sinica, Taiwan

Halide-based perovskite materials have garnered significant attention due to their diverse structures and various synthesis conditions. Serving as customizable optoelectronic materials, they

play pivotal roles in electronic applications like light-emitting diodes, backlight systems, solar cells, photodetectors, etc. Nevertheless, their intricate structural adjustment mechanisms remain significant challenges for future utilization. In this study, we successfully synthesized a series of $Cs_2Ag_{1-x}Pb_{2x}Bi_{1-x}Br_6$ materials with a hetero-valent substitution strategy, forming solid solutions bridging $CsPbBr_3$ perovskite and $Cs_2AgBiBr_6$ double-perovskite materials. High-resolution synchrotron X-ray diffraction, coupled with Rietveld refinement, confirmed that samples possess the third phase between the $CsPbBr_3$ perovskite and $Cs_2AgBiBr_6$ double-perovskite end-members. Theoretical calculations, X-ray absorption spectra, Raman spectra, and photoluminescent spectra are conducted to realize the solid-solution process. This study provides valuable insights into the diverse structures by hetero-valent substitution strategy and contributes to precise analysis for subtle changes in crystal structures.

8:00 PM EN05.04.16
Chlorine Addition Effect on The Properties and Stability of Flexible Printed Hybrid Halide Perovskite Solar Cells CrysaStavraki[1], AlexandrosZachariadis[1], SpyridonKassavetis[1], ChristosKapnopoulos[1], EiriniParaschoudi[1], AlexandrosPaliagas[1], VolhaHeben[1], ChristoforosGravalidis[1], EvangelosMekeridis[2], ArgirisLaskarakis[1] and StergiosLogothetidis[1,2]; [1]Aristotle University of Thessaloniki, Greece; [2]Organic Electronic Technologies P.C. (OET), Greece

Flexible printed perovskite solar cells based on Hybrid Organic–Inorganic Metal Halides have attracted significant attention due to the combination impressive power conversion efficiency and low-cost production and their impressive increase in power conversion efficiency.In this work we focus on the flexible printed perovskite solar cells and in the addition of Chlorine anion addition into CH3NH3PbI3 perovskites effectively improves the crystallinity, stability and as a result the performance and durability of the of flexible printed perovskite solar cells (PSCs). The flexible printed PSCs were fabricated in the inverted structure using one-step slot-die coating that involves the sequential printing of PEDOT:PSS/CH3NH3PbI3/PCBM layers on top of flexible PET/IMI substrates, while the top electrode (silver, Ag) was grown by thermal evaporation in vacuum. The effect of PbCl2 addition to perovskite precursor solution was primarily studied in terms of surface morphology and structure of the perovskite layer due to the variations of chlorine ratio in the precursor solution. X-Ray Diffraction showed the effect of chlorine addition on the crystal grain size and orientation, the surface topography characteristics were evaluated by Atomic Force Microscopy (AFM), while UV-Vis optical characterization and nIR-Vis-UV Spectroscopic Ellipsometry (SE) were used to study the optical properties and measure / control the thickness of each printed layer.
The printed hybrid halide perovskite layers were of high crystalline quality as the [(110), (220), (330)] diffraction peaks of CH3NH3PbI3 XRD appeared in the XRD spectra, while the analysis of the AFM images showed that the perovskite crystals' size was enlarged by more than 150 nm and the RMS surface roughness increased up to 30 nm as the PbCl2 addition to perovskite precursor solution increases. Analysis of the SE spectra provided us with information on the printed perovskites thickness (> 400 nm), the quality and enables the study the effect $PbCl_2$ addition on the printed perovskite stability and degradation mechanisms through the changes in the PbI2 absorbance peak in 4.64 eV. The stability studies are also supported by the nanoindentation testing, that provides information on the mechanical properties (elastic modulus, hardness and printed layers adhesion) of the individual layers and the device as well as the mechanical stability of the printed perovskite layers. Finally, we focus on the effect of the printed hybrid halide perovskite properties to the PSCs devices electrical characteristics and power conversion efficiency.

Thermomechanical Durability Study of Flexible Hybrid TCEs on PET made by Photonic Curing JustinC. Bonner[1], RobertPiper[1], BishalBhandari[1], MatthewDavis[2] and JuliaW. Hsu[1]; [1]University of Texas at Dallas, United States; [2]Energy Materials Corporation, United States

Solution-deposited transparent conducting electrodes (TCEs) can potentially reduce the cost of perovskite solar cell (PSC) manufacturing. However, high-temperature thermal annealing is still needed to convert solution-deposited metal oxide films and is not compatible with plastic substrates. Photonic curing is an alternative to thermal annealing; instead of heating directly, it uses a xenon flash lamp to pulse broadband light onto a sample for micro to millisecond durations. Light absorption, dependent on material optical constants, is converted to heat during a flash from the lamp; a thin absorbing layer is selectively heated during a light pulse while the nonabsorptive plastic layer does not heat up significantly. In our lab, we fabricate hybrid TCEs consisting of silver nanowires (AgNWs) and indium zinc oxide (IZO) on polyethylene terephthalate (PET) by blade coating and photonic curing. Because solution-deposited metal oxides have lower conductivity, adding AgNWs is crucial to achieve a low sheet resistance. The AgNW layer determines the sheet resistance, transmittance, and energy needed from the flash lamp to convert the IZO, which decreases the roughness of our hybrid TCEs and prevents device shorting.

While the PET substrate does not heat up significantly during photonic curing, subsequent processing of device layers and operating conditions often require high temperatures or temperature cycling that can lead to oxide cracking. Oxide-based TCEs and PET substrates are known to have a coefficient of thermal expansion (CTE) mismatch because a metal oxide has a CTE ten times smaller than the CTE of the plastic substrate. When a TCE made with a plastic substrate and brittle metal oxide is heated to elevated temperatures, the CTE mismatch will induce cracks in the metal oxide film, leading to high resistance and open circuit devices. In this work, we study the thermomechanical durability, particularly the cracking failure in the IZO layer, of the AgNW + IZO TCEs on PET substrates. Thermomechanical durability is tested by heating the PET/TCE samples to 120°C for 10 minutes, a typical annealing temperature and time used for PSC fabrication. We investigate the cause(s) for IZO cracking including IZO thickness, relative humidity during coating, PET substrate thickness, thermal and mechanical properties, and surface treatment. We then devise processing conditions to alleviate the thermomechanical failures. TCEs that survive the thermomechanical durability test will be used to make PSCs and benchmarked to PSCs made on commercial flexible TCEs. The success in producing a robust TCE will facilitate roll-to-roll manufacturing of PSCs.

This work is supported by DOE SETO DE-EE0009518.

Enhanced Humidity Stability of 2D Perovskites using Sulfonium Cations DanielRatchford, GloriaBazargan, BlakeS. Simpkins, JeffOwrutsky and MatthewD. Thum; Naval Research Laboratory, United States

Metal halide 2D perovskites, consisting of alternating layers of metal halide octahedra sheets and cations, have broad technological appeal because of their tunable mechanical, optical, and electrical properties. Compared to 3D perovskites, 2D perovskites offer a greater flexibility in the range of cations that can be incorporated into a stable crystal structure, which then offers the potential for a broader range of material properties. Here, we discuss our work on the synthesis and characterization of lead halide perovskites which contain fluorinated phenethylsulfonium (FPES) cations. We fabricate thin film perovskites which incorporate varying amounts of this new sulfur-containing cation mixed with conventional cations (phenethylammonium and methylammonium) and compare material optical properties and stability under humid conditions. We use visible absorption spectroscopy to measure the degradation of samples at 90% RH. We show that incorporating the FPES cation can dramatically slow down humidity induced degradation, while also reducing the charge carrier recombination lifetimes. This work highlights that sulfonium cations could play an important role in enhancing the environmental stability of lead halide perovskites.

Expanding the Interface Engineering for Efficient Perovskite X-Ray Detectors Thanh HaiLe and WanyiNie; Los Alamos National Laboratory, United States

Although perovskite material-based detectors exhibit remarkable optoelectronic performance, they face a significant challenge in terms of operational stability, which does not meet market demands. Several technological strategies have been suggested to tackle the instability problem attributed to halide ion migration. While these methods have resulted in some progress, they have not yet yielded a solution ready for the market. Here, we present evidence that a zero-dimensional PEA_2ZnI_4 material can significantly enhance surface passivation in 2D perovskite single crystals and create stronger two-dimensional/zero-dimensional heterojunctions compared to their lead-based counterparts. The resulting 0D/2D configuration forms a unique and well-organized multi-dimensional interface, resulting in an impressive external quantum efficiency increase of up to 30%, surpassing the 8% improvement seen in 2D perovskite devices. Furthermore, our device maintains 100% initial efficiency even after undergoing 1000 on-off cycles and enduring over 70 hours of continuous illumination at 178.7 μGy/s while under an applied voltage of 10V. Additionally, our unencapsulated device exhibits no loss in performance under normal measurement and storage conditions (temperature: 25 ºC, humidity: 20 to 60%) for up to 2 months. These findings significantly broaden the range of materials available for low-dimensional interface engineering and create an opportunity for the timely commercialization of perovskite x-ray detectors.

Enhancing The Bending Stability of Flexible Perovskite Solar Cells based on Stainless Steel Substrate through Interface Incorporation of Buffer Layer onto TiO2 KyunghwanKim[1], SolheeLee[1], Jae-KeunHwang[1], WonkyuLee[1], DowonPyun[1], JiyeonNam[1], Seok-HyunJeong[1], Ji-SeongHwang[1], SujinCho[1], YoungminKim[2], Hae-SeokLee[2], YoonmookKang[2], YounghoChoe[1] and DonghwanKim[1]; [1]Korea University, Korea (the Republic of); [2]KU-KIST Green School, Korea (the Republic of)

As the importance of renewable energy is increasingly emphasized, photovoltaic technology stands at the forefront of this energy transition. Building-integrated photovoltaics (BIPV) and vehicle-integrated photovoltaics (VIPV) are extending the application scope of traditional solar systems, exploring their potential in more diverse and complex environments. In response to these advancements, researchers continually delve into this domain, aiming for more efficient and sustainable energy solutions.
The first-generation crystalline silicon solar cells have already demonstrated high efficiency and reliability in their performance. However, the wafer's inherent physical properties present

limitations in flexibility and adaptability to diverse curvatures. In contrast, perovskite thin-film solar cells emerged to address these challenges, expanding applicability not only to traditional glass substrates but also to flexible substrates of various forms and materials. Specifically, when applied to intricate structures such as BIPV and VIPV, their utility and cost-effectiveness are anticipated to significantly increase.
In this study, we investigated the fabrication process of these perovskite solar cells on stainless steel (SS) substrates, leveraging the substrate's mechanical robustness, thermal and moisture stability, and excellent corrosion resistance. To evaluate their suitability for BIPV and VIPV applications, bending tests were conducted under varying curvature conditions ranging from 3mm to 15mm. Damage to the Electron Transfer Layer (ETL) and the perovskite layer was observed in these tests, affirming their substantial impact on the solar cell's performance and stability. Consequently, to fortify damage during the bending process, the insertion of a buffer layer between these layers was proposed to enhance the bending stability and performance of perovskite solar cell.

SESSION EN05.05: Halide Perovskites Photovoltaics and Stability I

2D or Not 2D for High Efficient NIP Perovskite Solar Cells GiuliaGrancini; University of Pavia, Italy

Three-dimensional (3D)/low-dimensional (LD) perovskite solar cells (PSCs) offer an effective strategy to overcome the trade-off between perovskite solar cells device performance and stability. Improving the device longevity, while concomitantly simultaneously enhancing increasing the solar cell open circuit voltage and fill factor of the solar cell is the current challenge. Despite being one of the most popular and effective way processing techniques, whether the presence of this surface LDP layer would be - or not-represents the winning crucial path for the future of this technology remains elusive. In particular, atomic layer combined surface and bulk passivation using surface modifiers such as organic dopants, casts the doubts on the effective need for of having an homogeneous LDP cover capping layer. In this talk, I will discuss the interfacial passivation with different cations such as M-PEAI, M-PEABr, and M-PEACl, showing the role of the passivation and how different halides affect the device performance of the devices. In addition, I will compare recent results obtained in the 3D/LDP configuration with the surface cation passivation strategy, which can still pushes produce the performances to values comparable to the LDP/3D bilayers. I will providing a comprehensive perspective on the benefits from of the two different strategies, but also presenting how LDP interfaces can play a role in alternative new configurations, such as tandem solar cells [1,2].

Acknowledgements I acknowledge the “HY-NANO” project that has received funding from the European Research Council (ERC) Starting Grant 2018 under the European Union’s Horizon 2020 research and innovation programme (Grant agreement No. 802862).

Hot Carriers in Metal Halide Perovskites: Cold Background Effect and the Hot Phonon Bottleneck TimFaber[1], LadoFilipovic[2] and Lambert Jan AntonKoster[1]; [1]University of Groningen, Netherlands; [2]TU Wien, Austria

The goal of third-generation PV is to go beyond the Shockley–Queisser limit, the theoretical limit of 33 % for a single junction solar cell. The hot carrier solar cell concept has been proposed to overcome this limit, by harvesting carriers before they have lost their surplus energy. Theoretically the prevented thermal losses could boost the efficiency up to 66%.

One promising type of materials for these purposes are perovskites. Next to having excellent PCE, being cheap and solution processable, some perovskites have shown very long cooling times, the key requirement for a hot carrier solar cell. We wish to shed light on why relaxation times are found to be so long in perovskites.

By using an Ensemble Monte Carlo (EMC) simulation we are able to simulate the trajectories of charge carriers and model their interactions with their environment. In the EMC random free flight times are generated and interrupted by scattering events with desired scattering mechanisms. It is this freedom of choice which makes the EMC an excellent tool in order to investigate what exactly causes charge carriers in halide perovskites to cool.

In this contribution we first identify the roles of electron-phonon and electron-electron scattering in the thermalisation and cooling process. We show how these processes depend on several material parameters. We zoom in on how cooling times are impacted by the degree of background doping and show how an ensemble of background carriers can have a detrimental effect on the cooling time.

Secondly, we quantify the effect of a hot phonon bottleneck on the cooling time. The hot phonon bottleneck has been put forward as a prominent mechanism explaining the extended cooling times measured for perovskites. We show on what scale the hot phonon bottleneck could extend cooling times and how it depends on carrier concentration and phonon lifetime.

Our results give important insights in the hot carrier cooling dynamics of perovskites, and are highly relevant for the discussion on whether or not perovskites are suitable candidates for a hot carrier solar cell.

8:45 AM EN05.05.03
Unlocking the Potential of Single-Crystal Hybrid Perovskites: Pushing the Limits to Achieve Stable and Efficient X-Ray Detection BekirTuredi[1,2,3], KostiantynSakhatskyi[1,2], GebhardJ. Matt[1,2], ErfuWu[2], AnastasiiaSakhatska[1,2], VitaliiBartosh[1,2], MuhammadN. Lintangpradipto[3], RounakNaphade[3], IvanShorubalko[2], OmarF. Mohammed[3], SergiiYakunin[1,2], OsmanM. Bakr[3] and MaksymV. Kovalenko[1,2]; [1]ETH Zürich, Switzerland; [2]Empa–Swiss Federal Laboratories for Materials Science and Technology, Switzerland; [3]King Abdullah University of Science and Technology, Saudi Arabia

Recently, hybrid metal halide perovskites have emerged as promising candidates for X-ray detectors, attributed to their cost-effective, scalable, and robust solution growth, as well as their competency in detecting individual gamma-photons under high bias voltages. Yet, the rapid degradation of perovskites, being mixed electronic-ionic conductors, under high electric fields presents a significant obstacle to the advancement of perovskite-based X-ray detectors.
In response to this challenge, we devised an innovative strategy that harnesses the photovoltaic mode of operation at zero-voltage bias. This approach employs thick and uniform methylammonium lead iodide ($MAPbI_3$) single-crystal films, with thicknesses extending up to 300 µm, solution-grown directly onto hole-transporting electrodes via the space-confined inverse temperature crystallization (ITC) technique.
Our results reveal that this approach engenders both near-optimal and long-term stable performance in perovskite X-ray detectors. We achieved an impressive detection efficiency of 88% and a noise equivalent dose of 90 pGy_{air} (below the dose of a single incident photon) with 18 keV X-rays, thereby enabling single-photon counting as well as low-dose and energy-resolved X-ray imaging. Furthermore, we fabricated array detectors that showcased high spatial resolution, reaching up to 11 lp mm^{-1}..
Our study evidences that hybrid perovskites are viable materials for developing cost-effective commercial detector arrays for X-ray imaging technologies. The operational stability of the device matches the intrinsic chemical shelf lifetime of MAPbI3, registering at least one year in the investigated case. Furthermore, our results indicate that perovskite X-ray detectors can approach ideal detection performance and are amenable to medical diagnostic applications, where the radiation dose can be potentially minimized to its fundamentally lowest limit, as dictated by Poisson photon statistics.
In conclusion, this research unveils a pioneering approach to constructing a near-ideal X-ray detector utilizing hybrid metal halide perovskites, overcoming the significant issue of rapid degradation under high electric fields, thereby displaying promise for commercial application in medical diagnostics. By highlighting the direct growth of the single crystal on pixelated substrate, the study paves the way for the commercial implementation of perovskite-based array detectors. This development could bring about a new era in the field of medical imaging, with low-cost, low-dose, and high-resolution imaging becoming widely accessible.

Interface-Driven Stability for Halide Perovskite Photovoltaics—A Fundamental Understanding ZonglongZhu; City University of Hong Kong, Hong Kong

Organic-inorganic hybrid perovskite solar cells (PSCs) have shown great progress over the past decade, with power conversion efficiencies (PCEs) of single-junction devices approaching silicon photovoltaics (PVs). However, their long-term stability still lags behind silicon-based competitors, which has significantly decelerated their commercialization progress. Faced with this challenge, major efforts have been made to unravel instability mechanisms, develop long-term performance-tracking protocols, and explore various approaches for enhancing the stability of PSCs. Among these strategies, interface manipulation is the most critical as it could simultaneously passivate or anchor the perovskite surface defects and acts as a barrier to protect the bulk of perovskite from the external environment. Recently, the development of diversified interface modification molecules and interfacial regulation strategies has greatly contributed to the improvement of PSC stability. This presentation will elucidate the factors influencing the stability of PSCs, provide an in-depth understanding of device degradation mechanisms, and present advanced approaches to reveal them. Additionally, we will discuss pressing topics on interface manipulation, including low-dimensional perovskite capping layers, interface modification and reaction, and charge transport layer design. Lastly, we will provide insights into the core aspects related to the future development of PSC stability.

Design Strategies for Efficient, Stable and Commercially Viable Inverted Perovskite Solar Cells YiHou[1,2]; [1]National University of Singapore, Singapore; [2]Solar Energy Research Institute of Singapore, Singapore

Inverted perovskite solar cells (PSCs) have immense potential as a standalone technology or as a complement to silicon in tandem configurations. Nonetheless, the primary barriers impeding the commercialization of state-of-the-art inverted PSCs are still the interface recombination losses and degradation. Through the development of novel interface materials and innovative device design concepts, we demonstrate the first instance of inverted structured perovskite solar cells surpassing conventional structured perovskite solar cells in terms of performance, specifically in an active area of 1 cm^2. These findings have been validated and certified by the NPVM, with the inverted PSCs achieving a certified steady-state efficiency of 24.8% for an area of 0.05 cm^2, and a record-breaking certified steady-state efficiency of 24.0% for an area of 1 cm^2. Furthermore, these inverted PSCs exhibit stable performance under maximum power point tracking. In this presentation, I will provide insights into the rationale behind inverted perovskite design, elucidate how thin-film-based perovskites approach the Shockley-Queisser limit, and unveil the potential of this technology in both single-junction and tandem devices.

9:45 AM EN05.05.06
Approaches to High-Efficiency III-V/Si and Perovskite/Si Tandem Solar Cells MasafumiYamaguchi[1], TatsuyaTakamoto[2], KyotaroNakamura[1], RyoOzaki[1], NobuakiKojima[1] and YoshioOhshita[1]; [1]Toyota Technological Institute, Japan; [2]Sharp Corporation, Japan

PV-powered vehicle applications are very attractive for reducing CO_2 emission and creation of new market [1]. Development of high-efficiency (> 30%) and low-cost solar cell modules is very important. Although Toyota Prius and Nissan eNV 200 demonstration cars installed with Sharp's high-efficiency III-V 3-junction solar cell modules with an efficiency of more than 30% have demonstrated longer driving range of 26 km/day average compared to 16 km/day average for Sono Motors Sion installed with Si back contact solar cell modules with an efficiency of 21.5%, cost reduction of multi-junction (MJ) solar cells is necessary for PV-powered vehicle applications. Development of Si tandem solar cells [2] such as III-V/Si and perovskite/Si tandem solar cells is very promising for cost reduction.
This paper presents our results for III-V/Si 3-junction tandem solar cells and modules, and analytical results for efficiency potential of various Si tandem solar cells including perovskite/Si tandem solar cells.
Previously, the authors have demonstrated 34.1% efficiency with 23 cm^2 area 4-terminal InGaP/GaAs/Si 3-junction solar cell by using Si heterojunction solar cell with an efficiency of 24.9% as a bottom cell. Most recently, the authors have achieved a new record efficiency (33.7%) with 4-terminal InGaP/GaAs/Si 3-junction solar cell module with an area of 775 cm^2.
Si 3-junction tandem solar cell modules with an efficiency of more than 35% are shown to have driving distance potential of more than 30 km/day average and more than 50 km/day on a clear day. Toward 35% efficiency Si tandem solar cell modules, efficiency potential of various Si tandem solar cells was analyzed by using external radiative efficiency (ERE) [3,4]. The authors have defined bandgap energy Eg dependence of $\triangle$Voc,rad (= Eg/q – Voc,rad) for radiative open-circuit voltage Voc,rad relative to Eg/q as $\triangle$Voc,rad [V] = 0.1708 + 0.0671 Eg [eV].
The efficiency of Si tandem solar cells in radiative limit was calculated by assuming ERE of 100%, optical loss of 2% and resistance loss of 2%. High efficiency of 43.2% and 47.9% is expected with 2-junction solar cell and 3-junction solar cells. Practically feasible efficiencies estimated by assuming ERE of 10%, optical loss of 2% and resistance loss of 2% are 40.8% for 2-junction Si tandem solar cells and 45.4% for 3-junction Si tandem solar cells. Because optimum bandgap energy combination [5] of Si tandem solar cells is 1.73 eV/Si (1.11 eV) and 2.01 eV/1.50 eV/Si (1.11 eV), optimization of bandgap energy for perovskite/Si tandem solar cells is necessary. Because 3-junction tandem solar cells have higher potential efficiency by 4-5% compared to 2-junction tandem solar cells, development of high-efficiency perovskite based 3-junction solar cells is suggested to be very attractive. Several loses such as non-radiative recombination, optical and resistance losses in Si tandem solar cells are discussed in this paper.

Engineering Ligand Reactivity Enables High-Temperature Operation of Stable Perovskite Solar Cells So MinPark[1,2], MingyangWei[3], JianXu[2], KennethR. Graham[4], MichaelGraetzel[3] and EdwardSargent[1,2]; [1]Northwestern University, United States; [2]University of Toronto, Canada; [3]EPFL, Switzerland; [4]University of Kentucky, United States

Perovskite solar cells consisting of interfacial two-dimensional/three-dimensional heterostructures that incorporate ammonium ligand intercalation have enabled rapid progress toward the goal of uniting performance with stability. However, as the field continues to seek ever-higher durability, additional tools that avoid progressive ligand intercalation are needed to minimize degradation at high temperatures. We use ammonium ligands that are nonreactive with the bulk of perovskites and investigate libraries varying ligand molecular structure systematically. We find that fluorinated aniliniums offer interfacial passivation and simultaneously minimize reactivity with perovskites. Using this approach, we report a certified quasi-steady-state power-conversion efficiency of 24.09% for inverted-structure PSCs. In an encapsulated device operating at 85 degrees Celsius and 50% relative humidity, we document a 1560-hour T85 at maximum power point under 1-sun illumination.

Achieving Over 3000 Hours of Stability in Perovskite Solar Cells Through Nickel Oxide Treatment and Balanced Charge Extraction ZahraLoghman Nia, ArtemMusiienko and AntonioAbate; Helmholtz-Zentrum Berlin, Germany

Perovskite solar cells currently face challenges in terms of stability within their existing architecture. The commonly used hole transfer materials in inverted perovskite solar cells typically consist of organic compounds such as PTAA and SAM [1]. In our research, we have developed a new treatment procedure for NiO, a promising inorganic hole transfer material, which significantly improves the stability of perovskite solar cells. Our findings demonstrate the exceptional long-term ageing performance of doped NiO (Li, Mg) with an insignificant loss of less than one percent over a period of 3000 hours.
To investigate the underlying factors responsible for the observed stability enhancement, we conducted a comprehensive analysis employing various measurements, including Kelvin Probe (KP), Ultraviolet Photoelectron Spectroscopy (UPS), Atomic Force Microscopy (AFM), Time-Resolved Surface Photovoltage (TRSPV), and Time-Resolved Photoluminescence (TRPL). Through our study, we have successfully demonstrated that our new treatment method for NiO facilitates improved hole extraction and mitigates the accumulation of free charges within perovskite solar cells. The boosted stability is primarily attributed to the optimized properties of NiO as a result of our treatment procedure.
In conclusion, our research presents a significant advancement in the field of perovskite solar cells by introducing a novel treatment method for nickel oxide. The achieved stability enhancement through this method offers promising prospects for the commercial viability of perovskite solar cells.

Melting and Glass Formation in Hybrid Metal Halide Perovskites DavidB. Mitzi; Duke University, United States

Crystalline metal halide perovskites have generated intense recent interest, due to outstanding and versatile semiconducting character and associated prospective device applications. So-called two-dimensional (2D) perovskites offer the widest range of tunability within this family, due in part to the essentially unlimited range of prospective organic cations that can be employed. While most work targeting tunability in these systems has focused on optoelectronic properties, another interesting research direction relates to thermal properties—e.g., particularly as they relate to melting and ordering. Ability to melt hybrid perovskites provides an alternative solvent-free approach for film deposition, as well as offering pathways for controlling grain nucleation/growth. While hybrid perovskites are often susceptible to decomposition at temperatures below the prospective melting transitions, over the years we and others have shown that, through tailoring metal/halogen and molecular interactions within the hybrid, the melting temperature can be reduced over a >100 °C range for Ge-, Sn- and Pb-based 2D perovskites (e.g., see refs.[1-3]) thereby enabling the formation of relatively stable hybrid melts. Most of these melts crystallize rapidly upon cooling; however, appropriate selection of organic cation component can favor a glassy state during cooling.[3,4] Demonstration of a reversible transition between the glass and crystalline states, each with distinct physical properties, opens new opportunities for application, and points to a new direction of fundamental study related to understanding and broadening the range of local structure, crystallization kinetics, and properties exhibited by the hybrid glass state.

11:30 AM EN05.05.10
Degradation Mechanisms in Triple-Cation Perovskite and Protection by a 2D Capping Layer IsaacMetcalf and WenbinLi; Rice University, United States

We have used in-situ Wide-Angle X-Ray Scattering to investigate the degradation mechanism of unencapsulated mixed-cation, mixed-anion ($Cs_{0.05}MA_{0.16}FA_{0.79}$)Pb($I_{0.83}Br_{0.17}$) halide perovskite films under various external stimuli (light/humidity/temperature), with and without a capping layer of 2D perovskite. Under combined light and humidity, the perovskite film segregates into nonperovskite phases of $FAPbI_3$, $CsPbI_3$, and $MAPbI_3$●H2O. This process appears to consume PbI_2, which itself is a degradation product that appears before phase segregation. Temperature accelerates this degradation process but the mechanism is the same for temperatures below 100ºC. Under dark humid conditions we see no formation of nonperovskite phases and PbI_2 persists as the only degradation product, suggesting that light activates the phase segregation. Moreover, no degradation was seen in samples exposed to light and humid N_2, suggesting that the degradation process is also oxygen-catalyzed. We further performed degradation tests on 2D Ruddlesden-Popper perovskites with a butylammonium (BA) A'-site cation. Under humid conditions these 2D perovskites degrade into BA and MA hydrate phases. When the humidity is reduced the 2D partially recovers, forming the same or lower n-value films. With capping by BA-based 2D perovskite, the degradation of mixed-cation, mixed-anion 3D under light and humidity is suppressed but the same degradation products form. Under combined light and humidity the 2D and 2D hydrate diffraction signals disappear over time but 2D continues to have a protective effect on the 3D, suggesting that it intercalates into the 3D layer.

11:45 AM EN05.05.11
Defect Passivation and Gradual Energy Band Modulation for Efficient and Stable Perovskite Solar Cells Soo-KwanKim[1], JinseckKim[2], BumjoonJ. Kim[2] and JongminChoi[1]; [1]Department of Energy Science and Engineering, Daegu Gyeongbuk Institute of Science and Technology (DGIST), Korea (the Republic of); [2]Department of Chemical and Biomolecular Engineering, Korea Advanced Institute of Science and Technology (KAIST), Korea (the Republic of)

Passivation engineering is crucial for achieving high power conversion efficiency (PCE) and long-term stability in perovskite solar cells (PSCs). A promising strategy involves introducing passivation polymers to the grain boundaries (GBs) of perovskite film, where defects are densely formed during the film growth. These defects trigger non-radiative recombination, negatively impacting the performance of PSCs. Additionally, they serve as pathways for oxygen, humidity, and lithium ions, further degrading the perovskite active layer. As such, defect restoration is necessary for stability and humidity resistance. The principle of Lewis adduct formation offers a simple and effective method for passivation. The primary component of perovskite defects, the uncoordinated lead ion (Pb^{2+}), is known to be a Lewis acid. The polymer's Lewis base can neutralize these Lewis acids, forming Lewis adducts. Consequently, the polymer can physically cover and neutralize defects, leading to high photovoltaic factors and long-term stability.
However, traditional polymer-based approaches for GB passivation can face limitations, such as increased series resistance and insufficient passivation coverage. To date, no solution has simultaneously addressed these issues. High polymer concentration can cover the entire perovskite surface, leading to high series resistance. In contrast, a lower concentration mitigates series resistance yet results in uneven passivation coverage. The GBs are locally exposed at the interface, leading to open-circuit voltage loss (V_{oc}) through non-radiative recombination.
In this study, we introduce a novel multifunctional polymer to passivate perovskite solar cells, addressing the aforementioned limitations. Our polymer was successfully introduced into both the perovskite film and the hole transport layer (HTL), facilitating comprehensive passivation of defect sites within the active perovskite layer. Moreover, this strategy offered several benefits for perovskite devices. Firstly, there was a significant reduction in the band offset between the perovskite active layer and the hole transport layer (HTL). Secondly, our polymer was found to mitigate lithium-ion diffusion from the HTL to the perovskite, substantially reducing hysteresis and enhancing the stability of PSCs. Lastly, the integration of our passivation strategies resulted in the suppression of pinhole formation at the HTL and reduced the surface energy difference between the perovskite films and the HTL interface. This set of improvements suppressed void formation between interfaces, thus enhancing charge extraction and reducing charge recombination losses.
Consequently, the PSCs integrated with our polymer exhibited a remarkable increase in power conversion efficiency (PCE), reaching up to 24.0%, compared to the control devices (21.0%). Furthermore, our integrated PSCs retained 92% of their initial PCE after 2000 h of storage under ambient conditions. Under damp-heat conditions (85 °C and 85% relative humidity), the cell preserved 80% of their initial PCE after 432 hours.

SESSION EN05.06: Halide Perovskites Photovoltaics and Stability II

WITHDRAWN 11/8/2023 EN05.06.01 Stable n-i-p Perovskite Solar Cells Enabled by a New Spiro-OMeTAD Doping Strategy FengGao; Linkoping University, Sweden

Record efficiencies of perovskite solar cells (PSCs) are usually obtained in the n-i-p structure with spiro-OMeTAD as the hole transport layer. Spiro-OMeTAD is conventionally doped by hygroscopic lithium salts with the assistance of volatile 4-tert-butylpyridine, which, however, brings a time-consuming doping process as well as poor device stability. We successfully develop an instantly efficient and clean doping strategy to replace the conventional spiro-OMeTAD doping. As demonstrated by experimental and theoretical investigations, the radical dopant leads to significant increase of the conductivity through efficient hole polarons generation. The ionic salts can further modulate the work function with negligible effects on the film conductivity, critical for reaching optimal open-circuit voltage values by a favorable energetic level alignment. Spiro-OMeTAD based on our new doping strategy enables PSCs with a high power conversion efficiency over 25% and an excellent stability against moisture, heat and illumination. Our findings pave the way for achieving PSCs with high efficiencies and excellent stability at the same time. In addition, our doping strategy goes beyond traditional organic semiconductor doping, providing new understanding of organic doping mechanisms which can inspire further optimizations of different optoelectronic devices.

2:00 PM EN05.06.02
Additive Engineering for Thermally Stable Perovskites XiwenGong; University of Michigan, United States

Organic-inorganic perovskites offer exceptional optoelectronic properties but suffer from poor thermal stability, hampering their practical application in photovoltaics. I will discuss a systematic investigation of the impact of the molecular structure of base additives on the thermal stability of perovskite. By synthesizing additives with controllable coordination numbers, molecular weights, and steric hindrance, we systematically study the impact of these molecular properties on the morphological, optoelectronic properties, and thermal stability of perovskite films. This study provides rational molecular design strategies for additive engineering in perovskites, enabling efficient defect passivation and enhanced thermal stability.

2:15 PM EN05.06.03
Low-Dimensional Perovskite Materials for Efficient and Stable Light-Emitting Diodes WallaceC. Choy; University of Hong Kong, China

Low-dimensional halide perovskite emitters with the advantages of quantum confinement effects have emerged as a novel class of revolutionary semiconductors with high color purity, wide color gamut, low cost, and a simple solution process for vivid natural color yet cost-effective displays. However, perovskite materials commonly exhibit environmental instability due to humidity, light, and/or elevated temperature significantly hindering their applications in light-emitting diodes (LEDs) where reported lifetimes are commonly in the order of minutes. In this talk, we will discuss some of our recent work on perovskite LEDs. Regarding quasi-2D perovskites, limited attention has been paid to rational design to balance the carrier confinement and transfer in quasi-2D perovskites, which is essential to achieve high-performance PeLEDs. By using blue PeLEDs as an example, we will enhance the hole injection for better balance carrier and improve the efficiency [1], we also modulate the n-phase distribution [2,3] and optimize the carrier transfer and confinement to improve the performances of PeLEDs [4]. For perovskite nanocrystals (NCs), we will introduce new ligands to synthesize red color perovskite ($CsPbI_3$) NCs. The ligand can significantly stabilize the $CsPbI_3$ NCs without any crystalline deformation on the NC crystal structure. Additionally, these chemically crosslinked PMAs also significantly reduce Pb_{Cs} deep defects. Moreover, $CsPbI_3$ NCs exhibit increasing exciton binding energy and reduced longitudinal-optical (LO) phonon energy [5,6]. Recently, by designing the multifunctional-group ligands for ion migration suppression and carrier transportation enhancement, we further improved the efficiency and stability of the pure red and pure green perovskite LEDs meeting the standard of Rec. 2100 for promoting their display applications.

Scalable Interfaces Passivation for Perovskite Solar Cells DavidS. Ginger; University of Washington, United States

Halide perovskite semiconductors are being explored for applications including solar photovoltaics (PV), light emitting diodes (LEDs), radiation detectors, and even sources of quantum light. While perovskite semiconductors are often described as remarkably defect tolerant, they are not defect free. As these materials race towards commercialization, it is important to understand how different processing methods lead to semiconductor films with different levels of efficiency and stability. In this talk I will discuss defects and heterogeneity, and our ability to control them at perovskite interfaces from the molecular to macroscopic scale. We show how processing additives can undergo unexpected chemical reactions that alter the growth processes in perovskite films, leading to improved uniformity with processing over large areas, and how interfacial layers can improve overall photovoltaic performance, as well as stability under reversed bias conditions.

Making High-Efficiency Halide-Perovskite Solar Photovoltaics More Durable: Challenges and Opportunities NitinP. Padture; Brown University, United States

The unproven durability of perovskite photovoltaics (PVs) is likely to pose a significant technical hurdle in the path towards the widespread deployment of this burgeoning thin-film PV technology. The overall durability of perovskite PVs, which includes operational stability, is directly affected by the mechanical reliability of metal-halide perovskite materials, cells, and modules, but this issue has been largely overlooked. Thus, there is a sense of urgency for addressing the mechanical reliability issue comprehensively, and help perovskite PVs reach their full potential. This presents many challenges, but it also offers vast research opportunities for making meaningful progress towards more durable perovskite PVs. Here I will highlight the important challenges and opportunities, together with best practices, pertaining to the three key interrelated elements that determine the mechanical reliability of perovskite PVs: (i) driving stresses, (ii) mechanical properties, and (iii) mechanical failure. I will also present examples of approaches to mitigate failure and extend the durability of perovskite PVs.

4:00 PM EN05.06.06
Efficient All-Perovskite Tandems Enabled by Surface Anchoring of Bifunctional Long-Chain Amphiphilic Ligands AidanMaxwell and HaoChen; University of Toronto, Canada

Perovskite solar cells (PSCs) in the stability-enhancing pin structure are limited by nonradiative recombination at the materials interface with the electron transport layer (ETL). This recombination is particularly acute in narrow-bandgap (~ 1.2 eV) mixed Pb-Sn PSCs, a crucial active layer in emergent all-perovskite tandem solar cells: these suffer higher V_{OC} deficits than do their Pb-based counterparts due to Sn-related surface oxidation and consequent detrimental p-doping. Our photoluminescence quantum yield studies herein indicated that state-of-the-art ethane-1,2-diammonium (EDA) passivation only partially alleviates harmful perovskite/ETL quasi fermi level splitting losses. We pursued physical separation at the defect-rich perovskite:ETL interface to reduce non-radiative losses: our target was to unite chemical surface coordination of Sn sites with physical interlayer separation, an approach we implemented by introducing amphiphilic long-chain carboxylic acid ligands at the perovskite surface. Treatment with oleic acid (OA), a long-chain carboxylic acid, led to carrier dynamics and surface chemistry indicative of reduced carrier recombination at the perovskite/ETL interface, and evidence of coordination with surface Sn^{2+}. The addition of OA reduces the V_{OC} deficit to 0.34 V, resulting in a 0.89 V V_{OC} and PCE of 23.0% (22.4% stabilized) for 1.23 eV Pb-Sn PSCs. Incorporating the OA-treated Pb-Sn layer into a monolithic all-perovskite tandem, we report 27.3% PCE (26.4% certified) having a record V_{OC} of 2.21 V.

Unraveling Perovskite Metal Shunting in Reverse Bias: Insights for Enhanced Module Design IsaacGould, DanielMorales and MichaelMcGehee; CU Boulder, United States

In a photovoltaic module under partial shading conditions, shaded subcells may experience reverse bias. For perovskite solar cells reverse bias often rapidly leads to degradation. One of the most common forms of degradation is shunting which is linked to metal migration.Our findings suggest that the metallic anodic interface's oxidation leads to the formation of mobile metallic cations. These metal ions migrate across the device under the reverse bias field, and electroplate on the opposite electrode, forming metal filament type shunts. Time-of-flight secondary ion mass spectroscopy confirms the infiltration of metal into the perovskite layer during reverse bias operation. Relating the shunt resistance to the radius of the shunt leads to a calculation of 10-35 nm. High current density through these nanosized filaments generates significant localized heating, causing substantial damage to the adjacent perovskite material. To mitigate this issue, we advocate for using ion barriers, like atomic layer deposited tin oxide, between the perovskite layer and the metal electrode. Notably, cells with the NIP orientation do not exhibit this shunting phenomenon, suggesting that halide-induced oxidation of the metallic electrode occurs exclusively when it serves as the anodic electrode during reverse bias operation.

The understanding of metal migration and shunting mechanisms in perovskite solar cells is invaluable for improving solar module design and optimization. Once shunting is stopped reverser bias breakdowns can range from -3V to -15V. High breakdown opens the possibility of bypass diode implementation, although resistance losses from the transparent conducting oxides must be managed. With a low voltage breakdown (-3V), self-bypassing is possible, as the resultant temperature increase is a modest 5°C, assuming uniform heating. This can still be problematic as reverse bias breakdown can lead to redox of halide species and other electrochemical degradations to proceed.The trade-offs in perovskite solar module design necessitate crucial decisions that can affect the module's efficiency, cost, and reliability. A thorough understanding of perovskite chemistry, the implications of shunting, and the role of different interlayers in the module is essential to guide these decisions towards optimal solar module design and performance.

Investigation of The Influence of The Voids Formed During The Operation of The Device on The Thermal and Light Stability of Perovskite Solar Cells MengruWang; University of North Carolina at Chapel Hill, United States

The formation of voids in the perovskite films close to the embedded bottom interface has been reported to form during film deposition and limit the efficiency and stability of perovskite solar cells. Here we studied the voids formed during the long-term operation or thermal stress for a typical perovskite made by solution process, even if the initial perovskite films are already optimized to avoid voids during film deposition. These voids preferred to assemble along grain boundaries at the bottom interface. Detailed studies show that the voids originated from the shrinking of perovskites caused by the leaving of residual dimethyl sulfoxide (DMSO) and the conversion of the amorphous phase to the crystalline phase as a result of solid-state ion diffusion. Surprisingly, we found the formation of these voids did not notably impact the solar cell thermal stability. After decreasing the amorphous region in perovskites by thermal annealing, the light stability of perovskite solar cells was actually improved despite of the creation of voids by thermal annealing. The annealed devices maintained 90% of their initial efficiencies after annealing and light soaking for 1900 hours at open circuit conditions under one-sun light at 50 °C. The positive iodide interstitial density in the perovskite films was actually reduced during post-annealing despite the generation of three-dimensional voids, which further confirms that removing the amorphous region is an effective method to enhance the operational stability of perovskite solar cells.

Photonic Processing for Perovskite Halide Thin-Film Defect-Tolerant Crystal Growth SandySanchez; Ecole Polytechnique Federale de Lausanne, Switzerland

Metal halide perovskite solar cells have achieved record efficiencies of over 25%, comparable to mainstream silicon solar cells. However, the processing method and operational stability need further development to bring this technology to commercialization. In this context, we use a flash-infrared annealing method, which is environmentally friendly and rapid processing, without the use of toxic chlorobenzene, to process highly stable perovskite solar cells. Therefore, this work reveals the phase stabilization mechanism for perovskite halide films through thermodynamic, structural, and photophysical analysis related to process parameters optimization.[1] Measuring the enthalpy changes of the FAPbI3 composition at different heating rates

allows us to calculate an activation energy of 1.8 eV for the black perovskite phase transition. We explore different heating regimes for triggering the phase transformation and analyze the evolution of the microstructure with an empirical calculation of the average crystal growth velocity required to form a compact film on the micron and submicron scales. A critical interplay between perovskite halide thin-film crystallization phenomena and manufacturing aspects will be addressed, using oxidizing agents to achieve outstanding device stability of more than 1500 h under an MPPT scan.[2]

Bandgap Bowing in Inorganic Lead-free Perovskite-Inspired Materials FangSheng, EuniceAissi, AlexanderE. Siemenn, BasitaDas, HamideKavak and TonioBuonassisi; Massachusetts Institute of Technology, United States

The recent success of lead-halide perovskites has inspired the search for similar materials, with potential advantages of greater stability and absence of lead. Some of these materials form alloy series that exhibit a property known as “bandgap bowing”, whereby a mixed alloy AB has a lower bandgap than either phase-pure A or B, for example $Cs_3(Bi_{1-x}Sb_x)_2(I_{1-x}Br_x)_9$ reported in Ref. [1].

Bandgap bowing can be expensive and challenging to predict by first-principles simulations, motivating the application of high-throughput methods to experimentally synthesize alloy series and quickly measure them. As a benchmark, we consider spin coating and UV-Vis, which requires approximately 15 minutes per sample for synthesis and annealing, and 30 minutes for characterization.

In this work, we employ a high-throughput workflow that combines direct multi-material printing of alloy series with an automated computer-vision-based bandgap extraction, to experimentally screen for bandgap bowing in a broader materials space of ABX_3 and $A_3B_2X_9$ alloys. The high-throughput synthesis is conducted by our direct multi-material printer, Archerfish, which has the capability to print and anneal 1000 unique alloy materials in 15 minutes. Bandgaps for each of the 1000 alloys are measured using a hyperspectral camera operating in reflectance mode, in 2 minutes. Finally, bandgaps are autonomously extracted using an algorithm in 30 minutes, with potential to accelerate using more powerful computation. We report bandgap bowing effects in $Cs_3(Bi_xSb_{1-x})_2I_9$ and compare with density functional theory calculations. We then screen broader range of elements including Ge, Ga, and Sn on B sites and Cl^-, Br^- on X sites.

8:00 PM EN05.07.02

Static and Dynamic Disorder in Formamidinium Lead Bromide Single Crystals GuyReuveni[1], YaelDiskin-Posner[1], ChristianGehrmann[2], ShravanGodse[2], GiannisG. Gkikas[3], IsaacBuchine[4], SigalitAharon[1], RomanKorobko[1], ConstantinosC. Stoumpos[3], DavidA. Egger[2] and OmerYaffe[1]; [1]Weizmann Institute of Science, Israel; [2]Technische Universität München, Germany; [3]University of Crete, Greece; [4]Bar-Ilan University, Israel

The distinction between the average and the local structure has crucial importance in crystalline materials where the two are not overlapping. In this work, we show that formamidinium-based are distinct from methylammonium-based halide perovskite crystals because their inorganic sub-lattice exhibits intrinsic local static disorder that co-exists with a well-defined average crystal structure. This combination of order and disorder makes formamidinium-based halide perovskites interesting. Our study combines terahertz−range Raman scattering with single-crystal X-ray diffraction and first-principles calculations to probe the evolution of inorganic sublattice dynamics with temperature in the range of 10–300 K. In my talk, I will present results from probes of different scales of the crystalline structure - local and average. I will show how temperature affects the interplay between the two expressions of disorder in these materials - static and dynamic disorder. Our results potentially have significant implications for the optoelectronic and thermal stability properties of FA-based lead halide perovskites.

Effect of Grain Boundaries on the Mechanical Properties of Organic-Inorganic Halide Perovskite Polycrystalline Thin Films and Bulk Crystals MadhujaLayek, MeaghanDoyle, AnushRanka, ZhenghongDai, InseokYang and NitinP. Padture; Brown University, United States

The past several years have observed a growing interest in hybrid organic-inorganic perovskites (HOIPs) owing to their remarkable application potential in optoelectronics, especially photovoltaics. In order to manufacture efficient and reliable perovskite solar cells (PSCs) that can operate satisfactorily for decades, it is critical to study the mechanical properties of MHPs that are inherently compliant, soft, and brittle. Thus, we have employed multi-beam optical stress sensor (MOSS) curvature measurement and X-ray diffraction (XRD) techniques to estimate Young's modulus of polycrystalline methylammonium lead iodide ($MAPbI_3$) thin film. Furthermore, we synthesized and sintered HOIP powders into bulk crystals to understand the effect of grain size on Young's modulus and other relevant mechanical properties of HOIPs. We aim to provide an in-depth understanding of the mechanical properties of HOIPs to effectively use them in PSCs.

Synthesis of Bismuth Based-Perovskite Nanocrystals for CO2 Reduction AntikGhosh[1,2,3], DmitryAldakov[2,1,3] and VincentArtero[1,2,3]; [1]Commissariat à L’énergie Atomique et Aux Energies Alternatives, France; [2]Centre National de la Recherche Scientifique, France; [3]Université Grenoble Alpes, France

Abstract: Solar driven CO_2 valorization into hydrocarbon fuels using semiconductor catalysts offers a promising energy conversion pathway to have impactful solutions to environmental degradation and energy crisis problems. The solar light not being sufficient enough to break the high energy C=O bond in CO_2, an external photosensitizer (PS) coupled to a co-catalyst is used in this process. The PSs used presently are often hard to synthesize, they are toxic and have limited stability and light absorption capacity. Colloidal semiconductor nanocrystals (NCs) can have strong light absorption and stability; in addition, their properties can be easily optimized by the size/or composition control. We propose to use halide perovskite NCs as PSs for the CO_2 reduction. Halide perovskite nanocrystals (NCs) have been widely considered as promising materials as light-harvester emitters due to their wide range of benefits combining those of conventional colloidal semiconductor NCs including tunable bandgap, high absorption coefficients, strong photoluminescence, flexible crystal structure and low fabrication cost due to the processability from solution. Recently, perovskite NCs were successfully used for the photocatalytic CO_2 reduction, however most of them are still based on toxic lead and have limited stability in polar medium used in photocatalysis[1]. Among lead free alternatives, one of the most promising is bismuth halide perovskite $A_3Bi_2X_9$ (A=cation; X=Br, I) NCs combining good absorption in the visible range, higher stability, and much lower toxicity compared to the lead-based counterparts[2]. They can be synthesized using Hot-injection or Ligand assisted reprecipitation (LARP), however numerous challenges still exist, namely to synthesize the NCs with a small controlled size, to properly purify them, and to accurately study their crystalline structure and optical properties.

We have developed a new approach to synthesize air-stable bismuth halide perovskite NCs in ambient conditions with a high reaction rate using cesium halide NCs as the templates[3]. By optimizing synthesis protocols, we managed to obtain air-stable $Cs_3Bi_2Br_9$ and $Cs_3Bi_2I_9$ NCs of around 10 nm with a good size dispersion. In addition, by a modified hot-injection method using various ligands we have synthesized $Cs_3Bi_2I_9$ nanoplatelets under ambient condition. Synthesis details, structural and optoelectronic properties will be discussed, as well as their perspectives for the photoelectrocatalytic CO_2 reduction application.

Experimental Characterization of Metal Oxide Thin Films and Their Numerical Simulation as a Hole Transport Material in Inverted Perovskite Solar Cells FernandoT. da Rocha Arita and AndreSantarosa Ferlauto; UFABC - Federal University of ABC, Brazil

The rapid populational and technological growth in the last decades has required larger material production and, consequently, more demanding power usage. The long-term scarcity and the price volatility of fossil fuels are not the only problems associated with a non-renewable-based electric power matrix. Climate Change can already be perceived locally and globally and, if not reduced, will become an existential threat to life on Earth. Among the many ways to reduce the effects of climate change, the electrification of the power matrix associated with cleaner and more efficient means of power obtainment, such as solar power, is crucial. Hybrid perovskite-based solar cells have been widely studied throughout the last decade due to the rapid progress in conversion efficiency in the last few years. State-of-the-art devices have achieved efficiencies above 25%, close to the efficiencies of commercial devices. The current hindrance to the large-scale production of this kind of solar cell is its stability facing degradation processes to adjacent layers and external factors, mainly humidity. P-type metal oxide semiconductors are promising candidates as a hole transport material in inverted perovskite solar cells, due to their enhanced optoelectronic properties: improved hole mobility, suitable bandgaps and high transparency, and fitting energy levels with the active layer [1]. These materials also act as humidity barriers and their chemical stability mitigates some degradation processes [2]. The present study involves the experimental characterization of sputtered thin films that feeds the materials' optoelectronic properties into a numerical simulation of inverted perovskite solar cells using SCAPS (Solar Cell Capacitance Simulator). Reactive sputtering provides more precise control of thin film stoichiometry and can be used to determine an adequate composition that leads to the maximization of the device's efficiency. Numerical simulations can help to screen through materials providing cost reduction and time optimization, although it does not predict how well these materials would perform in a stability test. Copper aluminate delafossite and copper oxide thin films have been deposited using reactive RF-sputtering and characterized by X-ray diffraction, Raman Spectroscopy, X-ray Photoelectron Spectroscopy, Four-probe Resistivity measurement, and UV-Vis Spectroscopy. Scanning Electron Microscopy, Contact Angle measurements, and Ellipsometry were also performed to study the deposition dynamics and the thin film surface.

Lighting the Way Forward: Exploring Structure-Bandgap Relationships in Hybrid Organic-Inorganic Perovskites OmarAllam[1,1], YoonseoNah[2], IlgeumLee[2], Dong HaKim[2] and Seung SoonJang[1]; [1]Georgia Institute of Technology, United States; [2]Ewha Womans University, United States

Hybrid organic-inorganic perovskites (HOIPs) have recently gained significant traction across various applications, largely due to their remarkable electrical and optical properties such as high photoluminescence quantum efficiency and brilliant light emission. In this research, we harness the power of density-functional theory (DFT) to investigate the intricate relationships between structure and bandgap of 2D HOIPs, aiming to achieve precise modulation for diverse optoelectronic applications. The influence of spacer size in the interlayer region of 2D HOIPs, a crucial aspect that remains underexplored, is a primary focus of our study. Leveraging DFT, we uncover a pivotal link between the steric dimensions of the organic spacer components and the bandgap of perovskites. Furthermore, while it is established that the perovskites' bandgap can be tuned by altering the halide mixture, these mixed halide perovskites unfortunately demonstrate spectral instability, an issue that hinders their application in commercial LED technologies. Through the application of the nudged elastic band (NEB) method, our DFT analyses reveal the underlying mechanism behind this spectral instability, tracing it to the migration of mixed halides. By employing DFT, our mechanistic exploration yields crucial insights into the process of bandgap tuning in HOIPs and elucidates the fundamental causes behind the observed spectral instability in devices utilizing mixed halide compositions.

Understanding the Effect of Post-Growth Vacuum Annealing on 2D Hybrid Organic-Inorganic Perovskite Thin Films ManosiRoy[1], JoseCastaneda[2], SharondaLeBlanc[2] and AdrienneD. Stiff-Roberts[1]; [1]Duke University, United States; [2]North Carolina State University, United States

The rapid advancements in power conversion efficiency (PCE) of perovskite active regions, achieving a remarkable 26% in 2023, have positioned them as leading contenders in the development of high-efficiency solar cells. However, the issue of moisture instability in three-dimensional (3D) perovskites poses a significant hurdle for the commercialization of perovskite solar cells.[1] To address this challenge, the use of more environmentally stable, two-dimensional (2D) hybrid organic-inorganic perovskites (HOIPs) as a passivating layer for the 3D perovskite active region shows promise in improving stability.[2] One of the key obstacles in this context is the lack of desired alignment or orientation of the 2D sheets comprising organic and inorganic layers. Traditional solution-based processing methods tend to align these sheets parallel to the substrate, limiting charge transport in the vertical direction. While resonant infrared matrix-assisted pulsed laser evaporation (RIR-MAPLE) yields a random orientation of crystallites and offers a partial remedy to the problem, the ultimate goal is to deliberately promote vertical orientation of the crystallites.[3, 4] Therefore, it is crucial to better understand the RIR-MAPLE synthesis process to influence the orientation of the films, and one possible approach is to conduct post-growth vacuum annealing.[1] Accordingly, phenethylammonium lead halide 2D HOIPs will be grown for comparison using RIR-MAPLE at 50-degree celsius without and with a post-growth vacuum annealing step at three distinct temperatures – 60, 90, and 110-degree celsius. The films will be characterized using a full suite of standard techniques, including X-ray diffraction (XRD) to confirm crystal structure and conduct crystallite size analysis (using the Williamson-Hall method), Stokes shifts (derived from photoluminescence (PL) and UV-Vis spectroscopy), and scanning electron microscopy (SEM) and atomic force microscopy (AFM) to determine surface morphology. In addition, the full-width-half-maximum values for XRD peaks corresponding to different orientations of crystallites will be used to quantify changes in vertical orientation.[4] Overall, this investigation will shed light on the potential of employing post-growth vacuum annealing to promote vertical orientation of crystallites in 2D HOIP thin films deposited using the RIR-MAPLE, paving the way for future explorations in this area.

8:00 PM EN05.07.08

Dimethylammonium-Incorporated Mixed Halide Perovskite Nanocrystals for Stabilized Red Emission ShaoniKar[1,2], BernardWenger[2] and HenrySnaith[1]; [1]University of Oxford, United Kingdom; [2]Helio Display Materials Ltd., United Kingdom

In addition to their stellar performance in photovoltaics, metal halide perovskites have seen a meteoric emergence in several other optoelectronic applications of which light emission is of special significance. Perovskites have been used in light emitting diodes (LEDs), lasing and displays (as colour-converting phosphors) to achieve record efficiencies with immense potential to compete with the commercial standards of III-V and organic LED (OLED) systems within a relatively short time. With high exciton binding energies affording enhanced quantum confinement of carriers, low-dimensional perovskites are especially useful for realizing colour-pure, highly efficient emission. Among such systems, all-inorganic perovskite nanocrystals are attractive candidates owing to easy bandgap tunability through compositional engineering, narrow emission peaks and high photoluminescence quantum yields.

Cesium lead halides of the form $CsPbX_3$ are the most commonly demonstrated workhorse systems in this category with halide tuning determining the emission range. Cesium lead iodide ($CsPbI_3$) nanocrystals have been shown to be promising but their device application is still inhibited by their inherent ambient instability. With facile conversion of the metastable black perovskite γ-phase into the yellow δ-phase at room temperature, this material has hardly been effective under sustained optical or electrical excitation. In addition, this composition shows emission outside the visible range (around near-IR wavelengths) which severely limits their usage in displays and other common applications. With addition of bromine (Br), $CsPbI_xBr_{3-x}$ nanocrystals are formed with ideal bandgaps for application in visible range LEDs and displays with emission wavelengths lying within the Rec 2020 colour gamut. Furthermore, in contrast to the pure-iodide compositions that require high temperature-based (hot injection) processes to form the perovskite phase, mixed-halide nanocrystals afford facile synthesis through ligand assisted reprecipitation (LARP) in ambient conditions due to the possibility of crystallization at much lower temperatures. However, these materials are still plagued by phase separation under optical or electrical excitations of intensities typical in a working device.

In this work, we try to alloy the A-site of the pure-red emitting $CsPbI_2Br$ with dimethylammonium (DMA) to improve its phase stability under excitation while retaining high photoluminescence quantum yields. DMA, among other organic cations, has recently been shown to alloy successfully with Cs in 3D perovskite thin films and lend it stability under operational conditions. However, with lower-dimensional nanocrystals, the nucleation and growth kinetics are radically different and further intricacy is introduced with the remnant (unwashed) ligands that are unavoidable in the synthesis process. To our knowledge, this is the first study of DMA-alloying through facile LARP synthesis techniques. We propose a novel synthetic route at room temperature and then study the crystal structure and morphology as a function of different DMA contents through an interplay of crystallographic and optical data. We

report higher ambient stability even under intense optical excitation. Finally, we employ these materials as the emitter layer in LEDs and find significant improvement in LED performances with notably improved air-stability in the DMA-incorporated variant.

Deterministic Solution-Processed Fabrication of Halide Perovskite Heterostructures FaizMandani, SirajSidhik, AltafPasha, AndrewJ. Torma and AdityaD. Mohite; Rice University, United States

Heterostructures play a crucial role in the semiconductor industry as they offer unique optoelectronic properties. However, the conventional methods used for fabricating heterostructures involve specialized and costly processes such as chemical vapor deposition, epitaxial growth, or e-beam deposition. Halide perovskites have emerged as a promising material for various optoelectronic applications due to their tunable bandgap, high carrier mobility, and solution processability. In recent years, considerable efforts have been made to develop perovskite heterostructures using vapor phase techniques[1]. These techniques aim to enhance photogeneration, fine-tune band alignments, and passivate the underlying semiconductor. In our previous work, we introduced a solution processed technique for depositing selective (Ruddlesden-Popper) two-dimensional perovskite on top of three-dimensional perovskite[2]. We achieved this by leveraging solvent properties such as dielectric constant and Guttman number.
However, the development of a universal solution processed approach for fabricating multilayer perovskite heterostructures has remained a challenge. To address this, we conducted detailed perovskite-solvent interaction studies to gain a deeper understanding of perovskite solvation dynamics. In this study, we present a solvation-based approach to synthesize perovskite seed solutions, enabling the fabrication of 2D/3D, 3D/2D, and even 3D/3D heterostructures. This approach allows us to create an arbitrary number of layers with any perovskite phase while maintaining high optoelectronic quality and scalability. To demonstrate the universality of our approach, we successfully created formamidinium lead iodide (FAPbI3)/Dion-Jacobson 2D (3D/2D) perovskite and methylammonium lead iodide (MAPbI3)/MAPbI3 (3D/3D) heterostructures. We validated the quality and characteristics of these heterostructures through optoelectronic and cross-sectional analyses. The introduction of this universal approach marks a significant milestone in solution processed heterostructures, extending its applicability beyond perovskites to the broader field of semiconductors. This advancement opens up new possibilities for the synthesis of high-quality, scalable heterostructures, revolutionizing the semiconductor industry.

Light-Induced Expansion Kinetics of Lead Halide Perovskite Crystals Measured via Laser Interferometry ChristopherPetroff, Kuan-TingLiu, EmilyE. Hiralal, LaraA. Estroff and JohnA. Marohn; Cornell University, United States

Light-induced changes to lead halide perovskite (LHP) crystals can provide key information about their electrical properties and degradation mechanisms. It is shown in the literature that LHP crystals exhibit light induced expansion, so called “photostriction” [1]. Generally, it is concluded that these—mainly atomic force microscopy (AFM) derived—data are the result of the photoinduced production and diffusion of electrons. We assert that the several second expansion onset and decay shown in the literature and in our data, is inconsistent with the sub-microsecond timescale of electronic diffusion. We instead propose that this expansion is due to the light-induced creation of ionic vacancies [2–4]. The formation of ionic vacancies should exhibit an activated temperature dependence. We are developing a series of variable temperature, laser interferometric measurements of LHP crystals to study these expansion kinetics. Laser interferometry is ideal for this kinetics study, as it offers better temporal resolution than the AFM data in the literature; AFM is limited by the time constants of the phase-locked loop whereas laser interferometry is only limited by the bandwidth of the photodetector.

Using laser interferometric measurements, we show non-thermal, light-induced expansion of methylammonium lead tribromide ($MAPbBr_3$) perovskite crystals, even when excited below band gap. The expansion displays two-rate kinetics and hysteresis with a rapid (10 s) expansion followed by continued slow (10s of seconds) expansion; upon returning to the dark, a rapid contraction is observed which does not reach baseline. We are working to explore this effect and its kinetics across various temperatures; illumination wavelengths; and perovskite crystal compositions, including the all inorganic cesium lead tribromide ($CsPbBr_3$) system.

Long-Lived Spin-Triplet Excitons in Manganese Complexes for Room-Temperature Phosphorescence Mi HeeJung; Sejong University, Korea (the Republic of)

Low dimensional metal halides perovskites have become emerging candidates as applications of light emitting diodes due to the quantum confinement effect by tuning their composition and structure. However, it suffers from longstanding issues of environmental stability and lead toxicity. Herein, we report phosphorescence manganese halides, $(TEM)_2MnBr_4$ (TEM = $HN(CH_2CH_3)_3$, triethylammonium) and $(IM)_6[MnBr_4][MnBr_6]$ (IM = $C_3H_6N_2$, imidazolium) with photoluminescence quantum yield (PLQY) of 50% and 7%, respectively. $(TEM)_2MnBr_4$ with a tetrahedral configuration exhibits brilliant green light emission centered at 528 nm, while $(IM)_6[MnBr_4][MnBr_6]$ compound, in which octahedral and tetrahedral units coexist, exhibits red colored emission at 615 nm. The excite state of $(TEM)_2MnBr_4$ and $(IM)_6[MnBr_4][MnBr_6]$ found to exhibit distinct photophysical emission characteristics consistent with triplet state phosphorescence. Efficient phosphorescence was achieved with a long lifetime of several milliseconds, 0.38 ms for $(TEM)_2MnBr_4$ and 5.54 ms for $(IM)_6[MnBr_4][MnBr_6]$, respectively, at room temperature. By studying the temperature dependent PL and single-crystal X-ray diffraction measurements and compared our results with the previously reported analogs, we have found a direct correlation between Mn×××Mn distances to the PL emission. Our study reveals that the long distance between the Mn centers has made a significant contribution to the long-lived phosphorescence with a highly emissive triplet state.

Magnetic Resonance Spectroscopy as an Investigation Tool for The Structure of Ytterbium-Doped Cesium Lead Chloride Perovskites ThiagoRubio, HannahVan Son, SedaSarp, IverJ. Cleveland and ClaudiaE. Avalos; New York University, United States

In the search for methods to push the power conversion efficiency of photovoltaic (PV) devices beyond the Shockley-Queisser limit, doping halide perovskites with lanthanide ions, such as Yb^{3+}, has shown promising results. This is due to quantum cutting, the conversion of one high energy photon into two (or more) low-energy photons. Quantum cutting materials can then be utilized as a down-converting layer in PV cells, where the wavelength of the incoming photons can be shifted from the UV to the near IR region, and then be used by the photoactive layer for electricity generation [1].
Understanding the doping mechanism and the defect structure in these materials is essential in order for a more effective insertion of the dopant into the host crystal lattice and subsequent higher photoluminescence quantum yields (PLQY) to be obtained. The doping sites can be studied by means of the effects they produce in the other species in the host structure. Many times, the dopant species only produces local effects. Magnetic resonance spectroscopic techniques such as nuclear magnetic resonance (NMR) and electron paramagnetic resonance (EPR) can probe local environments and can provide information about doping that techniques that probe long-range order, i.e. X-ray diffraction, are not able to [2,3,4].
In this project, ytterbium-doped cesium lead chloride (Yb^{3+}:$CsPbCl_3$) perovskite powders were synthesized using dry ball-milling, a method that has been shown to yield high photoluminescence quantum yields due to the emission of Yb^{3+} in the near-infrared region [5]. Solid-state NMR was used to give an insight into how the local environments of the probed nuclei are affected by the insertion of Yb^{3+} to the crystal lattice, and to determine whether the insertion of Yb^{3+} into the crystal lattice was uniform. ^{133}Cs NMR data revealed that longitudinal relaxation times (T_1) for cesium nuclei decrease with increasing amounts of ytterbium added to the composition. Furthermore, the stretching parameter obtained from a stretched exponential fit of the T_1 data collected showed that this decrease is due to a uniform distribution of paramagnetic centers in the structure. ^{207}Pb NMR data showed that the chemical environments of the detectable lead sites is not distorted due to the insertion of Yb^{3+}, this is evidenced by no change in the chemical shift anisotropy fit of the static NMR signal with increased doping. PLQYs above 135% were obtained for all samples.

Stable and Efficient Large Area 4T Si/perovskite Tandem Photovoltaics with Sputtered Transparent Contact AnantaPaul, AbhijitSingha, SakshiKoul, VikasSharma, SudhanshuMallick, K.RBalasubramaniam and DineshKabra; Indian Institute of Technology Bombay, India

With the boost in the thin film-based energy and optoelectronics devices' performance, there is an urgent need to improve and modify one of the essential components of such devices: transparent electrodes. In particular, we need to deposit high-conductive and transparent electrodes to fabricate the next-generation tandem structure while maintaining low sputtering damage. Si-perovskite tandem PV devices in the four-terminal (4T) configuration could solve the problems associated with the stability gap between the component perovskite and Si devices. We report the fabrication of NIR-transparent perovskite solar cells (PSCs) with the stable triple cation perovskite as the photo-absorber and subsequent integration with a Si solar cell in a 4T tandem device. The critical development of the sputtered top transparent conducting electrode (TCE) layer and oxide buffer layer at room temperature leads to reproducible, highly efficient NIR-transparent PSCs of both small area (0.175 cm^2) with PCE of 17.1% and large area (0.805 cm^2) with PCE of 16.0%. Electrically disparate, optically coupled 4T tandem devices of the optimized PSCs with commercial monocrystalline PERC Si solar cells exhibit greater than 26% PCE. In addition to enabling industry-compatible TCE-based low-cost Si/perovskite tandem photovoltaics, this study could also be the gateway for the potential use in niche applications like building integrated photovoltaics.

Photostability of Formamidinium-Based Mixed-Halide Perovskites HalynaOkrepka, MaksymZhukovskyi and MasaruKuno; University of Notre Dame, United States

Light-induced anion photosegregation is a near-ubiquitous response of lead-based, mixed-halide perovskites to illumination. It is observed as unwanted, yet reversible, changes of the optical and electronic response of these materials when subjected to above-gap excitation and represents an impediment to proposed uses of mixed-halide perovskites in applications such as tandem solar cells.
Photosegregation sensitivity depends on the nature of the A-cation (methylammonium (MA^+), formamidinium (FA^+) and Cs^+). For $APb(I_{1-x}Br_x)_3$ photostability rank order follows $CsPb(I_{1-x}Br_x)_3$>$FAPb(I_{1-x}Br_x)_3$>$MAPb(I_{1-x}Br_x)_3$. Qualitatively, this stems from well-known chemical and thermal instabilities of MA^+ as well as to the generally robust nature of all-inorganic Cs-based perovskites.
Here, we assess the relative proclivity of formamidinium-based mixed-halide perovskites such as formamidinium/methylammonium $[(FA,MA)Pb(I_{1-x}Br_x)_3]$, formamidinium/cesium $[(FA,Cs)Pb(I_{1-x}Br_x)_3]$, and formamidinium/methylammonium/cesium $[(FA,MA,Cs)Pb(I_{1-x}Br_x)_3]$ iodide/bromide perovskites to photosegregate under illumination. Goals of the study are to establish their photosegregation propensity and, where possible, compare observations to a recently developed model for light-induced, mixed-halide photosegregation. The model currently explains numerous features of the phenomenon, including the existence of excitation intensity (I_{exc}) thresholds, I_{exc}-dependent photosegregation rates/rate constants, and temperature insensitive, as well as carrier diffusion length-dependent terminal halide stoichiometries.

8:00 PM EN05.07.15
Overcoming Evaluation Challenges of Perovskite Solar Cells with a Multi-Channel Maximum Power Point Tracking (MPPT) Integrated PV Power Analyzing SystemP.V.V.Jayaweera[1], S.Maeshima[1], SatoshiUchida[2], ShojiKaneko[1] and HiroshiSegawa[2]; [1]SPD Laboratory, Inc., Japan; [2]RCAST, The University of Tokyo, Japan

The rapid research and development of perovskite solar cell (PSC) for practical applications are driven by both global warming concerns and industrial demands. Due to the distinctive characteristics exhibited by PSC, such as hysteresis, establishing a universally standardized and rational evaluation process becomes challenging. In this study, we present an equipment system designed to address this challenge. Hysteresis in I-V measurements, caused by capacitance components in stacked PSC, can lead to overestimation or underestimation of the performance. PSC exhibiting hysteresis in the I-V curve manifests two distinct maximum power points in the forward and reverse I-V curves, which depend on the scan speed, starting point, and direction of the scan. By implementing Maximum Power Point Tracking (MPPT), the genuine maximum output power of PSC can be promptly determined. Our newly developed device enables simultaneous I-V tracing and MPPT for up to six solar cells, facilitating research and development. The system continuously plots the light intensity and temperature data alongside the maximum power point, allowing each sample to handle up to 10 V and 1 A capacity. With six independently programmable electronic loads integrated into the analyzer, the MPPT algorithm individually maintained each sample at its maximum power point, ensuring efficient power generation. This multi-channel MPPT-integrated PV power analysis system offers a comprehensive solution to the evaluation challenges faced in PSC research and development. It enables accurate and efficient assessment of PSC performance, contributing to the advancement of practical applications and standardization of evaluation methods.

High Performance Inorganic $CsPbI_2Br$ Perovskite Solar Cells via Crystallization Management Soo WoongJeon, Min JuJeong and Jun HongNoh; Korea University, Korea (the Republic of)

Inorganic $CsPbI_2Br$ perovskite has a substantial potential for triple-junction tandem solar cells as a top subcell, however it exhibits relative instability in the air compared with organic-inorganic perovskites as well as significantly lower efficiency than the theoretical efficiency limit. To further enhance the air-stability and efficiency of $CsPbI_2Br$-based perovskite solar cells (PSCs), it is vitally crucial to improve the crystallinity and passivate the defects within films that accelerate the phase transformation to the photo-inactive phase in the air. Here, it is reported that crystallization management via incorporating sodium formate (NaFo) in a $CsPbI_2Br$ perovskite solution effectively leads to enlarged grain size and the reduced trap density. The Na^+ cation and $HOOC^-$ anion produce a synergistic effect for engineering the defects by acting as cation and pseudo-halide anion passivators, respectively. As a result, the NaFo-incorporating device shows an improved power conversion efficiency (PCE) of over 17% and a fill factor (FF) of 84.5%. To the best of our knowledge, this progressive FF value is the highest value among $CsPbI_2Br$-based PSCs reported thus far. In addition, the NaFo-incorporated device shows improved air stability compared to the control device, retaining over 95% of its initial PCE for 1000 hours under 10% relative humidity at room temperature without any encapsulation.

8:00 PM EN05.07.17
Photovoltaic Performance Analysis of Organic and Inorganic Hole Transport Layer for Cu-Ag-Bi-I Based Perovskite Solar Cell Md Arif UlIslam, ShinyaKato and TetsuoSoga; Nagoya Institute of Technology, Japan

In this study, the environmental friendliness of Cu_6AgBiI_{10} (CABI), a cheap and non-toxic material, has received the most attention for the investigation. Recently, the inorganic Cu-Ag-Bi-I base compounds have shown great potential for solar, optoelectronic, and other applications. Their outstanding stability, high absorption coefficients, and ability to transport charged carriers are all factors that make them attractive.In this study, we investigated the performance of organic and inorganic Hole Transport Layers(HTL) on Cu-Ag-Bi-I based solar cells, conducted experimental and simulation analyses to improve their efficiency, and explored new approaches for optimizing solar cell devices.The method used was a single-step spin coating using hot-casting droplets poured onto pre-heated substrates. To anneal films, two-step annealing was used. In the first step, the films were annealed in the glove box at 75°C for 3 minutes before being annealed at 150°C for 6 minutes in the second step on the hot plate.The films were characterized using XRD, UV and SEM to identify the structural, optical, and surface morphological behavior and properties of these materials and device simulations for optimizing their photovoltaic performances.In addition, P3HT, PEDOT:PSS, Spiro-MeOTAD, NiOx, CuSCN, and CuO were used as layers for hole transport to identify the most suitable HTL layer for the FTO/(c+mp)TiO_2/CABI structure using the SCAPS-1D solar cell device simulation tool. This study demonstrates that inorganic HTLs are more crucial than organic HTLs in terms of the efficiency and performance of solar cells. In the six structures of devices, the best-optimized device design, FTO/(c+mp) TiO_2/CABI/CuO/Au was found with an efficiency of 2.08%. The effects of absorber layer thicknesses of absorber and ETL layers, rate of generation, recombination, capacitance voltages, current density voltage, and the characteristics of quantum effectiveness are investigated. The SCAPS-1D results were compared with similar experimental results of the photovoltaic devices. The research revealed that HTLs are a key factor in the efficiency of CABI solar cells. The research reveals that HTLs are key to CABI solar cell efficiency.

Efficient and Stable Perovskite Quantum Dot Solar Cells via Incorporation of Multifunctional 3D Star-Shaped Organic Semiconductors SeyeongLim, Dae HwanLee and TaihoPark; Pohang University of Science and Technology, Korea (the Republic of)

$CsPbI_3$ perovskite quantum dots (PQDs) exhibit superior optical and optoelectronic characteristics, such as tunable bandgap, high photoluminescence quantum yield, and high absorption coefficient. Owing to these advantages, the $CsPbI_3$ PQDs have been considered as promising and effective photovoltaic absorber. Since PQDs have been stabilized with long-chain ligands, the ligand exchange using short ligands is indispensable to enhance the electronic coupling within PQD solids and then realize high-efficiency solar cells. However, the inefficient ligand exchange

can form trap states on the PQD's surface, leading to low device performance and stability. Herein, we demonstrate that a newly designed and synthesized three-dimensional (3D) star-shaped semiconductor (Star-TrCN) can be chemically bound with PQDs through theoretical modelling and experimental validation. The hybrid films of Star-TrCN and PQDs show reduced surface trap states and improved cubic-phase stability. As a result, the Star-PQD hybrid devices not only achieve improved device stability over 1000 h at 20–30% relative humidity, but also increase power conversion efficiency up to 16.0% by establishing a cascading energy band structure.

8:00 PM EN05.07.19
The Deposition of $CH_3NH_3PbI_3$ Thin Film using Close Space Sublimation for Large Scale Perovskite Solar Cells YoungminKim, WonkyuLee, YounghoChoe, DonghwanKim, YoonmookKang and Hae-SeokLee; Korea University, Korea (the Republic of)

Abstract
To achieve large-scale perovskite solar cells and to deposit on a textured silicon wafer to apply silicon-perovskite tandem solar cell, it is crucial to implement the fabrication process for pin-hole-free thin film with optimal crystalline morphology and full coverage. In this work, we used a close space sublimation deposition to grow a high quality $CH_3NH_3PbI_3$ thin film in a different temperature. Reducing the process temperature is highly advantageous in fabricating perovskite films since perovskite materials exhibit significant degradation and adverse effects on crystal structure when exposed to high temperature. Therefore, the process temperature was conducted at the minimum temperature at which the MAI powder was sublimated. And The thickness of PbI_2 precursor determines the thickness of perovskite film. The PbI_2 precursor was adjusted using the sputtering method, and we controlled the thickness of PbI_2 by the sputtering time. The results indicate that high quality perovskite films with variable thickness can be obtained by the close space sublimation process demonstrated here. Although $CH_3NH_3PbI_3$ was selected for this study, this close space sublimation method demonstrated can be easily applied to other hybrid perovskites.

Keywords: solar cells, large-scale perovskite, pin-hole-free, close space sublimation, sputtering method, temperature

Defect Passivation for Highly Efficient Perovskite/Silicon Tandem Solar Cells So JeongPark, Deok KiCho, GeonpyoHong and Jin YoungKim; Seoul National University, Korea (the Republic of)

Halide perovskites are promising photovoltaic materials, the power conversion efficiency (PCE) of the single junction solar cell has been improved to 26.0%, which is approaching the Schockley-Queisser limit. Perovskite/silicon tandem solar cells are attractive candidates to overcome the theoretical limit efficiency. Controlling the perovskites with a bandgap of ~1.7 electron volts is indispensable to enhance the photovoltaic performance. In this study, we developed high-performing perovskite top cells with a thiocyanate (SCN^-) based additive and attained a PCE of 21.01% without hysteresis. The additive strategy led to improved crystallinity, enlarged grain size, and reduced defect density. Non-radiative recombination responsible for open-circuit voltage decreased from the enhancement of perovskite film quality. By regulating the window layer thickness consisting of fullerene and indium tin oxide, an efficient semi-transparent cell was produced to minimize the short-circuit current density reduction caused by optical loss. The efficiency over 28% of a monolithic two-terminal perovskite/silicon tandem solar cell was achieved.

8:00 PM EN05.07.21
High Reproducible Fabrication of Perovskite Solar Cells using an Automated Perovskite Film Coating System NaotoEguchi, KoheiYamamoto and TakurouN. Murakami; The National Institute of Advanced Industrial Science and Technology, Japan

Perovskite solar cells are expected to be the next generation of solar cells due to their favorable characteristics such as high conversion efficiency, light construction, and flexibility. However, there are considerable variations in perovskite solar cell's performances even though the solar cells are fabricated under the same conditions. Consequently, when evaluating new materials or new processes, it is necessary to fabricate many devices for comparing them with considering the large variations. This can be related to both cost increasing and time consuming for R&D.

One of the reasons for the variability in the performance of perovskite solar cells is the sensitivity of crystal growth in the perovskite layer to environmental factors such as temperature, humidity, and solvent evaporation rate. It is well known that these environmental factors influence the morphology of the film, making it important to control the atmosphere during deposition processes.[1–3] In addition, the widely used anti-solvent method for fabricating high-efficiency perovskite solar cells can cause significant changes in the film morphology and the solar cell performances based on the factors such as the drop volume, timing, and drop rate of the poor solvent. As a result, even when perovskite solar cells are fabricated under consistent conditions, their performances are still variable. In particular, the manual dropping of the poor solvent during the spin-coating of the perovskite precursor solution by human hands induces slight variations in the drop timing or drop speed, which leads to variations in the solar cell performances.

In this study, the low reproducibility, which is one of the challenges for perovskite solar cells, was improved by automating the dropping process of poor solvents and substrate transfer during the coating of perovskite layer. To remove human involvement in the perovskite layer coating process, an automated coating system was developed by integrating a robotic arm with a spin coater, an automatic solution drop system and a hot plate. This system enabled the transfer of glass substrates, the dropping of poor solvents during spin coating, and the heating of substrates on the hot plate. Using this automated coating system, we evaluated the performance variations of perovskite solar cells and compared them to those fabricated manually. The results showed that the perovskite solar cells fabricated using the automated coating system had reduced standard deviation of photoelectric conversion efficiency from 0.61 to 0.40 compared to those fabricated by hand. This system is expected to enable more objective evaluation of new materials and new processes, leading to reduced development time and costs.

Enhanced Perovskite Solar Cells Performance Through Surface Engineering Investigation of a Zn-Complex Based Hole-Transporting Materials ChaochinSu[1], Wen-renLi[2], YogeshTingare[1] and HsuYa-Chun[1]; [1]Taipei Tech, Taiwan; [2]National Central University, Taiwan

Interface Engineering plays a critical role in the performance of perovskite solar cells (PSCs). High-quality perovskite films with suitable hole transport properties of the hole-transporting materials HTMs are critical factors in obtaining high-performing PSCs. Small inorganic molecule HTMs have attracted considerable interest in PSCs because of their structural flexibility, operational durability, and good hole mobilities, but they suffer unsatisfied cell efficiency. In this work, a ligand **BT28** and its zinc-based coordination complex **BTZ30** were designed and synthesized as hybrid organic-inorganic structured HTMs for PSCs applications. Both HTMs exhibit similar optical and electrochemical properties. The mixed-halide perovskites can be grown uniformly with large crystalline grains on top of both HTMs. However, it is discovered that the BTZ30-based solar cell exhibited a higher power conversion efficiency close to 20%. This can be due to the higher hole mobility of **BTZ30** than that of BT28. The high hole mobility of **BTZ30** is attributed to low trap-assisted recombination and efficient charge extraction efficiency, indicating a good perovskite/HTM interface. The PSC fabricated with the metal-containing HTM **BTZ30** shows the best power conversion efficiency (PCE) of 19.50%, which is higher than the PCE of 18.01% from the PSC fabricated with its ligand and non-metal HTM **BT28**.

Thermal and Electrical Properties of ZnO-PCBM Composite Layer for p-i-n Perovskite Solar Cells SeongtakKim, Dong-woonHan and Chan BinMo; Korea Institute of Industrial Technology, Korea (the Republic of)

Expectations for commercialization of perovskite solar cells are increasing with the recent announcement of 25.8% efficiency. However, the stability of perovskite solar cells is still lower than that of silicon solar cells, which is an obstacle to commercialization. Solar cells driven in the field not only emit most of their energy as heat, but are also exposed to high temperatures of 80°C or more during operation, so thermal stability is very important. When the heat of the solar cell increases, not only the power conversion efficiency decreases, but also the stability of the perovskite(PVSK) materials becomes weak. In particular, since the p-i-n thin-film perovskite solar cells almost use an organic materials manufactured by a low-temperature process or a solution process, the thermal conductivity is very low. In general, phenyl-C61-butyric acid methyl ester(PCBM) is mainly used as electron transfer layer(ETL) of p-i-n structure, but its thermal conductivity is only 0.07W/mK preventing heat transfer inside the perovskite from escaping to the outside. In this study, the PCBM-ZnO composite layer was applied to improve the heat dissipation performance of the solar cell. The heat dissipation performance and electrical properties were investigated according to the amount of ZnO added between PCBM and perovskite layer. The addition of ZnO improved the thermal conductivity of ETL and improved the thermal stability of the PVSK layer. When the ZnO content was too high, ZnO was accumulated at the interface between PVSK and PCBM, reducing the solar cell efficiency. Therfore, it was confirmed that the ZnO content of 0.1 wt% was the optimal composition in this

study. In conclusion, the improvement effect of the solar cell due to the application of the PCBM-ZnO composite layer was confirmed.

8:00 PM EN05.07.24
The Big Bang of Halide Perovskites: The Starting Point of Crystallisation AnaPalacios Saura[1,2], JoachimBreternitz[3], ArminHoell[1] and SusanSchorr[1,2]; [1]Helmholtz-Zentrum Berlin für Materialien und Energie, Germany; [2]Freie Universität Berlin, Germany; [3]FH Münster, Germany

Halide perovskites (HPs) are extremely popular amongst the scientific community, not only for their astonishing increase in power conversion efficiency up to 26%[1], but also for using low-cost solution-based processing methods.
Some of the distinctive properties of HPs are the decrease in solubility with increasing temperature[2], and the bandgap tunability via anion and cation substitution[3]. With this study we aim to elucidate the role of the A-cation in the crystallisation process as well as how the precursors are arranged prior to crystallisation. For this reason, we investigated the precursor solution of different HPs ($RbPbI_3$, $KPbI_3$ and $NaPbI_3$) using small angle X-ray scattering (SAXS) as well as the precursor solution of $MAPbI_3$ at increasing temperature (from room temperature up to 120°C). The binary precursors (e.g. RbI and PbI_2 to synthesise $RbPbI_3$) were dissolved in common solvents to synthesise HPs such as γ-butyrolactone (GBL), dimethylformamide (DMF) and mixtures thereof.
SAXS is a non-destructive technique based on the scattering length difference between the scattering objects in a solution. Applying SAXS, the size and shape of nanoscale particles (scattering objects) can be investigated, as well as their adjacent distance and interactions with each other.[4,5] We performed SAXS experiments at BESSYII, at the PTB's four-crystal monochromator beamline[6] using the ASAXS endstation.[7]
The SAXS pattern of all the measured samples show a peak in the scattered intensity at q-values between 2.5 and 3.3 nm^{-1}. The presence of such peak is a clear indication of the existence of interacting scattering objects in solution. The position of the peak correlates with the distance between adjacent scattering objects (d_{exp}). In a previous study[8], we developed a core-shell model with [PbX_6] (X = I, Br) octahedra surrounded by randomly oriented solvent molecules to explain d_{exp} in HPs with a molecular A-cation (MA^+, FA^+), showing that the size of the agglomerates changes with the composition of HPs precursors and with the solvent, but not with the A-cation. However, when alkali metals are used as A-cation, we can demonstrate that d_{exp} not only depends on the solvent but also on the A-cation. This is explained by the smaller ionic radius of alkali metals compared to the molecular cations [9,10] therefore the charge density is higher. For this reason, we extended the previous model to take this phenomenon into account. Based on this information, the extended core-shell model assumes that the A-cation and the solvent molecules compete to surround the [PbI_6] octahedra. In this A-cation core-shell model, the core is composed of [PbI_6] octahedra, which can be arranged as a single octahedron or a corner-sharing octahedra. The [PbI_6] octahedra of adjacent scattering objects are surrounded by a solvent shell with randomly oriented molecules or by an A-cation shell. The SAXS data analysis (using SASfit[11]) shows higher polydispersity as the previous model, which indicates an increase in the heterogeneity of the solution, this is in agreement with the proposed extended model.
We will discuss the influences of the A-cation and solvent on the core as well as the solvent shell of the scattering objects since they have the potential to influence the crystallization process of the HP and therefore the performance of a device produced from solution processing.

Semi-Transparent Perovskite Solar Cells: Unveiling The Trade-Off Between Transparency and Efficiency NagehK. Allam; American University in Cairo, Egypt

Semi-transparent perovskite solar cells (Pero-SCs) are realized by tuning the band gap of the perovskite to resolve the trade-off between the transparency and efficiency of the photo-absorber. We synthesized wide-bandgap MAPbI3−xBrx perovskite, and the transparency and efficiency of the corresponding semi-transparent Pero-SCs were investigated systematically by varying the I : Br ratio and thickness of the perovskite film. Increasing Br content widened the bandgap of perovskite (i.e., blue shift of the absorption edge), and led to an increase in the average visible transmittance (AVT). This strategy allowed for high AVTs, and concomitantly achieved high power conversion efficiencies. Meanwhile, increasing the Br content could facilitate formation of perovskite films with large grains that were highly crystallized. Compared with the narrow-bandgap perovskite, the wide-bandgap perovskite showed advantages for obtaining semi-transparent Pero-SCs with thick perovskite films (>200 nm) and high (20%) transparency.

Crosslinkable Siloxane Induced Direct Patterning of Highly Stable Halide Perovskite Nanocrystals Sang WooBae[1], Jin MinPark[1], JunhoJang[2], HyukminKweon[1], Byeong-SooBae[2], Do HwanKim[1] and Young HoonKim[1]; [1]Hanyang University, Korea (the Republic of); [2]Korea Advanced Institute of Science and Technology, Korea (the Republic of)

High resolution patterning of color conversion layers (CCLs) is essential for the demonstration of color converting light-emitting diodes (LEDs). Conventional color converting materials such as organic phosphor and inorganic quantum dot (QD) so far suffer from low color purity and high materials cost. Metal halide perovskite nanocrystals (PNCs) have been regarded as a promising color converting material in CCLs due to their high absorption coefficient, spectrally narrow light, easy color tuning, low materials cost, and high photoluminescence quantum efficiency (PLQE). However, the instability of PNCs in thermal treatment and in polar solvents limits its high resolution patterning through consequent photolithography process and its long-term stability in various condition. To enable low-cost direct patterning without using a high polarity photoresist and improve the stability of patterned PNCs, we here introduce the direct optical patterning of crosslinkable siloxane resin/PNC composite. Multicolored patterning of PNCs in micrometers was demonstrated by siloxane resin pinning (SRP) process which mitigate the high viscosity and concomitant shrinkage problem in the siloxane/PNC composites. The patterned PNCs showed stable photoluminescence quantum efficiency (PLQE) in harsh liquid environments (e.g., in water, acid, or base solutions, and in various polar solvents), which provide the breakthrough into high density PNC-based micro-LED.

8:00 PM EN05.07.28
Tailoring the Molecular Structure of Dopant-Free Polymeric Hole Transport Materials for Improved Charge Extraction in Perovskite Quantum Dot Solar Cells Dae HwanLee, SeyeongLim and TaihoPark; Pohang University of Science and Technology, Korea (the Republic of)

We have developed three dopant-free hole transport materials (HTMs) as an alternative to the commonly used doped Spiro-OMeTAD in perovskite quantum dot solar cells (PQD-SCs). The dominant HTM, Spiro-OMeTAD, requires the use of doping systems to enhance charge mobility. However, these dopants can lead to the degradation of PQD-SCs, making the development of efficient dopant-free HTMs crucial for commercialization. In our study, we designed three types of dopant-free HTMs: Asy-PDTS, Asy-PSDTS, and Asy-PSeDTS. To improve their electrical properties, we incorporated a chalcogenide-based fluorinated benzothiadiazole rigid segment acceptor unit. This rigid segment acted as an effective charge hopping channel, compensating for the impaired electrical properties through side chain engineering. Through a conformation-locking approach utilizing chalcogenide-fluorine noncovalent interactions, we achieved favorable planar structures with face-to-face stacking of the rigid segments. Among the optimized devices, the one utilizing Asy-PSeDTS exhibited remarkable performance. It achieved a power conversion efficiency (PCE) of 15.2%, the highest reported PCE among dopant-free HTM-based PQD-SCs. Additionally, this device maintained 80% of its initial PCE even after 40 days, demonstrating superior stability compared to other dopant-free HTM-based PQD-SCs.

8:00 PM EN05.07.29
Enhancing the Device Performance and Stability of Inverted Perovskite Solar Cells using Zr-Based Metal-Organic Frameworks(MOFs) Jin HyoungKim, TaeminKim, MinohLee and YongseokJeon; Korea University, Korea (the Republic of)

Inverted perovskite solar cells have drawn much attention due to their reduced hysteresis, low-temperature processability, and as a suitable structure for perovskite/silicon tandem solar cells. However, just as conventional perovskite solar cells, their long-term stability remains a major challenge for applications and commercialization, since they are extremely vulnerable to the degradation accelerated by environmental factors such as moisture, air and light. In this study, we explored the use of UiO-66 metal-organic frameworks (MOFs) and its derivatives, UiO-66-NH2 and UiO-66-COOH, as a means of improving the efficiency and stability of the inverted perovskite solar cells. UiO-66 and its derivatives are Zirconium-based metal-frameworks with terephthalic acid organic linkers plus functional groups, known for their high chemical stability and absorption of ultraviolet (UV) light which is damaging to the operation of perovskite solar cells. We found that incorporating UiO-66 interlayer between the hole-transporting layer, poly[bis(2,4,6-trimethylphenyl)amine] (PTAA), and perovskite layer improved the morphology and crystallinity of the perovskite, thereby enhancing the performance. Also, it improved the stability of inverted perovskite solar cells, especially against continuous light irradiance. The device

achieved the efficiency of 18.5%, showing an increase from 17.6% of the control device, and maintained higher than 98% of the initial efficiency under 1200 seconds of one-sun irradiance. To the best of our knowledge, the achieved efficiency is the second-highest PCE of inverted perovskite solar cells using MOFs. In addition, we found that incorporating the MOFs into the perovskite precursor also enhanced the device performance with enhanced long-term stability, with higher efficiency than the control device achieved and maintained over 90% of it after 1000 hours, due to the passivation induced by the Lewis base functional groups of organic linkers. Our findings suggest that using UiO-66 metal-organic frameworks and its derivatives between/in perovskite solar cell layers could be a promising strategy for enhancing the stability of inverted perovskite solar cells, both extending broader applications of MOFs and making the MOF-applied inverted perovskite solar cell devices attractive for applications such as perovskite/silicon tandem solar cells.

8:00 PM EN05.07.30
Anion-Dependent Piezoelectric Power Generation in Lattice-Strained Hybrid Halide $MAPbX_3$ (X = I, Br, and Cl) Thin Films Da BinKim[1,2], Kyeong SuJo[1], Kwan SikPark[1], JuHan[1] and Yong SooCho[1]; [1]Yonsei University, Korea (the Republic of); [2]University of Toronto, Canada

The compositional dependence of piezoelectricity in halide perovskite materials has rarely been reported based on experimental results. To the best of our knowledge, for the first time, we demonstrate experimental evidence of the dependence of piezoelectricity and electromechanical energy harvesting performance on the anions in a hybrid halide thin-film system of $MAPbX_3$ (X = I, Br, and Cl). As expected from their crystal structures, i.e., tetragonal $MAPbI_3$, cubic $MAPbBr_3$, and cubic $MAPbCl_3$, the highest piezoelectricity was observed in $MAPbI_3$, which electromechanically harvested the largest amount of energy owing to its ferroelectricity possessing permanent dipoles based on PbI_6 octahedra. Interestingly, cubic $MAPbBr_3$ and $MAPbCl_3$ also delivered considerable piezoelectric energy harvesting performance, unlike other cubic oxide-based perovskites, as they are associated with organic MA^+ ions in soft phonon modes, which can induce lattice distortion under a mechanical stimulus. The origin of the piezoelectricity even with the cubic halides is discussed as being related to the tolerance factor and bond strength, with experimental support for the estimated effective piezoelectric coefficient and grain boundary potential. Such experimental results on piezoelectricity and energy harvesting for $MAPbBr_3$ and $MAPbCl_3$ have not been reported thus far. In addition to exploring the anion-dependent piezoelectricity in flexible $MAPbX_3$ halide thin films, we attempted to enhance their electromechanical power-generating capability by incorporating vertical tensile lattice strain (for extra lattice extension between electrodes) and by applying an optimal poling field (for vertical domain orientation). Introducing out-of-plane tensile strain and poling effectively improved the harvesting performance of all three halide thin films, with their performance increasing in the order $MAPbCl_3$ < $MAPbBr_3$ < $MAPbI_3$, as anticipated from their piezoelectricity. Notably, the output voltage and current demonstrated herein of 23.1 V and 1,703 nA for the ~486 nm-thick $MAPbI_3$ thin film are the highest values reported for any thin-film-based perovskite halide harvesters to date.

8:00 PM EN05.07.31
Fabrication of Electrospun Nanofiber Yarns Decorated with Organic-Inorganic Double Halide Perovskite for Wearable Piezoelectric Applications SeongcheolAhn, YujangCho and Il-DooKim; Korea Advanced Institute of Science and Technology, Korea (the Republic of)

Research efforts are actively focused on capturing energy from renewable sources due to concerns about environmental pollution and resource shortages. Among the various methods, the piezoelectric nanogenerator (PENG) stands out as it harvests energy from the deformation of a crystalline material using the piezoelectric effect. This technique shows promise in converting mechanical energy into electrical energy in an eco-friendly manner. The piezoelectric organic-inorganic hybrid nanocomposite is able to utilize the advantages of high piezoelectricity of piezoelectric ceramics, dielectric properties, and flexibility of polymers. The organic-inorganic hybrid piezoelectric material-based PENG is fabricated by the composite of halide double perovskite (HDP) and PVDF piezoelectric materials. After mixing the HDP in the polymer matrix, an organic-inorganic hybrid nanocomposite yarn was fabricated with enhanced efficiency characteristics of HDP while maintaining the flexibility and processability of the polymer. Also, the nanofiber (NF) yarn platform, composed of ultrahigh-density polymeric NFs electrospun by two spinnerets with opposite applied bias, has attained great attention as a suitable flexible substrate featuring a large specific surface area and high porosity. The 1D-type PENG using organic-inorganic nanocomposite is flexible and can be applied to wearable devices, electronic devices, etc.

8:00 PM EN05.07.32
Thermal Co-Evaporation of Lower-Dimensional Metal Halide Perovskites KunalDatta and Juan-PabloCorrea-Baena; Georgia Institute of Technology, United States

Lower-dimensional perovskite structures have advanced the field of perovskite-based optoelectronics through their bandgap tunability, high defect tolerance and low ion mobilities, either used as active layers or at charge-transport interfaces. However, solution-based processing of such materials typically yields poor structural selectivity due to the interactions between precursor ions and the solvent. This results in the formation of phase gradients across the thickness of thin films that develop bandgap and energetic barriers, thereby impeding charge-carrier transport and optoelectronic performance.

This work describes thermal co-evaporation methods for the deposition of high quality lower-dimensional Ruddlesden-Popper perovskites as a route to develop structurally homogeneous thin films for optoelectronic devices such as photovoltaics, light emission and light detection. The dimensionality (*n*-value) of the structures, and thereby the optical bandgap, is controlled accurately through precursor deposition rates. The work assesses the role of deposition conditions, substrate functionalization and post-deposition treatment in determining crystallographic structure and phase purity. As a result, in addition to being commercially scalable, conformal and demonstrating precise thickness control, the elimination of the precursor-solvent interaction in thermal co-evaporation depositions ensures an accurate and consistent precursor stoichiometry leading to phase homogenization and improved charge-carrier transport.

Optimization of Aerosol Assisted Post-Treatment Strategies for Enhanced Performance Combined with Long-Term Stability of Halide Perovskite Photovoltaics Ravi KantMisra, MadsarHameed and JoeBriscoe; Queen Mary University of London, United Kingdom

Perovskite photovoltaic (PPV) has emerged as an outstanding photovoltaic technology in the past few years, with certified power conversion efficiency reaching up to 26% for single junction devices and 33.7% for tandem devices with silicon cells [1]. Our group recently demonstrated a new solvent-based post-treatment strategy of perovskite films resulting in excellent reproducibility and uniformity by exposing a perovskite film to the vapourised solvents via an aerosol-assisted chemical vapour deposition system [2]. Using this process, we achieved enhancement of both photovoltaic power conversion efficiency (PCE) and stability in a range of perovskite compositions and device architectures, which we have linked to improvements in both the nanoscale and macroscale uniformity of the material, including a reduction of defects and trap states.

In this talk, I will discuss our more recent developments of this process to include organo-halide salts in the solvent aerosol, such as MACl, leading to substantial enhancement of the post-crystallisation grain growth and recrystallisation process [3]. This leads to films that are comprised of ultra-large grains (~1-5 μm) where local traps are almost completely eliminated, as confirmed at the nanoscale via photoconductive atomic force microscopy. The large grains have also allowed us to visualise local variations in photoluminescence (PL) emission at the grain boundaries using hyperspectral PL mapping. The substantial reduction in trap states and increase of film homogeneity leads to photodetectors that can operate at ~1.5 orders of magnitude lower light levels than those made with conventional spin-coated films, demonstrating the potential to substantially enhance PSCs for low light applications, such as indoor PVs. We have also recently identified that among all additives, using MASCN creates the greatest enhancement of this effect, leading to substantial grain grown and associated PCE and stability enhancement in PSCs [4]. The aerosol assited post-tretment has also been successfully tested for the performance recovery of mixed cation perovskite solar cells following degradation, proving its versatility in microstructural optimisation of PPV films, and performance recovery of degraded devices (unpublished results).

We are now implementing our established aerosol-assited post-treatment strategy towards morphological improvements, minimizing grain boundaries in double and triple cation containing perovskite materials and devices, and the results will form part of this talk.

Mixed Ruddlesden-Popper and Dion-Jacobson Phase Perovskites for Stable and Efficient Blue Perovskite LEDs Pui KeiKo; The Hong Kong University of Science and Technology, Hong Kong

Producing efficient blue and deep blue perovskite LEDs (PeLEDs) still represents a significant challenge in optoelectronics. Blue PeLEDs still have problems relating to color, luminance, and

structural and electrical stability so new materials are needed to achieve better performance. Recent reports suggest using low n states (n = 1, 2, 3) to achieve blue electroluminescence in quasi-2D Ruddlesden-Popper (RP) perovskite films. However, there are fewer reports on the other quasi-2D structure, Dion-Jacobson (DJ) perovskites, despite their highly desirable optical properties, due to the difficulty in achieving charge injection. To resolve this issue, here we have mixed DJ phase precursors, propane-1,3-diammonium (PDA) bromide into RP phase perovskites and fabricated low-dimensional PeLEDs. It was found that these specific precursors aid in suppressing both the low n (n = 1) and high n (n ≥ 4) quasi-2D RP phases and is an effective strategy in blue-shifting sky-blue RP perovskites into the sub-470 nm region. With optimization of the PDA concentration and device layers, we achieved an EQE of 1.5% at 469 nm and stable electroluminescence (EL) for the first deep blue PeLED to be reported using DJ perovskites.

8:00 PM EN05.07.35
Highly Stable Tin Iodide Perovskites Synthesized in Ambient Aqueous Phase using Alkali Iodides and Ascorbic Acid KojiYokoyama, ShunYokoyama and HideyukiTakahashi; Tohoku University, Japan

Tin iodide perovskites ($ASnI_3$) are emerging as photoactive layers in photovoltaics due to their excellent optical and electronic properties. However, their preparation typically requires an inert environment and anhydrous organic solvents due to their vulnerability to oxygen and moisture. These conditions have resulted in complex and environmentally unfriendly processes. Previous studies have reported the aqueous-phase synthesis of $ASnI_3$ using hydroiodic acid (HI) as a solubilizer and hypophosphorous acid (H_3PO_2) as a reductant. Nevertheless, HI is highly unstable and cannot be used in ambient air, and both HI and H_3PO_2 are hazardous chemicals. Consequently, there is a high demand for more stable solubilizers and safer reductants to enable a facile and green synthesis of $ASnI_3$ in an ambient aqueous phase. In this study, we present the ambient aqueous-phase synthesis of $ASnI_3$ perovskites using alkali iodides and ascorbic acid (AA). Aqueous solutions containing 6.0 mol L^{-1} of HI, lithium iodide (LiI), or sodium iodide (NaI) as solubilizers and 1.0 mol L^{-1} of H_3PO_2 or AA as reductants were prepared. Subsequently, 0.5 mol L^{-1} of tin iodide was dissolved in these solutions to prepare tin precursor aqueous solutions. The valence states and complex structures of tin species in these precursor aqueous solutions were characterized via electrospray ionization time-of-flight mass spectrometry (ESI-TOFMS). 0.5 mol L^{-1} of organic cation iodides was added to the precursor aqueous solutions, and the resulting precipitated samples were collected by suction filtration. Structural, compositional, and optical characterizations were carried out for the samples immediately after synthesis and after exposure to ambient air using X-ray diffractometry (XRD), X-ray photoelectron spectroscopy (XPS), and optical absorption/photoluminescence measurements.
The tin precursor aqueous solutions containing HI turned muddy and degraded rapidly, even though they contained reductants, whereas those containing LiI or NaI remained completely transparent and stable even in ambient air. Tin species formed complexes with the reductant molecules in the solutions containing reductants. ESI-TOFMS analysis revealed that the reducing and chelating abilities of AA efficiently stabilized the Sn^{2+} valence states. The resulting samples were determined to be pure-phase $ASnI_3$ perovskites. Interestingly, XRD, XPS, and optical measurements clearly indicated that $ASnI_3$ perovskites synthesized using NaI and AA exhibited excellent stability after exposure to ambient air. Detailed analyses suggested that Na^+ ions and a trace amount of AA molecules present on the sample surface passivate the surface defects and stabilize the $ASnI_3$ phases.
In conclusion, we successfully prepared highly stable tin precursor aqueous solutions even in ambient air, using stable alkali iodides and safe AA. Highly stable $ASnI_3$ perovskites were synthesized from the solutions containing NaI and AA. These findings pave the way for the green fabrication of highly efficient and long-life perovskite photovoltaics.

8:00 PM EN05.07.36
Highly Efficient and Stable Perovskite Photocathode for Hydrogen Generation in Acidic and Basic Conditions SaikiranS. Khamgaonkar and VivekMaheshwari; University of Waterloo, Canada

In the pursuit of sustainable energy solutions, the direct conversion of solar energy into fuels, such as hydrogen, through photoelectrochemical systems (PEC), holds immense promise. Organo lead halide perovskites with their excellent optoelectronic properties and their reported record photovoltaic efficiencies are therefore being researched for integration in PEC. Particularly, their integration as photocathodes for the hydrogen evolution reaction (HER) is gaining attraction due to their impressive HER photocurrent density (~ -20 $mA.cm^{-2}$) and high onset potential (~ 1 V). However similar to photovoltaics, the limited stability of perovskites in PEC devices is a critical challenge. This is further amplified due to immersion in an aqueous medium which is required for the operation of the PEC devices for HER. Previous research work have primarily focused on enhancing the extrinsic stability of the perovskite layer through the implementation of moisture-resistant encapsulant layers like Ni, Field metal, conductive carbon paste, metal oxide, or Ti foil. However, little attention has been paid to addressing both the extrinsic and intrinsic stability of the perovskite film, which is crucial for prolonged device operation. Intrinsic stability, crucially linked to ion migration effects leading to perovskite degradation, complements extrinsic stability, which is governed by the degradation of the perovskite structure due to decomposition with water (in the case of PEC). Moreover, selecting a catalyst capable of exhibiting exceptional stability and performance in extreme pH conditions poses a further challenge. While the kinetics of HER are facile in acidic conditions, alkaline environments present a hurdle due to the sluggish water dissociation step. Therefore, there is need for a single catalyst that can exhibit excellent HER performance and stability in extreme pH conditions In this work, we have fabricated a highly efficient and stable perovskite-based photocathode which displays excellent HER performance with enhanced stability. To enhance both performance and internal stability, a polymer additive has been introduced into the perovskite thin film. The use of the polymer greatly improves the solar cell efficiency, the polymer-perovskite cells have an efficiency of ~ 15.3 %, while the pristine perovskite cells show an efficiency of ~ 12 %. Additionally, we have synthesized a bimetallic catalyst comprising Au, Pt, and Ni, characterized by low overpotential and Tafel slope values for HER in highly acidic and basic conditions. The polymer-conjugated photocathode with the bimetallic catalyst layer exhibits excellent HER performance both in acid and basic electrolyte and shows high photocurrent density (~-20 $mA.cm^{-2}$), high onset potential (~ 0.95 V), and a half-cell solar to hydrogen conversion efficiency (HC-STH) of 10.11 %. More impressively, the photocathode exhibits an unprecedented stability, with T_{80} (time for 80% degradation) values of approximately 70 hrs. (H_2SO_4) and 78 hrs. (KOH), retaining over 50 % of its initial photocurrent after 120 hrs. of operation. These stability values are the highest reported among various perovskite-based photocathodes.

SESSION EN05.09: Halide Perovskites for Energy Applications

Functionalized MXenes for Stable Halide Perovskite Solar Cells MonicaLira-Cantu; Nanostructured Materials for Photovoltaic Energy, Spain

Perovskite solar cells (PSCs) with an accredited power conversion efficiency (PCE) above 25% demonstrate a great potential towards commercialization. Currently, PSCs are largely susceptible to poor stability and durability issues which restricts their utility in practical applications. Shallow and deep defects in perovskites are a major contribution to the stability loss and this loss can be minimized by passivating the defects through surface functionalization. Materials functionalization and modification has been employed as an strategy to improve the stability of PSCs by controlling the surface properties by bringing novel chemical, electronic and optical properties. Two-dimensional (2D) materials are excellent candidates for potential applications including photovoltaics owing to their high conductivity, hydrophilicity, flexibility, and surface modifications. In this work, we apply the 2D Ti_3C_2 MXene in a normal PSC configuration of the type: FTO / c-TiO_2 / m-TiO_2 / halide perovskite (HP) / MXene / Spiro-OMeTAD / Au. We used the quadruple halide perovskite (HP) $Rb_{0.05}Cs_{0.05}MA_{0.15}FA_{0.75}Pb_{1.75}(I_{0.95}Br_{0.05})_3$ as the absorber, and the MXene (Ti_3C_2-T_x) at the interface of HP and the hole transport layer (HTL) to fabricate HP/MXene heterojunctions. We employed the organic ligand 3-Phosphonopropionic acid (H3pp) to functionalize the bulk of the MXene and the bulk of the HP. The functionalization of only the MXene transport layer resulted in PSC with 19. 89 % efficiency, the functionalization of both, the MXene and the Halide Perovskite layers, resulted in champion PSCs with 21.95% PCE. Both indoor stability studies under ISOS-L protocol (continuous MPP tracking under N_2 atmosphere for 1000 h) and outdoor stability analyses under the ISOS-O protocol (MPP tracking, encapsulated devices) demonstrated the superior stability of PSCs when the 2D MXene interface is employed, especially under high humidity (60-85%) conditions where the PSCs showed excellent recovery after a low light irradaition and rainy day. The best results were observed for the PSC with the functionalization of both the MXene layer and the HP absorber layer. The ISOS-L protocol study revealed almost 100% retaining of the PSC device. Outdoor testing under ISOS-O protocol for > 600 h holding devices at open circuit voltage revealed a T_{80} of 600 h, while the control devices showed T_{80} at about 250 h. Thermal admittance spectroscopy (TAS) revealed that the functionalization of the halide perovskite rwaults in shallow defect passivation, when the functionalization takes place at the MXene interface, TAS analyses revealed the reduction of both deep and shallow trap state densities. This report provides pioneering study of additive engineering for adabtable bulk passivation and interface passivation through MXene nanosheets.

2:00 PM EN05.09.02
Probing Photostability of Tin-Containing Mixed Halide Perovskites: The Good and The Bad KrishanuDey[1,2] and SamuelD. Stranks[2,2]; [1]University of Oxford, United Kingdom; [2]University of Cambridge, United Kingdom

Mixed halide compositions offer interesting avenues to tune the bandgap of perovskites to make them suitable as wide bandgap absorbers in perovskite-based multijunction solar cells and as emitter layers in red and blue perovskite light emitting diodes (LEDs). However, the instability of bromide/iodide (Br/I) mixtures under light illumination has been long reported, where low-bandgap iodide-rich phases tend to form for >20% Br contents, resulting in the funnelling of photogenerated carriers and red-shifting of photoluminescence (PL). Over the years, various

mechanisms have been presented to account for such halide segregation effects – yet the exact mechanism remains elusive. Very recently, the model of halide oxidation has been found to be powerful in explaining the mechanism of excitation-induced halide segregation in lead-based mixed halide perovskite compositions and is consistent with most of the reported experimental observations.

On the other hand, several strategies related to compositional engineering and defect passivation have been devised to mitigate the issue of halide phase segregation under operational conditions. However, many of these approaches demonstrate the mitigation of halide segregation only under certain chosen operational conditions (e.g. light intensity, time under illumination, halide ratio etc.) and hence definitive conclusions regarding the applicability of those approaches under other (potentially harsher) conditions cannot always be guaranteed.

In this work, we systematically study the impact of Sn incorporation on the photostability of mixed halide perovskites. While a clear redshift in the PL peak and absorption onset is observed under light soaking for Pb-based compositions, which signifies photoinduced halide segregation, no such shifts are observed for Sn-containing compositions irrespective of the Pb/Sn mixing ratio. Furthermore, while halide segregation in Pb perovskites is often associated with an increase in luminescence under light, we observe an opposite effect of photodarkening for Sn-containing perovskites, possibly due to the formation of photoinduced defects. We also visualize the difference in the impact of light soaking between Pb and Sn-containing perovskites in the microscale using wide-field hyperspectral photoluminescence imaging. It is important to note that we explored a wide variety of processing and operational conditions to assess the extent of photostability of Sn-containing mixed halide perovskites, which suggests an intrinsic stability against halide segregation in these materials. Subsequently, we also investigated the impact of light soaking on the resulting charge carrier dynamics and charge transport in mixed halide perovskites with and without Sn in the composition, which again exhibit distinctive trends. Moreover, scan-rate dependent field effect transistor (FET) measurements and electrochemical impedance spectroscopy measurements on fabricated p-i-n solar cells, aided further by ab-initio simulations also reflect the trend of suppressed ionic migration in Sn-containing mixed halide perovskites as compared to their Pb-only analogues. Next, we rationalize the contrasting trends of photostability of Pb-only and mixed Pb-Sn mixed halide perovskites by suggesting a hypothesis of preferential Sn^{2+} oxidation over I^- oxidation in the presence of photogenerated holes, which seems to explain most of our experimental observations. Finally, we highlight important differences in the degradation pathways of Pb-only and mixed Pb-Sn based solar cells, thereby indicating that the seeming absence of halide segregation in mixed Pb-Sn devices does not alone guarantee an improvement in their operational stability.

Therefore, our work represents an important advance in the understanding of halide segregation behaviour in mixed halide perovskites, which can be further leveraged to demonstrate efficient and stable solar cells, LEDs and a plethora of other optoelectronic devices.

2:15 PM EN05.09.03
Diamine-Templated Crystal Growth of Perovskite Films for Record p-i-n Perovskite Solar Cells HaoChen[1,2], JunkeWang[1], BinChen[2] and EdwardSargent[1,2]; [1]University of Toronto, Canada; [2]Northwestern University, United States

Energy loss of perovskite/ETL interface is the limiting factor for pin perovskite solar cells, various methods are explored to address this issue, for example, post-treatment with organic salts are normally used to get more n-type surface, so as to gain good energy alignment between perovskite and ETL. Here, by using a diamine molecule in the bottom surface to template the crystal growth of perovskite film, we get highly oriented perovskite films with more n-type characters, after combining with the 2D passivation, the energy loss was reduced effectively, based on this, we get above 26% PCE for pin perovskite solar cells in the lab, and 25.75% PCE from fast scan and 24.9 % QSS PCE (Certified in Nrel), which are the record efficiencies for pin PSCs, and 1 cm2 devices also shows 23.8 % PCE, except for the record PCE, the devices also show great operational stability, after 1000 illumination, the device shows no degradation.

Current Understanding of Phase Transformations in Lead Halide Perovskites Juan-PabloCorrea-Baena; Georgia Institute of Technology, United States

Halide perovskites have shown great promise for applications that span from solar cells to lasers and radiation detectors. However, these materials suffer from rapid phase transformations upon exposure to external stimuli. Therefore, it is essential to unravel the mechanisms that lead to these phase transformations in order to design materials that can withstand different environmental conditions. Thus far, there is little understanding of how chemistries influence phase transformations in lead halide perovskite when these are exposed to external stimuli. In this presentation, I will discuss the role of chemistry on phase transformations of lead halide perovskites through in-situ synchrotron-based techniques. The importance of these phase transformations on the optoelectronic properties of the halide perovskite materials will also be discussed.

4:00 PM EN05.09.05
From PL-Inactive to PL-Active: Synthesis and Properties of Novel PL-Active 2D Lead-Free Double Perovskites ChunyangChi and AndrewB. Wong; National University of Singapore, Singapore

In this work, novel two-dimensional lead-free double perovskites ($(R)_4M_aM_bM_cX_8$, a+b+c=2) were synthesized to achieve novel compositional and dimensional tunability. Herein, PL-inactive $(PA)_4AgInBr_8$ was alloyed with Mn^{2+} with the goal of forming PL active materials.

Bandgap and PL emission turnability were explored through halogen substitution (chlorine and iodine). An enhanced PL emission was observed for mixed halogen phases. Three emission pathways are investigated including band edge emission, emission stemming from self-trapped excitons, and the unique energy transfer process of alloyed Mn^{2+} ions, which will be discussed.

Quantification of Strain and Its Impact on the Phase Stabilization of All-Inorganic Cesium Lead Iodide Perovskite HanK. Le[1], Chung-KuanLin[1], JianboJin[1], YeZhang[1], ZhenniLin[1], ArturasVaillionis[2,3], NobumichiTamura[4] and PeidongYang[1]; [1]University of California, Berkeley, United States; [2]Stanford University, United States; [3]Kaunas University of Technology, Lithuania; [4]Advanced Light Source, United States

Halide perovskites have emerged as a compelling class of materials and garnered significant interest for its impressive performance in photovoltaic technologies, with power conversion efficiencies (PCEs) of perovskite solar cells (PSCs) increasing from 3.8% to a certified 25.2% and rivaling commercial silicon solar cells in recent years. A type of all-inorganic perovskite, cesium lead iodide ($CsPbI_3$) draws special attention owing to its suitable bandgap for photovoltaics (~1.73 eV) and its superior thermal tolerance as compared to the organic-inorganic hybrid counterparts. Despite these advantages, a main obstacle to realizing the commercial applications of these materials lies in the long-term phase instability and interconversion between different $CsPbI_3$ polymorphs. The high-temperature (high-T) perovskite γ-phase of $CsPbI_3$ readily undergoes phase transition at ambient conditions to a low-temperature (low-T) non-perovskite δ-phase with a poorer optoelectronic performance, thus hindering commercialization of these materials in photovoltaics. Here, we present the epitaxial growth of $CsPbI_3$ nanoplates on muscovite mica single crystal substrates, and demonstrate that the high-T phase stability of these nanoplates is enhanced by a strained interface. Strain is measured as a function of nanoplate thickness on a single particle level through spatially resolved structural and optical characterizations, and found to increase with decreasing thickness. From quantitatively tracking the $CsPbI_3$ phase transition for thin (<400 nm) and thick (>400 nm) nanoplates using *in situ* photoluminescence optical microscopy, we observe a larger fraction of thin nanoplates still maintaining their high-T phase after one month as compared to the thick counterparts. The enhanced phase stabilization of the strained high-T nanoplates is most likely owing to the strain-induced energy destabilization for the low-T phase relative to the high-T phase. The strain is suggested to originate from several factors, including lattice mismatch, thermal expansion coefficient mismatch, and ionic and van der Waals forces that contribute to the strong substrate-lattice interaction. These findings establish a fundamental understanding of the impact of lattice strain on perovskite phase stabilization, thereby driving advancements in the rational design of long-term, stable optoelectronic devices.

Unraveling The Magnetic Interactions in Halide Double Perovskites: A High-Throughput Study UtkarshSingh[1], JohanKlarbring[1], IgorA. Abrikosov[1] and SergeyI. Simak[1,2]; [1]Linköping University, Sweden; [2]Uppsala University, Sweden

In recent years, lead-free halide double perovskites (LFHDPs) have attracted attention for their significant chemical versatility [1] and potential as multifunctional materials [2]. The exploration of their magnetic properties however, has remained relatively uncharted [3, 4]. Our study elucidates the mechanism of magnetic exchange interactions in halide double perovskites (HDPs), revealing a general propensity towards antiferromagnetic ordering with low Néel temperatures (< 50 K), while highlighting exceptions that are predicted to exhibit ferromagnetic behaviour and relatively high Curie temperatures.

Employing a high-throughput approach, we identified ferromagnetic compounds in $Cs_2HgCrCl_6$ (~ 450 K), $Cs_2AgNiCl_6$ (~ 190 K), and $Cs_2AuNiCl_6$ (~ 240 K) as noteworthy candidates, with the latter two exhibiting potential for robust half-metallicity due to a large gap in the insulating channel.

To comprehend the observed magnetic properties in HDPs, we leverage the Magnetic force theorem [5] and calculate energy-resolved and orbital-resolved magnetic exchange interactions.

Contextualizing these resolved magnetic interactions within the nature and strength of bonding interactions using Density of States (DOS) and Crystal Orbital Hamilton Population (COHP) [6] analysis, the reasons for observed disparities in magnetic strength are unveiled. The comparison of these findings with well known oxide double-perovskites exhibiting high Curie temperatures [7, 8] enriches our understanding of magnetism in HDPs, and underscores the intricate mechanisms at play.

This nuanced understanding enables a more informed approach towards the design of HDPs with tailored magnetic properties. By providing insights into the magnetic behaviors of HDPs that aim to guide potential design strategies, this research could represent a step towards a deeper understanding of HDPs and encourage further exploration in this dynamic field.

What is in Your Perovskite Precursors? Improving Reproducibility and Stability of Perovskite Films via Purification of Precursors ConnorDolan, SeanP. Dunfield, EmmaYakel, ShiweiLiu, JackR. Palmer and DavidP. Fenning; University of California, San Diego, United States

While much effort has been given to reducing or passivating intrinsic defects both in the bulk and at interfaces of perovskite devices, relatively few efforts have been made toward understanding and mitigating the presence of extrinsic impurities. Despite this, even small concentrations of extrinsic impurities have been shown to play a role in altering film formation and seeding the nucleation of macroscale degradation under operational stressors. Further, minute changes in precursor stoichiometry and impurity profiles even in different bottles of precursor from the same supplier have been shown to be a significant barrier to reproducibility in perovskite solar cell fabrication.
In this work, we demonstrate Solvent Orthogonality Nucleation Induced Crystallization (SONIC) purification for removing extrinsic defects present in commercially available precursors commonly used to fabricate high efficiency perovskite solar cells. SONIC purification uses the slow diffusion of an antisolvent into a perovskite precursor solution to induce supersaturation, enabling controllable growth of high quality perovskite single crystals. Using a combination of inductively coupled plasma mass spectrometry and proton nuclear magnetic resonance, we demonstrate that there are significant impurities present in even the highest purity commercially available precursors and that SONIC purification is more effective at removing impurities than strategies commonly employed in the literature. We demonstrate that SONIC purification is effective for both high purity (99.99% trace metals basis) and low purity (99% trace metals basis) from different suppliers. This enables increased reliability in processing of perovskite precursors toward consistent impurity profiles to mitigate batch-to-batch and supplier-to-supplier variability. Finally, we show that perovskite thin films made from purified precursors demonstrate improved performance and stability over films made from as-received precursors. SONIC purification provides a method for removing extrinsic defects present in commercially available precursors, enabling improved stability and reproducibility in perovskite fabrication.

Understanding the Switching Mechanism in Halide Perovskite Memristors DeepakYadav, KanhaiyaL. Yadav and MonojitBag; Indian Institute of Technology Roorkee, India

Halide perovskite memristors have garnered attention for storage and neuromorphic computing applications. However, the switching mechanism between high-resistive and low-resistive states remains insufficiently understood. This study investigates the switching mechanism in ITO/$MAPbBr_3$/Au memristors. Impedance spectroscopy was employed to analyze the set-reset states at different applied biases. Results indicate that at zero and low applied biases (<0.5 V), the ac conductivity follows Jonscher's power law, suggesting limited ion migration. However, anomalous conductivity behaviour was observed at high applied biases (>0.5 V), indicating ionic conduction at low frequencies. Additionally, we found that illumination leads to faster switching, attributed to enhanced halide ion/vacancy movement. In conclusion, this study deepens our understanding of charge transport in $MAPbBr_3$ perovskite-based memristors, facilitating the development of more efficient devices for widespread application.

8:00 PM EN05.10.02
Diverging Expressions of Anharmonicity in Halide Perovskites AdiCohen[1], ThomasM. Brenner[1], JohanKlarbring[2], RiturajSharma[1], DouglasH. Fabini[3], RomanKorobko[1], PabitraK. Nayak[4], OlleHellman[2] and OmerYaffe[1]; [1]Weizmann Institute of Science, Israel; [2]Linköping University, Sweden; [3]Max Planck Institute for Solid State Research, Germany; [4]Tata Institute of Fundamental Research, India

The structure-function relationship in materials sciences is based on the concept of the minimal unit cell as the representative building block. The harmonic approximation, which relays on the unit cell symmetry, provides simple solutions to atomic motions in the form of a well-defined normal modes. However, materials exhibiting strong anharmonicity challenge the representation of the minimal unit cell by violating the derived symmetry.
In this study, we conducted a comparative analysis of the anharmonic motion in $Cs_2AgBiBr_6$ and its lead-free counterpart, $CsPbBr_3$, to investigate the validity of the minimal unit cell in materials with pronounced anharmonicity. We observed significant differences in their expression of anharmonic behavior by applying low-frequency Raman spectroscopy and a symmetry-based analysis. In $Cs_2AgBiBr_6$, the anharmonicity manifests as a displacive phase transition while preserving well-defined normal modes across the measured temperature range. Conversely, $CsPbBr_3$ exhibits dynamic symmetry breaking, leading to the breakdown of the normal mode picture.
Based on these findings, we propose a criterion to determine how well the minimal unit cell, which represents the averaged structure, coincides with the local structure. We argue that the breakdown of the normal mode picture, as exemplified by $CsPbBr_3$, plays a critical role in accurately calculating and understanding the functional properties of materials.

Interstitial Defect Relaxation DFT Study of Lead Halide Perovskites KumarP. Miskin and PauletteClancy; Johns Hopkins University, United States

Perovskite solar cells have garnered a lot of attention in the last decade. The efficiency obtained for solar cells using metal halide perovskites (MHP) have exceeded 22%. A major reason for this is the high carrier lifetimes in these materials [1]. These high efficiencies have been obtained despite relatively high defect densities as compared to those in Silicon solar cells, giving rise to an appreciation of high defect-tolerance in MHPs. Polycrystalline films made using metal halide perovskites can exhibit high defect densities of ($10^{15} – 10^{16}$ per ����^{3}), with minimal effect on efficiency. However, the origin of this tolerance is still a matter of active research. Halide defects (vacancies and interstitials) are some of the most common defects in perovskites.

This is due to low defect formation energy in these systems. DFT studies exist to quantify the formation energies of halide defects [2]. Our work will study the relaxation of these interstitials back to their lattice site using DFT (Quantum Espresso). The recombination pathway as well as the activation energy for this relaxation will help us better understand how these defects affect the recombination time for photogenerated carriers. The pathway to relaxation can be estimated using Nudged Elastic Band calculations (NEB).

Water-Assisted Morphology and Crystal Engineering of Hybrid Organic-Inorganic Halide Perovskite: Implications for Optoelectronic Properties Andre LuizM. Freitas and JoseA. Souza; UFABC, Brazil

The versatile application of hybrid organic-inorganic halide perovskites relies heavily on their crystal organization, which gives rise to distinct electronic structures. By manipulating the dimensionality and incorporating quantum confinement effects within the layered building blocks composed of n layers of $[MX_6]^{4-}$ octahedra, the optoelectronic properties of lead halide perovskites can be further modulated. In this study, we present a water-assisted approach for the formation of microwires and 2D layered morphologies, achieved through a dissociation-recrystallization process using $MAPbBr_3$ microcubes. Along with a systematic alteration of the bandgap energy, our investigation uncovers variations in trap- and exciton-assisted recombination lifetimes, attributed to changes in exciton binding energy and structural confinement. Notably, the control of water and organic molecules within the precursor ionic solution plays a pivotal role, inducing or inhibiting growth and confining charge transport in specific directions, resulting in modified optical properties and exciton dynamics. This work sheds light on the significance of water-assisted methodologies and structural manipulation in hybrid organic-inorganic halide perovskites, providing a pathway towards advanced control and optimization of their optoelectronic characteristics.

Self-Leveling Inks for Engineering Large Area Uniformity in High-Performance Flexography-Printed Perovskite Solar Cells JuliaHuddy and William J.Scheideler; Dartmouth College, United States

Solution processing of metal halide perovskites can offer opportunities for efficient roll-based manufacturing of emerging flexible optoelectronic devices such as lightweight photovoltaics and light emitting diodes (LEDs). However, current techniques for perovskite deposition are limited by damaging subtractive scribing steps and lack wide processing windows that offer high uniformity. This work presents a class of self-leveling perovskite inks with specifically engineered viscosity, Marangoni coefficients, and drying rates to ensure ultra-uniformity. We show rapid open-air fabrication of double cation perovskite solar cells (PSCs) using high-speed (60 m/min) flexography, printing films over 500 cm^2 in < 1s with high photoluminescent uniformity (RMS variation < 4 %). Integrating inline N_2 drying, we achieve highly uniform patterns with < 25 µm features and single-micron line edge roughness, ideal for solar module and perovskite LED integration. XRD and SEM reveal the impact of the ink design and anion composition on perovskite crystallization while 2D scanning photoluminescence (PL) resolves a correlation between ink leveling dynamics and optoelectronic quality. This allows us to optimize the self-leveling inks for mitigating Saffman-Taylor instabilities inherent in contact-based ink transfer, leading to enhanced uniformity, higher photovoltaic performance, and improved operational stability. Our flexography printed n-i-p planar PSCs achieve a photovoltaic conversion efficiency > 20 %, the highest reported for PSCs fabricated by roll-based methods. Collectively, these results illustrate how self-leveling inks can broaden process windows for perovskite device manufacturing by healing coating defects rather than freezing non-uniformities that otherwise lead to stability weakpoints.

8:00 PM EN05.10.06
Towards Highly Efficient Fully Evaporated Perovskite/Si Tandem Solar Cells SofiaChozas Barrientos[1,2], LidonGil-Escrig[1,2], FedericoVentosinos[1,2], ManuelPiot[1,2] and HenkJ. Bolink[1,2]; [1]Instituto de Ciencia Molecular (ICMol), Spain; [2]Universitat de València, Spain

Thanks to its abundance on Earth, its suitable bandgap, and its non-toxicity, silicon dominates over 90% of the photovoltaic market. However, the efficiency of single-junction silicon cells is approaching its theoretical limit of 29%, with a current experimental record of 26.8%. In the quest for overcoming this limit and for reducing the cost of electricity, perovskite/silicon tandem cells have become the most promising contenders.

Pyramid texturing is a standard process in the fabrication of the best performing silicon technologies since it is known to enhance light trapping in the infrared and to reduce primary reflection due to double-bounce effects. However, most of the perovskite-on-Si work has been reported on flattened silicon substrates due to the incompatibility of the textured surfaces with the standard solution-processing of the top perovskite absorbers.

Here, we present the conformal vacuum deposition of wide bandgap perovskites atop fully textured silicon heterojunction cells. We have optimized vacuum deposition processes for different wide bandgap perovskite compositions, mainly FACsPbIBr and MAPbIBr. Their bandgaps range between 1.65 and 1.70 eV, making them ideal candidates as top cells in perovskite/Si tandems. As evidenced from cross-sectional SEM images, our co-evaporation processes enable a conformal coverage of the pyramidal surface of the silicon substrates avoiding shorts between the subcells. This leads to Voc values of above 1.8 V, which correspond well to the sum of the Voc of the perovskite top cell and the silicon bottom cell. Moreover, the use of QCM sensors for monitoring the sublimation of the top cell enables fine tuning of the absorber thickness. This allows to achieve current matching between the subcells as we have been able to demonstrate through EQE measurements. The J-V curves show FFs above 70% and no detectable hysteresis. All in all, we will show our latest results on perovskite/Si tandems employing textured Si and fully sublimed top cells.

8:00 PM EN05.10.07
The Outstanding Role of Dielectricity in Hybrid Solar Cell Absorbers DoruC. Lupascu, YoungU. Jin, AndreiKarabanov, LarsL. Schaberg and NielsBenson; University of Duisburg-Essen, Germany

The perovskite crystal structure has been hosting a multitude of functionalities discovered over the last seventy years spanning from magnetism, ferroelectricity to supraconductivity. The most recent developments have brought forward hybrid halide perovskites containing a halide ion and small organic molecules as constituents of the crystal structure. The forerunner material is methylammonium lead iodide. One of the most remarkable properties of these emergent materials is their high charge carrier mobility and an outstanding robustness of the electronic properties towards lattice defects. In this presentation the role of dielectric effects will be discussed covering a very broad frequency range. Paraelectric effects will be contrasted to the role of apparent ferroelectricity, charge disorder and the potential misinterpretation of a number of experiments in this context. The hyperpolaron is shown as the charge carrier type peculiar for the hybrid perovskites.

8:00 PM EN05.10.08
Investigating The Effect of Annealing Environments on Cs and MA Containing FAPI Perovskites MuhammadU. Farooq[1], SevanGharabeiki[1], DingYong[2], MohammadK. Nazeeruddin[2], SusanneSiebentritt[1] and AlexRedinger[1]; [1]Université du Luxembourg, Luxembourg; [2]École Polytechnique Fédérale de Lausanne, Switzerland

Interface and grain boundary passivation is essential to achieve high power conversion efficiencies (PCE) in solar cells. In this work, we show how different atmospheres during post-deposition annealing of $Cs_{0.05}MA_{0.05}FA_{0.9}PbI_3$ can be used to change the surface properties and reduce interface recombination.
A comparative study was carried out on high-efficiency (~24%) $Cs_{0.05}MA_{0.05}FA_{0.9}PbI_3$ perovskites [1]. After deposition, these perovskite absorbers underwent annealing in three different environments i.e., N_2, O_2, and air. Device performance was best for the samples annealed in air, reaching 25.1% power conversion efficiency, whereas the devices produced from absorbers annealed in N_2 and O_2 showed reduced PCEs. Calibrated Photoluminescence (PL) measurements were carried out on all samples to extract the quasi-Fermi level splitting (QFLs). In contrast to the device results, the nitrogen-annealed sample exhibited the highest QFLs value in agreement with time resolved photoluminescence where we found the longest decay times. A comparison

between QFLs and V_{OC} showed that the air-annealed samples, which produced the best devices, were not interface-limited, whereas the other two sample types showed a substantially lower V_{OC} compared to the QFLs. The PCE improvement after air annealing, therefore, needs to be related to better interface passivation. Although the N_2 annealed samples exhibited the best optoelectronic properties, i.e., highest QFLs, the interface to the extraction layer was substantially worse, compared to the air-annealed samples.

To gain more insights into the surface properties, atomic force microscopy (AFM) and Kelvin probe force microscopy (KPFM) measurements were conducted in a nitrogen environment. The air-annealed sample showed the highest mean work function (4.9 eV), the O_2-annealed sample showed a slightly lower mean work function (4.7 eV), while the N_2-annealed sample exhibited the lowest work function amongst the three (4.6 eV). In all three cases, a PbI_2 secondary phase was observed on the surface of the films. It was found that the PbI_2 work function was lower than the mean perovskite work functions for both N_2 and O_2 annealed samples. However, it was higher than the mean work function for the air-annealed sample. In addition to the average work functions, we analyzed approximately 100 grain boundaries for the three sample types and found that the different annealing atmospheres did not change the grain boundary band bending significantly.

From our measurements, we conclude that annealing in different atmospheres allows changing the recombination activity of the surface. Both the perovskite surface and the PbI_2 secondary work functions were affected by the treatment. Annealing in air showed to be most beneficial since the surface was better matched to the extraction layer allowing for higher V_{OCs} and thereby better devices.

Controlling The Crystallization of Pure Bromide Quasi-2-Dimensional Perovskite Crystals for High Efficiency Pure-Blue Light-Emitting Diodes SeoyeonPark[1], JoonyunKim[2], GuiM. Kim[1], Doh C.Lee[1], SooheyongLee[3], Byeong-GwanCho[3] and ByunghaShin[1]; [1]Korea Advanced Institute of Science and Technology, Korea (the Republic of); [2]Samsung Advanced Institute of Technology, Korea (the Republic of); [3]Korea Research Institute of Standards and Science, Korea (the Republic of)

Metal halide perovskites have emerged as promising candidates for next-generation display applications due to their remarkable color purity and tunable bandgaps by adjusting the composition of halide anions. Mixed halide perovskites allow for facile bandgap tunability through composition control, but they have limitations in terms of emission spectral stability due to halide segregation occurring during device operation. An alternative approach to widen the bandgap involves constructing a quasi-2-dimensional structure using a single halide anion, leveraging the confinement effect. However, this approach often results in multi-bandgap phases, leading to a red-shifted emission due to energy funneling toward a phase with a bandgap lower than the target. Here, we synthesized $(PBA)_2Cs_{n-1}Pb_nBr_{3n+1}$ quasi-2D perovskite crystals where '*n*' indicates the number of $PbBr_6$ octahedral sheets in each repeating unit. To achieve pure-blue emission within the range of 460-470 nm, the target wavelength by the ITU-R Recommendation BT.2020 (Rec. 2020), the industry standard for 4K and 8K ultra-high definition television standard, we manipulated the crystallization process of the quasi-2D perovskite prepared by solution process. The manipulation involved controlling the distribution of different '*n*' (i.e., different bandgap) phases, with a specific focus on ensuring the dominance of the phase with the smallest bandgap, which is also the target emission bandgap. We attained pure-blue photoluminescence (PL) at 461 nm with a relatively narrow full-width at half maximum (FWHM) of 25 nm through a two-step crystallization control process. Initially, we performed a coarse adjustment of the PL wavelength by changing the solute concentration and solvent polarity, as these factors heavily influence the diffusion of cations, a crucial determinant for the value of '*n*'. Subsequently, we further enhanced the PL quantum yield (PLQY) from 31% to 51% through fine-tuning in the second-step crystallization process, which involved the incorporation of trioctylphosphine oxide (TOPO) as an additive during the antisolvent treatment. The antisolvent treatment with TOPO slightly slowed down the diffusion of precursors, resulting in halide-vacancy passivation and well-ordered crystals and leading to faster carrier transfer between phases. Based on these strategies, we successfully fabricated pure-blue light-emitting diodes (LEDs), which exhibited a relatively low turn-on voltage of 3V and an external quantum efficiency of 2.5% at an emission peak of 465 nm with a FWHM of 29 nm.

8:00 PM EN05.10.10

Compositional Engineering of Single-Crystal Perovskite for Highly Efficient Photovoltaics You JinAhn[1], Jin YoungKim[1] and Ik JaePark[2]; [1]Seoul National University, Korea (the Republic of); [2]Sookmyung Women's University, Korea (the Republic of)

Organic-inorganic lead halide perovskite materials have received great attention for promising opto-electric devices. To achieve high performance solar cells, defect control in perovskite materials is very crucial. Single-crystal perovskite-based solar cell exhibits excellent carrier diffusion length and light absorption due to significantly reduced bulk defects. In here, we discuss compositional engineering of single-crystal perovskite films for highly efficient perovskite solar cells. Single crystal perovskite films were grown by space-limited inverse temperature crystallization (ITC) method. Due to different solubility of perovskite precursor solute, γ-butyrolactone (GBL) and *N*,*N*-dimethylformamide (DMF) solvent ratio should be precisely controlled for compositional engineering. We investigated the effect of mixture solvent on growing single crystal perovskites. X-ray diffraction patterns confirmed that composition of perovskite can be controlled by the composition of perovskite precursor solution. We successfully synthesize wide-bandgap perovskite films and confirmed using UV-vis-NIR analysis. Single-crystal films over 4 mm were grown on ITO/PTAA substrates, and we fabricated single-crystal perovskite-based solar cells. The device shows high external quantum efficiency due to the micrometer-size film thickness. The best performing devices exhibited power conversion efficiency of over 20%.

8:00 PM EN05.10.11

Atomistic Origin of Transparent Absorption Spectra of Halide Perovskites Young WonWoo[1,2], SavyasanchiAggarwal[3], SeánR. Kavanagh[3,2], AlexM. Ganose[2] and AronWalsh[2]; [1]Yonsei University, Korea (the Republic of); [2]Imperial College London, United Kingdom; [3]University College London, United Kingdom

Differential spectroscopy has emerged as a valuable characterisation tool in materials science. Transient absorption spectroscopy (TAS) involves probing changes in optical absorption following laser excitation. While TAS spectra provide information about carrier recombination kinetics, interpreting individual features remains challenging. In this talk, we present a novel procedure to calculate TAS spectra for crystals using first-principles density functional theory calculations. Our approach simulates changes in band-to-band transitions within the electronic band structure, encompassing ground-state bleaching and photo-induced absorption processes.

This methodology is particularly relevant to the investigation of halide perovskite materials, where TAS can provide insights into their unique optical properties and charge carrier dynamics. Applications will be given to a range of inorganic and hybrid perovskite compositions. Our procedures are implemented in the PyTASER code, an open-source package that facilitates the implementation of our simulation approach to help accelerate materials characterisation and bridge the gap between modelling and measurements for researchers working on halide perovskites.

Optimal Passivation Strategy using (α-Methylguanido)acetic Acid for Stable Perovskite Solar Cells JihyunMin, Dae HwanLee and TaihoPark; Pohang University of Science and Technology, Korea (the Republic of)

Defects are easily generated in perovskite, and these defects reduce the efficiency of perovskite solar cells (PSCs). Therefore, it is important to control defects. In this study, we tried to passivate perovskite using creatine, which is known as (α-Methylguanido) acetic acid. To find the optimal passivation strategy, we conducted two methods: passivating bulk perovskite by adding creatine as an additive to the perovskite precursor, and passivating the surface of perovskite by introducing it as an interlayer. The results showed that only the method of introducing creatine into the interlayer formed 2D perovskite. This is because the activation energy to form 2D perovskite when introduced as an interlayer is smaller than when introduced as an additive, and it can be formed at an annealing temperature of 150 °C. When creatine was introduced into the interlayer, it was confirmed that the appropriate energy level was appropriately adjusted for good charge transfer and the defect density was also reduced. As a result, PSCs introduced with creatine recorded a PCE of 22.6%, showing high stability even under high temperature conditions of 85 °C and 50% relative humidity conditions.

8:00 PM EN05.10.13

Exploring a Novel Family of Conjugated Polymers for High Efficiency and Thermally Stable Perovskite Solar Cells SanggyunKim, SinaSabury, Carlo Andrea RiccardoPerini, JohnR. Reynolds and Juan-PabloCorrea-Baena; Georgia Institute of Technology, United States

Long-term stability remains to be one of the critical challenges for organic-inorganic hybrid perovskite solar cells (PSCs). One of the most important limiting factors toward achieving long-term stability has been attributed to the hole transport layer (HTL), originating from interfacial degradation between perovskite and HTL, thermal/moisture induced degradation, and ionic migration. In this work, we examine novel conjugated polymer (CP)-based HTLs that are resistant to high temperatures in PSCs. CPs offer efficient hole extraction/transport properties, easy processing, and low-production cost. We highlight differences in optoelectronic properties, crystallinity, and stability of the CPs with respect to its different chemical structures using measurements including UV-VIS, UPS, DSC, GIWAXS, and XPS. These new polymers are further incorporated into devices to analyze its photovoltaic performance and stability at elevated temperature under illumination over 200 hours.

Charge Transfer Doping of Ruddlesden–Popper Metal–Halide Perovskites via Bulk Incorporation of Organic Molecular Dopants Kyeong-YoonBaek[1,2], JonghoonLee[1], JeongjaeLee[1], HeebeomAhn[1], YongjinKim[1], KeehoonKang[1] and TakheeLee[1]; [1]Seoul National University, Korea (the Republic of); [2]Harvard University, United States

Ruddlesden–Popper metal–halide perovskites have recently attracted much attention as next-generation semiconducting materials due to their outstanding opto-electrical properties. However, these low dimensional materials critically suffer from relatively poor electrical conductivity, which is challenging to tune with traditional method of bulk atomistic doping. While doping with molecular dopants, a family of versatile dopants for molecular design has been suggested as a solution to this problem.[1,2] Nonetheless, the action of these dopants was typically restricted to perovskite surfaces, therefore significantly reducing their doping potential. In this study, we report successful bulk inclusion of 'magic blue', a molecular dopant, into two-dimensional (2D) Ruddlesden–Popper perovskites.[3] Our doping strategy of immersing the perovskite film in dopant solution increased the electrical current up to ~60 times while maintaining clean film surface. We provide a full mechanistic picture of such immersion doping, in which the solvent molecule facilitates bulk diffusion of dopant molecule inside the organic spacer layer, based on the optimum solvent processing. The immersion doping method developed in this work which enables bulk molecular doping in metal–halide perovskites in general will provide a strategic doping methodology for controlling electrical properties of low dimensional metal–halide perovskites for electronic and optoelectronic devices.

Switchable Interfacial Reaction Enables Bright and Stable Deep-Red Perovskite Light-Emitting Diodes YangLiu and YizhengJin; Zhejiang University, China

The all-inorganic black phase $CsPbI_3$ perovskite has garnered significant interest for its exceptional optical properties, superior chemical and thermal stability, excellent charge transport characteristics, and solution processability, making it a promising material for photovoltaic applications and light-emitting devices. Despite these advantages, the requirement of high formation temperature exceeding 300 ºC and the tendency for spontaneous phase transition to yellow non-perovskite phase at room temperature present significant challenges for the development of high-performance $CsPbI_3$-based optoelectronics (*ACS Energy Lett.* **3**, 1787–1794 (2018); *Science* **365**, 679–684 (2019)).

One approach to address these problems is to grow nanocrystals with ligand-passivated surfaces which can passivate the surface traps and stabilize the black phase $CsPbI_3$. Similarly, quasi-2D $CsPbI_3$ perovskites with high PLQYs can be formed and stabilized under low temperatures. However, the long-chained ligands of QDs or the excess large organic ammonium spacer layers of the quasi-2D perovskites shall deteriorate the charge transport in perovskite light-emitting diodes (PeLEDs), hampering the realization of stable and bright PeLED.

Alternatively, it has been established that the interfacial deprotonation reactions between the perovskite intermediates and the basic ZnO-based ETLs can regulate the crystallization process by an interionic exchange process, enabling the formation of high-quality bulk $CsPbI_3$ perovskite films (*Nat. Commun.* **11**, 4736 (2020)). The obtained films maintain the excellent carrier transport property of $CsPbI_3$ and would alleviate the Auger effects. These superiorities suggest that $CsPbI_3$ PeLEDs based on ZnO ETLs would deliver efficient electroluminescence (EL) under high current densities.

However, the uncontrollable deprotonation reaction between ZnO and perovskites would further exhaust the residual organic ammonium cations and lead to the undesired phase transition. As a result, the long-term operational stability of the $CsPbI_3$ PeLEDs remains modest. For example, the most stable PeLED based on this method shows a T_{50} lifetime of 1.7 h under a constant current density of 100 mA cm^{-2} (*Adv. Mater.* **33**, 2105699 (2021)). A comprehensive understanding and rational design of the chemically active interfaces between perovskite and the ZnO layer is crucial for developing high-performance perovskite optoelectronic devices.

Here, by designing a switchable interfacial deprotonation reaction between perovskite and the ETLs, we fabricate high quality $CsPbI_3$ perovskite films for stable and bright deep-red LEDs. Our approach starts with a precursor solution containing guanidium iodide and a layer of alkaline $Zn(OH)_2$. Upon annealing, the interfacial deprotonation reaction is switched on, leading to the formation of high-quality $CsPbI_3$. Simultaneously, the alkaline $Zn(OH)_2$ layer is in-situ converted to the alkalescent ZnO, which subsequently switches off the detrimental interfacial reaction that generates the undesirable yellow-phase $CsPbI_3$ perovskites. As a result, PeLEDs based on $CsPbI_3$ show a long half-lifetime of ~33.6 h at 100 mA cm^{-2} and an exceptionally high radiance of ~1980 W sr^{-1} m^{-2}. Moreover, by partly substituting iodide with bromide, we achieve colour-stable deep-red PeLEDs with an enhanced luminance of over 33500 cd m^{-2} and an unprecedented operational half-lifetime of 50.3 h at 100 mA cm^{-2}, representing the brightest and most-stable solution-processed LEDs in the entire deep-red region.

8:00 PM EN05.10.16
Additive Engineering in 2-Methoxyethaol Based Perovskite Film Formation for Perovskite Solar Cells Sung HunLee and Hyo JungKim; Pusan National University, Korea (the Republic of)

Perovskite solar cells (PSCs) have attracted significant attention because of their unique characteristics such as low-cost fabrication through solution processes and excellent photoelectric properties. Solution-processed perovskite films using polar aprotic solvent such as dimethyl sulfoxide (DMSO) generally required auxiliary process like anti-solvent drop. However, the anti-solvent dripping process has strict process window to form a uniform film such as dripping duration, volume, and pressure of the anti-solvent.
Recently, solvent engineering using 2-methoxyethanol (2MOE), which has selective solubility that dissolves methylammonium iodide (MAI) but not PbI_2 alone, have been studied for perovskite film formation for an anti-solvent free process. Although perovskite phase film could be obtained on the 2MOE solvent system without the anti-solvent process, the film generally has many pinholes leading to low power conversion efficiency (PCE) in PSCs. This problem is caused by low coordination with the precursor and high volatile of 2MOE.
To overcome this issue, we applied several additives, which affect to the kinetics of crystallization, in the 2MOE-based anti-solvent free process. First, we used various co-solvents, such as dimethyl sulfoxide (DMSO) and N-methyl-2-pyrrolidone (NMP), that can induce intermediate phases in which highly coordinated system with the precursors and solvents (MAI-PbI_2-DMSO and MAI-PbI_2-NMP). The formation of intermediate phases retarders crystal growth of perovskite and leads to high crystallinity of the perovskite. Through this, we found that NMP is a suitable additive for pinhole free perovskite film. We obtained an efficiency of 20.39% with the maximum efficiency for the device based on the $MAPbI_{3-x}Cl_x$ film fabricated with a 2MOE-based solution containing NMP.
Second, we compared film formation by adding alkyl amines with different chain lengths in 2MOE single solvent system. Through this, we found that the uniform and dense film could be obtained by adding small molecule of oleyamine (OAm) having long 18-carbon chain without anti-solvent dripping. In that study, we measured real-time grazing incidence wide angle X-ray scattering (GIWAXS) in spin cast process to study how the added alkylamine affected to film quality. We found that the longer alkyl chain of alkyl amines induced the faster nucleation and fast crystal growth of perovskite in film formation. We fabricated inverted PCSs using the high-quality film containing OAm as a light absorption layer and obtained PCE of 21.01%.

Metal Microgrid Embedded Transparent Electrode for Enlarge Perovskite Solar Cells HyungwooKim and KwanyongSeo; Ulsan National Institute of Science and Technology, Korea (the Republic of)

Organic-inorganic hybrid perovskite (OIHP) solar cells have attracted much attention as next-generation energy devices. In the fabrication of OIHP solar modules, the unit cells are designed by considering the charge carrier loss in the collection process through transparent electrodes. However, in the modularization process of OIHP solar cells, the optical dead area increases, resulting in the degradation of the overall module efficiency. To mitigate the efficiency loss, it is crucial to enlarge the size of the unit cells. However, as the unit cell size increases, the power loss due to the inherent electrical resistance of transparent electrodes also becomes more critical, leading to a decrease in the fill factor (FF) of OIHP solar cells and modules. For example, when the voltage and current density at the maximum power point of the OIHP solar cell is 1.0 V and 23.5 mA/cm^2, respectively, the power loss will become the same as the overall photo-generated power when the carriers need to move over 3.5 cm to be collected through the ITO layer which has a sheet resistance of 10 ohm/sq. Therefore, the lower sheet resistance of transparent electrodes would be essential to realize the larger-sized OIHP solar cells. Here, we report a hybrid transparent electrode in which a metal microgrid is embedded into the glass substrate, and ITO covers the substrate. The hybrid electrodes exhibit excellent sheet resistance of lower than 1 ohm/sq and comparable optical transmittance (~82%, @300-800 nm) to that of ITO/glass substrate (~83%, @300-800 nm). When utilizing the developed hybrid electrode, the OIHP single solar cell with a size of 12.25 cm^2 shows an open-circuit voltage of 1.04 V, a short-circuit current density of 20.1 mA/cm^2, FF of 65.8%, and an overall efficiency of 13.8%. In particular, the FF of the OIHP solar cell based on the hybrid electrode is 2.01 times higher than that of the OIHP single solar cells based on an ITO/glass substrate (32.7%), confirming that charge carriers are collected efficiently. Our work suggests enormous potential for significant performance improvement of large-scale OIHP solar cells.

8:00 PM EN05.10.18
Hybrid Energy Harvester Based on ZnO Piezoelectric Nanogenerator and Perovskite Solar Cell YuanZhang, JoeBriscoe and XuanLi; Queen Mary University of London, United Kingdom

Mechanical energy is the one of the most abundant and accessible energy sources, and has been widely harvested by large-scale technologies such as wind power or tidal stream generators. Piezoelectric nanogenerators (PENGs) provide a potential way to convert small mechanical energy such as body motion or vibration into electricity, which can be used to power small portable electronics, medical bio implants, remote wireless sensors etc.[1] Also, solar energy offers the potential to provide much higher power levels than motion since the sun delivers more energy to the earth in 1 h than the entire planet consumes in one year. However, light is not always available, nor is movement, therefore a hybrid energy harvester that can make use of both sources provide a more reliable and high-level of power for small, portable or self-powered devices.
Here, a solar and piezoelectric hybrid energy harvester (HEH) combining PENGs and perovskite solar cell with the structure of PET/ITO/ZnO seed layer/ZnO nanorods/perovskite/hole transport layer/Au (Figure a) was designed, fabricated and tested. Oscillation (NG) and illumination (PV effect) testing indicated that HEHs operated as kinetic and solar energy harvesters both separately and simultaneously. (Figure b) The length and diameter of ZnO nanorods (Figure c and d), and the recipe of perovskite ($MAPbI_3$, $CsPbI_2Br$ and $CsPbI_{1.5}Br_{1.5}$) were optimised to achieve the enhancement of both PV and NG output performance. The coupling effect between perovskite and piezoelectric ZnO nanorods, as known as the piezo-phototronic effect, was also investigated.

8:00 PM EN05.10.19
Solvent-Annealing Assisted 3D Printing of High-Performance, Freestanding Perovskite Nanolasers ShiqiHu and Ji TaeKim; The University of Hong Kong, Hong Kong

Inorganic metal halide perovskites are emerging as promising optoelectronic materials due to their strong, tunable, and high-color-purity photo- and electroluminescence, and solution processability[1–3]. Recently, extensive research has been made to utilize perovskite nanowires as lasers due to their structural benefits such as ultra-compact sizes, highly localized coherent output, and efficient waveguiding[4,5]. The current fabrication of perovskite nanowires relies on electron beam lithography, photolithography, chemical vapor deposition, solution-phase synthesis, and nanoimprinting. That is to say, these processes are energy- and labor-intensive, which is in stark contrast with the industrial low-cost requirements. Furthermore, technological challenges associated with individual tailoring of nanowire geometries remain unresolved, making it difficult to manipulate stimulated emission characteristics at the single nanowire level. A new method that can fabricate perovskite nanowires with programmed shape, dimension, and placement is in great demand for addressing the abovementioned issue.

Here, we demonstrate an electrohydrodynamic (EHD) 3D printing of perovskite nanowires for high-performance bespoke lasers. The printed perovskite nanowire presents a two-photon pumped Fabry–Pérot (FP) mode lasing. By adjusting the height of a freestanding nanowire at will, we are able to select the lasing mode and also control the lasing threshold and mode spacing ($\triangle\lambda$). On this basis, we successfully demonstrated the 3D printed nanowires arrays for multi-level anti-counterfeiting security labels by storing information in the cavity-height-dependent features such as the lasing threshold and mode spacing ($\triangle\lambda$), which are unclonable. More importantly, solvent annealing was exploited to increase the grain size and crystallinity by promoting recrystallization in the printed nanowire. As a result, the lasing threshold was drastically improved from 25 $\mu J/cm^2$ to 3 $\mu J/cm^2$, which is the leading record for $CsPbBr_3$ FP lasers. It is also worth mentioning that the advanced features of our technique such as maskless operation and low-cost production with high stability make it an effective platform to bring the proof-of-concept demonstration into practical commercial application. Likewise, these outcomes not only give us inspiration for the function-oriented design of the nanolaser-based devices but also facilitate the development of high-performance perovskite-based photonic anti-counterfeiting applications. Last but not least, our method could provide an excellent platform to construct scalable, on-demand laser-based photonic devices.

8:00 PM EN05.10.20
Multifunctional Phosphine Oxide Additives for High-Efficiency $CsPbBr_3$ Perovskite LEDs Jung MinHa[1], Jong minHan[2], Myoung HoonSong[2] and Han YoungWoo[1]; [1]Korea University, Korea (the Republic of); [2]Ulsan National Institute of Science and Technology, Korea (the Republic of)

Perovskite light-emitting diodes (PeLEDs) are gaining attention as next-generation display devices due to their narrow bandwidth, high external quantum efficiency (EQE), and luminance. The crystallinity, crystal size, and defects density of perovskite have strong impacts on its optical and photoelectrical properties, as they generate trap states that induce non-radiative recombination, leading to low EQEs in the device. To achieve high-performance perovskite emissive layers, various additives have been utilized for defect passivation, including Lewis bases such as amines, carboxylates, and phosphine oxides. In particular, triphenylphosphine oxide (TPPO) not only efficiently passivates defects through strong binding with lead ions but also provides robust stability against external environmental stimuli such as oxygen, moisture, and heat. In this study, TPPO-2 and TPPO-4, where two and four TPPO molecules are covalently bonded, respectively, were introduced into the 3D nanostructured perovskite emissive layer and their effects on crystalline growth and device performance were studied depending on the number of TPPO functional moieties. Bifunctional or tetrafunctional TPPO derivatives not only effectively suppressed surface defects by forming stronger bonds with $PbBr_2$ but also delayed the binding of bromide with $PbBr_2$ due to large steric hindrance when mixed with the perovskite precursor, allowing the formation of perovskite films with smaller grain size. The PeLEDs with the tetrafunctional TPPO-4 showed the best EQE of ~21%, demonstrating their great potential as a multifunctional additive.

8:00 PM EN05.10.21
Nanostructure Strategies for Improved Perovskite Solar Cells AntonioGarcia-Martin; Instituto de Micro y Nanotecnologia, CSIC, Spain

Organic-inorganic hybrid perovskite solar cells have attracted much attention due to their high power conversion efficiency (＞23%) and low-cost fabrication. Directions to further improve these solar cells include strategies to enhance their stability and their efficiency by modifying either the perovskite absorber layer or the electron/hole transport layer. For example, the transparent electron transport layer (ETL) can be an important tuning knob influencing the charge extraction, [1] light harvesting, [2] and stability [3] in these solar cells, or the use of up-conversion nanoparticles to get better performance in the near IR part of the visible spectrum. [4] Here we present two strategies based on nanostructuration, first a fundamental study of upconversion fluorescence enhancement effects near Au nanodisks by scanning near-field optical microscopy and second the effects of a nanocolumnar TiO2 layer on the performance and the stability of Cs0.05(FA0.83MA0.17)0.95Pb(I0.83Br0.17)3 perovskite solar cells. For the first case, the enhancement and localization of light near the metallic structures are directly visualized by using a single Er/Yb-codoped fluorescent nanocrystal glued at the end of a sharp scanning tip. [5] For the second we find that, compared to devices with planar TiO2 ETLs, the TiO2 nanocolumns can significantly enhance the power conversion efficiency of the perovskite solar cells by 17 % and prolong their shelf life. By analyzing the optical properties, solar cells characteristics, as well as transport/recombination properties by impedance spectroscopy, we observed light-trapping and reduced carrier recombination in solar cells associated with the use of TiO2 nanocolumn arrays. [6]

Beginner's Guide to Visual Analysis of Perovskite Solar Cell Current-Voltage Characteristics AlbertThese[1,2], ChristophJ. Brabec[1] and VincentLe Corre[1]; [1]Institute Materials for Electronics and Energy Technology, Germany; [2]Friedrich-Alexander-Universität Erlangen-Nürnberg (FAU), Germany

The current-voltage characteristic (JV) is a critical tool for understanding the behavior of solar cells. In this presentation, I will provide an overview of the critical aspects of JV analysis and introduce a user-friendly flowchart that facilitates the swift identification of the most probable limiting process in perovskite solar cells, based mainly on the outcomes of light-intensity-dependent JV measurements.
The flowchart was developed through extensive drift-diffusion simulations and a rigorous literature review, with a specific focus on perovskite solar cells (it is also applicable for organic solar cells with minor adjustments). Hereby, each loss mechanism is supported by a drift-diffusion simulation showing the exact influence on the main JV parameters, namely short-circuit current, open-circuit voltage, and fill factor. The flowchart also suggests an additional experiment besides JV characteristics to get a more accurate and definitive prediction of the main losses.
It is therefore a valuable starting point for the analysis of experimental data and provides guidance to quantify the main loss processes of perovskite solar cells.

Interplay of Structural and Optoelectronic Properties in Triple-Cation Mixed-Halide Perovskites TomJ. Savenije, JiashangZhao, SanderLooman, XiaohuiLiu, ReinderBoekhoff, BahiyaIbrahim and JosThieme; Delft University of Technology, Netherlands

State-of-the-art triple cation, mixed halide perovskites have been extensively studied in perovskite solar cells in both n-i-p and p-i-n configurations showing very promising performances and stabilities. However, fundamental understanding of how the structure and morphology of $Cs_{0.05}FA_{0.85}MA_{0.10}Pb(I_{0.97}Br_{0.03})_3$ affect the electronic properties is lacking, in particular for samples with a small excess of PbI_2. Despite the advantages of using excess PbI_2 with respect to the improved performance, also stability issues are reported. Therefore, it is worth to investigate the role of excess PbI_2 at various phases. Here temperature-dependent XRD, photoluminescence (PL) in combination with electrodeless microwave photoconductivity measurements (TRMC) were carried out on stoichiometric CsMAFA thin films (control) and on films with 5% excess PbI_2. Angle dependent XRD shows that for the latter sample the PbI_2 resides predominantly at the interface between the quartz substrate and perovskite. Temperature dependent XRD indicates that both CsMAFA samples undergo a phase transition from cubic to tetragonal at ~ 280 K, which is coupled to a decrease in PL intensities and an enhancement of the charge carrier mobilities. Next, a second transition at ~ 170 K results in an opposite trend with increasing PL intensities, while photoconductivity signals are substantially reduced. It is found that for the control sample the latter transition is retarded by the substrate leading to a layered system comprising both structures. This leads to very large differences in photoconductivity between excitation from the front and through the substrate. We suspect that for the excess PbI_2 sample, the PbI_2 at the interface cancels the effect of the substrate. The reduction in photoconductivity below 170 K for both samples in combination with an extension in lifetimes as found from the TRMC measurements is related to the increase of strain, which is in accordance with the XRD data. At these low temperatures this strain leads to a highly defective material resulting in the prolonged, selective trapping of one type of carrier. Most interestingly all observed phenomena are all fully reversible.
Finally, to gain more knowledge regarding the individual mobilities of electrons and holes of excess charge carriers in CsMAFA, TRMC was carried out on bilayers of HTL/CsMAFA, CsMAFA/ETL. First of all, the TRMC signal heights of all bilayers were reduced to about half of the bare CsMAFA layer. We attribute this to the efficient charge transfer of one type of carrier from CsMAFA to a selective TL. Since the mobility in all investigated TLs is more than an order of magnitude lower than that in CsMAFA, the TRMC signal in the bilayer originates mainly from the carrier residing in the perovskite layer. From the reduction, we come to balanced electron and hole mobilities for CsMAFA of 16 and 12 cm^2/Vs, respectiviely independent of the investigated configuration. Moreover, the charge carrier lifetime was elongated in comparison with the bare CsMAFA layer, indicating that both electron- and hole-transfer are efficient and that interfacial recombination occurs on a longer timescale than the decay in the single layer. In summary this work provides information on the relationship between structure and opto-electronic properties, which is important to rationally design and optimize devices including solar cells.

8:00 PM EN05.10.24
Thick and Efficient Perovskite Solar Cells Enabled by Fast Co-Evaporation ManuelPiot, JavierSebastien, NathanRodkey, KassioP. Zanoni, MicheleSessolo and HenkJ. Bolink; Institut de Ciència Molecular (ICMol), Spain

Conformal deposition of perovskite on textured silicon for perovskite/silicon tandem solar cells remains challenging using the widely-used solution spin-coating route. In contrast, perovskite thermal evaporation allows highly-controlled thin film deposition, ensuring conformality on large areas, regardless on the surface texture. To take advantage of the full photocurrent generating capabilities of the perovskite front cell, rather thick films are required. Currently, most perovskites are sublimed in a single approach by co-sublimation of the precursors. This deposition technique is usually done under high vacuum and the deposition rates of each precursor are monitored using quartz crystal microbalances (QCMs). However, due to the slow deposition rates (< 1 Å/s) it is challenging to deposit sufficiently thick perovskite films that are required for highly efficient perovskite/silicon tandem devices.
Herein, we explore the co-evaporation of $CH_3NH_3PbI_3$ (MAPI) perovskite using faster deposition rates (> 2 Å/s), by simultaneously subliming CH_3NH_3I and PbI_2. These rates are deduced by scaling up linearly the initial speed by a factor of up to 8 times, leading to quick and reproducible evaporation processes. Moving to faster deposition speeds, a change in crystallite orientation is observed by XRD and GIWAXS, showing a preferential growth along the (202) family of planes, as opposed to the (110) orientation.
Thanks to these faster deposition speeds, 1 µm-thick MAPI films can be deposited in a short amount of time. This allows a noticeable J_{sc} gain in planar glass based single junction solar cells (~0.8 mA), due to an enhanced absorption of the infrared light, as revealed by EQE. On the other hand, the FF drops to lower values, possibly due to a diffusion length problem.

8:00 PM EN05.10.25
Potential of Close-Space Sublimation for Scalability of Perovskite Solar Cells NathanRodkey, InmaGomar Fernández, FedericoVentosinos, CristinaRoldan-Carmona and HenkJ. Bolink; Universitat de València, Spain

Vacuum techniques for perovskite photovoltaics (PV) are promising in their potential for scalability but are rarely studied with techniques that are readily adaptable for industry. Co-sublimation is one such technique, whose potential as a dry, additive technique for highly uniform and large-area depositions makes it attractive as an industrial candidate for perovskites. However, low-deposition rates, and its dependence on high-vacuum and in-situ rate monitoring make integration on large scales difficult to imagine. Furthermore, the organic sources used (e.g. FAI and MAI) tend to be unstable, decomposing over time. This is severe enough that the organic sources are not reused, instead discarded after each evaporation. In this work, we study the use of close-space sublimation (CSS) for making perovskite solar cells, a technique that has already seen wide-spread use in industry, including in PV and benefits from high material-transfer and low working pressures. We show that organic sources of FAI used in these systems can be cycled multiple times (>30 depositions) and estimate they can be continuously sublimated for months before needing replacement. We show the conversion of inorganic perovskite precursor layers in a 2-step process using CSS for the organic, FAI source. We show that a rough vacuum process (10 mbar) can be used for the sequential conversion of evaporated $PbI_2/PbCl_2/CsI$ thin-films. The $FA_{0.9}Cs_{0.1}PbI_3$:Cl perovskites converted in this work have a bandgap at 810 nm (1.53 eV), with large grains (>400 nm). Devices were then thermally stressed at 85 ºC and exhibited a stable photoconversion efficiency (PCE) for >650 hours. This thermal stressing was found to be necessary for high -performing devices, who experienced an increase in average PCE from 12.2 – 17.5% after 1 week annealing. We report a champion cell of 18.7% PCE. To explain this drastic increase in PCE, we collect the JV characteristics of the devices at varying light intensities (dark, 0.1, 0.5, and 1 sun) and use drift-diffusion simulations to explain the transformation. These drift-diffusion simulations are powered by SIMsalabim, and by fitting multiple JV curves at different light intensities, we are able to ensure a unique fit of the data. In this way, a reduction in trap density of 5 orders of magnitude was observed after 1 week of thermal stressing.

8:00 PM EN05.10.26
Double Punch for Suppressing Phase Segregation: Interface Engineering with Synergistic Passivation and Efficient Hole Extraction ZhaojieZhang[1], JuliaMartin[2], RonaldL. Grimm[2] and DhandapaniVenkataraman[1]; [1]University of Massachusetts--Amherst, United States; [2]Worcester Polytechnic Institute, United States

In p-i-n perovskite solar cells (PSCs), the buried hole transport layer (HTL)/perovskite interface plays a vital role in dictating the performance and stability of the full photovoltaic device. However, the impact of HTLs on vertical phase segregation remains unknown. This work systematically explores the impact of electronic and chemical properties of HTLs on vertical halide segregation of mixed-halide perovskite materials. Here, we demonstrate that PTAA/CuI_xBr_{1-x} bilayer HTL significantly suppresses light-induced vertical phase segregation of $MAPb(I_{0.7}Br_{0.3})_3$. We used grazing-incidence X-ray diffraction (GI-XRD) to capture the depth-resolved composition change of $MAPb(I_{0.7}Br_{0.3})_3$ at the interface and bulk with different HTLs under illumination. Electronic properties including hole density, hole mobility, and energy levels of CuI_xBr_{1-x} were systematically characterized to reveal the impact of HTL on phase segregation. By manipulating the illumination and electronic properties of HTL, we illustrate the interplay between illumination direction, interfacial defects, charge carrier extraction, and vertical phase segregation. Our findings demonstrate that the PTAA/CuI_xBr_{1-x} bilayer, with its synergistic passivation and efficient hole extraction ability, stabilizes the interface and bulk of the mixed halide perovskite layer, preventing phase segregation and possible amorphization. This work highlights that synergetic passivation and efficient hole extraction pack a more powerful punch for suppressing the vertical phase segregation in mixed-halide perovskite.

8:00 PM EN05.10.27
Interstitial Defect Thermodynamics Drive Phase Separation in Lead Halide Perovskites RossKerner[1], JohnL. Lyons[2], KaiZhu[1] and JosephJ. Berry[1,3,3]; [1]National Renewable Energy Laboratory, United States; [2]U.S. Naval Research Laboratory, United States; [3]University of Colorado Boulder, United States

Lead halide perovskites show unrivaled performance and versatility in optoelectronic devices; however, the issues of photo- and electrochemical stability and halide phase segregation remain a challenge to take full advantage of halide perovskites. Here, we describe our proposed model to explain how homogeneously mixed iodide (I):bromide (Br) perovskite alloys (e.g. $MAPbBr_xI_{1-x}$) phase separate into I-rich and Br-rich regions under bias or illumination. The model predicts iodine +1 interstitials play a critical, intrinsic role giving rise to unequal fluxes of halide species – the origin of voltage- or photo-induced compositional instabilities. We briefly review our recent experimental results testing the model and discuss in detail our recent density functional theory (DFT) computations comparing the relative formation enthalpies of I_i^+ versus Br_i^+ interstitial defects in different halide compositions. We find that I_i^+ defects are energetically favorable by 0.1-0.4 eV over Br_i^+ under most conditions, and also show that I_i^+ is further stabilized when surrounded by iodide first- and second-nearest neighbors. In other words, I_i^+ will be most stable and favorably migrate towards iodide-rich regions making them more iodide-rich. Thus, we confirm our model's core assumption and elucidate a major fundamental, thermodynamic driving force for halide phase separation following oxidation and creation of I_i^+ defects. Overall, this body of work brings a level of clarity to interstitial defect chemistry and physics in halide perovskites, advancing our understanding a step closer to that of more conventional semiconductors.

Molecular Locking with All Organic Surface Modifiers Enables Stable and Efficient Slot Die Coated Methyl Ammonium Free Perovskite Solar Modules PremJ. Rana[1,2],

BennyFebriansyah[2], Teck MingKoh[2], Subodh GautamMhaislkar[2] and NripanMathews[2]; [1]Tandem PV, United States; [2]Nanyang Technological University, Singapore

The power conversion efficiency (PCE) of the state of the art large area slot diecoated perovskite solar cells (PSCs) is now over 19%, but issues with their stability persist owing to significant intrinsic point defects and a mass of surface imperfections introduced during fabrication process. We report the utilization of a hydrophobic all organic salt to modify the top surface of large area slot die coated methylammonium (MA) free halide perovskite layers. Bearing two molecules each of which is endowed with anchoring groups capable of exhibiting secondary interactions with the perovskite surfaces the organic salt acts as a molecular lock by effectively binding to both anion and cation vacancies, substantially enhancing the materials intrinsic stability against different stimuli. It not only reduces the ingression of external species such as oxygen and moisture but also suppresses the egress of volatile organic components during the thermal stability testing.
The treated PSCs demonstrate efficiency of 19.28% (active area of 58.5 cm2) and 17.62 % (aperture area of 64 cm2) for the corresponding mini-module. More importantly, unencapsulated slot-die coated mini-modules incorporating the all-organic surface modifier show ~80% efficiency retention after 7500 hours (313 days) of storage under 30% relative humidity (RH). They also remarkably retain more than 90% of the initial efficiency for over 850 hours while being measured continuously.

8:00 PM EN05.10.29
Enhancing Interfacial Properties via Ionic Exchange for the Highly Efficient Sn-Pb Mixed Perovskite Based Solar Cells SangheonLee, ChangyongKim, HyeminLee, Seok BeomKang, Joo woongYoon, Sang WonLee and Dong HoeKim; Korea University, Korea (the Republic of)

Sn-Pb mixed perovskite is considered as an ideal light absorber not only for single-junction solar cells, but also for bottom cells of muti-junction solar cells due to its narrow-band gap feature. The p-orbital hybridization of Sn^{2+} and Pb^{2+} causes an upward shift of the valence band maximum (VBM) and conduction band minimum (CBM) in addition to the bandgap reduction. This results in the highest occupied molecular orbital level of poly[3,4-ethylenedioxythiophene]:poly[styrene sulfonate] (PEDOT:PSS) having an ideal band alignment with the VBM of Sn-Pb mixed perovskite. Therefore, the PEDOT:PSS is the most widely used hole transport layer (HTL) in p-i-n structured Sn-Pb mixed perovskite solar cells (PSCs).

However, PEDOT:PSS showed several critical drawbacks that affected the device performance such as their acidic condition, inferior molecular structure, and nonideal absorption property. Among them, the inappropriate molecular structure composed of hydrophilic PEDOT molecule and hydrophobic PSS molecule does not form a uniform and ideal micro structured surface when it has been coated. Therefore, it has been induced undesirable interface like voids between PEDOT:PSS and perovskite. Various studies have been conducted to obtain better interfacial properties with respect to the perovskite precursor, like adding additives. However, the origin of the undesirable interface was due to the structural limit of the PEDOT:PSS molecule. Therefore, fundamental research is needed to address these issues from the perspective of the PEDOT:PSS surface.

This study introduces an effective ionic exchange for PEDOT:PSS surface modification to drastically enhance the interfacial properties between PEDOT:PSS and perovskite. The surface modified PEDOT:PSS by ionic exchange brought the conformal interfacial contact and enhanced charge extraction confirmed via time-resolved photoluminescence (TRPL) analysis. As a result, we achieved more than 20% efficiency of p-i-n structured Sn-Pb mixed PSCs. The mechanism of ionic exchange also had been elucidated through various surface analysis and density functional theory (DFT) calculations. In addition, we confirmed that this ionic exchange was also effective for tandem devices. In conclusion, we fabricated all-perovskite tandem solar cells with an approaching 24% efficiency through this ionic exchange

8:00 PM EN05.10.30
Efficient Perovskite Solar Cells with Improved Carrier Transport via Composition-Graded Titanium Oxynitride Electron Transport Layer YonghoonJung; Seoul National University, Korea (the Republic of)

State-of-the-art perovskite solar cells (PSCs) have achieved power conversion efficiencies (PCEs) exceeding 25% by enhancing the charge transport layers to facilitate efficient carrier transport while minimizing non-radiative recombination. The effective transport of charge carriers through the perovskite and the charge transport layers can improve the fill factor and open-circuit voltage. An ideal electron transport layer (ETL) should possess complete and conformal coverage, as well as optimal band alignment that facilitates efficient extraction of electrons. Additionally, the minimal defect density in charge transport layers is essential to prevent detrimental interface recombination. While TiO_2 has been widely used as an ETL, it exhibits limitations as an ideal ETL due to an energy level mismatch and relatively poor electrical characteristics. Specifically, the conduction band minimum (CBM) of TiO_2 is slightly higher than that of $MAPbI_3$, leading to a significant energy barrier for electron extraction. Additionally, the relatively low conductivity and mobility of TiO_2 hinder efficient charge transfer. To address the limitations of TiO_2, metal doping such as Nb, Al, and Li has been employed to modify its electronic band structures and improve its electrical properties.
In this study, nitrogen is incorporated into TiO_2 using the pulsed laser deposition (PLD) method to form titanium oxynitride (TiO_xN_y), resulting in enhanced electron transport characteristics including minimal defect density. Controlled substrate temperature and oxygen partial pressure during the deposition facilitated the achievement of optimal thin-film characteristics, including high transparency typical of TiO_2 semiconductors and high conductivity typical of nitrogen-rich TiN. Furthermore, TiO_xN_y thin films with graded atomic ratio nitrogen to oxygen (N/O) are achieved by sequentially changing the oxygen partial pressure during the process. The graded TiO_xN_y thin film exhibits characteristics that enable the achievement of superior functionality as an ETL compared to TiO_xN_y thin films without grading. By increasing the oxygen partial pressure during the deposition process, the CBM was raised, leading to a reduced energy offset with the mesoporous TiO_x layer directly above it. Furthermore, TiO_xN_y fabricated in a multilayer structure can provide a continuous variation of energy levels within the ETL, optimizing the electron pathway and improving charge transport, ultimately enhancing charge extraction capabilities. This alignment facilitates the selective transfer of electrons to the respective electrodes while inhibiting hole transport. The accurate composition control of TiO_xN_y films is characterized using such as atomic force microscopy, X-ray photoelectron spectroscopy, ultraviolet photoelectron spectroscopy, and Hall measurement to uncover the mechanism behind the enhanced properties. The conformally deposited films with high crystallinity and tailored optoelectrical properties exhibit effective suppression of interfacial recombination as an ETL, resulting in solar cell devices and resulting in high PCEs.

8:00 PM EN05.10.31
Tunable Anode Work-Function by Self-Assembled Monolayers for High-Performance Pure Blue Light-Emitting Diodes Low Driving Voltage Hyo JaeLee, Jung JaeDo and Jae WoongJung; Kyung Hee University, Korea (the Republic of)

Organometallic trihalide perovskites have garnered significant attention for their potential in light-emitting diode applications, thanks to their unique characteristics including excellent color purity, color tunability, and ease of solution processing through scalable printing technology. Presently, perovskite emitters have achieved comparable electroluminescence and quantum efficiency to organic and quantum-dot display technologies in green and red-emitting perovskite light-emitting diodes (PeLEDs). However, blue-emitting PeLEDs still face challenges in terms of electroluminance, operational stability, and efficiency, primarily due to the relatively wide bandgap of the perovskite emitters ($E_g > 2.5$ eV), which thus requires high driving bias for device operation. In this study, we propose a straightforward interfacial engineering approach to reduce the driving voltage of pure-blue PeLEDs by employing self-assembled monolayer (SAM) molecules on the indium tin oxide (ITO) electrode. The SAM layer facilitates the control of the electronic structure of the ITO surface by modulating its work function, thereby improving hole extraction properties at the lower internal interface. Furthermore, the functionalized SAM molecules interact with the under-coordinated perovskite lattices, providing interfacial interaction with the perovskite layers and facilitating radiative carrier recombination at lower driving bias. These desirable characteristics of SAM molecules enable enhancements in the electroluminescence and quantum efficiency of pure blue emission while requiring lower driving voltage. Moreover, the superior properties of the perovskite film, coupled with the reduced driving voltage, contribute to an extended operational stability of blue electroluminescence in PeLEDs. Consequently, this strategy demonstrates the remarkable potential of achieving high-performance PeLEDs with blue light emission, which is highly attractive for full-color perovskite display technologies.

8:00 PM EN05.10.32
Bandgap Optimization by Cu Doping of Ag-In Halide Double Perovskites for Photovoltaic Applications ShunnosukeIkegaya, KojiYokoyama, ShunYokoyama and HideyukiTakahashi; Tohoku University, Japan

Lead iodide perovskites ($APbI_3$, where A represents organic cations) have been used as photoactive layers in perovskite photovoltaics due to their excellent optical and electronic properties. However, the toxicity of Pb and the ambient instability caused by the degradation of organic cations and iodide anions have hindered their widespread use. Metal halide double perovskites ($A_2B^IB^{III}X_6$, where B^I, B^{III}, and X represent monovalent and trivalent metal cations, and halide anions, respectively) have been theoretically proposed as Pb-free halide perovskites. Theoretical calculations predict that $Rb_2CuInCl_6$ double perovskites have a direct and optimal bandgap of 1.36 eV, whereas they cannot be synthesized directly due to their low thermodynamic stability. Instead, we focused on $Cs_2AgInCl_6$ double perovskites, which can be synthesized directly and exhibit superior ambient stability; however, they have a large bandgap (>3.0 eV), making them unsuitable for photoactive layers. Recent studies have reported that Cu^{2+} doping reduces the bandgap of $Cs_2AgInCl_6$ from 3.0 to 2.2 eV. Furthermore, it was demonstrated that Cu^+-Cu^{2+}-In^{3+}-based layered perovskites exhibited better optical properties than perovskites composed of Cu^+ or Cu^{2+} alone. In this study, we present the synthesis of Ag-In double perovskites with an optimal bandgap as photoactive layers through $Cu^{+/2+}$ doping.
All of the following processes were performed at 75°C in ambient air. Ag-In precursor aqueous solutions (denoted as S1) were prepared by dissolving AgCl and $InCl_3 \cdot 4H_2O$ in concentrated HCl. Precursor aqueous solutions containing only Cu^{2+} (denoted as S2) were prepared by dissolving $CuCl_2 \cdot 2H_2O$ in concentrated HCl. Precursor aqueous solutions containing only Cu^+ (denoted as S3) were prepared by dissolving CuCl with reductants in concentrated HCl. Precursor aqueous solutions containing Cu^+ and Cu^{2+} simultaneously (denoted as S4) were prepared by dissolving CuCl and/or $CuCl_2 \cdot 2H_2O$ with reductants in concentrated HCl. Ultraviolet-visible (UV-Vis) absorption spectra of the S2-S4 solutions were measured to evaluate the

valence states and complex structures of Cu species in these solutions. The solid samples precipitated by adding CsCl into the S1 solutions, the S1/S2 mixtures, the S1/S3 mixtures, or the S1/S4 mixtures were collected and washed. The composition, structure, and bandgap of the resulting samples were evaluated by inductively coupled plasma-mass spectrometry (ICP-MS), X-ray diffraction (XRD), and optical absorption measurements.
The S2, S3, and S4 solutions turned yellow, colorless, and dark, respectively. The UV-Vis spectra of these solutions indicated that the S2 and S3 contained only $[Cu^{II}Cl_4]^{2-}$ and $[Cu^{I}Cl_4]^{3-}$ complexes, respectively, whereas the S4 contained mixed-valence $Cu^{+/2+}$ species. The resulting samples from the S1 solutions were completely white in color. XRD analysis confirmed the presence of the $Cs_2AgInCl_6$ phase in these samples. In contrast, the resulting samples from the S1/S2 and the S1/S3 mixtures were yellow and pale yellow, respectively. These samples had a smaller bandgap compared to $Cs_2AgInCl_6$. Trace amounts of Cu were detected via ICP-MS, indicating that Cu doping of the $Cs_2AgInCl_6$ can reduce the bandgap. Interestingly, the resulting samples from the S1/S4 mixtures exhibited darker colors than the samples doped with Cu^{+} or Cu^{2+} alone, suggesting that simultaneous $Cu^{+/2+}$ co-doping leads to emergent optical properties in these samples.

8:00 PM EN05.10.33
Electrical Field-Assisted Direct Ink Deposition of Methylammonium Lead Iodide Layer for Fabricating Large-Scale Inverted Perovskite Solar Cell BanashreeGogoi, CarsonGockley, SushmithaVenu, YizhenZhu, RaveenaPhadnis, XiangjiaLi, WilliamT. Petuskey and TerryL. Alford; Arizona State University, United States

A high-performing perovskite solar cell (PSC) requires an outstanding perovskite layer in excellent contact with high-performing charge transfer layers. Commercial development of simple and scalable deposition techniques will need to focus on processes that yield smooth films of uniform composition, microstructure and composition. Ideally, it is desired that the same technique be used sequentially for all of the layers. Several techniques aspire to this goal including one-step chemical solution processes using spin coating and ceramic processing approaches such as doctor-blading, slot-die coating, inkjet printing, and spray coating. As an alternative, we report on the electric field-assisted direct ink deposition (EF-DID) fabrication process for rapid printing of large-area perovskite nanofilms.
Our prior work successfully demonstrated the utility of EF-DID in fabricating PEDOT:PSS hole transport layers. Now we demonstrate its application for depositing perovskite films. Essentially, this technique forms a stable electrospray condition that yields a uniform, large grain-sized perovskite film deposits. Concurrent heat treatment thermally converts the perovskite precursor solution in orthorhombic methylammonium lead iodide ($CH_3NH_3PbI_3$). Post-deposition, solvent vapor annealing (SVA) refines the films to improve their surface smoothness and to greatly reduce pinhole defects. With very little experimental effort, a ten-fold improvement in the power conversion efficiency (from 1 to 10%) was achieved, suggesting that even greater efficiency can be anticipated in the future.

8:00 PM EN05.10.34
Microstructure Refinement of Open-Air, EF-DID Fabricated Films of $MAPbI_3$ Perovskites by Solvent Vapor Annealing (SVA) and Selected Enabling Surfactants BanashreeGogoi, CarsonGockley, SushmithaVenu, YizhenZhu, RaveenaPhadnis, XiangjiaLi, TerryL. Alford and WilliamT. Petuskey; Arizona State University, United States

The constant drive towards the large-scale application of perovskite solar cells has increased the demand for innovating new techniques for fabricating high quality thin films of the perovskite and adjacent charge transport layers that possess a high degree of uniformity in microstructure, composition and reduced defect density. There are many different approaches that produce that produce basic films but are deficient in their surface coverage, surface morphology and film microstructure. There is a great need for the development of post-deposition treatments that markedly improve the uniformity of film thickness, grain distribution and grain-size distribution, and that also greatly reduce surface roughness, cracks and pin-holes. In this project, we report on the refinements achievable using solvent chemical vapor annealing in combination with selected enabling surfactants. We report on the refinements made on films produced by an open-air fabrication technique termed electrical field-assisted direct ink deposition (EF-DID).

For post deposition refinement, we adapted the technique reported by Zhou, et al. who use methylamine gas (MA) as the chemical annealing agent. We compare the microstructural characteristics of $MAPbI_3$ films before and after chemical annealing and with and without the addition of a surfactant. For the latter, we used polyoxyethylene (20) sorbitan monolaurate (TWEEN-20) as an example of what can be achieved. Compared to the non-vapor annealed films, the MA-treated films and Tween-20 showed an enhanced grain distribution and density. Property measurements of inverted photovoltaic devices using MA-treated perovskites showed a ten-fold increase in the power conversion efficiency compared to the non-MA treated devices.

Enhancing the Performance of the $MAPbI_3$ Perovskite Solar Cells Synthesized in an Ambient Environment via Modification of the SnO_2 Electron Transport Layer BiplavDahal; Florida International University, United States

The tin oxide (SnO_2) electron transport layer (ETL) plays a vital role in the photo-conversion efficiency (PCE) and stability of organic-inorganic perovskite solar cells (PSCs). However, SnO_2 ETL-induced defects such as hydroxyl groups, oxygen vacancies, exposed Sn atoms, and dangling bonds hinder device performance. In this study, rubidium chloride (RbCl) has been used to modify the SnO_2 ETL. $MAPbI_3$ perovskite film formed on the RbCl-modified SnO_2 ETL exhibits improved crystallinity with enlarged grain size and reduced grain boundaries, and enhanced optical absorption. The Hall-effect measurements indicate the improved carrier mobility and the dark J-V curve shows the increment of electrical conductivity for the RbCl-modified SnO_2 ETL. X-ray photoelectron spectroscopy (XPS) results demonstrate the surface defects passivation of the perovskite layer by modifying the SnO_2 ETL. A champion PCE of 19.35% has been achieved for the RbCl-modified SnO_2 ETL-based devices with improved stability, while the control devices with unmodified SnO_2 ETL show a PCE of 17.18%.

SESSION EN05.11: Poster Session V: Structure Property Relationships in Halide Perovskites

Effects of Light and Electricity on Mechanical Properties of Metal Halide Perovskite Single Crystals MeaghanDoyle, MadhujaLayek, AnushRanka, ZhenghongDai and NitinP. Padture; Brown University, United States

Metal halide perovskites (MHPs) have emerged as promising light absorber materials for their use in perovskite solar cells (PSCs). Although significant progress has been made in enhancing the efficiency and operational stability of PSCs, their mechanical reliability needs to be improved if they are to operate efficiently for many years. However, the mechanical properties of MHPs have not been fully explored. This is especially important because MHPs possess poor mechanical properties — they are compliant, soft, and brittle. To that end, we have used nanoindentation and micro-indentation to study the plastic deformation, elastic deformation, and fracture properties of MHP single crystals of various compositions. We also investigated the effects of creep as well as light and electricity on the mechanical properties of MHP single crystals. These parameters impact the mechanical properties of other similar semiconductors, and in MHPs such effects could translate to important implications for PSCs. Through this we aim to provide a more comprehensive understanding of mechanical properties of MHPs, which are relevant for understanding and enhancing the mechanical reliability of PSCs.

8:00 PM EN05.11.03
Crystal Growth Regulation via Co-Spacer Cations Mixed with Methylammonium in Lead Iodide in Perovskite Photovoltaics Mi HeeJung; Sejong University, Korea (the Republic of)

In this work, we used co-spacer cations to control the phase distribution by mixture of benzylammonium (BZA) and guanidium (GA). We observed that the crystal structure was different when two dimensional (2D) perovskite was prepared only with BZA and when 2D perovskite was prepared by combination of BZA and GA. The perovskite film prepared from these mixed cations demonstrated increased grain size and enhanced crystallinity from BZA based perovskite to GA based perovskite. Thus, perovskite solar cells from these mixed cation perovskite exhibits the power conversion efficiency (PCE) of 14.95% ~ 16.23 % and GA based device shows PCE up to 18.31%. Our studies reveal the size and the nature of the organic spacer cation is related to the overall stability of the corresponding lead iodide and suggest that the phase distribution of the 2D perovskite is finely controlled by the mixture of two different large organic cations.

8:00 PM EN05.11.04
Design and Characterization of Low-Dimensional Perovskites with Multiple-Ring Aromatic Cations AndreiMitrofanov[1,2], YonderBerencén[3], ElahehSadrollahi[2], KhrystynaRymsha[1], RegineBoldt[1], DavidBodeshiem[2], HendrikWeiske[4], FabianPaulus[2], QuinnBesford[1], AgnieszkaKuc[3] and BrigitteVoit[1,2]; [1]Leibniz Institute of Polymer Research, Germany; [2]Technische Universität Dresden, Germany; [3]Helmholtz-Zentrum Dresden-Rossendorf, Germany; [4]Universität Leipzig, Germany

Metal halide perovskites have become promising next-generation semiconducting materials for many applications due to their prominent optoelectronic properties and ease of manufacturing. These materials are widely tailorable in composition, which allows the incorporation of various organic cations. Tuning the structure of the organic molecules can cause remarkable changes in the structural arrangement of halide perovskites resulting in the formation of two-dimensional (2D) layers, one-dimensional (1D) chains, or isolated zero-dimensional (0D) clusters and, as a consequence, the modification of the optoelectronic properties of the perovskite system.
In recent works devoted to the low-dimensional metal halide perovskites, significant attention has been paid to the molecular engineering of the functionalized cations. This allows the design of a variety of new organic-inorganic hybrid materials, in which semiconducting organic and inorganic layers are assembled at the molecular scale. High structural distortion of the resulted low-dimensional perovskite structures induces electron-phonon coupling and enhances the self-trapped excitons (STEs) processes, resulting in an enhanced broadband emission [1,2]. In addition, it has been demonstrated that perovskites grown in a form of atomically thin sheets possess unique features compared to their bulk counterparts [3]. For example, hybrid perovskite sheets exhibit an unusual structural relaxation, which leads to a band gap shift. Consequently, the controllable synthesis of ultrathin perovskite sheets has gained a great research interest for implementation in high-performance optoelectronic devices.
In this work, we fabricated several low-dimensional hybrid organic-inorganic metal halides, based on multiple-ring aromatic ammonium cations and lead iodide with a strong focus on structural and optoelectronic investigation. Examination of the influence of organic cations on the structural properties reveals that the number and position of amino groups at the aromatic ring affect the dimensionality of the perovskite, resulting in 2D and 1D corner- and face-sharing structures with different optical behaviors. Highly distorted 1D perovskites show broadband emissions originating from STEs. Theoretical results reveal, that the organic cations in the 1D compounds strongly contribute to the band structure resulting in strong orbitals hybridization. Using a facile and fast template-assisted crystallization method we have synthesized metal halide perovskite few-layer free-standing nanosheets with micron size containing the naphthalene diammonium-based linker. Varying the synthetic conditions, we can modulate the thickness and lateral sizes of the nanosheets, making them promising candidates for optoelectronic applications.

Maximizing Photoluminescence Quantum Efficiency of Stacked Halide Layer for Highly Efficient Perovskite Solar Cells Min JuJeong and Jun HongNoh; Koera University, Korea (the Republic of)

To further approach the theoretical limit of perovskite solar cells (PSCs), it is cucial to analyze and interpret the external photoluminescence quantum efficiency (PLQE) of a light-absorbing halide layer stacked with charge transporting layers (CTLs) rather than solely as a halide layer. Here, we propose the next phase research direction for reaching radiative limit of PCE by maximzing PLQE of the stacked halide layer. We demonstrated that controlling the bottom charge transporting layer (CTL)/perovskite interface is a main factor to maximize PLQE in full device stack. On combining interface and bulk engineering, the FTO/bottom CTL/halide structure and full device stack exhibited an enhanced external photoluminescence quantum efficiency (PLQE) of 40.67% and 15.57%, respectively. As a result, the device combined with the interface and bulk engineering showed a certified quasi-steady-state (QSS) efficiency of 25.06%. The certified open-circuit voltage (Voc) of 1.18 V is 94.93% of the radiative limit Voc of 1.243 V, the highest value among certified QSS Voc of PSCs. This research approach provides a promising direction for reaching the theoretical limit of PSCs by maximizing PLQE.

8:00 PM EN05.11.06
Origin of Excitonic Absorption in Multi-Grain CsPbBr3 Perovskite Nanocrystals for Photodiode Applications AtifSuhail[1] and MonojitBag[2]; [1]IIT Rorrkee, India; [2]Indian institute of Technology Roorkee, India

Inorganic halide perovskite nanocrystals exhibit some extraordinary properties compared to their parent materials due to the finite size effect. However, the exciton dynamics in these nanocrystals are not well understood due to the wide variation of structural properties. In this study, we have synthesized single-grain and multi-grain nanocrystals of $CsPbBr_3$ and analyzed the excitonic absorption and photoluminescence by correlating them with their structural properties. There exist two types of excitonic absorption; low energy localized excitons having binding energy from 64 to 156 meV and near band-edge excitons having binding energy from 18 to 23 meV. Small-size single-grain nanocrystals have a relatively higher bandgap of 2.576 eV due to increased micro-strain compared to multi-facet polyhedral with multi-grain nanocrystals. The broadening of the near band-edge excitonic absorption peak is possibly due to the presence of different sizes, shapes, and nature of the grain boundaries which also modulate the photoluminescence decay lifetime. The overall steady-state photoluminescence is higher in single-grain nanocrystals compared to multi-grain nanocrystals due to the localization of excitons. Therefore, these single-grain nanocrystals can be used for efficient light emission in perovskite photodiodes while multi-grain nanocrystals could be better suited for photodetector application.

Keywords: Halide perovskites; Nanocrystals; Excitonic absorption; Grain boundaries; Photoluminescence lifetime.

Effect of Hole Transport Layer on Energy Loss of Pervskite Solar Cell HeunjeongLee, TranH. Nhan, DongchanLee and ShinukCho; University of Ulsan, Korea (the Republic of)

The performance of perovskite solar cells (PVSCs) is most affected by the crystallinity of perovskite. Among several conditions, the interfacial properties between the charge transfer layer and the perovskite active layer, where the perovskite crystalline structure begins, are also one of the factors that have a great influence. Thus, various studies have been performed the ways to modify HTL to improve the device performance in the p-i-n structure. As the crystallinity including grain size of perovskite layers is influenced by the HTLs, the various charge dynamics will be also changed. Until now, however, there is little research related to energy loss analysis about the perovskite layer depending on HTLs. In this study, the difference in V_{oc} between PEDOT:PSS and NiO_x was explained through energy loss analysis. Despite the energy levels of PEDOT:PSS and NiO_x are similar to -5.0 eV and -5.1 eV, respectively, significant V_{oc} difference is observed between PEDOT:PSS based PVSCs (0.933 V) and NiO_x based PVSCs (1.088 V). Our energy loss analysis clearly indicated that this V_{oc} difference originated by non-radiative recombination. It is known that the non-radiative recombination in PVSCs is generally occurred by traps in the perovskite film, which is generated by grain boundary and defects of perovskite film. The perovskite film on NiO_x showed a larger grain size and improved crystallinity compared to the perovskite film on PEDOT:PSS. Therefore, we concluded that the increased V_{oc} in PVSCs using NiO_x HTL was due to the decrease in non-radiative recombination induced by the improved morphology.

8:00 PM EN05.11.08
Effects of Precursor Purity and Post-Synthesis Treatments on Mechanochemical Mn^{2+} and Rb^{1+} Co-Doped $CsPbCl_3$ Perovskite Powder IvyK. Jones[1], UweHommerich[1], KeseteGhebreyessus[1], VadivelJagasivamani[1], DemetrisGeddis[1], KabirAl Amin[1], S. B.Trivedi[2], Amanda LTiano[3] and SethFraden[3]; [1]Hampton University, United States; [2]Brimrose Corporation of America, United States; [3]Brandeis University, United States

Inorganic halide perovskites (HPs) exhibit optimum optoelectronic material characteristics such as wider band gaps, enhanced atmospheric stability, and improved photoluminescence quantum yield, as well as demonstrated balanced and higher carrier mobility in comparison to hybrid organic-inorganic HPs. The synthesis of perovskite material often involves the utilization of toxic and large quantities of hazardous complex solution-based techniques which are not eco-friendly. Alternately, crystal growth methods require highly purified precursors that have negative ecological impacts on the environment, leading to increased pollutants within the atmosphere, and accompanied by high-energy consumption deemed an unsustainable practice. Mechano-chemical synthesis is considered a green chemistry method that significantly can reduce the use of complex and time-consuming reactions, energetic-enabled conditions, expensive precursor sources, hazardous reagents, catalysts, additives, surfactants, and overall waste. In this study we report fluorometric characterization results of mechano-chemical synthesis of manganese (Mn^{2+}) doped $CsPbCl_3$ halide perovskite powder surface-purification treatment and ligand-mediated techniques using ultrasound sonification to assist in the dissolution of unreacted precursors and accelerate the ionization of ligand-affinity kinetics, respectively. The grinding process is considered a non-homogeneous synthesis approach which may result in residual unconsumed precursor present in the sample leading to surface defects during post-synthetic treatments. Dry and wet high-energy ball-milling experiments used low purity (2N) precursors: CsCl and $PbCl_2$ and the (non-anhydrous) hydrated $MnCl_2$ dopant source. Synthesized HPs were characterized by X-ray diffraction, optical microscopy, scanning electron microscopy, transmission electron microscopy, and steady-state & time-resolved spectroscopic studies. The dopant-dependent HPs powders and supernatant (powder and oleylamine diluted in hexane) exhibited a broad band Mn^{2+} emission band at room temperature with average peak wavelengths of 620 nm and ~ 606 nm, respectively. The oleylamine purity: > 50.0% vs. 70% will also be evaluated for effects on the fluorometric properties of the ligand-mediated doped perovskite. Room-temperature (RT) lifetime transients of the dopant-dependent HPs powder ranged from 0.49 – 0.74 ms and supernatant were 1.36 – 1.72 ms, comparable to previously reported RT lifetimes for Mn^{2+} doped $CsPbCl_3$ nanoparticles and bulk crystals at 1.10 ms and 0.70 ms, respectively. Comparative studies of the fluorescent properties of Mn^{2+} doped $CsPbCl_3$ prepared by microwave-assisted, and melt-synthesis will also be presented.

8:00 PM EN05.11.09
Organic–Inorganic Gas Sensor Based on a Perovskite Nanocrystal–Conductive Polymer Hybrid DuhoJang, MingHong and Yeong DonPark; Incheon National University, Korea (the Republic of)

We present a novel approach for fabricating organic-inorganic hybrid gas sensors by blending perovskite nanocrystals with a conductive polymer matrix. Organic semiconductors (OSCs) hold considerable potential as sensing materials for printed organic gas sensors. However, they face challenges in terms of limited sensitivity and poor stability under ambient conditions, which hinder their development compared to inorganic-based gas sensors. To overcome these limitations, we have incorporated functional nanomaterials into the organic semiconductors. In this study, we introduce a perovskite-structured material, specifically $CsPbBr_3$, into the conductive polymer matrix, resulting in a significant enhancement of the gas-sensing performance of the sensors while retaining their high responsivity and response rates. Moreover, we have employed a zwitterionic polymer surface modification with a hydration treatment to further improve the adsorption of target gas molecules on the perovskite surface. Our results demonstrate that the amide group of the encapsulation polymer exhibits a strong affinity towards NO_2 gas molecules, and this affinity is enhanced upon hydration of the polymer. Additionally, the presence of perovskite materials within the semiconducting polymer layer acts as a protective barrier, effectively shielding the polymer thin film against oxidation during extended storage under ambient conditions, owing to the perovskite crystals' ability to adsorb oxidizing molecules. This approach addresses the limitations of OSCs, resulting in improved gas-sensing performance, enhanced responsivity, and increased stability, thus paving the way for practical applications in gas sensing and detection.

Synergetic Effect of Aluminium Oxide and Organic Halide Salts on Surface Passivation and Stability Enhancement of Perovskite Solar Cells EunyoungChoi[1,2,3], Jin-WonLee[4], Jae SungYun[5,3] and HelenH. Park[4,6]; [1]Diamond Light Source, United Kingdom; [2]University of Cambridge, United Kingdom; [3]University of New South Wales, Australia; [4]Korea Research Institute of Chemical Technology (KRICT), Korea (the Republic of); [5]University of Surrey, United Kingdom; [6]University of Science and Technology (UST), Korea (the Republic of)

Although long-chain organic halide salts have been effectively used in three-dimensional (3D) perovskite-based solar cells for surface passivation, it has been reported that unexpected halide defects could be formed from the organic halide salts and the solvents used for dissolving the organic halide salts, which results in degradation of the devices. In this work, aluminium oxide (AlO_x) via atomic layer deposition (ALD) was introduced onto octylammonium iodide (OAI) on the perovskite layer to suppress the generation of undesired defects while still obtaining the benefits of organic halide salts. The devices incorporating AlO_x on OAI-treated perovskites (OAI/AlO_x) show enhancement in both device performance and photostability compared to devices with only OAI surface passivation. Diffusion of aluminium from AlO_x into the perovskite is observed from surface characterization. Photo-generated carrier transport in both the surface and bulk of the perovskite absorber is investigated by wavelength-dependent surface photovoltage microscopy, and grazing-incidence-wide-angle X-ray scattering was utilized to investigate the crystallinity changes of the perovskite under prolonged illumination. The effects of the inorganic oxide layer on the stability and performance of organic halide salt-treated devices will be addressed, and the mechanisms involved in the enhanced performance and stability will also be discussed.

8:00 PM EN05.11.11

Off-Stoichiometric Perovskite Photodetectors for Direct Time-Of-Flight Distance Measurements LorenzoJ. Ferraresi[1,2], SergeyTsarev[2,1], SebastianSabisch[2,1], FrankKrumeich[2], VladyslavHnapovskyi[2,1], GebhardJ. Matt[2], SergiiYakunin[2,1], IvanShorubalko[1] and MaksymV. Kovalenko[2,1]; [1]Empa—Swiss Federal Laboratories for Materials Science and Technology, Switzerland; [2]ETH Zürich, Switzerland

Hybrid organic-inorganic metal halide perovskites have recently emerged as a promising alternative to conventional semiconductors for their use in optoelectronic devices such as vertical photodiodes, offering a tuneable band gap and near-unity quantum efficiencies. They can be deposited with facile and diverse methods. The latest feat focused on reducing their defect density to minimise the noise and improve charge collection efficiencies. Yet the response times are limited by the devices' capacitance and, intrinsically, by the lifetime and transit time of the charge carriers. The capacitance limitation can be addressed only to a limited extent via the reduction of the active area of the photodiode, increasing in the meantime the fabrication complexity for comparable signal amplitudes. Alternative strategies focused on the intrinsic properties of semiconductors - such as exploiting the photo-Dember effect or engineering the defect-limited carrier lifetimes - elevated photodetectors to the femtosecond regime, and have yet to be considered for perovskite devices.
In this study, we explored controlled photocurrent quenching through the introduction of selective recombination sites, to obtain fast, one-mm^2 perovskite photodiodes with response times beyond their capacitance limitations. By choosing suitable charge transport layers, and by offsetting the perovskite precursor stoichiometry, the density of interfacial recombination sites can be controllably increased, as highlighted through an in-depth study of photocurrent transients under picosecond laser pulses. The device photo-response is tuned to observe an isolated sharp signal with ns decay and a 3-dB drop at 15 MHz, enabling the resolution of distances in the cm-range using direct time-of-flight measurements. These results are a major leap towards the development of wavelength-selective, cost-effective, and fast perovskite photodetectors with improved photo-response for Light Detection and Ranging (LiDAR) applications. LIDAR sensors are of paramount importance in highly automated processes and for self-driving cars.

Lead Halide Perovskites and Its Applications in Whispering Gallery Mode Micro-Lasing SubitanLaskar and CSudakar; Indian Institute of Technology Madras, India

Ultrahigh luminescence quantum yield (~100%), low non-radiative recombination rates, and tunable spectral emissions from the ultraviolet to the visible range can be achieved through lead halide perovskites (LHP) ($APbX_3$; A= Rb^+, Cs^+, and X= Br^-, I^-); hence they are promising candidates for optoelectronics and photonics applications. However, a lack of atmospheric stability impedes their effective use as photovoltaic absorbers. Highly emissive perovskite quantum dots (PQDs) are being investigated to develop solar cells, efficient lasers, LEDs, etc. Here, we report the bandgap tunability and stability of $APbX_3$ PQDs synthesized through the hot-injection method. Structural characterization through X-ray diffraction (XRD) reveals highly phase pure cubic polymorph of PQDs. The A-site ions have a significant impact on the photophysical and chemical properties. Cs^+ cations are substituted with Rb^+ at the A site, and anionic X sites are substituted either with Br^- or I^- or a combination of halide ions in these PQDs to study the changes in structure and optical properties. With increasing Rb^+ concentration, the bandgap of $Cs_{1-x}Rb_xPbX_3$ is shown to vary between 1.7 eV to 3.2 eV, as evident from the blueshift observed in the photoluminescence peak. Bandgap is also shown to be tunable by alloying I^- with Br^- in $CsPbX_3$ and $Cs_{0.5}Rb_{0.5}PbX_3$. The latter is found to be more stable than the former when stored in laboratory conditions. A detailed analysis will be presented on the effect of cationic and anionic substitution on the absorbance and emission spectra of PQDs. These quantum dots are further used for whispering gallery mode (WGM) lasing from PQDs coated on TiO_2 spherical microcavities. The photoluminescence emission from a $CsPbI_3$-QDs gain medium strongly couples with a TiO_2 microspherical resonating optical cavity. Spontaneous emission in these microcavities switches to a stimulated emission above a distinct threshold point of 708.7 W/cm^2. Quality factor as high as Q~1195 for WGM micro-lasing is demonstrated at room temperature. $CsPbI_3$-QDs/TiO_2 microcavities are found to be photostable even after continuous laser excitation for 75 minutes. [1] The $CsPbI_3$-QDs/TiO_2 microspheres are promising as WGM-based tunable microlasers. Results on WGM micro-lasing using $Cs_{0.5}Rb_{0.5}PbX_3$ will be presented.

Binary Microcrystal Additives Enabled Antisolvent-Free Perovskite Solar Cells with High Efficiency and Stability ZhuP. De; Southern University of Science and Technology, China

Developing a facile method to prepare high-quality perovskite films without using the antisolvent technique is critical for upscaling production of perovskite solar cells (PVSCs). However, the as-prepared formamidinium (FA)-based perovskite films often exhibit poor film quality with high density of defects if antisolvent is not used, limiting the photovoltaic performance and long-term stability of derived PVSCs. Herein, we adopt pre-synthesized 3D methylammonium lead chloride ($MAPbCl_3$) and 1D 2-aminobenzothiazole lead iodide ($ABTPbI_3$) microcrystals into self-drying perovskite precursor, which serve as seed crystals to promote nucleation and growth of $FAPbI_3$-based perovskites without involving the antisolvent extraction. The as-prepared perovskite films with homogeneous morphology and enhanced structural stability can be achieved by alloying with MA cation and Cl anion. Meanwhile, analysis shows the presence of ABTPbI3 at grain boundaries can help passivate the defects due to the interaction between ABT cations and undercoordinated Pb2+ ions, reducing the non-radiative recombination loss. Consequently, the devices exhibit a champion PCE of 23.27% for the small-area device (~ 0.09 cm2) and 21.52% for the large-area device (~ 1.0 cm2), which are among the highest efficiencies reported for PVSCs without using antisolvents. Moreover, the optimized devices without encapsulation showed improved light-soaking stability, which can retain 92% of its initial efficiency under continuous illumination at the maximum power point (MPP) for over 1000 h. This strategy enabled by combinations of pre-synthesized microcrystals provides valuable guidance to improve film quality of antisolvent-free perovskites, and expands its applications in highly-efficient and stable perovskite photovoltaic devices.

8:00 PM EN05.11.14

Achieving Nearly 100% Quantum-Efficient Lead-Free Perovskite Solar Cells with 34.67% Power-Conversion Efficiencies Through Band and Defect Engineering-Based Material Design Optimization SaleemAl Dajani[1,2,1]; [1]King Abdullah University of Science and Technology, Saudi Arabia; [2]Massachusetts Institute of Technology, United States

Perovskite-based solar cells (PSCs) have been the subject of intense research due to their high-power conversion efficiency (PCE), but their stability and lead content have limited their practical applications. In this study, we numerically simulate oxide/perovskite/oxide-type PSCs using the one-dimensional solar cell capacitance program (SCAPS-1D) and optimize performance by tuning electronic, interfacial and defect properties. Based on these calculations, we report that a significant improvement could be achieved in the quantum and power-conversion efficiencies of a solar cell based on optimizing the design of perovskite material constituents and interfaces.

Initially, we assess the effect of various oxide-based electron transport layers (ETLs) and hole transport layers (HTLs) on PSC performance and identify a solar cell with TiO2 as an ETL and NiO as an HTL (FTO/n-TiO2/CsSnI3/p-NiO) exhibiting the highest calculated PCE of 31.09%, with a fill factor (FF) of 88.43%. Next, we optimize the thickness of the TiO2, NiO, and CsSnI3 layers of the benchmarked device, along with their bulk and interface defects, using detailed numerical simulations.

We successfully demonstrate that by engineering defects in CsSnI3 and optimizing the material properties at the interface, the PCE and V_{OC} could be further improved to 34.67% and 1.16V respectively, representing a significant jump from the initial PCE of 31.09% with a 0.98V open-circuit voltage at roughly the same FF and short-circuit current density. The specific improvements made include optimizing the band alignment of the materials to maximize light absorption, reducing the density of defects in the materials to improve charge carrier transport, and engineering the interfaces between the materials to improve charge transfer.

Our results provide important insights into the selection of CsSnI3 as a lead-free absorber with optimized band alignment and interfacial defects, highlighting the importance of a comprehensive approach to optimizing the performance of oxide/perovskite/oxide-type solar cells that considers a range of electronic, interfacial, and defect properties. Our work demonstrates potential improvements of perovskite materials for high-efficiency solar cells. We believe that our study has significant implications for the development of practical solar cells with optimal performance based on solution-processed perovskite materials.

8:00 PM EN05.11.15

Rigorous Optical Dispersion Data Analysis of Single Crystal $MAPbBr_3$ for Optimized Perovskite Solar Cell Active Layer Absorption ChristopherMcCleese[1,2], MichaelC. Brennan[1,3], LirongSun[1,3], NinaHong[4], NathanEpiscopo[5], C.V.Ramana[5], TodGrusenmeyer[1] and PeterStevenson[1]; [1]Air Force Research Laboratory, United States; [2]General Dynamics Information Technology, United States; [3]Azimuth Corporation, United States; [4]J.A. Woollam Company, Inc., United States; [5]The University of Texas at El Paso, United States

Lead halide perovskites have garnered significant attention for optoelectronic applications including photovoltaics, light-emitting diode, photodetector, and laser technologies. However, material quality and stability issues lead to a wide range of reported values for the electrical and optical properties which may complicate device design and optimization strategies for commercialization. Critical to the development of perovskite solar cells (PSC) are the optical properties (refractive index, n, and extinction coefficient, k), which describe the way perovskites interact with light and subsequently function as a photovoltaic material. Optimizing perovskite active layer absorption necessitates solar cell optical coating design iterations using material optical constants derived from rigorous optical dispersion data analysis. The refractive index and extinction coefficient for $MAPbX_3$ have been observed to significantly vary in the literature depending on the processing methodologies. If such optical dispersion variation is ignored in practice at the design stage, PSCs can exhibit parasitic device absorption by non-perovskite (non-active) layers resulting in variable optical transmission, reflectance, or haze-like characteristics within solar radiation bands of interest (300-2500 nm). To our knowledge, no comprehensive experimental optical dispersion data analysis to derive the optical constants of $MAPbX_3$ has been performed to include notable anomalous optical dispersion characteristics including the band edge transition (bandgap ~539 nm) and methylammonium spectral overtones below the band edge (observed within 1050-2050 nm). As such, the optical property determination of exemplary $MAPbX_3$ has been largely under approximated and, consequently, evokes optical property uncertainty with respect to prior reports. Proper fundamental derivation of $MAPbX_3$ optical constants is critical toward the development of high-performance electronic and optoelectronic perovskite devices. Here, we present a rigorous optical dispersion data analysis of single crystal $MAPbBr_3$ via variable angle spectroscopic ellipsometry appended with transmission intensity spectra to provide a robust derivation of the optical constants for normal and anomalous optical dispersion regimes. Using derived optical constants for our single crystal $MAPbBr_3$, exemplary modeled solar cell optical device designs are optimized for perovskite layer absorption and we compare our derived optical properties to illustrative $MAPbBr_3$ literature values reported to-date.

8:00 PM EN05.11.16

The Quest for the Missing Link – From Lead Complexes to Perovskite Formation KaiO. Brinkmann[1], TimoMaschwitz[1], LenaMerten[2], FerayÜnlü[3], AndreasKotthaus[1], CedricKreusel[1], ManuelTheisen[1], HenrikWeidner[1], Jaffres AnaelMorgane[4], AlexanderHinderhofer[2], ChristianWolff[4], Stefan F.Kirsch[1], SanjayMathur[5], FrankSchreiber[2] and ThomasRiedl[1]; [1]Bergische Universitat Wuppertal, Germany; [2]University of Tübingen, Germany; [3]Helmholtz-Zentrum Berlin für Materialien und Energie, Germany; [4]École Polytechnique Fédérale de Lausanne, Switzerland; [5]University of Cologne, Germany

Perovskite solar cells currently enter a stage, where market introduction is within reach. For serious upscaling, control over the quality of the perovskite material is most critical. To this end, the community currently relies heavily on laboratory experience, engineering, and fine-tuning approaches. A key challenge is the controlled growth of perovskite crystallites while processing thin films. Several strategies are currently in use, such as like anti-solvent or additive engineering. While the impact of these strategies is well-evidenced in the resulting layers, the underlying mechanisms that govern the crystallization process are still subject to a vigorous debate. A frequently cited theory is that the nuclei for the perovskite crystallization evolve from intermediate Pb^{2+}-MA^{+}-I^{-}-solvate clusters. [1] A dominant role of solvate clusters implies a strong impact of complexing and coordination in the precursor solution on the crystallization process. Reports of the colloidal structures and Lewis-base-acid interactions in the perovskite precursor ink seemingly support this theory. [2] As of yet, however, insights that unambiguously link the complex formation in the precursor inks to the perovskite formation are lacking.
We present a holistic approach in which we study the entire course of perovskite formation. We begin with as study of lead complexation in the precursor stage (using NMR and electrical conductivity measurements in the solution) and proceed with in-situ GIWAXS investigations during thin film deposition and along the way to thin film formation (bare layers and solar cells). We systematically study the impact of common solvents like DMF, DMSO and NMP. As an exemplary additive, to study the influence of Lewis-base additives, we chose thiourea, which is a strong sulphur donor and an effective crystallization mediator. With ^{207}Pb NMR and conductivity studies, we found a strong and systematic impact of the choice of solvents on the formation of lead complexes in the precursor solution, as well as indications, that may imply the presence of 3D corner sharing structures already in the precursor ink. Importantly, the differences in lead complexation depending on the solvent apparently diminish with increasing the concentration of the precursor ink; the final grain sizes remained largely unaffected by even strong variations found in the diluted precursors. On the other hand, the addition of thiourea did not affect the nature of lead complexes in the precursor solution. By in-situ GIWAXS, we are finally able to identify the annealing step as the decisive stage, where the presence of the additive affects the formation of perovskite grains and their crystallographic orientation. We could further substantiate our interpretation by FTIR studies. As such, for the first time, we provide a convincing link between precursor chemistry and final thin film formation.

All-Solution-Processed Fabrication of Intrinsically Flexible Multicolor Perovskite Light-Emitting Diodes and Photodetectors on Diverse Substrates (Elastomer, Paper, Textiles, etc.) JunyiZhao and ChuanWang; Washington University in St. Louis, United States

Owing to the unique properties such as tunable bandgap and strong optical absorption, perovskite holds great potential for optoelectronic device applications. Although significant progress has been made to explore high-performance light-emitting diodes (LEDs) and photodetectors (PDs) using perovskite, existing fabrication techniques based on the rigid substrate are unable to meet the growing demand from large-area flexible displays. In this work, we report all-solution-processed perovskite LEDs (PeLEDs) and photodetectors (PePDs) fabricated on various unconventional substrates commonly found in our daily life, including paper, textiles, plastics, rubber, metal, and even three-dimensional surfaces using a versatile and low-cost direct writing approach. Compared to conventional spin-coating and vacuum-evaporation processes, the direct writing approach enables mask-free patterning and allows even untrained individuals to “draw” a batch of high-performance LEDs/PDs in a time-efficient and energy-saving manner. A significant challenge when implementing optoelectronic devices on paper and textiles is the rough surface morphology of yarn and fiber networks, which can lead to nonuniform film thickness and leakage current. To address this issue, we have demonstrated that blending ionic polymer poly(ethylene oxide) (PEO) with poly(3,4-ethylenedioxythiophene) polystyrene sulfonate (PEDOT:PSS) not only enhances the conductivity and flexibility of the polymer conductors, but also achieve local self-planarization. For the emissive layer, we have successfully achieved multicolor LEDs covering the entire visible spectrum on both paper and textile substrates by substituting halide elements in the perovskite material ($MAPbX_3$) and formulating inks with varying halide compositions. Meanwhile, the brightness and efficiency of LEDs could be further boosted by introducing the butylammonium (BA) group to reduce the perovskite structure dimensionality to form 2D Ruddlesden−Popper perovskite (RPP) structures. Furthermore, we have conducted systematic investigations on perovskite-polymer composites and demonstrated that the morphology and optoelectronic properties of the perovskite photoactive layer can be tuned by incorporating different polymer additives. Specifically, PEO allows for precise and smoother perovskite film deposition by tuning ink rheology and viscosity, while polystyrene (PS) increases the density and uniformity of crystal arrangement, resulting in improved LED brightness and reduced current leakage. Poly(methyl methacrylate) (PMMA) helps reduce grain defects and boundaries, benefiting carrier diffusion in photodetectors. The PeLEDs written on paper substrates exhibited a brightness as high as 15,225 cd m^{-2}, a current efficiency of 6.65 cd/A, and a turn-on voltage of 2.4 V. Owing to the extraordinary flexibility of each functional layer, the written LEDs on the paper substrate could be bent to a 1 mm extreme curvature radius for over 5000 cycles without decay in performance. In summary, the written perovskite optoelectronic devices are ideally suited for low-cost and large-area emerging application scenarios such as deformable displays, wearable E-Textiles, E-Papers, and E-packaging.

8:00 PM EN05.11.18

Enhancing Efficiency of Quasi-2D PeLEDs Through Anti-Solvent Treatment-Induced Phases Modulation LyuchaoZhuang, QiWei, ChuanzhaoLi and Shu PingLau; The Hong Kong Polytechnic University, Hong Kong

Quasi-2D perovskite has drawn considerable attention for application in perovskite light-emitting diodes (PeLEDs) due to their higher exciton binding energy and moisture resistance. However, the inhomogeneous distribution of phases formed in spin-coated quasi-2D perovskite films inevitably leads to energy transfer loss, limiting the emission performance. Here, we systematically investigated the phases modulation behavior for a series of anti-solvent with different polarity -namely, the toluene (TO), diethyl ether (DE), chlorobenzene (CB), anisole (AN), ethyl acetate (EA). Due to the strong hydrogen bonding interaction between EA and organic spacer cations, it will hinder the organic and $[PbBr_6]^{4-}$ combination. The crystallization rate of intermedia phases slows, resulting in a large proportion of high-n phases formation subsequently. As a result, an efficient energy cascade is ensured with a narrow distribution centered around the desired phases. Leveraging these insights, we achieved PeLEDs with improved external quantum efficiency (EQE) of 4.21%, 7.11%, and 8.77%, corresponding to ~490 nm, ~497 nm, and ~503 nm emissions, respectively. Furthermore, the anti-solvent treatment strategy provides a guide to regulate the phase distribution for eliminating energy transfer loss to fabricate efficient quasi-2D PeLEDs.

8:00 PM EN05.11.19

Ionization of Hole Transport Materials as a Method for Improving the Photovoltaic Performance of Inverted Perovskite Solar Cells Wen-renLi[1], YogeshTingare[2], ChaochinSu[2], Dibyajyoti GHosh[3], HsinhanTsai[4], WanyiNie[4], Chien-HsiangLin[1], Sheng-ChinChou[2], Ning-WeiLai[2] and Xin-RuiLew[1]; [1]National Central University, Taiwan; [2]National Taipei University of Technology, Taiwan; [3]Indian Institute of Technology Delhi, India; [4]Los Alamos National Laboratory, United States

Increasing energy demands and concerns over global warming have led to a focus on the development of solar energy technologies. Perovskite solar cells (PSCs) have emerged as one of the most promising photovoltaics and are being investigated extensively. In inverted PSCs, hole transport materials (HTMs) assist directional charge transfer and electron blocking and also play an critical role in forming large-grained perovskites which enhance cell performance. In this work, we demonstrate a strategy for increasing the power conversion efficiency (PCE) of the device by ionizing HTMs, which introduces hydrophilicity into the HTM, improved interfacial properties, and excellent surface topographies. A comparative study of different ionizing counter anions showed that ionization also affects the absorption and emission properties, energy levels, and hole mobility of HTMs. Perovskite morphology significantly impacts PSC performance, and the anion groups like sulfoxide, SCN^-, and iodide contribute effectively to the film formation and defect passivation of perovskites. Ionic dopant-free HTM with iodide entity was found to efficiently passivate the dominant surface halogen vacancy due to its smaller size, lowering the density of charge-trapping defect states and achieving a hysteresis-free power conversion efficiency of 20.46%, which was 1.71% higher than that of the non-ionic HTM. Detailed research and analysis using atomistic modeling were also investigated, providing valuable insights into the correlation between anion size and perovskite passivation and efficiency. Durability is an important aspect in PSCs and can be assisted by a suitable HTM. As result, the devices based on HTM with iodide and non-ionic HTM retained 97% and 89%, respectively, of their original PCE for 500 hours, but the device fabricated with PEDOT: PSS retained about 81% of its PCE for the same time. This study provides a technologically relevant solar cell demonstration with a mechanistic understanding of the interfacial material design. Studying other charged molecules with varying properties and sizes as counterions to develop high-performing PSCs will also be reported in the meeting.

8:00 PM EN05.11.20

Comparative Study of Shelling $CsPbBr_3$ Quantum Dots with CdS and TiO_2NoahJ. Pitcher, BryceBaird-Taylor, DanielMuscato, IsakHurtic and Yiliang (Yancy)Luan; Binghamton University, The State University of New York, United States

Halide perovskites (HP) have been attractive in the development of optoelectronics due to their many favorable properties, such as high efficiency and adjustable band gap. However, HP are unstable when exposed to an ambient atmosphere, including varying moisture, light, and heat, which limits their applications. Furthermore, HP quantum dots (QDs) have enhanced properties and improved stability compared to perovskite thin films because of the quantum effect. However, better stability is still desired for the introduction of HPQDs into optoelectronics. Shelling engineering is a powerful method that can boost the stability of nanomaterials. Nevertheless, it is still challenging to effectively shell HPQDs due to the harsh conditions required by the process. In this report, we will present the shelling of $CsPbBr_3$ QDs with titanium dioxide (TiO_2) and cadmium sulfide (CdS), respectively. The two shelling methods will be demonstrated in parallel with each of the protocols, structures, and properties of the products. Our results indicate that the shelling with CdS was successfully achieved, while the QDs collapsed during the shelling with TiO_2. Additionally, the photoluminescence of our HPQDs is dependent on the amount of CdS introduced during shelling. This research does not only demonstrate successful shelling of HPQDs with CdS, but also yields constructive insights for the shelling engineering of nanomaterials.

8:00 PM EN05.11.21

Performance of Flexible $MAPbI_3$ Solar Cells Made on Different Transparent Conducting Electrodes with Different Hole Transport Layers BishalBhandari, RobertPiper, JustinC. Bonner and JuliaW. Hsu; The University of Texas at Dallas, United States

Perovskite solar cells (PSCs) have gained interest as a viable technology in recent years because of their low fabrication cost, solution processability, and high-power conversion efficiency. Commercializing perovskite solar cells requires high-throughput and low-cost manufacturing, e.g., solution-based roll-to-roll (R2R) process for making flexible PSCs. Transparent conducting electrodes (TCEs) are critical for flexible PSCs to achieve high efficiency. In our laboratory, flexible hybrid TCEs are made on polyethylene terephthalate (PET) with R2R flexographically printed Ag metal lines by blade coating silver nanowires (AgNWs) and planarized with indium zinc oxide (IZO) on top, and then the entire stack is photonic cured. With this process, we achieve TCEs with transmittance averaged between 400 and 700 nm wavelengths (T_{avg}) = 81 ± 0.4 %, sheet resistance (R_{sh}) = 11 ± 0.5 Ω/sq, and root-mean-square surface roughness (σ_{rms}) = 4.3 ± 0.4 nm. Flexible PSCs were fabricated on the hybrid TCEs and compared to devices made on commercially available PET/TCEs. We also investigated the J-V characteristics of these flexible PSCs using different hole transport layer materials. TCEs with comparable electrical, optical, and morphological properties displayed varied J-V performance with different hole transport layers. These results are surprising because, normally, other than transmittance and sheet resistance, TCEs are not considered to have a great effect on solar cell performance. We perform additional studies to probe the factors that influence the J-V characteristics of these flexible PSCs, such as contact resistance losses and interfacial properties between the TCE and the charge transport layers. The size of devices is also varied to study upscaling behavior. We aim to understand the charge extraction and recombination process and gain insights into the underlying mechanism affecting the performance and efficiency of flexible PSCs.

This work is supported by DOE SETO DE-EE0009518.

Substrate Functionalization to Control Phase Purity in the Co-Evaporation of $FAPbI_3$Andres FelipeCastro Mendez, Juan-PabloCorrea-Baena and CarloPerini; Georgia Institute of Technology, United States

A major challenge for perovskite solar cell commercialization is scalability. Thermal evaporation offers advantages such as higher uniformity, better thickness control, non-soluble materials deposition, and removal of the solvent orthogonality constraint that solution processing has. Co-evaporation of FAPbI3 is a promising choice for the fabrication of high efficiency and scalable perovskite solar cells. However, non-perovskite hexagonal phases are more stable at room temperature, and the presence of these phases is detrimental for the device performance. In this work, we study the role of substrate functionalization on the phase purity and composition of the co-evaporated layer. We show that the growth of hexagonal phases is preferred on substrates without functionalization, possibly as result of a FA+ deficiency in the layer. On the other hand, phosphonic acids remediate this problem by enhancing the adsorption rate of organic cations on the substrate and creating the right environment for the formation of pure cubic-phase films.

Solution Processing Defects and Their Role in Device Stability and Reverse Bias Degradation for Perovskites Solar Cells SamuelA. Johnson, IsaacGould, GabrielMcAndrews, DanielMorales and MichaelMcGehee; University of Colorado, Boulder, United States

Solution processing metal halide perovskites has numerous advantages when it comes to scaling up manufacturing relative to other methods, including speed and energy input, but reproducibility and reliability are complicated by physics dictating coating (e.g. surface tension and dewetting). Void defects and pinholes form via tension created by volume reduction during the drying phase, a fundamental force involved in film formation from solution, yet are seldom discussed. In this work, we systematically investigate the origin and impacts of ‘void defects’, points where the intrinsic perovskite absorber is missing and inherent to any solution-deposition process, to find they are a ubiquitous feature in solution processed perovskite devices, irrespective of perovskite composition and architecture. Experimental data and equivalent-circuit modeling show many of these defects behave as diodes with slightly lower turn-on voltages in parallel with the remainder of the device. Therefore, they have minimal detrimental effects on forward-bias photovoltaic performance, producing a small deficit in Voc and FF. However, we reveal these defects significantly undercut reverse-bias stability where they break down at lower voltages, shunting current, resulting in local ohmic heating, followed by the melting and propagation of burning metal shunts across the surface for some architectures. This effect produces catastrophic degradation of the solar module that would never be suitable for scaling up. It is therefore critical to mitigate such defects for widespread implementation of perovskite PV by all available means, and we demonstrate optical profilometry and PL-mapping as high-throughput detection methods for these defects as well as improved particle control and solution wetting as possible preventative measures, as well as strategies to minimize the effects use of thick oxide transport layers and contacts. While vapor- and hybrid-phase perovskite deposition methods demonstrate radically reduced defect density, their large-scale employment may be difficult making the elimination or passivation of these defects through a single or combination of strategies necessary to unlock defect-free large area solution processed coating techniques.

Effects of Van der Waals Interactions on Excitonic Properties of Lead Halide Perovskite Photovoltaic Materials AmirA. Farajian; Wright State University, United States

Excitons dissociation and diffusion are among the key properties that determine the efficiency of light harvesting in photovoltaic materials. As representatives of a promising category of novel photovoltaics, lead halide perovskites include both bonding and non-bonding interactions. In order to assess, and engineer, excitonic properties of these materials, theoretical calculations can complement experimental results to determine the effects of van der Waals interactions. The focus of this work is to utilize density functional theory simulations that explicitly incorporate van der Waals interactions to estimate excitonic properties. The results reveal how van der Waals interactions affect key excitonic characteristics, e.g., binding energies and effective masses, and help determine strategies for constituent selection towards improving light-harvesting efficiency.

Chemical Reaction Kinetics of the Decomposition of Low Bandgap Tin-Lead Halide Perovskite Films and The Effect on The Ambipolar Diffusion Length YuhuanMeng, PreethamP. Sunkari, MarinaMeila and HughW. Hillhouse; University of Washington, United States

Understanding the degradation mechanism and quantifying the degradation rate of hybrid organic-inorganic halide perovskite (HP) materials are essential for achieving the commercialization of HP solar cells. Here, we focus on evaluating the reaction products and kinetics of the degradation of mixed Sn-Pb halide perovskite ($FA_{0.75}Cs_{0.25}Pb_{0.5}Sn_{0.5}I_3$) thin films in response to oxygen, moisture, and illumination using in-situ measurements of optical transmittance, photoluminescence, X-ray diffraction, and UV-Vis-NIR spectroscopy. We determined that the decomposition occurs by a dry oxidation pathway ($1x10^{-8}$ mol/(m^2s) at 25 °C in air) and a water-accelerated oxidation pathway ($3x10^{-8}$ mol/(m^2s) at 25 °C in 50% RH air). In 50% RH air, the water-accelerated oxidation dominates at low temperatures, but the dry oxidation pathway (which has a higher activation energy) dominates at temperatures greater than 40 °C. A kinetic rate expression for the decomposition is determined and validated with a mean test error of 18%. Further, we developed a predictive model of the decay of the diffusion length (predicting the time required for the diffusion length to decrease to 80% of its initial value) with a prediction test error of 32% by machine learning. The chemical decomposition rate expression was selected as the most dominant feature in all 3-feature models with low prediction test error. This work highlights the significance and utility of quantitative measurements of perovskite degradation to make reliable predictions about device lifetimes, particularly when dealing with limited datasets.

SESSION EN05.12: Structure Property Relationships in Halide Perovskites I

Update on The Synthesis and Surface Chemistry of Highly Luminescent Lead Halide Perovskite Nanocrystals MaksymV. Kovalenko[1,2]; [1]ETH Zurich, Switzerland; [2]Empa–Swiss Federal Laboratories for Materials Science and Technology, Switzerland

Colloidal lead halide perovskite (LHP) nanocrystals (NCs), with bright and spectrally narrow photoluminescence (PL) tunable over the entire visible spectral range, are of immense interest as classical and quantum light sources. Severe challenges LHP NCs form by sub-second fast and hence hard-to-control ionic metathesis reactions, which severely limits the access to size-uniform and shape-regular NCs in the sub-10 nm range. We show that a synthesis path comprising an intricate equilibrium between the precursor (TOPO-$PbBr_2$ complex) and the [$PbBr_3^-$] solute for the NC nucleation may circumvent this challenge [1,2]. This results in a scalable, room-temperature synthesis of monodisperse and isolable $CsPbBr_3$ NCs, size-tunable in the 3-13 nm range. The kinetics of both nucleation and therefrom temporally separated growth are drastically slowed, resulting in total reaction times of up to 30 minutes. The methodology is then extended to $FAPbBr_3$ (FA = formamidinium) and $MAPbBr_3$ (MA = methylammonium), allowing for thorough experimental comparison and modeling of their physical properties under intermediate quantum confinement. In particular, NCs of all these compositions exhibit up to four excitonic transitions in their linear absorption spectra, and we demonstrate that the size-dependent confinement energy for all transitions is independent of the A-site cation. We then show that this synthesis – relying on the labile ligand capping with TOPO-phosphinic acid mixture – makes for a convenient platform for the subsequent surface functionalization with diverse capping ligands [3]. Robust surface functionalization of highly ionic surfaces, as is the case of LHP NCs, has remained a formidable challenge due to the inherently non-covalent weak surface bonding. Leveraging the vast and facile molecular engineering of phospholipids, we present their efficacy as surface-capping ligands for LHP NCs. Molecular dynamics simulations and solid-state NMR confirm that the surface affinity of these zwitterionic molecules is primarily governed by the geometric fitness of their anionic and cationic moieties. Judicious selection of the ligands yielded colloidally robust $FAPbBr_3$ and $MAPbBr_3$ NCs and enabled colloids in a variety of solvents, from n-hexane to alcohols. We will discuss the atomistic details of the ligand surface binding, ranging from conventional alkylammonium ligands [4] to diverse zwitterionic moieties. In particular, we show that solution and solid-state NMR readily captures the surface binding motifs and the impact of the ligands on the surface structure of $CsPbX_3$ NCs [5]. We also present non-hydrolytic coating of perovskites with amorphous metal oxides [6] and exploration of other semiconductive perovskite NCs within the AMX_3 perovskite family.

High-Performance Perovskite Solar Cells Incorporated with Conjugated Organic Molecules LeningShen, TaoZhu and XiongGong; The University of Akron, United States

In the past years, perovskite solar cells (PSCs) as alternative cost-effective solar technology have drawn great concentrations in both academic and industrial sectors. High power conversion efficiency (PCEs) has been reported from the PSCs based on three-dimensional (3D) perovskites, but 3D perovskites are sensitive to moisture and air. Moreover, unbalanced charge transport within perovskites restricts further boost PCEs of PSCs. In this presentation, we reported efficient and stable PSCs based on either the perovskite: polymer bulk heterojunction composites or ternary perovskite-organic composites. Systemically studies demonstrated that an extended spectral absorption, enhanced and balanced charge transport, improved film morphology, enlarged crystallinity, and suppressed ion immigration movement were observed from the above two different systems compared to those based on the 3D perovskites. As a result, PSCs with over 23 % PCEs, dramatically enhanced stability, and suppressed photocurrent hysteresis were demonstrated. These results indicated that our studies provided a facile and promising way to realize high-performance PSCs, where perovskites are incorporated with conjugated organic molecules.

8:45 AM EN05.12.03
Achieving Metal Doping of Strongly Confined Perovskite Nanocrystals under Ambient Conditions ZacharyVanOrman, MateoC. Wuttig and SaschaFeldmann; Harvard University, United States

Halide perovskite (HP) nanocrystals (NC) hold great promise for optoelectronic applications due to their high photoluminescence (PL) quantum yields and energetic tunability *via* composition and size.[1] Further, doping M^{2+} metal cations into the HP lattice can enhance the radiative rate of the NC emission, and, in the case of manganese, it can simultaneously introduce an additional decay pathway in the form of long-lived Mn d-d orange PL.[2,3] However, so far, M^{2+}-doped $CsPbCl_3$ NC synthesis relies on hot injection, making it challenging to achieve strongly confined NCs.[4] Recently, a novel synthesis method has been reported for HP NCs using complexation agents, resulting in the capability of synthesizing strongly confined HP NCs.[5]
Using the complexation agent synthetic approach, we now show that facile M^{2+} doping of $CsPbX_3$ NCs for various dopants (Mn, Ni, Zn) can be achieved, without the necessity of inert synthesis conditions or high temperatures.[6] This gives access to a highly controlled size-dependence series for doped NCs, especially in the strongly confined regime (down to ~ 3.5 nm) which was previously inaccessible for doped perovskite NCs. We demonstrate that doping Mn and other divalent transition metals can vary the optical properties in vastly different and opposing ways, depending on the degree of quantum confinement and doping concentration. The presented work therefore not only outlines a new and improved synthetic approach for doped HP NCs but also elucidates the impact of metal doping on the resulting optical properties under confinement.

Enabling Robust Chemical State Analysis of Sn-Based Perovskites via Auger Parameter Analysis in XPS AlexanderWieczorek and SebastianSiol; Empa - Swiss Federal Laboratories for Materials Science and Technology, Switzerland

Sn-based perovskites exhibit compelling properties such as reduced toxicity and lowered band gaps over those purely based on Pb. As a result, they are of increasing interest for photovoltaic applications in single-junction and all-perovskite tandem applications.[1]

For high performances, control of the oxidation state and interfacial chemistry is paramount, which can be determined using X-Ray photoelectron spectroscopy (XPS). However, the minor chemistry related shifts of the Sn core level emission complicate the analysis, especially for semiconducting materials. Here, surface band-bending as well as differences in the work function can be particularly pronounced

In this presentation, we demonstrate that studies based on the modified Auger parameter α' provide a robust method to resolve different chemical states in Sn-based perovskites. Using a set of reference samples, we identified a high sensitivity to the halide, resulting in a shift of up to $\Delta\alpha' = 2$ eV between $ASnI_3$ and $ASnBr_3$-type polycrystalline perovskite thin-films.[2] Observed dependencies of α' on the Sn oxidation state and local chemistry provide a framework that enables reliable tracking of degradation as well as X-site composition for Sn-based perovskites and related compounds. More recently, we successfully applied this framework on Sn-based perovskite nanocrystals to ensure the absence of Sn(IV) impurities upon optimized synthesis procedures.[3]

The higher robustness and sensitivity of such studies not only enables more in-depth surface analysis of Sn-based perovskites than previously performed, but also increases reproducibility across laboratories. Due to the facile data analysis, this method is ideal for high-throughput studies that are increasingly being adopted in the development of new semiconducting materials.[4]

Advancements in Pulsed Laser Deposition of Hybrid Halide Perovskites MonicaMorales-Masis; University of Twente, Netherlands

In this presentation, we present recent progress in utilising Pulsed Laser Deposition (PLD) as a vacuum-based single-source deposition method for a wide range of hybrid and organic halide perovskites. We address the specific challenges associated with hybrid film growth, such as incompatible volatility and solubility, by employing laser ablation of a solid target containing dry perovskite precursors. The quality of the thin films can be tuned by controlling parameters like laser fluence, target composition, and process pressure.

The first part of the presentation focuses on the development of $MA_xFA_{1-x}PbI_3$ and $Cs_xFA_{1-x}PbI_3$ absorbers with tunable MA/FA ratios, as determined by XPS, NMR, and microstructure analysis. We demonstrate P-i-n solar cell devices incorporating PLD $MA_xFA_{1-x}PbI_3$ absorbers with power conversion efficiencies exceeding 17%.

The second part of the presentation highlights the epitaxial formation of PLD-grown $MAPI_3$ and $CsPbI_3$ on lattice-matched substrates. PLD enables precise control over film thickness and deposition rate, which facilitates the investigation of polymorph stabilization, and the impact of strain on the optoelectronic properties of perovskite materials.

By combining controlled growth through PLD with insights into structural-property relationships, we can pave the way for designing a new generation of complex, stable, and non-toxic hybrid perovskite films.

A 0-D Barrier Layer Increases Stability in Mixed Sn-Pb and All-Perovskite Tandem Cells ChongwenLi[1,2], LeiChen[3], FangyuanJiang[4], ZhaoningSong[3], BinChen[1], XiaomingWang[3], EsmaUgur[5], AdamBalvan[1], XuefeiWu[6], ZacharyFink[6], Carlo Andrea RiccardoPerini[7], Juan-PabloCorrea-Baena[7], Zheng-HongLu[2], ThomasRussell[6], StefaanDe Wolf[5], MercouriG. Kanatzidis[1], DavidS. Ginger[4], YanfaYan[3] and EdwardSargent[1]; [1]Northwestern University, United States; [2]University of Toronto, Canada; [3]The University of Toledo, United States; [4]University of Washington, United States; [5]King Abdullah University of Science and Technology, Saudi Arabia; [6]Lawrence Berkeley National Laboratory, United States; [7]Georgia Institute of Technology, United States

Perovskite tandem solar cells promise performance beyond the detailed balance limit of single-junction solar cells; however, non-radiative recombination and its progressive worsening with time, especially in the mixed Sn–Pb low-bandgap layer, currently limit performance and stability. We find that mixed Sn–Pb perovskite thin films exhibit a compositional gradient, with an excess of Sn on the surface – and we show this gradient exacerbates oxidation and increases the the rate of recombination. We develop a materials processing strategy wherein diamines preferentially chelate Sn atoms, removing them from the film surface and achieving a more balanced Sn:Pb stoichiometry, making film surface resistive to Sn oxidation. This process forms electrically-resistive low-dimensional barrier layers, passivating defects and reducing interface recombination. Further regulating the dimensionality of the barrier layer to 0-D using 1,2-diaminopropane results in more uniform distribution and passivation. Tandems achieve a power conversion efficiency of 28.8%. Encapsulated tandems retain 90% of initial efficiency following 1000 hours operating at the maximum power point under simulated one-sun illumination in air without cooling.

10:30 AM EN05.12.07
Interlayer Ordered Mixed-Spacer 2D Halide Perovskites XiaotongLi[1], HaoDong[2], GeorgeVolonakis[3], ConstantinosC. Stoumpos[4], JackyEven[3], ClaudineKatan[3], PeijunGuo[2] and MercouriG. Kanatzidis[1]; [1]Northwestern University, United States; [2]Yale University, United States; [3]University of Rennes, France; [4]University of Grete, Greece

Two-dimensional (2D) halide perovskites exhibit extraordinary stability and structural tunability because they can incorporate different organic cations as spacers. Their structures can be divided into the Ruddlesden-Popper (RP) and Dion-Jacobson (DJ) phases depending on the spacers. When different spacers are mixed into one perovskite structure, they are usually disordered and occupy the same interlayer space. In this work, we demonstrate that when cyclic 1,2,4-triazolium (Tz) is used as a spacer and combined with another linear spacer such as propylammonium (PA) or butylammonium (BA), the interlayer ordered mixed-spacer 2D perovskites can form. The Tz and PA (BA) spacers occupy separate interlayer spaces and show two different interlayer distances. The octahedra next to the Tz spacers resemble the stacking of the DJ phase while those adjacent to the PA (BA) layers exhibit the stacking of the RP phase. The bandgaps of $(PA)(Tz)PbBr_4$ and $(BA)(Tz)PbBr_4$ are in between the parent $n = 1$ compounds ($(PA)_2PbBr_4$ or $(BA)_2PbBr_4$, and $(Tz)_2PbBr_4$). DFT calculations suggest that the band structures of $(PA)(Tz)PbBr_4$ and $(BA)(Tz)PbBr_4$ combine features from parent compounds yet differ from a simple superposition. This way, we are able to combine the properties of different spacers (cyclic and linear, aromatic and aliphatic) in one structure. This work expands the structure types in 2D perovskites and suggests many possible combinations of spacer cations for all kinds of optoelectronic applications.

All-Inorganic Quantum Dot in Perovskite PbS-$CsPbBr_3$ for High Energy Radiation Scintillation GraysonC. Johnson, HarithaRajeev, SammyFieser, Seung-HunLee and JoshuaChoi;

University of Virginia, United States

Efficient and stable scintillators are crucial for medical imaging, high energy physics, security, and other fields. However, current scintillators are typically produced as single crystals in energy intensive, high-cost processes. Recently, inorganic-organic quantum-dot-in-lead halide perovskites compatible with scalable, low-cost, and large area manufacturing have been synthesized to address these shortcomings. Still, organic components result in lower stability of 3D lead halide perovskites compared to their all-inorganic counterparts. Here, we synthesize all-inorganic PbS quantum dot in $CsPbBr_3$ perovskites at the gram scale and demonstrate their utility as an ionizing radiation scintillator. Emissions under X-ray excitation span from 1400 nm to 1000 nm depending on the PbS quantum dot size. This material retains luminescent activity after exposure to ambient conditions at least 3 times longer than the PbS quantum dots in hybrid methylammonium lead bromide perovskites. Finally, this material was successfully pressed into bulk, polycrystalline pellets that may be used as individual pixels for high energy radiation detection devices.

11:00 AM *EN05.12.09
Defects Activity in Metal Halide Perovskites AnnamariaPetrozza; Istituto Italiano di Tecnologia, Italy

Bandgap tuning is a crucial characteristic of metal-halide perovskites, with benchmark lead-iodide compounds having a bandgap of 1.6 eV. To increase the bandgap up to 2.0 eV a straightforward strategy is to partially substitute iodine with bromine in so-called mixed-halide lead perovskites. Such compounds are prone, however, to defect-induced halide segregation resulting in bandgap instabilities, which limits their application in tandem solar cells and a variety of optoelectronic devices. The optimization of the perovskite composition and surface passivating agents can effectively slow down, but not completely stop, such light-induced instabilities. Here I will show how we identify the defect and the relative intra-gap electronic state/charge carrier dynamics that triggers the material transformation and bandgap shift. It allows us to engineer the perovskite band edge energetics by engineering the chemical composition of the perovskite crystalline unit to radically deactivate the photo-activity of such electronic states and stabilize the perovskite bandgap over the entire spectral range above 1.6 eV. Overall, I will show how the photo-instability of lead based single and mixed halide perovskites, which can been seen as photo-degradation and bandgap photo-destabilization, has the same root. Then, I will conclude my lecture showing how, by halides alloying, we can achieve photo-stable bandgaps in a broad spectral range from NIR to 2 eV, in tin-based perovskites. Here, the defect chemistry modulates the electronic property of the semiconductor switching from a highly p-doped to an intrinsic one

11:30 AM EN05.12.10
Structural and Photophysical Consequences of the Interplay Between Cations in 2D Ruddlesden-Popper Metal Halide Perovskites WillaMihalyi-Koch[1], GiuliaFolpini[2], DanieleCortecchia[2], KyanaM. Sanders[1], AnnamariaPetrozza[2] and SongJin[1]; [1]University of Wisconsin–Madison, United States; [2]Istituto Italiano di Tecnologia, Italy

2D hybrid lead halide perovskites have been widely studied for optoelectronic and photovoltaic applications. Given the toxicity of lead, there is renewed interest in lead-free 2D halide perovskites including those based on Sn^{2+} and Ge^{2+}. Changing the B-site metal cation can have structural consequences due to different ionic radii and lone pair activity. Here, we report a series of 2D Ruddlesden-Popper metal iodide perovskites based on a new spacer cation, 4-bromo-2-fluorobenzylammonium that contain different B-site [Pb, Sn, Ge] and A-site cations [Cs, methylammonium (MA), and formamidinium (FA)]. Comparing across 8 crystal structures, we investigate the structural changes that result from varying the cations and the dimensionality of the perovskite (*i.e.*, $n = 1$, $n = 2$, vs. 3D). Strong lone pair effects and reduced B-site radii lead to distinct changes in the octahedral tilting and spacer cation packing in the Ge-based perovskites, while the Sn and Pb-based perovskites are structurally analogous. Although the Ge perovskites exhibit weak, broad photoluminescence (PL), the PL emission from the Sn and Pb perovskites containing the 4Br2FBZ spacer cation appears bright and color-pure at room temperature. However, through temperature-dependent photoluminescence and lifetime measurements, we reveal that the photophysical behaviors of the Sn and Pb 2D perovskites are different despite their structural similarities. Understanding the interplay of cation effects and the impact on the optoelectronic properties is important for informed materials design of lead-free 2D perovskites.

11:45 AM EN05.12.11
Controlling Phase Transitions in 2D Perovskites with Organic Cation Alloying RandKingsford and ConnorG. Bischak; The University of Utah, United States

Ruddlesden-Popper (RP) two-dimensional perovskites are quantum well materials with alternating layers of organic cations and inorganic octahedral layers. These materials have numerous applications due to their optoelectronic properties, including light-emitting diodes and photodetectors. RP perovskites also undergo structural phase transitions at relatively low temperatures, in which the organic layers undergo an ordered-to-disordered transition. Here, we present a synthetic strategy to tune the structural phase transition temperature of RP perovskites by alloying hexylammonium (HA) and pentylammonium (PA) cations. We also explore the connection between this phase transition and changes in the emissive properties of RP perovskites. Surprisingly, we find that HA_2PbI_4 and PA_2PbI_4 exhibit different changes in emissive properties upon undergoing the phase transition: the photoluminescence spectrum of HA_2PbI_4 decreases in intensity and blueshifts and the photoluminescence spectrum of PA_2PbI_4 exhibits an increase in intensity and redshifts. We attribute these changes in the photoluminescence spectra of HA_2PbI_4 and PA_2PbI_4 to changes in the degree of octahedral distortion. Last, we leverage changes in the photoluminescence of HA_2PbI_4 and PA_2PbI_4 to directly observe phase transition dynamics with photoluminescence microscopy. Our study represents an important step towards understanding couplings between structural dynamics and changes in optical properties in RP perovskites.

SESSION EN05.13: Structure Property Relationships in Halide Perovskites II

1:30 PM *EN05.13.01
From 2D to 3D Metal Halide Perovskites Nanoastructures LoredanaProtesescu; University of Groningen, Netherlands

Metal halides perovskites with nanoscale geometries have revolutionized the field of solution-processed photovoltaics and light-emitting devices due to their strong absorption and exceptional photoluminescence properties combined with a remarkable tolerance to structural defects. However, the further development of these materials to practical commercialization is hindered by their toxic components like lead and their inherent structural lability. Moreover, we still have little understanding of their crystallographic structures, chemical and physical interactions, and surface chemistry at a fundamental level.
The chemical design of metal halide perovskites proved to be the key to addressing those issues. Our recent findings confirm that a direct transition of the synthetic approach at nanoscale from Pb to Sn halide perovskites is not feasible. For Sn-based perovskites nanostructures, the structural dynamics between 3D cuboids and 2D Ruddlesden-Popper nanosheets colloids are highly dependent on the synthetic strategy. The presence of both species has a direct impact on the optoelectronic properties. Moreover, heterostructures containing halide perovskites nanocrystals are the next step towards obtaining accessible materials for industry. With the help of polymers or metal-organic frameworks, we can access air stable materials or ultra-small quantum dots.

2:00 PM EN05.13.02
Nearly Perfect Perovskites: Disorder and Anharmonicity in $APbBr_3$ ($A = MA^+, FA^+, Cs^+$) NicholasJ. Weadock[1], CameronMacKeen[2], KileyMayford[2], XixiQin[3], JulianVigil[4], YevgenyRakita[5], HemamalaKarunadasa[4], VolkerBlum[3], MichaelF. Toney[1] and FrankBridges[2]; [1]University of Colorado at Boulder, United States; [2]University of California, Santa Cruz, United States; [3]Duke University, United States; [4]Stanford University, United States; [5]Ben-Gurion University of the Negev, Israel

Lead halide perovskite (LHP) semiconductors remain at the forefront of materials for high-performance optoelectronic devices. A defining characteristic of LHPs is the low point defect formation energy, yielding point defect concentrations as high as 10^{15} cm^{-3} [1]. This high defect concentration, combined with ionic bonding and a soft lattice [2], suggests a high degree of both static and thermally induced disorder in LHPs.

Here, we use extended X-ray absorption fine structure (EXAFS) and single-crystal X-ray diffraction (XRD) measurements to characterize disorder in the nearest neighbor Pb-Br bond for $MAPbBr_3$, $FAPbBr_3$, and $CsPbBr_3$. Surprisingly, the static disorder for all compositions is negligible, with low temperature disorder dominated by zero-point-motion. The disorder becomes significant as the temperature is increased, with subtle changes in bond character observed for $MAPbBr_3$ and $FAPbBr_3$. The high degree of thermal disorder manifests as an asymmetric Pb-Br pair distribution function (PDF), observable even at low temperatures of 150 K. Several origins of this asymmetry have been proposed, including single-site anharmonic potentials [3,4] and Pb split-sites [5,6]. We compare several asymmetric models to the experimental PDFs obtained from EXAFS and demonstrate that the asymmetry arises from an anharmonic interatomic potential.

Our results improve the understanding of point defects and intrinsic doping in LHPs: although the defects are charged, a lack of static disorder from coulombic interactions confirms the near complete ionization of these defects at room temperature. Finally, we will discuss the possibility of implementing these “nearly perfect” crystals for low temperature applications in quantum computing.

NJW, XQ, VB, and MFT gratefully acknowledge full support from the Center for Hybrid Organic Inorganic Semiconductors for Energy (CHOISE), an Energy Frontier Research Center funded by the Office of Basic Energy Sciences, Office of Science within the U.S. Department of Energy through contract number DE-AC36-08G028308.

Thermotropic Liquid Crystals Enable Efficient and Stable Perovskite Solar Cells and Modules YiYang, ChengLiu, BinChen, MercouriG. Kanatzidis and EdwardSargent; Northwestern University, United States

Perovskite solar cells (PSCs) have seen impressive progress in performance and stability, yet maintaining power conversion efficiencies (PCEs) when scaling areas remains a challenge. Here we find that the additives used to passivate large-area perovskite films often co-crystallize near-simultaneously with perovskites or tend to aggregate at the surface/interface, which contributes to defects and to spatial inhomogeneity. We therefore introduce a thermotropic liquid crystal (TLC) additive with heightened diffusion ability at the perovskite annealing temperature to enable uniform, low-defects, and stable large-area perovskite films. We document as a result small-area PSCs achieving a PCE of 25.6% and modules having a certified PCE of 21.6% at an aperture area of 31 cm^2. These retain performance under the damp-heat test (ISOS-D-3, 85% relative humidity, 85°C) with T_{86} of 1200 hours, and show high resistance to reverse bias with (ISOS-V-1, negative V_{mpp}) and without bypass diodes.

Direct Observation of Contact Reaction Induced Ion Migration and Its Effect on Non-Ideal Charge Transport in Lead Triiodide Perovskite Field-Effect Transistors YouchengZhang and HenningSirringhaus; University of Cambridge, United Kingdom

The migration of ionic defects and electrochemical reactions with metal electrodes remains one of the most important research challenges for organometal halide perovskite optoelectronic devices. There is still a lack of understanding of how the formation of mobile ionic defects impact charge carrier transport and operational device stability, particularly in perovskite field-effect transistors, that tend to exhibit anomalous device characteristics. Here, we investigate the evolution of the n-type FET in $CsFAMAPbI_3$ during repeated measurement cycles as a function of different metal source-drain contacts and precursor stoichiometry. The channel current increases for high work function metals and decreases for low work function metals when multiple cycles of transfer characteristics are measured. The cycling behaviour is also sensitive to the precursor stoichiometry. These metal/stoichiometry-dependent device non-idealities are correlated with the quenching of photoluminescence near the positively biased electrode. Based on elemental analysis using electron microscopy our observations can be understood by an n-type doping effect of metallic ions that are created by an electrochemical interaction at the metal-semiconductor interface and migrate into the channel.
Our findings improve our understanding of ion migration, contact reactions and the origin of non-idealities in lead triiodide perovskite FETs.[1] These findings shed light on how bias-induced migration of extrinsic metallic ions impacts charge transport at a device level, revealing the widespread nature of this phenomenon when perovskite is in direct contact with metals. Our work underscores the crucial role of careful metal selection and precise composition control for the successful design of durable and reliable perovskite-based optoelectronic devices.

3:15 PM EN05.13.05
Understanding Charge Transport in High Performance Mixed Lead-Tin Halide Perovskite Transistors KrishanuDey[1,2], SamuelD. Stranks[2,2] and HenningSirringhaus[2]; [1]University of Oxford, United Kingdom; [2]University of Cambridge, United Kingdom

Metal halide perovskites have earned the distinction of one of the most exciting semiconductor technologies in the last decade, with the photovoltaic single junction power conversion efficiencies already demonstrating ~26% and all-perovskite tandem efficiencies exceeding 28%. However, due to the soft nature of the halide perovskite lattice, field-driven charge transport studies using 3D perovskite field effect transistors (FETs) have largely remained under the cloud of undesirable ionic migration effects near room temperature. In addition, the presence of methylammonium at the A-site in many high performing 3D perovskite compositions introduces additional instabilities, which limit the reliable room temperature operation of FETs.

In this work, we address both these challenges and demonstrate that FETs based on methylammonium-free, mixed-metal (Pb-Sn) perovskite compositions do not suffer from ion migration effects as significantly as their pure-Pb counterparts and reliably exhibit hysteresis free p-type transport with high mobility reaching 5.4 cm^2/Vs, ON/OFF ratio approaching 10^6 and promising operational stability, which are among the best reported metrics in the field of thin film perovskite FETs. Density functional theory calculations suggest that incorporation of Sn to partially replace Pb at the B-site of perovskite modifies the electronic structure to obtain a reduced hole effective mass and additional density of states at the valence band, thereby resulting in a pronounced p-type transport. The reduced ion migration is also manifested in an activated temperature dependence of the field-effect mobility with low activation energy, which reflects a significant density of shallow electronic defects in mixed Pb-Sn perovskites. This is sharply in contrast to the expected trend of negative temperature coefficient of mobility in the case of Pb perovskite FETs due to ion-induced field screening for the carriers in the channel. It is important to note that such interesting and distinctive trends of temperature-dependent mobility trends were never observed heretofore in 3D hybrid perovskite FETs owing to undesired ionic migration effects. We also visualize the suppressed in-plane ionic migration in Sn-containing perovskites compared to their pure-Pb counterparts using photoluminescence microscopy under bias and this can have significant ramifications for the applications of mixed-metal perovskites in future optoelectronics. Moreover, we also observe, for the first time, reversible electrochemical reduction of Sn^{4+} to Sn^{2+} happening under bias. Using spectroscopic measurements, we have established Sn^{4+} as a major source of defect in these Sn-containing perovskites and therefore such precise control of defect dynamics upon biasing brings out the transformative nature of these materials for designing high performance electronic devices.

In conclusion, this work represents the first comprehensive study of the field-driven charge transport on such low bandgap mixed Pb-Sn compositions, which have recently demonstrated significant progress in single junction and tandem solar cells, near-infrared light emitting diodes and photodetectors. Our work also establishes FETs as a powerful and reliable platform for providing fundamental insights into the doping, defects, instabilities, and charge transport physics of halide perovskite semiconductors to advance their applications in a plethora of semiconductor devices.

Supramolecular Assembly of Halide Perovskite Building Blocks ChengZhu[1,2] and PeidongYang[1,2]; [1]UC Berkeley, United States; [2]Lawrence Berkeley National Laboratory, United States

Metal halide ionic octahedron, $[MX_6]^{n-}$ (M = Pb^{2+}, Sb^{3+}, Te^{4+}, etc., X = Cl^-, Br^-, I^-), is the fundamental building block and functional unit of halide perovskites. The properties of the extended solids are dictated by the way how these octahedra are assembled, connected, and interact with the surrounding atomic environment. Hence, the ability to manipulate and control the assembly of the octahedral building blocks is paramount for constructing new perovskite materials. Here, we propose a systematic supramolecular strategy as a new method for the assembly of a family of $[MX_6]^{n-}$ into an extended network. Crown ethers are used to bind with various alkali metal cations to form supramolecular cations, two of which can sandwich one halide octahedron to form a structurally and optoelectronically tunable dumbbell structural unit. The dumbbell building blocks can be further assembled into extended crystals with diverse packing geometries and symmetries. Starting from the prototypical example of $(18C6@Cs)_2TeCl_6$ crystal structure, we can explore the synthetic space along: (1) varying the size of the crown ether (18C6 and 21C7), (2) changing the octahedra center cation (8 different metal cations), (3) tuning the halide anion (Cl^-, Br^-, and I^-), (4) modifying the alkali metal cation coupled with the crown ether, and (5) introducing 1D and 2D electronic dimensionality by connecting the octahedra. With all these synthetic possibilities, this supramolecular assembly route introduces a new general strategy for

designing halide perovskite structures with tailorable optoelectronic properties. For example, the supramolecular-assembled crystals have strong photoluminescence (PL) with a highly tunable emission color. $(18C6@Cs)_2ZrCl_6$ has a very bright blue emission, and the PL quantum yield is 12.57%. Furthermore, by varying the alkali metal cation from K^+ to Rb^+ to Cs^+, the PL spectra continue to redshift. We expect that the assembly approach of the supramolecular building blocks could bring a new general method for halide perovskite materials discovery, and we could further appreciate the structural and functional versatility of halide perovskites.

3:45 PM EN05.13.07
Direct Experimental Evidence for Defect Tolerance in Pb-Halide Perovskites, at Last DavidCahen[1,2], NagaP. Jasti[2,1], SigalitAharon[1], YishayFeldman[1] and IgalLevine[3]; [1]Weizmann Institute, Israel; [2]Bar-IlanUniversity, Israel; [3]HZB, Germany

While *defect tolerance* (DT) lacks direct *experimental* evidence, it is widely used as the basis for the exceptional optoelectronic properties of Halide Perovskites, HaPs, and their devices. It became a "fact" in the field, also when the initial theoretical model and computational support for it, was challenged. DT in semiconductors implies tolerance to *structural defects* without the *electrical and optical effects* (e.g., traps), associated with such defects. As such it also directly impacts what we view as the stability of such materials.
We present the first DIRECT experimental evidence for DT in Pb-HaPs by comparing the structural quality of 2D, 2D-3D, and 3D Pb-iodide perovskite single crystals with their optoelectronic characteristics using high-sensitivity methods. Importantly, we get information from the materials' bulk, because we sample *at least* ~0.1 to several µm, from the sample's surface. Therefore, we assess the intrinsic bulk (and not only surface-) properties of HaPs. The results point to DT in 3D, to a lesser extent in 2D-3D, but not in the crystals. We ascribe such dimension-dependent DT to the higher number of (near)neighboring species, available to compensate for structural defect effects in the 3D than in the 2D crystals. Our experimental results and their interpretation can now guide the search for, and design of other materials with DT.

4:00 PM EN05.13.08
Temperature-Dependent Reversal of Phase Segregation in Mixed-Halide Perovskites AdamD. Wright[1,2,3]; [1]University of Oxford, United Kingdom; [2]University of Warwick, United Kingdom; [3]Princeton University, United States

Tandem solar cells with metal halide perovskite top cells have achieved power conversion efficiencies better than single-junction silicon solar cells. However, the success of these devices is constrained by the phenomenon of halide segregation, which afflicts the mixed iodide-bromide compositions used to achieve the necessary wide bandgaps. When exposed to above-bandgap illumination, these mixed-halide perovskites de-mix into iodide-rich and bromide-rich regions. This phase segregation is deleterious to the performance of mixed-halide perovskites in tandem cell applications, but none of the multiplicity of proposed models have been able to fully explain all reported observations of light-induced halide segregation.

In this study[1], I report on the influence of temperature and light intensity on light-induced halide segregation in $MAPb(Br_{0.4}I_{0.6})_3$ by measuring changes in the photoluminescence spectra across an exceptionally wide parameter space. I reveal a reversal in the temperature trend in halide segregation rate, which speeds up as temperature is increased from 125 K to ≈290 K, but slows down again with further increases in temperature. I attribute this reversal to the trade-off between the temperature activation of segregation, e.g. through enhanced ionic migration, and its inhibition by entropic factors. I further show that while halide remixing indeed occurs at highly elevated light intensities, and becomes more pronounced at higher temperatures, this effect is only transient, reversing on its own over the time scale of minutes under continued illumination. I utilize our findings to elucidate the validity of the most commonly examined models describing the origins of halide segregation, and discuss their relevance to applications of mixed-halide perovskites in tandem and concentrator solar cells.

Bimolecularly-Passivated Interface Enables Efficient and Stable Inverted Perovskite Solar Cells ChengLiu, BinChen, MercouriG. Kanatzidis and EdwardSargent; Northwestern University, Afghanistan

Compared to the n-i-p structure, inverted (p-i-n) perovskite solar cells (PSCs) promise increased operating stability; however, to date, these photovoltaic cells suffer lower power conversion efficiencies (PCEs), the result of nonradiative recombination losses, particularly at the perovskite/C_{60} interface. Here we hypothesize that implementing the two functions is highly needed at the interface – 1) passivation of surface defects; and 2) the reflecting of minority carriers away from the interface and back into the bulk. We incorporate one molecule to passivate surface defects and suppress recombination via chemical interactions with perovskite. The other molecule was employed to repel minority carriers and reduce contact-induced interface recombination, achieved through field-effect passivation. The approach leads to a 5-fold increase in carrier lifetime and a 3-fold reduction in photoluminescence quantum yield (PLQY) loss, enabling the first certified quasi-steady-state PCE over 25% for inverted PSCs with stable operation at 65°C for over 2,000 hours in ambient air. We produce monolithic all-perovskite tandem solar cells with 28.1% PCE.

4:30 PM EN05.13.11
Architecture Optimization Improves Reverse Bias Stability in p-i-n Structured Perovskite Solar Cells FangyuanJiang[1], YangweiShi[1], TankaR. Rana[1], DanielMorales[2], IsaacGould[2], DeclanP. McCarthy[2], JoelSmith[3], GreysonChristoforo[3], MuammerY. Yaman[1], FaizMandani[4], HannahContreras[1], StephenBarlow[2], AdityaD. Mohite[4], HenrySnaith[3], SethR. Marder[2], J. DevinMacKenzie[1], MichaelMcGehee[2] and DavidS. Ginger[1]; [1]University of Washington, United States; [2]University of Colorado Boulder, United States; [3]University of Oxford, United Kingdom; [4]Rice University, United States

As perovskite photovoltaics make strides towards commercialization, reverse bias instability has been considered a serious challenge. We systematically investigate methods to improve reverse bias behaviors of p-i-n structured perovskite solar cells, including passivating halide vacancies, changing the electron transporting layer, and systematically varying the hole transporting layers and metal electrodes. Our results suggest that having a robust polymer hole transporting layer and an electrochemically stable electrode are important for preventing reverse bias breakdown of p-i-n perovskite solar cells. This result is surprising since much of the current effort and understanding has focused on the perovskite/electron transport layer/metal electrode interface. Nevertheless, with appropriate hole transporting layers, and optimized top electrode, we demonstrate breakdown voltages exceeding -15 V, comparable to that of silicon photovoltaics. Furthermore, our optimized solar cells demonstrate completely recoverable device performance even after being stressed at high reverse bias for many hours (i.e., at –7 V for 9 hours both in the dark and under partial shading). Following these observations, we propose a self-consistent model which highlights the role of electrochemical reaction pairs that has not been appreciated previously.

Bioinspired Liquid Encapsulation Platform for Protection of Optoelectronic Devices HaichaoWu, ZacharyA. Goodwin, BaptisteLemaire, YanhaoYu, NicolaMolinari, BorisKozinsky and JoannaAizenberg; Harvard University, United States

The next-generation semiconductors and devices, such as halide perovskites and flexible electronics, are extremely sensitive to water, thus demanding highly effective protection that not only seals out water in all forms (vapor, droplet, and ice), but simultaneously provides mechanical flexibility, durability, transparency, and self-cleaning. Although various solid-state encapsulation methods have been developed, no strategy is available that can fully meet all the above requirements. Here, we report a bioinspired liquid-based encapsulation strategy that offers protection from water without sacrificing the operational properties of the encapsulated materials. Using halide perovskite as a model system, we show that damage to the perovskite from exposure to water is drastically reduced when it is coated by a polymer matrix with infused hydrophobic oil. With a combination of experimental and simulation studies, we elucidated the fundamental transport mechanisms of ultralow water transmission rate that stem from the ability of the infused liquid to fill-in and reduce defects in the coating layer, thus eliminating the low-energy diffusion pathways, and to cause water molecules to diffuse as clusters, which act together as an excellent water permeation barrier. Importantly, the presence of the liquid, as the central component in this encapsulation method provides a unique possibility of reversing the water transport direction; therefore, the lifetime of enclosed water-sensitive materials could be significantly extended via replenishing the hydrophobic oils regularly. We show that the liquid encapsulation platform presented here has high potential in providing not only water protection of the functional device but also flexibility, optical transparency, and self-healing of the coating layer, which are critical for a variety of applications, such as in perovskite solar cells and

bioelectronics.

8:15 AM *EN05.14.02
Towards Efficient and Stable Perovskite Light Emitting Diodes DanielCongreve[1], SebastianFernandez[1], ManchenHu[1], MaheshGangishetty[2], ShaocongHou[2], QiminQuan[2], WilliamMichaels[1], PournimaNarayanan[1], NataliaMurrietta[1], ArynnGallegos[1], GhadaAhmed[1], JunruiLyu[1], QiZhou[1], BalreenSaini[1] and TracySchloemer[1]; [1]Stanford University, United States; [2]Rowland Institute at Harvard, United States

Perovskite LEDs are an exploding field, with high performance red and green devices demonstrated by many groups. However, two key challenges towards commercialization remain: poor performance at higher energies, and poor overall stability (particularly at those higher energies). Here, we demonstrate investigations into both issues. First, we identify two crucial issues holding blue materials back: the low internal photoluminescence yield and the LED device structure itself. By rectifying these issues, we were able to build LEDs that were 60x brighter than control, and, when combined with red and green downconverters, white light emitting LEDs. We further demonstrate how careful control over fabrication conditions allows for more uniform thin films, creating violet LEDs with 5x the efficiency over control devices. Finally, we study the interplay between efficiency and stability in green LEDs, showing that while an additive material can increase efficiency, it also leads to a stability decrease, highlighting the need for global evaluation of these changes to the device composition.

8:45 AM EN05.14.03
Designing Metal Halides for Fast Neutron Imaging Scintillators: Lessons from Perovskite Nanocrystals and Ionic Liquids KyleM. McCall; University of Texas at Dallas, United States

The lead halide perovskites have captivated the research community due to their exceptional optoelectronic properties that enable high performance as solar cells and light emitters. In particular, perovskite nanocrystals (NCs) have demonstrated their potential as next-generation light emitters, with applications ranging from QLED displays to X-ray scintillators. Recent work on metal halides for fast (high-energy, >1 MeV) neutron detection has shown that they have the potential to deliver low-cost, efficient scintillators for this application, with the advantages of high spatial resolution, low gamma-ray sensitivity, and negligible afterglow on the timescale of seconds. However, there are several challenges to overcome before these materials can displace the commercial polypropylene screens (embedded with microscale ZnS:Cu phosphors).
This presentation will summarize three studies in this field, which have each contributed design rules that will enable a more complete understanding of how to design metal halides for this application. A first comparison of perovskite nanocrystals with a variety of other halide and chalcogenide NCs showed that $FAPbBr_3$ NCs offered the highest light yield, while $CsPbBrCl_2$:Mn^{2+} NCs offered the highest spatial resolution. Composition and thickness-dependent measurements highlighted the need to 1) enhance concentration and 2) reduce self-absorption for all NC systems. Subsequently, we sought to further test these design rules by 1) exploring the use of metal halide ionic liquids for maximal concentration, and 2) separately pursing the optimized synthesis and doping in $CsPb(Br_xCl_{1-x})_3$:Mn^{2+} NCs to improve concentration and eliminate reabsorption.
These follow-up studies showcased the importance of these design principles for improved fast neutron scintillation, as the latter system demonstrated the capacity for concentrations above 100 mg/mL while essentially eliminating self-absorption, while the former system yielded significantly higher spatial resolution and competitive light yields. This presentation will synthesize this series of results into a succinct summary of the needs of this lesser-known application, providing the fundamental background to engage with the burgeoning field of fast neutron imaging and design the perovskite materials that can deliver the next generation of fast neutron scintillators.

9:00 AM EN05.14.04
Efficient and Stable Perovskite Light Emitting Diodes by using Stablized Interface TianjunLiu, SamuelD. Stranks, NeilGreenham and RichardH. Friend; University of Cambridge, United Kingdom

Metal halide perovskites have shown great optoelectronic properties for light emitting diodes (LEDs), such as high photoluminescence quantum yields (PLQYs), tunable bandgap, narrow emission linewidths and high charge-carrier mobility. Owing to the development of the strategy of defect passivation and controllable growth of grains, the external quantum efficiencies (EQEs) of perovskite light emitting diodes (PeLEDs) have achieved more than 25%. Furthermore, critical interface engineering has also been developed for fabricating PeLEDs with long operational stability, making a key step toward practical applications and future commercialization. We report an efficient PeLED with EQE > 24% in near infrared emission range by using organic additives. Owing to the stablized interface, the achieved devices present long term operational stability with T50 above 800 hours at current density of 20 mA/cm2. <quillbot-extension-portal></quillbot-extension-portal>

9:15 AM EN05.14.05
Continuous-Wave Amplified Spontaneous Emission and High-Current-Density Operation from a Transparent Perovskite LED Architecture KarimElkhouly[1,2], IakovGoldberg[1,2], XinZhang[1,2,3], NiravAnnavarapu[1,2], WeimingQiu[1], CedricRolin[1], JanGenoe[1,2], RobertGehlhaar[1] and PaulHeremans[1,2]; [1]Imec, Belgium; [2]KU Leuven, Belgium; [3]Fudan University, China

Metal halide perovskites are excellent candidates for the gain material in thin film laser diodes. They exhibit high optical gain, low amplified spontaneous emission (ASE) thresholds, and a wide emission wavelength tunability. These attributes have facilitated notable advancements such as optically-pumped pulsed and continuous-wave (CW) lasing from a large library of optical cavities, operating under both room-temperature and cryogenic conditions. The successful development of perovskite laser diodes and their prospective heterogeneous integration into photonic circuits would pave the way for a multitude of applications in domains such as sensing, ranging, data communication, and miniaturized displays.

However, achieving a current-injection perovskite laser, a promising yet complex feat, remains elusive due to the inherent complexity of the optoelectronic design challenges. Firstly, there is the necessity for high internal quantum efficiency (IQE) at extreme current densities ranging from hundreds to thousands of A/cm^2. This demands effective strategies for mitigating Joule heating, a problem magnified by perovskites' inherent low thermal conductivity and diminished stability at such high current densities. Secondly, the device stack must be optimized in terms of its optical design to maximize the net modal gain. This imposes stringent criteria on the thickness and conductivity of the layers comprising the device stack. In particular, the key challenge stems from the presence of conductive metal electrodes in the vicinity of a gain layer. It's essential, on the one hand, that electrodes inject kA/cm^2 current densities into the device. On the other hand, these highly conductive layers contribute to substantial free-carrier optical absorption, thereby increasing ASE threshold and current density necessary for ASE/lasing. In the last step toward a laser, a high quality-factor optical cavity has to be integrated into the perovskite LED (PeLED) without compromising the device performance and reliability.

In this work, we embed a perovskite waveguide stack, optimized for high-current density operation, into a scaled (50 um in diameter) transparent LED architecture with reduced optical losses. We reliably operate this miniaturized PeLED in a sub-µs pulsed mode above 3 kA/cm^2 without irreversible degradation. At these current densities, the device delivers EQEs above 1% at 77 K. Moreover, we achieve low ASE thresholds (< 10 µJ/cm^2) from this fully contacted electrical structure at 77 K using 3-ns optical pumping. This PeLED allows us to achieve several crucial milestones towards injection lasing: 1) ASE enhancement at synchronized photo-electrical co-excitation; 2) optically-pumped CW ASE when excited with 1-µs-long optical pulses; 3) electroluminescence brightness levels close to half of the brightness produced by CW optical pumping at ASE threshold. These milestones set us within reach of realizing a perovskite-based thin-film laser diode. Finally, we will also discuss novel concepts of integrating a fully functional PeLED with optical cavities for future thin-film perovskite laser diodes.

9:30 AM EN05.14.06
On the Photolysis of Mixed Halide Perovskite Nanocrystals MichaelC. Brennan[1,2] and TodGrusenmeyer[1]; [1]Air Force Research Lab, United States; [2]Azimuth Corporation, United States

Colloidal mixed halide perovskite nanocrystals (NCs) irreversibly degrade when exposed to ultraviolet—visible irradiation. Here, mixed halide perovskite NC photolysis is tracked via mass spectrometry, electron microscopy, and photoluminescence. The data shows continuous wave ultraviolet—visible irradiation causes the heavier halides within the alloy to sublimate. This ultimately transforms $CsPb(I_{1-x}Br_x)_3$ and $CsPb(Cl_{1-x}Br_x)_3$ ($x\approx0.50$) NCs into $CsPbBr_3$ and $CsPbCl_3$ NCs, respectively. Time-resolved mass spectrometry demonstrates real-time desorption of volatile halide species (e.g. $I_{2(g)}$/$HI_{(g)}$) during irradiation. Energy-dispersive X-ray spectroscopy confirms near complete expulsion of I^- from $CsPb(I_{1-x}Br_x)_3$ and Br^- from $CsPb(Cl_{1-x}Br_x)_3$ NCs. Electron diffraction and cathodoluminescence establish lattice contractions and emission blueshifts consistent with formation of single halide perovskites from parent mixed halide alloys. Finally, increasing photolysis rates at higher temperatures follow an Arrhenius relationship with an effective activation energy of ~62 kJ mol^{-1} for $CsPb(I_{1-x}Br_x)_3$ NCs ($x\approx0.50$). Altogether, this work provides important insight into the photolysis of colloidal perovskite NC alloys.

9:45 AM EN05.14.07
Experimentally Observed Defect Tolerance in the Electronic Structure of Lead Bromide Perovskites GabrielJ. Man[1,2,3], AleksandrKalinko[4], DibyaPhuyal[5], PabitraK. Nayak[6], HåkanRensmo[2] and SergeiM. Butorin[2]; [1]MAX IV Laboratory, Sweden; [2]Uppsala University, Sweden; [3]GJM Scientific Consulting, United States; [4]Deutsches Elektronen-Synchrotron DESY, Germany; [5]KTH Royal Institute of Technology, Sweden; [6]Tata Institute of Fundamental Research, India

Point defect tolerance in materials, which extends operational lifetime, is essential for societal sustainability, and the creation of a framework to design such properties is a grand challenge in the material sciences. Using three prototypical lead bromide perovskites in single crystal form and high-resolution synchrotron-based X-ray spectroscopy, we reveal the unexpectedly pivotal role of the A-cation in mediating the influence of photoinduced defects. Organic A-cation hydrogen bonding facilitates chemical flexing of the lead-bromide bond that mitigates the self-doping effect of bromide vacancies. The contribution of partially ionic lead-bromide bonding to the electronic band edges, where the bonding becomes more ionic upon the formation of

defects, mitigates re-hybridization of the electronic structure upon degradation. These findings reveal two new general design principles for defect tolerance in materials. Our findings uncover the foundations of defect tolerance in halide perovskites and have implications for defect calculations, all beam-based measurements of photophysical properties and perovskite solar cell technology.

Perovskites—From Bulk to Nano LeaNienhaus; Florida State University, United States

Triplet generation at a hybrid inorganic/organic semiconductor interface is a promising approach to increase the (photo-)excited state recombination lifetime, and thus, facilitate energy harvesting. One of the possible applications using the generated spin-triplet excitons is photon upconversion, which describes the process of shortening the wavelength of the light emitted after irradiation.

Recently, perovskite materials have emerged as triplet sensitizers for photon upconversion. To fully understand the triplet generation mechanism, a fundamental understanding of the underlying perovskite properties is required. Here, I will present the current understanding of charge transfer at the perovskite/organic interface resulting in triplet generation interrogated by a combination of scanning probe microscopy and optical spectroscopy. Of particular interest are the nanoscale properties of the perovskite and how surface treatments or added stressors influence the fundamental optoelectronic properties of the perovskite both on the ensemble and at the nanoscale. [1,2,3]

Implementing QD-In-Host Structure for High Efficiency in Deep-Blue Perovskite LEDs Kyung YeonJang[1], Seung-JeWoo[1], HyereeKim[1] and Tae-WooLee[1,1,2]; [1]Seoul National University, Korea (the Republic of); [2]SN Display Co., Ltd., Korea (the Republic of)

Metal halide perovskite light-emitting diodes (PeLEDs) have recieved substantial interest due to their exceptional color purity, satisfying the Rec. 2020 color gamut standard, and impressive efficiency in pure-green and pure-red perovskite nanoparticle LEDs. However, the challenge lies in achieving high efficiency in the deep-blue region, an area hitherto under-explored. This study focuses on using $CsPbBr_3$ quantum dots (QDs) as the light-emitting layer in PeLEDs. We identify two obstacles that need to be overcome: the difficulty in ligand post-treatment and the spectrum red-shift in the film state.
Here, we propose an alternative ligand enriched with a chemical passivation process, effectively amplifying the photoluminescence quantum yield (PLQY) of deep-blue QDs from 15% to nearly 90%. Furthermore, to address the spectrum red-shift induced by energy transfer or electronic coupling, we introduce a QD-in-host structure to physically sperate the QDs in the film state. A reduction in the concentration of QDs in the film yielded a blue-shift of approximately 7 nm in the emission spectrum. By incorporating these strategies, we achieved a maximum external quantum efficiency of 6.2% at a peak wavelength of 462 nm. The findings of this study provide crucial strategies for deep-blue QD PeLEDs, which hold potential for broad applicability across diverse PeLED types.

Ultra-Stable Dual-Color Emitting Lead-Free Double Perovskite Cs_2SnI_6 with a Wide Emission Span FuqianYang; University of Kentucky, United States

We have developed a green-route approach to prepare lead-free double perovskite Cs_2SnI_6 powder and nanocrystals, using an environmentally friendly aqueous solution. The sonication of the Cs_2SnI_6 powder in hexane under ambient conditions leads to the formation of Cs_2SnI_6 nanocrystals. The Cs_2SnI_6 powder and nanocrystals exhibit band gaps of 1.3 and 2.8 eV, respectively. There is a difference of 1.5 eV in the band gaps. The Cs_2SnI_6 nanocrystals with good long-term structural and optical stabilities have a PLQY of ~7% and a PL peak wavelength of 440 nm over a span of 50 days. The dual-color emission of the perovskite Cs_2SnI_6 is likely due to the dependence of dielectric constant on crystal size instead of the effect of quantum confinement.
This work is supported by the NSF through the grant CMMI-1854554 and CBET- 2018411.

Dimensionality and Tunability in The Tin Halide Perovskite Colloidal Nanostructures KushagraGahlot and LoredanaProtesescu; University of Groningen, Netherlands

The chemistry of tin-halide perovskites remain under-developed when compared to their lead counterparts in bulk as well as in nano owing to their inability to provide a stable Sn(II) oxidation state to maintain pristine crystal structure phase in ambient conditions. Hence, a simple reciprocation of the synthetic conditions from Pb-halide perovskites doesn't suffice. In this work, I will discuss the physical and chemical parameters which can help us to achieve a stable, tunable and monodisperse $CsSnX_3$ perovskite nanocrystals with defined optical features.[1] Pertaining to the formation energies of these perovskite nanostructures, the studies on the interplay of the 2D Ruddlesden-Popper ($L_2Cs_{n-1}Sn_nX_{3n+1}$) crystal phases and 3D $CsSnX_3$ nanocrystals were performed with respect to ligand combinations (ammonium, carboxylate, phosphinate), metal precursor ratios and temperature when SnX_2 salt is used as a precursor in order to understand the nucleation mechanism of nanocrystal formation. Moreover, the successful transformation of a purified 2D Ruddlesden-Popper (L_2SnX_4) phase to form 3D $CsSnX_3$ nanocrystals via a hot-injection approach and their ability to undergo post-synthetic anion exchange processes at room temperature using benzoyl halides will be discussed in details. X-ray diffraction and scattering studies conjoined with optical spectroscopy and electron microscopy helps us in acquiring the useful insights in directing the chemistry of Sn-halide perovskites at nanoscale. This research work showcases the insistent necessity for the development of mechanistic understanding to design efficient synthetic routes in order to achieve high-quality tin-halide perovskite nanocrystals.

Nanostructure Modification on Thermally Evaporated Perovskite Films Toward Large-Area Light-Emitting Diodes Chan-YulPark[1], Jung-MinHeo[1], Joo SungKim[2,3], EojinYoon[1] and Tae-WooLee[1,1,2]; [1]Seoul National University, Korea (the Republic of); [2]SN Display Co. Ltd, Korea (the Republic of); [3]Soft Foundry, Seoul National University, Korea (the Republic of)

In the contemporary era of digital society, there is a rising demand for vibrant color displays applicable in wearable electronics, indoor lighting, and expansive display systems. Metal halide perovskites have emerged as a highly promising material due to their advantages such as cost-effectiveness, excellent color purity with narrow full width at half maximum (FWHM, ~20nm), and the ease of color tuning by altering halide components. Nonetheless, despite the high-efficiency perovskite light-emitting diodes (PeLEDs) with external quantum efficiency (EQE) of over 20% was achieved through facile spin-coating methods, it couldn't be applied to the fabrication of large-area devices due to the low uniformity of the film. To overcome these limitations, a thermal evaporation method utilizing all-inorganic 3D $CsPbBr_3$ powders as precursor was developed. However, their use as emitters showed poor emission efficiency arising from critical drawbacks such as large crystal size, low exciton binding energy, and high defect concentration.
In this study, we introduced a new thermal evaporation method by co-evaporating 3D $CsPbBr_3$ and bulky ammonium cation (benzylammonium bromide, BzABr) to achieve quasi-two-dimensional (quasi-2D) perovskites with energy funneling and strong charge confinement. The existence of quasi-2D perovskites with efficient charge funneling and quantum confinement was confirmed by optical analysis. The grain size was also reduced from 80 to 50 nm, which could induce additional spatial charge confinement for efficient radiative recombination. Compared to the pristine 3D $CsPbBr_3$ film, the quasi-2D perovskite film showed tenfold-increased photoluminescence (PL) intensity. PeLEDs based on the thermally-evaporated quasi-2D perovskite thin films showed a maximum current efficiency of 3.6 cd/A and a maximum luminance of 1700 cd/m^2, showing an considerable improvement than that of Compared to PeLEDs based on thermally-evaporated 3D $CsPbBr_3$ without light emission due to the low luminous efficiency and high leakage current, PeLEDs based on the thermally-evaporated quasi-2D perovskite thin films showed a maximum current efficiency of 3.6 cd/A and a maximum luminance of 1700 cd/m^2, showing the great possibility of efficient PeLEDs based on thermal

evaporation method. . This work represents a significant advancement towards the commercialization of metal halide perovskites for future vivid color displays by successfully addressing a critical challenge in the fabrication of large-area perovskite-based display devices.

10:35 AM EN05.15.02
Color-Stable Mixed-Halide Blue Perovskite Light-Emitting Diodes Seong EuiChang[1], Joo SungKim[2,3] and Tae-WooLee[1,1,2]; [1]Seoul National University, Korea (the Republic of); [2]SN Display Co. Ltd., Korea (the Republic of); [3]Soft Foundry, Seoul National University, Korea (the Republic of)

Metal halide perovskites have emerged as a highly promising candidate for the advancement of next-generation light-emitting materials owing to their exceptional optoelectronic properties, including superior color purity, high photoluminescence quantum efficiency, and facile tunability of their bandgap through facile compositional control. As a consequence of these advantages, efficient perovskite light-emitting diodes (PeLEDs) with external quantum efficiency (EQE) surpassing 20% have been successfully demonstrated. However, the realization of efficient and stable blue-emitting PeLEDs, which are crucial for achieving vivid emission across the entire color gamut, has proved to be a formidable challenge, primarily due to the spectral instability exhibited by mixed-halide composites employed for blue emission. In this investigation, we present the successful realization of color-stable mixed-halide blue PeLEDs achieved through the implementation of core/shell perovskite nanograins with mitigated halide segregation. By employing shell materials that effectively bind at the grain boundaries, we effectively suppress the electric-field-induced segregation of halide ions, resulting in stable and narrow emission spectra during the operational lifetime of the devices. Our study thus presents a promising strategy for the realization of stable mixed-halide perovskite materials with complete suppression of halide segregation, thereby facilitating the development of bandgap-tunable perovskite optoelectronic devices.

10:40 AM EN05.15.03
Carbon Nanoflake Based Materials for Charge Transport Layers of Perovskite Solar Cells: Insight from Atomistic Modeling into Nanosizing and Functionalizations Suitable for Electron and Hole Transport RuichengLi, KeisukeKameda, SergeiManzhos and ManabuIhara; Tokyo Institute of Technology, Japan

A key bottleneck on the way to practical deployment of perovskite solar cells (PSC) are charge transport materials. Charge transport layers are needed to achieve high performance with PSCs, but hole transporting materials (HTM) and electron transporting materials (ETM) used in high-performance lab-scale PSCs are relatively high-cost. Another key bottleneck, low cell stability, is related to the issue of charge transport layers, as high-performance HTMs typically require the use of dopants that are detrimental to cell stability.
Recently, the use of carbon-based materials for both HTM and ETM has been gaining attention, in particular due to the possibility of synthesizing such materials from biomass or plastic wastes. This promises combining large-scale, low cost production with environmental remediation. Much of such research is empirical, without detailed insight into electronic properties of the synthesized materials. Such insight is needed to understand the possibility of forming correct band alignment and to ensure adequate charge transfer properties and for rational design of carbon-based HTMs and ETMs.
Carbon nanoflakes are one promising type of carbon based materials. Their size and functionalization/doping can be controlled, albeit imperfectly. We perform ab initio and semiempirical calculations to understand what sizes, shapes, and functionalizations can allow carbon nanoflakes to achieve band alignment and charge transport properties suitable for their use as either HTM or ETM. We include the effects of solid packing in the calculations and show that they substantially affect electronic properties. We show, in particular, that nanoflake sizes required for HTM capability should be as small as 1.5 nm, which is much smaller than nanoparticle sizes typically used in the literature. We also show that different functionalizations can make the same nanoflakes work as either ETM or HTM, and can also be used to control charge transport properties. Conversely, our results indicate that tight control of the presence of functional groups is required during synthesis to preserve HTM or ETM capability of such materials.

Inorganic-Derived Zero-Dimensional Perovskite Induced Surface Lattice Matching for Efficient and Stable All-Inorganic Perovskite Solar Cells Jin HyuckHeo, Jin KyoungPark and Sang HyukIm; Korea University, Korea (the Republic of)

The inverted inorganic $CsPbI_3$ perovskites solar cells (PSCs) are prospective candidates for next-generation photovoltaics owing to inherent robust thermal/photo-stability and compatibility for tandems. However, the performance and stability of the inverted $CsPbI_3$ PSCs fall behind the n-i-p counterparts due to poor energetic alignment and abundant interfacial defect states. Here, we implement an inorganic 0-dimensional Cs_4PbBr_6 with good lattice matching and exhibits enclosed stability with $CsPbI_3$ as a surface anchoring capping layer. The heavy n-type feature of the Cs_4PbBr_6 perovskite induces enhanced electron-selective junction and thus facilitates efficient charge extraction and effectively inhibits non-radiative recombination. Consequently, the $CsPbI_3$ PSCs with Cs_4PbBr_6 demonstrate the highest PCE of $CsPbI_3$-based inverted PSCs, reaching 20.38 % power conversion efficiency (PCE) from a unit cell and 17.39 % PCE from a module with a 64 cm^2 aperture area. Furthermore, the resulting devices retain 92.48 % after 1000 hours under simultaneous 1-sun and damp heat (85 ºC / 85 % relative humidity (RH) environment.

10:50 AM EN05.15.05
Enhancing Exciton Confinement in Perovskite Light-Emitting Diodes Through Spray-Coating: The Energy-Well Band Structure Approach Jin KyoungPark, Jin HyuckHeo and Sang HyukIm; Korea University, Korea (the Republic of)

Metal-halide perovskite materials have garnered significant interest as potential candidates for next-generation light emitters. These materials possess unique properties such as high color purity, narrow spectral emission, high photoluminescent quantum yield, and solution processability. However, bulk metal-halide perovskite films suffer from low exciton binding energies, necessitating the fabrication of uniform polycrystalline films with small grain sizes to enhance quantum efficiency. Exciton confinement can be achieved through top-down and bottom-up methods. Several studies have successfully improved the efficiency of perovskite light-emitting diodes (PeLEDs) by enhancing the charge confinement effect. However, the translation of these advancements into commercial products remains challenging due to the limitations of the spin-coating process. Spray-coating, on the other hand, offers an economical and scalable alternative, enabling the fabrication of uniform thin films on a large scale. It provides greater design freedom and minimal influence from chemical orthogonality, allowing controlled stacking of layers and compositions.
In this study, we present a breakthrough in PeLEDs by constructing an energy-well band structure through spray-coating. By incorporating a Cs_4PbBr_6 layer onto the $CsPbBr_3$ film using the spray-coating technique, we have observed a significant enhancement in both photoluminescence (PL) and electroluminescence (EL) efficiency, reaching up to 23,415 cd/m^2 and 13.08%, respectively. Additionally, Cs_4PbBr_6, an inorganic perovskite material, exhibits a substantially wider bandgap than $CsPbBr_3$, making it suitable for improving the energy band structure and serving as a passivation layer.
The observed improvement can be attributed to the increased exciton binding energy achieved through the modified structure. To further enhance the confinement of excitons, we have introduced adjustments to the device structure by incorporating both a buried layer and an overlying layer of Cs_4PbBr_6. This modification facilitates the formation of an energy-well structure, thereby enhancing the confinement and stability of excitons within the device. Consequently, our optimized $CsPbBr_3$ PeLED with the Cs_4PbBr_6 well demonstrates impressive performance metrics, including a maximum luminance of 25,261 cd/m^2, a maximum current efficiency (CE) of 65.85 cd/A, and a maximum external quantum efficiency (EQE) of 14.72%.

10:55 AM EN05.15.06
Lead Free Halide Perovskite Based Asymmetric Flexible Supercapacitor AnkurYadav and MonojitBag; Indian Institute of Technology Roorkee, India

Supercapacitors (SCs) have received a lot of attention as storage devices because of their high-power density and long-life cycle when compared to batteries. The choice of electrode materials is crucial in increasing the capacitive performance of SCs. Lead halide perovskites have achieved extraordinary success in a wide range of applications, including solar cells, light-emitting diodes, detectors and so on. In recent studies with non-aqueous electrolytes, halide perovskite-based supercapacitors emerged as promising material for energy storage applications. The majority of halide perovskites research has been focused on Pb-based materials, due to their excellent properties, and well-understood formation process. However, lead (Pb) toxicity is still a source of contention. Pb, a very toxic element, can accumulate in the human body and induce a variety of brain-related symptoms including abdominal pain, constipation, and headaches. Lead's immediately dangerous to life or health (IDLH) value is only 100 mg m^3, indicating that humans are extremely vulnerable to Pb poisoning. Therefore, a non-toxic element must be used to replace Pb in these perovskite materials. Several attempts have been made to substitute Pb in perovskite materials with group 14 elements such as tin (Sn) and germanium (G). However, Sn and Ge replacement in perovskites results in poor stability due to oxidation effects. Bismuth (Bi) is an element that is adjacent to Pb and has properties that are similar and comparable to Pb's. We have fabricated lead based ($MAPbI_3$) and lead free ($MA_3Bi_2I_9$) based supercapacitor for energy storage applications. The specific capacitance is around 250 F/g for $MAPbI_3$ whereas it is around 320 F/g for $MA_3Bi_2I_9$ based electrode as calculated from Galvanometric charge discharge (GCD) measurement. It is also confirmed from the Cyclic voltammetry that the lead-free electrode has higher capacitance than lead based electrode. Cyclic stability shows capacitance retention around 81% for $MAPbI_3$ and 91% for $MA_3Bi_2I_9$ for 1500 cycles as measured from three electrode measurements. Furthermore, we have fabricated gel electrolyte-based asymmetric device for both lead based ($MAPbI_3$) and lead free ($MA_3Bi_2I_9$) materials. The lead-free device shows decent areal capacitance ~30 mF/cm^2 with energy density around 5 µWh/cm^2 and corresponding power density ~200 µW/cm^2 @0.25 mA/cm^2. The lead-free based device is also able to drive white and yellow LED’s. with single cell. The gel electrolyte device shows stability around 88% for 1500 cycles. We have also fabricated lead free flexible device on stainless steel substrate. The flexibility test was performed on our custom-built programmable setup for bending angles and bending cycles**.** The device shows capacity retention around 92% for 180° bending angles and 86% for 200 bending cycles.

11:00 AM EN05.15.07
Theoretical Insights into Cs_2MSbX_6 (M = Cu, Ag, Na, K, Rb, Cs and X = Cl, Br) Halide Double-Perovskite Materials for Optoelectronic Applications PriyaJohari and SurajitAdhikari; Shiv Nadar University, India

Lead-halide perovskites $APbX_3$ (A = Cs, CH_3NH_3 and X = Cl, Br) have attracted broad interest in photovoltaic applications over the past decade due to their suitable bandgap and high optical absorption ability [1]. But lead-induced toxicity and materials instability has sparked interest in alternative materials with properties like $APbX_3$ perovskites. Recently, lead-free inorganic double halide perovskites $Cs_2M(I)M(III)X_6$ have been proposed as promising nontoxic materials with enhanced chemical stability for optoelectronic applications [2]. However, not much has been explored in the context of their mechanical, transport, and excitonic properties, which play a crucial role in defining an efficient and flexible optoelectronic device. We have, therefore, systematically conducted a series of state-of-the-art first-principles density functional theory, hybrid density functional theory, and many-body perturbation theory (namely GW and BSE) calculations to investigate the mechanical, transport, and excitonic properties of Cs_2MSbX_6 (M = Cu, Ag, Na, K, Rb, and Cs; X = Cl, Br) along with their structural, electronic, and optical properties. Our results indicate that all the systems maintain the standard cubic lattice and show high phase stability against decomposition (decomposition enthalpy > 20 meV/atom). Band structure calculations (HSE06 and G_0W_0@PBE) reflect that the compounds have a wide range of tunable bandgaps (1.2 eV - 5.2 eV), and the bandgap decreases on going from Cl to Br. BSE calculations reveal that these materials have excellent absorption capabilities from visible to ultraviolet light region. Investigation of transport properties and excitonic parameters elucidates that most of the Cs_2MSbX_6 materials exhibit small charge carrier effective masses (higher mobility) and low to moderate exciton binding energy as well as longer to shorter exciton lifetime, which make them suitable for a solar cell application. Further, on calculating the mechanical properties these compounds are found to exhibit low elastic moduli that decrease from Cs_2MSbCl_6 to Cs_2MSbBr_6. Furthermore, except $Cs_2CuSbBr_6$, these compounds are predicted to be ductile in nature with a noticeable elastic anisotropy, revealing these materials to exhibit good flexibility. Further, on considering the mixed halide double perovskites $Cs_2MSbBr_{6-x}Cl_x$ (x = 0-6, M=Ag) it is found that the optoelectronic properties can be widely tuned, and thus, such materials may a suitable component for the future generation of optoelectronic devices. Overall, our study predicts Cs_2MSbX_6 to be a stable double perovskite with a wide range of tunable optoelectronic properties, and promising transport and excitonic properties, providing a helpful guide to developing next-generation photovoltaics and flexible optoelectronics.

Highly-Sensitive X-Ray Detectors Based on Single-Crystal Mixed-Halide Perovskite $CsPbBr_{3-x}(Cl, I)_x$RongWu and FangzeLiu; Beijing Institute of Technology, China

Lead halide perovskites are emerging materials for a variety of optoelectronic applications, for example, photovoltaics, light-emitting diodes, photodetectors, lasers and photocatalysts. During the past few years, they have been extensively studied for radiation detection, especially for X-ray detectors due to their high absorption cross section, high carrier mobility lifetime product, tunable direct bandgap and low-cost synthesis. Perovskite X-ray detectors have shown higher sensitivity as well as lower detection limit compared with conventional Se and CdZnTe detectors. Despite the rapid advances in perovskite X-ray detectors, their performance is significantly hindered by the intrinsic limitations of perovskites, including low stability, low resistivity and high ion migration. Compared with hybrid organic-inorganic perovskites, all-inorganic $CsPbBr_3$ has attracted a lot of interests mainly for its high thermal stability. Various solution growth methods have been proved as effective routes to achieve large-size $CsPbBr_3$ single crystals. However, achieving stable perovskite X-ray detectors with suppressed ion migration and low dark current remains a challenge.
Here, we synthesized mixed-halide perovskite $CsPbBr_{3-x}(Cl, I)_x$ single crystals with x ranging between 0 and 0.3. The structure and composition of single crystals are verified using XRD, EDS, UV-vis absorption and photoluminescence. The single crystal X-ray detectors show high sensitivity exceeding 3×10^4 μC Gy_{air} cm^{-2} and low detection limit below 50 nGy s^{-1} for 90 keV X-ray under 500 V cm^{-1} electric field. By constructing detectors with high and low work function contacts, we find that the dark current mainly originates from the hole current, and therefore using low work function contact can effectively suppress the dark current, achieving a low current density of ~40 nA cm^{-2} under 500 V cm^{-1} electric field, which is lower than 1/100 of the dark current density using high work function contacts. The halide doping and contact engineering prove that the mixed-halide perovskites are promising materials for high-performance X-ray detectors.

11:10 AM EN05.15.09
Exploring Self-Assembled Hole Transport Materials in p-i-n Perovskite Solar Cells MinsikShin[1], DongminYoon[2], HongyiHuang[3], YifanYin[4] and MiriamRafailovich[4]; [1]Seoul International School, Korea (the Republic of); [2]North London Collegiate School Jeju, Korea (the Republic of); [3]Shenzhen Middle School, China; [4]Stony Brook University, The State University of New York, United States

Renewable energy plays a crucial role in combating climate change, and one of the primary focuses is improving the efficiency and production of solar cells. Over the past decade, perovskite solar cells (PSCs) have garnered significant attention due to the extraordinary evolution of the power conversion efficiency (PCE): perovskites are a class of materials with unique crystal structures, represented by the chemical formula ABX3. Here, A denotes monovalent organic cations like methylamine (MA+), formamide (FA+), or cesium, while B refers to metal cations such as lead and tin. Finally, X represents halide anions. The inverted structure PSCs, also known as p-i-n PSCs offer several advantages, including lower production costs and enhanced stability compared to the conventional n-i-p PSCs. However, the inverted PSCs face the challenge of lower device efficiencies. In this study, we focus on two distinct materials for the Hole Transport Layer (HTL): PTAA and Meo-2PACz. Our primary goals involve investigating the fabrication process to create an optimal substrate for subsequent perovskite layer deposition and evaluating the efficiency of MeO-2PACz as a Hole Transport Material in inverted p-i-n perovskite solar cells. By exploring these aspects, we aim to contribute to the ongoing efforts to enhance the performance of PSCs.
Fabricating the solar cell, the HTL was first deposited onto the ITO glass through spin-casting. Two solutions were used: 1 mM Meo-2PACz in ethanol and 2 mg/ml PTAA in chlorobenzene. The spin-casting was done at 4000 rpm for 30 s, followed by annealing at 100°C for 10 minutes. Next, a 1.2M MAPbI3 precursor solution in a mixed solvent of DMF/DMSO (v:v=9:1) was spin-casted on the glass at 4000 rpm for 30 s. 150 μL of toluene was dripped onto the surface 10 s after the beginning of spinning, the as-casted film was annealed at 100°C for 10 min. The subsequent steps involved spin coating a 20 mg/ml solution of PCBM at 1500 rpm for 30 s, followed by spin coating a 0.5 mg/ml BCP at 4000 rpm for 30 s. Finally, Ag electrodes (100 nm) were deposited using physical vapor deposition (PVD).
In terms of measurements, the surface roughness of Meo-2PACz and PTAA coated substrates was investigated using Atomic Force Microscopy (AFM). Both films exhibited relatively small surface roughness. Fourier Transform Infrared Spectroscopy showed peak shifts of the phosphate functional group due to its reaction with the glass substrate. Contact Angle measurements demonstrated that Meo-2PACz exhibits higher hydrophilicity, which enhances nucleation and crystal growth. X-ray Diffraction (XRD) analysis revealed that both perovskites coated onto Meo-2PACz or PTAA substrate show a similar crystallinity. Scanning Electron Microscopy (SEM) revealed that the perovskite prepared from the Meo-2PACz-coated substrate had a larger average grain size. Furthermore, PV Performance testing confirmed Meo-2PACz's superiority as a Hole Transport Material, achieving a higher PCE of 17.7% compared to PTAA's 16.3% PCE in the fabricated inverted p-i-n device.

11:15 AM EN05.15.10
Surface Reconstruction of Inorganic Perovskite by The Nanosecond Laser Pulse Hyong JoonLee, Seok YeongHong, Jin KyoungPark, Jin HyuckHeo and Sang HyukIm; Korea University, Korea (the Republic of)

While the organic-inorganic hybrid metal halide perovskite has recently achieved remarkable performance in photovoltaics, all-inorganic perovskite ($CsPbI_{3-x}Br_x$, X = 0~3) has been proposed as a stable alternative to their organic counterparts. The all-inorganic perovskite demonstrates robust thermal- and photo-stability owing to relatively high thermal decomposition temperature and high ion migration activation energy. Moreover, their suitable energy bandgap (>1.65 eV) offers wide opportunities for applications such as single-junction photovoltaics, tandem solar cells, and indoor photovoltaics. However, inorganic perovskite suffers from rapid crystallization during the film fabrication process, resulting in morphological and surface electronic inhomogeneities. Such inhomogeneities act as charge recombination centers and deter efficient charge extraction, leading to poor reproducibility and performance.
In this study, we implement a nanosecond pulsed laser as an effective tool to reconstruct the surface of inorganic perovskite films. The pulsed lasers are powerful instruments that provide rapid, accurate, and precise processes and are readily accessible as they are already widely adopted in industries. With careful control of the pulse energy, we were able to homogenize the surface potential of inorganic perovskite. In addition, we thoroughly characterize the impacts on the various perspectives including crystallinity, morphology, chemical features, optoelectronic properties, and device performance of the inorganic perovskite film. We believe our study on the inorganic perovskite-laser pulse interaction offers an insightful approach for optimizing inorganic perovskite solar cells and potentially any other applications involving pulsed laser processes.

11:20 AM EN05.15.11
Crosslink Polymer Strategy to Minimize Voltage Loss in Wide-Bandgap Perovskites for All-Perovskite Tandem Solar Cells XinZheng; Huazhong University of Science & Technology, China

In recent years, the photoelectric conversion efficiency (PCE) of perovskite solar cells (PSCs) has exceeded 25%. However, according to Shockley-Queisser's limitations, the maximum theoretical efficiency of a single-junction solar cell is about 33%. The room for efficiency improvement of single-junction perovskite solar cells is very limited. Therefore, the development of tandem solar cells is an important way to break the limit and further improve the efficiency of PSCs. The theoretical limit efficiency of double-junction tandem solar cells (TSCs) can reach 46%, which is much higher than that of single-junction solar cells. In practice, The efficiency of all-perovskite tandem solar cells (28%) has surpassed that of single-junction perovskite solar cells (26%). Wide-bandgap (WBG) mixed-halide perovskites show promise of realizing efficient tandem solar cells but at present suffer from large open-circuit voltage loss because of excess lead iodide and light-induced halide phase segregation.
Here, a crosslink polymer strategy with high crosslinking degree and high density of functional groups is reported for finely regulating the crystal growth of $FA_{0.8}Cs_{0.2}Pb(I_{0.6}Br_{0.4})_3$, thereby obtaining high-performance PSCs. The pentaerythritol tetraacrylate (PTA) is introduced to form hydrogen bonds and strong Pb–O bonds with perovskite precursors, realizing the complete elimination of excess lead iodide. Besides, this uniformly distributed PTA crosslink polymer system passivates the defects and inhibits the photo-induced halide segregation effectively. The prepared PSCs with a band gap of 1.77 eV yield an impressive open-circuit voltage (V_{OC}) of 1.36 V, corresponding to a record low V_{OC} -deficit of 0.41 V and an efficiency of 19.58%. With these WBG perovskite subcells, we report 27.3% monolithic all-perovskite TSCs shows an outstanding combination of a high V_{OC} of 2.15 V and a FF of 81.4% with improved operational stability.

11:25 AM EN05.07.25
Heterostructure Solar Cells Fabricated via Sequential Spin and Transfer Printing Technique AnjaliThakran[1,2], MarioHofmann[1] and Chih WeiChu[2]; [1]National Taiwan University, Taiwan; [2]Academia Sinica, Taiwan

Among the top contenders in photovoltaic materials, mixed halide organic/inorganic perovskite solar cells (PSCs) have attracted the market with strong potential of their facile processing methods, low temperature processability and cost-effectiveness over Si based solar cells (1/3 of the cost). The inherent properties of perovskites such as ambipolar nature, widely tuneable bandgap, low exciton binding energy, high mobility and long carrier lifetime have been extensively explored in electronic applications. However, the single junction solar cells based perovskites limited by their Shockley and Queisser limit and heterostructure/multi-junction device are limited with their complex stacked device architectures. Herein, we have demonstrated a successful approach of sequential spin and transfer printing technique to fabricate NBG perovskite over WBG perovskite to form a heterostructure. With as-adopted transfer printed technique on pre-fabricated spin coated layer, we are successfully able to fabricate two-solution processable layers on top of each other without any harmful dissolution. In results, we have obtained enhanced performance of stacked device compared to their single-junction counterpart. With our morphology studied, we have observed full coverage of surface, better crystal quality and less pin-holes film formation in heterostructure. Apart from it, the well-designed band alignment between top and bottom layer leads the effective transport of carriers through the device, therefore improved performance. Togetherness, with optimum parameters of film thickness, the obtained external quantum efficiency shown stronger intensity and enhanced spectral response. The single WBG layer are able to cover wavelength range around ~ 700 nm and with printed top layer onto it, the spectral enhanced till ~ 950 nm. Additionally, we can tune spectral response through composition variation in top and bottom layers. The purposed strategy can be implemented to stacked architecture including application including photodetector, sensors, transistor and LEDs.

Development of High-Performance Sn Based Halide Perovskite Transistors Yong-YoungNoh; Pohang University of Science and Technology, Korea (the Republic of)

Developing high-mobility p-type semiconductors that can be grown using cost-effective scalable methods at low temperatures, has remained challenging in the electronics community for the integration of complementary electronics with the well-developed n-type metal oxide counterparts. Tin (Sn^{2+}) halide perovskites emerge as promising p-type candidates but suffer from low crystallisation controllability and high film defect density, which result in uncompetitive device performance. In this talk, I would like to introduce a general overview and recent progress of our group of p-type Sn-based metal halide perovskites for the application of field-effect transistors (FETs). In the first part of the talk, I will mainly address inorganic perovskite thin-film transistors with exceptional performance using high-crystallinity and uniform cesium-tin-triiodide-based semiconducting layers with moderate hole concentrations and superior Hall mobilities, which are enabled by the judicious engineering of film composition and crystallization. The optimized devices exhibit high field-effect hole mobilities of over 50 $cm^2 V^{-1} s^{-1}$, large current modulation greater than 108, and high operational stability and reproducibility [1]. In the second part of the talk, I will introduce A-site cation engineering method to achieve high-performance pure-Sn perovskite thin-film transistors (TFTs). We explore triple A-cations of caesium-formamidinium-phenethylammonium to create high-quality cascaded Sn perovskite channel films, especially with low-defect phase-pure perovskite/dielectric interface. As such, the optimized TFTs show record hole mobilities of over 70 $cm^2 V^{-1} s^{-1}$ and on/off current ratios of over 10^8, comparable to the commercial low-temperature polysilicon technique level. The p-channel perovskite TFTs also show high processability and compatibility with the n-type metal oxides, enabling the integration of high-gain complementary inverters and rail-to-rail logic gates.

Water-Based and Defect-Free 2D Material Inks for Printed Electronics CinziaCasiraghi; University of Manchester, United Kingdom

Solution processing of 2D materials allows simple and low-cost techniques, such as ink-jet printing, to be used for fabrication of heterostructure-based devices of arbitrary complexity [1]. Our

group has developed highly concentrated, defect-free, printable and water-based 2D crystal formulations, enabling fabrication of large area arrays of photosensors on plastic [2], printed capacitors [3], transistors [3,4], and memristors on both rigid and flexible substrates [5]. Furthermore, we have demonstrated simple and scalable fabrication of graphene-silicon rectifying devices with ON/OFF ratio higher than three orders of magnitude and a remarkable photovoltaic effect, whose fabrication is compaticle with back-end-of-line fabrication processes [6]. Finally, inkjet printing can be easily combined with 2D materials produced by chemical vapour deposition, allowing simple and quick fabrication of complex circuits on paper, such as high-gain inverters, logic gates, and current mirrors [7].

Excitons in Two-Dimensional Metal Halides Maria AntoniettaLoi; University of Groningen, Netherlands

Metal halide perovskites are under the spotlight for optoelectronic applications due to their remarkable photophysical properties. 3Dimensional compounds of this family have been used to demonstrate highly efficient solar cells, light emitting diodes, and x-ray detectors. Very recently, 2D and quasi-2D Ruddlesden–Popper phases, have also been explored for optoelectronic devices.
Layered perovskites afford specific advantages over other inorganic 2D materials such as transition metal dichalcogenides. As they are easily grown by both solution methods and vapor transport methods at low temperature, and they display a tuneable direct bandgap. In my presentation I will discuss the excitonic properties, of Ruddlesden–Popper phases based on Pb and on Sn, concluding on the metal influence on their physical properties. I will further underline the prospective for these materials in new optoelectronic devices.

11:30 AM EN06.01.03
Exploring the Potential of 1T-TiS_2 Electrode Materials for Supercapacitors AliD. Ucar, SumeyyeKandur, Mete BatuhanDurukan and HusnuE. Unalan; Middle East Technical University, Turkey

The distinctive characteristics of two-dimensional materials have attracted considerable interest for their prospective applications, especially in the field of energy storage. The relatively well studied transition metal dichalcogenides (TMDs), such as molybdenum disulfide (MoS_2) and tungsten disulfide (WS_2), have been shown to have electronic, chemical, and optical properties that can be tailored through fabrication methods. Relatively less studied and the lightest member of the TMD family, titanium disulfide (TiS_2) is a promising material for supercapacitor electrodes. In this work, electrically conductive bare 1T-TiS_2nanosheets were fabricated and utilized as electrodes for supercapacitors. For this purpose, self-standing and flexible TiS_2 films were fabricated through vacuum filtration. Bare TiS_2 films showed poor cyclic stability in aqueous electrolytes. Therefore, a simple dopamine treatment was developed to enhance the enhance oxidation stability of the TiS_2 films. The resulting 1T-TiS_2 filmbased symmetric supercapacitor devices showed a specific capacitance and capacity retention of 10 F/g (at a scan rate of 100 mV/s) and 90% after 5000 cycles in 2M Li_2SO_4/0.1 M thiourea electrolyte, respectively.

The Influence of Cation Structure on Ionization Energies in 2D Organic Metal Halide Perovskites and Best Practices for Defining Ionization Energies HarindiR. Atapattu, SyedJoy, HenryPruett, KevinPedersen and KennethR. Graham; University of Kentucky, United States

The ionization energy (IE) and electron affinity (EA), which are equated with the valence band maximum and conduction band minimum, respectively, are important material parameters for semiconductor device design and understanding device physics. Thereby, determining relationships between organic metal halide perovskite (HP) structure and the IE and EA is critical for development and selection of HPs for targeted device integration. Currently, it is not well understood how structural changes to the HP shift the IE and EA, and furthermore, assigning the IE and EA in organic metal halide perovskites (HPs) is not straightforward. In three-dimensional (3D) HPs, the IE and EA are typically assigned based on Gaussian fits to the lowest energy feature; whereas, in two-dimensional (2D) HPs the IE and EA are commonly assigned based on linear fits to the leading edge of the signal onset. In this work we use a combination of techniques, including ultraviolet photoemission spectroscopy (UPS), electrochemistry, and photoluminescence (PL) quenching measurements to determine the most appropriate method to assign the ionization energy. In the case of PL quenching, a series of hole accepting materials with varying IEs are deposited on top of the HPs, and based on quenching of the HP PL as a function of IE of the hole accepting material we are able to determine the range in which the HP IE lies for both Ruddlesden-Popper (RP) and Dion-Jacobson (DJ) phase HPs. We further investigate how the structure of the A*-site organic cation impacts the IE in both RP and DJ Pb- and Sn-based HPs. In RP phase HPs containing phenethylammonium (PEA) derivatives as the A*-site cation, we find that appending an electronegative substituent at the 4-position of the phenyl group results in an increase in the IE relative to PEA, whereas when an electronegative substituent is attached at the 2-position the IE decreases relative to PEA. Overall, changing the position of the substituent in 2D HPs can result in a 1.0 eV change in the IE, which highlights the wide tunability of frontier energy levels provided by minor variations to the A*-site cation structure.

SESSION EN06.02: Layered Perovskites and 2D Materials

2D Carbides and Nitrides (MXenes) for Energy Storage—Use in Passive and Active Components YuryGogotsi; Drexel University, United States

Nanomaterials, particularly, two-dimensional (2D) materials, are among promising candidates to address some of the ongoing challenges in manufacturing batteries and supercapacitors and enable devices with superior performance metrics and a lower cost.[1,2] Two-dimensional metal carbides and nitrides (MXenes) are a very large yet quickly growing family of 2D materials with the formula of $M_{n+1}X_nT_x$ where M is an early transition metal, X is carbon or nitrogen, and T_x refers to the surface terminations. Molecular dynamics and *ab initio* simulations, along with experiments, show that the electronic, optical, and, most importantly, electrochemical properties of MXenes distinguish them from other widely studied 2D materials. Chemical and electrochemical insertion of ions and molecules between the MXene layers allows modification of their properties, as well as electrochemical charge storage and harvesting, which use both, double-layer and redox mechanisms. The high electronic conductivity (~20,000 S cm^{-1}), redox-active surfaces, cation intercalation in 2D slits between MXene layers, and rich chemistry of these materials with more than 50 different compositions reported, have enabled their use as charge storage hosts and building blocks of passive cell components in various types of energy storage devices.[3] Freestanding, binder-free films of $Ti_3C_2T_x$ are capable of ultra-high-rate pseudocapacitive charge storage in protic electrolytes delivering ~400 F g^{-1} (1500 F/cm^{-3}) at rates of up to 100 V s^{-1} and volumetric energy and power densities several times higher than conventional carbon-based capacitive electrodes. MXenes can intercalate a variety of monovalent and multivalent cations from aqueous or non-aqueous electrolytes and, therefore, can be used as electrodes for emerging new battery chemistries. Their mechanical robustness and high conductivity expand their use as current collectors, conductive additives in electrodes and also building blocks for conformal coatings to avoid dendrite growth in metal batteries. Yet, unlike most other 2D materials, the synthesis and processing of MXenes is scalable and cost-effective, and they can be processed in large batches from aqueous solution into powders, dispersions, and films. The combination of these properties and scalable synthesis, not only renders MXenes as interesting materials for academic research and development studies but also as practical materials of choice for future charge storage applications.

2:00 PM *EN06.02.02
Understanding Complex Layered Halide Perovskites: Double Perovskites and Mosaic Perovskites BridgetConnor[1], AlexanderSu[1], JiayiLi[1], FengKe[2], YuLin[2], LinnLeppert[3] and HemamalaKarunadasa[1,2]; [1]Stanford University, United States; [2]SLAC National Accelerator Laboratory, United States; [3]University of Twente, Netherlands

Layered halide perovskites offer a flexible platform for tuning optoelectronic properties through changes in composition. One of the most intriguing aspects of 2D halide double perovskites is the change in bandgap symmetry with dimension, observed for certain compositions. For example, the indirect gap of Cs_2AgBiX_6 converts to a direct gap at the $n = 1$ (monolayer) 2D perovskite, whereas the direct gap of Cs_2AgTlX_6 transitions to an indirect gap at the $n = 1$ limit. I will present a molecular orbital analysis that explains this transition and allows us to predict which double perovskite compositions will feature such a change in band dispersion pattern upon dimensional reduction. I will also present our recent studies on further increasing the

accessible electronic structures of 2D perovskites by incorporating three stoichiometric octahedral metals. We refer to this family as “mosaic perovskites” due to the numerous local packing arrangements of the three different metal-halide octahedra that nevertheless maintain a fixed metal ratio. Notably, mosaic perovskites allow for Cu(I/II) mixed valence and sets the stage for many more mixed-valence metal combinations to be incorporated into halide perovskites.

2:30 PM EN06.02.03
Enhanced Air Stability in 2D Tin Halide Perovskites Enabled by Rational Spacer Cation Design ChristopherT. Triggs, R. DominicRoss, WillaMihalyi-Koch, CatherineClewett, KyanaM. Sanders, IliaA. Guzei and SongJin; University of Wisconsin--Madison, United States

Two-dimensional (2D) tin halide perovskites are lead-free semiconductors promising for photovoltaic, optoelectronic, and spintronic devices. However, their inherent instability to air and humidity relative to their toxic lead counterparts makes them more difficult to study and employ in applications. In this work, we report two new 2D tin perovskite crystal structures and systematically compare them among a series of Ruddlesden-Popper (RP) and Dion-Jacobson (DJ) tin iodide perovskites to elucidate the spacer cation structural motifs that enable better air stability, as well as the underlying mechanism of how they protect the inorganic sublattice from degradation. Using solid-state NMR, we find 2D tin perovskites decompose into ligand salts and SnO_2 upon exposure to ambient air, which are localized at the crystal surfaces and produced at varying rates depending on the spacer cation. Direct comparisons between the studied phases demonstrate substantially enhanced air stability compared to the benchmark $(PEA)_2SnI_4$ (PEA = phenethylammonium) phase by use of halogenated aromatic spacer cations in RP perovskites or bulky ringed spacer cations in DJ perovskites. Interestingly, X-ray photoelectron spectroscopy depth profiling, complemented by synchrotron X-ray absorption spectroscopy, revealed that the long term bulk stability of 2D tin perovskites is not solely due to surface-level protection by the hydrophobic spacer cations as generally believed, but also due to effective subsurface protection from strong interlayer interactions that prevent penetration of air and water underneath the surface of the crystal. This study informs how we can rationally design 2D tin perovskites for enhanced air stability to enable further property studies and eventual applications in stable, high performance devices.

2D Materials for the Electrocatalytic Conversion of CO_2 and Water Depollution DamienVoiry; University of Montpellier, France

Mitigating climate change and securing water resources are two of the major challenges of the century[1,2]. In this context, membranes and electrocatalysis process are promising avenues to reduce the energy footprint, while mitigating carbon dioxide emissions. Our research aims to evaluate the potential of low dimensional materials for membrane and electrocatalytic applications.
Due to their atomic thickness and confined interlayer spacing, nanolaminate membranes made of re-stacked 2D nanosheets could theoretically enable improved separation performance. We developed a novel strategy to control the interlayer spacing and improve the separation performance of nanolaminate membranes using covalent functionalization of exfoliated nanosheets. The functionalized MoS_2 membranes demonstrated remarkable performance for water purification and desalination, while they have enabled to discriminate the role of the surface and stacking disorder on the nanofluidic behavior of water in the laminates[3].
We also investigated the influence of surface chemistry on the electrocatalytic behavior of low dimensional materials. In particular, we have developed a new strategy to enhance the conversion of CO_2 to hydrocarbon molecules with two or more carbon atoms (C_{2+}) via molecular doping of a metal catalyst[4]. Specifically, we have identified electrophilic functional groups that can direct electrochemical reactions to produce C_{2+} species such as ethanol and ethylene and improve reaction rates at the catalyst surface.
In my presentation, I will review our recent findings on understanding electrocatalytic and nanofluidic phenomena that take place on the surface of low dimensional materials.

Two-Dimensional Organic-Perovskite Hybrid Materials and Heterostructures LetianDou; Purdue University, United States

Epitaxial heterostructures based on oxide perovskites and III–V, II–VI and transition metal dichalcogenide semiconductors form the foundation of modern electronics and optoelectronics. Halide perovskites—an emerging family of tunable semiconductors with desirable properties—are attractive for applications such as solution-processed solar cells, light-emitting diodes, detectors and lasers. Their inherently soft crystal lattice allows greater tolerance to lattice mismatch, making them promising for heterostructure formation and semiconductor integration. Atomically sharp epitaxial interfaces are necessary to improve performance and for device miniaturization. However, epitaxial growth of atomically sharp heterostructures of halide perovskites has not yet been achieved, owing to their high intrinsic ion mobility and their poor chemical stability. Therefore, understanding the origins of this instability and identifying effective approaches to suppress ion diffusion are of great importance. In this talk I will present an effective strategy to substantially inhibit in-plane ion diffusion in two-dimensional halide perovskites by incorporating rigid π-conjugated organic ligands. Highly stable and tunable lateral and vertical epitaxial heterostructures, multiheterostructures and superlattices will be demonstrated. Furthermore, using these 2D heterostructures as a new platform, I will present our recent efforts in 1) quantitatively understanding the anion inter-diffusions and migrations, and 2) controlling and manipulating exciton transport and light-emission in halide perovskites.

4:15 PM EN06.02.06
Unveiling Electronic and Excitonic Properties of 2D Ruddlesden-Popper Perovskites Based on Bifunctional Ligands XinjueZhong[1], XiaojuanNi[2], AlanB. Kaplan[1], XiaomingZhao[1], MarkoIvancevic[1], MelissaL. Ball[1], ZhaojianXu[1], HongLi[2], BarryP. Rand[1,1], Yueh-LinLoo[1,1], Jean-LucBrédas[2] and AntoineKahn[1]; [1]Princeton University, United States; [2]The University of Arizona, United States

Two-dimensional (2D) Ruddlesden-Popper halide perovskites exhibit remarkable tunability of optoelectronic properties and good environmental stability achieved through the selection of organic cations. The incorporation of bifunctional ligands featuring non-ammonium terminus and functional groups capable of forming extra bonding motifs within the organic bilayer provides an effective strategy to engineer perovskite structures and introduce additional functionalities.
Here, we explore a series of n = 1 2D perovskites incorporating organic ligands with diverse functional groups (-CN, -OH, -COOH, -Ph, and $-CH_3$), each exhibiting distinct bonding characteristics and dielectric properties, and report on the impact of these bifunctional ligands on the electronic and excitonic properties of these 2D perovskites.[1]
We perform ultraviolet and inverse photoemission spectroscopies (UPS/IPES) to determine the energy positions of the valence band maximum and conduction band minimum, and the electronic, or single-particle, gap of these 2D perovskites. We observe a strong correlation between the electronic gaps of the -CN, -COOH, -Ph, and $-CH_3$-based perovskites and the in-plane Pb-I-Pb bond angle, aligning with earlier findings regarding the relationship between optical gaps and the in-plane Pb-I-Pb bond angle.[2] Interestingly, the gap of the -OH-based perovskite deviates significantly from this trend. We conduct density functional theory calculations and tight-binding model analysis to further elucidate this structure-property relationship. We attribute the “-OH” anomaly to band dispersion along the out-of-plane direction, caused primarily by interlayer electronic coupling present in $(OH\text{-}EA)_2PbI_4$. By subtracting optical gap from single-particle gap, we estimate the exciton binding energy (E_b) in these 2D layers, which ranges from 420 meV for $(CH_3\text{–}PA)_2PbI_4$ to 130 meV for $(OH\text{–}EA)_2PbI_4$. This large variation is attributed to specific structural aspects, such as in-plane Pb-I-Pb bond angle, interlayer spacing, and the dielectric constant of the bifunctional ligands.
Our results provide deeper insights into the complex impact of organic ligands on the electronic and excitonic properties of 2D perovskites, in particular the substantial role of strong interlayer electronic coupling. These findings contribute to a better understanding of the structure-property relationship in such materials, facilitating the design and optimization of perovskite-based devices for various applications.

Valence Alternation in Quasi-One-Dimensional Antimony Selenide XinweiWang[1], SeánR. Kavanagh[1,2] and AronWalsh[1,3]; [1]Imperial College London, United Kingdom; [2]University College London, United Kingdom; [3]Ewha Womans University, Korea (the Republic of)

Antimony selenide (Sb_2Se_3) has emerged as an earth-abundant and environmental-friendly alternative among thin-film photovoltaic light absorbers due to its promising optoelectronic properties. A distinguishing feature of Sb_2Se_3 is its anisotropic crystal structure, which is composed of quasi-one-dimensional (1D) $[Sb_4Se_6]_n$ ribbons. However, the current record conversion efficiency of Sb_2Se_3 (~ 10%)[1] is far from optimal. It has been reported that orientation control of Sb_2Se_3 films is important to achieve high device performance [2], but the underlying physics remains unclear.

In this talk, I will present our most recent work[3-5] investigating reasons that affect the conversion efficiency in Sb_2Se_3 based on first-principles calculations. I will first introduce the anisotropy in bulk Sb_2Se_3 structure and the resulting impacts on structural, electronic and optical properties. Then I will present results on the unusual defect physics. Multi-electron negative-*U* transitions between defect charge states can be understood from valence alternation enabled by large local structural rearrangements. Finally, I will discuss potential strategies to optimize the performance of Sb_2Se_3-based photovoltaics.

Patterning Edge-Like Defects and Tuning Defect Propagation on the Basal Plane of Ultra-Large MoS_2 Monolayers Toward Hydrogen Evolution Reaction BiancaR. Florindo[1], LeonardoH. Hasimoto[1,2], NicolliS. de Freitas[1], GraziâniCandiotto[3], ErikaN. Lima[4], Cláudiade Lourenço[1], CarlosOspina[1], JeffersonBettini[1], EdsonR. Leite[1], RenatoS. Lima[1], RodrigoB. Capaz[1] and MuriloSanthiago[1,2]; [1]Brazilian Nanotechnology National Laboratory, Brazil; [2]UFABC, Brazil; [3]UFRJ, Brazil; [4]UFR, Brazil

The catalytic sites of MoS_2 monolayers towards hydrogen evolution are well known to be vacancies and edge-like defects. However, it is still very challenging to control the position, size, and propagation of defects on the basal plane of MoS_2 monolayers by most of defect-engineering routes. In this work, the fabrication of arrays of etched windows on ultra-large supported [1] and free-standing MoS_2 monolayers using focused ion beam (FIB) is reported for the first time. By tuning the Ga^+ ion dose it is possible to confine defects near the etched edges or propagate them over ultra-large areas on the basal plane. The electrocatalytic activity of the arrays toward hydrogen evolution reaction (HER) was measured by fabricating microelectrodes using a new method that preserves the catalytic sites. We demonstrate that the overpotential can be decreased up to 290 mV by assessing electrochemical activity only at the basal plane. HRTEM images obtained on FIB patterned freestanding MoS_2 monolayers reveal the presence of amorphous regions and X-ray photoelectron spectroscopy indicate excess of sulfur in these regions. Density-functional theory calculations provide identification of catalytic defect sites. Our results demonstrate a new rational control of amorphous-crystalline surface boundaries and future insight for defect optimization in MoS_2 monolayers.

Highly Stable Perovskite Solar Cells Coated with Solar Transparent and Thermally Emissive Mesoporous Nanoparticles HeesukJung[1,2], Sung YoonMin[3], ByungsooKang[1], YongseokYoo[4], JinhunJang[5], Yeoun-WooJang[4], HyojeongChoi[6], Hyeong WonLee[6], SwarupBiswas[6], YongjuLee[6], MansooChoi[4], PhillipLee[1], Min SeokJang[3], HyeokKim[6] and ShuYang[2]; [1]Korea Institute of Science and Technology, Korea (the Republic of); [2]University of Pennsylvania, United States; [3]Korea Advanced Institute of Science and Technology, Korea (the Republic of); [4]Seoul National University, Korea (the Republic of); [5]Frontier Energy Solution, Korea (the Republic of); [6]University of Seoul, Korea (the Republic of)

Continuous heat generation in perovskite solar cells (PSCs) due to repeated exposure to solar light is detrimental to the device lifetime. Existing active cooling strategies often require extra energy input. Meanwhile, most passive radiative cooling materials are not solar transparent or require complex fabrication processes. Here, we design, synthesize, and assemble mesoporous silica nanoparticles in multi-layered stacks to create a graded refractive index (GRI) coating for PSCs. The coating offers not only high transparency in the visible wavelength but also high emissivity in the mid-infrared regions. When applied to PSCs that are placed outdoors for 20 days, 81.2±9.50% of the initial photo conversion efficiency (PCE) is maintained, whereas PCE of the pristine PSCs decreases significantly to 8.44±6.84%. The calculated cooling power of the GRI coated PSCs is 28.9% more than that of the pristine PSCs. Our study sheds light on efficient cooling materials that will assist broader adoption of PSCs.

8:00 PM EN06.03.02
Ramifications of B Site Cation Variation in Some Piezoelectric Organic-Inorganic Hybrid Halometallates MichaelWells[1], JacobL. Hempel[1], SantoshAdhikari[2], Y.T.Cheng[1,1], SeanParkin[1], ChristopherSutton[2] and AronJ. Huckaba[1]; [1]University of Kentucky, United States; [2]University of South Carolina, United States

The need for alternative energy sources is rising align with increased utilization of dwindling fossilfuels. One way to help meet the ever-increasing demand is to develop materials and devices that turn wasteforces like vibrations into electricity through the piezoelectric effect. Ceramics such as Lead zirconium titanate(PZT) and Barium titanate (BTO) and polymers like poly (vinylidene difluoride) (PVDF) have been the goldstandard materials, but recently organic-inorganic hybrid metalates (OIHMs) have come to the forefront of thefield, due to high piezoelectric moduli and voltage constants. OIHMs have a basic structure of ABX,are simple to synthesize and process with solution methods, and can be deposited on a variety of substrates.Here we report efforts to probe the effects of the B-site cation identity on chlorometallate structures in piezoelectric materials with chiral and achiral A site cations. Screening many transition metal and main group heavy element B-site cations andsingle or dicationic chiral ammonium cations led to the formation of single-crystalline piezoelectric OIHMs.Piezoresponse force microscopy (PFM) was used to measure local piezoelectric response values of the OIHMs, and other material properties were correlated with material structure.

8:00 PM EN06.03.03
Single Crystalline Thin Films of the Dielectric SrTiO3 and the Multiferriocs BiFeO3 Solid Solution WegdanOsman[1], AbhijitBiswas[2], SatishOgale[2] and DetlefBahnemann[3,4]; [1]Alexandria University, Faculty of Science, Physics Department, Egypt; [2]Indian Institute of Science Education & Research (IISER), Pune Dr. Homi Bhabha Road, Pashan, India; [3]Institute of Technical Chemistry Leibniz Universität Hannover Callinstr., Germany; [4]Saint-Petersburg State University, Laboratory Photoactive Nanocomposite Materials, Russian Federation

This work was motivated by the strong need for sustainable clean energy source for water splitting and other photocatalytic reactions. Solid Solution is a powerful technique to change the physiochemical properties and the band structure of the materials like band gap, band edge positions and chemical stability compared to its single constituents. In this study we use single crystalline, epitaxial, solid solution of the multiferroics BiFeO3 and the dielectric SrTiO3 with nominal composition (BFO)x(STO)1-x where 03 (STO) substrates having different orientations, namely, (001), (011) and (111) to study the electric polarization influence of the BFO on the charge separation. Conductive SrRuO3 (SRO) buffered STO substrates were used as electrodes for the photoelectrochemical (PEC) measurements and their photoelectrochemical properties were investigated varying BFO: STO compositions percentage.

We anticipate that both the photovoltaic effect of the ferroelectric BFO and the change in the BFO: STO compositions have major influence on the PEC properties. Ferroelectricity contributes to the charge separation and collection by the inherent electric field due to spontaneous polarization. On the other hand, when SrTiO3 is added to BiFeO3, significant band structure changes occurs; the conduction band minimum position is raised and an exponential tail of trap states from hybridized Ti 3d and Fe 3d orbitals emerges near the conduction band edge. These shallow trap states strongly prevent the fast recombination of electrons and holes in the mixed solid solution films, carrier lifetimes are increased, and the photocurrent density in the visible-light region is significantly increased when compared to the single constituents. In the BFO90%-STO10% case in which the solid solution is mostly dominated by the BFO phase, photocurrent was highest for photoelectrodes on the STO (111) which is known to have the largest remnant polarization compared to the (011) and (111) directions for BFO. BFO75%-STO25% on STO (011) case among our composition series exhibited the highest photocurrent density. However, we found that for the other composition percentages namely, BFO50%-STO50% and BFO25%-STO75%. The highest photocurrent was also recorded for photoelectrodes on STO (011). Photocurrent decreases with the increase of the SrTiO3 content in the solid solutions. In case of pure BFO and STO, photocurrent was significantly small and incorporation of only 10% STO enhanced the photocurrent greatly to 0.003mA/cm2. Furthermore, electrochemical impedance Spectroscopy (EIS) spectra reveal that the solid solution of the photoelectrodes on (011) exhibits the smallest impedance value hence it shows the highest photocurrent. The reduction of impedance indicates an improved efficiency of photogenerated charge transport at the electrode/electrolyte interface. The EIS results agree well with PEC performance.

Tailoring Reduced Graphene Oxide Layer onto Microstructured Surface for Enhanced Boiling Heat Transfer MaroosolYun, Dong IlShim, JuyeongNam and Hyung HeeCho; Yonsei University, Korea (the Republic of)

As cooling capacity demands for systems of high heat flux, such as nuclear fusion reactor, integrated chip cooling, continuously grows, boiling heat transfer which utilizes latent heat accompanied by phase change could be an advantageous thermal management method with smaller superheat of system. Two major factor, critical heat flux (CHF) and heat transfer coefficient (HTC), which indicates the maximum cooling capacity of nucleate boiling and heat transfer efficiency, respectively, can be employed for determining boiling heat transfer performance. CHF and HTC can be enhanced by promoting bubble nucleation and supplying working fluid to the heated surface to fully utilize the latent heat of vaporization. Nanoparticle coating with graphene related particles on heated surface could promote bubble nucleation as it generates smaller bubbles compared to the plain surface, by offering nucleation sites (micro-sized cavities) in the coating. However, hydrophobic coating layer could block liquid paths, which leads to immature critical heat flux by rejecting working fluid supply. To ensure liquid paths with hydrophobic particle coating, hydrophilic liquid paths should be secured. In this study, we propose tailored coating of reduced graphene oxide (rGO) particle on the micropillar array and plain surfaces. The rGO-coated surfaces were prepared by stepwise methods of deep reactive ion etching (DRIE) and nanofluid boiling with 0.0005 wt% rGO solution. Micropillars are made to be 10 um in height, 4 um in diameter, and 20 um in pitch, respectively, and nanofluid boiling step was controlled for surface tailoring. First, surfaces were coated by nanofluid boiling with increasing heat fluxes immediately before CHF, which results in completely coated micropillar and thick porous coating on plain surface. Then, we run nanofluid boiling at 60 W/cm^2 heat flux for overnight, which is equivalent to the full coating procedure to make thin floating layer on the micropillar. Experimental surfaces of Plain, fully coated micropillar, lightly coated recorded 89 W/cm^2, 201W/cm2, and 238 W/cm2 in CHF and 20.4 kW/m2K, 45.9 kW/m2K, and 90.98 kW/m2K in maximum heat transfer coefficient, respectively. CHF and HTC records confirm that surface with floating rGO layer demonstrates superior heat transfer performance to the fully coated micropillar surface. The notable improvement on CHF and HTC in the tailored rGO surfaces indicates ensuring liquid path beneath the hydrophobic rGO layer by tailoring deposition condition could improve nanoparticle-coated surfaces heat transfer performance, allowing 160% increased HTC compared to the plain surfaces. This study will be helpful for s for enhanced boiling heat transfer on cooling systems for high heat flux devices like heat exchangers and fusion reactors.

Weak-Localization Phenomena as a Tool for Quantification of Defects in MXenes and 2D Metallic Nanolayers BarbaraPacakova[1,2], AnupmaThakur[2], Nithin ChandranBalachandran Sajitha[2], KarelVyborny[3], AnnabelleHarding[2] and BabakAnasori[2]; [1]Norwegian University of Science and Technology, Norway; [2]IUPUI, United States; [3]Institute of Physics, CAS, Czechia

Weak localization[1] (WL) is a quantum phenomenon, where at cryotemperatures, electrons in the metal move around a closed loops and return to their initial point of origin rather than proceeding forward in the lattice, which increases resistivity of metal with decreasing temperature. Typically, metals with defects exhibit transition from normal metallic conductivity to WL regime at low temperatures. In this study, we introduced defects in MXene flakes, such as vacancy clusters and flake boundaries and measured the temperature and field dependence of the resistivity in 2D metallic MXene films. We observed the transition temperature to WL state increases with increasing the amount of defects in MXene flakes. Properties of the 2D nanosheets were also studied by complementary experiments such as XRD, AFM and SEM. Our results indicated that measurements of the temperature and field dependencies of resistivity, can be used as a sufficient and superior technique to understand the amount of defects in the MXenes and 2D metal nanosheets in general, by determining coherence length of electrons at low temperatures in the WL regime. We thus present how the overall quality of 2D flakes in MXene films can be determined by investigating their transport properties. This technique gives a broader picture of MXene defects compared to more localized defect characterization techniques such as transmission electron microscopy.

Graphene Aligned 2D Charge Transport Network for the Thick Electrode for Lithium-Ion Batteries via the Spark Plasma Sintering Process BoNie and HongtaoSun; Penn State University, United States

Developing electrochemical energy storage that can achieve high areal, volumetric, and gravimetric performance simultaneously presents a significant challenge from both a fundamental and technological standpoint. Increasing the thickness and density of electrodes to enhance areal and volumetric performance while maintaining high gravimetric performance is a straightforward yet problematic approach. The insufficient charge transports in these electrodes, which have high mass loading and density, can severely degrade energy storage performance.
In this study, we address this challenge by developing a graphene-based network that is automatically aligned within thick electrodes, fabricated through energy-efficient spark plasma sintering. The electrodes exhibit a high electrode density (2.0-2.3 g cm^{-3}) and high mass loading (70-100 mg cm^{-2}). Leveraging the exceptional properties of vertically aligned graphene-based networks, anisotropic pore channels, and intrinsic properties of two-dimensional (2D) graphene (e.g., superior thermal and electrical conductivity as well as the large surface area), efficient charge transport is enabled throughout the entire electrode thickness. Furthermore, by incorporating a small amount of carbon nanotubes to improve electrode integrity, the hybrid carbon network and characteristic alignment structure of the sintered lithium iron phosphate ($LiFePO_4$) electrodes perform high areal (8.6 mAh cm^{-2}), volumetric capacity (246 mAh cm^{-3}), uncompromised gravimetric performance (164 mAh g^{-1}) at normal current (<2 mA cm^{-2}), and stable cycling with a capacity retention of 84% after 200 cycles under a current density of 4.5 mA cm^{-2}. The automatic alignment of the graphene-based network through the spark plasma sintering process provides a promising approach for designing efficient charge transport pathways in high-energy-density batteries.
The insights gained from this graphene alignment strategy can be applied to various other electrode materials in energy storage systems, such as batteries, fuel cells, and supercapacitors. Furthermore, our future research will focus on extending this approach to solid-state systems by incorporating an ionic conducting phase.

8:00 PM EN06.03.07
Liquid Crystal-Regulated Vertical Aligned Graphene Current Collector for High-Performance Lithium Metal Batteries YifangDing, JuchenZhang and HongtaoSun; Penn State University, United States

Lithium metal batteries (LMBs) hold immense promise as high-energy-density energy storage due to their exceptional theoretical capacity and low voltage potential. However, practical implementation faces challenges such as volume expansion and dendrite growth during cycling of Li metal anodes. To address these issues, the structural design of three-dimensional (3D) current collectors for the anode has emerged as a viable solution by mitigating volume changes and suppressing dendrite growth during Li deposition/stripping.
In this study, we introduce a strong-base-regulated alignment of graphene oxide (GO) liquid crystal that can be utilized as a 3D graphene current collector after thermal reduction for high-performance lithium metal batteries. This innovative design facilitates homogeneous Li transport and uniform Li deposition, thereby enhancing cycling stability in LMBs. To create the vertically aligned structure, the key aspect of our approach involves the utilization of potassium hydroxide (KOH) as a strong base. The use of KOH induces the formation of a vertical aligned GO LC phase in a freestanding pallet at a relatively low concentration of GO solution.
The strong-base-induced vertical aligned graphene current collector exhibits short ion-transport pathways on the upper surface, reducing the concentration gradients and minimizing local overpotentials. This promotes uniform Li deposition and mitigates dendrite formation throughout the current collector, addressing the critical challenge of dendrite growth and improving cycling stability. Moreover, the reduced graphene material offers high electrical conductivity, facilitating rapid electron transports during battery operation. This feature enhances the overall rate capability of LMBs, allowing for high current densities without compromising cycling stability. In additional to electrochemical characteristics, mechanical properties were also investigated through dynamic mechanical analyzer to confirm the robustness of the vertical aligned graphene current collector.
With its excellent conductivity, high porosity, and good elasticity of the LC phase-regulated 3D graphene network, it emerges as an ideal candidate for current collectors in high-performance LMBs. The findings demonstrate the great potential to significantly enhance the performance and safety of LMBs.

8:00 PM EN06.03.08
Biexciton-Induced Hyper-Raman Scattering in Two-Dimensional Halide Perovskite ($(C_6H_5C_2H_4NH_3)_2PbI_4$ under Resonant Two-Photon Excitation Seung HanShin and Joon IkJang; Sogang University, Korea (the Republic of)

$(C_6H_5C_2H_4NH_3)_2PbI_4$ is a prototype two-dimensional (2D) halide perovskite, exhibiting various excitonic phases due to strong quantum and dielectric confinements, thereby ideal for investigating fundamental exciton physics. Being four-body quasiparticles in a semiconductor, biexcitons are typically generated via inelastic Coulomb binding of two excitons under strong pulsed excitation. However, they can be efficiently generated by resonant two-photon exciton utilizing the effect of giant oscillator strength. Here, the biexciton level of $(C_6H_5C_2H_4NH_3)_2PbI_4$ is precisely determined to be 4660.8meV by resonant two-photon excitation, which is also confirmed by considering the mechanism for the biexciton photoluminescence (PL) process. The corresponding two-photon absorption coefficient turns out to be extremely large ($\beta = 2.0\times10^5$cm/MW) due to the giant oscillator strength for the transition. Intriguingly, upon increasing the excitation intensity, a new sharp peak emerges near the high-energy onset of the biexciton PL line, corresponding to the k = 0 state. This peak shifts by $\Delta2\omega$ when the excitation photon energy is varied by $\Delta\omega$ near the two-photon resonance. We show that this strong signal arises from two-photon hyper Raman scattering into the exciton level, where the biexciton state only serves as a virtual intermediate state. This Raman peak is highly suppressed under co-circular polarized excitation, which is also consistent with the two-photon selection rules for the angular momentum of the biexciton. Moreover, the threshold for stimulation in the Raman process is determined to be 80 MW/cm^2 at 10 K, which gradually increases with temperature. Our findings highlight highly nonlinear optical properties of this important material and its potential for biexciton-based photonic applications.

Keywords: 2D halide perovskites, biexcitons, hyper Raman scattering, giant two-photon absorption, stimulated Raman scattering

Pathways to Successful Deployment of Perovskite Solar Cell Technology: A Data-Driven Approach on Research Trends Through Bibliometrics Jun-SeokYeo[1], JihongKim[1] and Seung-HoonLee[2]; [1]Korea Institute of S&T Evaluation and Planning, Korea (the Republic of); [2]Kongju National University, Korea (the Republic of)

Achieving the goal of global carbon neutrality by 2050 will require faster technology innovation and deployment across a range of sectors including power generation, transportation, industrial processes, and more. In particular, an energy transition based on renewable energy is a prerequisite for the new-zero emission of other sectors. Among the next-generation power sources, photovoltaic (PV) has been considered as a viable technology for the energy transition. Especially, hybrid organic-inorganic perovskite solar cells (PeSCs) have been intensively researched due to their high performance, light weight, affordability, and wide range of applications. In this study, we systematically examined the research trends and the cooperation networks by bibliometric methods, focusing on the social acceptance of the technology. A total of 8,607 documents published from 2019 to 2021 were investigated. First, we determined the commercialization factors by considering the LCOE and environmental impact; cost, efficiency, stability, scaling-up, and public acceptability. All publications were categorized by publication years and the commercialization factors. In addition, a variety of bibliometric methods were used: (1) statistical analyses, (2) topic modeling based on publication abstracts, and (3) social network analysis of institution-level co-authorships. These strategic analyses will provide different aspects of the scientific findings and facilitate further discussion on PeSC research directions.

Determining Bandgap Energy of Arbitary Low-Dimensional Structures from Simulated Absorbance PhilipM. Chamberlin and KofiAdu; The Pennsylvania State University, United States

Low-dimensional structures are critical in developing the next generation of energy harvesting devices, such as photovoltaics. The bandgap energy of a material is critical in determining the wavelength range that can be absorbed by a given material and is influenced by quantum confinement effects. We propose a flexible program made in MATLAB that can analyze absorbance data of arbitrary low-dimensional structures to determine the bandgap energy using the Tauc plot and sigmoid-Boltzmann methods. We analyzed absorbance data generated using a COMSOL Multiphysics simulation of absorbance of exotic nanostructures. This program can be extended to all configurations, from zero dimensional structures to bulk materials.

Quantum Confinement Effect in Photoluminescence of TMDs Quantum Dot: Analytical Approach IanEckenrode, SadiqAlli, RachelDesulme, DylanHartmann and KofiAdu; The Pennsylvania State University, United States

As a new class of fluorescent quantum dots (GQDs) of two-dimensional nanostructures such as graphene and transition metal dichalcogenides (TMDs) have drawn increasing attention due to their exceptional properties and potential applications, such as light emitting diodes. Even though there is extensive data on photo-response of GQDs, limited studies have focused on how size distribution affects the photoluminescence (PL). We develop an empirical model that captures such relationship. Our preliminary analysis indicates band gap tuning due to quantum confinement effect. the experimental results that could be attributed to synthesis conditions and the influence of functional groups termination and edge effect, inhomogeneous layer number distributions, and the absorption effect on the PL.

Low-Cost Graphitic Carbon Nitride Based Cathode Host for High Energy Density Flexible Lithium-Sulfur Pouch Cells VijayKumar, RituMalik and MohiniSain; University of Toronto, Canada

Lithium–sulfur batteries (LSBs) have emerged as a highly promising energy storage and conversion system due to their remarkable theoretical specific capacity and energy density. However, the widespread adoption of LSBs faces significant challenges, primarily attributed to the shuttle effect and sluggish redox kinetics of polysulfides. Additionally, conducting realistic investigations at the pouch cell level is challenging, requiring the development of a scalable preparation method for sheet-type cathodes with high sulfur utilization and loading. To address these challenges, we have developed a novel approach utilizing a three-dimensional hybrid sulfur host comprised of graphitic carbon nitride (GCN) and functionalized carbon nanotubes (CNTs). This hybrid composite was synthesized through a self-assembly method followed by calcination. Through structural analysis, it was discovered that the carbon nitride sheets were grown in situ on the surfaces of the carbon nanotubes, establishing C−N bonds that created a larger π-conjugated system. This distinctive structural linkage not only facilitated improved conductivity but also resulted in the presence of an adequate number of nitrogen-containing functional groups. Consequently, it enabled efficient electron transfer from the carbon nanotubes to the carbon nitride. The hybrid composite, serving as a sulfur host, effectively alleviates the shuttle effect caused by intermediate polysulfides. This is achieved through its high sulfur utilization and robust chemical interaction with polysulfides. In practical terms, a modified composite cathode with an impressive sulfur content of 80 wt% and areal sulfur loading of 7.5 mg/cm2 exhibits a high specific capacity of 780 mAh/g, while retaining 85% capacity after 300 cycles at 1 C. These exceptional electrochemical performances can be attributed to the abundant N atoms present in the GCN, which effectively anchor lithium polysulfides. This study not only makes a valuable contribution to the rational design of multi-functional bilayer structures but also presents a novel design approach that holds immense potential for the commercialization of flexible lithium-sulfur batteries with high-energy density.

Dual Confinement of Sulfur in MXenes for Application in Carbonate Electrolyte Li-S Batteries MaryHassig, MichelW. Barsoum and VibhaKalra; Drexel University, United States

Metal-sulfur, also known as lithium-sulfur (Li-S) batteries are of increasing interest for transport technology as their theoretical energy density is ~2,600 Wh/kg, more than 7x the theoretical energy density of a Li-ion battery. Li-ion batteries used in cars use a carbonate electrolyte, compared to an ether electrolyte, for safety concerns. However, more than 90% of Li-S battery research is performed with an ether electrolyte. Herein, we propose a synthesis method of confining sulfur (S) in and on multi-layer Ti_3C_2 MXene for use in the cathode of a Li-S battery with a carbonate electrolyte, for specific use in the electric vehicle industry. Combining both physical and chemical sulfur confinement helps optimize the sulfur loading percentage and helps minimize the creation of polysulfides (PS). Thus the PS do not react with the carbonate species and shut down the battery. This lack of PS also helps decrease the amount of shuttling and limits the decrease in battery performance. As MXenes are one of the few 2D materials that have functional groups that can be chemically modified, the groups can be replaced with S-terminations. MXenes can dually immobilize the S by physically confining the S between the layers. The combination of the two methods leads to increasing S loadings and S utilization for an increased energy density.

8:00 PM EN06.03.14
Investigation Resistive Switching Mechanism of 2D Inorganic Halide Perovskite $CsPb_2Br_5$ Microsheet Based Memristor UijinJung, ZhaozhongTan, WonjunHeo, SangminKim and JinsubPark; Hanyang University, Korea (the Republic of)

Resistive switching (RS) devices based on inorganic metal halide perovskites (IMHPs) are currently under extensive investigation as prospective materials for next-generation memory due to their inherent hysteric behavior, simple manufacturing process, and improved environmental stability. However, the RS operations of polycrystalline IMHPs based devices are generally governed by migrations of ions and defects along to grain-boundaries (GBs) with low activation energies, which hinder the emergence of RS behavior coming from the IMHPs material itself. In addition, GBs in the IMHPs layer greatly increase the leakage current in the high-resistance state (HRS), degrading the RS characteristics, especially the narrowing of the on/off resistance window. Herein, we fabricated RS devices using GBs-free single crystal $CsPb_2Br_5$ microsheet and analyzed their RS characteristics. Through high-resolution transmittance electron microscope (HRTEM) and selected area diffraction (SAED) pattern and Raman analysis, we confirmed that the synthesized microsheet was pure single crystal $CsPb_2Br_5$ without any other impurities. The vertical-type device was fabricated by depositing the top and bottom electrodes (T and BE) on the $CsPb_2Br_5$ (001) and (00-1) plane. In terms of effects of TE materials, RS did not occur when the inert electrode was used as the TE, unlike previous reports, but, the RS devices with active metal TE showed bipolar non-volatile RS characteristics, and exhibited an on/off resistance ratio (~10^8) with low operating voltage (~0.32V). In addition, a reset voltage-driven multi-level operation was also shown, and each state had a large on/off resistance window up to ~10^2. On the other hand, a planar-type device in which both electrodes are formed on the (001) plane of $CsPb_2Br_5$ microsheet was also fabricated, and the RS characteristics were investigated. Unlike the vertical-type device, the device with inert metal electrode exhibited volatile RS characteristics, while the device with an active metal electrode showed non-volatile RS characteristics with a short retention time. Through nudged elastic band (NEB) calculations, we know that the bromine vacancy defects which mainly present inside $CsPb_2Br_5$ crystal prefer movement in the (001) plane rather than the [001] direction corresponding with the measured RS characteristics of the device based on the inert metal electrode. Moreover, the presence of Ag elements in $CsPb_2Br_5$ in the LRS was confirmed through auger electron spectroscope (AES) depth-profile analysis, which suggests that active metal ion migration and redox reaction are the

main causes of RS in vertical-type $CsPb_2Br_5$ based memristor. This study can provide insight into the influence of the used active electrode as well as internal defects in the material in the HPs based RS device.

Colloidal Synthesis of Quaternary Chalcohalide Nanocrystals IrinaGushchina[1,2], StefanoToso[2], MasaruKuno[1] and LiberatoManna[2]; [1]University of Notre Dame, United States; [2]Istituto Italiano di Tecnologia, Italy

Thanks to their optoelectronic properties, good stability, and abundance of elements involved, chalcohalides of IV and V group metals are considered promising candidates for future electrical and optical applications.[1-2] However, their limited processability in bulk form, which requires maintaining high-temperature conditions for long times, represents a challenge for their implementation in functional devices. This has recently stimulated the exploration of alternative synthetic routes based on colloidal chemistry for obtaining the same materials in milder conditions, resulting in the successful preparation of lead- and bismuth- based ternary chalcohalides.[3-5] However, these materials are all indirect-gap semiconductors, which limits their applicability to light harvesting and thermoelectric devices.
Nevertheless, direct-gap materials are within reach if we start considering quaternary chalcohalides, with general formula $M_aM'_bE_cX_d$ (M and M' = metals; E = S, Se, Te; X = Cl, Br, I).[6] In this study, we explore the colloidal synthesis of quaternary sulfohalide nanocrystals containing Pb, Bi, and Sb. Through the choice of precursor concentrations, metals feed ratios and reaction temperatures, this highly tunable synthetic approach offers control over the composition, morphology and ultimately properties of the reaction product. Our investigations confirm the direct gap of these materials, which can be tuned in the visible spectrum by alloying different metals and halides in the structure. This, combined with the remarkable stability of these materials, offers a first step towards real-world applications in optoelectronic devices.

Elastic Crystalline Silicon Solar Mini-Module Based on All-Back-Contact Structure JeonghwanPark and KwanyongSeo; Ulsan National Institute of Science and Technology, Korea (the Republic of)

Flexible and foldable solar cells have attracted numerous interests because they can provide continuous power on uneven surfaces of wearable applications. Crystalline silicon (c-Si) solar cells currently account for more than 95% of the total solar cell market share due to the abundance of Si and stability and high efficiency of the c-Si solar cells. However, c-Si solar cells are difficult to bend and stretch because they tend to become brittle when external forces are applied. Therefore, c-Si solar cells need to be installed on mechanically flat surfaces due to their rigid nature. In this work, we have demonstrated an elastic c-Si solar mini modules through the novel design of an all-back-contact configuration and the introduction of PDMS-based elastic interconnecting electrodes. The elastic c-Si solar module exhibited a module efficiency of 15.0% and a high voltage output of 4.87 V, with a size of 12 cm^2. Additionally, the elastic solar module demonstrated stable photovoltaic properties by maintaining less than a 4% reduction in initial efficiency under both folding and stretching conditions (up to a strain of 40%). We expect that this module can overcome the existing limitations of solar module installation and seamlessly integrate with flexible or wearable electronics, providing a continuous power source.

8:00 PM EN06.03.17
Molecular Insight into Charge Storage Mechanism in 2D Conjugated Covalent Organic Frameworks ZhengnanTian, VinayakS. Kale, OsamaShekhah, MohamedEddaoudi and HusamN. Alshareef; KAUST, Saudi Arabia

2D conjugated covalent organic frameworks (COFs) are currently attracting significant interest as host materials in electrochemical energy storage. They show some intriguing properties, such as designable conductivity, tunable layer distance, and flexible stacking form. However, there has been a lack of deep understanding of the charge storage mechanism related to conjugation degree, stacking model, and pore accessibility. Therefore, by topochemical molecular design, we synthesized two different aromatized imine-based 2D conjugated COFs. According to the detailed electrochemical analysis, in situ measurements, and theoretical simulation, we have discovered a charge storage mechanism that shows that ion diffusion kinetics, which is controlled by the stacking model of the COF, play a more important role than electron migration kinetics, which are controlled by the degree of conjugation, in the charge storage process. We believe this new understanding can be leveraged to design and develop more suitable 2D conjugated COFs for electrochemical energy storage.

8:00 PM EN06.03.18
MXene Sandwiched with Micro Polymer Fibers for Supercapacitor Energy Storage ZuwangWen, YoungseokKim, JaeilPark, MinhuHuang and Myung-HanYoon; Gwangju Institute of Science and Technology, Korea (the Republic of)

MXene (Ti_3C_2Tx), is considered as a promissing electrode material for supercapacitors due to its metallic conductivity, large specific surface area and fast surface redox reaction capability. However, MXene flakes are inclined to stack together, resulting in servere loss of electrochemically active sites that restricts the electrochemical energy storage capability. Herein, we demonstrated a simple and effective strategy to fabricate MXene/PEDOT:PSS micro fibers sandwich structure films via alternative filtering MXene and PEDOT:PSS fiber dispersions with different mass ratio. The conductive cystallized PEDOT:PSS fiber self-fused into porous fibillar networks not only acted as conductive brige facilitating electron transport, but also played a role as pillar between MXene nanosheets to expose more electrochemical active surfaces and shorten electrolyte ion pathways. As a result, the as-prepared composite film delivered a capacitance higher than 300 F/g with good rate performance in 1M H_2SO_4 electrolyte, which is better than the compact packed pristine MXene film. Furthermore, the PEDOT:PSS fiber networks improved composite film flexibility enables it bend and fold to arbitrary shapes without apparent elcetrical/electrochemical damage. This work reveals the improtance of MXene based electrode architecture on electrochemical performance and guide on designing hierarchical composites materials for energy storage, catalysis, and flexible electronics applications.

Keywords: Ti_3C_2Tx MXene, PEDOT:PSS fibers, Flexible composite electrode, Supercapacitor

Redox based Chemical Organometallization: A Novel Strategy for Phase Engineering in Transition Metal Dichalcogenides JuhwanLim, EbinSebastian, PratyushGhosh, JihoHan, ChristophSchnedermann and AkshayRao; University of Cambridge, United Kingdom

Phase engineering in transition metal dichalcogenides offers the ability to tune electric and optical properties, leading to enhance performance in electrical, optoelectronics and energy applications. Among the various available methods (i.e. chemical, electrochemical, optical, and mechanical approaches), chemical lithiation using pyrophoric n-butyllithium has been most widely used for inducing crystallographic phase transformation, from the semiconducting octahedral (2H) to the metallic trigonal prismatic (1T) phase in group 6-TMDs. Here, the donation of electron as well as gliding and adsorption of lithium ion play pivotal roles in driving the phase transition.
In this study, we demonstrate a novel facile and safe method to synthesize organometallic agents, which are then utilized for lithiating and sodiating 2H-MoS_2 and 2H-WS_2 to phase engineer 1T-Li_xMoS_2, 1T-Na_xMoS_2, and 1T-Na_xWS_2. Our approach is based on the correlation between the chemical redox potential and electrochemical potential, which were determined with in-situ optical reflectance measurements. In electrochemical measurements, MoS_2 exhibits discrete electrochemical potentials for a phase transition (PT) and further decomposition (amorphization, D) at both electrochemical lithiation (PT : 1.13 V, D: 0.55 V versus Li/Li^+), and electrochemical sodiation (PT : 0.9 V, D: 0.8 V versus Na/Na^+) processes. Therefore, we employed a reduced species of anthracene (redox potential around 0.9 V versus Li/Li^+) to align the chemical redox potential with that of MoS_2. Remarkably, the use of anthracene facilitates a rapid and safe approach for both lithiation and sodiation, which yields high-quality metallic 1T-MoS_2.
We have extended this approach to reliably synthesize metallic 1T-WS_2. WS_2 displays distinct electrical potential values for phase transition and subsequent decomposition only when interacting with sodium (PT: 1.1 V, D: 0.55 V versus Na/Na^+), while both potentials are nearly indistinguishably close with lithium. Thus, by employing an anthracene-sodium system, we are able to produce 1T-Na_xWS_2. Furthermore, we demonstrate that this process can be complemented by above-gap light, which accelerates the reaction by up to 1000 times. We carefully examined each TMD flakes with different phase, by monitoring the change of A-exciton photoluminescence, the emergence of Raman J peaks, and shifts of Raman peaks.
Taken together, our study reveals a novel method to synthesize organometalization agents, for advanced, safe phase engineering of 2D materials by creating cation intercalation structures, which can be further accelerated by integration of above-gap light illumination.

Fabrication and Characterization of Nanoscale Multilayered Thin-Film Thermoelectric Materials and Devices FabianSanchez[1], EltonMawire[1], EricSmith[1], KimKisslinger[2] and

ZhigangXiao[1]; [1]Alabama A&M University, United States; [2]Brookhaven National Laboratory, United States

In this study, we report the growth of nanoscale multilayered thermoelectric thin films and fabrication and characterization of integrated thermoelectric devices for the application of high-efficiency energy conversion and solid-state cooling. Nano multilayered Bi_2Te_3/Sb_2Te_3, Sb/Sb_2Te_3 and Te/Bi_2Te_3 thermoelectric thin film materials were grown on various substrates using the e-beam evaporation. The multilayered thin films were prepared with 100 to 300 layers, where each layer is about 3 to 5 nm thick. The effect of substrates on the growth of films such as the crystalline structures in the films was studied. Integrated thermoelectric devices with a high density of thermoelectric elements were fabricated with the nanoscale multilayered thin films using the clean room-based microfabrication techniques such as UV lithography. Plasma-enhanced atomic layer deposition (PE-ALD) was used to grow zirconium dioxide (ZrO_2) as the insulation layer in the device fabrication. X-ray diffraction and high-resolution tunneling electron micrograph (HRTEM) were used to analyze the nanoscale multilayered thin films. The fabricated device was cooled in liquid nitrogen or annealed at 150 ^oC for 30 min, respectively. HRTEM was used to analyze the cross-section of the nanoscale multilayered thin films for the three cases: as-grown, after being cooled in the liquid nitrogen, and after being annealed. The thermoelectric characteristics of the fabricated devices were measured and compared for the three cases of as fabricated, after being cooled, and after being annealed, respectively, showing that the integrated thermoelectric device had the highest efficiency of thermal-to-electrical energy conversion after being cooled in the liquid nitrogen. The fabricated nanoscale multilayered thin-film thermoelectric materials and devices could be used for the application of high-efficiency energy conversion and solid-state cooling.

Carrier Type Switching in Bismuth Telluride through *In-Situ* Organic Molecule CoatingJun BeomPark[1], WeiWu[2], JasonY. Wu[2], RijanKarkee[1,3], TheresaM. Kucinski[1], KarenBustillo[4], MattSchneider[1,1], DavidA. Strubbe[3], ColinOphus[4] and MichaelT. Pettes[1]; [1]Los Alamos National Laboratory, United States; [2]University of Connecticut, United States; [3]University of California, United States; [4]Lawrence Berkeley National Laboratory, United States

Thermoelectric materials have gained significant attention for their ability to efficiently convert waste heat into electricity. Among these materials, Bi_2Te_3 stands out as a near-room temperature thermoelectric material due to its exceptional properties, such as high electrical conductivity and relatively low thermal conductivity. Furthermore, low-dimensional Bi_2Te_3 nanostructures has also shown promise in enhancing thermoelectric properties, but it faces challenges, such as chalcogen vacancies and surface oxidation. To address these challenges, various methods have been proposed, including oxygen plasma treatment, superacid treatment, and atomic layer deposition (ALD) of Al_2O_3 to prevent surface oxidation. Simultaneously, several approaches have been explored to enhance thermoelectric properties of nanostructures through employing external dopant layer, such as tetrafluoro-tetracyanoquinodimethane (F_4-TCNQ). Here, we demonstrated the successful synthesis of Bi_2Te_3/F_4-TCNQ layered nanostructures through catalyst-free chemical vapor deposition (CVD). Even after a month of exposure to air, TEM analysis revealed an oxidation-free interface, confirming the efficacy of the coating as an oxygen diffusion barrier. In addition to this, the majority carrier type of the nanostructures switched from *n*-type to *p*-type and their Seebeck coefficient increased over an order-magnitude. It confirms that this in-situ organic layer coating not only provides an oxidation-protecting layer, but also act as a hole-injecting layer that can lead to a significant improve of thermoelectric characteristics. Finally, the F_4-TCNQ-coated Bi_2Te_3 exhibited an order-of-magnitude higher thermoelectric figure of merit (zT) that peaks at a minimum of 10–20 times improvement 250 K.

8:00 PM EN06.03.23
Graphenylene-Based Single-Atom Catalysts for Hydrogen Evolution Reaction CaiqueC. de Oliveira[1], LannaE. Lucchetti[1], JamesM. Almeida[2] and PedroA. Autreto[1]; [1]Federal University of ABC, Brazil; [2]Centro Nacional de Pesquisa em Energia e Materiais (CNPEM), Brazil

Owning to high-energy density and eco-friendliness, hydrogen (H_2) can provide clean energy as an alternative to fossil fuels. However, the main bottleneck of this energy carrier is the reliance on fossil fuels reforming methods, which are harmful to the environment. On the other hand, H_2 can be produced without emissions by electrocatalytic water splitting, in the hydrogen evolution reactions (HER). Yet, further developments are needed to make this technology economically viable and abundant, low-cost catalysts with high activity are demanded [1]. To date, Pt metal group materials and transition metal compounds such alloys are helded as reference catalyst [2]. Nonetheless, these materials are susceptible to corrosion and exhibit low selectivity, not to mention the low availability and high production costs. Alternatively, 2D carbon-based materials possess high chemical resistance, superficial area and elevated electronic conductance, boosting the hosting capacity of these materials. Single Atom catalysts (SACs) can optimize the catalytic activity, enhancing selectivity and reducing the metal atom loading on the host matrix. In this work, state-of-art ab-initio calculations based on Density Functional Theory were carried out to investigate the catalytic performance of metal decorated Graphenylene (BPC@M, with M = Mo, W, V, Nb, Pd, Pt and Zr), a 2D sp^2 carbon allotrope composed by carbon rings with 4 and 6 atoms [3]. Our results show that the metal atoms act as active sites strengthening the interaction with the adsorbate thus reducing the free energy of adsorption.

Exfoliated Hafnium-Based Nanosheets as Catalysts for Oxygen Evolution in Acid ManishChhowalla; University of Cambridge, United Kingdom

The zero pH condition of proton exchange membrane (PEM) water electrolyzers means that only a few metal oxide catalysts involving rare and expensive metals are sufficiently stable for the oxidation reaction. Therefore, earth-abundant acid-stable oxygen evolution reaction (OER) catalysts are required for sustainable water splitting. We report electrochemically exfoliated nanosheets from HfS_2 as stable and high-performance OER catalysts in pH 0 media. The oxidation during synthesis and composition of mixed amorphous and crystalline regions (a/c-HfS_xO_y) render this material sufficiently conductive to allow electrocatalytic activity while remaining stable in the acidic environment. a/c-HfS_xO_ycatalysts exhibit among the highest reported mass activity of ~103,000 A/g at an overpotential of 0.5 V versus RHE and excellent stability. Efficient PEM water electrolyzers are demonstrated using low-dimensional noble-metal-free catalysts.

Advancing Design and Discovery of 2D and Quasi-2D Perovskites via Combinatorial Synthesis and Characterization JongheeYang[1], FoadianElham[1], BenjaminLawrie[2], JuanitaHidalgo[3], SergeiV. Kalinin[1], Juan-PabloCorrea-Baena[3] and MahshidAhmadi[1]; [1]University of Tennessee, Knoxville, United States; [2]Oak Ridge National Laboratory, United States; [3]Georgia Institute of Technology, United States

The emergence of 2D and quasi-2D perovskites has opened exciting possibilities for next-generation optoelectronic devices. These materials exhibit unique electronic, optical, and transport properties, making them promising candidates for a wide range of applications including solar cells, light emitting diodes and radiation sensors. However, their complex structural and compositional nature presents significant challenges in the design and exploration of these materials.
In this talk, I will discuss the use of high-throughput combinatorial synthesis and characterization techniques for the design, discovery, and exploration of 2D and quasi-2D hybrid perovskites [1,2]. By leveraging the power of automation, we can rapidly synthesize a diverse library of 2D and quasi-2D hybrid perovskite compositions and systematically investigate the effects of different synthesis parameters on the layer thickness and properties of these materials, facilitating the discovery of novel structures with enhanced performance.
Furthermore, high-throughput characterization techniques including photoluminescence and Grazing-Incidence Wide-Angle X-ray Scattering (GIWAXS) [3] allow for rapid and comprehensive analysis of the synthesized materials. This multidimensional high-throughput characterization approach helps us understand the influence of synthesis parameters and composition on layer thickness, multi-phase formation and crystal structure on the optoelectronic properties of 2D and quasi-2D perovskites, paving the way for targeted design strategies.
I will showcase recent advances in this field, including the discovery of new perovskite phases, general phase distributions in the quasi-2D hybrid perovskites compositional space, offering a

comprehensive guide for designing phase-controlled systems [4].

Correlation Between Electronic Properties and Surface Reactions of Doped and Undoped MoS2 Films for Hydrogen Production CarmelaAruta[1], PaoloBarone[1], PasqualeOrgiani[1], PieroTorelli[1], LucaBraglia[1], ElisaRiedo[2], NanYang[3] and ZhiweiNie[3]; [1]National Research Council, Italy; [2]New York University, United States; [3]ShanghaiTech University, China

MoS_2 is gaining more and more importance in the field of energy applications. In particular, it is well known that MoS_2 has interesting hydrogen evolution reaction (HER) properties for electrochemical water splitting. H 1s - S 3p orbital overlap can be modified by doping MoS_2 with transition metal ions in order to tune H adsorption and thus HER activity. Among these, Co and Mn have shown great potential. To address these issues, we used a multipurpose pulsed-laser deposition (PLD) facility directly connected to the distribution chamber of the synchrotron beamline to produce and characterize MoS_2 films grown on different substrates, with different thickness and doped with Co and Mn. The in-situ transfer technology allowed measurements by surface sensitive X-ray photoemission (XPS) and X-ray absorption (XAS) techniques avoiding any surface contamination that may affect the sample properties. We observed that the MoS_2 interacts with the substrate at the interface which affects the electronic properties. In-operando XAS characterizations were performed with different gas environment on undoped and doped MoS_2 films in a reaction cell. The results demonstrate that the electronic structure is modified by reduction or oxidation atmospheres and are correlated with the electrocatalytic performance for HER, investigated by polarization curves. The measurements show a very high stability after many cycles and a decrease of the overpotential for hydrogen evolution in doped samples. Our study allows to understand the chemical environment, atomic response and changes in the electronic state during the absorption and desorption processes.

Two Dimensional Ferroelectric-Based Catalysts for Enhanced CO_2 Reduction JoshuaYoung and MoLi; New Jersey Institute of Technology, United States

The electrochemical CO_2 reduction reaction (CO2RR), which can turn CO_2 into to C1 and C2 products, has been proposed as a route to both combat global warming and produce value-added fuels; however, a lack of efficient catalysts is limiting its implementation. Recently, single atom and dual atom catalysts (SACs and DACs, respectively), have been shown to enhance the CO2RR but still suffer from scaling relationships limits. In this work, we show that 2D ferroelectric (2DFE) materials, which display a spontaneous electric polarization in a single monolayer that is switchable by an applied electric field, can be used to overcome limiting scaling relationships and break the Sabatier principle, leading to enhanced CO2RR propensity. We first show that the predicted 2DFE MXene Y_2CO_2 with an O vacancy can preferentially adsorb CO_2 or CO. We then investigated the reduction CO_2 to various C1 products (e.g., methanol, formic acid, etc.) and find that switching the direction of the polarization changes the shape of the reaction pathway. Second, we investigated the CO2RR on SAC and DAC-doped graphene interfaces with the 2DFE In_2Se_3. In this case, the reduction of CO_2 to CO is greatly enhanced compared to the free standing doped graphene layer regardless of the SAC/DAC coordination environment. In both systems, the asymmetry in the surface electron density allows for the tuning of surface adsorption and intermediate stability, as well as activation of alternative pathways. By combining the catalytic properties of 2D-support SACs and DACs with the switchable polarization of 2DFEs, such heterostructures can exhibit higher efficiency and selectivity for CO2RR than existing catalysts and provides a unique route to overcome these issues.

9:45 AM EN06.04.05
New Lamellar Materials as Anode Electrodes for Alkali Metal Ion Batteries VincentSeznec[1,2,3], XiChen[1,2,3] and LaureMonconduit[4,3]; [1]Laboratoire de Reactivite et Chimie des Solides, France; [2]University of Picardie Jules Verne, France; [3]Réseau sur le Stockage Electrochimique de l'Energie RS2E, France; [4]Institut Charles Gerhardt, France

Recent studies have shown that two-dimensional (2D) materials, such as siloxene and germanane, as electrode in alkali metal ion batteries can lead to excellent performance. The improved electrochemical behavior of these 2D active materials could be due to the limited volume change during charge and discharge, based on an intercalation rather than an alloying mechanism. In addition, if Si is effective in reducing costs due to its low price and abundant resource reserves, its conductivity is low, while Ge can provide higher electronic conductivity than Si, but is more expensive. In this respect, in order to integrate their cheapness and excellent conductivity, we propose a series of layered materials (named siliganes, *i.e.*, $Si_{1-x}Ge_x$, $0.1 < x < 0.9$), which consist of 2D Si-Ge composites. Through a simple method, the Ca^{2+} cations were completely removed from the precursor $Ca(Si_{1-x}Ge_x)_2$, and the lamellar siliganes were obtained. The layered materials were tested in Na- and K- ion batteries. Based on the better electrochemical performance, we identified siligane_$Si_{0.1}Ge_{0.9}$ as the best candidate. At a current density of 0.05 A g^{-1}, its reversible capacities of the Na ion and K ion cells were 276 mAh g^{-1} and 132 mAh g^{-1} after 50 cycles, respectively.

Layer-By-Layer Assembly of 2-Dimensional MXene Nanosheets with Polyelectrolyte Energy Storage Applications JunyeongYun[1], MichelW. Barsoum[2], MicahGreen[1], MiladinRadovic[1] and JodieLutkenhaus[1]; [1]Texas A&M University, United States; [2]Drexel University, United States

A broad family of two-dimensional ceramic nanosheets referred to as MXenes have caught the world's attention because of their wide compositional diversity and tailorability to different engineering applications including energy storage. One challenge is to translate these applications into a thin-film platform. This presentation will discuss the water-based solution-assembly of two-dimensional MXene nanosheets with polyelectrolyte using the layer-by-layer assembly technique. This approach produces conformal MXene-based coatings on a variety of surfaces including hydrophobic poly(dimethylsiloxane), glass, thread and fiber, and silicon. The result is a conformal coating consisting of a brick-and-mortar-type architecture with tunable layer thicknesses. We take advantage of the MXene-polymer morphology for electrochemical energy storage in wire shaped capacitors consisting of reduced graphene and MXene or capacitor thin films of polyaniline with MXene. Last, the energy storage mechanisms for $Ti_3C_2T_x$ MXene multilayer (ML) sheets is proved using electrochemical impedance spectroscopy (EIS) and cyclic voltammetry coupled with in situ gravimetric electrochemical quartz crystal microbalance with dissipation (EQCM-D) measurements in various electrolytes. EIS frequency-dependent mass changes associated with the transfer of hydrated cations are revealed. This study demonstrates that although cations are primarily responsible for the energy storage mechanisms in $Ti_3C_2T_x$ MLs, the anion and the time scale of observation can have a strong effect.

11:00 AM *EN06.04.07
Application of 2D Transition Metal Sulfides in Energy Storage HongliZhu; Northeastern University, United States

The emergence of metallic phase two-dimensional molybdenum disulfide (MoS2) introduces a new class of materials boasting superior electrical conductivity and catalytic activity. This presentation aims to provide a comprehensive review of the atomic structures and electrochemistry of metallic MoS2, an essential element in an array of established and burgeoning technological applications, with detailed studies of our lab in hydrogen evolution reaction, lithium ion and sodium ion batteries, supercapacitor, and all solid state Li sulfur batteries.
For example, recently, in our lab, a highly conductive carbon fiber decorated with hybrid 1T/2H MoS2 nanosheets is designed. The high chemical and electrochemical compatibility among MoS2 and sulfide solid state electrolyte can greatly improve the stability of the cathode and therefore maintain pristine interfaces. The uniform distribution of electrical conductive metallic 1T MoS2 on carbon fiber benefits the electron transfer between carbon and sulfur. Meanwhile, the layered structure of MoS2 can be intercalated by a large amount of Li ions facilitating ionic and electronic conductivity. In consequence, the charge transfer and reaction kinetics are greatly enhanced, and the decomposition of SSEs is successfully relieved. As a result, the all solid state lithium sulfur delivers an ultrahigh initial discharge and charge capacity of 1456 and 1470 mAh g−1 at 0.05 C individually with ultrahigh coulombic efficiency and maintains high capacity retention of 78% after 220 cycles. The batteries also obtain a remarkable rate performance of 1069 mAh g−1 at 1 C.
This talk will span the exploration of the atomic and band structures of metallic MoS2, its electrical and optical properties, fabrication methodologies, and prominent emergent applications in the realm of electrochemical energy storage and conversion. A central feature of the talk will be the intricate relationship between the atomic structure, properties, and performance of metallic MoS2, emphasizing the critical importance of understanding these fundamentals for emerging energy applications.

11:30 AM EN06.04.08
Layered Vanadium Disulfide Electrodes for Printed Zinc Ion Batteries StefanoTagliaferri, NagarajuGoli, EvanFisher, MariaS. Sokolikova and CeciliaMattevi; Imperial College London, United Kingdom

Aqueous Zinc Ion Batteries (ZIBs) are receiving growing attention as beyond-lithium power sources for wearable electronics and sensors, owing to their high theoretical capacity, environmental friendliness, and low cost. However, Zn^{2+} ions have a high charge density, almost double the charge density of Li^{+}, which is detrimental for the intercalation kinetic and the structural stability of the battery electrodes.
Layered transition metal dichalcogenides (TMDs) have ideal features for high-performing energy storage devices, including high surface area and large two-dimensional diffusion channels inside their structure. The adjacent layers in the TMD structure are connected by weak van der Waals interactions, resulting in a large interlayer spacing which enables rapid ion diffusion kinetic and promotes the reversible insertion and extraction of multivalent ions. Among TMDs, vanadium disulfide is a promising cathode material for ZIBs, owing to its large interlayer spacing (~ 5.76 Å) and metallic character. Despite these beneficial features, vanadium disulfide has mainly been investigated in coin-cell batteries, which are difficult to directly integrate in wearable electronics.
Here, we demonstrate the combination of an easily-scalable hydrothermal synthesis with a room-temperature 3D Printing process to fabricate vanadium disulfide electrodes with customized geometry. The hydrothermal vanadium disulfide was mixed with a polymeric binder and conductive additives to obtain a stable ink with optimal printability. The architecture of the VS_2 electrodes was rationally tailored *via* the printing process to facilitate the electrolyte penetration and promote fast charge transfer. Finally, the printed vanadium disulfide electrodes were coupled with zinc anodes to assemble aqueous zinc-ion batteries. The full cells were tested in a water-in-salt electrolyte, which improved the stability of the vanadium disulfide electrode, extending the achievable potential window and energy density.

SESSION EN06.05: Low-Dimensional Perovskites—Optoelectronics and Theory
Session Chairs: Volker Blum and Maria Antonietta Loi
Tuesday Afternoon, November28, 2023

1:30 PM *EN06.05.01
2D Layered Halides Perovskites Optoelectronic Properties Manipulation by Crystalline Orientation Rational Control GiuliaGrancini; University of Pavia, Italy

In recent years, the interest in low-dimensional perovskite (LDP or 2D perovskite) materials has flourished. This is due to their beneficial effects in perovskite-based photovoltaics, enabling devices with record power conversion efficiencies and prolonged stability. These materials are mainly utilized as surface modifiers, enabling 3D/2D heterostructures, acting as passivating agent. However, the research on the implementation of LDPs as self-standing absorbing material is limited, especially for LDPs with low dimensionalities (n=1,2,3). The main challenges are related to their optoelectronic properties, such as reduced carriers' diffusion length and high exciton binding energies, that limit their performances. Nevertheless, LDPs still represent a valid candidate for applications where wide bandgap (>2 eV) materials are required. Indeed, LDPs circumvent the problem of halide segregation typical of 3D perovskite for such band gaps, guaranteeing prolonged stabilities of the device. Here, we present a powerful strategy to optimise LDP optoelectronic properties by finely controlling the crystallization of the material in a preferential direction. Our approach consists in orienting the inorganic sheet of the LDP material in the same direction of the charge extraction of the photovoltaic device, in order to maximize the transport of carriers and their collection at the electrodes. The preferential crystalline orientation of the LDP has been studied by advanced X-Ray Diffraction techniques, high resolution TEM imaging and directional dependent conductivity analysis, confirming the validity and the potential of the solution. The rational control over the crystal growth direction has allowed to fabricate a 2.1 eV LDP-based solar cell with power conversion efficiency about 10%, as well as semi-transparent devices with a high degree of transparency (Average Visible Transmittance >30%). The chemical composition of the LDP and its improved intrinsic stability guaranteed much prolonged stability with respect to the state of the art devices with such high band gap. These results pave the way to the implementation of LDP for wide bandgap photovoltaic applications, such as semi-transparent and multi-junction tandem devices.

Acknowledgements I acknowledge the "HY-NANO" project that has received funding from the European Research Council (ERC) Starting Grant 2018 under the European Union's Horizon 2020 research and innovation programme (Grant agreement No. 802862).

Synergy of 3D and 2D Halide Perovskites for Durable & Efficient Photovoltaics AdityaD. Mohite; Rice University, United States

Three-dimensional (3D) organic-inorganic lead halide perovskites have emerged in the past few years as a promising material for low-cost, high-efficiency optoelectronic devices. Spurred by this recent interest, several subclasses of halide perovskites such as two-dimensional (2D) halide perovskites have begun to play a significant role in advancing the fundamental understanding of structural, chemical, and
physical properties of halide perovskites, which are technologically relevant. While the chemistry of these 2D materials is similar to that of the 3D halide perovskites, their layered structure with a hybrid organic-inorganic interface induces new emergent properties that can significantly or sometimes subtly be important. Synergistic properties can be realized in systems that combine different materials
exhibiting different dimensionalities by exploiting their intrinsic compatibility. In many cases, the weaknesses of each material can be alleviated in hetero architectures. For example, 3D-2D can demonstrate novel behavior that neither material would be capable of separately. Here I will describe how the structural differences between 3D halide perovskites and 2D halide perovskites give rise to their disparate materials properties, discusses strategies for realizing mixed-dimensional systems of various architectures through solution-processing techniques, and presents a comprehensive outlook at the use of 3D-2D systems in solar cells. Finally, we investigate applications of 3D-2D systems beyond photovoltaics, and offer our perspective on mixed-dimensional perovskite systems as semiconductor materials
with unrivaled tunability, efficiency and technologically relevant durability.

2:30 PM EN06.05.03
Optical Control of Polarization in 2D Hybrid Molecular Crystals LinaQuan and YixuanDou; Virginia Tech, United States

Spontaneous polarization is a key in developing advanced functional materials for a broad range of applications such as memory device, piezoelectric sensors, radio frequency/microwave devices, and many other systems. To manipulate structural polarization in organic-inorganic hybrid system, external stress and electric fields can induce the switching of ferroelectric polarization domains. When it comes to the electric field control, the limitation is anticipated involving the requirements for circuits and complicated device fabrication. In this presentation, I will talk about the observation of optically induced switchable polarization in 2D hybrid molecular crystal. By employing a number of advanced characterization tools, such as X-ray diffraction scattering measurement under the photo-excitation, we were able to probe and study the excited state structural dynamics from 2D hybrid molecular crystal with a clear observation of reversible lattice expansion and contraction in various time-scales.

2:45 PM EN06.05.04
Disentangling The Relationship between Cation and Perovskite Structures MarcinGiza[1], JustasDeveikis[2], JamesLloyd-Hughes[2], RebeccaL. Milot[2] and PabloDocampo[1]; [1]University of Glasgow, United Kingdom; [2]University of Warwick, United Kingdom

Layered perovskites utilising bulky organic cations have recently emerged as promising candidates for tackling the issues faced by conventional perovskite materials, such as their degradation in ambient conditions. Combining the benefits of good stability with desirable properties like efficient charge extraction relies on a precise understanding of the perovskite energetics, careful control of band alignment and optimised layer quality. In order to make further progress and guide future synthetic efforts, the relationship between the structure and optoelectronic properties of these films needs to be fully disentangled. Here, the interlayer spacing and the distortion of the crystal dictate the majority of the optoelectronic properties of the material. Typically, this is explained by a tunnelling mechanism, where the barrier width determines the likelihood of the process, and therefore the charge transport properties. In addition, the relative positions of the energy bands also influence this parameter, determined by the degree of distortion in the lattice. In these systems, the organic cations determine the structure, affecting every key property of the material at the same time, making disentangling these effects difficult. As such, an effort must be made to methodically investigate the structure-property relations of layered perovskite materials. Here, the crystal structures of a family of closely related cations are used to link how elements of the molecular structure impact the spacing and symmetry of the resulting perovskite layer. The optoelectronics of the resulting materials are also studied, to draw links between the perovskite structure and their optical bandgap, thus identifying key parameters which need to be target in order to effectively tailor future perovskite materials.

3:00 PMBREAK

3:30 PM *EN06.05.05
Structural and Optoelectronic Properties of 2D Multilayered Perovskites JackyEven[1], MikaelKepenekian[2], GeorgeVolonakis[2], PedesseauLaurent[1], SimonThébaud[1], MariosZacharias[1],

WeiLi[3], MercouriG. Kanatzidis[4], AdityaD. Mohite[5] and ClaudineKatan[2]; [1]INSA Rennes, France; [2]Université de Rennes, France; [3]Nankai University, China; [4]Northwestern University, United States; [5]Rice University, United States

2D multilayered perovskites share similarities with 3D perovskites including direct electronic band gaps, strong spin-orbit coupling, sizeable optical absorptions, small effective masses, Rashba-like effects [1]. Interestingly, they exhibit other attractive features related to tunable quantum and dielectric confinements, strong lattice anisotropy, more complex combinations of atomic orbitals and lattice dynamics, extensive chemical engineering possibilities. This will be illustrated by recent combined experimental and theoretical studies on excitons, formation of edge states, hot carrier effects and carrier localization [3-6]. More, combined in 2D/3D bilayer structures using new versatile growth methods, excellent solar cell device stability can be achieved [7]. Band alignment calculations nicely explain the difference of performances for ni-p or p-i-n devices [8]. The lattice mismatch concept can provide guidance for the choice of the proper 2D/3D combination [1,2].

Structural, Electronic, Electron-Phonon and Chiral Properties of Layered Organic-Inorganic Perovskites from First Principles VolkerBlum; Duke University, United States

Layered organic-inorganic perovskites and related halides offer broad tunability of their electronic, optical and spin properties by tailoring their organic and inorganic components. This talk focuses on first-principles structure and electronic structure predictions from large-scale spin-orbit coupled hybrid density functional theory. We show that quantum-well like energy level alignment can be predicted faithfully, i.e., in agreement with the experimentally observed optical response, at this level of theory. In a particular example, we further show how close alignment of the valence bands of the organic and inorganic components can be exploited to induce laser-controlled, coherent charge oscillations between the spatially separate organic and inorganic components. We next explore chiral systems, i.e., perovskites that either incorporate a chiral organic component or those that spontaneously break their symmetry, showing that a simple structural parameter can account for predicted relativistic splitting of the conduction bands, as well as for the associated chiroptical response. Based on the same rationale, we then explore perovskite nanostructures, i.e., quantum dot arrays and platelets with chiral organic functionalization, which also show significant spin-dependent optical responses. Finally, a key prerequisite for practical semiconductor applications of any material is dopability. For the paradigmatic layered halide perovskite phenethylammonium lead iodide, we explain experimentally observed, weak n-doping by Bi incorporation and and weak p-doping by Sn incorporation through the interaction of either substituent with intrinsic defects in the material. This work would not be possible without numerous collaborators, including experimental colleagues around the world and the very large group of contributors to the FHI-aims code, used in this work, as well as the open-source Electronic Structure Infrastructure ELSI and the CECAM Electronic Structure Library (ESL). Funding from the National Science Foundation under awards number 1729297 and 1450280 is gratefully acknowledged. Work on doping and chiral systems was primarily supported as part of the Center for Hybrid Organic Inorganic Semiconductors for Energy (CHOISE), an Energy Frontier Research Center funded by the Office of Basic Energy Sciences, Office of Science within the U.S. Department of Energy.

Structure-Property Correlation and Strong Electronic Cross-Talk in Low Dimensional Metal Halide Hybrids JanardanKundu; Indian Institute of Science Education and Research Tirupati, India

Low dimensional (2D, 1D, 0D) metal halide hybrids, supporting strongly bound excitons, show narrow band edge and broadband self-trapped excitonic (STE) emission. In the absence of general guidelines to enhance this broadband emission, structure-property correlation can be beneficial in designing highly emissive materials. This talk will highlight the fundamental factors that control the emissive properties of main group ns^2 metal halide based low dimensional (1D, 0D) hybrids. Our current results on utilizing doping strategy for the synthesis of multi-metallic halide hybrids that manifest interesting photo-physical properties and structural control will be showcased. Effects of electronic interaction between the metal halide units in such multi-metallic low dimensional hybrids will be highlighted. Mechanism of the electronic cross-talk between the isolated metal halide units in such systems will be discussed. Utility of such multi-metallic halide hybrids for anti-counterfeiting and negative thermal quenching applications will be highlighted. The talk will conclude with outlook of our current research work highlighting the existing issues in white light emission using main group low dimensional metal halide hybrids.

Modelling Orientational Disorder and Phase Transitions in Hybrid Piezoelectric Materials from First Principles KasperTolborg and AronWalsh; Imperial College London, United Kingdom

Piezoelectric materials interconvert electrical and mechanical energy and find applications in diverse areas as sensors, actuators, and high precision motors. However, current state-of-the-art Pb-based piezoelectric ceramics pose significant environmental issues and preclude design of biocompatible devices. In recent years, solution processable, flexible and potential biocompatible hybrid organic-inorganic piezoelectric materials rivalling the performance of lead-based ceramics have been discovered [1,2].

The most promising candidates are based on low-dimensional inorganic frameworks with perovskite inspired structures, and they feature order-disorder phase transitions close to room temperature. Above these phase transitions, disordered, centrosymmetric phases appear, destroying their piezoelectric performance. Furthermore, conventional computational methods fail to predict the large piezoelectric response of this materials category [3]. Thus, modelling of this materials class must include entropic effects to phase stability [4], and nanoscale effects for response properties.

Here, we present the development of coarse-grained model Hamiltonians for the correlated disorder of dipolar organic cations in the archetypical 1D hybrid hexagonal perovskite, $TMCMCdCl_3$ (TMCM=trimethylchloromethyl ammonia) from first principles [5]. Coupled with Monte Carlo simulations, we predict and rationalise its order-disorder phase transition, showing that vibrational entropic contributions are key for quantitative agreement with the experimental phase transition temperature. This highlights the importance of vibrational entropy in describing phase stability for a materials class seemingly driven by configurational entropy.

Based on an observed easy stabilisation of anisotropic, two-dimensional disorder in the system, we calculate defect formation energies of isolated and extended orientational defects, which are shown to be easily formed at ambient conditions. Switching of these defects is suggested to be the origin the strong, unconventional piezoelectric response [5].

Solution Processed $Cs_2PbI_2X_2$ for Interface Passivation in $CsPbI_2Br$ Solar Cells GaukharNigmetova, ZhuldyzYelzhanova, GulzhanBizhanova, HryhoriiParkhomenko, meruyertTilegen, DamirAidarkhanov, VladimirPavlenko, Chang KeunLim, AskhatN. Jumabekov, TriPham, MannixBalanay and AnnieNg; Nazarbayev University, Kazakhstan

Hybrid halide perovskites have shown promise as absorber materials for third-generation solar cells. However, improving the stability of perovskite solar cells (PSCs) remains a key challenge for commercialization. All-inorganic Cs-based perovskites have recently gained attention for their enhanced thermal stability compared to organic-cation perovskites. This work focuses on CsPbI2Br absorbers with a 1.9 eV bandgap. We demonstrate an effective surface modification technique by forming 2D Cs-based perovskite nanostructures via solution processing on CsPbI2Br thin films. The 2D Cs2PbI2X2 layer passivates defects at the CsPbI2Br surface, leading to improved photovoltaic efficiency and device lifetime. Controlling the nanomorphology of the 2D perovskite layer is critical for optimized passivation. Our experiment conditions show the evolution of Cs2PbI2X2 growth on 3D perovskite thin films.
This work demonstrates the approaches for tuning the morphology of Cs2PbI2X2 through solution-processing parameters. Understanding the crystallization dynamics of the 2D Cs2PbI2X2 nanostructures will also provide insights into developing other scalable solution processing techniques for large-scale manufacturing. Overall, this work shows that interfacial engineering of CsPbI2Br PSCs via incorporation of solution-processed Cs2PbI2X2 enables improvment of photovoltaic performance, motivating further study of 2D perovskite crystallization and nanostructure control for advancing all-inorganic PSC technologies.

Exploring the Structural Origin of Self-Trapped Exciton Emission in $Cs_7Cd_3Br_{13}$AndrewGruber, KulatheepanThanabalasingam and KyleM. McCall; University of Texas at Dallas, United States

Low-dimensional metal halides with self-trapped exciton emission are a burgeoning materials class with important applications in solid-state lighting, X-ray scintillation, and luminescent solar concentrators. These materials exhibit effective and intrinsic self-trapping, with dual excited state origins arising from either Jahn-Teller distortion or ns^2 lone pair dynamics. The intrinsic nature of this emission makes it ideal for testing structure-property relationships, as altering the composition, coordination, or dimensionality directly impacts the resulting excited state and thereby the resultant optical properties.
One such material is $Cs_7Cd_3Br_{13}$, which adopts a complex mixed 1D-0D structure with isolated $[CdBr_4]^{2-}$ tetrahedra and corner-connected 1D chains of $[CdBr_4Br_{2/2}]^{3-}$ octahedra. This compound has demonstrated orange STE emission at room temperature (PLQY above 9%), derived from the Jahn-Teller related distortion of the excited state, but it is unclear whether this emission is derived from the octahedral or tetrahedral cadmium halide subunits. We hypothesize that the straight octahedral chain is the emissive subunit in this system, as this coordination is unknown amongst inorganic cadmium halides. This work aims to elucidate the structural origin of STE emission in this compound using a combination of chemical substitution and temperature-dependent photoluminescence (PL) studies (PL emission, PL excitation, and time-resolved PL). Zn^{2+} has been chosen as an isoelectronic dopant that will exclusively occupy the tetrahedral site, providing a structural knob that can tune this emission as a function of temperature if the tetrahedral unit is involved in the excited state, thereby revealing whether this tetrahedral unit is responsible for the room-temperature emission. The upper limit of this doping will also be explored up to 66.7%, as Zn^{2+} may be able to fully substitute the $CdBr_4$ tetrahedral units, resulting in the theoretical compound $Cs_7Zn_2CdBr_{13}$. This work will illuminate the effective emissive subunit in $Cs_7Cd_3Br_{13}$ and add to the growing body of knowledge on transition metal halides with Jahn-Teller-active excited states.

The Role of Structure on Light Matter Interactions in Ruddlesden Popper 2D Perovskites MartinGomez, EstebanRojas-Gatjens, VictoriaQuiros Cordero, Carlo Andrea RiccardoPerini, CarlosSilva and Juan-PabloCorrea-Baena; Georgia Institute of Technology, United States

Two-dimensional (2D) halide perovskites are promising for light emitting applications due to their tunable emission bandwidth, strong oscillator strengths, and low non-radiative recombination rates. These organic-inorganic heterostructures with confined excitons offer an ideal platform to study light-matter coupling, when standing electromagnetic waves interact near resonantly with matter excitations. However, the relationship between structural modifications and changes in excited states and their coupling with light remains poorly understood. In this study, we employ a combination of structural and optical characterization techniques including Grazing Incidence Wide Angle X-ray Scattering (GIWAXS), X-Ray Diffraction (XRD), Absorption, Photoluminescence, and Resonant Impulsive Stimulated Raman Scattering (RISRS) to investigate the effects of induced modifications to local atomic structure in PEA_2PbI_4 Ruddlesden-Popper Metal Halides (commonly known as 2D perovskites). By studying the influence of structural modifications on excited states we gain insights into the interplay between structural properties and light-matter interactions in 2D halide perovskites.

New Paths for Low-Dimensional Lead-Free Perovskites: From Traditional Wet Chemistry to *In Situ* SynthesisRafaelAbargues; Universidad de Valencia, Spain

Metal Halide Perovskites (MHP) have attracted significant research interest due to their unique properties and potential applications in photovoltaics, optoelectronics, and catalysis. Due to the huge concerns about lead toxicity in traditional metal halide perovskite, Lead-free perovskites have gained significant attention in recent years as alternative materials that can offer similar or better performance. Sn has been extensively investigated as an alternative to Pb in perovskite materials because they have a similar crystal structure as Pb-based MHP and can exhibit desirable optoelectronic properties, including high absorption coefficients and long carrier lifetimes. However, Sn perovskites also face challenges that must be addressed for widespread implementation. One of the major issues is their lower stability compared to lead perovskites, especially when exposed to moisture or elevated temperatures due to the prone of Sn(II) to oxidize to Sn(IV). Tin perovskites tend to undergo phase transitions and degrade more easily, decreasing device performance over time.
Researchers are actively working on improving the stability and performance of tin perovskites through various synthetic strategies. These include compositional engineering, dimensionality, interface modifications, encapsulation techniques, and device architecture optimization. Among them, low-dimensional perovskite structures, particularly layered structures, often exhibit improved stability compared to their bulk counterparts. The reduced dimensionality can mitigate ion migration and phase instability issues, leading to enhanced device performance and longevity. In low-dimensional materials, the confinement of charge carriers can lead to quantum confinement effects. These effects result in unique electronic properties, such as increased exciton binding energy and efficient charge transport. This can be advantageous for achieving high-efficiency solar cells and other optoelectronic devices.
Our research group has conducted investigations into the synthesis of low-dimensional Sn halide perovskites from micro and nanocrystals using different chemical routes, from traditional wet chemistry to in situ synthesis. We explore the versatility of the hot-injection approach for the dimensionality control of tin (II) halide perovskites microcrystals using 2-thiophene ethylene amine (TEA) as a bulky cation. TEA-Sn molar ratio plays an essential role in the formation and stabilization of 0D Sn-based MHP with excellent photoluminescence quantum yields (PLQY > 70%). Moreover, we report on a novel approach for the in-situ synthesis of 2D and 0D TEA_2SnX_4 nanocrystals embedded in a nanocomposite with excellent stability. This technique is low-cost and low-energy demanding, allowing modifications to precursor solutions for compatibility with commercial printing techniques, ultimately contributing to the success of MHP. The in-situ synthesis approach also offers a low-carbon footprint synthetic route, making it more sustainable than traditional wet chemistry. We demonstrated how adjusting crystal growth from macro to nanoscale, using innovative synthetic routes [1] and surface treatments, can alter optoelectrical response through fundamental changes in surface and bulk structure and composition.

Ternary Perovskite-Organic Composites for High-Performance Perovskite Solar Cells XiongGong and LeningShen; University of Akron, United States

Metal halide perovskites (MHPs) have emerged as promising photovoltaic materials due to their remarkable optoelectronic properties and the feasibility of cost-effective, high-throughput manufacturing of perovskite solar cells (PSCs). Over 25% of power conversion efficiencies (PCEs) have been reported for the PSCs based on three-dimensional (3D) MHPs. However, 3D MHPs are sensitive to moisture and oxygen, resulting in significant degradation of their performance under ambient atmosphere. Compared to 3D MHPs, two-dimensional (2D) MHPs possess improved photostability and chemical stability. The PSCs in which 2D MHPs are incorporated within the 3D MHPs network exhibit improved stability with respect to purely 3D systems, but lower record PCEs. In this presentation, I would like to report a breakthrough work in achieving enhanced PCEs, increased stability, and suppressed photocurrent hysteresis by incorporating n-type low-energy-gap conjugated organic molecules into 2D:3D mixed MHPs composites, where 2D MHPs were created by using conjugated organic cations rather than widely used non-conjugated organic cations. The resulting ternary MHP-organic composites displayed extended absorption in the near-infrared region, improved film morphology, enlarged crystallinity,

balanced charge transport, efficient photoinduced charge transfer, and suppressed the counter-ion movement. As a result, the ternary MHP-organic solar cells exhibited PCEs over 23%, which are among the best PCEs for PSCs with p–i–n device structure. Moreover, the ternary MHP-organic solar cells possessed dramatically enhanced stability and diminished photocurrent hysteresis. All these results demonstrated that the strategy of exploiting ternary MHP-organic composite thin films provides a facile way to realize high-performance PSCs. To further boost the PCEs of PSCs, we have synthesized various conjugated oligomer cations and then developed 2D:3D mixed MHP composites, where the 2D MHPs are created by using the above-conjugated oligomer molecules as the space cations. Afterward, these 2D:3D mixed MHPs composites are incorporated with n-type low-energy-gap conjugated organic molecule electron acceptors to form ternary MHP-organic composites for approaching high-performance PSCs. Conjugated oligomers are used as the space cations since they possess an enhanced density of states, which could further boost the charge transport of the resultant 2D MHPs in comparison to conjugated organic cations. As we expected, boosted PCEs and stability, and significantly suppressed photocurrent hysteresis are observed from the PSCs based on these newly developed MHP-organic composites.

Application of Low Dimensional Materials in Solar Cells YanfaYan; The University of Toledo, United States

Low dimensional materials are gaining attentions in fabrication of efficient and stable thin-film solar cells. They are either used as absorbers or interfacial layers. In this talk, I will present two representative cases. For the case of absorber, I will present our work on fabrication of efficient thin film solar cells based on Antimony chalcogenides (Sb_2Ch_3). I will introduce the method developed to grow highly oriented films to promote extraction of photo-generated carriers. In the case of interfacial layer, I will present our work on utilizing layered perovskites to passivate and stabilize three-dimensional perovskite solar cells.

Methylammonium and Bromine Free Phase-Pure Dion Jacobson 2D Lead Halide Perovskites for High Efficiency and Durable Wide Bandgap Solar Cells AyushAgrawal, JinHou, FaizMandani and AdityaD. Mohite; Rice University, United States

In the last decade, three-dimensional (3D) metal halide perovskite solar cells have displayed tremendous progress in photoconversion efficiencies. The tunable bandgaps enable mixed halide perovskite compositions to be used as the wide bandgap (WB) sub-cell in Si-perovskite and all perovskite tandems. However, halide segregation and ion migration of I-Br mixed halide systems under photo-illumination create bandgap instability that limits the long-term durability of these wideband gap subcells. 2D halide perovskites, on the other hand, have demonstrated better durability against moisture and photo illumination due to their large organic cations but still lag in efficiency due to >2eV band gaps and charge extraction barriers. Furthermore, the methylammonium (MA^+) cation used in quasi-2D (<n>=2) perovskites is hygroscopic and can still limit the stability of the perovskite. Here, we synthesize formamidinium (FA^+) based 2D Dion Jacobson (DJ) perovskite solar cells with diammonium organic spacer cation. Optical absorption on FA 2D DJ reveals a band gap of 1.7-1.8eV for n=3 perovskites, ideally suited for building bottom cells for perovskite-perovskite and Si-perovskite tandems. Films fabricated using the phase-selective memory seeds[1] process preserved the phase purity of the n=3 2D perovskite. FA 2D DJ perovskites demonstrate commercially viable durability against temperature, moisture, and maximum power point (MPP) tracking. These properties make FA 2D DJ perovskites promising candidates for wide bandgap subcells in perovskite-perovskite tandem.

Memory Seeds Enable High Structural Phase Purity in 2D Perovskite Films for High-Efficiency Devices. *Advanced Materials* **2021**, *33* (29), 2007176. https://doi.org/10.1002/adma.202007176.

11:15 AM EN06.06.08
Band-Like Transport and Charge Carrier Dynamics in BiOI Films SnigdhaLal[1], MarcelloRighetto[1], AleksanderUlatowski[1], SilviaG. Motti[1,2], ZhuotongSun[3], JudithL. Driscoll[3], RobertHoye[1] and LauraHerz[1]; [1]University of Oxford, United Kingdom; [2]University of Southampton, United Kingdom; [3]University of Cambridge, United Kingdom

Following the emergence of lead halide perovskites (LHPs) as materials for efficient solar cells, research has progressed to explore stable, abundant and non-toxic alternatives. However, the performance of such lead-free perovskite-inspired materials (PIMs) still lags significantly behind that of their LHP counterparts. For bismuth-based PIMs, one significant reason is a frequently observed ultrafast charge-carrier localization (or self-trapping), which imposes a fundamental limit on long-range mobility. BiOI is a widely studied 2D layered material which has recently been explored as a Pb-free PIM for photovoltaic applications. A wide bandgap material, it is highly suitable for tandem applications. However, despite reported defect tolerance and strong band-edge absorption, the power conversion efficiencies for BiOI-based devices has remained stunted with record efficiencies reaching barely 2%. An extensive photophysical study is needed to elucidate the performance limiting factors for BiOI along with highlighting the true intrinsic potential of the material as a photovoltaic absorber.
Here, we report the charge-carrier dynamics of BiOI and show that unlike many other Bi-based compositions such as $Cs_2AgBiBr_6$ and Ag-Bi iodides, BiOI shows sustained band-like transport with respectable mobilities. Crucially our investigation reveals an absence of self-trapping despite the presence of strong electron phonon coupling and lower dimensionality. Using optical pump terahertz probe (OPTP) spectroscopy, time resolved microwave conductivity (TRMC) spectroscopy and time resolved photoluminescence (TRPL) spectroscopy, we unravel the early and long-time charge-carrier dynamics in BiOI and show that the material performance is limited by the presence of multi-phonon emission mediated non-radiative channels in the material. Using temperature-dependent OPTP transient, we quantify the bimolecular recombination constant and show that the material has low rates of band-to-band recombination likely originating from an indirect bandgap. Taken together with a slightly higher-lying direct bandgap, such low levels of intrinsic band-to-band recombination set high upper limits of achievable charge-carrier lifetime. Altogether, this contribution highlights the promise of BiOI solar cells.

SESSION EN06.07: 2D Materials for Energy Conversion and Energy Storage II
Session Chairs: Mona Zebarjadi and Hongli Zhu
Wednesday Afternoon, November29, 2023

1:30 PM *EN06.07.01
Thermoelectric Properties in Phase-Transition-Induced Thermal Hysteresis for Refrigeration MonaZebarjadi; University of Virginia, United States

The phase transition from crystal to crystal or crystal to amorphous is accompanied by electron and phonon dispersion changes and hence sharp modifications of electronic and phononic transport properties versus temperature. In particular, the strong variations of the Seebeck coefficient and the heat capacity with temperature can be used for the design of heat management devices. Sharp changes in the Seebeck coefficient result in significant Thomson coefficients ($\tau = TdS/dT$, T is temperature). The Thomson effect induces heat release or absorption under the simultaneous application of a charge current and a temperature gradient in conductors, with applications in refrigeration. Thomson modules are not currently used. Their efficiency is barely studied as most materials show a minor Thomson coefficient much smaller than the Seebeck. Recently, Uchida's group reported a giant Thomson coefficient for FeRh alloys as a result of a phase transition. In this talk, I will present our results of phase transition-induced thermal hysteresis in FeRh alloys and 1T'-Td phase transition in type II Weyl semimetallic layered materials $MoTe_2$ and $Mo_{1-x}W_xTe_2$. In the latter case, we show consistency between the Seebeck hysteresis and direct measurements of the crystallographic angle using temperature-dependent X-ray diffraction. I will discuss how the Thomson coefficient is related to other materials' properties and can be used for refrigeration.

2:00 PM EN06.07.02
Two-Dimensional Li_xMoS_2/Graphene Heterostructures for Li–S Batteries ZhuangnanLi and ManishChhowalla; University of Cambridge, United Kingdom

Abstract
Lithium-sulfur (Li-S) batteries based on redox chemistry can store more energy than conventional insertion-type lithium-ion technologies[1,2]. Our previous discoveries have shown that compact electrodes assembled from monolayered nanosheets of lithiated metallic 1T phase molybdenum disulfide (Li_xMoS_2) are electrically and ionically conductive, lyophilic and catalytically active[3-6]. In this presentation, I will describe a sulfur host design of two-dimensional (2D) Li_xMoS_2/graphene heterostructure for Li-S batteries. The construction of heterointerfaces results in charge transfer from graphene to Li_xMoS_2, which yields enhanced catalytic activity and promotes redox kinetics for sulfur conversion. The accumulation of greater charge in the Li_xMoS_2 layer of heterostructures also reduces its Lewis acidity compared to that of bare Li_xMoS_2. The resultant ampere-hour-scale Li-S pouch cells deliver energy density of exceeding 400 Wh kg^{-1}. This work demonstrates an universal strategy of using 2D heterostructures to tune the electrode properties for realising practical energy storage.

Enhanced Photoelectrochemical Water Splitting with Doped Transition Metal Dichalcogenide Nanofilms CansuIlhan[1,2,3], ScottMonaghan[2,3], LevgenNedrygailov[3], MickMorris[1] and PaulHurley[2]; [1]Trinity College Dublin, Ireland; [2]Tyndall National Institute, Ireland; [3]Amber Centre, Ireland

Photoelectrochemical water splitting to produce hydrogen fuel from solar energy conversion has been a hot topic for at least the past few decades. Nevertheless, Solar-to-Hydrogen Efficiency levels have been severely limited due to many factors, including light absorption, charge separation and transport, surface chemical reaction rate. [1] Novel and emerging materials that may just address key bottlenecks are some of the transition metal dichalcogenides (TMDCs) due to their tunable band gap and an ability to be doped *n*-type or *p*-type. [2] In recent times, nanometer thickness control, uniformity and large area growth of continuous films have been demonstrated by rapid deposition methods in manufacturing-compatible processes. [3] However, little is known about the effect of different impurity concentrations incorporated into TMDCs, particularly on the semiconductor transport properties; the structural, chemical, and physical stability; and their photoelectrochemical properties. In this work, we focus on the enhanced water splitting capability of Si-based photoanode/cathode and tandem diode cells when combined with novel doped transition metal dichalcogenide (TMD) materials in an acidic aqueous medium. We use thermally assisted conversion (TAC) processes to form *n*-type and *p*-type TMDCs by converting transition metals to sulphide-based TMDCs with different impurity concentrations. The photoelectrochemical responses were assessed by standard potential sweep methods and electrochemical impedance spectroscopy. To determine transport properties, TMDCs were studied with 4-point resistivity measurements and AC Hall-effect measurements. Structural, chemical, optical and physical properties were characterized using Raman spectroscopy, X-Ray diffraction, UV-Vis spectroscopy, and atomic force microscopy. The performance of the cells was assessed within a purposely built PEC setup. The integrated light source was a G2V Pico Var Solar Simulator with 32 LEDs, providing an AM 1.5G 1.0 simulated Sun equal to a total irradiance of 87.2 mW cm^{-2} with a spectral range of ~350 nm and ~1450 nm. We show that the doped TMD nanofilms acting as photoelectrodes provide a significant enhancement of PEC water splitting response when compared to the underlying silicon photoelectrodes without the nanofilms. We analyze the correlation between the increased activity with and without the nanofilms, the influence of their doping density and doping type on the mechanisms and compare the different cell geometries. Finally, we assess a selection of TMDCs using photoelectrochemical methods to understand their potential contribution to solar energy conversion and hydrogen fuel generation.

Phase Engineering and Electrical Doping of 2D Materials for Energy Applications AlbertDavydov; National Institute of Standards and Technology, United States

The ability to manipulate electronic, chemical, magnetic, and optical properties of layered van-der-Waals materials via controllable synthesis and processing enables their energy-related applications, including solid-state batteries, catalysis, photovoltaics, and thermoelectrics. This talk focuses on two metal chalcogenide compounds from the 2D materials family, $MoTe_2$ and InSe, to demonstrate the synthesis of specific crystal phases with tailored n- and p-type doping for photodetector and thermoelectric applications.

Semiconducting 2H- vs. metallic 1T'- polytype of $MoTe_2$ was controlled via chemical-vapor-transport (CVT) growth by manipulating processing temperature and by alloying $MoTe_2$ with W (to form $Mo_{1-x}W_xTe_2$ solid solutions), while the doping of 2H-$MoTe_2$ phase was controlled by choosing relevant CVT transport agent: I_2 for p-type and $TeCL_4$ for n-type. Semiconducting γ-InSe bulk crystals were grown by the Bridgman method with in-situ substitutional doping by Sn and Zn, for n- and p-type respectively. The increasing Sn doping level for the n-InSe case was quantified by inductively coupled plasma mass-spectrometry (ICP-MS) and X-ray fluorescence (XRF) analyses, while electrically active Sn concentration was evaluated using van-der-Pauw Hall measurements.

To demonstrate the utilization of crystal phase control and tailored electrical doping in 2D materials, the talk will conclude with employing electrically tunable γ-InSe layers in p/n homo- and hetero-junction photodetectors, while thermoelectric properties of 1T'phase of $MoTe_2$ and $Mo_{1-x}W_xTe_2$ alloys will be reported in details in a parallel invited talk by Prof. Mona Zebarjadi.

4:00 PM *EN06.07.05
Two-Dimensional Graphene and MXene for Flexible and Stretchable Displays Tae-WooLee[1,2]; [1]Seoul National University, Korea (the Republic of); [2]SN display Co. Ltd., Korea (the Republic of)

Two-dimensional materials, such as graphene and MXenes, offer promising alternatives to brittle indium tin oxide (ITO) for flexible and wearable displays. However, their practical application has been impeded by the high electron and hole injection barriers at the electrode/organic interfaces. To overcome this challenge, post-fabrication treatments were employed to modify the work function of 2D electrodes. Electron-withdrawing or electron-donating polymeric overcoating allowed for precise control of charge transfer doping, resulting in improved electroluminescent efficiency with reduced injection barriers. These surface modifications not only enhanced the environmental stability of the 2D electrodes in ambient air but also maintained their electrical properties. Furthermore, to address charge injection issues at stretchable electrode interfaces, a graphene layer can be introduced atop a silver nanowire percolation network, forming a two-dimensional stretchable contact electrode. This approach achieves remarkable current efficiencies among all intrinsically stretchable light-emitting diodes. These advancements in 2D materials establish a solid foundation for the practical implementation of 2D conductive materials in flexible and stretchable displays.

A 5 V-Class Cobalt-Free Battery Cathode with High Loading Enabled by Dry Coating WeiliangYao[1], ChouchaneMehdi[2], WeikangLi[1], ShuangBai[1], ZhaoLiu[3], LetianLi[3], AlexanderChen[1], BaharakSayahpour[1], RyosukeShimizu[1], GaneshRaghavendran[1], SchroederMarshall[4], Yu-TingChen[1], DarrenTan[1], BhagathSreenarayanan[1], Crystal KWaters[5], AllisonSichler[5], BenjaminGould[5], Dennis JKountz[5], DarrenJ. Lipomi[1], MinghaoZhang[1] and Y. ShirleyMeng[2]; [1]University of California San Diego, United States; [2]The University of Chicago, United States; [3]Thermo Fisher Scientific, United States; [4]Army Research Directorate, United States; [5]The Chemours Company, United States

Transitioning toward more sustainable materials and manufacturing methods will be critical to continue supporting the rapidly expanding market for lithium-ion batteries. Meanwhile, energy storage applications are demanding higher power and energy densities than ever before, with aggressive performance targets like fast charging and greatly extended operating ranges and durations. Due to its high operating voltage and cobalt-free chemistry, the spinel-type $LiNi_{0.5}Mn_{1.5}O_4$ (LNMO) cathode material has attracted great interest as one of the few next-generation candidates capable of addressing this combination of challenges. However, severe capacity degradation and poor interphase stability have thus far impeded the practical application of LNMO. In this study, by leveraging a dry electrode coating process, we demonstrate LNMO electrodes with stable full cell operation (up to 68% after 1000 cycles) and ultra-high loading (up to 9.5 mA h cm^{-2} in half cells). This excellent cycling stability is ascribed to a stable cathode–electrolyte interphase, a highly distributed and interconnected electronic percolation network, and robust mechanical properties. High-quality images collected using plasma focused ion beam scanning electron microscopy (PFIB-SEM) provide additional insight into this behavior, with a complementary 2-D model illustrating how the electronic percolation network in the dry-coated electrodes more efficiently supports homogeneous electrochemical reaction pathways. These results strongly motivate that LNMO with a high voltage cobalt-free cathode chemistry combined with an energy-efficient dry electrode coating process opens up the possibility for sustainable electrode manufacturing using cost-effective and high-energy-density cathode materials.

Solution-Processed Transition Metal Dichalcogenide 2D Nanoflakes for Photoelectrochemical Energy Conversion KevinSivula and RebekahWells; Ecole Polytechnique Federale Lausanne, Switzerland

Given their established robustness and favorable optoelectronic properties, the layered semiconducting transition metal dichalcogenides (TMDs, e.g. MoS_2 and WSe_2) are attractive for optoelectronic applications including photoelectrochemical solar fuel production.[1] Recent advances in the liquid-phase exfoliation (LPE) of semiconducting TMDs into mono- or few-layered 2D nanoflake dispersions and their processing by inexpensive roll-to-roll techniques suggests that large-area TMD-based devices can be fabricated in a scalable manner and at low cost.[2] However, the high concentration of defects in these materials act as recombination sites for photogenerated carriers and limit their performance. In this presentation the challenges with charge transport, separation, recombination, and interfacial transfer in LPE TMD nanoflake thin film devices will be discussed with respect to the 2D flake size and defect passivation/charge extraction treatments.[3] Our results give insight into the roles of both edge and internal defects and suggest routes for improvement. In addition to suitable defect mitigation techniques [4], we show that the exfoliation conditions play an important role on the performance of 2D TMD nanoflake films. Indeed, a powder-based electrochemical intercalation technique [5] can produce internal quantum efficiency for photon harvesting up to 90%. Moreover, for solar-driven H2 production, we show that WSe_2 nanoflake thin films achieve absorbed-photon-to-current efficiency over 50% and photocurrent densities for solar water reduction at 4 mA cm^{-2} under standard testing conditions.[4] These results suggest that roll-to-roll processed 2D TMDs are promising for economical solar-to-hydrogen conversion with a photoelectrochemical tandem cell.

Carbon Nitride Thin Films: An Innovative Platform for Energy Conversion and Storage PaoloGiusto; Max Planck Institute, Germany

Carbon nitrides are a class of polymeric materials with ideal formula C_3N_4, which have recently attracted much attention especially in photocatalysis with visible light. However, up to now, their application in fields like optics was hindered due to the low-homogeneity thin films available. Herein, we present an innovative method to produce polymeric carbon nitride (pCN) thin films with tunable thickness by means of chemical vapor deposition. Eventually, the pCN thin films are stable, homogeneous, with very high refractive index and high transparency in the visible range.(1) These films were also used to develop innovative batch and microfluidic pCN-coated photoreactors with at least an order of magnitude higher efficiency compared to analogous bulk photocatalysts. (2) In energy storage devices, our group exploited carbon nitride thin films for anode-free lithium batteries, increasing the stability of the Cu current collector and generating a uniform and dense lithium plating with a good cycling stability. In sodium-ion batteries, pCN was exploited as inter-active interphase enhancing the sodium storage performances by 30% by means of a conformal coating of about 10 nm over a carbon anode material derived from lignosulfonate.(3) The exploitation of thin film technology coupled with the outstanding properties of pCN materials is still in its infancy but it sets the premises for significant improvements in a wide spectrum of application, especially where surfaces and interfaces play a key role.

Energy Level Engineering, Co-doping and Extended Conjugation in Heptazine Frameworks: Towards Efficient Solar Energy Conversion using Carbon Nitride-Based Heterojunctions KaziM. Alam, JohnGarcia, NarendraChaulagain, NavneetKumar and KarthikShankar; University of Alberta, Canada

Carbon nitride (C_xN_y) is a layered crystalline polymeric organic semiconductor consisting of nanosheets of sp^2-hybridized triazine heterocycles. C_xN_y aggregates can either be large (3D crystals or sub-micron sized nanosheets) or small (truncated nanosheets or small spherical nanoparticles resembling quantum dots). The conjugated nanosheets allow for relatively fast charge transport, a high active surface area and the customizability of surface reaction sites. Consequently, carbon nitrides have shown remarkable performance as electrocatalysts, photocatalysts, optoelectronic sensors and carrier transport layers for a range of applications including, but not limited to - water splitting, CO_2 reduction, photovoltaics, photodetectors, water treatment and fuel cells. Carbon nitride combines the aforementioned advantages with scalable synthesis compatible with the use of agricultural wastes as precursors and an elemental constitution made of earth abundant elements. Insofar as the electronic applications of C_xN_y are concerned, further enhancements in the performance of based optoelectronic devices require the following conditions to be met: (i) Narrowing of the electronic bandgap (ii) Increase in carrier mobility (iii) Availability of high quality interfaces for exciton dissociation and charge transfer and (iv) Achievement of high photoluminescence and/or electroluminescence quantum yields. These technical challenges are interconnected and not entirely independent of each other. Herein we present a sequence of materials synthesis, device fabrication and compositional doping strategies to address these challenges and achieve the desired enhancements. We show that incorporation of graphene-like sp^2 carbon regions within C_xN_y nanosheets through the formation of carbon-rich carbon nitride extends π-conjugation and improves carrier transport. A secondary positive effect of such carbon-rich regions in C_xN_y is the reduction in intra-sheet and inter-sheet hydrogen bonding, which is widely believed to be a source of non-radiative recombination in C_xN_y. Doping and co-doping C_xN_y by highly polarizable main group elements such as S, P, Se, etc enriches the electron density in the nanosheets and increases the dielectric constant of carbon nitride, which in turn increases carrier mobility and reduces the exciton binding energy. We found that main group element-doped carbon-rich carbon nitrides exhibit narrow bandgaps as low as 1.5 eV and generate photocurrent densities as large as 5 mA/cm^2 for photoelectrochemical water splitting under AM1.5G one sun illumination. Finally, we tacked the issue of heterojunction formation through operando matrix-assisted solid-state condensation polymerization and electrophoretic anodization. The device testing data has been backed up by extensive characterization using XANES, SSNMR, HRXPS and HRTEM.

9:30 AM EN06.08.04
Low Dimensional Composite Materials as Binder-Free Anode for Energy Storage Applications KavinArunasalam, KevinSynnatschke, MeiyingLiang and ValeriaNicolosi; Trinity College Dublin, Ireland

The prolonged use of non-renewable energy such as fossil fuel and coal is having a deteriorating impact on our environment leading to severe climate changes. Hence, there is a dire need to explore new methods for energy generation and storage which are environmentally friendly, cost-effective and sustainable. Sodium-ion batteries have been attracting great interest as an alternative to lithium-ion batteries due to their material abundance, lower cost, and sustainability. However, a high-performance viable anode for the sodium-ion battery has yet to be discovered because of the difference in its molecular size and intercalation mechanism to the comparatively smaller lithium ions.

This issue has garnered global research interest in the quest to develop anodes with expanded interlayer spacing capable of accommodating sodium ions. This area of study has emerged as a promising field within material science, particularly in the realm of 2D materials research. 2D materials are known for their unique structure and electronic properties such as hardness, tuneable band gap by variation of the number of layers and their high surface area. These properties make them intriguing candidates for applications in batteries and electrocatalysis. Black phosphorus, a well-studied 2D class material, has previously been reported to show very high theoretical capacity for both sodium and lithium-ion battery systems but suffers from low cycling stability due to chemical and structural instability.[1] To overcome this problem, we decided to explore the prospect of a new 2D composite material made from nanosheets of black phosphorus (phosphorene) and MXene ($Ti_3C_2T_x$) to be potentially used as an anode in a sodium-ion battery. The MXene layers with terminating fluorine and oxygen functionals are expected to promote the growth of stable solid-electrolyte interfaces (SEI) which in turn is expected to further improve the overall coulombic efficiency of the battery.[2][3]

Both nanomaterials were synthesized via liquid-phase exfoliation (LPE). Phosphorene is notorious for being oxidized easily. Hence, to protect the phosphorene, a novel layer-by-layer (LBL) vacuum filtration technique was implemented to obtain the electrode. The resulting electrodes were then assembled in a lithium-ion coin cell to study their cycling stability and rate capacity, given the similarity of the lithium and sodium ion intercalation mechanism in the anode. XPS, SEM, EDX, UV-Vis, XRD and AFM characterization were performed on the composite nanomaterial to study its morphology, as well as compositional and structural changes upon processing. It was found that the electrode material showed a high discharge capacity of 700 mAh/g at 0.2 C with 98% coulombic efficiency for 100 cycles which indicates a promising performance potential for sodium ion battery systems.

In conclusion, the layer-by-layer MXene-phosphorene composite structure effectively shields the phosphorene nanosheets from extensive oxidation in ambient conditions. This preservation of phosphorene enables a reversible reaction and ensures excellent cycling stability as an electrode material. Moreover, the inclusion of the MXene component acts as a conductive binder in this

composite eliminating the need for traditional non-conductive binders like PVDF and CMC. This substitution reduces dead volume within the anode and enhances the material's specific capacity. Finally, the composite's large interlayer spacing highlights its potential application as an anode in sodium ion battery systems, emphasizing the need for continued exploration and research in this area.

Thermal Transport Characterization Method for 2D Layered Materials and Their Polymorphs SungjinPark, KyominKim and WoochulKim; Yonsei University, Korea (the Republic of)

Two-dimensional (2D) layered materials are known to possess different physical properties than bulk materials due to the weak van der Waals bonds between their layers. Graphene is a representative 2D material whose material properties is known to different from its bulk counter part [1]. The material properties of 2D materials can be further altered by changing the stacking sequence of the interlayers such as in MoS_2 where different stacking sequences lead to the 2H and 3R polymorphs [2]. $NbSe_2$ is a 2D layered material whose new polymorphic form (2H-3R) was discovered recently [3]. This work proposes a method to characterize the thermal transport properties of 2D layered materials by measuring the thermal conductivity of the different polymorphs of $NbSe_2$ using the in-house T-bridge method. Photolithography technique was utilized to fabricate the micro-scale T-bridge device and mechanical exfoliation was used to obtain thin 2D layered $NbSe_2$ samples for their bulk material. The thermal conductivity of various thickness 2H-$NbSe_2$ and 2H-3R-$NbSe_2$ was measured, and results showed that the difference in stacking sequence of the 2D layered material can alter its thermal transport properties. The in-house T-bridge method can be further utilized to measure the thermal transport of various 2D layered materials and their polymorphs.

Photothermal Processing of Layered Materials under Controlled Pressure for Energy Storage Applications NajmaKhatoon, BinodSubedi, AhmadMajed, JulieAlbert, MichaelNaguib and DouglasB. Chrisey; Tulane University, United States

2D layered materials are promising candidates for synthesizing materials with customizable properties contributing from each layer. Enhanced electrical, mechanical, thermal and optical properties by tailoring the layers makes layered materials highly versatile and adaptable for various applications. MXenes are one such example of 2D layered materials class. Their high conductivity, excellent chemical stability, good mechanical properties, tunable surface chemistry, large specific area, and ability to integrate with other materials makes them an excellent customizable layered material. Titanium carbide (Ti_3C_2-T_x) MXene, where T_x are surface terminations, have high conductivity, and excellent Li-ion diffusion properties. Intercalation of ions/molecules in Ti_3C_2 layers is one route to enhance its electrochemical properties. Silicon-based nanomaterials are promising candidates for intercalation due to due to their higher theoretical specific capacity.
In this work, we intercalated PDMS (Polydimethylsiloxane) in Ti_3C_2 with initial d-spacing ~1 nm. Intercalation of PDMS resulted in increase of d-spacing from 1 nm to ~12 nm. The intercalated PDMS was converted into silica (SiO_2) by processing it through a unique process of photonic curing. Our results showed that after photonic curing the d-spacing changed from 12 nm to ~ 5 nm. The PulseForge parameters were 450 V bank voltage 7 pulses, and ~ 4 Jcm^{-2} per pulse fluence. Furthermore, we cured the intercalated MXene under controlled pressure and in a different gas environment. Results showed a less oxidation rate of MXenes when cured under controlled pressure. The stability of reversible electrochemical reactions was observed in the cyclic voltammetry of MXene intercalated within cured PDMS, indicating the enduring nature of these reactions throughout repeated cycling. This study demonstrates the potential of photonic curing as a cost-effective and scalable method for synthesizing customizable layered materials with precise control over the nanostructure within the layers. The process offers an instantaneous and roll-to-roll compatible approach for large-scale synthesis.

Colloidal Quantum Dot Near-Infrared Light Emitting Diodes with High External Quantum Efficiency MariaVasilopoulou; National Centre for Scientific Research Demokritos, Greece

Semiconductor colloidal quantum dots (CQDs) have become a prominent class of solution-processed emitting nanocrystals owing to their potential to provide size- and composition- tunable luminescence of high colour purity. Importantly, their emission can be extended deep into the second biological near-infrared (NIR) window (1000-1700 nm, NIR-II) where related lighting technologies based on organic and perovskite semiconductors have so far failed to access. However, the application of NIR-II CQD light emitting diodes (LEDs) is still hindered by low efficiencies mainly attributed to low photoluminescence quantum yield (PLQY) and poor charge transport properties of pure CQDs films. Here, we report NIR-II CQD LEDs with unprecedented external quantum efficiency (EQE) of 16.98% and power conversion efficiency (PCE) of 11.28% at 1397 nm. This extraordinary performance stems from a combinatorial device engineering approach that allowed us to achieve high PLQY in CQDs-embedding films and charge balance close to unity in the CQD-emissive device. More specifically, we employed a binary emissive layer consisting of silica-encapsulated Ag_2S CQDs dispersed into a cesium-containing triple cation perovskite matrix that serves as an additional passivation medium and carrier supplier to the emitting CQDs. Furthermore, we applied successful engineering at the hole injection contact through inserting a thin porphyrin interlayer to balance the device current and enhance carrier radiative recombination. The remarkable efficiency of our devices surpasses the performance of any previously reported CQD NIR LED. Additionally, it represents a record efficiency for any solution-processed lighting source in the second NIR-II window and foreshadows CQD technologies that will transcend the lighting products already available in the market.

11:15 AM EN06.08.08
Edge Engineering of Two-Dimensional Transition Metal Dichalcogenides GuoxiangHu; Georgia Institute of Technology, United States

Two-dimensional (2D) transition metal dichalcogenides (TMDCs) have attracted tremendous interest as functional materials due to their exceptionally diverse and tunable properties, especially in their edges. In addition to the conventional armchair and zigzag edges common to hexagonal 2D materials, more complex edge reconstructions can be realized through careful control over the synthesis conditions. However, the whole family of synthesizable, reconstructed edges remains poorly studied. Here, we develop a computational approach integrating ensemble-generation, force-relaxation, and electronic-structure calculations to systematically and efficiently discover additional reconstructed edges and screen their functional properties. Using MoS_2 as a model system, we screened hundreds of edge-reconstruction to discover over 160 reconstructed edges to be more stable than the conventional ones. More excitingly, we discovered new synthesizable reconstructred edges with record thermodynamic stability, in addition to successfully reproducing recently synthesized edges. We also find our predicted reconstructed edges to have multi-functional properties—they show near optimal hydrogen evolution activity over the conventional edges, ideal for catalyzing hydrogen-evolution reaction (HER) and also exhibit half-metallicity with a broad variation in magnetic moments, making them uniquely suitable for nanospintronic applications. Our work reveals the existence of a wide family of synthesizable, reconstructed edges in 2D TMDCs and opens a new materials-by-design paradigm of ‘intrinsic’ edge engineering multifunctionality in 2D materials.

11:30 AM EN06.08.09
Promising Properties of 2D Layered Cobalt and Nickel Nitrides as Negative Electrodes for Li-Ion Batteries Jean-PierrePereira-Ramos[1], YanlongZhou[1,2], NicolasEmery[1], OlivierNguyen[2] and RitaBaddour-Hadjean[1]; [1]ICMPE CNRS, France; [2]Technocentre Renault, France

2D materials largely dominate the field of Li-ion batteries with the transition metal oxides LCO (LiCoO2), NMC LiNixMnyCoz) and NCA (LiNixCoyAlz) used as positive electrode materials and carbon graphite as negative electrode. However graphite suffers from a low rate capability and from a limited specific capacity. Intensive research has been made to find alternative anode materials such as the LiAl, LixSn, LixSi..alloys or transition metal oxides as conversion materials. But in all cases, huge volumetric changes occur upon discharge-charge reaction inducing a fast capacity decline. In spite of numerous studies, this important drawback has never been solved as yet.
We have decided to explore the group of lithiated transition metal nitrides as alternative negative electrode materials to overcome safety issues related to the use of graphite at high current. Some of these compounds were firstly investigated in the wide voltage window 1.4V-0V leading to high specific capacities but also to irreversible structure change with the irreversible oxidation of nitride anion framework. Hence poor electrochemical properties were achieved. Our key idea has been to rigorously control the upper cut-off voltage inside the stability domain of the nitride framework which is strongly dependent on the metal and metal content.
The present work reports the chemical synthesis and the structural characterization of lithium nitridocobaltates Li3-2xCoxN and Li3-2xNixN nitridonickelates with $0.1 \leq x \leq 0.6$. These 2D compounds with an hexagonal symmetry constitute unique examples of intercalation compounds based on the nitrogen framework in which lithium can be reversibly inserted and extracted

due to numerous cationic vacancies. With a mean working voltage around 0.5V, these “zero strain” materials deliver high specific capacities in the range 200-320 mAh/g with a remarkable stability over at least 100 cycles. In addition to a complete investigation of their electrochemical features in the 1V-0.02V potential range, we have elucidated the electrochemical mechanism involving the Co and Ni redox species (I/II/III) in relation with the tiny structural changes revealed through operando XRD experiments. A detailed kinetic study of the charge-discharge process in the case of nickel-based compounds allows to give a complete picture of electrochemical performances of these 2D lithiated nitrides as negative electrode materials for Li-ion batteries.

Solar Energy Conversion and Storage Potential of 2D Covalent Organic Frameworks Elucidated by Excited-State Electronic Structure Simulation HenryThornes, CharlieDeFreest, HosannaAbbay, TomWheaton, MeganRobbins, AlanaSullivan and TimKowalczyk; Western Washington University, United States

Two-dimensional covalent organic frameworks (COFs) are valued for their high porosity and surface area, highly useful properties for gas separations and heterogeneous catalysis. However, their framework structure is also intrinsically valuable as a design space for organic materials bearing embedded chromophores that confer a degree of synthetic control over intermolecular stacking arrangements. In past work, we computationally explored the potential of 2D COFs as a platform for singlet fission. Here we report electronic structure simulations characterizing the capabilities of photoactive COFs for selected energy conversion and storage applications. First, we show the impact of chromophore embedding and functionalization on the photophysical properties of families of emissive COFs, one of which may serve as a stepping stone to realizing singlet fission experimentally in a COF. Second, we computationally probe the potential of COFs as a platform for fine control of solar energy conversion and storage via embedding of a photoisomerizable molecular solar thermal fragment within the framework. The simulations apply recent advances in excited-state methods to characterize the effects of interlayer stacking on photophysical properties and guide the design of COFs for renewable energy applications.

SESSION EN06.09: Layered Perovskites and 2D Materials for Energy Conversion and Energy Storage

NiFeZnP Nanosheets with Enriched Phosphorus Vacancies for Supercapattery Electrodes NagehK. Allam; American University in Cairo, Egypt

Designing and fabricating outstanding electrode materials *via* simple preparation routes are viable ways for improving the performance of electrochemical supercapacitors. We report on the synthesis of NiFeZn phosphide interconnected nanosheets with abundant phosphorus vacancies (P_v-NiFeZnP) *via* a facile reduction route at room temperature. The fabricated P_v-NiFeZnP was fully characterized using energy-dispersive spectroscopy, field emission scanning electron microscopy, electron paramagnetic resonance, and X-ray photoelectron spectroscopy techniques. Owing to the porous interconnected nanosheet structure and the superior stability enabled by the direct binder-free growth on Ni foam, the P_v-NiFeZnP electrode, with optimized phosphorus vacancy formation, exhibits a superb electrochemical performance of 631.8 mC/cm^2 (equivalent to 1579.5 mF/cm^2), which is significantly higher than those reported in the literature. Also, the P_v-NiFeZnP||activated carbon asymmetric device exhibits a very high Coulombic efficiency (~100%) and excellent long-term stability (98.8% capacity retention after 7500 cycles). The fabricated device can deliver 122.1 μWh/cm^2 energy density at a power density of 750 μW/cm^2. The fabricated NiFeZnP electrode is therefore a promising candidate for supercapacitor applications.

1:45 PM EN06.09.02
High Pressure Synthesis of Low Dimensional Pnictogen Chalco-Halides Based on (Sb,Bi)(S,Se)(Br,I) for Emerging Energy Applications IvanCaño Prades, AlejandroNavarro Güell, EdoardoMaggi, CibránLópez, MarcelPlacidi, LluísSoler Turu, ClaudioCazorla, JoaquimPuigdollers and EdgardoSaucedo; Universitat Politècnica de Catalunya, Spain

There is an increasing interest in the development of novel van der Waals materials with low dimensionality and with exotic properties, for emerging energy applications such as photocatalysis, photovoltaic and thermoelectric devices. Among them, pnictogen chalco-halides with low dimensional morphology (commonly quasi-one-dimensional nanocolumnar structures) are attracting a lot of attention due to the unusual combination of bandgaps suited for different energy applications, excellent stability, and possible high tolerance to defects. Despite these clear advantages, it is very complex to synthesize this type of materials containing one halogen and one chalcogen in the structure, even if there are clear evidence that these materials can be synthesized at relatively low temperature (< 400 C). In this work, we will present first a detailed DFT modelling of the structure, stability and optical properties of pnictogen chalco-halides based on (Sb,Bi)(S,Se)(Br,I). Theoretical calculations confirm the high stability of all possible ternary compounds, with band structures and bandgaps very well suited for different energy applications. Then, we will present an innovative synthesis route for complex pnictogen chalco-halide compounds based on a sequential process, starting with the co-evaporation of chalcogen thin films, followed by a high-pressure reactive annealing (from 2 atm up to 20 atm) under halogen atmosphere. Using this innovative approach, the complete set of ternary van der Waals (Sb,Bi)(S,Se)(Br,I) chalco-halide semiconductors are synthesized, including: SbSBr, SbSI, BiSBr, BiSI, SbSeBr, SbSeI, BiSeBr, and BiSeI. It will be also demonstrated for the 8 compounds, that high purity phase can be synthesized through a thin film-to-nanocolumns topological transformation. All the possible ternary compounds exhibit orthorhombic Pnma structure with quasi-one-dimensional nanocolumnar morphology; which thicknesses, heights, and densities can be tuned by changing the temperature and pressure during the synthesis process. The bandgap of the materials ranges from 1,25 eV for BiSeI up to 1.93 eV for SbSBr, covering a wide range of energy applications and correlating very well with the DFT calculations. A complete comparative analysis of the morphology, structure, optic, and electric properties of the 8 compounds will be presented. As examples, two possible applications of these (Sb,Bi)(S,Se)(Br,I) low dimensional structures will be proposed. In one hand, first solar cell prototypes will be shown, with very encouraging open circuit voltages around 600 mV, and conversion efficiencies exceeding 1% level in a very short period. In a second hand, some of these compounds were tested as visible light sensitized of TiO_2photocatalytic activity for hydrogen production, demonstrating an impressive hydrogen evolution increase of up to 90% under white light illumination. Finally, a comparative analysis and possible future applications of these novel low dimensional materials will be presented, and a perspective for their future accelerated development will be proposed.

2:00 PM EN06.09.03
O, N-Enriched, Self-Activated, Holey Carbon Sheets for Low-Cost and High-Loading Zinc-Ion Supercapacitors ZhixiaoXu and XiaoleiWang; University of Alberta, Canada

Low-cost and high-loading cathodes are crucial for the practical application of zinc ion supercapacitors but achieving high performance in high-loading electrodes has remained a challenge due to sluggish ion transport, increased resistance, and unstable structure. Guided by theoretical calculations, high-loading carbon cathodes based on holey activated carbon sheets (HACS) were fabricated from a carefully chosen molecule. By subjecting the molecule to a simple pyrolysis-leaching treatment, it can be converted into HACS with large surface area, hierarchical porous structure, and electroactive oxygen/nitrogen dopants. Remarkably, when combined with an aqueous binder, the optimized HACS-based high loading electrode (16.1 mg cm^{-2}) exhibits outstanding performance, delivering high-capacitance (454 F g^{-1}, capacity: 208 mAh g^{-1}) and fast-rate (1 A g^{-1}) capability even under lean electrolyte conditions (6.2 μL mg^{-1}). This leads to maximal areal energy and power densities of 2.40 mWh cm^{-2} and 10.7 mW cm^{-2}, respectively. This outstanding performance can be attributed to fast ion transport enabled by through-plane pores of HACS, as well as abundant double-layer and redox-active surfaces from favorable heteroatom-doped porous nanosheets. With its cost-effectiveness, elemental abundance, and structural tunability, this molecular carbon strategy could serve as a platform for making self-activated carbon electrodes at the molecular level towards practical supercapacitors.

2:15 PM EN06.09.04
Enhancing Transport in Formamidinium Lead Iodide Quantum Dot Solar Cells by Substitution of Octadecene BrunoAlessi[1], DavideMariotti[2] and VladimirSvrcek[1]; [1]AIST: National Institute of Advanced Industrial Science and Technology, Japan; [2]Ulster University, United Kingdom

Perovskite quantum dots (QDs) solar cells are recently becoming very popular as they currently hold the record power conversion efficiency (PCE) of over 16% with a light absorber film made of stacked perovskite QDs of mixed cation Formamidinium (FA)/Cesium lead (Pb) iodide (I).[1] The most common synthesis method (hot injection) is based on the injection at moderate temperatures (50 to 120 °C) of a cation-oleate compound into a saturated lead iodide solution in Octadecene (ODE) in the presence of Oleic Acid and Oleylamine.[2] This leads to the formation of thick colloids where particles are capped by long chain ligands. However, for application in solar cells these long insulating ligands need to be exchanged in favor of shorter ones, leading to higher interparticle hopping probabilities for photocarriers. $FAPbI_3$ QDs themselves have ideal bandgap (~1.5-1.6 eV) for the single junction design and longer photocarrier lifetimes, however a reliable and satisfactory ligand exchange protocol is lacking. To have an efficient ligand exchange recipe that does not compromise the structural integrity of the quantum dots, significant efforts have been made in a plethora of studies by addition of small molecules during the synthesis process, zwitterionic compounds or Pb- FA- and I- containing salts and amino acids during the QDs film formation, nonetheless there is still room for improvement.

In this study we explore a different approach to synthesize $FaPbI_3$ QDs by changing one of the main solvents used in the synthesis stage. Specifically, we replaced ODE with a shorter chain

linear alpha olefin. Despite facing some experimental challenges, we successfully obtained high-quality films of $FaPbI_3$ QDs using this new method. Furthermore, we correlate the new synthesis method with ODE-based QDs in terms of the purification protocol, synthesis practice, optical properties, and their application in QDs solar cells. The results revealed superior photoluminescence properties for the QDs synthesized with the new solvent. QDs obtained in this way have a narrow photoluminescence emission peak at 1.61 eV and exhibit higher absolute quantum yields ranging from 70% to 80% and only a small blueshift ($\Delta\lambda$=5 nm) compared to the ODE-based QDs. Additionally, we compare the performance of the two systems in prototype solar cells, specifically by using layers of stacked QDs with equal thickness (100 nm). The prototype solar cells incorporating the QDs synthesized with the new solvent showed a PCE of 4.9% with 1.06 V open-circuit voltage (V_{OC}). In relation to an ODE-based solar cell of the same thickness it represents a two-fold increase in PCE, as well as consistently higher V_{OC} and short-circuit current density (J_{sc}). Furthermore, we investigate how the new solvent enhances the performance of $FaPbI_3$ QDs based solar cells without compromising the stability and optical properties of individual quantum dots.

Influence of Doping Density on the Optoelectronic Properties of V-Doped WS_2 Monolayers JohnB. Asbury; Pennsylvania State University, United States

A critical step in the development of transition metal dichalcogenides (TMDs) as next generation electronic and photonic materials is to identify pathways to control their electronic properties using chemical doping methods. The controllable incorporation of dopant atoms into a TMD host lattice during growth requires the ability to predict dopant atom reactivity in comparison to the host lattice during the nucleation, growth and annealing stages. Toward this end, we investigated the growth of V-doped WS_2 monolayers by Atmospheric Pressure Chemical Vapor Deposition and examined the spatial distribution of V atoms in WS_2 crystallites and their influence on the defects and optoelectronic properties of the monolayers using temperature-resolved time-dependent photoluminescence microscopy (μPL). We observed that the V-doping density was higher in the centers of the crystallites where the initial nucleation process began. The V-doping density decreased as the growth continued, leading to non-uniform doping densities and a spatial gradient in the optical bandgaps of the WS_2 monolayers. Regions of the WS_2 monolayers with higher V atom density exhibited defect-related emission features at low temperatures in the μPL measurements that were red-shifted by 0.2 eV relative to defect-related emission peaks in regions with lower V atom densities. Scanning transmission electron micrographs of the V-doped WS_2 monolayers indicated the presence of two or more neighboring V dopant atoms paired with sulfur vacancies (V-V-S_V) in the more heavily V-doped regions with the lower energy defect-related emission. Our findings suggest that dopant-defect interactions can influence the distribution of dopants and defects in TMD monolayers. Learning to control the doping density and predicting such dopant-defect interactions may provide a framework for understanding the chemical reactivity and growth conditions needed to utilize TMDS in next generation electronic and photonic materials applications.

First-Principles Study of N, P, Si, C-Functionalized Ti_2B as Potential Anode Materials for Metal-Ion-Batteries ShaiokhB. Abi and AhmedZubair; Bangladesh University of Engineering and Technology, Bangladesh

The design and development of the next-generation energy storage device are strongly tied to the exploration of alternate electrode materials for rechargeable metal-ion batteries to lithium. Recently, non-lithium-ion batteries, such as sodium-ion batteries, potassium-ion batteries, magnesium-ion batteries, calcium-ion batteries, and zinc-ion batteries, have thus received substantial interest from researchers. This work explored N, P, C, and Si-functionalized Ti_2B, a 2D nanomaterial, as anode materials for metal-ion batteries using first-principles calculations. Density functional theory (DFT) was the theoretical foundation for the first-principles computations performed here. The ion-electron interaction was described using the projected augmented wave (PAW) method, and the exchange-correlation functional was defined using the generalized gradient approximation (GGA) in the Perdew-Burke-Ernzerhof (PBE) functional. We created the unit cell of Ti_2B monolayer with a sufficient vacuum between layers, and it was optimized until the appropriate threshold of total energy and force were reached. We added N, P, C, and Si to the optimized Ti_2B monolayer at different sites creating Ti_2BN_2, Ti_2BP_2, Ti_2BC_2, and Ti_2BSi_2. We optimized these structures' geometry to determine the most stable configurations with minimum ground-state energy. Phonon dispersion calculations showed no negative frequencies implying their dynamic stability. From the band structure and density of states calculations, Ti_2BN_2 and Ti_2BP_2 had degenerate spin-up and spin-down bands, indicating that both are non-magnetic. However, there were spin-up and spin-down band splitting of Ti_2BSi_2 and Ti_2BC_2, revealing that they are magnetic. The total magnetization value of 0.13 and 0.26 μB/cell was found for Ti_2BSi_2 and Ti_2BC_2, respectively. The structures had significant electronic states close to the fermi level according to the partial density of states referring to their good electrical conductivity. To investigate the viability of these structures as anode materials in metal-ion batteries (MIBs), we adsorbed sodium at three different sites- the top of a functional atom, the top of the first Ti atom, and the top of the second Ti atom of the structures. The most favorable adsorption site for sodium was on top of the first Ti atom. Therefore, we utilized this configuration for further investigation. The adsorption energies were -0.78 eV, -1.03 eV, -1.51 eV, and -1.82 eV for single sodium adsorption on (2×2×1) Ti_2BN_2, Ti_2BC_2, Ti_2BP_2, and Ti_2BSi_2 supercells, respectively. Furthermore, the adsorption of the sodium atom layer was also performed. We added layers on both the top and bottom of the structures. The adsorption energies were negative, suggesting layer adsorption was favorable too. The adsorption energy values were -0.73, -0.95, -1.36, and -1.38 eV per atom for Ti_2BN_2, Ti_2BC_2, Ti_2BP_2, and Ti_2BSi_2, respectively. Bader charge density calculation and charge density difference plot showed the charge transfer between sodium and functionalized Ti_2B monolayers—the electron localization function of the structures agreed with these findings. Finally, we conducted diffusion calculations to explore the migration properties of metal ions over the structure. For diffusion, we selected two paths; path-1 started from the first Ti atom to the second Ti atom through to another Ti atom in the first position, and path-2 started from the first Ti atom to the boron atom through to another Ti atom in the first position. The energy barriers for path-1 and path-2 were 0.32 and 0.86 eV for Ti_2BN_2 and 2.51 and 0.82 eV for Ti_2BP_2. The findings from our study confirmed N, P, C, and Si-functionalized Ti_2B as potential candidates for anode materials in rechargeable sodium-ion batteries.

High Capacity NH_4^+ Charge Storage in Covalent Organic Frameworks ZhengnanTian, VinayakS. Kale, OsamaShekhah, MohamedEddaoudi and HusamN. Alshareef; KAUST, Saudi Arabia

Ammonium ions (NH_4^+), as nonmetallic charge carriers, have spurred great research interest in the realm of aqueous batteries. Unfortunately, most inorganic host materials used in these batteries are still limited by the sluggish diffusion kinetics. Here, we report a unique hydrogen bond chemistry to employ covalent organic frameworks (COFs) for NH_4^+ ion storage, which achieves a high capacity of 220.4 mAh g^{-1} at a current density of 0.5 A g^{-1}. Combining the theoretical simulation and materials analysis, a universal reaction mechanism of nitrogen and oxygen bridged by hydrogen bonds is revealed. In addition, we explain the solvation behavior of NH_4^+ leading to a relationship between redox potential and de-solvation energy barrier. This work provides a new insight into NH_4^+ ion storage in host materials based on hydrogen bond chemistry. This mechanism can be leveraged to design and develop COFs for electrochemical energy storage.

Magnon Selection Rules in NM/TMDC/FM Trilayer Structures ChanhoPark, Jae WonChoi, YunhoKim, Min-SungKang, No-WonPark and SangkwonLee; Chung - Ang University, Korea (the Republic of)

The spin Seebeck effect, widely known as the spin-wave analogue of the Seebeck effect, is the crucial makeshift for detecting the spin current resulting from nonequilibrium magnetization, which transfers angular momentum to adjacent system via spin waves.[1] Throughout astonishing works in spintronics for more than a decades the field has suggested schematics with normal metal deposited on ferromagnetic substrate, such that one makes the magnetization out of the equilibrium state, generating quantum properties for magnetization distribution called magnons. The injection of magnons to the interface of the normal metal / ferromagnetic insulator metal (NM/FM) heterostructures is usually referred as injection of the spin current, since the magnons themselves contain spin-polarized quantities for each component.[2] The injected spin current is then converted into voltage signal, named as Inverse Spin Hall Effect (ISHE) voltage.
In this paper, we conducted SSE signal detecting experiments on basic well-known Pt/YIG ($Y_3Fe_5O_{12}$) structure and Pt/ML MoS_2/YIG structure, where ML MoS_2 fits in the category of monolayer transitional metal dichalcogenide (ML TMDC) layers and checked their temperature dependence ranging from 190- 300 K. We firstly assumed both samples obey 3D spin-to-charge conversion. We gave both samples temperature gradient dT = 1 K out of plane, to observe maximum SSE voltage on both samples under same dT.
Results shows that the ISHE voltage of Pt/ML MoS_2/ YIG yields is much less Pt / YIG, about ~ 27 times lower than that of the Pt/YIG system at 190 – 300 K. This can be inferred as such that MoS_2 monolayer considerably blocks the injection of spin current.
On the other hand, we kept obtaining wavy signals in Pt/ML MoS_2/YIG structure even though magneto-resistance (MR) effects were excluded. This is assumed for different magnetic properties on MoS_2 layer which have already been reported. With competing diamagnetism in ML MoS_2 itself and ferromagnetism in MoS_2 induced from magnetic proximity effect from YIG substrate,[3] significant portion of the magnons are blocked where they should not if they were in original Pt/YIG system. Finally, we theoretically calculated the temperature dependent ISHE voltages by combining a conventional Boltzmann transport equation with the magnon relaxation time model, and the results were consistent with the experimental results of both for Pt / YIG and Pt / ML MoS_2 / YIG structures. Our finding presents an important achievement in understanding and measuring the LSSE and provides a promising platform, with a high spin-mixing conductance and thermoelectric performance, for two-dimensional interlayered Pt / YIG systems.

Ultrathin Two-Dimensional Transition-Metal Alloy Nanofilm Stabilized Photoanodes for Efficient Solar Water Oxidation FeiXiang, NingLi, ArturoBurguete-Lopez, ZhaoHe, MaximElizarov and AndreaFratalocchi; King Abdullah University of Science and Technology, Saudi Arabia

Harvesting solar energy for photoelectrochemical (PEC) hydrogen production has attracted significant research interest in contributing to the clean energy economy and sustainable development. Despite the progress achieved in photocathodes with an applied bias photon-to-current efficiency (ABPE) above 12%, the poor kinetics and chemical instability of photoanodes in the alkaline medium limit the efficiency and long-term operations of the entire PEC devices. The current state-of-the-art efficiency of the photoanode side is below 4%, and the corresponding operation time is around 30 hours. Although the additional protective layer coating, such as TiO_2 and SiO_x, prolongs the photoanode lifetime to around 200 hours, the ABPE efficiency greatly drops to below 1%. In this work, we engineer ultrathin two-dimensional nickel-iron (NiFe) alloy film as protective and catalytic layers on Si photoanodes, extending the device lifetime to above 250 hours without compromising the PEC performances. The optimized photoanodes exhibit a low onset potential of 1.06 V versus the reversible hydrogen electrode (RHE) at the photocurrent density of 10 mA cm^{-2} and high saturated current density of around 39 mA cm^{-2} under one sun illumination, reporting an applied bias photon-to-current efficiency (ABPE) of 4.24%. We employ aberration-corrected scanning transmission electron microscopy combined with electron energy loss spectroscopy (STEM–EELS) to visualize the atomic-level structural and chemical information at the crystalline/amorphous hybridized interfaces. We apply high-resolution X-ray photoelectron spectroscopy to trace the chemical species changes in the NiFe alloy layer after the PEC reaction. Benefiting from the NiFe alloy coating strategy, the PEC photoanodes operate for over 250 hours with 90% retention of its initial current density during continuous working conditions under a large current density above 30 mA cm^{-2}. This work opens the pathway to the designing and implementing earth-abundant, highly efficient, and stable PEC devices with 2D transition-mental alloy film for green hydrogen production and can be extended to other solar-assisted catalytic fields, such as CO_2 reduction and ammonia synthesis.

4:15 PM EN06.09.10
Enhanced Thermoelectric Transport Characteristics of a Novel BiSbTe-WSe_2 Composite Film KaranGiri, Yen-LingWang, Ling-ChunChao, Chuan-WenWang, Hung-ShuoChang, Wen-ChiehHsieh and Chun-HuaChen*; National Yang Ming Chiao Tung University, Taiwan

A novel technique is developed to combine a layered structure transition-metal dichalcogenide material, tungsten diselenide (WSe_2), recognized for its extremely low thermal conductivity, with another layered structure material, bismuth antimony telluride (BiSbTe), renowned for its exceptional performance in waste heat recovery applications. To enhance the thermoelectric properties even more, WSe_2 as a secondary target is encapsulated periodically in the primary target $Bi_{1.5}Sb_{0.5}Te_3$ using a pulse laser deposition technique. The WSe_2, for the first time, is co-ablated with the BiSbTe at four distinct deposition temperatures, resulting in hetero-nanocomposite thin films. The diffractogram of BiSbTe-WSe_2 composite thin film exhibits sharp peaks indicating strong crystallinity and evidence that the crystals are growing in a highly c-oriented manner. The electrical transport properties are significantly improved due to the optimized hole concentration, measured in the order of 10^{19} and 10^{20}. The electrical conductivity is significantly increased from 134 S cm^{-1} for the sample grown at 573 K to 1200 S cm^{-1} that grown at 723 K. The room temperature Seebeck coefficient is 250 μV K^{-1} for the sample grown at 673 K and 360 μV K^{-1} for that grown at 723 K. The overall outcome is a significant increase in the power factor which is computed as 12 to 156 μW cm^{-1} K^{-2} demonstrating outstanding room temperature thermoelectric performance. The observed values are rather adequate, demonstrating an excellent trade-off between them. In addition to electrical characteristics, the specimens have a low electronic thermal conductivity, k_e. The calculated room temperature k_e values are 0.10 W m^{-1} K^{-1} and 0.87 W m^{-1} K^{-1} for the samples grown at 573 K and 723 K, respectively. The enhanced thermoelectric transport characteristics of the periodically encapsulated WSe_2 in the BiSbTe matrix place it among the best thermoelectric materials with excellent performance for thermoelectric conversion such as solid-state refrigeration and power generation.

Flat-Optics Photon Harvesting in Large-Scale 2D Semiconductor Layers for Photoconversion Applications GiulioFerrando[1], MatteoGardella[1], GiorgioZambito[1], PhamDuy Long[2], SiHieu Nguyen[2], Chi LeHa[2], Thanh TungNguyen[2], MariaC. Giordano[1] and FrancescoBuatier de Mogeot[1]; [1]University of Genoa, Italy; [2]Vietnam Accademy of Science, Viet Nam

The development of clean light harvesting platforms and technologies is crucial in view of a new generation of photonic devices with impact in renewable energy conversion and environmental applications. For this purpose, nanophotonic methodologies hold great promise. Specifically, both plasmonics and flat optics approaches offer exciting opportunities to enhance light-matter interactions at the nanoscale, making them highly appealing for applications in photoconversion and sensing.
In this context, we present innovative solutions for large-scale light trapping to maximize photon harvesting in ultra-thin semiconductor layers. Within them an emerging class of materials is represented by the Two-dimensional (2D) Transition Metal Dichalcogenides semiconductor (TMDs) layers that are characterized by exceptional optoelectronic properties tunable in the Visible and Near-Infrared spectrum [1]. Among them few-layer MoS_2 is notable for an electronic bandgap in the Visible range and a high optical absorption coefficient. Such intriguing optical response combined with high chemical reactivity qualifies this 2D semiconductor layer as a promising candidate in photoconversion and energy storage applications [2].
The first solution presented is based on large area plasmonic metasurfaces obtained by ion beam assisted self-organized process. Nanostructured templates that can be used to laterally confine arrays of plasmonic nanoantennas with tunable optical response [3].
The second solution is based on large area periodic nanograting templates, fabricated by Laser Interference Lithography, to reshape large-scale (cm^2) two-dimensional MoS_2 semiconductor layers as an active optical element featuring a flat optics configuration that enhances the light coupling by arising of photonic anomalies [4,5].
Light harvesting performances of the proposed solutions were tested by photocatalytic and photoelectrochemical experiments. The plasmonic system is used in an Oxygen Evolution Reaction (OER) reaction with both the function of a transparent electrode and a co-catalyst coupled to an ultra-thin film of TiO_2. On the other hand the subwavelength reshaping of ultra-thin semiconductor layers results in enhanced methylene blue photobleaching [6].
These light harvesting platforms are thus promising in view of various large-scale applications such as waste water treatment, dye molecules sensing and energy storage.

Controlling The Hydrogen Evolution Activity by Tailoring The Outer Transition Metal Layers in Double Transition Metal MXenes AnupmaThakur, Nithin ChandranBalachandran Sajitha, BrianWyatt and BabakAnasori; Indiana University- Purdue University Indianapolis, United States

Two-dimensional transition metal carbides, nitrides, or carbonitrides, known as MXenes, have shown great promise as active materials in catalytic applications such as the hydrogen evolution reaction. In double transition metal (DTM) MXenes two different transition metals occupy the metal sites which can enhance the tunability of MXenes electrocatalytic properties. The transition metal occupying the outer atomic layers controls the hydrogen evolution reaction (HER) performance based on their basal plane catalytic activity. We investigated out-of-plane ordered DTM MXenes, with inner layers of transition metal (M″: Ti) sandwiched by outer layers of different transition metals (M′: Mo, W, Cr) in a layered $M'_2M''C_2T_x$ MXenes. We investigated the role of exposed basal plane transition metals on the HER catalytic activity of these out-of-plane ordered DTM MXenes and compared their behavior to a mono-transition metal MXene, $Ti_3C_2T_x$. $W_2TiC_2T_x$ MXene shows the lowest HER overpotential of 147 mV at 10 mA/cm^2 under acidic conditions compared with $Mo_2TiC_2T_x$, $Cr_2TiC_2T_x$, and $Ti_3C_2T_x$ MXenes. The improved electrocatalytic performance of $W_2TiC_2T_x$ can be due to the presence of tungsten atoms in the outer M' layers. Additionally, $W_2TiC_2T_x$ MXene showed long-term stability of more than 24 hours. Our findings further demonstrate that MXenes are precious-metal-free 2D flakes with highly HER active basal planes and promising and tunable electrocatalysts for clean

energy applications.

8:30 AM EN06.10.03
Computationally Guided Design of Single-Atom Catalysts Embedded on Reduced Graphitic Carbon Nitride Monolayers MukeshJakhar and VeronicaBarone; Central Michigan University, United States

The design of efficient single-atom catalysts (SAC) with optimal activity and selectivity for sustainable energy and environmental applications remains a challenge. Herein, first-principles calculations are performed to validate the feasibility of single TM atoms (3d, 4d, and 5d series) embedded in two different conformations of graphitic carbon nitride (g-C_3N_4) monolayers (planar and corrugated). We explore the effects of g-C_3N_4 monolayer nitrogen vacancies on the absorption of SAC considering three potential absorption scenarios, i.e. *on-vacancy*, *via-substitution*, and *on-center*, that correspond to different experimental conditions. Our results highlight the most stable configurations with the lowest formation energies and find that the absorption of single TM atoms *on-vacancy* and *on-center* sites are more favorable than *via-substitution*. Furthermore, in addition to thermodynamics stability, electrochemical stability is also investigated through the calculation of the dissolution potential of the SACs. Within the scenarios considered in this study, we find that Co, Fe, Rh, Ir, Pt, and Ni will produce the most robust SAC on reduced g-C_3N_4. Our findings provide guidance for the design and development of g-C_3N_4 sheets decorated with single TM atom catalysts for applications such as pollutant degradation, CO_2 reduction, N_2 fixation, selective oxidation, water splitting, and metal ion-based batteries.

8:45 AM EN06.10.04
Enhancing Sodium and Potassium-Ion Storage in 2D $MoWSe_2$: Effect of Upper Voltage Cut-Off SonjoyDey, ArijitRoy and GurpreetSingh; Kansas State University, United States

The superior properties, such as large interlayer spacing and the ability to host large alkali-metal ions, of two-dimensional (2D) materials based on transition metal di-chalcogenides (TMDs) enable next-generation battery development beyond lithium-ion rechargeable batteries. In addition, compelling but rarely inspected TMD alloys provide additional opportunities to tailor bandgap and enhance thermodynamic stability. This study explores the sodium-ion (Na-ion) and potassium-ion (K-ion) storage behavior of cation-substituted molybdenum tungsten diselenide ($MoWSe_2$), a TMD alloy. This research also investigates upper potential suspension to overcome obstacles commonly associated with TMD materials, such as capacity fading at high current rates, prolonged cycling conditions, and voltage polarization during conversion reaction. The voltage cut-off was restricted to 1.5 V, 2.0 V, and 2.5 V to realize the material's Na^+ and K^+ ion storage behavior. Three-dimensional (3D) surface plots of differential capacity analysis up to prolonged cycles revealed the convenience of voltage suspension as a viable method for structural preservation. Moreover, the cells with higher potential cut-off values conveyed improved cycling stability, higher and stable coulombic efficiency for Na^+ and K^+ ion half-cells, and increased capacity retention for Na^+ ion half-cells, respectively, with half-cells cycled at higher voltage ranges.

***Operando* Methods for Mechanistic Studies of Energy Systems**HectorD. Abruna; Cornell University, United States

This presentation will deal with the use of *operando* methods for mechanistic studies energy systems with emphasis on fuel cells and battery materials and technologies. The presentation will begin with a brief overview of the methods employed with emphasis on the use of X-ray based methods, transmission electron microscopy (TEM) under active potential control, confocal Raman spectroscopy and microscopy and DEMS (differential electrochemical mass spectrometry) coupled with SEIRAS (surface enhanced infra-red absorption spectroscopy). The utility of these methods will be illustrated by case studies focusing on non-precious metal electrocatalysts for the oxygen reduction reaction (ORR) in alkaline media, Li/S batteries the reduction of carbon dioxide and the oxidation of ethanol. The presentation will conclude with an assessment of future directions.

11:00 AM EN07.01.02
Tuneable Ethylene Production using the Electrochemical Oxidative Coupling of Methane (EOCM): Exploiting Oxygen Evolution to Create the Active Oxygen Species FilipGrajkowski, SubhashChandra, SanazKoohfar, DonghaKim, GeorgiosDimitrakopoulos and BilgeYildiz; Massachusetts Institute of Technology, United States

Ethylene (C_2H_4) is one of the most valuable compounds in the chemical industry as it is used as a building block for a wide range of applications. The current ethylene production pathway via

the steam cracking of naphtha or ethane is highly endothermic, resulting in ethylene production being the second-biggest CO_2-generating process in industry.[1] In 1982, Keller and Bhasin first reported on an alternative ethylene production method,[2] the oxidative coupling of methane (OCM). In this approach, CH_4 is oxidised on oxide catalyst surfaces by adsorbed O_2-derived species to yield C_2H_6 and the desired C_2H_4. Unfortunately, this thermochemical OCM approach suffers from significant "deep oxidation" where CH_4 is instead combusted to CO/CO_2 and H_2O: this arises as the products of oxidative coupling are more reactive than the parent CH_4. In order to improve the C_2 selectivity and yield of OCM processes, recent works have focused on integrating OCM activity into typical solid oxide electrolyser systems.[3] In this electrochemical OCM (EOCM) approach, O^{2-} ions from the cathode side are transported across the solid electrolyte to the anode where they oxidise CH_4 molecules to yield the desired C_2 (C_2H_4 and C_2H_6) products.

In this study, inspired by recent results using mixed ionic-electronic conductors for EOCM, we use $La_{0.3}Sr_{0.7}TiO_3$ as the anode material for EOCM. By using combined electrochemical and gas chromatographic analyses, we demonstrate that this titanate system can successfully yield the desired C_2 products and can respond to changes in the O^{2-} flux. We highlight that the C_2 selectivity of the reactor can be tuned using the applied potential: we show a tuneability in the C_2 selectivity with enhancements of >3x at higher currents relative to lower currents. These results are rationalized mechanistically with reference to the oxygen evolution reaction which occurs at the anode surface. We demonstrate that by controlling the delivery of oxygen to the anode, we gain the ability to selectively produce the active oxygen species necessary for selective CH_4 activation towards C_2 products. These findings furnish the ability to increase both the CH_4 conversion and the C_2 selectivity and have finally broken the inverse relationship between the CH_4 conversion and the C_2 selectivity which dominates the thermochemical OCM literature. Additional chemical and structural characterizations illustrate that the anode material is stable under the EOCM operational conditions with no noticeable phase decomposition, a notorious limitation of other EOCM anodes.[3] The results presented herein can serve as a guide for the field on how to effectively choose the anode composition to enhance both the product selectivity and the overall performance of the combined reactor system.

Highly Stable Pentagonal 2D Palladium Diselenide Enables Rapid Electrosynthesis of Hydrogen PeroxideR. DominicRoss, GerardoJ. Quintana Cintron, KwanpyungLee, HongyuanSheng, JRSchmidt and SongJin; University of Wisconsin–Madison, United States

Electrosynthesis of hydrogen peroxide (H_2O_2) via the two-electron oxygen reduction reaction ($2e^-$ ORR) is promising for various practical applications such as wastewater treatment. However, few electrocatalysts are active and selective for $2e^-$ ORR yet also resistant to catalyst leaching under realistic operating conditions. Here, a joint experimental and computational study reveals highly active and stable $2e^-$ ORR catalysis in neutral media over 2D layered $PdSe_2$ with a unique pentagonal layered structure type. Computations predict active and selective $2e^-$ ORR on the basal plane and edge of $PdSe_2$, but with distinct kinetic behaviors. Electrochemical measurements of hydrothermally synthesized $PdSe_2$ nanoplates show higher $2e^-$ ORR activity than Pd_4Se and $Pd_{17}Se_{15}$, suggesting unique performance enabled by the $PdSe_2$ structure type. $PdSe_2$ on a gas diffusion electrode can rapidly accumulate H_2O_2 in a buffered neutral solution under high current density. Elemental analysis of the catalyst and electrolyte and synchrotron X-ray absorption spectroscopy confirm the chemical stability of $PdSe_2$ under these practical electrosynthesis conditions. This work establishes a new efficient $2e^-$ ORR catalyst with high intrinsic stability at practical current densities and opens catalyst designs utilizing the unique 2D pentagonal structure motif.

Activation Energies of Heterogeneous Electrocatalysis from First Principles SaeromYu, ZacharyLevell, RuoyuWang and YuanyueLiu; The University of Texas at Austin, United States

Electrocatalysis at solid-water interface is central to many technologies addressing energy and environmental challenges. However, the reaction kinetics at atomic level is not well understood and difficult to simulate due to the complexity of the electrochemical interface. Here I will present an advanced model, which accurately and efficiently simulates the realistic electrochemical interface, particularly the reaction activation energies. I will also show the application of this model to understand the electrocatalysis of single metal atoms embedded in nitrogen doped graphene (M-N-C), such as: (1) the active site structure in Ni-N-C for CO2 reduction; (2) the origin of high H2O2 selectivity of Co-N-C for 2e oxygen reduction; and (3) the kinetic mechanism of Fe-N-C for 4e oxygen reduction.

What Makes Lithium Unique for Nitrogen Reduction?IfanE. Stephens; Imperial College London, United Kingdom

There is a burgeoning interest in the development of a green method of ammonia synthesis; ammonia, already critical for fertilisers in the agricultural industry, is also being touted as a possible future energy vector or carbon-free fuel. The current method of production - the Haber Bosch process - is environmentally damaging and energy intensive but to date no viable alternative has been demonstrated. An electrochemical method operating under ambient conditions would be particularly attractive, as it would enable ammonia to be produced on a decentralised basis on-site and on-demand.[1]
Thus far, amongst solid electrodes, only lithium based electrodes in organic electrolytes can unequivocally reduce nitrogen to ammonia.[2,3] Even so, at present, the lithium based system is far too inefficient for practical uses; moreover, it is highly unstable.
In the current contribution, we will explore the underlying reasons why lithium is unique in its ability to reduce nitrogen to ammonia.[4,5] We use a combination of electrochemical experiments, cryo-microscopy, infrared spectroscopy, electrochemistry mass spectrometry, time-of-flight secondary ion mass spectrometry, X-ray photoelectron spectroscopy and density functional theory. By drawing from the adjacent fields of enzymatic nitrogen reduction and battery science, we will aim to build a holistic picture of the factors controlling nitrogen reduction. On the basis of our insight, we propose new avenues towards going beyond lithium in electrochemical nitrogen fixation.

2:00 PM EN07.02.02
Metal-Free Nanofibers with Tailored Electronic Structures for Highly Active and Selective Hydrogen Peroxide Electroproduction FeiXiang[1], XuhongZhao[2], JianYang[3], NingLi[1], XiaobinNiu[2] and AndreaFratalocchi[1]; [1]King Abdullah University of Science and Technology, Saudi Arabia; [2]University of Electronic Science and Technology of China, China; [3]Southwest Jiaotong University, China

Electrocatalytic hydrogen peroxide (H_2O_2) production via two-electron oxygen reduction reaction (2e- ORR) has attracted significant research interest as a promising alternative to the traditional energy-intensive traditional anthraquinone cycling process. However, designing low-cost, highly active, and selective electrocatalysts remains challenging due to the fierce competition from the four-electron reaction pathway. In this study, we engineer the electronic structure of electrospun nanofibers via fluorine and sulfur dual-doping to develop large-scale metal-free electrocatalysts for hydrogen peroxide production. Experimental and theoretical computation results demonstrate the manipulated electronic structures of the carbon active sites

after suitable fluorine and sulfur dual-doping, originating from intermolecular charge transfer and electron spin redistribution at the active sites. The optimized catalyst exhibits an onset potential of 0.814 V versus the reversible hydrogen electrode (RHE) in an alkaline medium and a selectivity of 99.1%, outperforming most of the previously reported carbon-based and metal-based counterparts. Density functional theory (DFT) results elucidate the manipulated free energy profiles and kinetic energy barriers in 2e- ORR after fluorine and sulfur dual-doping, confirming the enhanced activity and selectivity in the 2e- ORR pathway for hydrogen peroxide production. This fluorine and sulfur dual-doping strategy on carbon nanofibers from electrospinning provides the pathway to designing and implementing large-scale, low-cost, and highly efficient catalysts for hydrogen peroxide production. Moreover, this strategy also enjoys versatility in the materials for other catalytic fields, such as water splitting, CO_2 reduction, and ammonia production.

2:15 PM *EN07.02.03
Light-Driven Reduction of Carbon Dioxide with Hybrid Photoelectrodes JillianDempsey; University of North Carolina at Chapel Hill, United States

Integration of molecular catalysts that reduce CO_2 to CO with silicon photoelectrodes has been achieved through both covalent and non-covalent attachment methods. These hybrid photoelectrodes have been characterized by x-ray photoelectron spectroscopy, inductively-coupled plasma mass spectrometry, and attenuated total reflectance infrared spectroscopy. Cyclic voltammetry and bulk photoelectrolysis with product analysis are used to establish that these hybrid photoelectrodes are competent for light-driven fuel production with high Faradaic efficiencies.

8:00 PM EN07.03.01
A New Strategy for Improving Durability of Electrodes in Cell Reversal during Fuel Starvation Cycles of PEMFC with Reversal Tolerant Anode Chi-YeongAhn[1,2], So YeonLee[1,2] and HyungwonShim[1]; [1]Korea Research Institute of Ships & Ocean Engineering, Korea (the Republic of); [2]University of Science and Technology, Korea (the Republic of)

Due to the strengthening of environmental regulations of international societies, the introduction of eco-friendly technologies is being rapidly carried out in the marine and shipping sectors. Among them, fuel cells (especially PEMFC) are in the limelight as a propulsion system for small and medium-sized coastal ships due to fast starting characteristics and low operating temperature. However, ships require higher output than passenger cars, which require an FC capacity of about 100 kW. In the case of such a large-capacity FC, hydrogen may not be evenly diffused to the electrode when starting or when an electric load rapidly increases due to stoichiometry control. In some parts (or all) of the electrode where hydrogen supply is insufficient, fuel starvation will proceed, and cell reversal may occur. This cell reversal phenomenon causes severe degradation of the anode.
Degradation by cell reversal can be mitigated by adding a material with OER activity such as iridium oxide to the anode. This anode is called a reversal tolerant anode (RTA). In addition, several studies have been conducted on RTA under various conditions. However, we observed that when RTA was added in fuel starvation cycles, the anode was well protected but the cathode rather degraded. Therefore, in this study, we sought the cause of cathode degradation during fuel starvation cycles and conducted experiments to prevent it.

8:00 PM EN07.03.02
Unravelling Hidden Parameters during Electrode Processing: The Role of Coherent Workflows in Electrocatalysis DorisSegets[1,2]; [1]University of Duisburg-Essen, Germany; [2]Center for Nanointegration Duisburg-Essen (CENIDE), Germany

Micron and nano-sized functional materials play a key role for future technologies that are currently developed in the field of energy conversion (electrolysers, fuel cells) and electrocatalysis. While new materials with outstanding properties are continuously developed, they rarely find their way into – urgently needed – large scale production and industrial applications [1]. One reason for this are hidden parameters that occur during ink formulation, coating (and decal transfer), cell assembly, and operation. We propose the development of coherent workflows that help us to identify reliable correlations. These should be developed for each electrocatalyst, bridging synthesis, electrode and gas diffusion electrode (GDE)/membrane electrode assembly (MEA) fabrication, and testing. All information, including “negative” results like crack formation, delamination, structural ageing and dissolution, must be reported until the relevant hidden parameters are deciphered, and the design chain is understood. Then, materials and electrodes derived from complementary processes and exhibiting subtle variations in composition and structure, can be evaluated against each other.
However, this implies to fill the “blackbox” between technical catalysts and electrochemical testing in flow cells, GDEs or MEAs, with quantitative data on powders, ink formulations and coating properties. In the past years, we developed a toolbox of methods that starts from key control characteristics for technical catalysts, i.e., ball-milled pentlandites for hydrogenation reactions, that thereon enable the in situ analysis of ink formulations and pastes during the dispersion process and at application concentration [2,3]. This is followed by the assessment of the resulting coatings from large-area crack analysis down to the level of surface roughness and pore size characteristics [4]. Finally, this input is connected with performance and stability testing results to enable the comparison of different materials, the assessment of structure property relations, and ultimately to establish inline process control during electrode manufacturing. In this contribution, the developed methods will be summarized and related to their current limitations and prospects, in particular for unraveling hidden parameters during GDE assembly as well as in line process control.

Phase Engineering of Noble Metal-Based High-Entropy Alloy Nanocrystals PengHan and YeChen; The Chinese University of Hong Kong, Hong Kong

High-entropy alloys (HEAs) possessing five or more elements exhibited unique physical and chemical characteristics. Delicate size/shape and composition control would significantly boost their performance toward various catalytic reactions. However, the phase-dependent properties of HEAs are rarely studied because controlling the crystal structure of HEAs with the same composition is extremely challenging. Herein, through facile wet chemistry and subsequent heat treatment, quinary and senary noble metal-based HEA nanocrystals with well-controlled phases, including hexagonal close-packed (*hcp*) and face-centered cubic (*fcc*) phases are successfully synthesized. The phase of noble metal-based HEA nanocrystals is tunable by altering the types of metal precursors and the temperature during heat treatment. The effect of the crystal structure on the catalytic performance of noble metal-based HEA nanocrystals is also investigated. This work opened a significant avenue in developing well-defined HEA nanocrystals with precise control over phases for heterogeneous catalysis.

Efficient Oxidation of Aqueous Persistent Organic Pollutants using Zwitterionic Hydrogel-Bound Iron(II) Ions as Heterogenous Fenton Catalysts DevashishGokhale, IanS. Chen and PatrickDoyle; Massachusetts Institute of Technology, United States

Persistent organic pollutants, such as xenoestrogens and PFAS, present a global challenge requiring immediate action. The Fenton oxidation reaction is an advanced oxidation process catalyzed by dissolved Fe(II) ions and their complexes, which converts hydrogen peroxide to hydroxyl radicals to degrade organic contaminants. Though the Fenton reaction is extremely promising for scalable water treatment, there are several limitations to its practical use, such as the difficulty in transporting and storing hydrogen peroxide. Further, though Fe(II) ions are called catalysts in Fenton processes, they are continuously oxidized to Fe(III) ions and are difficult to reuse or recover from water. Attempts to create a practical Fenton process have used electrochemical cells to produce hydrogen peroxide *in situ*, while replacing dissolved Fe(II) ions with heterogenous catalysts. Such catalysts typically encapsulate iron or iron oxide nanoparticles in polymers or support them on traditional adsorbents but have so far been limited by slow reaction rates due to reduced surface area, the need to adjust pH with acids, unintended substrate/polymer degradation by the Fenton reaction, and the release or slow dissolution of nanoparticles. These catalysts are also incompatible with other improvements to the traditional Fenton reaction, such as UV light to accelerate the production of hydroxyl ions.

A practical Fenton process to eliminate POPs will require the development of (1) a heterogenous catalyst that retains iron while (2) eliminating the need for acid addition, (3) is highly porous

and has a large effective surface area to preserve efficacy, (4) is transparent to UV radiation and (5) resistant to degradation by UV light, hydrogen peroxide, and the iron itself, (6) preferably does not use nanoparticles which may pose a threat to the environment if they escape the catalyst over long periods of time, and (7) can be regenerated and reused in a facile manner. Here, we introduce an innovative heterogeneous Fenton catalyst based on a zwitterionic hydrogel material that effectively addresses these challenges. Containing individually complexed iron ions in a highly porous scaffold, the hydrogel catalyst has a large effective surface area and exhibits kinetics comparable to homogeneous Fenton degradation. The complexed ions can initiate Fenton degradation at neutral, and even alkaline pH, eliminating the need for acid additions. At the same time, the zwitterionic hydrogel scaffold is specifically selected to be resistant to Fenton oxidation and strongly bind to the iron ions, enabling repeatable long-term use. Using our catalytic hydrogels, we showcase the rapid and complete degradation of three structurally disparate contaminants of major concern, ethinyl estradiol (a xenoestrogen), 2,4-dichlorophenol (a model pesticide and chlorinated aromatic) and perfluorooctanoic acid (PFOA, a model for PFAS), over multiple cycles of use at environmentally relevant concentrations. Our zwitterionic hydrogel-based Fenton catalyst offers a promising solution for the efficient and scalable degradation of persistent organic pollutants in electrochemical water treatment processes and beyond.

8:00 PM EN07.03.05
Electrosynthesis of Hydrogen Peroxide and Electro-Fenton Application using Metal Chalcogenide Electrocatalysts GerardoJ. Quintana Cintron, R. DominicRoss and SongJin; University of Wisconsin–Madison, United States

Hydrogen peroxide (H_2O_2) is an environmentally friendly oxidant that has diverse applications in wastewater treatment, paper bleaching, and chemical disinfection. However, its traditional production is costly, unsafe, and not energy efficient. Electrochemical production of H_2O_2 using the two-electron oxygen reduction reaction ($2e^-$ ORR) could enable decentralized production of H_2O_2 with just air and electricity. Furthermore, electrosynthesized H_2O_2 can be reacted with Fe^{2+} to produce hydroxyl radical (●OH) via the electro-Fenton (EF), which can break down or convert organic compounds that are otherwise difficult to oxidize directly. Metal selenides such as $CoSe_2$ and $NiSe_2$ have previously been demonstrated as effective electrocatalysts for the $2e^-$ ORR and EF. Here we further explore a series of Fe-Se compounds toward practical EF. Metal and selenium leaching was systematically studied through inductively coupled plasma-optical emission spectroscopy (ICP-OES) to understand better how the Fe ion leaches (Fe ion concentration) and can "self-catalyze" the EF reaction. The electrosynthesis of H_2O_2 and the electrochemical removal of model contaminant Rhodamine B via the EF process was studied with or without added Fe^{2+} with various metal selenide catalysts in a conventional H-cell and a gas diffusion electrode (GDE) flow cell. This work also studies the production of H_2O_2 through the cathodic reduction of oxygen in acidic and neutral medium by comparing the results obtained using different metal chalcogenide catalysts on a GDE flow cell setup.

8:00 PM EN07.03.06
Development of Double Doped Lanthanum-Strontium Titanate: Synthesis, Characterization and Nanoparticles Production by Exsolution for Promising Catalyst AntonioT. Oliveira and DanielZ. Florio; UFABC, Brazil

Climate change has emerged as one of the most significant concerns of this century. In 2021, global electricity production heavily relied on natural gas (22.79%), oil (2.75%), and coal (36.26%) [1]. However, electricity generation from these sources is strongly associated with greenhouse gas (GHG) emissions. Since 2015, various initiatives have been undertaken to achieve net-zero emissions by replacing fossil fuels with renewable energy sources. Among these alternatives, Solid Oxide Fuel Cells (SOFCs) have gained attention due to their high efficiency, fuel flexibility, and low-to-zero CO_2 emissions resulting from electrochemical conversion. In SOFCs, the anodes are responsible for fuel reduction reactions while the cathodes drive the oxidizing reactions. Perovskite materials have demonstrated excellent potential as SOFCs electrodes due to their high mixed ionic-electronic conductivity, catalytic properties, and chemical and thermal stability. Nowadays, one significant challenge associated with SOFCs is their operation with carbon-based fuels. When these fuels are applied, the anodes catalyze coke formation, leading to carbon deposition on the anode surface, which results in efficiency loss. To address this issue, several efforts have been dedicated to finding a solution, and one promising approach is the application of metallic nanoparticle exsolution at the electrodes. This process involves the *in situ* growth of nanoparticles anchored on the matrix surface. Exsolved nanoparticles have demonstrated tolerance to sulfur poisoning and resistance to coke deposition, preventing coarsening and catalyst deactivation. The present work seeks to obtain exsolved metal alloy nanoparticles anchored on a perovskite structure, thereby a more promising material for SOFC applications. The nanoparticle catalysts were obtained by dissolving the interest metal into a perovskite host and subsequently exposing it to a reducing H_2 atmosphere. The $La_{0.8}Sr_{0.2}Ti_{0.7}Ni_{0.3-x}Cu_xO_{3-\delta}$ (x = 0.1, 0.15, 0.2) powders were obtained by the Pechini synthesis route and calcined at 900 °C for 5 hours. Thereafter, the powders were heat-treated under 3 vol % H_2/N_2 atmosphere at 900 °C, 850 °C, 800 °C and 750 °C for 10 hours to obtain decorated NiCu nanoparticles alloys. The samples were characterized by scanning electron microscope, transmission electron microscope, X-ray diffraction, X-ray photoelectron spectroscopy, and electrochemical impedance spectroscopy. Rietveld refinement was performed to determine structural parameters such as crystal symmetry, crystallite size, strain, and phase content before and after reduction treatment. Preliminary results indicate successful synthesis route and reduction treatment were to obtain NiCu nanoparticles alloy.

Low-Cost 3D Printable Flow Reactors for Electrochemistry ErinHeeschen, ElenaDeLucia, YilmazA. Manav, DaisyRoberts, BenyaminDavaji and MagdaH. Barecka; Northeastern University, United States

Transition to carbon neutrality requires the development of more sustainable pathways to synthesize the next generation of chemical building blocks. Electrochemistry is a promising pathway to achieve this goal, as it allows for using renewable energy to drive chemical transformations. While electroreduction of carbon dioxide (CO2) and hydrogen evolution are attracting a significant research interest, there exist fundamental challenges in moving the research focus towards performing these reactions on scales relevant to industrial applications. To bridge this gap, we aim to facilitate the access of researchers to flow reactors, which allow characterizations of electrochemical transformations under the conditions closer to these deployed in the industry. Here we provide a 3D-printable flow cell design (manufacturing cost < $5) which consists of several plates, offering a customizable alternative to commercially available flow reactors (cost > $6,000). Proposed design and detailed build instructions allow a wide variety of chemical reactions in flow to be performed, including gas and liquid phase electroreduction, electroplating, and photoelectrochemical reactions, providing researchers with more flexibility and control over their experiments. By offering a low-cost reactor alternative, we reduce the barriers toward performing research on sustainable electrochemistry, supporting the global efforts necessary to realize the paradigm shift in chemical manufacturing.

Engineering the Electronic Structure of Aluminate Spinel Oxide using a High Entropy Approach FranciscoMarques dos Santos Vieira, IsmailaDabo, RaymondSchaak, ZhiqiangMao and RowanKatzbaer; The Pennsylvania State University, United States

Due to its high energy density, hydrogen fuel shows promise is the decarbonization of freight transport. However, there remain challenges in the synthesis of hydrogen fuel. Electrocatalytic water splitting holds the potential to sustainably produce hydrogen fuel provided suitable catalysts are identified. Here, we present the high entropy aluminate spinel oxide ($Fe_{0.2}Co_{0.2}Ni_{0.2}Cu_{0.2}Zn_{0.2})Al_2O_4$ ($A^5Al_2O_4$) as catalyst for the for the oxygen evolution reaction (OER) in an alkaline electrolyte, and explore its electronic structure. In High entropy oxides (HEOs), numerous cations coexist in a single sublattice forming a solid solution throughout the crystalline solid. The sharing of a sublattice gives rise to unique, and even enhanced, properties including improved catalytic performance. Experimental measurements indicate $A^5Al_2O_4$ has a bandgap far narrower than its parent phases. First principles calculations indicate that this narrowing of the bandgap is a consequence of the broadening of bands arising from the hybridization of the 3d states due to the variation of electronegativity across the 3d transition metal series. The observed narrowing of the bandgap in the high entropy spinel highlights a new method of engineering electronic structure using a high entropy approach to achieve desired material properties.

Pt-Ni-Ru Nanoframes with Superior Performance for Methanol Oxidation Reaction EduardoLezama, KiraShulman, YooraCho and Yiliang (Yancy)Luan; Binghamton University, The State University of New York, United States

Direct Methanol Fuel Cells (DMFCs) offer a promising solution for energy conversion with relatively low carbon emissions. Nevertheless, the efficiency of the anode is hindered by the sluggish kinetics of the Methanol Oxidation Reaction (MOR), preventing the widespread commercialization of DMFCs. Despite being a successful commercialized catalyst, Platinum (Pt) has been demonstrated to be costly and inefficient. Pt-based alloys with open structures offer feasible alternatives that have the potential to improve MOR while also being economically viable. This study synthesized Pt-Ni-Ru nanoframes (NFs) via a galvanic replacement process, resulting in remarkable MOR activity attributed to the combined effect of alloying and large surface area from the NFs. The Pt-Ni-Ru NFs exhibited mass and specific activities 2.8 and 2.0 times higher, respectively, compared to the commercial Pt/C catalyst. The study demonstrates that Pt-Ni-Ru NFs serve as a superior catalyst for the anode reaction in DMFCs, emphasizing the potential of open nanostructures and alloying in the advancement of future catalysts.

8:00 PM EN07.03.10

Structural and Electrocatalytic Properties of Pulsed Laser-Deposited Titanium Nitride/Titanium Oxynitride Thin Films SheilahCherono[1], IkennaChris-Okoro[1], ValentinCraciun[2,3], MihaiMaria[3,4] and DhananjayKumar[1]; [1]North Carolina Agricultural and Technical State University, United States; [2]National Institute for Laser, Plasma, and Radiation Physics, Extreme Light Infrastructure for Nuclear Physics, Romania; [3]University Politehnica of Bucharest, Romania; [4]Horia Hulubei National Institute for Nuclear Physics and Engineering, Romania

Pulsed laser deposition (PLD) technique has been used to grow titanium nitride (TiN) and titanium oxynitride (TiNO) thin films on sapphire (Al_2O_3), titanium dioxide (TiO_2) and niobium doped titanium dioxide (Nb -TiO_2) single crystal substrates using high vacuum conditions. A pulsed Krypton Fluoride (KrF) excimer laser (Wavelength=248nm, pulse duration=30ns) has been used, with a laser repetition rate of 10 Hz, 6000 pulses, and a deposition temperature of 600^o C. Structural properties of the films were investigated using X-ray Diffraction and Reflection (XRD, XRR) while X-ray Photoelectron Spectroscopy (XPS) and Rutherford backscattering spectrometry (RBS) was used for compositional investigations. XRD phi scans show the in-plane orientation of the deposited TiN film with respect to the substrate orientation; depending on the substrate orientation, films are either (111) or (200) oriented, thus offering different orientations for surface chemical reactions. The full-width half maximum (FWHM) value of plane (200) was 0.5754° for the film grown on undoped TiO_2 (110), while for those growing along the (111) plane was 0.1617° for the film on sapphire and 0.1457° for the film on Niobium-doped TiO_2 (100). Films deposited onto niobium-doped TiO_2 have shown the highest crystallinity, whereas those deposited onto undoped TiO_2 have shown poor crystallinity. The rocking curve results show that changing the substrate orientation can control the crystal quality of the grown TiN.

Simulation of the acquired XRR curves indicated mass densities from 5.2 to 5.4 g/cm3, very close to the TiN tabulated value, while the roughness was less than 1 nm indicating flat surfaces for chemical reactions. XPS analysis shows the initial film surface is oxidized, and the chemical formula indicates the existence of a composite made of TiO2+TiON+some TiN. After sputtering of the surface heavily oxidized layer is removed, and the chemical composition changes to TiN-TiON and some TiO_2. For the films deposited under low vacuum, the atomic oxygen concentration was lower than 10%, a result also confirmed by Rutherford backscattering spectrometry. Such films also exhibited resistivities around 70 mΩ.cm, which is close to the best-reported values. TiON films are epitaxial, despite the relatively high oxygen concentration. By controlling the oxygen-to-nitrogen ratio by regulating the vacuum level during PLD, optical bandgaps of the composite films were controlled from 2.1 eV to 3.2 eV, and electrocatalytic overpotentials for oxygen evolution reaction potentials as low as 300 mV at 10mA/cm^2 was obtained. The Tafel slopes, indicative of a rate of increase of electrode potential with respect to current, for these films, are determined to be in the range of 80−60 mV/decade. These results further demonstrate the superiority of TiNO thin film as an electrocatalyst for water oxidation to generate fossil-free fuels. The improvement in the electrocatalytic behavior of the TiNO thin films is explained based on an adjustment in the valence band maximum edge and an enhancement in the number of electrochemically active sites. Both effects are realized by the substitution of N by O, forming a TiNO lattice that is isostructural with the rock-salt TiN lattice.

This work was primarily supported by a DOE EFRC on The Center for Electrochemical Dynamics And Reactions on Surfaces (CEDARS) via grant # DE-SC0023415. The authors (IK, VC, and DK) also acknowledge the support of the NSF PREM via grant # DMR-2122067 PREM.

Development of Chemical Analysis Method and Reference Materials of Binary Pt Alloy Catalysts for a PEM-Type Hydrogen Fuel Cell SangrinLee and KwangsooLim; KTR(Korea Testing & Research Institute), Korea (the Republic of)

Recently, the development and application of polymer electrolyte hydrogen fuel cells (PEMFCs) are expanding. So, demand for platinum alloy catalysts which are a core materials for hydrogen fuel cell is growing exponentially. The price of a catalyst material using a precious metal is determined according to the content of the metal such as Pt, Pd etc... However, there are conflicts between companies, because of absence standard test method for analysis of novel metal contents in the catalysts. therefore, We tried to develop standard test methods and reference materials for elemental quantitative analysis of platinum alloy catalyst materials.
The elemental quantitative analysis method is fully developed based on ISO/IEC 17025 : 2017. Applying ICP/OES, the certified values of the mass fractions of Pt, Co, and Ni were assigned and their assoicated measurement uncertainties were evaluated. The mean measurement results obtained from 10 sample bottles were used to assign as the certified values for the RM and the between-bottle homogeneities were evaluated by ANOVA (on way layout) analysis method. The certified values and their associated expanded uncertainties at 95% level of confidence for mass fractions of Pt, Co in Pt3Co/C RM were 27.1 ± 1.0% (coverage factor, k = 3.18), 2.26 ± 0.14% (k = 2.0) respectively. In case of Pt3Ni/C, The mass fractions of Pt, Ni were 26.2 ± 0.6% (k = 2.0), 2.97 ± 0.22% (k = 2.0) respectively.
In this presentation, detailed analysis results, including the validation of the test method for analysis of standard materials will be introduced.

8:00 PM EN07.03.12

Improved Alkaline Hydrogen Oxidation on Strained-Modulated Pt Overlayers on Ordered Intermetallic PtSb Cores TianyaoGong[1], HamdanAlghamdi[1], DavidRaciti[2] and ShojiHall[1]; [1]Johns Hopkins University, United States; [2]National Institute of Standards and Technology, United States

Alkaline exchange membrane fuel cells (AEMFCs) have emerged as an inexpensive and robust renewable energy conversion device. However, the kinetics Hydrogen Oxidation Reaction (HOR) in alkaline conditions (the anode reaction of AEMFCs) is ~100x slower in than in acidic electrolytes. Significant progress has been made developing improved catalyst materials for alkaline HOR, yet due to the complexity of alloy surfaces, it is difficult to determine the true source of such enhancement.
To address this issue, here we report the use of Ordered Intermetallic Compounds (OICs) as a well-defined platform to produce strain modulated Pt overlayers. Two OICs phases of the Pt-Sb system, PtSb and $PtSb_2$, with different crystal structures were prepared. Electrochemical dealloying of the Pt-Sb alloys resulted in the formation of core shell Pt-Sb@Pt particles. By judicious choice of the OIC precursor material, we were able to produce PtSb@Pt and $PtSb_2$@Pt with compressive and tensile strain, respectively, relative to elemental Pt. It is worth noting that this approach cannot be accomplished with solid solution alloys (with an alloy core composed of the same two elements) since the d-spacing of the lattice follows Vegard's law. This enabled us to interrogate the role of how strain controls HOR performance without the possible influence of atoms with different identities on the surface of the Pt. PtSb@Pt exhibited a weaker HBE than Pt, enabling to achieve an exchange current density (j_o) 1.5x larger than benchmark Pt catalyst for alkaline HOR; whereas $PtSb_2$ exhibited tensile strain which increased the HBE, reducing the j_o by 1.5x to Pt catalyst. Interestingly we found no correlation with the OH_{ads} coverage as estimated by CO stripping. Therefore, this work revealed that HBE is the dominant parameter for improving the kinetics of Pt sites for alkaline HOR.

8:00 PM EN07.03.13

Effect on Oxygen Reduction Reaction of Iron Catalyst Synthesized by Aniline Monomer-Mediated Technique YeongeunChoi[1], SeungMinLee[1], JihyeokSong[2], Hyo EunBae[2] and Oh JoongKwon[1]; [1]Incheon National University, Korea (the Republic of); [2]Seoul National University, Korea (the Republic of)

An anion exchange membrane fuel cell (AEMFC), which uses hydroxyl conductive membranes instead of proton conductive ones, is highlighted as a replacement for a proton exchange membrane fuel cell. AEMFC has the advantage of using abundant and inexpensive transition metals, such as iron, cobalt, and nickel for catalysts owing to mild reaction conditions. Among numerous non-platinum metal catalysts (NPMCs), M-N-C catalyst has been reported considerably and Fe-N-C catalyst, which co-doped nitrogen and Fe, was considered the promising M-N-C owing to their high atomic utilization and excellent electrocatalytic performance. For the Fe-N-C catalyst, it is important to expose the maximum number of active sites and distribute the Fe in the Fe-N-C catalyst uniformly on a carbon support. Therefore, many researchers have been exploring Fe-N-C catalyst, in which Fe exist as a single atom. The common method for synthesizing single atom Fe-N-C includes the random mixing and high-temperature pyrolysis process, which tends to cause the aggregation of metals and leads to the degradation of catalytic activity. Thus, the research for preventing the aggregation of metals is crucial for high electrocatalytic activity.

This study explores the possibility of applying M-N-C to AEMFC through the development of Fe single atom. We adopted the method of aniline-mediated metal reduction and high-temperature pyrolysis for synthesizing the Fe-N-C catalyst. The Fe single atom reported high performance and durability and possess the optimal Fe-N_x coordination structure by optimizing the synthesis condition. The optimization of the synthesis conditions for the Fe-N-C catalyst proceeds through the control of the amount of Fe precursor and aniline and the temperature of pyrolysis. Several characterizations such as Thermogravimetric analysis (TGA), X-ray diffraction (XRD), Inductively coupled plasma-mass spectrometry (ICP-MS), and Scanning transmission electron microscopy (STEM) were introduced to investigate the catalyst properties. The uniform distribution of the single atom on the carbon support was confirmed by STEM and XRD, and the Fe content was checked to be about 1wt.% using ICP-MS and TGA. Furthermore, electrochemical measurements were conducted to present the correlation between catalytic activity and structure. The catalyst, which possesses single atom active sites, showed high electrochemical performance and durability for oxygen reduction reaction and proposed the applicability for AEMFC. The study proved that the Fe single-atom catalyst was successfully synthesized by metal reduction and pyrolysis processes

Tailoring the Ensemble Geometry and Electronic Properties of Active Sites in Catalytic Nanomaterials ChristinaLi; Purdue University, United States

Supported metal atoms and nanoparticles are found ubiquitously as heterogeneous catalysts for a wide variety of industrial, organic, and energy catalytic processes. The electronic and steric environment at the nanomaterial surface has a huge impact on the reactivity and selectivity of catalytic transformations occurring at surface active sites, but these properties are difficult to independently control through conventional materials synthetic methods. In this work, we develop molecularly-precise surface functionalization strategies in order to precisely tune both the ensemble geometry and redox properties of active site metal atoms. These strategies include 1) the adsorption of inorganic ligands on colloidal nanoparticle surfaces in order to synthesize monolayer and sub-monolayer core-shell catalysts, 2) control of bimetallic surface ensemble geometry in alloy nanoparticles, and 3) tuning the metal–sulfur coordination environment of single atoms supported on metal chalcogenide nanosheets for electrochemical catalysis. All of these strategies develop new structural frameworks for modulating the surface active site environment in order to access more reactive and selective nanomaterial catalysts.

Composition, Structure and OER Behaviors of Highly Catalytic Manganese-Doped Bismuth Ruthenium Oxide (MBRO) for Alkaline Water Splitting MasatsuguMorimitsu, SachiMatsuura, HayatoSuzuki and ChinamiIketani; Doshisha University, Japan

Water splitting using alkaline solutions is one of the most promising methods to produce green hydrogen and accounts for 61% of the world's hydrogen production capacity in 2020[1)]. The anodic reaction, which is oxygen evolution reaction (OER), occurs through a 4-elecron transfer in highly corrosive solutions. While currently nickel-based materials are used for the anode because of the chemical stability of their oxides and oxyhydroxides in alkaline media, the current density during electrolysis is limited due to the low catalytic activity of those materials and cannot be as high as PEM water splitting. Our group has recently developed bismuth ruthenate-based pyrochlore oxide as a new OER catalyst and has found some excellent properties on the polarization for and durability to OER in KOH solutions. In this paper, the composition, structure, and OER behaviors of manganese-doped bismuth ruthenium oxide (MBRO) are presented with the results by instrumental analyses and electrochemical measurements.

MBRO was prepared by calcination at 600 ºC of the precursor deposited in the solution which had been obtained by adding NaOH solution into the metal salt solution containing bismuth nitrate and ruthenium chloride with manganese nitrate. The composition and structure of the oxide were analyzed by AAS, RBS, EDX, XRD, and XAFS and the surface morphology and particle size were measured by SEM. The electrochemical performance was evaluated by Titanium Disk Method (TDM), in which the oxide particles loaded on a titanium disk (4 mm in diam.) was mounted in the rotating-disk electrode of a conventional three-electrode cell. The cell was also equipped with a platinum plate counter electrode and an Hg/HgO reference electrode. The electrolyte was 0.1 mol/L KOH solution and all measurements were performed at room temperature.

The obtained MBRO showed a single phase of pyrochlore structure and ruthenium at the B site was partly substituted with manganese. The particle size ranged from 20 to 40 nm, which was small enough to load it on a titanium disk without any binders or ionomers. The results obtained by polarization measurements revealed that the onset potential of OER was 0.45 V vs. Hg/HgO, which is the overpotential of 0.16 V, and the Tafel slope was ca. 39 mV/dec, while the other materials reported in the literature[2)] shows the overpotential higher than 200 mV and Tafel slope of 60 mV/dec or more. The above results suggest that MBRO is suitable for the anode material of alkaline water splitting to reduce the cell voltage at high current densities. In this work, MBRO-loaded graphite electrodes were prepared and examined for OER in 6 mol/L KOH solutions, of which the results will be also presented.

Tungsten-Induced *Operando* Transformations of the Perovskite $Ba_{0.5}Sr_{0.5}Ni_{1-x}W_xO_{3-\delta}$ Series during the Oxygen Evolution ReactionNatashaHales, EmilianaFabbri and ThomasSchmidt; Paul Scherrer Institute, Switzerland

Water electrolysis provides a means for long-term energy storage in the form of hydrogen gas, helping to offset seasonal variations in renewable energy production. Developing non-noble metal catalysts for the anodic oxygen evolution reaction (OER) is a key step in reducing the cost and increasing the energy efficiency and sustainability of this vital technology. Flame-spray synthesized perovskite oxides of the composition $Ba_{0.5}Sr_{0.5}Ni_{1-x}W_xO_{3-\delta}$ exhibit excellent OER activity in alkaline conditions. In particular, $Ba_{0.5}Sr_{0.5}Ni_{0.5}W_{0.5}O_{3-\delta}$, with a catalytic turn over frequency (TOF) five-times that of NiO, displays a competitive Tafel slope of 44.7 mV/dec. The perovskite structure, with its tunable ABO_3 formula, provides a unique opportunity to enhance the intrinsic activity of Ni sites with high-valence metal co-doping, and explore the relationship between structural properties and electrocatalytic activity.

B-site W doping strongly influences the oxidation state of surface Ni sites, as revealed by *ex-situ* soft X-ray absorption spectroscopy (XAS) at the Ni L-edge. A higher concentration of W^{4+} increases the Ni^{2+}/Ni^{3+} ratio, enhancing the intrinsic activity of the Ni active sites. In addition, analysis of the O K-edge indicates a positive correlation between W content and oxygen vacancy concentration, activating $Ba_{0.5}Sr_{0.5}Ni_{0.5}W_{0.5}O_{3-\delta}$ for the lattice oxygen mechanism (LOM), whereby mobile oxygen atoms can move through vacant lattice sites to participate directly in OER catalysis.[1] This pathway is largely considered to be more efficient than the traditional adsorbate evolution mechanism (AEM), leading to enhanced reaction kinetics and decreased OER overpotentials.[1]

Akin to the the well-known surface reconstruction processes of NiO during alkaline OER ($Ni^{II}O \rightarrow Ni^{II}(OH)_2 \rightarrow Ni^{III}OOH$), NiW perovskites experience complex, electrochemically-induced transformations under OER conditions.[2] Therefore, catalyst ‘pre-activation’ using cyclic voltammetry is essential to develop their high-performance final state *in-situ*. *Operando* hard XAS at the Ni K-edge and W L_3-edge revealed that NiW perovskites experience significant oxidation state changes at the catalytic Ni sites during cyclic voltammetry, with a strong overall trend of $Ni^{2+} \rightarrow Ni^{3+}$ oxidation. However, both the extent and rate of this oxidation are greatly influenced by the B-site W concentration. Furthermore, *operando* X-ray diffraction revealed significant surface reconstruction that facilitates a strong growth in electrochemically active surface area, but this process is also heavily dependent on the W content. It is evident that the ‘pre-activation’ of $Ba_{0.5}Sr_{0.5}Ni_{1-x}W_xO_{3-\delta}$ catalysts is a function of the Ni:W ratio; elucidating the ways in which high valence metal doping influences the catalyst activation mechanism will guide the development of future Ni-based OER catalysts, for which this process is intrinsically coupled with OER activity.

Discovery of High-Index Facet Nanocatalysts for Clean Energy Applications BoShen and ChadA. Mirkin; Northwestern University, United States

Nanoparticles with high-index facets are particularly attractive as electrocatalysts because such facets typically consist of a high density of low-coordinated atomic steps and kinks. However, the synthesis of high-index facet nanoparticles is very challenging, which prevents the wide application of such materials. Herein, we addressed this challenge by developing synthetic methods based on ligand-free, solid-state reactions. Combining synthetic techniques with high-throughput DFT simulations and machine learning, we have discovered a library of multimetallic high-index facet nanoparticles. Additionally, the size, composition, crystal structures, and phase structures of such materials can be further controlled by nanolithography, leading to a huge database of high-index facet catalysts, which can be used for a range of energy-related applications including electrooxidation of liquid fuels and CO_2 reduction.

Platinum Catalysts with Enhanced Activity and Durability Toward Oxygen Reduction YounanXia; Georgia Institute of Technology, United States

In this talk, I will discuss a number of new strategies for augmenting the mass activity and durability of Pt-based catalysts toward the oxygen reduction reaction (ORR), which is key to the operation of proton-exchange membrane fuel cells (PEMFCs). Specifcailly, the strategies include the formation of intermetallic compounds, creation of twin boundaries on the surface, and introduction of chemical linkage between Pt surface and carbon support. When integrated together, these strtegies can lead to the development of ORR catalysts with performance that meets the requirment set by DOE. For example, we were able to grow sub-2-nm Pt particles on a commercial carbon support *via* the galvanic reaction between a Pt(II) precursor and a uniform film of amorphous Se pre-deposited on the support. The residual Se could serve as a linker to strongly anchor the Pt nanoparticles to the carbon surface, leading to a catalytic system with extraordinary activity and durability toward ORR. Even after 20,000 cycles of accelerated durability test, the sub-2-nm Pt particles were still dispersed well on the carbon support, maintaining

a mass activity more than three times as high as the pristine value of a commercial Pt/C catalyst.

From Fundamental Studies to Applied Research: $SrIrO_3$ as Efficient Electrocatalysts for Proton Exchange Membrane Electrolyzer ZhenxingFeng; Oregon State University, United States

The search of efficient and stable electrocatalysts for oxygen evolution reaction (OER) in acidic electrolyte is the key to enable the commercialization of proton exchange membrane (PEM) electrolyzers and low hydrogen production price. However, there are few choices for such electrocatalysts due to the corrosive and oxidative conditions. As the discovery of $SrIrO_3$ as a new type of electrocatalysts in acidic OER, we have focused on the fundamental studies of mechanism that leads to its much better acitivity (~ 1000 times more) than the commercial standard, IrO_2. Using $SrIrO_3$ thin film epitaxially grown by molecular beam epitaxy (MBE) as the model system, we have studies the surface restructuring and Sr leaching in the reaction at the atomic scale. Later, using the learned knowledge, we design Ir less $SrIrO_3$-based catalysts in powder form that exhibit the same activity. We are currently extending our studies for this type of catalysts for general PEM electrolyzer applications.

11:00 AM EN07.04.07
Enhancing Hydrogen Evolution Reaction by Controlling Chemical States Through Electrochemical Reduction of Raney Nickel in Alkaline Water Electrolysis YoungHwaYun[1,2], ChangsooLee[1], SechanLee[1], MinJoongKim[1], JongHyeokPark[2] and HyunseokCho[1]; [1]Korea Institute of Energy Research, Korea (the Republic of); [2]Yonsei University, Korea (the Republic of)

Porous electrocatalysts based on nickel (Ni) have found extensive application in alkaline water electrolysis for the hydrogen evolution reaction (HER). The selective leaching of aluminum (Al) from Ni-Al alloys is widely employed as a prominent approach to increase the surface area of porous Ni during fabrication, resulting in high surface area in $Ni(OH)_2$. However, the $Ni(OH)_2$ hampers the HER due to its weak hydrogen adsorption energy. To enhance the hydrogen adsorption energy, it is essential to control the chemical state of the Ni by incorporating metallic Ni, which exhibits strong hydrogen adsorption characteristics. In this study, we controlled the chemical states of Ni through plasma vapor deposition (PVD), heat treatment, chemical leaching, and electrochemical reduction. The phase evolution of the electrocatalysts during fabrication was confirmed using a range of characterization techniques, including X-ray diffraction (XRD), scanning electron microscopy (SEM), transmission electron microscopy (TEM), and energy-dispersive X-ray spectroscopy (EDS). We revealed that the heat-treated Ni-Al alloy, possessing a thick Ni_2Al_3 surface layer, underwent selective Al leaching, resulting in the formation of biphasic interfaces comprising $Ni(OH)_2$ at the grain and NiAl IMCs near the grain boundary of the outermost surface layer. X-ray photoelectron spectroscopy (XPS) analysis confirmed that the coupled oxidation of the NiAl IMCs facilitated the partial reduction of $Ni(OH)_2$ to $Ni(OH)_2$/Ni at the grains during electrochemical reduction. The electrocatalyst containing partially reduced $Ni(OH)_2$/Ni exhibited an overpotential of 54 mV at 10 mA/cm^2, and in single-cell operation, it demonstrated a cell voltage of 1.675 V at 0.4 A/cm^2 at 50 °C.

11:15 AM EN07.04.08
Catalyst-Support Interactions in Zr_2ON_2-Supported IrO_x Electrocatalysts for Enhnaced Activity and Stability in the Acidic Oxygen Evolution Reaction. ChangsooLee[1], KihyunShin[2], YoungtaePark[1], YoungHwaYun[1], GisuDoo[1], MinJoongKim[1], SechanLee[1] and HyunseokCho[1]; [1]Korea Institute of Energy Research, Korea (the Republic of); [2]Hanbat National University, Korea (the Republic of)

Overcoming the challenge of developing highly active and durable Ir-based electrocatalysts for the acidic oxygen evolution reaction (OER) is difficult due to the corrosive conditions experienced during anodic processes. In this study, we present the utilization of IrO_x/Zr_2ON_2 electrocatalysts, which employ Zr_2ON_2 as a support material, to address the trade-off between activity and stability in the OER. Zr_2ON_2 was chosen for its exceptional electrical conductivity and chemical stability, as well as its ability to form strong interactions with the IrO_x catalysts. As a result, the IrO_x/Zr_2ON_2 electrocatalysts demonstrated remarkable OER performance, achieving an overpotential of 255 mV at 10 mA/cm^2 and a mass activity of 849 mA/mg_{Ir} at 1.55 V (versus the reversible hydrogen electrode). The activity of IrO_x/Zr_2ON_2 was sustained at 10 mA/cm^2 for 5 hours, while the unsupported IrOx catalyst and IrOx/ZrN underwent significant degradation. Through a combination of experimental X-ray analyses and theoretical interpretations, it was discovered that the reduced oxidation state of Ir and the extended Ir-O bond distance in IrO_x/Zr_2ON_2 effectively enhanced the activity and stability of IrO_x by modifying the reaction pathway from a conventional adsorbate evolution mechanism to a mechanism involving participation of lattice oxygen. These findings demonstrate that it is possible to significantly reduce the Ir content in OER catalysts through interface engineering without compromising their catalytic performance.

Designing Microenviroments for Selective CO_2 (Photo)Electroreduction FrancescaM. Toma[1,2]; [1]Helmholtz Zentrum Hereon, Germany; [2]Lawrence Berkeley National Laboratory, United States

(Photo)electrochemical reduction of carbon dioxide is a process in which multiple proton-electron transfers are necessary to yield valuable carbon-based products. This process also offers an efficient strategy to reduce the presence of greenhouse gases in the atmosphere while concurrently producing valuable carbon-based products. However, most of the existing CO_2 reduction catalysts still exhibit reduced selectivity for CO_2 reduction products and high activity for the competing hydrogen evolution reaction.
To understand how to tune catalytic activity and selectivity, the identification of specific structure–reactivity relationships can inform catalyst development. We demonstrate that the confined reaction environment enables changes in reaction selectivity and can impart atypical catalytic behaviors. In this talk, we clarify the role of subsurface oxygen, water, and CO_2 on Cu and Ag based systems for CO_2 electroreduction. We show the development of a predictive framework to tune the selectivity of CO_2 reduction on Cu and Ag by examining a series of polymeric and molecular modifiers. We also demonstrate how considerations about the local reaction environment have relevance for photoelectrochemical systems. This understanding can reveal design principles that enable development of active and selective catalysts and provide further insights into the CO_2 reaction mechanism on existing catalyst such as copper and silver.

SESSION EN07.05: Electrocatalyst Synthesis, Water Electrolysis, Fuel Cell Reactions II

Atomic-Scale Insights into Electrocatalyst Structure and Function ShojiHall; Johns Hopkins University, United States

The development of efficient renewable energy conversion and storage devices to curb climate change is one of the most important challenges of the 21st century. This can be addressed by using renewable electricity to manufacture chemical fuels and synthetic precursors, or by generating electricity with carbon-neutral fuel cell devices. However, electrocatalytic processes are hampered by low efficiencies and poor reaction selectivity because of a lack of rational methods available to create controllable catalyst materials with the preferred electrochemical activities. In this seminar Prof. Hall will discuss the use of ordered intermetallic compounds (OICs), which are alloys that display high electrocatalytic activities because their well-defined compositions and long-range atomic scale ordering enable predictable geometric and electronic interactions, in contrast to the more widely studied solid-solution type alloys. However, OIC materials are difficult to synthesize in nanomaterial form because conventional synthesis methods offer poor control over the composition, phase, and morphology. I will discuss our efforts on the synthesis, stability, and catalytic activity of OICs prepared by electrochemical methods at room temperature and atmospheric pressure. Our strategies include the use of electrochemically induced phase transformations which enables us to convert a base metal rich alloy to an OIC richer in nobler metal by removal of the base metal, and the direct production of OIC materials by electrochemical deposition. We will also discuss how we leverage the atomically precise configuration of atoms within OICs to reveal detailed insights into how a material's structure regulates its electrochemical properties. Developing new methods for preparing OIC compounds under ambient conditions is essential for designing catalysts for the next generation of renewable energy conversion devices.

2:00 PM EN07.05.02
Mitigating the Phosphate Anion Poisoning Effect on Oxygen Reduction Reaction (ORR) with a Hydrophobic Side Group HonghongLin, SiwenWang, LiangWang, GaohuaZhu, LingChen and HongfeiJia; Toyota, United States

High-temperature polymer electrolyte fuel cells (HT-PEMFCs) have been developed for heavy duty applications, utilizing phosphoric acid (H_3PO_4) to overcome the proton conductivity limit

of Nafion at elevated temperatures (120-220 °C). However, the adsorption of phosphoric acid onto the Pt catalyst hampers the oxygen reduction reaction (ORR) activity, necessitating a high Pt loading in HT-PEMFCs. Understanding the interaction between Pt and phosphate anions, as well as the anion adsorption effect on ORR, is crucial for activity improvement. In this study, we conducted a comprehensive theoretical and experimental investigation to gain insights into the effect of phosphate adsorption on ORR. While electrolyte adsorption inevitably obstructed active sites, our study revealed a weakened binding between Pt and key ORR intermediates, namely the OH_{ad}, in the presence of adsorbed anions. This weakened Pt-OH_{ad} binding had a beneficial effect on boosting the ORR kinetics. By appropriately modifying the side group structure of a substituted phosphonic acid (R-$PO(OH)_2$), the activity loss caused by anion adsorption could be effectively compensated through enhanced ORR kinetics. Our findings highlight an alternative approach, alongside catalyst material modulation, to mitigate the adverse effects of electrolytes in HT-PEMFCs. The tuning of catalyst interfacial structure using a hydrophobic surface modifier can also serve as a strategy to optimize ORR kinetics in both low-temperature (LT-) and HT-PEMFCs.

2:15 PM EN07.05.03
Probing the OER/ORR Mechanisms on MnO_2 using *Operando* TEY-STXM and Surface DFT CalculationsEvanZ. Carlson[1,2], XiaoZhao[1,2], MichalBajdich[3], HendrikOhldag[2], William C.Chueh[1] and J. TylerMefford[1]; [1]Stanford University, United States; [2]Lawrence Berkeley National Laboratory, United States; [3]SLAC National Accelerator Laboratory, United States

Harnessing the unique bifunctional OER/ORR activity of manganese oxides in regenerative fuel cells could help reduce their material and capital requirements. However, using MnO_2 in reversible, single-catalyst oxygen electrodes requires a better understanding of the structural and chemical motifs responsible for its high electrocatalytic activity.

In this talk, I will discuss our investigation of the atomic-scale origins of Mn oxide's bifunctional OER/ORR activity using a hybrid experimental-computational approach. Our model system, α-K_xMnO_2, is among the highest-performing Mn oxide catalysts for both the OER and the ORR, with ORR activity rivaling that of Pt in basic electrolytes.[1] The material's pH and cation-dependent activity is characterized via rotating ring disk electrochemistry (RRDE), and its voltage-dependent chemistry is probed via *operando* scanning transmission x-ray microscopy in bulk-sensitive transmission mode[2] and surface-sensitive total electron yield mode (TEY-STXM). Surface DFT calculations further reveal the active sites and mechanisms for both the OER and ORR, as well as an unusual cation-dependency.

Conductive Dithiolene-Based Metal-Organic Frameworks for Electrocatalytic H_2 Production SmarandaC. Marinescu; University of Southern California, United States

Sustainable hydrogen evolution reaction (HER) from water has emerged as a promising pathway for the storage and conversion of solar energy in chemical bonds. Hydrogen is a valuable energy carrier that can be transformed into electricity using fuel cell technology or used in the production of industrially relevant chemicals such as ammonia and methanol. Heterogenization of molecular catalysts is an attractive strategy to combine the advantageous properties of homogeneous and heterogeneous catalysis. Metal-organic frameworks (MOFs) have emerged as a promising class of materials; however, their insulating nature has limited their applications in electronics and electrocatalysis. We have demonstrated the successful integration of metal dithiolene units into one and two-dimensional frameworks by using dinucleating and trinucleating thiolate-based ligand scaffolds. The developed metal dithiolene frameworks display high activity for the electrocatalytic HER in acidic aqueous media. The HER performance of the MOF-based electrocatalysts is investigated, to understand the charge transfer properties of the constructed MOF/electrode architecture. Density functional theory calculations were applied to understand the structure of the MOF and its mechanistic pathways for the HER. We expect the design principles discovered in these studies to have a profound impact towards the development of advanced materials and sustainable technologies.

3:30 PM EN07.05.06
Investigation of FeOOH for Mechanisms in Water-Splitting Reactions AlexandraM. Anderson and WennieWang; University of Texas at Austin, United States

Electrolysis is at the forefront of methods of producing hydrogen by separating water into oxygen and hydrogen gas. The oxygen evolution reaction (OER) is known for having slower kinetics due to multiple proton-electron coupled transfer steps being involved. Transition metal oxyhydroxides have been demonstrated to have low overpotentials while being composed of abundant and cheap elements and may be an important materials platform in scaled-up hydrogen production.1 This project explores the relationships between structure and OER mechanisms in iron oxyhydroxides (FeOOH). Earth-abundant metals like Fe pose active catalytic sites and can be modeled in a FeOOH structure under alkaline conditions. Studies show that amorphous electrocatalysts exhibit greater catalytic activity compared to crystalline electrocatalysis, a trend which has often been attributed to amorphous electrocatalysts having a greater concentration of electrochemically accessible active sites.2,3 We hypothesize that the lack of long-range order in amorphous electrocatalysts may also introduce novel structural moieties not present in the crystalline form and play a role in enhanced electrocatalytic activity.

In order to begin testing this hypothesis, we study structure-property relationships between crystalline disorder and OER energetics using density functional theory (DFT) with a Hubbard U correction as implemented in Quantum ESPRESSO.4 We first discuss determining the Hubbard U correction value and constructing a representative adsorbate/surface structure using the crystalline structure. We manually manipulate the crystalline structure to imitate potential local structural distortions of the amorphous structure and compare computed overpotentials with the different structures and previously determined literature values. Finally, we present a rational model to understand the impact of structural distortion on electrocatalytic activity.

Multicomponent Alloy Nanoparticles as Efficient Oxygen Evolving Electrocatalysts LeanneJones and RobertWeatherup; University of Oxford, United Kingdom

Designing efficient and cost-effective catalysts for electrochemical water splitting will be pivotal in the global effort towards net zero [1]. The two half reactions of water splitting; the hydrogen evolution reaction (HER, $2H^+ + 2e^- \rightarrow H_2$) and the oxygen evolution reaction (OER, $2H_2O \rightarrow O_2 + 4H^+ + 4e^-$), currently rely on Pt group metals such as Pt and Ru, and Ir and Ru oxides, when performed in acidic media. Overpotentials are still observed for these catalysts due to the sluggish kinetics of the reactions, with OER typically the rate limiting reaction [2]. It is therefore instructive to find alternative oxides to replace Ir and Ru. Nonprecious transition metal-based oxides may provide cheaper and more abundant OER catalysts. Unfortunately, these oxides are not stable in the acidic media, and therefore must be studied in alkaline media [3].
The activity of transition metal-based catalysts relates to their electronic structure, specifically the energy difference between the valence d-band centre and the Fermi level (E_F) [4]. An increase in the energy difference usually results in a stronger interaction of the orbital and the adsorbate. The strength of this interaction in terms of catalytic activity is described by the Sabatier Principle. Therefore, tailoring the optimal energy of the d-band for the reaction of interest will allow for improved catalytic efficiency. Ni, Fe and Co based catalysts and their alloys have shown great promise as OER catalysts [5,6]. Multicomponent alloys (MCAs) exhibit improved corrosion resistance relative to the elemental constituents whilst still containing catalytically active elements such as Ni,Fe and Co. This synergistic relationship between the elements make MCAs promising as successful OER catalysts.
Here, size-selected nanoparticles are deposited via a state-of-the-art gas-phase synthesis. Using a quadrupole mass spectrometer placed in-line with the source, the size of the nanoparticles are well defined and controlled. Initial depositions of NiFeCoMoAl and NiFeCoMoCr have been successful, and characterised on an atomic scale using transmission electron microscopy (TEM). Hard and soft X-ray photoelectron spectroscopy (HAXPES and SXPS, respectively), measured at the i09 beamline at Diamond Light Source, gives depth resolved compositional information showing the presence of all elements as well as their possible arrangement within the nanoparticles. Meanwhile atom probe tomography (APT) measurements, made possible by simultaneous nanoparticle deposition and conventional magnetron sputtering, allow us to marry the information gathered using TEM and SXPS/HAXPES. The structural and chemical information thereby obtained is compared with electrochemical measurements of the intrinsic activities of different MCAs, revealing trends in valence band measurements from SXPS and activity. Unifying these complimentary techniques gives insight into the relationship between the atomic and electronic structure with electrochemical activities of MCA nanoparticles which will feed into future electrocatalytic design and will be a stepping stone in the wider effort of achieving net-zero emissions.

Simple Synthesis of Perovskite oxides/FeOOH with N-Doped Graphene Quantum Dots to Boost Electron Transfer Sang HeonKim and Jeong MinBaik; Sungkyunkwan University, Korea (the Republic of)

Bifunctional electrocatalyst requires superior charge transfer and good electrochemical performance to produce overall and stable water splitting reaction. Perovskite oxides (ABO_3) have a good performance in oxygen evolution reaction but poor in hydrogen evolution reaction. Iron (oxy)hydroxides (FeOOH) show good electrochemical performance in hydrogen evolution reaction but have low conductivity. Herein, we successfully synthesized the LaSrCoO/N-GQD/FeOOH composites via impregnation method and high energy ball-milling, which exhibited an efficient OER and HER performance with a lower overpotential of 300mV and 420mV at 10mA cm^{-2}. Also, composites have a lower Tafel slope value of 51mV dec^{-1} compared with simple LaSrCoO@FeOOH composites. In the overall electrochemical water splitting system, the LaSrCoO/N-GQD/FeOOH showed excellent stability at 1 A cm^{-2} over 100 h in full cell voltage. These LaSrCoO/N-GQD/FeOOH composites will provide the development of designing other electrocatalysts and give new way in boosting electron transfer induced by intermediate electron bridge materials.

Lattice Anion Redox in Perovskite Oxides under Oxygen Evolution Conditions AndrewAkbashev; Paul Scherrer Institute, Switzerland

Oxygen evolution reaction causes structural transformations and metal dissolution in most oxide electrocatalysts. In my talk, I will discuss how oxidative conditions cause intercalation of O^{2-} and can lead to the formation of oxidized oxygen inside the crystal lattice. Detection of anion oxidation is notoriously challenging and its unambiguous detection in electrocatalysts has been elusive so far. In our work, we used high-resolution resonant inelastic X-ray scattering (RIXS) to detect the oxidation state of oxygen in perovskites after OER, employing single-crystalline materials as model electrocatalysts. I will show that the emergence of oxidized oxygen depends on the transition metal and the amount of intercalation oxygen. In the end, I will discuss the possible relationship between lattice oxygen oxidation and the degradation of perovskite electrocatalysts during OER.

Unveiling the Optimal Interfacial Synergy of Plasma-Modulated Tetrametallic Ni−Co−Mn−Fe Phosphide Electrocatalysts Synthesized by a Facile Electrodeposition Method for High-Performance Overall Water Splitting: DFT Study MennaM. Hasan[1], AyaK. Gomaa[1], GhadaKhedr[2] and NagehK. Allam[1]; [1]American University in Cairo, Egypt; [2]Egyptian Petroleum Research Institute, Egypt

In the recent few decades, the demand for green sources of energy that are clean and sustainable became very essential to reduce the greenhouse and global warming problems. Consequently, there is an increasing demand to identify nonprecious, cheap bifunctional electrocatalysts for water splitting. Herein, nanosheets of different earth-abundant Ni, Co, Mn, and Fe combinations are electrodeposited over commercial Ti mesh and tested for the overall water splitting. The bare Ti mesh requires overpotentials of −486.6 mV at −10 mA cm−2 and 534.5 mV at 10 mA cm−2 for the hydrogen evolution reaction (HER) and oxygen evolution reaction (OER), respectively. However, the electrodeposited catalysts show much higher catalytic activity for both HER and OER with overpotentials of −300 and 279 mV at −10 and 10 mA cm−2, respectively, lowering the overpotential needed to drive the OER by 50%. Nevertheless, to enhance the electrocatalytic performance of the fabricated catalysts, they are phosphidized using different phosphorous precursors. The resulted NiCoMnFe−P catalysts exhibit much lower HER overpotential (−200 mV at −10 mA cm−2), which is 40% lower than that needed by the bare Ti mesh. For the overall water splitting, a cell voltage of 1.71 V is recorded to achieve a current density of 10 mA cm−2. Lastly, the stability test of the overall device reveals very high stability with current retention of 90% over 22 h of continuous electrolysis. Furthermore, the synergy between the metallic components in the absence and presence of P is elucidated using density functional theory calculations, revealing optimized GH* and GHd2O* for the HER reaction over the P-top site of the MnFeCoNiP catalyst. In addition, the calculations explain the superiority of the NiCoMnFe catalyst over the NiCoMnFeP counterpart for the OER.

8:00 PM EN07.06.02
MOF Tessellation of Cation Defects-Rich 3D Bifunctioanal ORR/OER Electrocatalyst for Rechargeable Zinc-Air Batteries GopalakrishnanMohan and SoorathepKheawhom; Chulalongkorn University, Thailand

A cost-effective bifunctional electrocatalyst for oxygen reduction reaction (ORR) and oxygen evolution reaction (ORR) is essential for rechargeable zinc-air batteries (RZABs). Herein, we report porous nanorod-like NiFe@MOFs with tunable structures and multiple coordination modes showing fascinating architectures for the preparation of high-performance electrocatalysts. By tuning the structure and optimizing the Ni/Fe ratio, $Fe_2O_3/Ni_{0.6}Fe_{2.4}O_4$@NC having a large surface area, porosity, and abundant cation vacancies, is successfully developed. It shows excellent activities for both ORR ($E_{1/2}$ = 0.856 V) and OER (η_{10} = 1.54 V @ 10 mA cm^{-2}). By using density functional theory (DFT) calculations, ORR and OER mechanistic pathways are studied. Furthermore, RZAB using $Ni_{0.6}Fe_{2.4}O_4$@NC catalyst demonstrates a high open circuit voltage (OCV) of 1.5 V, a peak power density of 187 mW cm^{-2}, and exceptional long-term cycling stability over 300 h (1800 cycles, 10 mA cm^{-2}). The flexible solid-state ZAB using $Ni_{0.6}Fe_{2.4}O_4$@NC catalyst exhibits a power density of 66 mW cm^{-2} and long-term durability over 43 h at 5 mA cm^{-2}. The proposed strategy allows for the rational design of cation defect-rich NiFe spinel structures attached to ultra-thin N-doped graphitic carbon sheets in order to enhance active site availability and facilitate mass and electron transport.

8:00 PM EN07.06.03
Evaluation of Activation Process for the Catalyst of Polymer Electrolyte Electrochemical Cell for Hydrogen Generation ItsukaAkita[1,2], MiyukiNara[2], KazukiKoike[1,2], TakayoOgawa[2], KatsushiFujii[2], SatoshiWada[2] and AtsushiOgura[1,3]; [1]Meiji University, Japan; [2]RIKEN RAP, Japan; [3]MREL, Japan

Requirements for renewable energy are increasing to suppress global warming and to keep natural resources. Hydrogen by water electrolysis is useful as an energy storage way to realize the use of fluctuating renewable energy sources. Especially, polymer electrolyte electrochemical cell (PEEC) is attractive since it is a practical method for hydrogen production. The PEEC has a flexibility of scale adaptability for systems ranging from W- to kW-scale. The efficiency improvement of PEEC is an important issue to improve the energy system performance. To obtain the optimal performance of PEEC, activation is practically important, however, the mechanisms are still obscure. It is believed to bring the membrane and catalyst into specific conditions by activation.
In this study, we focused on the activation of PEEC with the cathode catalyst of Pt/C and the anode catalyst of IrOx. We investigated the activation processes by current density. The idea is based on the changes in the valency of iridium oxide. The oxygen evolution reaction (OER) is promoted by the valence change of iridium. Various valency change models have been proposed, but they were difficult to specify because the reaction takes place at the interface and is difficult to observe. Recently, the results of in-situ and ambient XPS, XAFS, and DFT simulations suggested that metastable iridium oxides with valences higher than tetravalent are the main contributors to OER [1]. It was also reported that the valency change of iridium oxides depends on the applied voltage.
In this study, the valency controls with the electron injection speed, that is, the current. The amounts of electrons were not the same, but the current was applied at the same time. That is, the activating currents (none, 0.1, 1.0, 10, 100 mA/cm^2, in this order) were applied for 1 hour to evaluate the activation. The evaluation method was the current value at 2.0 V when the voltage was swept with 10 mV/s from 1.45 V to 2.0 V and then a constant voltage of 2.0 V was applied for 5 minutes after the voltage change. After the measurement, sweeping from 2.0 V to 0.0 V

with 1 mV/s and maintaining 0.0 V for 30 min was performed as deactivation process.
The voltage changes during the activation processes were different. The voltage reached 1.27 V and increased continuously even after 1 hr when the activating current was 0.1 mA/cm^2. The voltage reached 1.46 V before 1 hr passed and kept the values when the other activating currents were applied. The current density-increasing rates were also similar for all cases.
The turn-on current densities were the same for all activation processes at voltage sweeping. However, the current density slopes were different, and the current densities at 2.0 V applied were 0.573, 0.575, 0.602, 0.597, and 0.592 A/cm^2 when the activation currents were none, 0.1, 1.0, 10, and 100 mA/cm^2, respectively.
The current density changes during the voltage kept at 2.0 V were similar for all cases and the current density slightly decreased with time, except for no activation process which the current density increased at the beginning.
The valency change of IrOx was reported to occur at around 0.9, 1.3, and 1.5 V as valency from 3+ to 4 to 4+, respectively [1]. The results show the valency change at around 1.5 V is important to activate the IrOx. The activation current of 0.1 mA/cm^2 was not enough for activation from this. Since the current density at the 2.0 V application decreases with the activation current over 1.0 mA/cm^2, the amount of the activation charge and/or the activation speed may be also important for the activation process.

Balancing Volmer Step by Dual-Active Domains for Enhanced Hydrogen Evolution JinsongZhou[1,2]; [1]City University of Hong Kong, China; [2]ETH Zürich, Switzerland

Renewable energy technologies, due to anthropogenic effects on finite fossil fuel resources and the environment, are pivotal to the sustainable development of society. Hydrogen with high energy density makes it a potential alternative energy source and could be electrocatalytic produced by carbon-free water splitting with the support of other intermittent renewable energies.

As a half-reaction to directly generate hydrogen in alkaline/neutral media, the reaction kinetics of hydrogen evolution reaction (HER) is primarily determined by balancing the Volmer step. Bifunctionality as a proposed strategy, providing two types of active sites that possess different reaction processes, divides the Volmer step ($H_2O + e^- \rightarrow H_{ad} + OH^-$, ad means adsorption) into water dissociation ($H_2O \rightarrow OH_{ad} + H^+ + e^-$) and intermediates adsorption/desorption ($H^+ + e^- \rightarrow H_{ad}$ and $OH_{ad} + e^- \rightarrow OH^-$). However, sluggish OH_{ad} desorption because of relatively strong binding energy plagues water re-adsorption, which leads to poisoning effects of active sites and limits the overall HER reaction rate. Also, some active sites may directly act as spectators and do not participate in the reaction. Designing two appropriate active sites to achieve a balanced state of each performing its functions isn't easy. Furthermore, the activity comparison under approximate nanostructure between bifunctionality and single-exposed dual-active sites is not fully illustrated.

A facile three-step synthesis strategy is adopted to form prominent dual-active domains successfully. The active sites on different domains and the tuned electronic structure at the heterointerface trigger the bifunctionality to balance the Volmer step and improve the catalytic activity. The HER driven by the bifunctionality could significantly optimize the Gibbs free energy of water dissociation and intermediates adsorption/desorption, resulting in fast reaction kinetics and superior catalytic performance compared with the single-exposed dual-active domain by purely electronic modulation.

8:00 PM EN07.06.05
3D Printed Pyrolysed Electrode Modified with Nickel and g-C_3N_4 for Hydrogen Evolution Reaction NadiraMeethale Palakkool[1], MikeTaverne[1], KevinChung-Che Huang[2], VincentBarrioz[1], YongtaoQu[1] and Ying-LungDaniel Ho[1]; [1]Northumbria University, United Kingdom; [2]University of Southampton, United Kingdom

Hydrogen, derived from water electrolysis, has emerged as a promising alternative to fossil fuels, offering a clean and recyclable energy solution. However, despite its remarkable attributes, the widespread adoption of hydrogen faces significant challenges because of its viability as a practical solution. One of the major obstacles is the affordability of water electrolyser systems, which play a crucial role in the production of hydrogen through water electrolysis. Secondly, the sluggish kinetics of oxygen evolution reactions (OER) hinder the overall performance of the water electrolysis.
Herein, we propose the fabrication of a free-standing 3D electrode based on stereolithography 3D printing of polymer which can be functionalized via a series of post-processing treatments using non-noble metal-based materials. By subjecting the 3D polymer to a thermal decomposition process via vacuum furnace annealing, we were able to transform it into a conductive and stable electrode material. To enhance the electrochemical performance of the electrodes, post-processing involves nickel electroplating followed by chemical vapour deposition (CVD) of graphitic carbon nitride (g-C3N4), derived from melamine. These steps aimed at exploring the potential of further improving the conductivity and catalytic properties of the 3D electrodes. Different diamond lattice-based crystal structures such as tapsterite, rod-connected diamond (RCD) and F-rhombic dodecahedron (FRD) are investigated providing controllability over the electrode surface area and geometries. These geometries are inspired by the atomic arrangement of tapsterite, diamond-like crystals with interconnected rod-based structures, offering unique topological features for electrode design. Moreover, these structures provide a larger surface area, facilitating gas diffusion rate and thereby improving electrocatalytic water splitting.
Cyclic voltammetry measurements were conducted in alkaline electrolytes to evaluate the electrochemical behaviour of the 3D graphitic electrode. The CV curve exhibits a smooth and continuous shape without significant sharp peaks or irregularities. The current response shows gradual changes as the potential is scanned within the chosen range. One notable observation from the CV analysis is the increased area under the curve after post-processing of the electrode. This expanded area indicates improved electrochemical performance and suggests an enhanced active surface area of the electrode. To gain insights into the surface morphology and elemental composition of our sample, we performed scanning electron microscopy (SEM) and energy-dispersive X-ray spectroscopy (EDS) analysis. The rate of thermal decomposition was found to affect the morphology of the pyrolyzed carbon.
Furthermore, the EDS spectra of post-processed electrodes indicated the presence of nickel and nitrogen when compared to the pre-processed carbon electrode. The detection of nickel suggests successful electroplating, while the presence of nitrogen indicates the incorporation of carbon nitride during CVD steps. Owing to the low composition of nickel in the electrode, the electroplating process will be further optimized to enhance the deposition and improve their composition for desired electrochemical performance.
Further, this work explores the electrochemical performance of the 3D electrode via electrochemical measurements using rotating disk electrodes. Furthermore, the material will be characterized using X-ray diffraction spectroscopy (XRD) and X-ray photoelectron spectroscopy (XPS). In conclusion, this work aims at leveraging the capabilities of 3D printing technology and enhancing the commercial viability of hydrogen-generating systems using earthly abundant materials.

Structure-Activity Elucidation of Stainless Steel Waste Meshes as Efficient Oxygen Evolution Catalysts NagehK. Allam; American University in Cairo, Egypt

Herein, the ability to convert waste stainless steel (SS) 316L meshes into highly efficient and durable oxygen evolution reaction (OER) catalysts is demonstrated. The process involves surface treatment of previously anodized SS meshes in different gaseous atmospheres. The activity of the resulted electrocatalysts varies as-anodized SS annealed in oxygen (ASS-O_2) > anodized SS annealed in hydrogen (ASS-H_2) > anodized SS annealed in air (ASS-Air). The ASS-O_2 showed an impressive low overpotential of 280 mV at the benchmark current density of 10 mA/cm^2, which is 120 mV less than that of the as-received SS (SS-AR), and a low Tafel slope of 63 mV dec^{-1} in 1 M KOH. These findings have also been asserted by the estimated electrochemical active surface area, electrochemical impedance spectroscopy analysis, Mott–Schottky analysis, and the calculated turnover frequency, affirming the superiority of the ASS-O_2 electrocatalyst over the ASS-H_2 and ASS-Air counterparts. The high activity of the ASS-O_2 electrocatalyst can be ascribed to the surface composition that is rich in Fe^{3+} and Ni^{2+} as revealed by the X-ray photoelectron spectroscopy analysis. The simple method of anodization and thermal annealing in O_2 at moderate conditions (450 °C for 1 h) lead to the formation of a SS mesh-based OER electrocatalyst with activity exceeding that of the state-of-the-art IrO_2/RuO_2 and other complex modified SS catalysts. These results were also confirmed via density functional theory calculations, which unveiled the OER reaction mechanism and elucidated the d-band center in different SS samples with different oxygen content. The presence of oxygen moved the d-band center closer to the Fermi level in the case of ASS-O_2, explaining its superior activity.

8:00 PM EN07.06.07
Fabrication and Characterization of Ag/TiO_2 Composite Photoanode for Photoelectrochemical Water Splitting Application YaowapaTreekamol and RewatMaensiri; Khon Kaen University, Thailand

The purpose of this work is to investigate photoelectrochemical performance of composite electrode between titanium dioxide (TiO_2) and silver nanoparticles (AgNPs). AgNPs were employed due to a surface plasmon resonance effect that can improve visible light absorption and decrease electronhole recombination of TiO_2. Preparation of Ag/TiO_2 composite electrode with different amount of AgNPs
from 20, 40, 60, 80 and 100 ppm were carried out by ball milling process. After that, characterization by XRD, Raman, UV-Vis, SEM, EDX and FTIR technique were examined. The crystallinity and phase purity of bare TiO_2 and Ag/TiO_2 were
characterized by XRD and Raman analyses, which confirm the rutile phase and presence of AgNPs on surface of TiO_2, respectively. FTIR spectra result confirmed the presence functional group and interaction of AgNPs on surface of TiO_2. SEM images show that the distributed and particles size of bare TiO_2 and Ag/TiO_2 nanoparticles in the range of 20-30 nm. The elemental composition of Ag/TiO_2 was detected by EDX analysis that confirms the presence of oxygen, silver and titanium, respectively. The UV-Vis absorption spectra of AgNPs shows an absorption peak at 400 nm. Finally, photoelectrochemical performance were performed using cyclic voltammetry measurement. CV curves showed a current density at 1.23 V (vs. Ag/AgCl) for TiO_2 and Ag/TiO_2 electrode which are 1.15 and 1.83 μA/cm^2. It can be
concluded that an addition of AgNPs resulted in better photocurrent which related to higher photoelectrochemical performance in water splitting for hydrogen production.

8:00 PM EN07.06.08
Role of Nucleation Growth Reaction Parameters of 2D-MoS_2 Towards HER Application RameshAvala and SukantiBehera; Maulana Azad National Institute of Technology Bhopal, India

Transition metal dichalcogenides (TMDs) are a family of two-dimensional (2D) materials and MoS_2 has been used for electrical and electrocatalytic properties. Here we report the synthesis of powder molybdenum disulphide (MoS_2) by using wet-chemical method with varied reaction duration time (0, 2, 4, 6, 8 days) from each filtration, and towards hydrogen evolution reaction (HER). Powder 2D-MoS_2 was obtained by using ammonium heptamolybdate ($(NH_4)_6Mo_7O_{24}.4H_2O$) and thiourea (N_2H_4CS) as precursors and (N_2H_4) as a catalyst in the presence of basic media (pH=10). The single phase of MoS_2 was confirmed by operating the powder X-ray diffraction method. The major peak 2 value at 13.8 indexed as (002) plane. Also, Raman spectra (E^1_{2g} = 379 cm^{-1} & A_{1g} = 404 cm^{-1}) including extra peaks which is J_1, J_2, E_{1g}, and J_3 indicates both 1T/2H-MoS_2 phases. Spherical shape of morphological studies were characterized by scanning electron microscopy (SEM) & transition electron microscopy (TEM).The results of the electrocatalytic Hydrogen evolution reaction (HER) confirm that 1T/2H-MoS_2 synthesized with varied reaction parameters exhibit high efficiency with instant filtered material (0 days) compared to longer duration time.

8:00 PM EN07.06.09
RuO_2 Supported on the PdPb Multi-Frame for Enhanced Electrocatalytic Performance for Oxygen Evolution Reaction in Acidic Media DoyeopKim and KwangyeolLee; Korea University, Korea (the Democratic People's Republic of)

Electrochemical water splitting offers a promising carbon-free method for hydrogen production, which can greatly reduce reliance on fossil fuels. However, one major challenge in enhancing the efficiency of this process depends on the sluggish kinetics of the oxygen evolution reaction (OER). Existing catalysts based on Ru nanoparticles show remarkable activity for acidic OER but are susceptible to dissolution in acidic conditions, limiting their stability. We have developed a novel approach to synthesizing RuO_2 catalysts supported by PdPb multi-frames to address this issue. This involved a seed-mediated growth method followed by thermal oxidation, stabilizing the Ru-based nanocatalyst. Through temperature control of thermal oxidation, it is possible to adjust the degree of doping of Pd into RuO_2, and the presence of Pd doped in RuO_2 prevents overoxidation, leading to exceptional catalytic activity and remarkable stability for the acidic OER. This study suggests an ideal synthesis method for efficiently introducing dopants into RuO_2-based catalysts while also providing a new understanding of catalyst development with improved performance in acidic conditions for the OER.

8:00 PM EN07.06.10
Block Copolymer Mediated Synthesis of TiO_2/RuO_2 Nanocomposite for Efficient Hydrogen and Oxygen Generation BinodR. K C and BishnuBastakoti; NC A&T State University, United States

Abstract: Ruthenium oxide (RuO_2) is one of the most effective electrocatalysts reported for oxygen evolution reaction (OER) but still has insufficient stability for practical water splitting. To solve this problem, herein we report the fabrication of TiO_2/RuO_2 nanocomposite by sol-gel method. An amphiphilic block copolymer, poly (styrene-polyvinyl pyridine-ethylene oxide) was used as structure directing and stabilizing agent. The strong interaction of polymer with metal precursors led to the formation of a heterointerface for synergetic effect and acts as a bridge for the electron transport which can accelerate the water splitting reaction. Scanning electron microscopy, energy dispersive X-ray spectroscopy, transmission electron microscopy, and X-ray diffraction analysis of prepared TiO_2/RuO_2 sample revealed successful fabrication of TiO_2/RuO_2 nanocomposite. The electrochemical water splitting properties of prepared sample were measured by three electrode system in 0.1M KOH electrolyte which showed improved electrochemical properties of prepared sample.

This work was primarily supported by a DOE EFRC on The Center for Electrochemical Dynamics And Reactions on Surfaces (CEDARS) via grant # DE-SC0023415.

8:00 PM EN07.06.11
Heterostructured Ternary Transition Metal Oxide Composite as an Efficient Electrocatalyst for Improved Hydrogen Generation SoohongLee, MinKyeongKim and JohnHong; Kookmin University, Korea (the Republic of)

As the use of fossil fuels increases, there is growing concern about energy and environmental crises. Therefore, there is a significant demand for environmentally friendly and sustainable energy resources to replace them. Hydrogen is attracting attention as an energy resource that can replace fossil fuels because it is carbon-neutral and can achieve high energy generation efficiency through fuel cells. The most important topic related to hydrogen energy is how we can generate green hydrogen. One of the promising candidates for green hydrogen is water electrolysis, which involves both the oxygen evolution reaction (OER) and the hydrogen evolution reaction (HER). In practical water electrolysis, it is important to reduce over-potential and improve Tafel kinetics using efficient electrode catalysts. However, the most promising catalysts for water splitting, such as Pt, Ru, and Ir, are not abundant and have high costs. Therefore, finding a new noble metal catalysts that exhibit high reactivity, low cost, and long-term durability is important.

In this study, a highly efficient hydrogen generation catalyst with unique heterostructures was synthesized by utilizing three different transition metal composites through hydrothermal synthesis on a Ni-based substrate. Specifically, ternary transition metal oxides (TTMO) consisting of Ni, Fe, and Co were synthesized as the final catalyst product. According to the suggested electrode material, the synergistic contribution between these ternary transition metal atoms can lower the over-potential, increase the Tafel kinetics, and improve the long-term stability of the water-splitting system. The TTMO composites exhibit much better hydrogen evolution reaction (HER) performance than binary transition metal oxide composites, delivering current densities of approximately 10 and 100 mA cm^{-2} at low over-potentials of 43 mV and 86 mV, respectively, compared to 51 mV and 93 mV for binary transition metal oxide composites. Also, the TTMO composites show a Tafel slope of 33.54 mV dec^{-1}. Finally, the TTMO composite can result in long-term catalytic stability over 5,000 cycles at the high current density of 100 mA cm^{-2} with negligible over-potential degradation. The excellent performance of the proposed TTMO composites is attributed to their unique heterostructures and the newly designed ternary transition metal surface sites (balanced-hybridized sites). These findings provide insight into the utilization of ternary transition metal composites for HER and other catalysis applications.

8:00 PM EN07.06.12
Oxygen Evolution Reaction Properties of the Tetragonal Structure-Based Transition Metal Oxides Sung RyulChoi, SeojeongYoo and Jun-YoungPark; Sejong University, Korea (the Republic of)

ABSTRACT
The increasing share of renewable energy in overall energy production has emphasized the urgent necessity for the development of advanced energy storage and conversion technologies by using power-to-gas (P2G) technology. P2G technology involves the electrolysis of water to generate hydrogen using excess electricity derived from solar or wind power [1]. Additionally, it aims to address the technical challenges associated with intermittency power generations of renewable energy sources [1]. Among the available various P2G technologies, alkaline water electrolysis (AWE) is currently the most technically mature energy storage and conversion electrochemical device [2].
Despite its technical maturity, the commercialization of AWE technology faces a significant obstacle in the form of low energy conversion efficiency [3]. The primary reason behind this low energy efficiency in AWEs is the sluggish kinetics of the oxygen evolution reaction (OER) in the anode [4]. Although anode catalysts such as ruthenium and iridium have shown excellent OER activity, their practical application is hindered by their high cost due to scarcity and poor durability [5].
In contrast, transition metal oxides based on spinel, perovskite, and Ruddlesden-Popper structures have garnered considerable attention due to their exceptional OER activity and long-term durability, while being relatively more affordable [6-9]. Recently, Swedenborgite materials with a layered structure composed of triangular and Kagome layers arranged along the c-axis have received interest because of their high OER activity in the application of high-temperature solid-oxide cells [10-12]. In this study, we investigate the OER properties of the tetrahedral-structured Swedenborgite material, including its fundamental structure characteristics, the impact of transition metal doping, and the underlying OER mechanism.

InterIntermolecular Electron Transfer in Electrochemically Exfoliated BCN-Cu Nanosheet Electrocatalysts for Efficient Hydrogen Evolut MennaM. Hasan, GhadaKhedr, NagehK. Allam and FatmaZakaria; American University In Cairo, Egypt

The search for materials with superior electrocatalytic performance has attracted attention during the past few years aiming to identify a convenient material that works at a low overpotential with long-term stability. Herein, we introduce an innovative technique to fabricate two-dimensional BCN heterostructure nanosheets with various Cu:BCN weight ratios. The fabricated composites showed unique electrocatalytic properties for hydrogen evolution reaction (HER). The morphology and structure of the electrocatalysts were characterized using field emission scanning electron microscopy, Raman, Fouriertransforminfraredspectroscopy, andX-ray photoelectron spectroscopy techniques. Remarkably, this study reveals the effect of electrochemical chronopotentiometry on facilitating the electrochemical exfoliation and hence enhancing the catalytic activity of the fabricated nanosheets. This effect was further confirmed via density functional theory (DFT) calculations, unveiling the effect of the formed oxide layer on the charge transfer process. The overpotential of the 0.125 Cu-BCN composite at a current density of -10 mA/cm2 vs RHE is 50% lower than that of pristine BCN. These findings were also affirmed by the DFT calculations, which showed that incorporating copper on BCN has significantly reduced the GH*value of the HER and subsequently accelerates the kinetics of the reaction and the overall catalytic activity of the material.

Synthesis of Two-Dimensional Tantalum Carbo-Selenide and their Electrochatlaytic Performance for Hydrogen Production ElhamLoni[1], AhmadMajed[1], ChaochaoDun[2], KarammullahEisawi[1], AnikaTabassum[3] and MichaelNaguib[1]; [1]Tulane University, United States; [2]Lawrence Berkeley National Laboratory, United States; [3]University of the District of Columbia, United States

Two-dimensional transition metal carbo-chalcogenides (TMCCs) consist of early transition metal carbide core and chalcogen surface (e.g., S, Se, and/or Te). They are promising candidates for energy storage applications, such as ion batteries, supercapacitors, and water-splitting applications since they can have both properties of carbides and chalcogenides, such as electrical conductivity and catalytically active, respectively. In this work, we report on the synthesis of two-dimensional Ta_2Se_2C (2D-Ta_2Se_2C) through the electrochemical intercalation to introduce lithium into multilayer (m- Ta_2Se_2C), followed by sonication in deionized water. The m-Ta_2Se_2C material was obtained through a solid-state synthesis of $Fe_xTa_2Se_2C$, followed by a chemical etching process. The electrocatalytic performance of 2D-Ta_2Se_2C was found to be significantly superior to that of both multilayer Ta_2Se_2C and 2D-$TaSe_2$ when utilized as an electrocatalyst for the hydrogen evolution reaction. Notably, 2D-Ta_2Se_2C displayed an overpotential at 10 mA cm^{-2} of 260 mV, a Tafel slope of 91.4 $mV.dec^{-1}$, and an electrochemically active surface area of 780 $cm^2.g^{-1}$. These enhancements can be attributed to the extensive surface area of individual nanosheets, which maximizes the availability of catalytic sites, as well as the more open structure of Ta_2Se_2C in contrast to $TaSe_2$.

8:00 PM EN07.06.16
Investigating Synthesis Route Effect on the Electrochemical Performance of $LiNi_{0.6}Co_{0.2}Mn_{0.2}O_2$ Cathode Materials for Li-Ion Battery MesfinA. Kebede[1], EmmanuelMannzhi[2] and RebeccaMhlongo[2]; [1]University of South Africa - Science Campus, South Africa; [2]Sefako Makgatho Health Science University, South Africa

In this work Ni-rich $LiNi_{0.6}Co_{0.2}Mn_{0.2}O_2$ (NCM622) cathode materials were synthesized via combustion and solgel routes, to investigate the effect of synthesis route on the electrochemistry of the cathodes. The structural and electrochemical properties of the samples were confirmed by XRD, SEM, TEM and battery testing. The electrochemical properties of layered Ni-rich NMC622 cathode materials synthesized adopting these two synthesis routes were compared. The results confirm that the NMC622 cathode samples prepared by combustion synthesis route exhibited a better electrochemical performance than the samples synthesized by solgel method for the cycling stability and rate capability. The NCM622-Com delivered a first capacity of 206 mAh g^{-1} and retained 132 mAh g^{-1} after 100 cycles, whereas NCM622-Sol delivers only 141 mAh g^{-1} and retained 115 mAh g^{-1} after 100 cycles. Similarly, for the rate capability the NMC622-Com performed higher for all the current rates.
In this work, we are presenting the comparison of the sol-gel and combustion synthesis routes on the electrochemical performance of Ni-rich $LiNi_{0.6}Mn_{0.2}Co_{0.2}O_2$ cathode materials. The detail structural, morphological, cyclic voltammetry, and galvanostatic charge/discharge capacity results will be discussed.

8:00 PM EN07.06.17
Understanding of Growth and Electrolytic Hydrogen Evolution of Directly Deposited 2D NiO Electrodes *via* Alkali-free Chemical SynthesisUmeshT. Nakate[1], JeongsikChoi[2], Dong-WonKim[1,1] and SungjunePark[3]; [1]Hanyang University, Korea (the Republic of); [2]Jeonbuk National University, Korea (the Republic of); [3]Sungkyunkwan University, Korea (the Republic of)

Nanostructured metal oxides have been identified as potential candidates for electrochemical applications owing to their various properties such as high surface-to-volume ratio, number of active sites/ receptor functions, re-dox properties, thermal stability, semiconducting nature, structural properties, *etc*. The nano size (dimensions) has a significant impact on the physicochemical properties of metal oxide *via* its quantum effect. However, structural properties like growth, orientation, texture co-efficient, and defects also govern the performance of the material. The synthesis/preparation conditions primarily decide the nano size as well as the structural properties of the material. Hence, it is quite crucial to develop novel and unique synthesis routes to reveal the enhanced properties of the materials. Reducing the use of additional reactants and reagents/surfactants in synthesis could be advantageous in terms of synthesis cost reduction, unwanted impurities, crystal purity, repeatable output, growth simplicity, *etc*.
Herein, an alkali/buffer-free easy chemical hydrothermal route has been adopted to grow 2D NiO nanoplates electrodes. The synthesis parameters *viz* concentration and temperature could tune the thickness of the nanoplates leading to changes in structural and electrocatalytic properties. The electrochemical characteristics *viz* linear scan voltammetry (LSV), Tafel, Electrochemical impedance spectroscopy (EIS) Nyquist plot, cyclic voltammetry and chronopotentiometry, turnover frequency (ToF), Electrochemical surface area (ECSA), *etc* were investigated for prepared electrocatalyst electrodes. The electrocatalysts were characterized using XRD, FESEM, HR-TEM, EDS, mapping, XPS, *etc* standard tools. The different noble metal (Pd/Au/Ag/ Ru) decoration on the optimized 2D NiO electrodes was carried out *via* a wet impregnation technique and their electrolytic hydrogen evolution performance was studied. The Pd-decorated NiO electrodes were observed to have high hydrogen evolution performance. The different amounts of Pd decoration on NiO were performed and optimal Pd-NiO electrocatalyst was studied in detail. The optimal Pd-NiO electrodes exhibited a high HER activity with an overpotential of 90 mV, achieving a current density of 100 mA cm^{-2} and a Tafel slope of 52.05 $mVdec^{-1}$ in 1 M KOH solution.
Further, the density functional theory (DFT) studies were carried out *via* first principle calculation to support the experimental results. The Pd/NiO exhibited a lower water dissociation energy barrier (0. 35 eV) than NiO (0.46 eV), suggesting that the dissociation of H_2O easily occurs on the surface of the Pd/NiO catalyst. The formation of Pd/NiO heterojunction improves the HER activity. The change in Gibb's free energy of Pd/NiO heterostructures is about -0.52 eV, which is lower than pristine NiO (-0.78 eV). The experimental and theoretical analyses are in good agreement.
The present synthesis technique and architecture of Pd decorated NiO nanoplates is a promising strategy and could be the potential candidate for fulfilling sustainable energy needs *via* high-performance hydrogen evolution reaction.

SESSION EN07.07: CO2/NOx Reductions I

Insights into Interfacial Phenomena Driving Fast Carbon Isotopes Separation during CO2 Electroreduction MagdaH. Barecka[1], MikhailKovalev[2], MarshaZakir Muhamad[2], HangjuanRen[2,3], JoelW. Ager[4,5,6] and AlexeiLapkin[2]; [1]Northeastern University, United States; [2]Cambridge Centre for Advanced Research and Education in Singapore, Singapore; [3]University of Oxford, United Kingdom; [4]Lawrence Berkeley National Laboratory, United States; [5]University of California, Berkeley, United States; [6]Berkeley Education Alliance for Research in Singapore, Singapore

Isotopes of carbon and kinteic effects related to the reactivity of carbon 12 vs carbon 13 have been widely explored to elucidate reaction mechanisms and metabolic pathways. We discovered that under the conditions of carbon dioxide (CO_2) electroreduction in gas-diffusion electrodes, the kinetic isotope effect is much higher than expected based on known carbon kinetic isotope effect during CO_2 absorption in oceans or phosynthetic conversion of CO_2 to reduced forms of carbon. Our experiments demonstarte that CO_2 electroreduction strongly favours the conversion of the dominant isotope of carbon (^{12}C) and discriminates against the less abundant, stable carbon ^{13}C isotope during all steps of the electrochemical process, and mostly at the triple phase interface created in gas-diffusion electrode based reactors. Using a natural abundance CO_2 feed, we experimentally demonstrate enriching of the ^{13}C fraction to ~1.3% (+18%) in a single pass reactor, being an unprecendently fast isotope separation. This talk will provide insights into the interfacial phenomena, being a part of a complex istope discrimination mechanism, which we anticipate to be applicable across a wide range of electrochemical systems.

8:30 AM EN07.07.02
Influence of the Gas Diffusion Layer on the Reaction Microenvironment of Electrochemical CO2 Reduction Surani BinDolmanan[1], AnnetteBoehme[2,2], ZitingFan[3], HarryA. Atwater[2,2] and YanweiLum[1,3]; [1]Agency for Science, Technology and Research, Singapore; [2]California Institute of Technology, United States; [3]National University of Singapore, Singapore

Gas diffusion layers (GDL) have become a critical component in electrochemical CO_2 reduction (CO_2R) systems because they can enable high current densities needed for industrially relevant productivity. Besides this function, it is often assumed that the choice of catalyst and electrolyte play much more important roles than the GDL in influencing the observed product selectivity. Here, we show that tuning of the GDL pore size can be used to control the local microenvironment of the catalyst and hence, effect significant changes in catalytic outcomes. This concept is demonstrated using sputtered Ag films on hydrophobic PTFE substrates with 6 different pore sizes. Although Ag is known to be a predominantly CO generating catalyst, we find that smaller pore sizes favor the generation of formate up to a faradaic efficiency of 43%. Combined experimental and simulation results show that this is due to the influence of the pore size on CO_2 mass transport, which alters the local pH at the electrode, resulting in reaction pathway switching between CO and formate. Our results highlight the importance of the local microenvironment as an experimental knob that can be rationally tuned for controlling product selectivity: a key consideration in the design of CO_2R systems.

8:45 AM EN07.07.03
Boosting Selectivity Toward Formate Production using CuAl Nanowires by Altering the CO2 Reduction Reaction Pathway IbrahimM. Badawy and NagehK. Allam; American University in Cairo, Egypt

Understanding the fundamentals behind an electrocatalyst's selectivity enables the ability to steer product formation. Herein, Cu nanowires were doped with Al (12%) for CO2R. Al doping was found to enhance formate production by 16.9% over pure Cu nanowires. The DFT calculations ascribed the enhancement in the CO_2R performance to the change in the adsorption energy of the intermediates and thus the favourability of the reaction path involving the CO_2 adsorbing through its oxygen terminals. The COR experiments supported that conclusion when CuNW was discovered to produce higher Faradic Efficiency (FE) C_2H_4 than CuAlNW meaning that C-C dimerization is less supported on CuAl NW's surface.

9:00 AM EN07.07.04
Recovering Carbon Losses in CO2 Electrolysis using a Solid Electrolyte Reactor PengZhu and HaotianWang; Rice University, United States

The practical implementation of electrochemical CO2 reduction technology is greatly challenged by notable CO2 crossover to the anode side, where the crossed-over CO2 is mixed with O2, via interfacial carbonate formation in traditional CO2 electrolysers. Here we report a porous solid electrolyte reactor strategy to efficiently recover these carbon losses. By creating a permeable and ion-conducting sulfonated polymer electrolyte between cathode and anode as a buffer layer, the crossover carbonate can combine with protons generated from the anode to re-form CO2 gas for reuse without mixing with anodic O2. Using a silver nanowire catalyst for CO2 reduction to CO, we demonstrated up to 90% recovery of the crossover CO2 in an ultrahigh gas purity form (>99%), while delivering over 90% CO Faradaic efficiency under a 200 mA cm-2 current. A high continuous CO2 conversion efficiency of over 90% was achieved by recycling the recovered CO2 to the CO2 input stream.

9:15 AM EN07.07.05
Time Course of Product Selectivity by Ag Nanoparticle Modification on Metal Cathode Electrodes for Electrochemical CO_2 Reduction KazukiKoike[1,2], TakeharuMurakami[2], TakayoOgawa[2], KatsushiFujii[2], SatoshiWada[2] and AtsushiOgura[1,3]; [1]Meiji University, Japan; [2]RIKEN RAP, Japan; [3]MREL, Japan

Global warming is a major issue in modern society. The most significant cause of global warming is the increase in the concentration of carbon dioxide in the atmosphere. One of the technologies to reduce the concentration of carbon dioxide in the atmosphere is carbon dioxide reduction. Carbon dioxide reduction is a technology that uses electrical energy to electrochemically reduce carbon dioxide to formic acid, methane, ethylene, ethanol, and other substances. Current problems with electrochemical carbon dioxide reduction include the lack of product selection and the inability to operate for long periods of time. It is known that the selectivity of products varies with the material used for the CO_2-reduced cathode electrode and the cathode potential during the reaction. Especially for the electrode material, the metal type and crystal surface affect the products. The copper cathode has attracted much because of its high efficiency in generating ethylene, which is an industrially useful substance such as a raw material for plastics. However, the products have not yet been fully controlled. In addition, there is a problem in that the surface of copper changes after prolonged operation, making it decrease the ethylene reduction efficiently.
It is known that CO is produced as an intermediate product in the reaction process of CO_2 to ethylene. Therefore, spray coating the Cu electrode with Ag, which reduces CO_2 to CO well, is expected to improve the CO_2 reduction capability. The Ag nanoparticles were sprayed on the Cu electrode surface using a spray coating machine to modify the electrodes in this report. The evaluations were performed with electrochemical cyclic voltammetry and chronopotentiometry. The reduced products were evaluated by gas chromatography. The surface condition of the electrode before and after the reaction was also evaluated.
It was found that the metal cathode electrode modified with Ag nanoparticles improved the CO_2 reduction ability to ethylene compared with the bare Cu metal electrode. It was also confirmed that the potential during the reaction was stabilized by modification with Ag nanoparticles. The surface evaluation results showed that the surface showed dispersed Ag nanoparticles on the metal surface, and it has the possibility of the improvement of CO_2 reduction.

9:30 AM *EN07.07.06
Reactive Separations using a Cobalt Macrocycle Molecular Catalyst for Electrochemical Wastewater Refining of Nitrate to Ammonia WilliamTarpeh; Stanford University, United States

Enabling a sustainable food-energy-water nexus requires feeding a growing population while minimizing environmental impacts. Molecular catalysis of aqueous electrochemical nitrate reduction (NO_3RR) to ammonia can simultaneously reduce nitrogen pollution and electrify ammonia manufacturing. We focus on in this talk on Co(DIM), where DIM = 2,3-dimethyl-1,4,8,11-tetraazacyclotetradeca-1,3-diene, because it is the only water-soluble catalyst that has been reported to yield ammonia from NO_3RR with near full selectivity (> 95%). A dearth of experimental investigations prevents the rational design and implementation of NO_3RR molecular platforms such as Co(DIM). From an electroanalysis standpoint, kinetic benchmarking of Co(DIM)-mediated NO_3RR would contextualize the performance of Co(DIM) relative to state-of-the-art molecular electrocatalysts and quantitatively facilitate optimization goals for next-generation NO_3RR molecular catalysts. Molecular catalysts remain underutilized in electrochemical water treatment because they require separation of catalyst, wastewater, and product.

In this talk, we cover three main areas related to the development and characterization of Co(DIM). First, we describe its integration into electrochemical stripping as a reactive separation configuration that facilitates energy-efficient ammonia recovery. Second, we interrogate the stability of Co(DIM) in real wastewaters and describe electrocatalyst-in-a-box as a novel reactor design that enables catalyst reuse and continuous ammonia recovery. Finally, we elucidate the mechanism of Co(DIM) activation and catalysis to guide rational design of reactive separations, including catalyst immobilization. Together, these results will guide the rational design of molecular catalysts and reactive separations to valorize wastewater nitrate to ammonia and other products.

Compositional Control of Multidimensional Metal Sulfide Electrocatalysts to Drive CO_2 and CO Reduction to Alcohols JesusM. Velazquez; University of California, Davis, United States

The dichotomy of increasing energy demands and carbon emissions is imperative in energy-related research efforts that demand the development of new materials capable of addressing these concerns. An emerging technical avenue in this area is the conversion of vastly abundant renewable energy sources that can be harnessed and directed towards the synthesis of traditionally fossil fuel-based products from atmospheric feedstocks like CO_2. To this end, our work establishes structure—function relationships for materials within the versatile classes of MX_2 (M = Mo, W; X = S, Se) and Chevrel-Phase (CP) $M_yMo_6X_8$ (M = alkali, alkaline, transition or post-transition metal; y = 0-4; X = S, Se, Te) chalcogenides. The molybdenum sulfide structures from both families exhibit exceptional promise as CO_2R catalysts which can be accessed through synthesis techniques, such as hydrothermal or solid-state methods, that allow for control over the composition of these materials. Additionally, the use of membrane electrode assemblies (MEA) with molybdenum sulfide structures can maximize CO_2 interactions with the catalyst leading to

improved efficiencies toward selective alcohol production. Furthermore, CP catalyst framework is selective towards the electrochemical reduction of CO_2 and CO to methanol (only major liquid-phase product) under applied potentials as mild as -0.4 V vs RHE. This reactivity toward the electrochemical reduction of CO_2 and CO to methanol is correlated with an increased population of chalcogen states, as confirmed via X-Ray Absorption Spectroscopy. Overall, this work seeks to unravel optimally reactive novel small-molecule reduction catalyst compositions.

11:00 AM EN07.07.08
Electrochemical Reduction of Carbon Dioxide: Investigating Tunable Porosity and Surface Morphology in PFPE Gas Diffusion Layers for Enhanced Ethylene Selectivity EricA. Krall, MaxwellGoldman, XiaoxingXia, AndrewWong and SarahBaker; Lawrence Livermore National Laboratory, United States

The electrochemical reduction of carbon dioxide (CO2) into higher-value materials has emerged as a promising avenue towards establishing a sustainable solar-fuel-based economy. Much work has been done in recent literature to improve selectivity towards C_2+ products, notably, copper has exhibited distinctive catalytic properties by yielding higher-order hydrocarbon products, predominantly methane, ethylene, and ethanol, with compelling efficiencies. Consequently, substantial research efforts have been dedicated to understanding the unique catalytic characteristics of copper and unraveling the underlying mechanism governing the formation of hydrocarbons. These mechanistic insights, coupled with the understanding of CO2 reduction mechanisms on other metals and molecular complexes, serve as pivotal guidelines for designing future catalyst materials capable of efficiently and selectively converting CO2 into valuable products. To overcome the inherent solubility limitations of gaseous CO2, our electrochemical cell operates with CO2 in the gas phase. Leveraging the enhanced transport properties and reduced diffusion length of gaseous CO2 to the electrode surface, we employ a gas diffusion layer (GDL) made of a hydrophobic porous material, specifically PFPE (perfluoropolyether). This PFPE-based GDL facilitates the delivery of gas phase CO2 to the electrocatalytic interface.
Our research centers on the controllable and tunable porosity and surface morphology of the PFPE material within the gas diffusion layer. By varying the outer morphology of the catalyst surface, we aim to selectively tune the GDL to yield higher-order reduction products, particularly focusing on enhancing the production of ethylene. Through comprehensive studies and characterization, we investigate the influence of PFPE material properties, including porosity and surface morphology, on CO2 reduction and ethylene selectivity. By gaining insights into the correlation between the structural characteristics of the gas diffusion layer and the electrochemical performance, we aim to optimize the PFPE material design for efficient and selective CO2 reduction, specifically targeting ethylene as the desired product.
This research sheds light on the crucial role of gas diffusion layers and their tailored characteristics in achieving desired electrochemical CO2 reduction outcomes. The findings contribute to the development of advanced catalyst materials and pave the way for scalable and sustainable strategies in utilizing CO2 as a valuable feedstock for the production of high-value carbon products.

This work was performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344.

11:15 AM EN07.07.09
Norbornane Derived N-Doped sp^2 Carbon Framework as an Efficient Electrocatalyst for Oxygen Reduction Reaction, Hydrogen Evolution Reaction, and Desalination RupaliS. Mane[1], Dr. NeetuJha[1] and HigginsM. Wilson[2]; [1]Institute of Chemical Technology, India; [2]Pohang University of Science and Technology, Korea (the Republic of)

Hitherto, the development of Pt free bifunctional electrocatalyst for oxygen reduction reaction (ORR) and hydrogen evolution reaction (HER) is necessary for the advancement of sustainable and cost-effective solutions for energy conversion and storage technology. In this direction, herein we elucidated the usage of N doped sp^2 hybridized carbon framework (N-CF) as a metal-free electrocatalyst for ORR and HER. This work inspects the effect of N doping that converts a hybrid structure of CF {Norbornane or bicyclo [2, 2, 1] heptane structure} into planar N-CF. A series of N-doped CF with different doping concentrations has been prepared using a facile and cost-effective technique. This robust electrocatalysts exhibits a promotional effect in the activity, porosity, thermal and electrochemical stability for the ORR and HER reactions. A rich delocalized electronic density of the sp^2 bounded N species helps in modulating antibonding state of molecular oxygen and facilitates the breakage of O=O bond in ORR. It also promotes proton adsorption via bonding between proton and valence electron rich catalyst surface to aid HER. The research sought to investigate the employability of N-CF for fabricating sustainable energy devices with electrocatalyst possessing multiple electrocatalytic activities for ORR and HER. Density Functional Theory (DFT) computations reveals that active sites for HER are carbon atom located at the edge close to pyrrolic nitrogen and adjacent to graphitic nitrogen dopants.

11:30 AM *EN07.07.10
Challenges and Opportunities in Transitioning Electrochemical Conversion of CO_2 and other Renewable Feedstocks to Deployable Technology PaulKenis; University of Illinois, United States

Over the past decade or so, the electrochemical reduction of CO_2 has evolved from a barely studied topic to one of the most active research areas in the fields of electrochemistry and electrochemical engineering. The ongoing process of ‘the energy transition’, spurred by the need to drastically reduce global CO_2 emissions to achieve global sustainability, has driven the vigorous pursuit of different electrocatalysts, electrodes, and electrolyzer configurations that are able to reduce CO_2 -- an abundantly available, renewable feedstock -- to different value-added intermediates or products. These efforts go beyond ‘just’ CO_2 reduction. Electro-oxidation of for example renewable, bio-derived adducts for the manufacturing of chemicals that traditionally are derived from fossil fuels is also an active area of study. With many selective and efficient catalysts now available for these types of electro-oxidations and -reductions, attention has started to shift to topics such as catalyst stability, electrode durability, and electrolysis reactor design.
This presentation will provide insights into a number of practical aspects of turning advances in electrocatalyst and electrode design into scalable, durable processes. For example, CO_2 reduction is often unavoidably accompanied by carbonate formation. How can one suppress carbonate formation, or minimize the effects of carbonate formation on electrolysis performance? Can CO_2 electrolyzers operate on dilute CO_2 feeds, recognizing that CO_2 capture and its concentration, especially from the air, is highly energy intensive, regardless of what method is used? How realistic, technically and from a life-cycle perspective, are less energy-intense electrolytic co-conversion approaches where CO_2 is reduced on the anode in parallel with oxidation of a renewable substrate to a desired product on the anode (e.g. glycerol to lactic acid)? What are some of the typical byproduct waste streams available from biomass processing, e.g. ‘crude glycerol’ which also contains various amounts of NaOH, water, and methanol, and can one develop an electrolysis system and process that can tolerate the range in compositions? This presentation will explore some of these aforementioned challenges and opportunities based on our work as well as work by others in reactor engineering, process design, and techno-economic / life cycle analysis.

SESSION EN07.08: CO2/NOx Reductions II

1:30 PM *EN07.08.01
Electrocatalysis for Chemical Manufacturing of Ammonia and Environmental Remediation of Nitrate MartaHatzell; Georgia Institute of Technology, United States

Of the four major energy-use sectors (transportation, residential, commercial, and industrial), the industrial sector accounts for the largest amount of energy use (~33 EJ/year). This energy use results in nearly 1500 million metric tons of carbon dioxide emissions yearly [1]. The large carbon footprint is due to most modern industrial processes' reliance on process heat which is often derived from coal, natural gas, and petroleum. With rising concerns related to global carbon emissions, there is a strong interest in displacing process heat with electricity. However, direct use of electricity for chemical manufacturing processes is challenging if not impossible. This has motivated a strong need to rethink and redesign many catalytic and separations-based processes to decarbonize the chemical manufacturing sector.

Within the chemical commodity industry, transforming thermocatalytic and thermal-based separation and catalysis processes with electrochemical-driven processes is one way to electrify and decarbonize the chemical industry. Thus, the primary aim of this talk is to detail how photochemical and electrochemical processes may aid in achieving this goal. I will aim to discuss the thermodynamic and kinetic challenges and opportunities which exist when transforming thermocatalytic systems into electrocatalytic or photocatalytic processes. I will then aim to discuss the specific growing opportunities related to electrocatalytic and photocatalytic ammonia production. Focus here will be placed on describing the opportunities in tuning molecular scale mechanisms and atomic scale materials design to enable ideal conversion.

2:00 PM EN07.08.02
Towards Controlling the Microenvironment in Electrochemical CO_2 Reduction AndrewB. Wong; National University of Singapore, Singapore

The electrochemical CO_2 reduction reaction (CO_2RR) represents a critical approach toward the carbon-neutral generation of hydrocarbons. However, despite intense research efforts, the need remains to increase selectivity and activity for electrocatalysts for CO_2RR. Thus, there has been increasing interest in optimizing the microenvironment to boost the activity and selectivity of electrocatalytic sites for CO_2 conversion.

This presentation discusses several strategies that are being pursued in my research group to optimize the microenvironment for CO_2 conversion. These strategies include: (1) model systems to illustrate control of diffusion via engineering electrode structure at micro- and nano- length scales, (2) model systems to harness localization of tandem catalysts, (3) implementation of bioelectrochemical tandem systems for CO_2 conversion, (4) implementation of MOF/organic coatings to improve transport, and (5) implementation of high-temperature non-aqueous electrolytes.

Thus, this presentation surveys a wide range of ongoing research strategies to optimize the microenvironment toward more effective CO_2RR.

2:15 PM EN07.08.03
Enhancing Product Selectivity in CO_2 Reduction by Controlling Substrate Pore Size and Hydrophobicity in Gas Diffusion Electrodes FrancescoBernasconi[1,2], AlessandroSenocrate[1] and CorsinBattaglia[1,2]; [1]Empa–Swiss Federal Laboratories for Materials Science and Technology, Switzerland; [2]ETH Zürich, Switzerland

Electrochemical CO_2 reduction (CO_2RR) is a key technology to convert detrimental CO_2 emissions into sustainable fuels and chemicals, and close the carbon loop[1]. To ensure the economic competitiveness of CO_2RR, electrocatalysts need to be highly active, selective towards a desired product and stable. High activities can be achieved with gas diffusion electrodes (GDEs), circumventing mass transport limitations resulting from the low CO_2 solubility in water. However, product selectivity and stability still need to be improved before industrial implementation. In this work, we show that the GDE substrate pore size and hydrophobicity act as a powerful handle to tune selectivity and stability in both Ag and Cu GDEs[2,3]. GDEs with large pore size and weak hydrophobicity readily lead to flooding of the catalyst by water and, in the Ag case, yield poor selectivity towards CO and a significant production of H_2. In contrast, GDEs with small pore size prevent flooding of the catalyst, thus yielding a greatly improved Faradaic efficiency towards CO (up to 95% at 100 mA/cm^2 in neutral electrolyte), minimal H_2 evolution, and remarkable long-term stability (97% of initial CO selectivity retained after > 40 h). In the Cu case, we observe a strong enhancement in C_2H_4 selectivity when employing GDE substrates with small pores and strong hydrophobicity (up to 50% Faradaic efficiency in neutral electrolyte at 200 mA/cm^2 for > 3 h). Both CO_2 and CO reduction reactions indicate transport limitations of reactants to the catalyst sites for all GDEs, however this limitation is less severe for GDEs with small pore sizes. We rationalize these findings with the presence of an electrolyte layer covering the electrocatalyst, forcing the electrocatalytic reaction to take place at double phase boundaries. Experiments with variable pressures show that only GDEs with small pores can sustain large overpressure of the liquid phase (> 1 bar), which enhances the resilience of the reaction towards unexpected pressure spikes that might occur during start-up and operation. Our results emphasize the importance of substrate microstructure on GDE product selectivity and stability during CO_2RR, and represent a new scalable strategy to improve GDE performance.

Advances in Electrified CO2 Reduction to Chemicals and Fuels EdwardH. Sargent[1,2]; [1]Northwestern University, United States; [2]University of Toronto, Canada

I will review recent advances, at the level both of catalysts and systems, in efficiently electrochemically reducing CO2 and CO to chemicals (such as ethylene and propanol) and fuels (e.g. methane, ethanol). I will look at issues such as total voltage, single-pass utilization of the reagents, and overall energetic efficiency.

4:00 PM EN07.08.05
Electrochemical Growth and Restructuring of Cu Surfaces for Steering the Selectivity of Electrocatalytic CO_2Reduction JosephS. DuChene; University of Massachusetts Amherst, United States

The electrocatalytic reduction of CO_2 into value-added chemicals is commonly performed with catalysts composed of Cu due to its propensity for producing C_{2+} products like ethylene and ethanol. While promising, the reaction is known to suffer from poor selectivity. Several studies have shown that the surface facets of Cu catalysts play an important role in dictating the distribution of CO_2 reduction products, yet the dynamic nature of Cu surfaces leads to significant surface reconstructions that alter the catalyst selectivity over the course of the reaction. The factors governing the evolution of Cu surfaces during CO_2 reduction must be fully understood to enable control over these processes at the atomic level. Here, we discuss our efforts towards controlling the surface facets of Cu electrocatalysts via electrochemical treatments for steering the selectivity of electrocatalytic CO_2 reduction. Using both polycrystalline Cu foils and shape-controlled Cu or Cu_2O nanoparticles, we will show how the applied potential and chemical composition of the growth solution can be manipulated to tailor the surface facets of Cu electrocatalysts. Finally, we will present the results of electrocatalytic CO_2 reduction with these nanostructured Cu catalysts and highlight opportunities for using simple electrochemical techniques to tailor the surface facets of electrocatalysts at the nanoscale for the selective production of chemical fuels.

Electrocatalytic CO_2 Reduction using Heteroatom Doped Carbon Materials for Multi-Carbon Production Hyun-TakKim; Korea Research Institute of Chemical Technology, Korea (the Republic of)

Electrochemical reduction of CO_2 (CO_2R) to value-added chemicals and fuels presents a promising approach for mitigating the issues related to energy crisis and global warming. Different proton- and electron transfer steps and CO_2 reduction pathways are employed to convert CO_2 to C_1, C_2, or C_{2+} products. In addition, the production of liquid multicarbon alcohols is highly desired, because it possesses the potential to enable the synthesis of sustainable fuels that leverage high energy densities (21 MJ l^{-1} ethanol, 27 MJ l^{-1} propanol, and 34.2 MJ l^{-1} gasoline) for long-range and heavy-freight transportation applications. However, owing to the limited selectivity and low activity of the currently available catalysts, the production of multicarbon alcohols via direct CO_2 electroreduction is not economically viable.
Here, we report a heteroatom doped carbon based electrocatalyst that exhibits a Faradaic efficiency greater than 70% for CO_2 reduction (CO_2R) and 90% of C_{2-3} product selectivity. Density functional theory calculations suggest that CO_2 dual binding catalysts promote a C–C coupling between adsorbed CO intermediates and CO_2 for C_{2-3} formation. This high efficiency and the corresponding mechanism are explained by theoretical calculations and spectroscopic analyses. With the results, we suggest a molecular design strategy for next-generation CO_2 reduction catalysts for a green ocean and atmosphere.

4:30 PM EN07.08.07
High-Rate CO_2 Conversion to Ethylene via Molecularly Enhanced Electrochemical CO_2 Reduction TaeminLee[1], JongyounKim[1], Hyun DongJung[2], SeoinBack[2], YounguLee[1] and Dae-HyunNam[1]; [1]Daegu Gyeongbuk Institutes of Science and Technology, Korea (the Republic of); [2]Sogang University, Korea (the Republic of)

Electrochemical conversion of CO_2 into value-added fuels and feedstocks is a promising route to realize sustainable energy cycle and carbon neutrality. Continued efforts to achieve effective electrochemical CO_2 reduction reaction (CO_2RR) have resulted in achieving high selectivity for multi-carbon (C_{2+}) chemicals such as ethylene (C_2H_4) and ethanol (C_2H_5OH). To improve the productivity of C_{2+} chemicals, it is necessary to promote C-C coupling on the catalyst surface, as well as *CO formation by fast electron transfer even at high current density. However, even in the flow-type cell with a gas diffusion electrode, it still remains as a challenge due to the sluggish *CO formation on the catalyst surface.
In this work, we report the molecularly-enhanced CO_2 mass transport of Cu catalyst for high current density C_2H_4 production. We augmented ascorbic acid (AA) on Cu nanowires (CuNWs) using graphene quantum dots (GQDs) as a mediator to confine AA in heterogeneous electrocatalysts during CO_2RR. AA on CuNW surface enhanced the CO_2 conversion rate by promoting proton-coupled electron transfer (PCET) and providing strong hydrogen bonding site. The nanoconfinement effect and immobilization of AA by GQDs enable redox reversibility and high current density CO_2RR. In the CO_2RR of pristine CuNWs, there is less carbon monoxide (CO) formation in the low potential, and this limits the potential range for stable C_2H_4 production. However, Cu NWs modified with nanoconfined AA by GQDs (cAA-CuNWs) exhibited outstanding C_2H_4 production rates with Faradaic efficiency (FE) of 60.7% and C_2H_4 partial current density of 539 mA/cm^2, which is about 2.9-fold higher performance compared to that of pristine CuNWs. *In-situ* Raman spectroscopy revealed that higher population of *CO is covering cAA-CuNW surface by Cu-CO rotation and stretch peak intensity. Also, appropriate ratio of atop bound CO and bridge bound CO has proven the efficient C-C coupling of cAA on CuNW. Grand-canonical density functional theory (GC-DFT) verified that multiple hydrogen bonding sites of AA can effectively control the electronic distributions of water molecules surrounding CO_2, thereby improving *CO formation on the Cu surface. This offers the potential for harnessing AA as a promoter to enhance CO_2 mass transport toward high rate CO_2 to value-added C_{2+} chemical conversion.

4:45 PM EN07.08.08
Thermodynamically Designed Cu-Sn Bimetallic Alloy Electrocatalysts for Electrochemical CO_2 Reduction WoosuckKwon[1], SoohyunGo[1], DeokgiHong[2], Young-ChangJoo[2] and Dae-HyunNam[1]; [1]Daegu Gyeongbuk Institute of Science & Technology (DGIST), Korea (the Republic of); [2]Seoul National University, Korea (the Republic of)

Electrochemical CO_2 reduction reaction (CO_2RR) has received great attention as a promising strategy for carbon neutrality and net zero emission. Copper (Cu) is the element which binds neither *CO strong nor weak and enables C-C coupling for multi-carbon product formation by inducing *CO dimerization. To enhance the CO_2RR selectivity of Cu, modulating the d-band center of the heterogeneous catalysts is essential to control the intermediate binding energy. Recently, Sn has been widely applied as a bimetallic Cu alloy element, which can suppress hydrogen evolution reaction (HER) and enables to tune CO_2RR reaction pathway. Although Cu-Sn bimetallic alloy can have various intermetallic compounds, current approaches of Cu-Sn bimetallic catalyst to control Cu:Sn ratio, arrangement of components, structure, and oxidation states resulted in the limited phase control and narrow range of product selectivity control accordingly.
In this work, we developed a thermodynamically designed Cu-Sn bimetallic alloy electrocatalysts which enable the efficient control of CO_2RR selectivity. In the alloy fabrication, escaping from the Cu:Sn ratio control approach, we focused on modulating Sn vapor pressure for the controllable formation of Cu-Sn intermetallic compounds. We applied carbon (C) matrix which enables to modulate the microenvironment of Cu which interact with Sn vapor pressure during Cu-Sn alloy fabrication. Starting from the thermochemical computation to discover the processing window, we fabricated Cu-Sn-C nanocomposite combined with Cu, Sn precursors, and polymers by electrospinning and calcination. By controlling the allocation of Cu and Sn sources in the core/shell structured nanofibers, we successfully fabricated $Cu_{41}Sn_{11}$, Cu_3Sn, and Cu_6Sn_5 respectively. As the local Sn vapor pressure increases, Sn-rich compounds formed accordingly and resulted the increased selectivity of formate ($HCOO^-$). Interestingly, major CO_2RR product was shifted from formate to methane (CH_4) by controlling the stoichiometry of Cu-Sn alloy. $Cu_{41}Sn_{11}$ exhibited CH_4 faradaic efficiency (FE) over 40%. We believe that this approach can pave a way to design bimetallic alloy materials for efficient CO_2RR electrocatalysts.

Shape-Controlled Synthesis of 2H Au Nanomaterials for Highly Efficient Carbon Dioxide Reduction Reaction GangWang and YeChen; The Chinese University of Hong Kong, Hong Kong

Colloidal gold (Au) nanomaterials with fine controlled size and shape possess unique physicochemical properties and great potentials in various applications. However, most of the reported Au nanomaterials typically crystallize in the thermodynamically stable face-centered cubic (3C) phase, and there are still great challenges in synthesizing hexagonal close-packed (2H type) Au nanomaterials with high phase purity and controlled size and shape. Here, we report a one-pot colloidal synthesis of free-standing ultrasmall 2H Au nanosheets. A series of 2H Au nanomaterials with controlled shape are then synthesized using the 2H Au nanosheets as seeds. Moreover, the 2H Au nanomaterials exhibit superior electrocatalytic performance toward CO_2 reduction reaction than 3C Au nanoplates, possessing high Faradaic efficiency in a wide applied potential window. Our work provides an effective strategy to design and synthesize Au nanomaterials with unconventional crystal structure and demonstrates the potential of phase engineering in boosting catalytic performances of noble metal nanomaterials.

8:00 PM EN07.09.02
Synthesis of Ag-Sn Intermetallic Compounds via Mechanical Alloying as Selective Electrocatalysts for CO_2 Reduction Reaction TakeyukiKamimura, KazuyukiIwase and ItaruHonma; Tohoku University, Japan

The electrochemical CO_2 reduction reactions (CO_2RR) have attracted attention as a method to convert CO_2 into value-added products using electricity derived from renewable energy sources[1]. In CO_2RR, various products such as carbon monoxide (CO) and formate ($HCOO^-$) can be generated. Therefore, for CO_2RR catalysts, the higher selectivity for the desired products and suppression of the competing hydrogen evolution reaction (HER) is important.

Previous research has developed highly active and selective CO_2RR catalysts using various materials, such as polymers, organometallic complexes, and metal nanoparticles[2-4]. Among them, metal alloys catalysts are attracting attention as promising CO_2RR catalysts, as the catalytic activity and product selectivity can be tuned by choice of metal elements and their composition[5-7]. Intermetallic compounds, which have unique crystal structures and composition of metal elements compared to conventional metallic alloys, are expected to exhibit different reactivity and selectivity from conventional solid-solution alloy catalysts due to their unique atomic structures and electronic states. In this study, we synthesized intermetallic compounds composed of silver (Ag) and tin (Sn), which show high CO_2RR selectivity for producing CO and $HCOO^-$, and investigated whether the CO_2RR activity and selectivity could be enhanced. Specifically, we employed mechanical alloying as a synthetic method since it has been gaining attention in recent years to synthesize various kinds of materials[8].

Intermetallic compounds of Ag and Sn (Ag-Sn) were synthesized by mechanical alloying using a planetary ball mill using Ag powder (particle diameter 50-80 nm) and Sn powder (particle diameter 60-80 nm) at the desired ratio (Ag: Sn = 3:1 ~ 7:1) as the starting materials. The CO_2RR activity was evaluated by constant current measurements using gas diffusion electrodes as the working electrode and 1 M $KHCO_3$ as the electrolyte.

The powder x-ray diffraction (XRD) pattern showed that the sample at Ag: Sn = 7:1 can be attributed to the solid solution alloy of Ag and Sn, whereas the XRD pattern for Ag: Sn = 4:1 could be attributed to the ζ phase, which is an intermetallic compound phase. In both samples, no peaks of the unreacted precursor were observed, suggesting that the single phase of the Ag-Sn solid solution and the intermetallic compound phase was successfully synthesized. For the Ag: Sn = 4:1 sample, the concentration of Ag and Sn in the depth direction was analyzed by X-ray photoelectron spectroscopy (XPS) measurement. The results showed that the ratio of Sn on the surface was higher than the original Ag: Sn ratio (4:1). This result suggests that Sn atoms of the Ag: Sn = 4:1 sample are segregated on the surface. In contrast, the sample showed an intermetallic compound phase (ζ phase) as the bulk crystal structure. For CO_2RR activity at a constant current density (53.0 mA/cm^2), the synthesized Ag-Sn catalysts mainly produced $HCOO^-$. The faradaic efficiency of $HCOO^-$ generation for Ag: Sn = 4:1 sample was 84 %. This value was larger than that of the Ag: Sn = 7:1 sample (78%). For comparison, we evaluated the CO_2RR activity of the pure Ag and Sn powders, which were used as precursors. They predominantly produced CO and $HCOO^-$ with a respective faradaic efficiency of 89% and 62%. These findings imply that the formation of the ζ-phase, an intermetallic compound phase, may contribute to the generation of $HCOO^-$.

Development of Cost-Effective, Bespoke Tailored Ternary Nanoparticles as Catalysts for Lithium-Air Batteries Jong SeokNam[1], YujangCho[1], SeongcheolAhn[1], Min SooKim[1], JaewanAhn[1], HoJinLee[2], Ji-WonJung[2] and Il-DooKim[1]; [1]Korea Advanced Institute of Science and Technology, Korea (the Republic of); [2]University of Ulsan, Korea (the Republic of)

Lithium-air batteries, known for their exceptionally high theoretical energy density, have emerged as potential energy storage systems capable of replacing gasoline. However, their practical application is hindered by the challenging complete decomposition of insulating Li_2O_2 formed during the charge-discharge cycle. To overcome this, it is common to utilize precious metal catalysts such as iridium (Ir) and ruthenium (Ru), known for their high catalytic activity. Nevertheless, the scarcity and high cost of these precious metal catalysts pose significant barriers for commercial use. Hence, various research groups are striving to achieve high catalytic efficiency using non-precious metals. Metal oxides, in particular, have emerged as a versatile family of non-precious catalysts. They are favored for their intrinsic oxidation resistance, comparative stability, ease of synthesis and control, as well as the abundance of compositional and structural varieties.
In this study, we aim to explore the use of abundant, economically viable non-precious metals, specifically cobalt (Co), nickel (Ni), and iron (Fe), in lithium-air batteries. Our approach

involves adjusting the composition ratios of these metals to assess their relative catalytic efficiencies. Our research further includes: i) producing bespoke tailored ternary metal oxide nanoparticles from Co, Ni, and Fe using a rapid thermal process, ii) incorporating these nanoparticles onto a lightweight, porous, and highly conductive carbon nanofiber-based cathode for use in lithium-air batteries, and iii) assessing the potential for large-scale air battery production via surface optimization of carbon nanofibers integrated with these bespoke tailored ternary nanoparticles and the fabrication of pouch cells.

8:00 PM EN07.09.04

Regeneration of NiFe/LFNO for Solid Oxide Electrolysis Cell Application under Non-Ideal Condition MusaO. Najimu[1], MatthewHurlock[2], TinaNenoff[2], JonasBaltrusaitis[3] and KandisL. Abdul-Aziz[1]; [1]University of California, Riverside, United States; [2]Sandia National Laboratories, United States; [3]Lehigh University, United States

The structural reversibility of smart exsolved nanoparticle catalysts offer the opportunity for SOEC application in reversible modes, however, structural reversibility in the presence of anthropogenic contaminant poisoning is important for nonideal SOEC conditions. In addition to redirecting the reaction pathways and lowering the selectivity, this contaminant poisoning can lower the overall conversion of the carbon feeds due to the preferential conversion of the contaminants. Sulfur removal in H_2S-poisoned perovskite materials as well as the restoration of the activity of the poisoned materials, is typically achieved by oxidative treatment at 800 ºC. Here, the structural changes of SOx-poisoned NiFe/$LaFe_{0.9}Ni_{0.1}O_3$ (LFNO) material were tracked for regenerability using cycling dry methane reforming (DRM) experiments to assess the intrinsic regenerability. While reduction of as-prepared LFNO facilitates the exsolution of NiFe with the formation of La_2O_3 and $La(OH)_3$, DRM causes partial reincorporation of the exsolved NiFe nanoparticle. The exsolved nanoparticle demonstrates structural recyclability as oxidation after DRM reincorporates the NiFe nanoparticle back into the LFNO perovskite, while subsequent reduction causes the re-exsolution of the NiFe alloy nanoparticle. In addition, the DRM activity after the regeneration closely matches the DRM activity of freshly reduced LFNO perovskite, further demonstrating the reversibility of the exsolved NiFe/LFNO. However, using the same regeneration condition, the deteriorated DRM activity of the NiFe/LFNO material exposed to SOX at 600 ºC is not restored, possibly demonstrating the prohibitory effect of SOx exposure for regeneration. In addition to a direct comparison of the impact of the type of sulfur contaminant species on regeneration, the speciation of sulfur on the exsolved nanoparticle systems as well as the regeneration of this novel SOEC candidate will be discussed.

Bifunctional Catalytic Co_2VO_4 Nanoarray Grown on Carbon Nanofiber for Free-Standing Lithium-Air Battery Cathode MingyuSagong, Jong SeokNam, Seung HyunJeong and Il-DooKim; KAIST, Korea (the Republic of)

In recent research on cathode for LABs, systematic investigations have been conducted to develop rational catalysts with diverse morphologies. Studies have shown increased exposure to the high-activity surface leads to improved cycle life and cell performance. In particular, spinel cobalt oxide (Co_3O_4) draw attention due to Co^{2+}/Co^{3+} bifunctional catalytic activity and electrochemical stability in electrocatalys. Nevertheless, the efficacy of these applications was hindered due to the inherent constraints associated with their poor intrinsic electrical conductivity and comparatively low catalytic activity. To address these limitations, we have designed cobalt vanadium oxide uniformly decorated on the carbon nanofiber (Co_2VO_4@CNF) *via* hydrothermal synthesis as a free-standing cathode for LABs. By substituting vanadium for the octahedron site of Co_3O_4, vanadium atoms can offer an electron pathway and facilitate high electrical conductivity. In addition, the substitution of vanadium improves oxygen reduction reaction (ORR) performance through proper electron configuration of Co^{2+}. The oxide catalyst grown on the CNF facilitates the maximization of active catalytic sites and stable formation/dissociation of Li_2O_2, enabling greater capacity and longer cyclability. The findings indicate that the formation/dissociation process of Li_2O_2 is influenced by the presence of an appropriate catalyst and the surface chemistry. The air cathode structure composed of rational nanostructures and catalysts is expected to improve LAB performance in capacity and cyclability.

8:00 PM EN07.09.06

Palladium Nano-Catalysts Deposited via Atomic Layer Deposition for Ammonia-Fueled Protonic Ceramic Electrochemical Cells Heon JunJeong, WanhyukChang, Beum GeunSeo and Joon HyungShim; Korea University, Korea (the Republic of)

Solid oxide fuel cells (SOFCs), specifically ceramic fuel cells, have gained recognition for their ability to efficiently utilize various fuels and achieve high compound efficiencies through thermal cycling. As an alternative to conventional gas turbine plants, the integration of fuel cell and gas turbine hybrids in power generation systems has emerged as a practical solution. However, methane-based ceramic fuel cells pose challenges related to carbon emissions during combustion, as well as complexities in production, storage, and transportation.
This study aims to explore the potential of using ammonia as a carbon-free and eco-friendly fuel for protonic ceramic fuel cells (PCFCs), offering several advantages over methane gas. Ammonia provides a higher energy density, is cost-effective, and offers safer storage and transport compared to hydrogen. PCFCs operate at lower temperatures (<600 °C), exhibit minimal structural and material deterioration, and demonstrate higher ionic conductivity compared to SOFC electrolytes. Additionally, PCFCs produce only water and nitrogen as by-products, ensuring a cleaner and more efficient energy conversion process.
To optimize the performance and durability of ammonia-fueled PCFCs, we employed a catalyst treatment approach using palladium (Pd). By utilizing atomic layer deposition (ALD) on the anode surface, we achieved a uniform distribution of Pd catalysts, increased reaction sites, and improved thin film deposition. The Pd-treated PCFC samples demonstrated significant performance enhancements compared to untreated samples. Impedance analysis revealed improved current collection and a substantial reduction in polarization resistance, particularly at low temperatures. Stability tests further confirmed the effectiveness of Pd ALD in enhancing the performance and durability of ammonia-fueled PCFCs.
In this presentation, we will discuss the outstanding performance and durability of Pd catalysts in ammonia-fueled PCFCs, providing detailed insights into the experimental findings and their implications for practical applications.

8:00 PM EN07.09.07

Boosting the Visible-Light-Driven Selective Toluene Oxidation via Synergistic Effect Between Nanoparticulate Pd/$BiVO_4$ Photocatalyst and a Cyclic Nitroxyl Redox Mediator SayuriOkunaka[1] and HiromasaTokudome[2]; [1]Tokyo City University, Japan; [2]TOTO Ltd., Japan

Selective oxidation of organic compounds using semiconductor photocatalysts has been focused on the viewpoint of sustainable synthesis processes. Especially, the selective oxidation of C(sp^3)-H bonds in toluene, which is one of the C-H activation reaction, is an attractive reaction because the desired oxidation product, benzaldehyde, is extensively used as an indispensable intermediate in the synthesis of drugs, perfumes, and fine chemicals. Conventional synthesis of benzaldehyde involves TiO_2-based photocatalysts, however, they have brought the drawback of absorbing only UV light and the low selectivity due to its large bandgap. Therefore, developing visible-light responsible photocatalyst system for efficient toluene oxidation has been strongly desired to construct an alternative way to realize sustainable organic synthesis.
Recently, we reported photo-oxidation of toluene to benzaldehyde over visible-light responsible Pd-loaded $BiVO_4$ (Pd/$BiVO_4$) photocatalyst. However, it remains challenging due to its low efficiency. In this work, we introduce a novel strategy to apply a cyclic nitroxide compound as an efficient redox mediator along with Pd/$BiVO_4$ for toluene oxidation. Addition of a cyclic nitroxide significantly improved the toluene oxidation activity on Pd/$BiVO_4$ photocatalyst under blue-to-green light irradiation. In particular, *N*-hydroxyphthalimide (NHPI) boosted the benzaldehyde production up to ca. 28 times compared to without NHPI. The optimized conditions realized a toluene conversion in high efficiency (apparent quantum yield = 10.8 and 5.4 % at 420 and 520 nm, respectively) and with excellent selectivity. The superior conversion yield was realized by the synergistic effect between the presence of NHPI and the use of nanoparticulate Pd/$BiVO_4$ with a relatively large surface area.

8:00 PM EN07.09.08

Tailoring Ag Electron-Donating Ability for Organohalide Reduction: A Bilayer Electrode Design DwaipayanChakraborty[1], AliAbbaspourtamijani[1], HenryS. White[2], MatthewNeurock[3] and YueQi[1]; [1]Brown University, United States; [2]The University of Utah, United States; [3]University of Minnesota, United States

Electrochemical reduction of organohalides is a green and safe way for the reduction of environmental pollutants, synthesis of new organic molecules, and many other important applications. The presence of a catalytic electrode (i.e., electrocatalytic dehalogenation) can in many cases make the process more energetically efficient. Ag has been known to be very good catalysis for this purpose for a wide range of organohalides. In this work, we have particularly tried to put forward an electrode design strategy that can possibly be used to further increase the catalytic activity of pure Ag electrodes. We have shown how epitaxially depositing one to three layers of Ag on catalytically inert or less active support metal (defined as Ag/metal bilayer electrode) could increase the surface electron donating ability, thus increasing the adsorption of organic halide and the catalytic activity. Many factors, such as molecular geometry, lattice mismatch, work function, and solvents, contribute to the adsorption of organic halide molecules over the bilayer electrode surface. To isolate and rank these factors, we studied three model organic halides, namely, halothane, bromobenzene (BrBz), and benzyl bromide (BzBr) adsorption on Ag/metal (metal = Au, Bi, Pt, and Ti) bilayer electrodes in both vacuum and acetonitrile (ACN) solvent. The different metal support offers a range of lattice mismatches and work function differences with Ag. Our calculations show that the surface of Ag becomes more electron-donating and accessible to adsorption when forming a bilayer with Ti since Ti has a lower work function and almost zero lattice mismatch with Ag. We believe this study will increase the electron-donating ability of the Ag surface by choosing the right metal support which in turn can improve the catalytic activity of the working Ag electrode.

8:00 PM EN07.09.09

Deterministic Synthesis of Pd Nanocrystals Enclosed by High-Index Facets and Their Enhanced Activity Toward Formic Acid Oxidation MaochangLiu[1,2], Sang-IlChoi[1], SiyuZhou[1] and YounanXia[1]; [1]Georgia Institute of Technology, United States; [2]Xi'an Jiaotong University, China

Noble-metal nanocrystals enclosed by high-index facets are of growing interest due to their enhanced catalytic performance toward a variety of reactions. Herein, we report the deterministic synthesis of Pd nanocrystals encased by high-index facets by controlling the rate of deposition ($V_{deposition}$) relative to that of surface diffusion ($V_{diffusion}$). For octahedral seeds with truncated corners, a faster reduction rate (and thus deposition rate) than that of surface diffusion (*i.e.*, $V_{deposition}/V_{diffusion} > 1$) led to the formation of concave trisoctahedra (TOH) with high-index facets. When the reduction was slowed down, in contrast, surface diffusion dominated the growth pathway. In the case of $V_{deposition}/V_{diffusion} \approx 1$, truncated octahedra with enlarged sizes were produced. When the reduction rate was between these two extremes, we obtained concave tetrahexahedra (THH) without or with truncation. Similar growth patterns were also observed for cuboctahedral seeds. When the Pd octahedra, concave TOH, and concave THH were tested for electrocatalyzing the formic acid oxidation (FAO) reaction, those with high-index facets were advantageous over the conventional Pd octahedra enclosed by {111} facets. This work not only contributes to the understanding of surface diffusion and its role in nanocrystal growth but also offers a general protocol for the synthesis of nanocrystals enclosed by high-index facets.

Hierarchical NiFe@NiFe Layered Double Hydroxides for Efficient Solar-Powered Water Oxidation Deok KiCho, So JeongPark, GeonpyoHong and Jin YoungKim; Seoul National University, Korea (the Republic of)

The development of green hydrogen is crucial for achieving zero CO2 emissions and sustainable energy production. Solar-powered electrocatalysis, also known as photovoltaic-electrolysis (PV-EC), is a promising technology that has the potential to efficiently convert solar energy into hydrogen with high efficiency and durability. However, the sluggish kinetics of the oxygen evolution reaction (OER) pose a significant challenge to efficient water splitting. To overcome this, there is a pressing need to develop cost-effective catalysts with high electrochemical activity and stability, as well as scalable synthetic processes for large-scale production. Layered double hydroxides (LDHs) based on transition metals have garnered considerable attention as promising candidates due to their abundant availability, porous morphologies, and adjustable compositions.
In this study, a hierarchical heterogeneous $Ni^{2+}Fe^{3+}$@$Ni^{2+}Fe^{2+}$ LDH was successfully synthesized using a sequential electrodeposition technique. The synthesis process involved the use of separate electrolytes containing iron precursors with different valence states (Fe^{2+} and Fe^{3+}). By utilizing Fe^{2+} precursors, a well-defined nanosheet array of NiFe LDHs with high crystallinity, referred to as $Ni^{2+}Fe^{2+}$ LDH, was synthesized. On the other hand, employing Fe^{3+} precursors led to the formation of a thin layer of NiFe LDH with a relatively higher Ni content and lower crystallinity, denoted as $Ni^{2+}Fe^{3+}$ LDH. Different deposition behaviors depending on the oxidation state of the Fe precursor ions was attributed to their different solubility product constants (K_{sp}). The amorphous $Ni^{2+}Fe^{3+}$ LDH exhibited superior OER performance compared to its Fe^{2+}-based counterpart. The heterogeneous hierarchical OER catalyst electrode was prepared by a simple two-step electrodeposition process using the $Ni^{2+}Fe^{2+}$ LDH nanosheet arrays with large surface area. As a result of the synergetic effect between the large dual advantages of large surface area of the $Ni^{2+}Fe^{2+}$ LDH nanosheet arrays and excellent OER activity of $Ni^{2+}Fe^{3+}$ LDH, the $Ni^{2+}Fe^{3+}$@$Ni^{2+}Fe^{2+}$ LDH exhibited outstanding OER activity with overpotentials of 218 and 265 mV required to achieve current densities of 10 and 100 mA cm^{-2}, respectively. Moreover, it demonstrated exceptional long-term stability, sustaining efficient performance for 30 hours even at a high current density of 500 mA cm^{-2}. In a water splitting system, the electrolyzer, using a Sn_4P_3/CoP_2 electrocatalyst as the cathode, only required a cell voltage of 1.55 V to achieve a current density of 10 mA cm^{-2}. Furthermore, the solar-powered overall water splitting system, comprising our electrolyzer and a perovskite/Si tandem solar cell, exhibited a high solar-to-hydrogen conversion efficiency of 15.3%.

Introduction of Carbon Shells on Copper(I) Oxide Nanocrystals Inducing Selective CO_2 Electroreduction to Methane Jong-YeongJung and HyunjoonSong; KAIST, Korea (the Republic of)

Large-scale electrochemical CO_2 reduction reaction (CO_2RR) for methane production is crucial for achieving a carbon-neutral economy. However, practical methane production faces challenges from increased C–C coupling and the hydrogen evolution reaction. Here we introduced carbon shells on cuprous oxide nanocubes to preserve the copper oxidation states under reduction potential. As carbon shell thickness increased, methane production significantly improved. Optimizing the shell thickness to 50 nm resulted in a Faradaic efficiency of 50.2 ± 3.9% at a methane partial current density of −201 ± 16 mA cm^{-2} in alkaline electrolytes. Operando X-ray absorption confirmed that the carbon shells prevent the reduction of Cu_2O nanocubes under the negative bias and stabilize Cu(I) species. In situ Raman studies observed a remarkable peak assigning Cu hydroxide species. The carbon shells seem to impede the transport of hydroxide ions, leading to a high local pH and stabilizing Cu hydroxide species. Density functional theory calculations confirmed the role of surface-adsorbed *OH molecules to suppress *CO dimerization and the Barder charge of Cu atoms during *OH adsorption which remained under +1. This work presents a simple strategy to control the major products of CO_2RR and reveals the role of hydroxyl groups on the Cu_2O surface.

8:00 PM EN07.09.12
Acceptor Doping of Bismuth Vanadate to Realize Photocathodes for Hydrogen Evolution: Joint Experimental and Computational Investigations VrindaaSomjit[1], DayeSeo[2], Kyoung-ShinChoi[2] and GiuliaGalli[3,1]; [1]Argonne National Laboratory, United States; [2]University of Wisconsin–Madison, United States; [3]The University of Chicago, United States

Bismuth vanadate ($BiVO_4$) is a promising photoelectrode for water splitting due to its ease of synthesis, stability in aqueous conditions, and high electron-hole separation yield. Its favorable band edge alignment with the water oxidation potential has spurred extensive research into designing n-type $BiVO_4$ photoanodes for water oxidation [1]. However, relatively less attention has been given to the development of p-type $BiVO_4$ for water reduction to hydrogen gas. In this work, we show that calcium-doped $BiVO_4$ can serve as a photocathode that reduces water to hydrogen gas. Using density functional theory at the +U and hybrid levels, we report that Ca doping can shift the conduction band minimum (CBM) of $BiVO_4$ by 0.15 eV, moving it closer to the water reduction potential. This is consistent with experiments, which observe hydrogen evolution in Ca-doped $BiVO_4$ under illumination and a shift in the CBM towards vacuum. We show that changes to the electronic density of states and Bi-O bond lengths cause a sizeable shift in CBM. We also analyze compensation of the acceptor dopant by oxygen vacancies and hole polarons. Our work provides insight into the use of $BiVO_4$ as a photocathode, moving us towards the fabrication of p-n homojunctions based on $BiVO_4$ that could further increase charge separation efficiency, and development of electrodes for other important technological processes, like N_2 reduction to NH_3.

[1] Lee, D., Wang, W., Zhou, C., Tong, X., Liu, M., Galli, G., & Choi, K. S. (2021). The impact of surface composition on the interfacial energetics and photoelectrochemical properties of $BiVO_4$. *Nature Energy*, *6*(3), 287-294.

Selective Electrochemical Reduction of CO_2 on Compositionally Variant Bimetallic Cu–Zn Electrocatalysts Derived from Scrap Brass Alloys IbrahimM. Badawy; American University in Cairo, Egypt

The electrocatalytic reduction of carbon dioxide (CO_2RR) into value-added fuels is a promising initiative to overcome the adverse effects of CO_2 on climate change. Most electrocatalysts studied, however, overlook the harmful mining practices used to extract these catalysts in pursuit of achieving high-performance. Repurposing scrap metals to use as alternative electrocatalysts would thus hold high privilege even at the compromise of high performance. In this work, we demonstrated the repurposing of scrap brass alloys with different Zn content for the conversion of CO_2 into carbon monoxide and formate. The scrap alloys were activated towards CO_2RR via simple annealing in air and made more selective towards CO production through galvanic replacement with Ag. Upon galvanic replacement with Ag, the scrap brass-based electrocatalysts showed enhanced current density for CO production with better selectivity towards the formation of CO. The density functional theory (DFT) calculations were used to elucidate the potential mechanism and selectivity of the scrap brass catalysts towards CO_2RR. The d-band center in the different brass samples with different Zn content was elucidated.

Exploring the Synergies of Cu_2O-Based Heterostructures with Upconversion Materials: A Holistic Approach to Efficient Solar Water Splitting YerbolatMagazov, VladislavKudryashov, MagzhanAmze, KuanyshMoldabekov and NurxatNuraje; Nazarbayev University, Kazakhstan

The production of hydrogen fuel through solar-driven water splitting has become the most promising strategy for the renewable energy future. The majority of photoactive materials that are used to generate hydrogen and oxygen under solar irradiance utilize only UV and visible light. Considering that the UV accounts for 9.3% ($\lambda < 400$ nm), visible light is 54.1%, and the remaining 36.6% which accounts for infrared light ($\lambda > 800$ nm) results in substantial solar energy loss. Hence, one of the primary objectives of this study is to capture and fully utilize solar energy, particularly IR radiation by incorporating photon-upconverting materials into a water-splitting system. Our work is focused on the basic concept, in which a semitransparent stable electrode based on Cu_2O with protective layers absorbs UV-Visible light and the upconverter in a solid-state form consisting of PbS nanocrystals, sensitizer and emitter elements utilize the low energy photons and produce the higher one in the visible region through the triplet−triplet annihilation (TTA) process. This strategy provides a significant improvement in light harnessing capacity and offers a two-fold increase in terms of photocurrent density.

8:00 PM EN07.09.15
Salt Template Based Synthesis of Bi Nanoparticles and Their Electrochemical CO2RR Activity for Formic Acid Production ChoiSung Yeol and Jeong MinBaik; Sungkyunkwan University, Korea (the Republic of)

Fossil fuel combustion process has led to excess emission of carbon dioxide to air about 35 billion ton per year. It causes serious environmental crisis like global warming, acid rain, water pollution etc. Up to now, considerable strategies for reducing usage of fossil fuels are mostly focused on expanding renewable energy source (energy harvesting, green hydrogen, power generation from nature). But it is not sufficient for supplying increasing global energy demand[1] and for these reason, continuous CO_2 emission to atmosphere is inevitable. Carbon capture and utilization technology(CCUS) is rising as one of the most effective solution to these unavoidable combustion process. Among CCUS technology, Electroreduction of CO_2 to fuel (CO2RR) which can be achieved from catalytic conversion at heterogeneous interface is promising technology because CO_2 can be transformed to other value-added multi carbon products. Formic acid, which is most high value-added products, can be synthesized through flow-cell set-up what can make CO2 gas diffuses more easily to the catalytic active site. We coated Bismuth nanoparticle as active catalyst directly on Gas diffusion electrode by NaCl template method without adding any binder solution and checked the selectivity, efficiency of bismuth catalyst layer by analyzing final products using NMR, Gas chromatography spectroscopy method. The synthesized Bi NPs exhibits excellent selectivity to HCOOH(~90%) at -0.8V, and showed over than 30mA/cm^2 current density.

8:00 PM EN07.09.16

High Photocharging Current Density and Improved Hydrogen Evolution Through Photoelectrochemical Biomass Valorization on Mo-BiVO4 Photoanodes DebajeetK. Bora[1,2]; [1]Mohammed VI Polytechnic University, Morocco; [2]ETH Zurich, Switzerland

In the last decade, the application of n-type metal oxide photoelectrodes for photoelectrochemical solar water splitting to produce hydrogen has been a cornerstone of artificial photosynthesis research. With a theoretical STH efficiency of 9.1%, the use of BiVO4 as a highly efficient photoanode material is an intriguing possibility [1]. It is utilized extensively in photocatalysis and photoelectrochemical water splitting for hydrogen production due to its low bandgap and ability to absorb visible light. Recently, BiVO4 was to convert biomass into organic compounds with added value. Due to its well-matched VB position with the electrochemical oxidation potential of 5-hydroxymethyl furfuryl, it is employed in the conversion to 2,5 - furan dicarboxylic acid using TEMPO (2,2,6,6-tetramethylpyridine-1-oxyl) as an ion scavenger [2]. This work [3] aims to increase the photocurrent density to match the current state of the art, as well as the solar-to-hydrogen conversion efficiency and faradaic efficiency for hydrogen generation. PEC-based glycerol oxidation is utilized to produce value-added organics, with an emphasis on controlling the activity-selectivity factors of the $BiVO_4$ photoanode, as described in a recently published work. In the current case, hydrogen is forming as a byproduct of CO_2 along with the formation of formic acid/formaldehyde on the cathodic side. It also helps to avoid the formation of explosive H_2/O_2 mixtures caused by membrane leakage. In terms of kinetics, the oxidation of biomass by PEC is more advantageous than oxidation by water because it involves fewer intermediate reaction steps, which increases the associated potential. The most important research gap is the direct application of photoelectrochemical biomass oxidation to increase the solar-to-hydrogen conversion efficiency (STH) of existing Mo-$BiVO_4$ without resorting to costly modification techniques such as heterojunction formation or the tandem approach. A novel surfactant-mediated method has been developed to produce Mo-doped $BiVO_4$ photoelectrodes with well-controlled morphology and pure clinobisvanite phases, as confirmed by FESEM and XRD. The photoelectrode exhibits the typical absorbance band in the visible spectrum, proving its suitability for photoelectrochemical applications. When exposed via a full aperture under front light illumination, the photoanode exhibits a photocurrent density of 3.5 mA cm $^{-2}$, which is the highest among the existing pristine bismuth vanadate photoanodes without modification. Upon TEM beam exposure, the scratched nanoparticles constituting the photoelectrodes exhibit a unique phenomenon of dynamic crystallite fringes, indicating the photodecomposition nature of the photoelectrode. Mo-BiVO4 is further utilized for photoelectrochemical glycerol oxidation to prevent electron-hole recombination and enhance the STH efficiency, and it exhibits the highest current density of 5 mA cm^{-2} under backside illumination. A glycerol layer on the photoelectrode's surface obstructs photons, resulting in a decrease in photocurrent density under front light illumination. The photoelectrode exhibits photocharging, enabling the photocurrent density to reach a maximum of 8 mA cm^{-2} with a water splitting current density of 5.8 mA cm^{-2}. The effect is a result of the increased band bending at the photoelectrode's surface, which facilitated enhanced charge generation and prevented the recombination of excitonic pairs. Upon photoelectrochemical glycerol oxidation, the photoelectrode exhibits significant hydrogen gas evolution with the highest STH efficiency of 5.5% and IPCE of 52%.

Machine Learning Assisted Computational Design of High Entropy Alloy Electrocatalysts for Selective Nitrate to Ammonia Conversion BoyangLi, YingFang and GuofengWang; University of Pittsburgh, United States

Human activities have influenced global nitrogen cycle and caused many energy and environmental issues. A possible solution is to directly reduce nitrate to ammonia electrochemically, which can synergistically mitigate environmental problems and provide economic benefits by generating fertilizer using renewable energy. In this study, we employed a machine learning assisted computational approach to find a high entropy alloy (HEA) catalyst toward highly selective and stable electrochemical nitrate reduction (ENR) for nitrate to ammonia conversion under acidic conditions. First, we explored the composition space of 10 active elements (i.e., Ru, Pt, Pd, Cu, Fe, Co, Ni, Rh, Ir, and Mo) with the atomic ratio of each element ranging from 5 to 50%, with a 5% step size. We launched a composition screening to ensure the solid solution phase based on atomic size mismatch, mixing enthalpy, and Gibbs free energy of mixing, and identified 24 types of element compositions to be stable under any composition. By using the literature-reported synergistic pairs for ENR to further prescreening, we identified Ru-Pd-Pt-Cu alloy as an appropriate candidate to disperse Ru atom and improve the performance of ENRT to ammonia. Furthermore, we used the DFT method to optimize the adsorption configurations of all possible ENR intermediates on RuPdPtCu (111) surface and used the elemental types on the first neighboring and second neighboring positions as input features to fit the calculated adsorption energies using a linear regression model. Our results show that nitrate reduction species are more favorable to be adsorbed on the Ru atom (i.e., first neighboring site) as compared to the Cu, Pt, and Pd atoms, suggesting that the nitrate reduction will predominantly occur on the site containing at least one Ru atom in RuPdPtCu (111) surface. The limiting potential defined as the highest potential in which all free energy changes become downhill was predicted to be 0.17V for nitrate reduction reaction on RuPdPtCu(111) with the corresponding rate-determining step being the protonation of N to form NH. In comparison, the metallic Ru (0001) surface shows a lower limiting potential of -0.36 eV to promote nitrate reduction. This finding explains why the RuPdPtCu HEA catalyst exhibits a higher nitrate reduction activity than the unary Ru catalyst. Our predictions have been well validated by experimental measurement data.

8:30 AM EN07.10.02

Balanced NO_x^- and Proton Adsorption for Efficient Electrocatalytic NO_x^- to NH_3 Conversion YueHu[1,2], DongshengGeng[3] and QingyuYan[2]; [1]University of Science and Technology Beijing, China; [2]Nanyang Technological University, Singapore; [3]Nanjing University of Information Science & Technology, China

Electrocatalytic reduction of available nitrate (NO_3^-)/nitrite (NO_2^-) resources (eNO_x^-RR) to value-added ammonia (NH_3)[1] under ambient conditions is a green and promising alternative to the Haber−Bosch process.[2] In practical, NO_x^- resources can be obtained from two ways: 1) industrial and agricultural wastewater and polluted groundwater,[3] and 2) plasma-mediated nitrogen oxidation (p-NOR).[4] However, their NO_x^- concentrations are generally low.[5] Hence, electrocatalyst engineering is important for eNO_x^-RR to obtain both high NH_3 FE and high current density at low NO_x^- concentrations. Herein, we designed balanced NO_x^- and proton adsorption by properly introducing Cu sites into Fe_2O_3 electrocatalyst. During the eNO_x^-RR process, the excess H adsorption is balanced and the good NO_x^- affinity is maintained. As a result, the designed Cu-Fe_2O_3 catalyst exhibits promising performance with an average NH_3 FE of 98% and an average NH_3 yield of 15.65 mg h^{-1} cm^{-2} under the low NO_3^- concentration (32.3 mM) of typical industrial wastewater at an applied potential of -0.6 V vs. Reversible Hydrogen Electrode (RHE). Moreover, the concentration of NO_x^--N (451.6 μg ml^{-1}) in a simulated industrial wastewater can be decreased to the drinkable water level (NO_3^--N < 11.29 μg ml^{-1} and NO_2^--N < 0.91 μg ml^{-1}) after 160 min with an average NO_3^--to-NH_3 conversion efficiency of 85%. With direct current (DC) p-NOR generated NO_x^- (23.5 mM) in KOH electrolyte, the Cu-Fe_2O_3 catalyst achieves a FE of 98.83% and a yield of 15.09 mg h^{-1} cm^{-2} for NH_3 production at -0.6 V (vs. RHE). It is worth noting that the DC plasma energy consumption is only 13.5 W/h.

Optimization Strategies of Photovoltaics-Powered Green Hydrogen Production XuanjieWang, XinyueLiu and LenanZhang; Massachusetts Institute of Technology, United States

Green hydrogen production powered by photovoltaics provides a clean solution for energy conversion and storage. The key parameter of photovoltaic electrolysis (PV-EC) system is the solar-to-hydrogen (STH) efficiency. Previous studies have been mostly focused on improving the efficiency of each system individually using multi-junction PV materials, catalysts and electrolytes. However, the coupling between photovoltaic and electrochemical devices is still elusive to achieve high STH efficiency in a system level. In our study, the optimization strategies of PV-EC systems are demonstrated to approach thermodynamic limit (26.6%) for green hydrogen production. First, we list three design parameters for modeling, namely number of PV, number of EC and the area ratio between PV and EC. Then we model the crystalline silicon PV coupled with a real EC system. The STH efficiency varies under different PV and EC combinations. The STH efficiency map clearly defines three regions indicating the engineering space for PV-EC coupling, Tafel slope and area ratio. The optimization strategies presented in this study can lead to further advancements in coupled PV-EC systems with well-controlled performance for different conditions.

9:00 AM EN07.10.04
Ion Beam Analysis of $MoNi_4$-MoO_2 Catalyst Layer for Anion Exchange Membrane Electrolyzer YaminiKumaran[1], LatikaS. Chaudhary[1], IulianGherasoiu[2] and HaralabosEfstathiadis[1]; [1]SUNY Poly CNSE, United States; [2]SUNY Polytechnic Institute, United States

There has been an increased interest in Anion Exchange Membrane (AEM) electrolyzer technology enabling zero-gap configuration lately. This technology also allows non-noble metal-based materials to be used as catalyst layers in an alkaline environment. In this research, $MoNi_4$ supported by MoO_2 nanorods has proven to be a promising electrocatalyst for Hydrogen evolution reaction (HER) with a decreased overpotential of 40 mV at 10 mA/cm^2 with increased current density, and stability for almost 12 hours in half-cell configuration. However, it is important that the material be used as a catalyst layer in membrane electrode assembly to have the capacity to tolerate high steady-state potentials for extended periods of time in real operating systems. The aim of this study is to analyze the AEM electrode assembly with $MoNi_4$-MoO_2 as the cathode layer synthesized via hydrothermal synthesis for overall metal loading corresponding to the improved efficiency and catalyst dissolution arising due to the interaction between the catalyst layer and the ionomer membrane. The cathode catalyst synthesized was characterized by X-Ray diffraction, SEM and X-Ray photoelectron spectroscopy for structural, morphological and surface composition. Further, nuclear techniques like Rutherford Backscattering Spectroscopy (RBS) employed to provide information regarding the thickness and stoichiometry of the catalyst layer and metal dissolution in the ionomer membrane, and Nuclear Reaction Analysis (NRA) was utilized to study different defects in the ionomer membrane by high-resolution Hydrogen depth profiling after the operation. Overall, this work presents a better understanding of catalyst degradation effects on the ionomer membrane and vice versa responsible for the voltage and mass transport losses in AEM electrolyzers.

Metal Complex/Semiconductor Hybrid Photoelectrocatalysts and Photocatalysts for CO_2 Reduction AkinobuNakada[1,2]; [1]Kyoto University, Japan; [2]PRESTO/JST, Japan

Reductive conversion of CO_2 into energy-added molecules has been an important subject in various fields including materials chemistry, catalysis, electrochemistry, and photochemistry, from viewpoints of both decreasing CO_2 concentration and gaining energy and carbon resources. Among the various methods and schemes proposed, visible-light-driven CO_2 reduction in combination with water oxidation, one of the representative models of artificial photosynthesis, is an attractive solution because it enables abundant water and inexhaustible solar energy to be used to produce value-added chemicals. Molecular metal complexes and semiconductors are promising candidates for photocatalysts that can reduce CO_2 to CO, formate, formaldehyde, or other hydrocarbons. Although both molecular metal complexes and semiconductors have strengths and weaknesses, their weaknesses (low oxidation ability and low selectivity for reduction reactions) can be overcome via the construction of a suitable molecule/semiconductor hybrid material. However, facilitating electron transfer at the molecule/semiconductor junction while suppressing unfavorable back electron transfer events is challenging.
Here, our design principle for developing the hybrid photoelectrodes and photocatalysts will be reported, starting from introduction of selective electrocatalysis and photocatalysis of CO_2 reduction by a metal complex catalyst in aqueous solution. Subsequently, application of these metal-complex photocatalysts into a hybrid photoelectrode with semiconductor materials for photoelectrochemical CO_2 reduction will be presented. Simple hybrid photocatalysts directly connecting metal complexes and semiconductor particles, which facilitate photocatalytic CO_2 reduction via interfacial electron transfer without the aid of electrochemical techniques, will also be reported. Finally, we will report our recent approach for constructing hybrid photocatalysts with design-flexible conjugated polymers as a light absorber, a photoelectron transporter, and a suitable reaction center by site-selective modification of metal-complex catalysts.

An Integrated View of Multi-Step (photo)Electrocatalytic Reactions FrancesHoule; Lawrence Berkeley National Laboratory, United States

Our views of (photo)electrocatalytic reactions and how they are influenced by their environments are strongly shaped by atomic-level theoretical studies that examine reaction pathways to identify the most probable routes, and by macro-level observations of current densities, Tafel plots, and product distributions. Connecting these two very different pictures via multiscale stochastic kinetics simulations provides a way to examine factors that influence reactivity, and predict how systems can be designed for improved efficiency and selectivity. This talk will focus on the role of thermal steps and local fluctuations at the catalytic site level in influencing reactivity, and discuss how these characteristics are manifested in experimental studies.

10:45 AM EN07.10.07
Defect Engineering of WO3 by Rapid Flame Reduction for Efficient Photoelectrochemical Conversion of Methane into Liquid Oxygenates Ho KunWoo[1], AnkitGautam[1], Jaxiry S.Barroso-Martínez[1], Arthur P.Baddorf[2], KaiZhou[1], Yoon YoungChoi[1], JiajunHe[1], Alexander V.Mironenko[1], JoaquinRodriguez-Lopez[1] and LiliCai[1]; [1]University of Illinois, United States; [2]Oak Ridge National Laboratory, United States

Photoelectrochemical (PEC) conversion is a promising way to utilize methane (CH4) as a chemical building block without harsh conditions. However, PEC CH4 conversion to value-added chemicals remains challenging due to the thermodynamically favorable over-oxidation of CH4 to CO2. Here, we report WO3 nanotubes (NTs) photoelectrocatalysts for PEC CH4 conversion with high liquid product selectivity through defect engineering. By tuning the flame reduction treatment, the oxygen vacancies of WO3 NTs were carefully controlled. The optimized reduced WO3 NTs suppressed over-oxidation of CH4 and showed high C1 liquid selectivity of 69.4% and production rate of 0.174 μmol cm-2 h-1. Scanning electrochemical microscopy revealed that oxygen vacancies can restrain the production of hydroxyl radicals, the presence of which in excess could further oxidize C1 intermediates to CO2. In addition, optical characterization and computational studies elucidated that oxygen vacancies thermodynamically suppress over-oxidation. This work introduces a strategy to understand and control the selectivity of photoelectrocatalysts for direct CH4 conversion to liquids.

11:00 AM +EN07.10.08
***In-Situ* TEM Investigation on Redox Mechanisms of Transition Metal Oxides**XiaozhiLiu, YuePan, DanZhou and DongSu; Chinese Academy of Sciences, China

The physicochemical properties of transition metal oxides are determined by their phase structures, surface exposed atoms, morphology, and defects. Metal oxide catalysts usually undergo a series of activation and reaction processes in practical applications, which modulate their morphology and change their valence states and crystal phases. These structural variations alternate their properties significantly and have been believed to be a critical problem, e.g., in their catalytic applications. During reactions, metal oxides undergo either reduction or oxidation reactions depending on the ratio of reducing or oxidizing gases in the atmosphere. Although it is believed that *in situ* investigation of the reaction pathways is of importance to understand their intrinsic redox nature, as far as we know, the microstructural evolution during the redox of metal oxides is still not well understood. We have studied the dynamic reaction behaviors of iron oxides via *in situ* transmission electron microscopy (TEM) with a Climate system from DENSsolutions. We have achieved atomic-scale resolution imaging to visualize the evolution of phase boundary and the competitive transitions between Fe_3O_4, FeO, and Fe in the nanoreactor. Thus we found the inhomogeneous reaction pathways which are strongly affected by the trace amount of oxygen or water vapor in catalytic reactions. Our results could provide new insights into the redox reaction mechanism of transition metal oxides, and help to understand the role of these oxides in catalytic reactions.

Controlling C(sp^3)-H and C(sp^3)-C(sp^3) Transformations and Fuel Synthesis at Electrocatalytic Interfaces MarcelSchreier[1,2]; [1]University of Wisconsin-Madison, United States; [2]University of Wisconsin–Madison, United States

Producing fuels and chemicals using renewable electricity holds the promise to enable a circular economy based on sustainably produced carriers of electrical energy and sustainably produced chemicals. To date, the vast majority of electrocatalytic reactions are limited to the transformation of small inorganic molecules such as CO_2, H_2O, N_2, as well as the oxidation and reduction of alcohols. However, comprehensive electrification of the chemical industry will require electrocatalytic reactions that can promote the transformation of unactivated C(sp^3)-H and C(sp^3)-C(sp^3) bonds, which are central to today's industry.
In this presentation, I will show how fundamental understanding of the interfacial processes occurring in electrocatalytic reactions can be exploited to expand the reaction scope of electrocatalysis to the transformation of complex substrates involving the controlled activation of C-H and C-C bonds. In a first step, I will show how this approach allows us to transform ethanol to ethylene oxide, an important plastic precursor. Subsequently, I will discuss methods to electrocatalytically transform inert alkanes such as methane, ethane, and butane at room temperature.

2:00 PM EN07.11.03
Photochemical Diodes for Simultaneous Bias-Free Glycerol Valorization and Hydrogen Evolution Jia-AnLin, InwhanRoh and PeidongYang; UC Berkeley, United States

Finding sustainable and renewable energy is currently one of the most urgent challenges facing society today. Artificial photosynthesis offers a route to using solar energy to produce fuels such as hydrogen, a fundamental component for building a carbonfree economy. One such approach to realizing artificial photosynthesis is presented through the photochemical diode. Conventional approaches targeted the optimization of the overall water splitting (OWS) reaction in which hydrogen and oxygen are produced. However, the sluggish kinetics of the oxygen evolution reaction (OER) and the high thermodynamic potential requirement of 1.23 V for the OWS limit the current performance of bias-free photoelectrochemical (PEC) systems. Here, we offer an alternative approach by replacing the OER with the glycerol oxidation reaction (GOR) for value-added chemicals using Si photoanode. By employing a low overpotential catalyst such as PtAu for GOR, which shows a low onset potential of 0.4 V vs RHE electrochemically, the voltage requirements to couple with hydrogen evolution reaction (HER) become substantially lowered compared to OWS. As a result, the PtAu/Si photoanode exhibits a low GOR onset potential of −0.05 V vs RHE and a photocurrent density of 10 mA/cm2 at 0.5 V vs RHE. Coupled with a Si nanowire photocathode for the HER, the integrated system yields a high photocurrent density of 6 mA/cm2 with no applied bias under 1 sun illumination and can run for over 4 days under diurnal illumination. The demonstration of the GOR-HER integrated system provides a framework for designing bias-free photoelectrochemical devices at appreciable currents and establishes a facile approach to artificial photosynthesis.

2:15 PM EN07.11.04
Molecular Additives Steer Selectivity of CO_2 Photoelectrochemical Reduction over Gold Nanoparticles on Gallium Nitride AisuluAitbekova, NicholasWatkins, JonasPeters, TheodorAgapie and HarryA. Atwater; California Institute of Technology, United States

We demonstrate that functionalizing Au/p-GaN cathodic photoelectrochemical devices with molecular additives steers the selectivity for CO_2 reduction process toward reduced products of carbon dioxide and suppresses hydrogen generation via water splitting. The working hypothesis for this selectivity change is the suppressed proton transfer through hydrophobic molecular additive films, which results in the diminished hydrogen evolution reaction rates (Faradaic Efficiency to H_2 decreases from 90% to 18 %). Our work establishes a rigorous platform to elucidate structure-property relationships in photoelectrocatalysts and engineer active, stable, and selective materials for sustainable energy applications.

The wide bandgap semiconductor p-GaN exhibits stability under CO_2 photoelectrochemical conditions due to its nitrogen-rich surface. Additionally, its conduction band minimum is more negative than the CO_2 reduction potential. When combined with metals, such as gold nanoparticles, the semiconductor-metal interface forms a Schottky barrier. The downward bending of the conduction and valence bands drives electrons excited in p-GaN towards the metal-electrolyte interface, while the holes are transferred into the p-GaN bulk semiconductor.

Rising levels of greenhouse gases necessitate a reduction in the amounts of these harmful compounds in the atmosphere and a transition to sustainable production of fuels and chemicals. Photoelectrochemical CO_2 reduction (CO2R) is an appealing solution to convert carbon dioxide into higher-value products. However, CO2R in aqueous electrolytes suffers from poor selectivity due to the competitive hydrogen evolution reaction dominant in aqueous electrolytes. As noted above, our approach to overcome this challenge consists of (1) synthesis of metal/semiconductor structures with controlled properties and (2) functionalizing the metal/semiconductor surface with molecular additives.

2:30 PMBREAK

3:00 PM EN07.11.05
A Comprehensive Online Analytical System Coupled with Standardized Data Analysis for the Electrochemical Reduction of CO_2AlessandroSenocrate[1,2], PeterKraus[1], FrancescoBernasconi[1,2] and CorsinBattaglia[1,2]; [1]Empa–Swiss Federal Laboratories for Materials Science and Technology, Switzerland; [2]ETH Zürich, Switzerland

The electrochemical reduction of CO_2 (CO_2RR) is a promising way to convert detrimental CO_2 emissions into sustainable fuels and chemicals, and thus to achieve a circular carbon economy.[1] Depending on catalyst type and reaction conditions, different gaseous and liquid products can be obtained from the CO_2RR, and their production rates vary with reaction time. It becomes thus imperative, for any catalytic performance analysis, to be able to assess the product distribution online during CO_2RR.[2,3] However, while gaseous products are readily analyzed online by gas chromatography, liquid products are typically only assessed at the end of the reaction due to the lack of suitable automated liquid sampling and analysis methods. In addition, reaction parameters such as CO_2 mass flow rates, temperatures and pressures are seldom recorded, causing the loss of significant information on catalysts, electrodes, and electrolyzers behavior.
To overcome these issues, we assemble a comprehensive analytical system coupling online gas and liquid product analysis by gas and liquid chromatography leveraging a special automated liquid sampling valve with electrochemical protocols that assess CO_2RR performance, electrolyzer cell resistance and electrode surface area. In addition, we record CO_2 mass flow rates, electrolyzer temperatures, as well as gas and liquid flow pressures.[4] To rapidly and reproducibly handle the large and heterogeneous data volume obtained we implement a standardized data pipeline based on our own open-source software,[5] which automatically parses the numerous different raw data files, composes a data set following FAIR practices,[6] and post-processes and plots the data in a standardized way. We validate the analytical system by carrying out CO_2RR at 200 mA/cm^2 on Cu gas diffusion electrodes, following the changes in selectivity with reaction time for > 10 gaseous and liquid products, and recording mass flow rates, electrolyzer temperatures and pressures. The modular nature of our analytical system, combined with the standardized data pipeline, allows us to freely increase the number and type of sensors used with minimal impact on the data analysis time, as well as to multiplex our analysis to 8 parallel electrolyzer cells, paving the way for a much deeper and faster understanding of the function of CO_2RR catalysts, electrodes, and electrolyzers.

3:15 PM EN07.11.06
Computational Screening of Non-Copper Based Catalysts for Electrochemical CO2 Reduction Reaction SamiraSiahrostami; Simon Fraser University, Canada

Copper-based catalysts are currently being investigated as the most efficient catalysts for electrochemical CO2 reduction reactions (CO2RR) to valuable hydrocarbons such as methane, ethylene, and ethanol. Copper catalysts, on the other hand, are prone to restructuring and degradation, fueling the search for non-Cu catalyst families that enable C-C coupling. We use high-throughput DFT calculations to search a wide range of materials space and accelerate the discovery of more efficient catalyst materials beyond copper for CO2RR, as well as scale-up the use of the catalysts in electrochemical reactors to enable meaningful conversion. In this talk, I will discuss the use of robust high-throughput DFT calculations to screen a massive library of non-conventional classes of materials such as perovskites, transition metal nitrides[1], and metal organic frameworks[2] as well as the insights we can gain from them.

Simple Approach for Modeling Cyclic Voltammograms of Hydrogen Evolution Reaction - Application to Emerging Catalysts TimothyYang and WissamA. Saidi; U.S. Department of

Energy National Energy Technology Laboratory, United States

Hydrogen evolution reaction (HER) is the critical process for green hydrogen production. In analytical chemistry, cyclic voltammetry (CV) has been the practical technique to provide current-potential characteristics that can be further analyzed using the Butler-Volmer formulation. Due to the phenomenological nature of the BV formulation, there is a missing linkage between the analytical chemistry, theoretical electrochemistry and first-principles modeling. Herein, we develop an electrochemical CV model for HER from density functional theory calculations. At the equilibrium conditions, this CV model quantifies the HER exchange currents – the main analytical descriptor for HER rate, only using an easy-to-compute hydrogen adsorption free energy. Further, we show that the CV model reproduces experimental cyclic voltammograms with high fidelity. The success of the CV model is justified by the universality of the transfer coefficient and the absolute reaction rate for a one-step, one-charge transfer process. This framework for developing the electrochemical HER model from fundamental electrochemistry principles and computational quantum-mechanical approaches is general and applicable for any electrochemical reaction.

Multimodal *Operando* Studies of Evolving Cu Nanocatalysts for CO_2 ElectroreductionYaoYang[1], DavidA. Muller[2], HectorD. Abruna[2] and PeidongYang[1]; [1]UC Berkeley, United States; [2]Cornell University, United States

In an era of shifting the energy paradigm from fossil fuels to renewable energy, CO_2 reduction reaction (CO_2RR) emerges as a promising approach to covert greenhouse gas into valuable chemical fuels and close the carbon cycle for a sustainable energy supply. Since Cu remains the sole element for CO_2RR to multicarbon products (C_{2+}), significant efforts have been devoted to developing Cu electrocatalysts with higher selectivity and activity. One of the key challenges is understanding how to achieve and sustain electrocatalytic activity under operating conditions for extended time periods, and such fundamental understanding calls for the use of multimodal *operando* analytical methods.[1-4]
In our previous studies, we reported that sub-10 nm Cu nanoparticles (NPs) showed superior C_{2+} selectivity, relative to the larger sized Cu NPs, especially at low overpotentials.[5,6] In this work, we present a comprehensive *operando* correlative study of dynamic evolution of a family of monodisperse Cu NP ensemble electrocatalysts under CO_2RR.[1] *Operando* electrochemical liquid-cell scanning transmission electron microscopy (EC-STEM) and 4D-STEM reveal dynamic microscopic structural evolution at the nm scale.[2] Correlated *operando* high-energy-resolution fluorescence-detected (HERFD) X-ray absorption spectroscopy (XAS) reveals dynamic macroscopic changes in valence states and coordination environment. Statistical analysis of interparticle dynamics was probed by *operando* electrochemical resonant soft X-ray scattering (EC-RSoXS).[3] The multimodal *operando* methods, described herein, elucidate the longstanding enigmatic nature of Cu active sites for selective CO_2 electroreduction. The strategy described herein can serve as a general platform to resolve the electrocatalytic interface of nanoparticle catalysts under real-time operating conditions across multiple spatiotemporal scales, thus serving the fundamental understanding necessary to development of many other electrochemical reactions for renewable energy technologies.[4]

Facile Sythesis of Novel Pt-Ni-Cu Nanoframes via Simple Galvanic Replacement for Methanol Oxidation Reaction KevinWilk, YuhanHu, SamanthaFuscus, MarkusHiggins, KiraShulman, EduardoLezama and Yiliang (Yancy)Luan; SUNY Binghamton, United States

Pt-based catalysts play a crucial role in various applications, such as catalytic converters, petroleum refinement, and chemical production. However, the widespread use of Pt-based catalysts is hindered by their high cost. To address this issue, researchers have focused on combining Pt with non-precious metals to reduce Pt usage with intent to optimize electronic configurations for improved catalytic performance. Recently, there has been significant interest in nanoframes due to their unique open structure, which provides a large surface area and enhances catalytic performance compared to conventional solid nanoparticles. In this report, we present a facile preparation of novel Pt-Ni-Cu nanoframes from Pt-Ni nanocubes through a simple galvanic replacement process at high temperature. The resulting nanoframes retain the segregated Pt at the edges and diagonals of the Pt-Ni precursor while incorporating Cu into the alloy. The segregated Ni, except at the edges and diagonals, is selectively removed, resulting in a hollow structure through the Kirkendall Effect. The amount of Cu in the nanoframes can be controlled by adjusting the reaction time. The nanoframes were applied for methanol oxidation reaction (MOR), and the mass activity is proportional to the amount of Cu incorporated, which was adjusted by controlling the time on the synthesis of the nanoframes. These results not only highlight the exceptional potential of the Pt-Ni-Cu nanoframes as catalysts for MOR but also provide a promising solution to the cost-effectiveness challenge associated with Pt-based catalyst applications.

8:30 AM EN07.12.02

Segregation Engineering for Enhanced Stability of Electrocatalysts XuyangZhou[1], OlgaKasian[1,2,3], Raquel AymerichArmengol[1], SiyuanZhang[1], ChristinaScheu[1], GregoryB. Thompson[4], GerhardDehm[1], BaptisteGault[1,5] and DierkR. Raabe[1]; [1]Max-Planck-Institut für Eisenforschung GmbH, Germany; [2]Helmholtz Institut Erlangen-Nürnberg, Germany; [3]Friedrich-Alexander-Universität Erlangen-Nürnberg, Germany; [4]The University of Alabama, United States; [5]Imperial College London, United Kingdom

The challenge faced by energy conversions and storage devices, such as fuel cells and electrolyzers, lies in the gradual dissolution of the electrocatalysts during long-term and dynamic operation. This dissolution primarily starts at defects, specifically grain boundaries and dislocations. To tackle this issue and enhance the stability of electrocatalysts, we employ the design concept of segregation engineering, which leverages solute segregation prone to these internal defects.
In our study, we demonstrated the feasibility of this approach by stabilizing a model Pt catalyst through the addition of a more noble metal, Au, at approximately 5 at.%. By optimizing the heat treatment procedure, we successfully controlled the local chemistry of defects, achieving a local Au content ranging from no solute segregation to values as high as 30 at.%. The characterization of the nanoscale structure and chemistry of the defects was accomplished through a correlative study involving transmission electron microscopy and atom probe tomography. Moreover, we directly linked the structure and chemistry of these defects with electrochemical dissolution tests of Pt and PtAu alloys, employing on-line inductively coupled plasma mass spectrometry in a scanning flow cell set-up. By effectively stabilizing and passivating the most vulnerable sites, Au atoms, which were once segregated as defects, significantly enhance the stability of Pt electrocatalysts, reducing dissolution by more than an order of magnitude. Even after long-term testing (1000 cycles), the dissolution predominantly occurred at the segregated Au atoms, validating the potential of segregation engineering in enhancing the longevity of Pt electrocatalysts.
Our work highlights the significance of incorporating a stabilizing component like Au and considering the spatial distribution of this solute addition within the electrocatalyst, particularly concerning the chemical distribution at crystalline defects. This breakthrough opens up new pathways for the development of more stable nanoscale electrocatalysts, utilizing solute segregation to defects, and can be applied to a wide range of catalytic systems.

8:45 AM EN07.12.03

Active-Site Imprinted M-N-C Electrocatalysts: Tailor-Made Synthesis and Tuned Activity DavideMenga[1], Tim-PatrickD. Fellinger[2] and YangShao-Horn[1]; [1]Massachusetts Institute of Technology, United States; [2]Bundesanstalt für Materialforschung und -prüfung, Germany

Due to the abundance and inexpensiveness of their constituent elements and their atomic dispersion, metal- and nitrogen- co-doped carbons (M-N-Cs) are currently the best alternative among noble-metal-free catalysts set to replace critical raw materials in several fundamentally important electrochemical reactions such as oxygen reduction reaction (ORR) and CO_2 reduction reaction (CO2RR).
Due to the metastability of the active M-N_4 sites at the temperature of their pyrolytic formation, the final transition metal loading is currently limited and significant amounts of inorganic by-products are formed. Although synthesis protocols have been successfully optimized, multiple processing steps are required, making the preparation time-consuming.
In previous work, it has been showed that via an active-site imprinting strategy followed by a transmetalation reaction, Mg-N-C and Zn-N-C containing Mg-N_4 and Zn-N_4 sites respectively,

can be transformed into ORR active Fe-N-C electrocatalysts, avoiding the formation of elemental iron, or iron carbide side phases. This synthetic method allows for high yields, controlled morphology and high metal loadings.
In this contribution, it will be presented how $Zn{-}N_4$ sites in tailor-made Zn−N−C materials are utilized as an active-site imprint for the preparation of the corresponding M−N−C catalysts with a high loading of atomically dispersed metal. The current state of this class of materials is discussed in terms of synthetic methods, activity and stability.

9:00 AM EN07.12.04
3D Printed Continuous Nanoporous Cu/CuOx Electrodes for Highly Efficient Hydrogen Evolution Reaction AnandP. Tiwari and William J.Scheideler; Dartmouth College, United States

The sluggish kinetics of electrocatalysts in alkaline media cause stability as well as low active site issues, restricting the conversion of renewable energy into hydrogen. Synergistic enhancements such as the formation of free-standing nanoporous heterostructures, homogeneous diffusion of active materials into conductive supports, and atomic doping/defecting of active materials could promise to improve the kinetics and resolve key stability issues. Herein, we present scalable 3D-printing of continuous nanoporous Cu/CuO_x diffused carbon electrocatalysts for efficient alkaline hydrogen evolution reaction (HER) in which Cu/CuO_x acts as active sites, nanoporous carbon provides a higher conductive surface area to enhance HER kinetics, and periodic 3D lattice micro-structuring facilitates bubble evolution to improve stability. The resulting micro-architected porous electrodes deliver high electrocatalytic activity for HER, with an overpotential of 155 mV at a current density of 10 mA/cm^2 and a Tafel slope of 134 mV/dec, outperforming other 3D noble metal-free oxide materials. In addition, the as-fabricated catalysts also showed superior durability: up to 240 hours of continuous hydrogen evolution without any significant change in overpotential and current density, which is 10X better than reported 3D-printed catalysts. Our comparative analysis of multiple 3D lattice geometries indicates that our 3D-ordered nanoporous Cu/CuOx electrocatalysts maximize performance by exposing more active sites and allowing faster discharge of H_2 gas bubbles through engineered microchannels. We will finally discuss how our micro-architected approach to transforming 3D-printed lattices can be applied to a variety of earth-abundant electrocatalysts based on transition metal/metal oxides for enhancing performance and stability of additional reactions including OER.

9:15 AM EN07.12.05
Phase-Controlled Deposition of Ru on Pd Nanocrystal Templates: The Effects of Particle Shape and Size QuynhNguyen, AnnemiekeJanssen, ZhihengLyu, VeronicaPawlik, ChenxiaoWang and YounanXia; Georgia Institute of Technology, United States

Template-directed growth has been widely used for the phase-controlled synthesis of metal nanocrystals, but much remains to be discovered about the mechanistic details. In this work, we systematically investigate the roles played by the shape and size of Pd nanocrystal templates in controlling the crystal phase taken by the deposited Ru overlayers. For Pd cubic nanocrystals, a face-centered cubic (*fcc*) Ru shell is always favored when the particle size is varied in the range of 6−25 nm. In the case of Pd octahedral nanocrystals, we observe a size dependence, with 14-nm octahedra giving *fcc*-Ru but 20- and 26-nm octahedra resulting in hexagonal close-packed (*hcp*) Ru. This trend can be attributed to their difference in surface atomic arrangement, as the {100} facets on a cubic template cannot be matched by any facet of *hcp*-Ru, forcing the deposited Ru to take the *fcc* phase. In contrast, the {111} facets on an octahedral template can be matched by the {0001} facets of *hcp*-Ru, allowing the deposited Ru to take either an *hcp* or *fcc* phase. The crystal phase taken by the Ru shell is determined by the relative contributions from the surface and bulk energies of the deposited *fcc*- and *hcp*-Ru phases. Additionally, the water content in the reaction mixture also plays an important role in affecting the crystal phase taken by the Ru shell by altering the reduction kinetics. When tested as catalysts toward ethylene glycol oxidation, the *fcc*-Ru outperforms *hcp*-Ru while the cubic shape is advantageous over the octahedral counterpart.

9:30 AM EN07.12.06
Toward Scalable Nickel-Cobalt Based Anode Materials for Alkaline Electrolysis: Unveiling the Path from Micropowder Analysis to Electrochemical Performance VineethaVinayakumar[1,2], AdarshJain[1], MohitChatwani[1], TimoWagner[3], ChristianMarcks[4], NicolasWöhrl[3,2], AnnaK. Mechler[4] and DorisSegets[1,2]; [1]Institute for Energy and Materials Processes–Particle Science and Technology (EMPI–PST), University of Duisburg–Essen (UDE), Germany; [2]Center for Nanointegration Duisburg–Essen (CENIDE), University of Duisburg–Essen (UDE), Germany; [3]Faculty of Physics, University of Duisburg–Essen (UDE), Germany; [4]Electrochemical Reaction Engineering, RWTH Aachen University, Germany

The depletion of conventional energy resources has highlighted the need for sustainable alternatives, with hydrogen emerging as a promising option. However, the commercial-scale production of hydrogen remains a challenge (1). In this study, we focus on water electrolysis as an efficient method for energy conversion and storage, emphasizing the crucial role of electrocatalysis. Despite recent progress, establishing direct correlations between anode properties and performance in an industrial setting is crucial for the practical implementation of stable and highly efficient anodes for alkaline water electrolysis at pilot-scale systems. This requires linking the scale-up process with a comprehensive fundamental understanding, enabling successful scaling while maintaining optimal performance.
To address these challenges, we evaluate the cycle of anode generation starting from the characterization of micropowders through catalyst inks to final electrodes. Our primary goal is to achieve efficient hydrogen production on a commercial scale. To accomplish this, our methodology utilizes complementary techniques to thoroughly analyze the physical and chemical properties of materials throughout the entire process chain. By adopting this comprehensive approach, we aim to gain a deep understanding of the materials involved and optimize their performance for the production of hydrogen on a large scale. To evaluate the interdependencies between different stages and to find out the determining steps during electrode manufacturing, we developed a framework in the sense of a coherent workflow starting with the characterization of commercially available Ni- and Co-based micro powders. Subsequently, ink formulations were optimized using analytical centrifugation (2) and Hansen parameter calculations (3), followed by electrode layer fabrication using ultrasonic spray deposition of the ink on Ni plates. After optimizing each individual stage in the whole process chain, we also investigated the influence of post-treatments, specifically vacuum annealing, and surface plasma treatment, on the stability of electrodes against delamination. A framework based on atomic force microscopy was developed to precisely quantify micro features and analyze the surface characteristics of electrodes including large areas. Subsequently, the evaluated electrodes were subjected to functional testing as anodes in alkaline water electrolysis, revealing valuable correlations between the properties of the catalyst ink and coated electrodes with their electrochemical activity and stability. Consistent with the identified structural characteristics, our preliminary results demonstrate that plasma-treated Ni-Co-O electrodes exhibit reduced overpotentials and enhanced stability compared to both pristine and vacuum-annealed electrodes. This improvement can be attributed to the enhanced adhesion and favorable surface properties, including roughness, induced by the plasma treatment. This study contributes significantly to the evaluation of the system throughout its various stages, integrating valuable feedback from preceding steps to further optimize electrode performance. Notably, our approach proves particularly advantageous in facilitating the transition from laboratory-scale developments to scalable processing, bridging the critical gap for practical industrial applications.

Flow-Directing Electrodes with Multi-Scale Porosity for Controlling Transport and Reactions MaxA. Saccone, XiChen, PhilipR. Onffroy, WilliamTarpeh and JosephM. DeSimone; Stanford University, United States

Systems that simultaneously optimize transport and reaction parameters are crucial for chemical process intensification. In this talk, we discuss recent progress towards additively manufactured electrode materials that control flow fields in electrochemical systems with forced convection, coined “flow-directing electrodes.” We show how 3D printed micro-scale architected structures formed from metal-coated polymers, pure metals/oxides, or pyrolytic carbon can tune flow properties and prevent fouling in electrochemical systems while simultaneously providing pathways for electron transfer. We additionally show how to create multiscale hierarchy through the incorporation of nano-scale porosity in these systems via ZnO nanorod templating to tune specific surface area and permeability. We demonstrate the utility of such flow-directing electrodes for applications ranging from electrochemical remediation of per- and poly-fluoroalkyl substances (PFAS) where a nano-porous layer could act as a size-exclusion membrane to design of electrodes for redox-flow batteries where transport of working ions and redox-active material is maximized but transport and crossover of other species such as electrolytes and mediators is minimized. Flow-directing electrodes represent a paradigm shift in electrochemical reactor design in which high resolution vat photopolymerization printing techniques are used to create co-designed structures with complex geometry using electrically conductive functional materials—all leading to the ability to explore a wide landscape of previously impossible device designs.

Ratchet Based Ion Pumps for Fine Tuning of Electrochemical Reactions DafnaMeltser, AlonHerman, BrianA. Rosen and GideonSegev; Tel Aviv University, Israel

Precise control of electrochemical reactions can have a tremendous effect in enhancing the performance of electrochemical energy storage and conversion systems. However, electrochemical reactions are extremely sensitive to the physical and chemical environment at which the reaction takes place. Thus, control of the electrolyte ionic content and the electrochemical potential of

specific ions at the vicinity of the electrodes can enhance their selectivity towards the desired products and modify the overpotential of redox reactions. In this contribution we show that ion pumps based on a ratcheting mechanism can be used to tune the overpotentials of electrochemical reactions.
Flashing ratchets are devices that utilize temporal modulation of a spatially asymmetric electric field to drive a non-zero time averaged current. We have recently demonstrated experimentally first-of-their-kind ratchet-based ion pumps (RBIPs). Since the ion pumping modifies the electrochemical potential of ions, and redox reaction rates are determined by the electrochemical potential, ratchet-based ion pumping provides an additional degree of freedom in tunning electrochemical reaction rates and overpotentials.
RBIPs were fabricated by coating the two surfaces of nano-porous alumina wafers with gold forming nano-porous capacitors. The electric field within the nano-pores is modulated by oscillating the capacitors voltage. Hence, when immersed in solution, ions within the pores experience a modulating electric field resulting in ratchet-based ion pumping. The RBIP was placed as a membrane between two Pt electrodes inside a compartment filled with HCl solution. The application of an input signal to the ratchet is shown to accelerate or inhibit redox reactions on the surface of the Pt electrodes according to the ratchet properties. The combination of selective ion pumping with the control of reaction rates may also allow tuning the electrolyte content at the vicinity of the electrodes performing the electrochemical reaction independent of their potential thus providing another degree of freedom for the electrochemical process.

10:45 AM EN07.12.09
Suppression of Dopant Segregation and Improvement of Activity on a Perovskite Oxide Surface by Self-Formation of Ruddlesden-Popper Phase SanazKoohfar[1], MasoudGhasemi[2], TylerHafen[3], GeorgiosDimitrakopoulos[1], DonghaKim[1], S.Elangovan[3], JennaPike[3], EnriqueGomez[2] and BilgeYildiz[1]; [1]Massachusetts Institute of Technology, United States; [2]The Pennsylvania State University, United States; [3]OxEon Energy LLC, United States

Solid oxide fuel and electrolysis cells (SOFCs, SOECs) present a highly efficient platform for clean energy and chemicals conversion. However, degradation during operation challenges the commercialization and widespread feasibility of this technology. Segregation of dopants such as Sr and Ba to the surface is a main degradation mode that has been linked to the instability of the oxygen electrode surface. These segregated species form an insulating layer and leave behind a near-surface region that is depleted of the dopant. The segregated species on the surface suppress the oxygen reduction and evolution reactions. Improving the stability of surface chemistry and the resulting electrochemical activity on perovskite oxide oxygen electrodes is crucial for enabling efficient and durable SOFC/SOEC as a clean energy conversion platform. In this work, we take $La_{0.8}Sr_{0.2}Co_{0.8}Fe_{0.2}O_3$ (LSCF) as a state-of-the-art oxygen electrode, and we reveal that self-formation of Ruddlesden-Popper phase improves the surface chemistry, oxygen reduction kinetics, and electrochemical stability on it. We use X-ray photoelectron spectroscopy (XPS) and time of flight-secondary ion mass spectrometry (ToF-SIMS) to analyze surface and sub-surface chemistries. We reveal that the formation of Ruddlesden-Popper phase is accompanied by suppression of Sr dopant segregation. Moreover, our results show that B-site cations (Co and Fe) are depleted in the subsurface region. These findings reveal the structural elements that maintain an active and stable surface for oxygen reduction reaction on oxygen electrodes. Revealing this unique near-surface chemistry and phase formation is crucial in guiding the development of better surface chemistries for improving the oxygen electrode performance in SOFC/SOEC.

11:00 AM EN07.12.10
Covalent Anchoring of Macrocycles on Metallic Nanoparticles for Efficient Oxygen Reduction Reaction – A Joint Experimental and Theoretical Investigation Auguste Têtenoire, ArnaudFihey, CorinneLagrost and MikaelKepenekian; University of Rennes, France

The activation of O_2 through electrochemical reduction (ORR, oxygen reduction reaction) has shown promising results as alternative energy conversion technologies that can produce added-value chemicals from simple and abundant feedstocks. However, despite extensive efforts to develop catalytic materials with high reactivity and high selectivity, one can currently observe the lack of demonstrative performance for viable industrial applications. The deliberate surface modification of catalyst has been recently recognized as a powerful approach to design efficient and durable electrocatalysts [1]. It then becomes essential to obtain a good control over the spatial distribution of the chemical functions over the nanoobject surfaces. Recently, excellent catalytic properties towards ORR have been obtained in alkaline media of gold [2], silver [3], and platinum [4] nanoparticles when modified through the reductive grafting of rigid macrocycle calix[4]arene-tetradiazonium salts [5]. However, many fundamental questions, with important operational implications, remain open about these calixarene-modified surfaces. In particular, the conformation of the calixarene on the surface, and the structural, thermodynamic and electronic description of the interface. In addition, the C-Au bond has been poorly investigated in comparison to the S-Au bond.
Here, using spectroscopic studies coupled with computational modeling performed with density functional based tight-binding (DFTB) approaches, we investigate the interaction between calix[4]arene macrocycles and gold and platinum nanoparticles. After exploring the nature of the bond between the macrocycle and the gold surface thanks to a good agreement between measured and calculated Raman spectra, we describe the effect of calix[4]arenes on nanoparticles electrocatalytic properties [6].

Integrated photoelectrochemical devices have been proposed as a long-term, low-cost alternative to PV-electrolyzer systems for solar fuel production, but have historically lagged in performance metrics including efficiency, lifetime, and notably cost. We report technoeconomic analysis showing the critical role of photoabsorber and electrocatalyst cost in PEC devices, highlighting perovskite-perovskite tandems with low-PGM electrocatalyst loading as a platform capable of reaching $2/kg H_2. We demonstrate a technoeconomically-informed approach to PEC system design using a perovskite-perovskite tandem device encapsulated by a conductive adhesive-barrier. Through optimization of reactor design, electrolyte composition, and catalyst content, we show that the cost of unassisted PEC water-splitting can be reduced without compromising on stability or efficiency, ultimately reaching 18% STH with 10 μg Pt/cm^2 HER catalyst loading and an Ir-free anode in acidic media. These findings show that device cost can be decreased without compromising, or even with improvement, on performance parameters in PECs.

1:45 PM EN07.13.02
Phase-Controlled Growth of Cobalt Oxide using Atomic Layer Deposition for Photoelectrochemical Water Splitting SwapnilNalawade[1], MohaF. Hossen[1], ValentinCraciun[2], DhananjayKumar[1] and ShyamAravamudhan[1]; [1]North Carolina A&T University, United States; [2]National Institution for Laser, Plasma and Radiation Physics, Romania

Conformal cobalt oxide thin films, grown using an atomic layer deposition (ALD) method, have been found to possess remarkable photocatalytic capabilities assisted for solar-driven water oxidation. The present study has focused on establishing a structural property relationship to accomplish superior photoelectrochemical properties. During the ALD, bis (N-t-butyl-N"-ethylpropanamidate) cobalt (II) was used as a precursor with water vapor as a co-reactant. The ALD films, grown in the temperature range of 150 – 300^0 C, were characterized using x-ray diffraction (XRD), x-ray photoelectron spectroscopy (XPS), atomic force microscopy (AFM), and Raman spectroscopy. XRD and Raman spectroscopic analysis has indicated that cobalt oxide film has a phase change from rock-salt (CoO) to cubic spinel (Co_3O_4) structure around a temperature of 300^0 C. AFM has confirmed the flat deposition of cobalt oxide with RMS roughness less than 1 nm. The characterization techniques employed in this study have provided valuable insights into the structural and electrochemical properties of Co_3O_4. We have found that the overpotential for the solar-driven oxygen evolution reaction during water splitting is nearly 40% lower for the cubic spinel structure than for the rock salt structure.

This work was supported by a DOE EFRC at North Carolina A&T State University on the Center for Electrochemical Dynamics And Reactions on Surfaces (CEDARS) via grant #DE-SC0023415.

Electrosynthesis of Ethylene Oxide from CO_2 and Water Only Wan RuLeow[1] and EdwardSargent[2]; [1]Agency for Science, Technology and Research (A*STAR), Singapore; [2]University of Toronto, Canada

Ethylene oxide (EO) is among the world's most abundantly produced commodity chemicals due to its importance in the plastics industry, notably for manufacturing polyesters and polyethylene terephthalates (PET). The electrochemical production of EO from carbon dioxide (CO_2), water, and renewable electricity, can enable the consumption of 2 tons of CO_2 per ton of EO produced, in contrast to the emission of ~2 tons of CO_2 per ton of EO produced in existing thermochemical routes. This is achieved through an extended heterogeneous:homogeneous interface, using chloride as a redox mediator in conjunction with barium oxide-modified iridium oxide (BaO_x/IrO_2) catalysts. [1] [2] The catalysts enabled EO FEs of 85-91% and a selectivity of 98% in a current density range from 100 to 1500 mA/cm^2. When integrated into flow battery-analogue electrolyzer with an O_2/H_2O redox couple, we achieve record low energy input of 5.3 MJ/kg of EO, comparable to that of (emissions-intensive) existing industrial processes.

2:15 PM EN07.13.04
Tandem Electrosynthesis of Acetate on a Silver-Copper Oxide Catalyst RohamDorakhan[1], ByounghoonLee[1], IvanGrigioni[2], DavidSinton[1] and EdwardH. Sargent[1]; [1]University of Toronto, Canada; [2]Università degli Studi di Milano, Italy

Acetic acid is an important chemical feedstock with wide applications in pharmaceuticals, food and clothing. The electrocatalytic synthesis of acetic acid from CO_2 offers a low-carbon alternative to traditional synthetic routes. The direct electroreduction CO_2 suffers from a substantial CO_2 crossover energy penalty, and recent CO_2 crossover mitigation strategies having significant energy penalties themselves.
In this work, we demonstrate a two-step approach, where CO_2 is initially converted to CO using a solid-oxide electrolyzer, followed by a CO electroreduction system that electrochemically converts CO to acetic acid. Solid-oxide electrolyzers do not suffer from the CO_2 crossover issue, and have been shown to operate in an industrial setting. The bottleneck in this synthetic approach is hence identified to be the CO electroreduction system. Current CO-to-acetate catalysts do not operate at the desired performance metrics, with selectivity ranges of 20 – 48%. Moreover, the system should produce acetic acid a sufficiently high concentration to minimize separation costs.
Here we report a catalyst design strategy in which off-target intermediates (such as ethylene and ethanol) in the reduction of CO to acetate are destabilized. A porous Cu_2O nanoparticle structure is first synthesized, and galvanic replacement of Ag at various loadings produced a alloy surface with near-atomic level dispersion. On the Ag–CuO_2 catalyst with optimized loading, the destabilization of off-target intermediates leads to an acetate Faradaic efficiency of 70% at 200 mAcm^{-2}. The destabilization is investigated by a combination of *operando* Surface Enhanced Raman Spectroscopy (SERS) and theoretical modeling using Density Functional Theory (DFT). The destabilization is shown to affect all pathways of C_2 hydrocarbons, however ethylene and ethanol pathway are rendered energetically inaccessible, while the acetate pathway remains open. Moreover, we demonstrate 18 hours of stable operation of the catalyst in a membrane electrode assembly; the system produced 5 wt% acetate at 100 mAcm^{-2} and a full-cell energy efficiency of 25%, a twofold improvement on the highest energy-efficient electrosynthesis in prior reports.

Cu Surface Chemistry in Acid Media:Vibrational Spectroscopy, Mass Spectrometry and ECSTM Measurements DavidRaciti, AngelaR. Hight Walker and ThomasMoffat; NIST, United States

Copper electrodeposition is a central process in the metallization of microelectronics and more recently has found use as an important electrocatalyst in the conversion of CO_2 to hydrocarbons. Gaining mechanistic insight into the reactivity of Cu surfaces requires *in situ* and better still *in operando* measurements. Herein the utility of the combination of vibrational spectroscopy (SEIRAS, SHINERS), electrochemical mass spectrometry (EC-MS) and scanning tunneling microscopy (ECSTM) to examine the competitive and co-adsorption interactions between potential dependent halide adsorption, molecular adsorption, underpotential metal deposition and hydride formation on low index Cu single crystals surface will be detailed. Further still, the opportunity to study the impact of such interactions on metal deposition reactions will also be explored.

Urea Oxidation Reaction on Ni-Based Electrocatalysts: Combating with Oxygen Evolution Reaction. JiseonKim and KangwooCho; Pohang University of Science and Technology, Korea (the Republic of)

Along with the societal pursuit of sustainable carbon neutrality, electrochemical urea oxidation reaction (UOR) has been an overarching subject to substitute oxygen evolution reaction (OER), primarily owing to lower thermodynamic requirement (0.37 V) for molecular hydrogen generation. The UOR not only enhances the energy conversion efficiency from renewable energy into molecular hydrogen, but also reduces carbon and nitrogen pollution loadings of urea-rich wastewater. Nickel-based catalysts are up-to-date the most widely investigated materials as the UOR electro-catalyst. However, the UOR overpotential is in-fact predominantly consumed for formation of Ni^{3+} (the most common active site), and the gap between the onsets of UOR and OER is only < 300 mV. Moreover, competitions between UOR and OER has been noted to explain a current collapse near the OER onset. This presentation introduces our recent findings on Ni-based UOR electro-catalysts that were prepared by i) potentiostatic dealloying of commercial NiFe alloys under variable pH, and ii) one-pot thermochemical treatment of NiFe alloy foam in oxalic acid to create a self-supporting O-NFF. Regarding the former electrocatalysts, this study revealed that current inflections near the OER onset in the presence of urea could be associated with $Ni^{3+/4+}$ redox peaks. The peak location and intensity, in relation with the OER activity during repetitive cyclic voltammetry unraveled the roles of Fe on OER, under dynamic dissolution and precipitation of Fe to/from the electrolyte. Therefore, accelerated UOR kinetics on Ni^{3+} would be the key consideration to avoid interferences from OER. To this end, Cutting-edge figure-of-merits for UOR were noted for O-NFF including 500 mA cm^{-2} of current density at 1.47 V RHE and exceptionally low Tafel slope of 12.1 mV dec^{-1} (in 1 M KOH with 0.33 M urea). The oxalate ligands withdraw electrons from Ni-motif and provide H-bonding sites for energetically favorable binding of Ni with urea-O. Incorporation of Fe escalate the inductive charge accumulation on oxalate-O and strengthen the H-bonding to accelerate the C-N cleavage of *$CO(NH)_2$. The findings of this study could be further utilized within wastewater electrolysis cell for water-energy nexus.

SESSION EN07.14: Virtual Session

9:00 PM EN07.14.01
Lewis-Acid Induced Polarizability in Electrode-Electrolyte System for Electrochemical Ammonia Synthesis—A Step Towards Sustainability AshmitaBiswas[1], SamadhanKapse[2], BikramGhosh[1], RanjitThapa[2] and Ramendra SundarDey[1]; [1]Institute of Nano Science and Technology, Mohali, India; [2]SRM University, India

The ever-growing demands for ammonia in agriculture and transportation fuel stimulate researchers to develop sustainable electrochemical methods to synthesize ammonia ambiently, to get past the energy-intensive Haber Bosch process. Ambient here means, with no carbon emission, in aqueous medium and at room temperature and pressure. But, the most important factor that impedes the production rate of ammonia is the poor solubility of nitrogen in the aqueous medium because of its chemical inertness, which thereby makes way for the competitive hydrogen evolution reaction (HER) at the electrode surface. Several strategies have been imposed on the catalyst designing to prevent HER. From electrolyte point of view, mainly two conditions are followed to date to promote N_2 solubility and prevent this competitive HER:
(a) to optimize the proton concentration in the medium by using organic/aqueous electrolyte; although the production rate of NH_3 increased but the use of ethanol/methanol (C containing fuel) is not likely to be used in large proportion as electrolyte.
(b) to promote nitrogen solubility by using ionic liquid electrolytes; although it successfully suppressed HER and increased the Faradaic efficiency of NRR, but did not help much with respect to the yield or production rate of NH_3 synthesis. Moreover, most of the ionic liquid electrolytes require inert atmosphere for use and are generally costly. Thus, these two approaches cannot be regarded as "green" and "ambient" towards proficient NRR process.
Herein we introduce a new aqueous electrolyte ($NaBF_4$), which not only acts as an N_2-carrier in the medium but also works as a full-fledged "co-catalyst" along with our active material MnN_4 to deliver high yield of NH_3 (328.59 $\mu g\ h^{-1}\ mg_{cat}^{-1}$) at 0.0 V vs RHE. Our experimental and theoretical findings go hand-in-hand towards the understanding of the chemistry behind such high performance. We have undergone several experiments including NMR and also Hirshfeld surface analysis to establish the existence of BF_3 in our medium and the van der Waal interaction between free BF_3 and N_2 molecules forming a **Lewis acid-base adduct pair**. Unlike any other aqueous electrolyte, $NaBF_4$ is thus able to induce a local N_2 concentration in the vicinity of the catalyst surface. More interestingly, BF_3-induced charge polarization shifts the metal d-band center of MnN_4 unit close to the Fermi level, inviting N_2 adsorption facilely. The Lewis acidity of the free BF_3 molecules further propagates their importance in polarizing the N≡N bond of the adsorbed N_2 and its first protonation. This push-pull kind of electronic interaction has been confirmed from the change in d-band center values of MnN_4 site as well as charge density distribution over our active model units, which turned out to be effective enough to lower the energy barrier of the potential determining steps of NRR. Resultantly, a high production rate of NH_3 (2.45×10^{-9} mol s^{-1} cm^{-2}) was achieved, approaching the industrial scale periphery, where the source of NH_3 was thoroughly studied and quantitively confirmed (from $^{15}N_2$ isotope labelling experiment) to be chiefly from the electrochemical reduction of the purged N_2 gas. Therefore, this unique report where an aqueous electrolyte itself works as a "co-catalyst" may open up new vistas to study and understand the insights of the NRR in aqueous medium.

9:15 PM EN07.14.02
Accelerated Oxygen Chemisorption and ORR Activity on Cerium-Doped $LaFeO_3$ Perovskite Oxide MyungjuKim[1], KangheeJo[1], YongnamKim[2] and HeesooLee[1]; [1]Pusan National University, Korea (the Republic of); [2]Korea Testing Laboratory, Korea (the Republic of)

$LaFeO_3$-based perovskite oxides, which have both electronic conductivity and ionic conductivity, have been actively studied in energy conversion and storage fields including solid oxide fuel cells and metal-air batteries. Recently, doping elements with various valence states have been focused to enhance the electrochemical properties of $LaFeO_3$. Cerium forms a defect-rich structure since cerium has multivalence of Ce^{3+}/Ce^{4+}. These formed defects play a crucial role in catalytic activity by accelerating the adsorption of oxygen on the surface. Therefore, it is crucial to examine the effect of cerium doping on the electrochemical properties of $LaFeO_3$, specifically considering the influence of the defect structure.
This study investigated the effect of cerium doping on the polarization resistance of $LaFeO_3$ perovskite oxide (LCFOx, x = 1, 3, 5, 7) and analyzed the underlying mechanism in terms of the defect structure. The X-ray diffraction (XRD) patterns of the crystal structure revealed that doping cerium with ranging from 0 to 5 mol% resulted in the formation of a single perovskite phase with an orthorhombic structure of P*nma* space group. The Rietveld refinement analysis further demonstrated that cerium led to a decrease in the octahedral tilting and an increase in the Fe-O-Fe bonding angle, respectively. The formation of oxygen vacancies was observed through the electron paramagnetic resonance (EPR) spectrum and O 1*s* core-level spectrum. The La 3*d* and Fe 2*p* core-level spectra indicated that cerium doping did not affect the valence state of La ions, while it caused a reduction in the Fe^{3+}. Additionally, the O *K*-edge X-ray absorption spectrum (XAS) showed the hybridization between Fe 3*d* and O 2*p* orbitals upon cerium doping. The O_2-temperature programmed desorption (O_2-TPD) profile confirmed an increase in the concentration of surface-active oxygen species with cerium doping. The area-specific resistance (ASR) gradually decreased from 11.36 Ωcm^2 (LFO) to 4.65 Ωcm^2 (LCFO5) as the amount of cerium doping increased. Notably, the polarization resistance in the low-frequency range (R_2) exhibited a significant reduction of approximately 68%, indicating enhanced ORR activity attributed to accelerated oxygen adsorption. The ORR reaction steps were analyzed alongside electrochemical impedance spectroscopy (EIS) data using the distribution of relaxation times (DRT) technique.

9:30 PM EN07.14.03
Electrochemical Energy Harvesting from Phototrophic Biofilms Seeded with Wild-Type and Functionally Coated Phototrophs Mohd GolamAbdul Quadir[1], MelaniaReggente[2], CharlotteRoullier[2], ArdemisBoghossian[2], MassimoTrotta[3] and FabianFischer[1]; [1]University of Applied Sciences and Arts of Western Switzerland, Switzerland; [2]École Polytechnique Fédérale de Lausanne, Switzerland; [3]Institute for Physical-Chemical Processes-CNR, Italy

Oxygenic phototrophs have been reported to produce electrical current in a photoresponsive manner when interfaced with electrodes **[1]**. It has been experimentally demonstrated that the origin of this electron flux emanating from the cellular structures is a water splitting reaction at the oxygen-evolving complex of the Photosystem II **[2]**. However, this mechanism of electron conduction across the cell wall of oxygenic phototrophs is not deciphered with certainty. Additionally, the oxygenic microenvironment of these organisms further reduces the photocurrent output. The scientific community aims to exploit this low-magnitude electrical output for clean energy harvesting. To this end, phototrophs like *Rhodobacter* capsulatus **[3]** and *Synechocystis* PCC6803 **(unpublished data)** have been imparted with functional coatings for enhanced charge extraction from cells that increased the current output with anodically biased electrodes.
This study aims to investigate the electrochemical performance of biofilms initiated with wild-type and functionally coated cells. We optimize these biofilms for long-term viability that can be integrated into an electrochemical device for sustainable energy harvesting in a cost-effective manner. Additionally, we also study the influence of gradually increasing biochemical complexity of the extracellular biofilm matrix that ensues in response to various environmental and electrochemical stimuli over time. The biofilm matrix is a dynamic and biochemically active entity that helps the microorganisms to survive harsh environmental conditions **[4]**. In the context of low electrogenic performance of phototrophs, its role in electron conduction is also not well investigated. We deal with this aspect from both biochemical and material science perspectives **[5]**. Preliminary results indicate an influence of various biological, abiotic, and interfacial phenomena on electrochemical results.

Low-Temperature Synthesis of Cu/Cu_2O/CuO Nanostructures for Electrochemical Reduction of CO_2BishnuBastakoti[1], RabinDahal[1] and RohitSrivastav[2]; [1]North Carolina A&T State University, United States; [2]Pandit Deendayal Energy University, India

Electrochemical conversion of CO_2 into renewable energy is an exciting field and a promising method for generating renewable energy that also addresses the challenges of the energy crisis. Here, we successfully synthesized different morphology of Cu/Cu_2O/CuO nanostructures by the wet chemical method for electrochemical reduction of CO_2. The diffused metal ions from the $Cu(NO_3)_2$ ice cube were slowly reduced using $NaBH_4$ at room temperature. The slow release of the metal ions helps in modifications of morphologies of composite nanoparticles. The reduced species were further oxidized by dissolved oxygen. Different characterization techniques such as x-ray diffractometry, scanning electron microscopy, and x-ray photon spectroscopy further examined the prepared nanoparticles. The electrochemical reduction of CO_2 on Cu/Cu_2O/CuO nanostructures shows the generation of CO, CH_4, and C_2H_6 in 0.5 M $KHCO_3$ solution.

This research was supported by the National Science Foundation Excellence in Research 2100710.

Tailoring Binding Abilities by Incorporating Oxophilic Transition Metals on 3D Nanostructured Ni Arrays for Accelerated Alkaline Hydrogen Evolution Reaction JaerimKim, HyeonjungJung, Jeong WooHan and Jong KyuKim; Pohang University of Science and Technology, Korea (the Republic of)

Developing efficient and inexpensive electrocatalysts for the hydrogen evolution reaction (HER) in alkaline water electrolysis plays a key role for renewable hydrogen energy technology. The slow reaction kinetics of HER in alkaline solutions, however, has hampered advances in high-performance hydrogen production. Herein, we investigated the trends in HER activity with respect to the binding energies of Ni-based thin film catalysts by incorporating a series of oxophilic transition metal atoms. It was found that the doping of oxophilic atoms enables the modulation of binding abilities of hydrogen and hydroxyl ions on the Ni surfaces, leading to the first establishment of a volcano relation between OH-binding energies and alkaline HER activities. In particular, Cr-incorporated Ni catalyst shows optimized OH-binding as well as H-binding energies for facilitating water dissociation and improving HER activity in alkaline media. Further enhancement of catalytic performance was achieved by introducing an array of three-dimensional (3D) Ni nanohelixes (NHs) that provide abundant surface active sites and

effective channels for charge transfer and mass transport. The Cr dopants incorporated into the Ni NHs accelerate the dissociative adsorption process of water, resulting in remarkably enhanced catalytic activities in alkaline medium. Our approach can provide a rational design strategy and experimental methodology toward efficient bimetallic electrocatalysts for alkaline HER using earth-abundant elements.

9:55 PM EN07.06.15
Efficient Alkaline Hydrogen Evolution Reaction of Nitrogen Ion Irradiated NiO-Based Catalysts via Nitrogen Doping and Vacancy Engineering JaerimKim[1], Sang-MunJung[1], HyeonwoongHwang[1], BongwonKim[1], Yong-TaeKim[1], Dong-SeokKim[2] and Jong KyuKim[1]; [1]Pohang University of Science and Technology, Korea (the Republic of); [2]Korea Atomic Energy Research Institute (KAERI), Korea (the Republic of)

Development of efficient and inexpensive electrocatalysts for oxygen evolution reaction (OER) and hydrogen evolution reaction (HER) in alkaline water-electrolysis is of paramount importance in the hydrogen economy to meet future energy demands. Earth-abundant transition metal oxide-based catalysts including NiO have emerged as promising OER catalysts with the advantages of compositional and structural diversity, low cost, easy synthesis, and eco-friendliness. However, they are generally considered inactive towards HER because of limited catalytic active sites, poor electrical conductivity and adsorption abilities.
In this study, we developed a strategy to activate NiO catalysts for efficient HER by creating both nitrogen dopants and oxygen vacancies, which is enabled by ion irradiation technique. Nitrogen ion irradiation with various ion doses was conducted onto NiO-based catalysts that consist of an array of NiO nanorods (NRs) with abundant surface active sites and efficient channels for charge transfer and mass transport. It was found that the N ion irradiation causes not only doping of N atoms but also formation of oxygen vacancies in the NiO NRs, resulting in much enhanced hydrogen adsorption and electrical conduction of NiO NRs. Consequently, the optimized N-ion irradiated NiO NRs catalyst show highly improved HER performance, as well as OER. Our approach can provide an effective and unique methodology for designing efficient electrocatalysts consisting of earth-abundant elements for electrochemical hydrogen production.

10:00 PM EN07.05.05
Efficient Alkaline Hydrogen Evolution Reaction using Superaerophobic Ni Nanoarrays with Accelerated H_2 Bubble Release JaerimKim, Sang-MunJung, Yong-TaeKim and Jong KyuKim; Pohang University of Science and Technology, Korea (the Republic of)

Despite the adverse effects of H_2 bubbles adhering to catalyst's surface on the performance of water electrolysis, the mechanisms by which H_2 bubbles are effectively released during the alkaline hydrogen evolution reaction (HER) remain elusive. In this study, we conducted a systematic investigation on the effect of nanoscale surface morphologies on H_2 bubble release behaviors and HER performance by employing earth-abundant Ni catalysts consisting of an array of Ni nanorods (NRs) with controlled surface porosities. Both aerophobicity and hydrophilicity of the catalyst's surface vary according to the surface porosity of catalysts. The Ni catalyst with the highest porosity exhibits superaerophobic nature as well as the best HER performance among the Ni catalysts. It was found that the Ni catalyst's superaerophobicity combined with the effective open pore channels enables the accelerated release of H_2 bubbles from the surface, leading to a significant improvement in geometric activities, particularly at high current densities, as well as intrinsic activities including both specific and mass activities. It was also demonstrated that the superaerophobicity enabled by highly porous Ni NRs can be combined with Pt and Cr having optimal binding abilities to further optimize electrocatalytic performance. Our work can help to elucidate the fundamental and practical design rules for efficient alkaline HER catalysts consisting of earth-abundant elements.

Electrochemical Chloride-Mediated Marine Carbon Dioxide Removal SeoniKim, MichaelNitzsche, SimonRufer, KripaVaranasi and T. AlanHatton; MIT, United States

Negative Emissions Technologies (NETs) are crucial to avert catastrophic disruption of global climate patterns caused by the continuing atmospheric accumulation of CO_2 due to industrial emissions. The recent surge of interest in NETs in which CO_2 (currently at an atmospheric concentration of ~420 ppm) is removed from the ambient environment itself, by, e.g., direct air capture (DAC), has not yet been matched by a similar drive to reduce CO_2 in oceans, where increasing acidification has led to destruction of coral reefs, and reduced carbonate ion concentrations harm shellfish and other marine life. The total CO_2 accumulation rates by oceans rivals that in the atmosphere, and thus effective means for CO_2removal could augment the other NETs to reduce the environmental burden imposed by this greenhouse gas. The concentrations in water (on a volumetric basis) are much higher at 100 mg/L than that in the ambient air (0.77 mg/L), and thus smaller volumes will need to be treated than in DAC, which could provide a processing advantage.

In current approaches for the removal of CO_2 from oceanwaters bipolar membrane catalysis water splitting coupled with electrodialysis is used to modulate the pH and thereby release the CO_2 as a gas (low pH) or carbonate salt (high pH). We have proposed an alternative approach to marine carbon dioxide removal (mCDR) that does not require expensive membranes or addition of chemicals, is easy to deploy, and does not lead to formation of byproducts or secondary streams. In this approach, the pH is regulated through a chloride-mediated reaction with electrodes in asymmetric electrochemical cells through which the seawater flows. In the acidification cell the DIC speciation shifts from bicarbonate and carbonate to CO_2 which can then be

removed in a membrane contactor. The now-decarbonized water is introduced to a second electrochemical cell where the reverse reaction is promoted, the electrodes are regenerated, and the pH increases before the water is discharged back to the ocean. The CO_2 removal approach has perceived advantages in that it does not require expensive membranes or addition of chemicals, is easy to deploy, and does not lead to formation of byproducts or secondary streams.

We will discuss the overall electrochemical swing process, which can be enhanced through flexible electrode configurations to reduce transport and electrical resistances while enabling treatment of large quantities of water. Novel methods for the recovery of molecular CO_2 without the need for high vacuum desorption, and of calcium carbonate precipitates without fouling of the electrodes, will be highlighted.

9:15 AM *EN08.01.02
Bipolar Membranes for Electrochemical CO2 Capture ChengxiangXiang[1,2]; [1]California Institute of Technology, United States; [2]Captura Corporation, United States

Electrochemical CO2 capture, conversion and storage can play a significant role in reducing atmospheric CO2 concentration in the coming decades. Bipolar membranes that facilitate water dissociation reaction at the interface can be implemented in electrolysis, electrodialysis and other electrochemical devices for carbon capture, conversion, and long duration energy storge. In this talk, I will share recent developments in the synthesis, characterization, and electrochemical performances of catalyzed, asymmetric bipolar membranes for highly efficient acid and base generation both at Caltech and in Captura. I will talk about multiphysics modeling and simulation of BPMs for in-depth understanding of water dissociation mechanism as well as electroosmotic water transport at various current densities. Finally, I will discuss electrodialysis stacks development and deployment of Direct Ocean Capture (DOC) pilot systems for electrochemical CO2 capture at a near-ocean site.

9:45 AM EN08.01.03
Elucidating the Effect of Solvent on Electrochemical Reduction of CO_2 using a Data Driven Approach MatthewBliss, AniketKapote, KuldeepsinhRaj and Nav NidhiRajput; Stony Brook University, The State University of New York, United States

The electrochemical reduction of carbon dioxide (CO_2) has great potential to alleviate important environmental problems: the elevated presence of CO_2 in the atmosphere and the need for fossil fuel-based production of fuels and commodity chemicals. However, the application of electrochemistry to CO_2 reduction is hindered by low selectivity, activity and stability[1]. In aqueous media, the competing hydrogen evolution reaction (HER) and low solubility of CO_2 remain unresolved problems for selectivity; the use of nonaqueous solutions presents a possible path to mitigate these problems[2,3]. However, the current aprotic solvents are limited by their high viscosity, large overpotential due to absence of protons, and instability of reaction key intermediates. To overcome these challenges, we investigate the effect of the solvent's chemical class on properties relevant to the CO_2 reduction reaction such as CO_2 solubility, electrochemical stability, and transport properties using high-throughput multi-scale simulations. High-throughput density functional theory (DFT) calculations and classical molecular dynamics (CMD) simulations are performed to build large databases of electronic, thermodynamic, structural and dynamical properties using the computational infrastructures developed by our lab, coined **MISPR (**Materials Informatics for Structure-Property Relationships - https://github.com/molmd/mispr**)** and **MDPropTools (**https://github.com/molmd/mdproptools)[4]. In this work, we uncover important correlations between molecular features of solvents and bulk ensemble properties of electrolytes for CO_2 electroreduction.

Molecular Design of Redox-Active Materials for Selective Electrochemical Separations XiaoSu; University of Illinois Urbana-Champaign, United States

Achieving molecular selectivity is a critical challenge for deploying electrochemical separations for resource recovery, chemical and biochemical manufacturing, and environmental remediation. Leveraging redox-electron transfer can be a powerful pathway for accelerating separation kinetics, enhancing adsorption uptake, and controlling voltage for lower energy consumption. Here we discuss the molecular design of electroactive materials for two major directions in electrochemical separations: redox-mediated electrosorption and redox-mediated electrodialysis.
First, we discuss the development of redox-active materials for the selective binding of dilute ions from multicomponent mixtures. We highlight the bottom-up design of redox-copolymers, and synthetic modifications for enhancing affinity and reversibility. We demonstrate their capability for the capture and remediation of perfluoroalkyl substances (PFAS) through combinatorial monomer design, as well as strategies for coupling separation and reaction for the reactive separation of nitrate to ammonium. We unravel structure-function relationship between the redox-polymers and target species, such as the control of surface charge and hydrophocity for the capture of both short and long-chain PFAS.
Next, we discuss new materials design strategies for advancing redox-electrodialysis, including translating concepts from redox-flow batteries to improve membrane and redox-electrolyte selection. We substitute costly ion-exchange membranes with affordable nanofiltration membranes and soluble redox-copolymers, which significantly reduce energy consumption and the cost of desalination, while enhancing membrane stability. Our work establishes rational design principles of redox-materials, tailoring their properties for selective electrochemical separations.

11:00 AM EN08.01.05
Engineering Porous Carbon Electrodes for Selective Boron Removal via Electrosorption WeiyiPan[1], SohumPatel[1], EungjinAhn[2], ArpitaIddya[1], DebashisRoy[2], JovanKamcev[2] and MenachemElimelech[1]; [1]Yale University, United States; [2]University of Michigan–Ann Arbor, United States

Boron (B) is ubiquitous in seawater in the form of boric acid (H_3BO_3, pKa = 9.24) at low concentrations (4-6 mg/L). While boron is an essential micronutrient, excessive intake can be highly toxic to humans and many crops. Therefore, effective removal of boron during seawater desalination is crucial. Reverse osmosis (RO) membranes alone are insufficient for reducing the levels of uncharged boric acid to acceptable levels for human consumption and agricultural use. Consequently, additional high-pH RO passes are necessary, leading to an increase in overall energy consumption of ~10-15%. Furthermore, this non-selective removal process also eliminates other beneficial minerals, necessitating subsequent remineralization. An alternative method for boron removal would benefit from reduced energy consumption, lower capital costs, and the elimination of chemical dosing requirements.
Boron is well known to react with 1,3 diols to form characteristic borate-ester complexes. Selectivity for boron over other species is enhanced by the presence of two or more hydroxyl groups in the *cis* position (*vis*-diols); hence, numerous sorbents which incorporate *vis*-diol moieties have been developed. Nevertheless, the hydrophobic nature of the polymeric backbone hampers efficient boron transport, leading to slow kinetics and the need for large bed volumes, which are costly. The polymeric structure repeated swelling and shrinking during regeneration cycles accelerate capacity decline, shortening the resin lifespan. Regeneration requires substantial amounts of strong acids or bases, increasing financial and environmental burdens.
Electrosorption has emerged as a highly promising process for water deionization. It exhibits exceptional efficiency when applied to low salinity waters and for removing small quantities of salts. Consequently, utilizing electrosorption for boron removal, particularly from first-pass seawater RO permeate, could potentially be a promising application of this technology. We have recently developed a novel bipolar membrane (BPM) assisted electrosorption process for boron removal. With an applied voltage (< 1.2 V), BPM-facilitated water dissociation occurs with the anion-exchange layer (AEL) facing the anode, thus producing a high pH on the anode side, as is required for boron electrosorption. By further enhancing the selectivity of boron over competing anions (e.g., Cl^-), we can significantly reduce the specific energy consumption of the process (~ 2.5 kWh $g\text{-}B^{-1}$). This advancement would also enable direct application of the technology, unlocking its full potential.
Herein, we developed novel porous carbon electrodes that can selectively remove boron over competing anions during the BPM-assisted electrosorption process. We employed two fabrication methods for these porous carbon electrodes. In the first method, we deposited a functionalized polymeric thin film [e.g., poly(vinyl alcohol) and polydopamine] on porous carbon electrodes that could selectively allow borate anions to pass through over other competing anions in the presence of an electric field and accumulate in the electric double layer of the electrode micropores. In the second method, boron selective functional groups (e.g., N-methyl-D-glucamine) were directly appended to the micropore wall of the porous carbon electrode via chemical modification techniques, thereby eliminating the mass transfer limiting polymer layer between the carbon pore wall and the aqueous solution containing boron. To evaluate the boron removal capabilities of these electrodes, we conducted experiments using a custom-built BPM-assisted electrosorption cell with a solution mimicking first-pass seawater RO permeate (i.e., 5 mM NaCl and 1 mM B). The B/Cl selectivity of various electrodes was also calculated to compare their performance. Furthermore, detailed characterizations and molecular dynamic simulations were performed to gain deeper insights into the underlying mechanisms.

Perfect Monovalent Cation Selectivity with Capacitive Deionization AnkitaMathur[1], SallyNijem[2], RanaUwayid[1], ZoharSahray[1], AmitN. Shocron[1], CharlesDiesendruck[2] and MatthewSuss[1,2,2]; [1]Technion- Israel Institute of Technology, Israel; [2]Technion–Israel Institute of Technology, Israel

Irrigation is a huge consumer of freshwater, typically > 50% of the total water usage for most countries. When treating water for irrigation use, selective removal of monovalent sodium ions is a particular challenge, but necessary for cost-effective irrigation and resource recovery. Presence of excessive sodium ions in water may lead to low crop yield, decreased soil permeability and water infiltration rate, but other ions such as calcium should not be removed. Capacitive deionization (CDI) is an emerging electrochemical technology promising towards highly selective removal of ions from water via electrosorption [1]. Ion selectivity can be tuned by modifying the electrode pore structure and surface chemistry, in addition to cell parameters affecting electrosorption dynamics [2,3].
Here we show that utilizing judicious functionalization of microporous activated carbon cloth (ACC) electrodes can provide for exceptional selectively towards removal of Na^+ from feedwater. We show that a charging CDI cell can remove ~130 µmol Na^+ per gram carbon, with zero Ca^{2+} electrosorption, from a feed of 2 mM $CaCl_2$ and 17 mM NaCl, with low energy consumption of 0.36 kWh/m^3. We further describe the mechanism enabling such breakthrough selectivity results, which are based on the discovery of induced electric charge in asymmetric CDI cells. This study paves the way for more tunable selectivity and wider range of separations with CDI, and is especially promising for single-step treatment of water for use in irrigation.

11:30 AM EN08.01.07
Electrochemical Separation and Purification of Tungsten and Cobalt for High-Value Metals Recovery from Cemented Tungsten Carbides Shao-ChiLo, Tzu MingCheng and Chih-huangLai; National Tsing Hua University, Taiwan

Cemented tungsten carbide (WC-Co) , which consists of high-value metals such as tungsten (W) and cobalt (Co), is one of the important hard materials for cutting tools in industrial applications. The recovery and production of these valuable elements have drawn much attention due to the increased demand in the end-user industries such as mining, automotive, electronics, and even aerospace. Although the recycling methodology of WC-Co scraps has been developed for decades, energy consumption and wastewater discharge in the whole process remain a big concern for conventional approaches. Previously in the beginning of the year, our group demonstrated an energy-efficient approach called rapid breakdown anodization (RBA) for the first time to separate W and Co, and then convert WC-Co into high-purity hydrated tungsten oxide (WO_3-H_2O) and Co metal in one-step electrochemical process. By using RBA with WC-Co as a sacrificial electrode in acidic aqueous solution, effective cobalt leaching was achieved without encountering anodic passivation issue during the electro-dissolution. However, elements such as nickel (Ni), iron (Fe), and chromium (Cr) remained in the cobalt-rich (Co-rich) solution and became major impurities in recovered Co metal owing to large overpotential during RBA. To fulfill the electrochemical separation and purification of tungsten and cobalt for high-value metals recovery, it is critical to the explore selective adsorption materials and membranes for Co-rich solution purification. Here, we present the preliminary results on the selective removal of impurities such as Fe, Ni, and Cr from Co-rich solution by using alumina powder so that Co metal purity could be further enhanced after RBA. Eventually, an effective and environmentally-friendly pathway for WC-Co recycling is proposed with a significantly simplified process compared to traditional hydrometallurgical methods.

SESSION EN08.02: Electrochemical Separations II

Towards Accelerated Design of Selective Membranes: Integrating Theory, Characterization and Simulations RyanS. Kingsbury; Princeton University, United States

Precise separation materials capable of selectively permeating a single ion from an electrolyte have the potential to significantly enhance the performance of numerous electrochemical technologies, including processes for resource extraction, industrial waste recycling, and water purification. For example, materials that can selectively remove lithium from geothermal brine would contribute to stabilizing supply chains for clean energy technology.

Polymer membranes are a proven technology capable of other types of ion separations, but engineering them for precise selectivity is extremely challenging because differences in solute size or charge, which have historically guided membrane development, are often absent in ion-ion separations. As such, the next generation of membranes must go beyond size and charge to exploit differences in solute chemistry.

New approaches to membrane research are critical for efficiently meeting this need. Characterization methods and transport models must evolve to more explicitly connect to the molecular scale interactions of interest, and more emphasis must be placed on understanding 1) which membrane design strategies are most likely to be effective for a given separation problem and 2) how improved material performance would translate into process performance.

This talk will first present membrane performance data compiled from more than 40 studies across 8 different applications to identify strengths and weaknesses of current materials. Next, I will describe a theoretical framework called Barrier Network Analysis that quantitatively relates conventional membrane characterization data (such as conductivity and partition coefficients) to activation energy barriers associated with partitioning and diffusion of individual species. This kinetics-first approach connects experimental observations more directly to the molecular-scale energetic landscape and yields information that is more naturally comparable to the outputs of molecular simulations, which are another important tool for understanding chemical interactions between solutes and membrane materials.

Finally, I will present results from a study of alkali chloride separation by a water-stable polymer of intrinsic microsporosity (AquaPIM) membrane and a commercial cation exchange membrane. Using Barrier Network Analysis, we demonstrated that crossing the solution-membrane interface (i.e., partitioning) has a higher activation energy barrier than diffusion through the polymer for both membranes. This insight contrasts with historical assumptions in the popular Solution-Diffusion model and suggests that selective membrane design should, at least in some cases, prioritize selective interfaces rather than engineering the polymer itself.

I will close by discussing other implications of these findings for membrane design, and suggest ways that Barrier Network Analysis (and related approaches) can be used to guide future research.

2:00 PM EN08.02.02
Ratchet Based Ion Pumps for Selective Ion Separation AlonHerman[1], DafnaMeltser[1], EdenGrossman[1], KarenShushan[1], JoelW. Ager[2], ShaneArdo[2] and GideonSegev[1]; [1]Tel Aviv University, Israel; [2]University of California, Irvine, United States

Even though highly selective ion pumps are found in the membrane of every living cell, artificial ion selective separation is a longstanding unmet challenge in science and engineering. The development of a membrane-based ion separation technology can drive a dramatic progress in a wide range of applications such as: water treatment, extraction of lithium from seawater, solar fuels and more. In this contribution, we report the experimental demonstration of ion pumps based on an electronic flashing ratchet mechanism.
Electronic flashing ratchets are devices that utilize a temporal modulation of a spatially asymmetric electric field to drive steady state current. Like peristaltic pumps, where the pump mechanism is not in direct contact with the pumped fluid, electronic ratchets induce a net current with no direct charge transport between the power source and the pumped charge carriers. Thus, electronic ratchets can be used to pump ions in steady state with no electrochemical reactions between the power source and the pumped ions resulting in an 'all-electric' ion pump. Ratchet-based ion pumps (RBIPs) were fabricated by coating the two surfaces of nano-porous alumina wafers with gold, thus forming nano-porous capacitor-like devices. The electric field within the nano-pores is modulated by oscillating the capacitor voltage. Thus, when immersed in a solution, ions within the pores experience a modulating electric field resulting in ratchet-

based ion pumping. The RBIPs performance was studied for various input signals, geometries, and solutions. RBIPs were shown to drive ionic current densities of several uA/cm^2 even when opposed by an electrostatic force. A significant ratchet action was observed with input signal amplitudes as low as 0.1V thus demonstrating that RBIPs can drive an ionic current with no associated redox reactions.
An important hallmark of ratchets is the ability to invert the direction of particle flow with a change in the input signal frequency. The stopping frequency, which is the frequency at which the particle flux changes its direction, is determined by the potential distribution and particles transport properties. As a result, for a given ratchet, there can be a frequency at which particles with the same charge, but different diffusion coefficients, are transported in opposite directions. This concept, that was never applied to ion separations, can enable the extraction of ions with extremely low relative concentrations if their diffusion coefficient is even slightly different from the main ions in the solution. We show by simulation, that for the prevalent ions in water, ions with a relative diffusion coefficient difference as small as 1% can be driven to opposite directions with a velocity difference as high as 1.2 mm/s. Since the direction of ion transport is determined by the input signal frequency, the sorting properties can be tuned in real time providing a simple fit-to-purpose solution for a variety of ion separations applications.

2:15 PM EN08.02.03
Isotope Separation by Centrifuging an Electrolytic Solution YuanYang; Columbia University, United States

Enriched isotopes are critical to wide applications, such as nuclear reactors (e.g., $^{6/7}$Li, D), radiology (^{18}O), and fundamenal sciences (e.g., tracer and synthesizing superheavy elements). Current methods, such as gas centrifuge, requires hazardous precursors and have limited applicability. Here we developed a general method of separating isotopes by centrifuging a liquid (e.g., salt solution), which is governed by electrochemical transport equations in electrolytes. This technique can be applied to the majority of elements and does not require gasification of isotopes. We have demonstrated high separation factors of 1.046-1.067 per unit neutron difference (e.g., 1.434 in 40Ca/48Ca, 1.134 in 16O/18O), which are better than or comparable to various conventional methods. Modeling was established to understand the process, which is in good agreement with experimental results. The scalability of the technique has also been demonstrated by performing a three-stage enrichment of 48Ca.

Salinity Gradient Energy Harvesting using MXenes HusamN. Alshareef[1], SeunghyunHong[2] and JehadK. El-Demellawi[1]; [1]King Abdullah University of Science and Technology, Saudi Arabia; [2]Khalifa University, United Arab Emirates

2D MXene can be constructed into membranes or electrodes for ionic or molecular separation due to their intriguing features such as hydrophilicity, abundant surface terminal groups, and structural and chemical tunability. The high aspect ratio of MXene nanosheets provides nanochannels as diffusion paths for solute transport. The introduction of pores and modification of the interplanar spacing between neighboring sheets can also contribute to the formation of fluidic nanochannels. By tailoring the interlayer spacing of 2D MXene assemblies, it is possible to establish well-defined transport channels that enable size-selective sieving for specific ions or molecules. In addition to the interlayer distance, the lateral dimension (sheet size) of MXene nanosheets can be modified by adjusting synthesis conditions. Through geometric control over the constituent MXene sheets, the extended fluidic paths across the stack membranes provide the selective transport of solutes, which serves as the basis for the selectivity within layered membranes. The fluidic channel length in layered membranes can also be introducing controllable pores within the MXene sheets, which can enhance ionic diffusion kinetics. The ionic transport can further be enhanced by tuning the membrane thickness and using external stimuli that can enhance ionic transport within MXenes.

These fundamental features of ionic and molecular transport in MXenes can be the basis of many types of devices including sensors, iontronic devices, ionic separation, heavy metal ion extraction, capacitive deionization, and energy harvesting and storage. In this talk, I will discuss leveraging these basic concepts to develop MXene energy harvesters based on salinity gradients, thermal gradients, and ultrasound power absorption.

4:00 PM EN08.02.05
Monovalent Selective Cation-Exchange Membranes for Electrodialysis Pretreatment of Brackish Water Reverse Osmosis BrielleJanuszewski, HanqingFan and MenachemElimelech; Yale University, United States

Brackish water reverse osmosis (BWRO) can supplement dwindling freshwater resources because of its inland availability and energy efficient treatment compared to seawater. However, water recovery is limited to 50-85% by mineral scaling from primarily divalent cation-based scalants, such as Ca^{2+} and Mg^{2+}, leaving significant quantities of water unusable and in need of costly disposal. Thus, removing scale-forming divalent ions before RO is the key to increasing water recovery, but current approaches, such as solvent extraction or adding scale inhibitors, are thermally or chemically intensive, creating a need for an effective, additive-free scale-controlling strategy. Electrodialysis (ED) could be a thermal and chemical input free brackish water pre-treatment that can remove scale forming ions before the RO step by separating incoming brackish water, using valent selective cation exchange membranes (vsCEMs), into streams that are rich with monovalent or divalent cations. This valent selective ED could be used in a coupled ED-RO hybrid system to achieve high water recovery (>90%) and would be tunable for use with a variety of BW feeds, thus mitigating scaling, improving zero liquid discharge (ZLD) management, reducing the total levelized cost of treatment and process downtime, and extending the overall system lifespan. Here, we focus on monovalent selective CEMs (msCEMs) which enable monovalent cation transport and reject divalent cations. There are a few commercially available msCEMs but they suffer from low monovalent-divalent selectivity. Previous work to improve msCEMs revolves around charge-based exclusion, which is typically achieved by including a thin coating of oppositely charged functional groups (having the same charge as the counter-ions) on the membrane surface, which more strongly repels divalent ions. However, a systematic study of the fabrication and operating conditions and their effect on membrane performance has not yet been performed, preventing them from further improvement.
Here, we use a commercial CEM and two polyelectrolytes of opposite charge, poly(allylamine hydrochloride) (PAH) and poly(styrene sulfonate) (PSS), to deposit a thin selective layer using layer-by-layer assembly, whose facile fabrication and tunability allows for a cohesive study of structure-property-performance relationships within the same framework. Our results using a $(PAH/PSS)_{2.5}$ deposition on a commercial support show that we can make consistent, defect-free membranes with average Na^+/Mg^{2+} selectivities of ~25, showing a noticeable increase over the support layer's 0.5 Na^+/Mg^{2+} selectivity. Moreover, we show that the limiting current of these membranes is highly dependent on the ionic strength of the diluate and concentrate solutions, regardless of the ionic species present, with limiting current increasing with solution ionic strength. We show that our membranes are significantly monovalent cation-selective, while systematically revealing the relationships between the separation performance and operating conditions including applied current density, diluate and concentrate solution composition, and thin film composition. This work would advance the fundamental understanding of ion transport in ion exchange membranes and offer critical guidance for applying valent-selective ion exchange membranes in water and wastewater treatment.

Desalination Fuel Cell Stacks: Scaling Up the Co-Production of Electricity and Clean Water SalmanAbdalla, ShadaAbu Khalla and MatthewSuss; Technion, Israel

The demand for clean water and electricity is on the rise worldwide. However, the scarcity of clean water and the utilization of environmentally harmful electricity sources are significant concerns[1]. Currently, reverse osmosis (RO) is widely employed for desalination of seawater and brackish water[2], with approximate consumption of 3-4 kWh/m^3 for seawater desalination[3]. An emerging type of water treatment technology called a desalination fuel cell (DFC) was introduced, which utilizes chemical energy from a single electrochemical cell to simultaneously power water treatment and generate electricity[4]. The DFC incorporates a fuel cell anode and cathode to catalyze the conversion of chemical energy into electrical energy. It also employs a cation and anion exchange membrane to desalinate the water passing through the cell. Our research group introduced the concept of DFC in 2020, demonstrating its potential to produce up to 10 kWh/m^3 while desalinating water with seawater-level salinity[4].
In order to make this promising technology practical, it is crucial to propose and demonstrate scale-up strategies. In this study, we present the results of the first scaled-up DFC. We employed scaling rules associated with electrodialysis by increasing the number of membrane pairs to accommodate either two or three feed channels (figure 1 [5]). However, the three-feed channel device experienced high voltage loss in the ohmic region and a lower limiting current (figure 3a [5]). Nevertheless, the salt concentration behaved linearly with the current density as anticipated (figure 3c [5]). The primary voltage losses were predominantly observed in the cathode and anode sides, while the membrane potential loss was found to be negligible [6]. Our research demonstrated that by increasing the acid concentration in the catholyte and the base concentration in the anolyte channels, we were able to achieve a notable enhancement in the stack's performance (figure 4a [5]). The implementation of a higher pH anolyte and a more acidic catholyte resulted in improved performance, as anticipated due to the higher open circuit voltage (OCV) predicted by the Nernst equation. Additionally, we investigated the impact of flow rate in the feed channels, which is known to affect salt removal efficiency. Overall, our study successfully demonstrates the implementation of a scaled-up DFC, highlighting the importance of addressing voltage losses and optimizing electrolyte compositions for enhanced performance.

***Ex-Situ* Characterization of Carbon Slurries for the Flow-Electrode Capacitive Desalination**YousifAlkhulaifi[1], BenjaminAlessio[1], TomekJaroslawski[1], QiJiang[1], SwethaChandrasekaran[2], AlexandraOverland[2], MairaCerón[2], StevenHawks[2] and JuanG. Santiago[1]; [1]Stanford University, United States; [2]Lawrence Livermore National Laboratory, United States

Seawater desalination has great potential to meet the increasing global demand for freshwater. We are studying and developing a relatively new technology for desalination termed flow-electrode capacitive deionization (FCDI). FCDI cell design represents a significant development over standard capacitive deionization (CDI) cell by achieving continuous operation and the ability to process high salinity streams. These systems replace porous carbon-based solid electrodes with conductive carbon particles suspended in a continuously circulated electrolyte. We will present a study of the properties and chemistry of various carbon-based slurries. Particle type, size, shape, mass loading, and surface chemistry all play an important role in FCDI cells. Also important is the coupling among transport, charge exchange, and solution chemistry. We have developed an ex-situ experimental setup to quantify the charge transfer ability of carbon slurries, including carbon black and activated carbon. This ex-situ system enables convenient measurement of charge transport as a function of slurry properties and mixing. Our preliminary results suggest that the transport features, particle type, size, shape, and chemistry play a significant role in the charge transfer ability of the slurry.

Reinforced Composite Proton Exchange Membranes Through Polytetrafluoroethylene Surface Modification Yeon SuLee, HyunjunKim, SeonghyeonYang, YejiKim and Sung-KonKim; Jeonbuk National University, Korea (the Republic of)

As the problems of environmental pollution and resource depletion become serious, fuel cells using hydrogen, an infinite resource that occupies most of the universe and does not emit pollution, are emerging as an alternative to solve these problems. Among fuel cell types, Polymer Electrolyte Membrane Fuel Cell (PEMFC) is attracting attention for its advantages such as high efficiency and high energy density, but it is difficult to commercialize it due to high price of fuel cell manufacturing materials. Nafion composed of a single polymer of perfluorosulfonic acid is currently the most widely used and considered a major reason for increasing the price of Membrane electrode assembly (MEA), which is a key component of a fuel cell that produces electrical energy through an electrochemical reaction. Therefore, the reinforced composite membrane is getting attention in that it can reduce the amount of ionomer impregnation and improve ionic conductivity through thinning based on the excellent mechanical properties of the support polymer. In this study, a reinforced composite membrane is produced by a surface modification of porous polytetrafluoroethylene (PTFE) through plasma-assisted silane treatment, followed by Nafion impregnation. The surface modification of PTFE is adjusted by time on plasma and silane treatments. The optimum conditions are observed at 1 min of 10 W, 100 kHz, Ar plasma and 0.5 vol% silane treatment at room temperature for 1 min. After surface modification, the surface of PTFE becomes hydrophilic with a contact angle of 65~75 ^{o}. The tensile strength and elongation at break of PTFE/Nafion were much higher than those of commercial homogeneous Nafion membranes. This PTFE/Nafion composite membrane has a tensile strength of 16 N mm^{-1} and an elongation at break of 221 %. It also shows an ionic conductivity of 0.12 S cm^{-1}, similar to commercial homogeneous Nafion membranes.

8:00 PM EN08.03.02
Investigation of the Moisture Effects on Printed Nitrate-Selective Potentiometric Sensors for Direct Soil Monitoring Kuan-YuChen[1] and JosephAndrews[1,2]; [1]University of Wisconsin-Madison, United States; [2]University of Wisconsin–Madison, United States

As the demand for sustainable and efficient agriculture grows, there is an increasing need for reliable and cost-effective methods to monitor soil nutrient levels. Printed nitrate-selective potentiometric sensors have emerged as promising tools for in situ soil monitoring, offering real-time and continuous measurements of nitrate concentrations. However, the performance and longevity of these sensors can be influenced by environmental factors, particularly moisture content in the soil. This work presents the effects of soil moisture level on the functionality and accuracy of printed nitrate-selective potentiometric sensors, with the goal of enhancing their performance and reliability for soil nutrient monitoring applications.
Building upon our prior research, we successfully manufactured inkjet printed potentiometric sensors that are specifically tailored for the detection of the nitrate in soil. The printed sensors contain two electrodes, the reference (RE) and ion-selective electrode (ISE). The ISE is covered by a drop-casted nitrate-selective membrane, which only allows the ion of interest in soil, nitrate in this work, interacting with electrode. This interaction generates a measurable potential difference across the RE and ISE, which can be correlated to the nitrate concentration in the soil.
To measure nitrate contents in moist soil environments, a porous hydrophilic polyvinylidene fluoride (PVDF) film is introduced into the potentiometric sensor. The PVDF shields the electrodes from charged soil particles, while allowing the passage of water. This feature ensures effective operation and provides protection from the soil environments, enabling direct sensing of nitrate in a medium that is similar to in aqueous solutions. The printed potentiometric sensors exhibit sensitivities ranging from sensitivities 45 - 50 mV/dec.To evaluate the performance of the printed potentiometric sensors under realistic conditions, the sensors are testes in two common crop field soil texture classes: sandy soil and silt loam soil. These soil types were chosen to represent practical scenarios encountered in agricultural settings. A range of nitrate concentrations, representative of typical agricultural scenarios, are applied to the sensors, and the response of the sensors is recorded under different moisture conditions.
This study will provide valuable insights into the impact of moisture on the performance of printed sensors and contribute to the development of robust and moisture-tolerant sensor designs for accurate soil nutrient monitoring in agricultural systems. By understanding the impact of moisture on sensor performance and developing moisture-tolerant designs, this research contributes to the development of robust and reliable real-time sensing systems for precision agriculture. This research holds significant potential to advance the field of precision agriculture, enabling farmers to optimize fertilizer management practices, reduce environmental impacts, and optimize crop yields in a sustainable manner.

8:00 PM EN08.03.03
Interlocking Bipolar Membranes for Efficient Electrochemical Separations
Hyeon-BeeSong and Moon-SungKang; Sangmyung University, Korea (the Republic of)

A bipolar membrane (BPM) is a special type of ion-exchange membrane in which an anion-exchange layer (AEL) and a cation-exchange layer (CEL) are combined. Water molecules can be easily dissociated at the interface of the BPM by the strong electric field generated when a reverse bias voltage is applied through the membrane. The generated proton and hydroxide ions move out through the CEL and AEL, respectively, to produce acid and base solutions. Meanwhile, under a forward bias condition, protons and hydroxide ions move to the bipolar interface and neutralized again. Neutralization energy is generated according to the concentration of proton and hydroxide ions which move through the BPM and can be expressed as a junction potential (JP) value. When a BPM having an ideal JP is applied to an electro-membrane process, high separation and energy efficiencies can be obtained. In addition, the BPMs should have a highly adhesive bipolar junction for the long-term operation of electro-membrane processes. In this work, a novel BPM with an ideal JP and a highly adhesive bipolar junction property was developed and applied to several electrochemical separation processes such as acid-base flow battery and direct seawater electrolysis. The specially designed BPM was fabricated with poly(phenylene oxide) (PPO) based ionomers. In addition, an iron-based catalyst and a reinforcing material were introduced for excellent water-splitting performance and interfacial durability between the two ion-exchange layers, respectively. The prepared BPM not only had excellent interfacial adhesiveness and mechanical properties but also exhibited high water-splitting efficiency of 98% or more. The electrochemical separation processes employing the prepared BPM exhibited excellent performances comparable with those of commercial BPMs. This work was supported by the National Research Foundation of Korea (NRF) grants funded by the Korean government (MEST) (NRF-2022M3C1A3081178 & NRF-2022M3H4A4097521).

8:00 PM EN08.03.04

Enhancing Ion Conductivity and Robustness in Gel Polymer Electrolytes with a Semi-Interpenetrating Polymer Network Structure SeonghyeonYang, Yeon SuLee and Sung-KonKim; Jeonbuk National University, Korea (the Republic of)

In this study, we describe the synthesis of gel polymer electrolytes (GPEs) by casting a solution consisting of poly(ethylene glycol) methyl ether methacrylate (PEGMA) and trimethylolpropane ethoxylate triacrylate (ETPTA) combined with poly(vinylidene fluoride-co-hexafluoropropylene) (PVDF-HFP). The solution is subjected to thermal radical polymerization using different molar ratios. The resulting GPEs exhibit a semi-interpenetrating polymer network structure, as confirmed by morphological, structural, and electrochemical characterization. Among the various compositions investigated, the GPE with a molar ratio of PEGMA:ETPTA at 98:2, in the presence of 40 wt.% PVDF-HFP (relative to the total amount of PEGMA and ETPTA), demonstrates exceptional properties. It shows high ionic conductivity (1.46×10^{-3} S cm^{-1}) and excellent tensile strength (6.28 MPa at an elongation at break of 156%). Moreover, the GPE exhibits electrochemical stability up to 4.7 V (vs. Li/Li+). Based on these electrochemical performance results, the synthesized GPEs show great potential as polymer electrolyte membranes in the field of energy storage.

8:00 PM EN08.03.05
Controlled Fabrication of Mesoporous Electrodes with Unprecedented Stability for Water Capacitive Deionization under Harsh Conditions in Large Size Cells ManarM. Hazaa and NagehK. Allam; The American University in Cairo, Egypt

Capacitive deionization (CDI) is a feasible low-cost desalination technique for lowt o medium (brackish) salinity water. However, cycling stability and regeneration of the CDI electrodes are the bottlenecks hindering the practical application of the technology on large scale. Oxidation of the electrodes during the sequential adsorption and desorption processes is one of the most challenging problems hindering their long-term cycling performance. Herein, we demonstrated the ability to design and fabricate exceptionally stable CDI electrodes *via* a one-pot pyrolysis protocol. The optimized pyrolysis of nitrogen carbon precursors at different temperatures enabled the fabrication of carbon materials with a controlled amount nitrogen dopant (NDCs) with exceptional cycling stability. The NDCs showed high specific capacitance and dual *meso*/microporous structures with high salt adsorption capacity (SAC), reaching 26.5 mg g^{-1} in a single-pass desalination mode. Moreover, all NDC electrodes exhibited exceptional desalination stability performance over 150 successive charging/discharging cycles with 100% retention in aerated and deaerated solutions under harsh 1.4 V as the charging voltage. Moreover, all NDCs cells demonstrated charge efficiencies in the range from ~40 to 60%. The potential of zero charge (PZC) was determined for the tested NDC electrodes to elucidate their oxidation resistance (EOR). The electrodes exhibited a minimal shift in potential after the entire desalination stability tests, revealing minor electrode oxidation. The performance of our NDC-electrodes was compared against that of the commercially available activated carbon (AC) under the same experimental conditions, with the latter showing a server decrease in the SAC retention within the first few cycles.

8:00 PM EN08.03.06
Development of Layered Oxides for Electrochemically Driven Li Extraction from Dilute Li Sources GrantHill and ChongLiu; University of Chicago, United States

Due to the rising demand of Li-ion battery powered vehicles, the lithium supply chain is projected to experience strain in the coming decades. This strain can be mitigated by developing new Li extraction methods that can access unconventional Li sources such as seawater. Electrochemical Li extraction has demonstrated high selectivity and recovery rates from dilute Li sources; the insertion host material selection plays a key role in the overall performance. However, few materials have been explored nor have materials been tailored for Li extraction from these multi-cation solutions. With this in mind, we have explored the role of particle size and morphology of layered cobalt oxide on Li extraction from mixed Li and Na solutions. We have found that large particles form a core-shell structured $(NaLi)_{1-x}CoO_2$ by non-Faradaic ion exchange using parent $LiCoO_2$ with Na ions. Using electrochemical intercalation, this material successfully extracted Li from 1:20,000 Li to Na aqueous solution to 7.6:1 Li: Na, which is a Li selectivity of 1.5 x 10^5 over Na. Decreasing the particle size, parent $Na_{1-x}CoO_2$ was used to extract dilute Li from an organic solution and maintain high selectivity for multiple Li extraction sequences. After significant structural changes from the first Li extraction, high Li recovery performance can be maintained over multiple extraction sequences. Additionally, we also report C-rate dependence during the intercalation recovery step, indicating the importance of method development for optimizing material performance. This work highlights the importance of understanding the phase separation behavior of Li and Na in layered transition metal oxides for improved Li recovery capacity and lifetime.

Tailoring Vertically Aligned Multi-Layer Graphene Arrays for Selective Recognition of Dopamine Neurotransmitter: An Amperometric Approach AbdulrahmanAl-hagri and SelvaPalanisamy; Khalifa University, United Arab Emirates

The development of sensitive dopamine (DA) sensors has significantly contributed to our understanding of dopamine-related disorders and has enabled advancements in medical diagnostics and neuroscience research. Therefore, In the present work, a novel electrochemical sensing platform was developed using vertically aligned multi-layer graphene arrays (VA-MGA) for the selective detection of dopamine (DA). The preparation of high-quality VA-GA was achieved using the plasma-enhanced chemical vapor deposition method, eliminating the need for an additional catalyst. The formation of VA-MGA was confirmed using various physiochemical techniques such as transmission electron microscopy and Raman spectroscopy. The modified electrode, made of VA-MGA, was utilized for the electrochemical detection of DA using cyclic voltammetry and amperometry i-t methods. The electrochemical oxidation response and sensitivity of DA at the VA-MGA electrode was found to be 10 and 3 times higher than that observed with an unmodified and commercially available multilayer graphene modified electrodes. The VA-MGA sensor exhibited excellent analytical parameters for DA detection, including a wide linear range of 10 nM to 180 μM and a low detection limit of 2 nM. The sensor also demonstrated remarkable sensitivity, storage stability, and selectivity for DA detection, which makes it highly suitable for accurate detection of DA in medical diagnostics and neuroscience research. Furthermore, the practical application of the VA-MGA sensor for DA detection was demonstrated in various real samples.

Highly Selective Electrochemical Separations of Metals MartinZ. Bazant; Massachusetts Institute of Technology, United States

The selective separation of metals from aqueous solutions is a critical challenge for many problems in energy, health and sustainability. This talk will describe two classes of highly selective separation methods for metal ions, based on differences in either electrokinetic or electrochemical properties. The first involves the propagation of deionization shock waves through charged porous media. Shock electrodialysis can separate trace amounts of toxic lead from drinking water or radionuclides from nuclear wastewater with minimal energy consumption. Shock ion extraction integrates ion-exchange resins to amplify the separation of multivalent metal ions, such as cobalt, zinc, mercury, nickel and manganese. Further control of these separations is afforded by pH swings, which allow heavy metal cations to be separated by selectively forming oxyanions, as illustrated by chemical-free continuous separation of vanadium, molybdenum, tungsten, cobalt and nickel. The second method involves selective electrosorption of metal cations in capacitive electrodes. Functionalized nanoporous carbon electrodes can separate multivalent from monovalent cations with applications to transition metal recovery in Li-ion battery recycling. Intercalation electrodes can provide extreme chemical selectivity for lithium with applications to extraction from lithium brines and battery recycling leachates, eliminating the need for harsh reagents in traditional hydrometallurgical processes.

9:00 AM EN08.04.02
Polymeric Porous Electrodes for Electrochemically Mediated Carbon Dioxide Capture Youhong (Nancy)Guo and T. AlanHatton; Massachusetts Institute of Technology, United States

Carbon capture is a promising technology to mitigate emissions and achieve net carbon neutrality. Electro-swing reactive adsorption using redox-active species is emerging as a versatile platform for a sustainable decarbonization approach. However, the pricy electrode with limited gas diffusion has become one of the major factors hindering its practicality. Herein, we developed thick hydrogel coated-polymeric electrodes with high porosity that can effectively enhance the diffusion of carbon dioxide without the assistance of gas diffusion conduct. Such porous electrode also enables more interactive sites for redox-active polymers, leading to a ~ 90% quinone utilization efficiency at saturation. We also achieved continuous carbon capture-release operations with excellent capacity, stability, and Faradaic efficiency. Armed with lightweight and low-cost, as-developed electrodes present a vast potential to advance the future implementation of electrochemical carbon separation technologies.

9:15 AM EN08.04.03
Electrochemically-Mediated Enantioselective Interaction with Redox Metallopolymers Through Varied Chirality JeminJeon[1], Ching-YuChen[1], FábioZ. Galetto[1,2], JohannesElbert[1],

YuriG. Kappenberg[1] and XiaoSu[1]; [1]University of Illinois Urbana-Champaign, United States; [2]Universidade Federal de Santa Catarina, Brazil

Chirality plays a critical role in various industrial domains, such as molecular recognition, asymmetric catalysis and chiral purification[1]. Thus, constructing and leveraging precise chiral structures for enantioselective interaction has been a research hotspot in many scientific fields. In this research, we successively synthesized two types of chiral metallopolymers containing point chirality and planar chirality, respectively. Their chiral properties were characterized with circular dichroism and 2D nuclear magnetic resonance spectroscopy, followed by an investigation in their enantioselectivity with deprotonated amino acids and pharmaceutical carboxylates in electrical chemical systems. The point chiral polymers synthesized with Ugi's amine -inspired chiral monomers exhibits higher enantioselectivity compared with its chiral building block. 2D Nuclear Overhauser Effect Spectroscopy indicates the intramolecular interaction between the ferrocene moiety and alkyl backbone, and we infer that it is the emerging supramolecular chirality in the metallopolymer that resulted in enhanced selectivity[2]. The planar chiral polymers incorporated an additional functional group on the ferrocene, generating the stereogenic plane. Improved recognition was also observed in comparison with their monomer precursors, and the affinities toward analyte enantiomers were flipped when tested over their four enantiomeric and diastereomeric stereoisomers, respectively. Further investigations on solvent polarity, supporting electrolyte and pH effect revealed that the enantioselective interaction between the chiral polymer and analyte is influenced by the competition between π- π interaction, hydrogen bonding and steric effect. Our results demonstrate the potential of adopting chiral redox-metallopolymers in electrochemically mediated platforms for enantioselective sensing and separation.

Counterion Effects on Moisture Swing Direct Air Capture Applications KelseyB. Hatzell; Vanderbilt University, United States

Direct air capture (DAC) is essential for achieving reversing the growth in greenhouse gas emission. Conventional sorbent materials require a regeneration approach which is energy intensive. Here, we evaluate a novel moisture-swing direct air capture approach which utilizes water vapor as a means to regenerate a absorbent materials. We specifically examine five anions (carbonate, phosphate, sulfide, acetate, and borate) and study how they interact impact co2 absorption capacity and kinetics. We discovered that the local short-range order in micropores determines the amount of hydroxide formation in the moisture-controlled reversible hydrolysis/neutralization reaction to affect CO2 capture capacity. Among five anions, carbonate, phosphate, and borate exhibited greater ability to generate hydroxide and thus have higher capture capacity. A thorough understanding of the role anions impact moisture-swing DAC application can enable materials design strategies for advance climate materials.

10:30 AM *EN08.04.05
Electrochemically-Driven Solution-Phase CO_2 Capture MichaelJ. Aziz; Harvard John A. Paulson School of Engineering and Applied Sciences, United States

We investigate the mechanisms of and demonstrate the efficacy of CO_2 capture/release systems based on several thermodynamic cycles undertaken by aqueous solutions. Low-energy electrochemically-driven methods of making acid and base enable CO_2 capture by reaction with hydroxide and release upon acidification. Reactions among the various species of dissolved inorganic carbon (DIC) leading to CO_2 absorption and outgassing are caused by, respectively, diluting and concentrating the alkalinity in a solution. Redox-active organic molecules can reversibly bind CO_2 directly in one redox state and release it in the other. The same molecules can swing the pH by undergoing proton-coupled electron transfer, thereby enabling CO_2 capture by hydroxide.

11:00 AM EN08.04.06
Electrochemical Carbon Capture using Organic Dye Compound: System Design and Optimization in a Symmetric Cyclic Flow HyowonSeo, MichaelNitzsche, MichaelMassen-Hane and T. AlanHatton; MIT, United States

Electrochemical carbon capture systems are designed to effectively reduce atmospheric levels of carbon dioxide (CO_2) by capturing this greenhouse gas from industrial flue gas or directly from the air, thereby contributing to the mitigation of climate change. The electrochemical carbon capture system utilizes an organic dye compound, known as neutral red/leuco-neutral red (NR/NRH2), has been demonstrated for CO_2 capture from 15% CO_2 and ambient air. Through the application of electrochemical potentials, the pH of aqueous electrolytes is modulated to enable efficient separation of CO_2 from dilute sources. In order to assess the effectiveness of this system, an initial continuous flow system was constructed, which successfully demonstrated CO_2 separation capabilities using a mixture of 15% CO_2 and ambient air.

To enhance the stability of the system using NR/NRH2 redox couple, a cyclic flow configuration was subsequently constructed to investigate the performance of CO_2 capture under different operating conditions. These conditions include variations in current densities, liquid flow rates, feed gas composition, electrode materials, and system operation methods. The electrochemical process within the cyclic flow system was analyzed by examining the current and voltage responses under diverse electrochemical conditions. The integrated electrochemical system, operating under optimized conditions, underwent testing for carbon capture within the cyclic flow setup.

The demonstrated electrochemical carbon capture system design and optimization results will encourage future research into optimizing the electrochemical separation unit for long-term and stable operations in large-scale applications.

11:15 AM EN08.04.07
Continuous Carbon Capture via Oxygen/Water Electrolysis in a Solid Electrolyte Reactor PengZhu[1], HaotianWang[1] and T. AlanHatton[2]; [1]Rice University, United States; [2]Massachusetts Institute of Technology, United States

Electrochemical carbon capture technologies, with renewable electricity as the energy input, are promising for carbon management but still suffer from low capture rates, oxygen sensitivity, or system complexity. Here we demonstrate a continuous electrochemical carbon capture design by coupling oxygen/water (O_2/H_2O) redox couple with a modular solid electrolyte reactor. By performing oxygen reduction (ORR) and oxygen evolution reaction (OER) redox electrolysis, our device can efficiently absorb dilute carbon dioxide (CO_2) molecules at the high-alkaline cathode/membrane interface to form carbonate ions, followed by a neutralization process through the proton flux from the anode to continuously output a high purity (> 99%) CO_2 stream from the middle solid electrolyte layer. No chemical inputs were needed, nor side products generated during the whole carbon absorption/release process. High carbon capture rates (440 mA cm^{-2}, 0.137 $mmol_{CO2}$ min^{-1} cm^{-2} or 86.7 kg_{CO2} day^{-1} m^{-2}), high Faradaic efficiencies (> 90% based on carbonate), high carbon removal efficiency (> 98%) in simulated flue gas, and low energy consumptions (starting from ~ 150 kJ/mol_{CO2}) were demonstrated in our carbon capture solid electrolyte reactor, suggesting its promising practical applications.

SESSION EN08.05: Electrochemical Separations IV

1:30 PM *EN08.05.01
Lithium-Selective Adsorbents and Membranes for Electrochemical Wastewater Refining WilliamTarpeh; Stanford University, United States

With global lithium supplies projected to fall short of demand between 2023 and 2027, there is great motivation to develop new technologies capable of lithium recovery from alternative sources such as battery waste, produced water, and geothermal brines. In these sources, the co-existence of other impurities at much higher concentrations than lithium (e.g., >60,000 ppm Na+ versus 50-1000 ppm Li+ in brines) presents a challenge for high-purity lithium extraction. Selective electrodialysis is a candidate for lithium recovery that aligns with recent resource extraction priorities including developing electrified separation processes, although it requires the development of ion-selective membranes. To inform the design of such membranes, we first studied fundamental ion transport and selectivity mechanisms in commercially available membranes. We then synthesized a library of novel ligand-functionalized membranes (including acrylic acid and vinylpyridine ligands) to study the impact of additional ion-specific coordinative interactions on lithium selectivity in the selective electrodialysis process. Finally, we

integrated selective ion exchange resins into electrodialysis to accomplish in situ electrochemical regeneration that helps concentrate lithium from dilute sources and recovery high-purity lithium in electrochemical ion exchange reactors.

2:00 PM EN08.05.02
Augmenting the Interfacial Electrostatic Potential with Donnan-Enhanced Nanofiltration for Lithium Extraction from Salt-Lakes LucyA. Kanias, TrentLee, Zi HaoFoo and JohnH. Lienhard; Massachusetts Institute of Technology, United States

The exponential growth in the demand for lithium in the renewable energy and electric vehicle industries necessitates significant improvement in the efficiency of lithium production from primary sources. While lithium is abundant in salt lakes within South America and Asia, existing extraction methods based on brine evaporation are relatively costly and suffer protracted production cycles. By avoiding brine evaporation altogether, membrane processes such as nanofiltration can selectively concentrate monovalent ions, optimizing the extraction process directly from salt lakes while eliminating the environmental impacts of evaporation ponds.

The selectivity of conventional nanofiltration membranes can be attributed to their cross-linked polyamide active layer. The polyamide layer is typically fabricated by a condensation reaction between trimesoyl chloride and piperazine, along the interface of a polysulfone support layer and the organic monomer mixture. As a result of the charged moieties in the polyamide, the electrostatic potentials that form along the solution-membrane interface inhibit ions of the same charge from partitioning into the membrane, a phenomenon known as Donnan exclusion. However, the high concentration of the residual carboxyl moieties of the polyamide layer imparts a negative volumetric charge density to the active layer and attenuates the rejection of multivalent cations by Donnan exclusion.

To impart monovalent cation selectivity, emerging variants of nanofiltration employ a positively charged surface layer on the membrane that displays high water permeability and a positive volumetric charge density. Here, a Donnan-enhanced nanofiltration membrane employing a polyethyleneimine (PEI) surface layer is fabricated through a condensation reaction between perfluorosulfonic acid and the amine moieties in the polyamide layer, to attain enhanced Li^+/Mg^{2+} selectivity. In this study, we present empirical evidence for the success of this method, based on experiments with high-salinity multi-cation brines that represent those encountered in salt-lake lithium extraction. Our conclusions are derived from 1000 original concentration measurements spanning three feed salinities and three pH levels.

The water permeability of the Donnan-enhanced NF membrane decreases from 17.2 % on average from the added hydraulic resistance. Our streaming potential measurements indicate that the zeta potential of the NF membrane increases from − 17.2 mV to 19.8 mV with the addition of the PEI surface layer. Our experiments with binary cation solutions (i.e., Li^+, Mg^{2+}) reveal that the Li^+/Mg^{2+} separation factor increases from 39.1 with the unmodified membrane to 129.2 with the Donnan-enhanced membrane. Using multicomponent salt-lake brines from Salar de Atacama, Chile, the recorded Li^+/Mg^{2+} separation factors are 13.2, 18.1, and 87.3, for solution pH of 7, 4 and 2, respectively. In a single pass, the Donnan-enhanced NF membranes register an Mg^{2+} rejection of 96.8 % while raising the concentration of Li^+ by 17.7 %. The enhanced Li^+/Mg^{2+} selectivity at low solution pH arises from the protonation of the residual carboxyl moieties in acidic conditions ($pk_a \sim 4$). Lastly, we conduct a module-scale assessment of the process's membrane area requirement and energy efficiency.

Electrochemical Lithium Recovery: Investigating Electrode Behavior and Enhancing System Durability SeoniKim; Ewha Womans University, Korea (the Republic of)

The demand for lithium has been rapidly increasing due to the widespread use of secondary batteries. Currently, lithium production primarily relies on the time-consuming process of evaporation and precipitation from brine lakes. This method is limited to specific water sources with low ion concentrations, and environmental concerns have emerged surrounding its use.

However, the development of electrochemical lithium recovery systems, inspired by the principles of lithium-ion batteries, holds promise for alleviating these concerns. By utilizing cathodes, such as $LiMn_2O_4$ and $LiFePO_4$, which possess suitable channel sizes for selective Li^+ insertion, these systems can selectively recover lithium from various source waters with a wide range of Li^+ concentrations. However, a lack of understanding regarding the physicochemical behaviors of the Li^+-selective electrode under realistic operational conditions has been a hindrance. Furthermore, the stability and cost of the counter electrodes in this system present significant obstacles that impede its practical implementation.

This talk aims to delve into the physicochemical behavior of the Li+-selective electrode during the electrochemical lithium recovery process at various Li+ concentrations in the source water and the operation rate. Through the characterization of the electrodes using X-ray techniques, it was suggested that increasing the density research aims to tackle the increasing demand for lithium by advancing electrochemical lithium recovery systems. It will focus on investigating the behaviors of the Li^+-selective electrode during realistic operational conditions and propose strategies for enhancing the efficiency and durability of electrode designs.

In addition, this talk will explore the Faradaic and non-Faradaic capture of anions by modifying the silver-based electrode and utilizing a high-surface-area carbonaceous material, respectively. It was found that the system showed high stability by using those electrode materials. Moreover, a system that enables simultaneous lithium recovery and decomposition of organic pollutants will be introduced. This extends the applicability of the electrode to industrial wastewater, highlighting the versatility of the electrochemical system.

Electrified Mineralization of Nutrients from Real Municipal Wastewater and the Energy Implications Thereof Damilola ADaramola; Northeastern University, United States

Phosphorus and nitrogen are two of the three major nutrients required for plant and animal life and sustaining global population growth requires an anthropogenic impact on the natural cycles of these nutrients i.e., increased phosphorus mining and nitrogen fixation to sustain the per capita consumption of P and N availability, respectively.[1] However, this anthropogenic activity has also led decreased environmental sustainability: higher accumulation of N and P in water bodies due to nutrient runoff and leaching as well as higher greenhouse gas emissions from nutrient fixation, mining and transportation. Furthermore, the process energetics for solid P and N delivery are 4.0 and 5.7 GJ/t, respectively,[1] while the embodied energetics for P and N delivery are 10.4 and 55.5 GJ/t, respectively,[2] illustrating the key drivers for the associated GHG emissions.
An alternative, yet sustainable, anthropogenic approach is the recovery and re-use of these nutrients from waste via an electrical driving force.[3,4] Although a chemical approach to recovery enhances the circular economy of nutrient use, an electrical approach using renewable electrons extends from materials conservation to significant process decarbonization. This electrified approach will be discussed in this invited talk, based on the combined efforts of researchers at Ohio University and Northeastern University.
This presentation will describe an electrochemically-driven phosphorus and nitrogen recovery system using real wastewater from a municipal treatment plant as the substrate. Initial analyses consisted of 1-year of sampling from 3 different recycle streams at two different wastewater facilities: 4 million gallons per day and 100 million gallons per day throughput. Multivariate screening analyses of stream, design and operational variables on recovery efficiency and energy consumption from synthetic wastewater were conducted. These screening analyses were subsequently used to evaluate recovery efficiency and energetics with real wastewater as the treated substrate.

Ammonium Recovery from Manure Wastewater and Simultaneous Electrosynthesis using Ammonium-Ion Selective Redox Material RuiWang[1], KaiYang[1], CindyWong[2], HoracioAguirre-Villegas[1], RebeccaLarson[1], FikileBrushett[2], MohanQin[1] and SongJin[1]; [1]University of Wisconsin–Madison, United States; [2]Massachusetts Institute of Technology, United States

The greenhouse gas emissions and water contamination generated by livestock manure motivates the development of new approaches to reduce their environmental impacts and improve sustainability. Effective approaches to recover nutrients, especially ammonia, from manure wastewater to produce fertilizer are needed. Here we develop a new electrochemical strategy to achieve simultaneous ammonium (NH_4^+) ion recovery and electrochemical synthesis using potassium nickel hexacyanoferrate (KNiHCF) as the ammonium ion-selective redox material to mediate the process. The KNiHCF electrode spontaneously uptakes NH_4^+ (and K^+) from manure wastewater with a nutrient (NH_4^+ and K^+) selectivity of ~100% and oxidizes the organic

matter. Subsequently, NH_4^+-rich fertilizers are released electrochemically together with the electrosynthesis of value-added chemicals, such as H_2 as a green fuel or H_2O_2 as a disinfectant, without expensive ion-exchange membranes. The integrated process shows an estimated net profit for common cow dairy farms and could potentially reduce NH_3 emissions. These results provide a new conceptual strategy for distributed electrochemical resource recovery and on-demand electrochemical manufacturing that can improve agricultural sustainability and also open new opportunities for selective metal ion recovery towards zero liquid discharge water treatment and purification.

3:45 PM EN08.05.06
Separating Reactants in Membraneless Redox Flow Batteries: Leveraging Fluid Mechanics SofiaKuperman[1], RanSwisa[1], RobertGloukhovski[1], PrakashRewatkar[1], MohamedAsarthen[1], AnnaZigelman[1], MatthewSuss[1,2,3] and AmirGat[1]; [1]Technion - Israel Institute of Technology, Israel; [2]Technion–Israel Institute of Technology, Israel; [3]Technion – Israel Institute of Technology, Israel

Redox flow batteries are considered a highly promising electrochemical technology for grid-scale renewable energy storage. However, their commercialization has been hindered by high capital cost and balance of plant complexity. Single-flow batteries are an emerging subclass employing a membraneless cell design and simplified flow systems. Recently, single-flow zinc-bromine batteries leveraging novel multiphase electrolyte emulsions have been demonstrated. Such electrolytes are a mixture of a bromine-poor aqueous phase and bromine-rich polybromide phase, where in the latter phase the bromine is largely electrochemically inactive. However, separating the zinc and bromine reactants in the absence of a membrane is a challenging problem requiring deep understanding of multiscale flow phenomena and its coupling to battery performance.

In this work, we will briefly present our novel 2D analytical flow model describing the multiscale flow phenomena within such flow batteries. The model captures the concentration field of the polybromide phase, including sedimentation as this phase is denser. The model was validated with numerical simulations and experimental data. We will focus on how the predicted fluid mechanics phenomena support effective separation between the reactants, and how the model explains several counter-intuitive battery observations, such as decreasing electrolyte conductivity for decreasing flowrate. The model also points towards future battery optimizations for systems employing multiphase flow electrolytes, and thus is a key aspect towards unlocking their potential for low-cost renewable energy storage.

4:00 PM EN08.05.07
High-Performance Nanoparticle-Modified Membrane for Nonaqueous Redox Flow Batteries DanielJ. San Roman and PhilipCox; Mainstream Engineering Corporation, United States

For the effective implementation of environmentally friendly large scale renewable energy, low-cost grid-capable storage solutions must be implemented to accommodate the effective capture and load leveling of the typically periodic and variable production levels. One solution of particular interest is redox flow batteries (RFBs), which provide a high number of deep cycles and the ability to store large amounts of electrical energy cheaply and efficiently. However, aqueous RFBs typically suffer from low energy density, limited electrolyte stability, and capacity decay during cycling. Alternatively, switching RFBs to nonaqueous solvents and charge carrying redox complexes provides higher operating voltages allowing for higher energy density cells. However, to successfully implement these non-aqueous RFBs (NARFB) there remains the need to improve the durability of the cell membranes and reduce their susceptibility to crossover of active redox species.

To this end, Mainstream Engineering successfully demonstrated the preparation of a stable nanoparticle composite protective film that effectively reduces redox molecule crossover (> 90 % reduction compared to the non-reinforced anion exchange membrane [AEM]) with no effect on the key membrane ionic conductivity and shows promise as a high-performance membrane for NARFBs. Mainstream Engineering's approach to optimizing the AEM for NARFBs builds on our previous work developing scalable selective ion exchange membranes and membrane coatings of a fuel cell, batteries, and highly selective liquid and gas separation applications. For this work, we screened various potential AEMs for their chemical and mechanical stability in non-aqueous solutions as well as demonstrating a wide electrochemical stability window. After down selecting an AEM base membrane with excellent chemical stability, we formulated a nanoparticle/ionic binder coating to allow the deposition of a thin-film protective coating and the formation of a composite membrane on the AEM base membrane. We examined both screen printing and knife coating approaches to provide a robust, uniform, and repeatable method of coating the slurry compositions to provide a stable, uniform thin-film coating. The surface characteristics of our composite films were evaluated with optical and scanning electron microscopy, to determine the base porosity and the coating uniformity. These composite membranes were demonstrated to be both chemically and mechanically stable in the non-aqueous solvents. The ionic conductivity and iron tris(2,2'-bipyridine) (FeBpy) permeability of the films were benchmarked against commercially available AEMs. We have further optimized our composite membranes for decreased FeBpy permeability and performed half- and full- cell testing of our membranes, both under stationary and flowing electrolyte conditions. The performance of the protective film was further optimized via surface charge modifications of the nanoparticles to allow a 75% reduction in the ionic resistance of the nanoparticle modified membranes, lowering the cell voltage drop and improving the power density. Our materials show increased performance, by lowering the redox molecule crossover without increasing the membrane thickness or overall ionic resistance. Mainstream Engineering's novel composite AEMs provide a promising approach to solving outstanding membrane performance issues with current NARFB chemistries, providing a commercially viable path forward for high-energy density non-aqueous RFB storage technologies.

4:15 PM EN08.05.08
Membrane-Enabled Direct Extraction of Critical Metals MichaelBaird[1,2] and BrettA. Helms[2]; [1]University of California, Berkeley, United States; [2]Lawrence Berkeley National Laboratory, United States

Water treatment devices designed to extract critical elements from wastewater and natural brines rely on polymer membranes that exhibit selective permeability towards dissolved ions. However, the underlying design principles that govern selectivity between ions of similar size and charge (e.g. Li^+/Na^+) remain unclear because of natural tradeoffs in the solubility and diffusivity of dissolved species within a membrane. Given that these properties arise from the solvation environments made available to permeating ions, we proposed a membrane platform wherein specific coordination modes are enforced in at sub-nanometer length scales with rigid polymer backbones and pendant groups with unique geometries. To this end, a library of systematically tuned microporous polymers have been synthesized and evaluated for ion uptake, ionic conductivity, and salt permeability. Our results lend insights to an energy landscape model of ion transport across membranes, where the pendant is shown to influence the energetics of partitioning at the water-membrane interface, as well as hopping between adjacent solvation cages within the membrane.

Electrically-Modified Anion Exchange Membranes for Alkaline Membrane Water Electrolysis HaniehBazyar and AthanasiosPapageorgiou; TU Delft, Netherlands

Hydrogen has received much attention as a green energy alternative to replace fossil fuels in our effort to meet the requirements of global climate change. However, most of it is currently produced from fossil fuels through methane reforming, producing large amounts of carbon dioxide. Anion exchange membrane water electrolysers (AEMWE) constitute a promising new technology to produce high-purity green hydrogen through water electrolysis, that use less expensive non-platinum based electrocatalysts than proton exchange membrane electrolysers and low-cost polymer membranes. AEMWEs require membranes with high ion exchange capacity to achieve high hydroxide conductivity. However, this may lead to significantly low mechanical stability due to the increased water uptake and swelling ratio. Thus, the fabrication of AEMs with both high conductivity and mechanical stability is still a challenge [1].

In this study, novel membranes, based on poly(aryl quaternary ammonium), are fabricated through electrically-assisted solvent casting method. During the casting, DC and AC electric fields are applied on the polymer solution. The morphological and structural properties of the membranes are characterized by NMR and IR. The ion exchange capacity is measured through ion chromatography and the hydroxide conductivity is assessed via linear sweep voltammetry. The overall resistance of the cell and the durability of the membrane are investigated through electrochemical impedance spectroscopy and chronoamperometry, respectively.

We study how the application of an electric field improves the conductivity of the membrane by aligning the cationic groups of the polymer into ion channels, facilitating the movement of hydroxides. Results provide a comparison of the physicochemical and electrical properties of the membranes cast with and without the presence of various electric fields.

Nitrate Reduction Enhancements using Electrified Membrane Filtration LeaWinter[1], YingzhengFan[1], XiaoxiongWang[1,2] and ClaireButler[1]; [1]Yale University, United States; [2]Tsinghua University, China

The release of nitrate to the environment from wastewater effluent and agricultural runoff contributes to groundwater contamination, harmful algal blooms, and disruption of biogeochemical nitrogen flows. Nitrate conversion via electrochemical reduction can eliminate the production of concentrated waste streams while avoiding the addition of reductant or hole scavenger chemicals. However, major challenges for nitrate removal from water via electrochemical conversion involve reducing the use of expensive precious metal electrocatalysts while also improving the reaction activity and selectivity, stability, and mass transport of nitrate to electrocatalyst active sites. The use of electrochemical membranes (EMs) as multifunctional porous flow-through electrodes could potentially address these challenges based on improved mass transport and altered kinetics under flow conditions within membrane pores.

We fabricated conductive membranes using polymers combined with carbon nanotubes. The EMs showed significantly higher nitrate removal efficiency during electrified filtration compared to flow-by mode. The small pore sizes in the membrane reduced the diffusional boundary layer by several orders of magnitude with respect to flow-by mode, overcoming diffusional mass transport limitations. During electro-filtration, the nitrate conversion activity was easily controlled by tuning the permeate flow rate, regardless of applied potential. These enhancements and tunability demonstrate key advantages of employing membranes with pore sizes of < 1 µm as flow-through electrodes compared to conventional 2D electrodes and 3D electrodes with larger pore sizes. Additionally, the EMs demonstrated nitrate removal to below EPA drinking water limits in synthetic surface water with product selectivity to N_2 of over 80% and without showing loss of stability over a period of 10 h. The mechanically-flexible membranes provide an advanced electrochemical water treatment architecture involving inexpensive materials and green synthesis methods.

Electrolyte Composition Effects on Bipolar Membrane Polarization and Transport for Electrochemical Separations ThomasY. George[1], PaigeBrimley[2], WilsonSmith[2] and MichaelJ. Aziz[1]; [1]Harvard University, United States; [2]University of Colorado, Boulder, United States

Bipolar membranes (BPM), consisting of an anion exchange polymer membrane layer, a cation exchange polymer membrane layer, and a catalytic interfacial layer in between, enable electrochemical cells with strong gradients of pH between adjacent chambers. Bipolar membrane electrodialysis (BPMED) is a prominent example of an electrochemical separation process relying on this unique type of membrane material. In bipolar membrane electrodialysis, the BPM operates in “reverse bias,” dissociating water into hydronium and hydroxide at the interfacial layer, generating acidic and alkaline streams, while a third electrolyte chamber is essentially desalinated as it provides a source of counterions (*e.g.* K^+ and Cl^-) for the acid and base streams. Recently, this process has seen increased attention for applications in resource recovery and for removing anthropogenic carbon dioxide from the environment. Unlike the traditional application of BPMED, to generate pure acid and base as chemical products, the emerging applications involve the BPM contacting electrolytes that include supporting salt or environmental impurities, which can have significant effects on the polarization behavior of the membrane as well as its transport selectivity of protons/hydronium and hydroxide over their counterions and other salts in the electrolyte.

In this work, we systematically investigate the effects of ion size, charge, and concentration on salt crossover in a widely-used commercial BPM (Fumasep FBM) by combining polarization experiments in a four-electrode setup with a 1D continuum model of water dissociation and multi-ion transport. We find that salt crossover dominates at low current density, before the stronger electric field at larger applied potential drives water dissociation to dominate. Further, we investigate how the total ion concentration and ratio of supporting salt to acid and base concentration influence the overpotential across the membrane and the contributions of salt crossover to total current.

Both high overpotentials associated with water dissociation at high currents and the unwanted salt crossover at lower currents provide significant hurdles for the deployment of BPMs in electrochemical technology. This work emphasizes the importance of electrolyte effects on these phenomena, and may provide guidance both for designing new materials and for choosing electrolytes and operating conditions in electrochemical cells.

Impedance Analysis of Anion Exchange Membrane Electrolysis AthanasiosPapageorgiou and HaniehBazyar; TU Delft, Netherlands

Anion exchange membrane (AEM) electrolysis is a promising solution for low-cost hydrogen production from renewable energy sources on a large scale. However, the efficiency of AEM electrolysis is currently lower than that of traditional technologies, such as proton exchange membrane electrolysis. This deficiency in performance can be attributed to certain integral components of the membrane electrode assembly and the reaction kinetics. The measurement of these limitations involves assessing the ohmic and charge transfer resistances.

In this study, we aim to investigate and quantify the impact of various parameters such as voltage, temperature, flow rate, electrolyte concentration, and catalyst on the ohmic and charge transfer resistances using electrochemical impedance spectroscopy. The membrane electrode assemblies are fabricated using commercially available membranes, assessing the effect of different membranes on the performance of the electrolyser. In addition, the effect of DC and AC fields on the H_2 production is investigated, while the production of H_2 is quantified and compared to that calculated through the current output.

Controlling Protein Ad-and Desorption by an Electrical Switch on Polymer-Coated Carbon Electrodes Kiekede Boer and KarinSchroen; Wageningen University, Netherlands

Capacitive Deionization (CDI) has been widely researched and applied to remove salt ions from brackish water in an energy-efficient way. During operation, two charged electrodes electrostatically attract ions, which are released again to the bulk solution once the potential is removed, resulting in a brine and freshwater solution. Carbon is generally used as electrode material, because of its high specific surface area and electrical conductivity. Building upon this principle, our research focuses on the separation of whey protein isolate (WPI) using a similar setup. We have successfully achieved reversible adsorption of up to 10 mg of protein per gram of electrode material on polyelectrolyte-covered carbon electrodes.
To achieve this, positively and negatively charged polyelectrolytes are attached to the working and counter electrode, respectively, to create a surface charge in the absence of an electric field. The created surface charge enables spontaneous adsorption on the working electrode by electrostatic attraction with the negatively charged protein. Protein desorption is initiated by an electric field of -1.2 V, which neutralizes the positive chemical charges of the polyelectrolyte-covered working electrode through negative electronic charges. The negatively charged polyelectrolyte on the counter electrode prevents re-adsorption during this desorption phase. This set-up, with a spontaneous adsorption step, can be referred to as inverted capacitive deionization (iCDI). Adsorption is controlled by diffusion while desorption is mainly migration-driven due to the applied electric field, causing desorption to occur faster than adsorption.
Interestingly, salt adsorption and desorption occur in phases opposite to those of protein adsorption and desorption. This unique behaviour allows for simultaneous concentration and desalination of the protein solution. Furthermore, we have successfully enriched β-lactoglobulin during the active desorption phase, which represents a significant step towards a separation system with high capacity and selectivity.
Looking ahead, we envision the potential of implementing stimuli-responsive polymers in the porous carbon structure to improve both the selectivity and reversibility of these electrically-driven separation systems. Stimuli-responsive polymers exhibit unique properties, such as the ability to reversibly alter their charge, conformation, and/or wettability in response to an external stimulus (e.g., an electric field). This capability provides greater control over the charge distribution and surface properties of the electrodes, and consequently allows tuning of the interaction forces with the proteins. Our research highlights that a comprehensive understanding of the surface properties and the underlying interaction forces is essential in selecting an appropriate responsive polymer coating for proteins or other target molecules.

The ultimate objective is to combine stimuli-responsive polymers with porous carbon structure, exploiting their respective strengths, to develop a separation system characterized by a high adsorption capacity, reversibility, and selectivity. While the focus of the current system is on the food industry, its potential applications extend to other industries, including biotechnology, wastewater treatment and the biomedical industry.

Ion-Conductive Properties of Polymeric Ionic Liquid-Coated Core-Shell Nanoparticles for Anhydrous Proton Exchange Membrane KeisukeTabata, TsutomuMakino and AkitoMasuhara; Yamagata University, Japan

Polymer electrolyte fuel cells (PEFC) have attracted attention as next-generation energy sources for vehicles and distributed power sources. The operating environment of PEFC is expected to expand from the current low-temperature range (< 90ºC and high-humidified environment) to the high-temperature range (> 100ºC and low-humidified environment). Especially, the high-

temperature range operating PEFC are classified as HT-PEFC. However, conventional perfluorosulfonic acid electrolytes, such as Nafion, are unsuitable for HT-PEFC because the proton-conduction mechanism is dependent on hydrogen bonding between water molecules. Thus, there is an urgent need to develop proton exchange membranes suitable for HT-PEFC that conduct protons in high-temperature and low-humidity environments. In a previous study, it was discovered that high proton conductivity can be achieved by constructing nanosized proton-conductive channels and using ionic liquids as proton-conducting materials. However, a facile method for fabricating proton exchange membranes with no anisotropy in the direction of proton conduction has not yet been developed.
In this paper, we have proposed a procedure for constructing isotropic three-dimensional (3D) controlled ion-conductive channels employing polymeric ionic liquid (PIL)-coated core-shell nanoparticles. A PIL is an ion-conducting material containing an ionic liquid with a repeating polymer structure. In this system, we employed SiO_2 (silica) nanoparticles as the core nanoparticles and poly(1-vinylimidazole)/bis(trifluoromethanesulfonyl)imide (P1VIm/TFSI) as the PIL. The PIL-coated nanoparticles were then assembled, resulting in the 3D ion-conductive channels have been constructed by the contact of the PIL layers on the surface of the nanoparticles between adjacent particles. The PIL-coated nanoparticles were prepared using a unique precipitation polymerization technique applying precipitation polymerization.
The progress of the PIL coating onto the surface of the silica nanoparticles was determined using SEM-EDS mapping analysis. We have observed sulfur and fluorine elements originating from TFSI anion from the same position as silicon elements derived from silica nanoparticles, indicating that the PIL was successfully coated onto the surface of silica nanoparticles. The ionic conductivity of the PIL-coated nanoparticles was measured in a pelletized state prepared by simply pressing the nanoparticles. The pelletized PIL-coated nanoparticles exhibited ionic conductivity even under high-temperature and anhydrous conditions, with a maximum conductivity of approximately 10^{-4} S cm^{-1} (160ºC). Subsequently, to evaluate the construction of 3D ion-conductive channels, we have measured the anisotropy of the ionic conductivity of the pellets. Notably, there was no anisotropy in the ionic conductivity, and both vertical and horizontal directions achieved similar ionic conductivities. Furthermore, the ion-conduction mechanism was clarified by using variable-temperature ^{1}H solid-state MAS NMR spectroscopy. The imidazole N-H resonances in the PIL structure were observed at 9–12 ppm assigned to “mobile” protons which is contributing to the proton conduction. As this phenomenon was not observed with the PIL homopolymer, we have concluded that the coating of PIL onto the surface of the silica nanoparticles and the accumulation of PIL-coated nanoparticles increased the number of mobile protons.
In conclusion, we have achieved the facile construction of 3D ion-conductive channels by the accumulation of PIL-coated core-shell nanoparticles. Moreover, the ion-conduction mechanism was discussed using solid-state NMR spectroscopy, and the fabricated PIL-coated nanoparticles contained mobile protons. Thus, the PIL-coated core-shell nanoparticles and their assembly process are effective for developing a proton exchange membrane for HT-PEFC.

11:15 AM EN08.06.07
Exceptional Long-Term Stability of Titanium Oxynitride Nanoparticles as Non-Carbon-Based Electrodes for Aerated Saline Water Capacitive Deionization NagehK. Allam; American University in Cairo, Egypt

Carbon-based capacitive deionization (CDI) electrodes suffer from long-lasting stability challenges due to sets of parasitic side reactions, including the high oxidation rate of the electrodes during the desalination process. Consequently, it is essential to identify, design, and fabricate novel electrodes that overcome such challenges to achieve robust and high desalination performance. This work reports on the fabrication and utilization of titanium oxynitride ($Ti_xO_yN_z$) nanoparticles as stable non-carbon electrodes for capacitive deionization. The oxynitride nanoparticles were synthesized via a simple template-free approach and fully characterized using XRD, XPS, Raman, SEM, and BET techniques. Moreover, the fabricated electrodes were electrochemically evaluated via cyclic voltammetry (CV), galvanostatic charge-discharge (GCD), and electrochemical impedance spectroscopy (EIS) techniques. The electrode exhibited a pseudocapacitance behavior with a specific capacitance of 150 F/g. A symmetric configuration CDI setup was constructed, enabling the investigation of the effect of different flow rates and voltages. Remarkably, the $Ti_xO_yN_z$ CDI cell revealed a salt adsorption capacity (SAC) of up to 56.6 mg/g with fast adsorption kinetics. Moreover, the electrodes retained ~100% of its initial SAC even after 1960 cycles over 110 days of continuous testing. Furthermore, several post- characterization techniques such as XPS, XRD, FTIR, and potential of zero charge have been deeply studied and analyzed to unravel the observed exceptional stability of the tested electrodes.

11:30 AM EN08.06.08
Promoting the Selective Intercalation of Lithium in the Olivine $FePO_4$ Host GangbinYan and ChongLiu; University of Chicago, United States

The lithium supply challenge predominantly stems from the limitations of existing mining techniques in accessing lithium sources with intricate chemistry and low concentrations. Electrochemical intercalation presents an avenue for extracting lithium from diluted water sources. However, during the extraction process, the co-intercalation of lithium and its primary competitor, sodium ions, occurs. The comprehensive understanding of how host materials respond to this co-intercalation process remains an ongoing pursuit. Moreover, despite the well-acknowledged potential for lithium extraction, the reported selectivity for lithium can exhibit considerable disparity. This discrepancy in selectivity, as observed with olivine-type $FePO_4$, can span nearly three orders of magnitude, potentially arising from the diverse particle forms adopted (e.g., sizes, morphology, dominant facets, etc.).

In this talk, using one-dimensional (1D) olivine iron phosphate ($FePO_4$) as a model host, I will first introduce the co-intercalation behavior of lithium and sodium ions and the control of lithium selectivity through intercalation kinetic manipulations. By combining computational and experimental investigations, we noticed that lithium- and sodium-rich phases tend to separate in the host. Exploiting this mechanism, I will discuss how the sodium-ion intercalation energy barrier can be increased using partially filled 1D lithium channels, generated via non-equilibrium solid-solution lithium seeding or remnant lithium in the solid solution phases. Furthermore, the lithium selectivity enhancement during co-intercalation shows a strong correlation with the fractions of solid-solution phases with high lithium content (i.e., Li_xFePO_4 with $0.5 \leq x < 1$). Finally, I will delve into the impact of different structural forms of the host material. Specifically, I will discuss how these structural variations can influence particle kinetics and chemo-mechanical responses during Li/Na intercalation, ultimately affecting the preference for lithium.

Recycling and Upcycling of Spent Battery Materials via Molten-Salt Technologies TaoWang[1], HuiminLuo[1] and ShengDai[1,2]; [1]Oak Ridge National Laboratory, United States; [2]University of Tennessee, United States

The recycling and upcycling of end-of-life lithium-ion batteries (LIBs) has become an urgent and challenging issue with the surging use of LIBs, in which recovering high-value cathodes not only relieves the pressure on the raw material supply chain but also minimizes negative environmental impact. Beyond direct recycling of spent cathodes to their pristine states, the direct upcycling of spent cathodes to the next-generation cathodes is of great significance to maximize the value of spent materials and to sustain the fast development of LIBs. A novel molten-salt system was developed to directly upcycle spent NMC 111 to Ni-rich NMCs by simultaneously realizing the addition of Ni and the relithiation of Li in spent NMC 111. Our prior and present research activities through molten-salt techniques in this area will be summarized in this presentation. Quantitative, fundamental understanding of the mechanisms of solvent tunability, the factors limiting control over solvent flux properties, the forces driving chemical reactions, and modes of controlling redox reactions will be discussed.

11:00 AM *EN09.01.02
Lithium-Ion Battery Recycling: Options, Environmental Impacts and Economics RebeccaCiez; Purdue University, United States

Demand for transportation and electricity grid energy storage will require gigawatt hours of lithium-ion batteries to power these systems. Recycling battery materials can assist in meeting the material demands for these systems and for reducing environmental impacts. This talk will discuss the economic and environmental costs associated with producing and recycling lithium-ion batteries using different recycling pathways. Process-based cost models provide context for the costs of manufacturing battery materials from new materials, and the potential for profitability from recycling. Finally, this talk will discuss the state of battery recycling given recent advances in the industrial policy to support the development of local battery material supply chains.

11:30 AM EN09.01.03
Towards Sustainable Polymer Solid-State Batteries: A Mechanical-Hydrometallurgical Case Study KirstinSchneider[1,2], MarcoAhuis[3,2], PeterMichalowski[3,2], DanielGoldmann[1,2], ArnoKwade[3,2] and BengiYagmurlu[1,2]; [1]Technische Universität Clausthal, Germany; [2]Battery LabFactory Braunschweig, Germany; [3]TU Braunschweig, Germany

Lithium-ion batteries have become indispensable in various sectors for electrochemical energy storage. The rising demand for enhanced battery performance triggers the development of new technologies, such as solid-state batteries (SSBs). Featuring a solid electrolyte instead of a liquid one, SSBs hold great promise for next-generation energy storage. To promote battery circularity throughout the entire life cycle, it is essential to develop recycling concepts for next-generation SSBs even before their market introduction. However, literature currently lacks comprehensive studies on SSB recycling. Among the options for solid electrolytes, polymers stand out due to their potential for scalable production. With the use of new materials in polymer SSBs, there is an immediate need to assess their recyclability.
This study aims to explore mechanical-hydrometallurgical recycling routes for polymer SSBs, aiming to develop a holistic recycling concept. For this investigation, polymer SSB pouch cells, consisting of a polyethylene oxide/lithium bis(trifluoromethanesulfonyl)imide (LiTFSI) solid electrolyte, a lithium iron phosphate (LFP) cathode composite, and a Li metal anode, were utilized.
In the mechanical processing phase, we extensively explored the shredding properties of polymer SSB cells, with special attention to the critical safety considerations arising from the presence of Li metal. Based on the intrinsic properties of the materials used in polymer SSBs, an optimum shredding process has been identified to prepare the shredded material for subsequent hydrometallurgical processing. Ensuring the homogeneity of the crushed material and employing gentle disintegration techniques are crucial to avoid cross-contamination during further stages. Subsequently, in the hydrometallurgical processing step, we examined different leaching strategies for the shredded cells to extract valuable metals into the solution. Ultimately, we evaluated various precipitation strategies for impurity removal and Li recovery.
The obtained results provide valuable insights into the development of efficient recycling processes for SSBs. This forward-looking approach contributes to the establishment of a robust recycling industry that anticipates the evolving material flows of future battery technologies.

11:45 AM EN09.01.04
Eco-Friendly Process for Recovery of (Co,Ni) and $LiCO_3$ from Spent Lithium Batteries ValeryKaplan, EllenWachtel and IgorLubomirsky; Weizmann Institute of Science, Israel

Although Li-ion batteries were initially developed as a power source for portable devices, incorporation of Li-batteries in vehicles and industrial power banks has led to an exponential growth in the demand for both lithium and cobalt. While lithium production is almost exclusively oriented towards batteries, cobalt is also an essential component of high-strength alloys and magnets, with demand for batteries beginning to compete with these traditional applications. Recovery of Li and Co from spent Li-ion batteries poses technical challenges. In addition to the fact that opening and crushing spent batteries may result in self-ignition, current technologies generally aim at Co extraction only. Many of these technologies require sequential treatment with acids and bases, producing toxic waste, or involve dumping of crushed batteries into Co-smelting ovens. In both cases, lithium ends up in compounds from which it cannot be readily recovered. We have developed an economical procedure that recovers Co and Ni as metals, or alloyed with copper, and Li as $LiCO_3$. This process is based on treating crushed, spent batteries with dilute (4vol%) natural gas for 60 minutes in a temperature controlled furnace at 673-1123K. Following sintering, Li_2CO_3 is leached from the clinker with ice water, leaving all other components for further recycling. 30 minutes smelting at 1773K of the remaining filter cake in air in a closed ceramic crucible, allows recovery of heavy, non-ferrous metals (Ni, Co, Cu and their alloys) as mm-size ingots (39% Co, 32.2% Ni, 26.3% Cu). Iron compounds, remanent Li, Al and unburnt graphite are removed as slag. Neither corrosive acids nor costly reagents are required and hazardous liquid waste is not generated. This method was successfully tested with batteries from consumer electronics and with batteries used in the automotive industry. Since the proposed process does not use or produce toxic substances, is able to provide high recovery yield for Li (>95%) and can be run with simple equipment, it may be considered as suitable for straightforward scaling-up and industrial implementation.

SESSION EN09.02: Lithium-Ion Battery Recycling and Reuse II

1:30 PM *EN09.02.01
Selective Electrodeposition for Lithium-Ion Battery Recycling—Tuning Interfacial Chemistry for Selective Cobalt and Nickel Recovery XiaoSu and KwiyongKim; University of Illinois Urbana-Champaign, United States

The recovery of transition metals from battery recycling streams is a critical challenge for materials circularity in the future, especially with the growing demand on battery-related critical elements. Electrochemical separation approaches have been gaining traction as a modular and electrified platform for ion-selective recovery. However, key transition metals in batteries such as cobalt and nickel often possess close reduction potentials in aqueous media, thus impeding selective recovery by electrodeposition. Here, we overcome this challenge by combining electrolyte design with interfacial control, to enhance the selectivity between cobalt and nickel. First, through highly concentrated chloride solutions, we can discriminate between the two metals by charge, and through the application of charged polyelectrolytes, we can further enhance separation factor during electrodeposition. We implement this strategy for the recovery of cobalt, nickel, and manganese from commercially-sourced lithium ion batteries, and demonstrate the recovery of high purity transition metals. Finally, we discuss parallel directions in developing continuous electrochemical approaches for the selective recovery of lithium. Overall, we believe that electrochemical separations can play an important role in enabling sustainable and energy-efficient battery recycling technologies.

2:00 PM *EN09.02.02
Li Recovery from Brines using Recyclable Intercalation-Based Redox Membranes BeniaminZahiri[1], JohnCook[2], HengYang[2], BadriShyam[2], PaulBraun[1], RodrigoRodriguez[2] and YunkyuChoi[1]; [1]University of Illinois at Urbana-Champaign, United States; [2]Xerion Advanced Battery Corp, United States

The accelerated push towards renewable energy is leading to an exponential consumption of battery materials. Today, the United States net import reliance on battery materials varies widely from 25 to 80% (USGS Reports). If nothing is done, this import reliance is only expected to grow as electric vehicle and energy grid storage demands surge. Therefore, securing novel, domestic sources of critical lithium-ion battery components is of paramount importance and necessary to shield the U.S. from future global trade volatility and unforeseeable supply chain disruptions. The United States currently sources all its domestically produced lithium from one mine in Nevada where lithium carbonate is produced from evaporation ponds. Geothermal

brines have been identified as a domestic lithium source candidate with the capacity to fulfill the entire Li consumption needs of the U.S., but this resource is currently unexploited. Isolating a pure Li product from these hot brines poses a major challenge due to their corrosivity, elevated temperatures, high levels of dissolved solids, and numerous cationic species.
To address this challenge, we use a novel redox membrane concept for Direct Lithium Extraction (DLE). Our team's proprietary molten salt platform is capable of manufacturing fully dense layered, spinel, and olivine transition metal oxide battery cathode materials. We demonstrate that dense cathode materials could function as membranes between the input (lithium brine source) and output (enriched lithium product) streams while permitting Li-flux via an electrochemically driven redox reaction. Unlike traditional membranes, which utilize concentration gradients to drive ion migration between solutions, an electrochemical driving force is envisioned to selectively mobilize lithium cations through a dense, electroplated transition metal oxide membrane. Extracted lithium will be directly converted to a highly valuable LiOH product. Transition metal oxides are ideal candidates for lithium brine extraction due to their capability to selectively uptake lithium ions, high degree of chemical stability at elevated temperatures, and high corrosion resistance. We show that such intercalation based membranes are highly selective for lithium ions over other competing ions such as sodium as well as multivalent cations including calcium and magnesium. Selectivity factors of over 100 has been achieved in our benchtop testing. Continuous operation of this novel redox membrane concept in a flow cell format will also be presented. Combined electrochemical and characterization data confirm the applicability of such concept in several lithium brine streams from geothermal to salar brine compositions. Summary of techno-economics of Li extraction using these membranes, that are recyclable, will also be presented.

2:30 PM EN09.02.03
Alternative Process Chain via Selective Leaching, Flotation and Smelting for LIB Recycling MonikaKeutmann, DanielDotto Munchen and BerndFriedrich; IME RWTH Aachen, Germany

The increasing demand for batteries, particularly in the electric vehicle and renewable energy sectors, necessitates sustainable and efficient methods for battery recycling. This work presents a comprehensive proof of concept for a battery recycling process chain that employs selective leaching with an organic acid, flotation, and smelting to recover valuable metals. This process aims to extract lithium, graphite, cobalt-nickel alloy, and manganese from spent batteries.
Selective leaching with an organic acid was utilized as the initial step to extract lithium from black mass. This method ensures the targeted recovery of lithium without compromising the quality of other valuable components. The leaching process generated a lithium-rich solution, which underwent subsequent purification steps to obtain a high-purity lithium salt.
The flotation technique was employed to recover graphite, a critical component used in battery anodes. By selectively floating graphite particles, the process achieved efficient separation from other materials, enhancing the purity and recovery rate of graphite.
Following flotation, the remaining battery black mass was subjected to pyrometallurgy to recover cobalt, nickel, and manganese. Pyrometallurgy involves high-temperature processing, enabling the formation of a cobalt-nickel alloy, that can be further treated to produce precursor material for battery production. Manganese, on the other hand, was found in the slag produced during pyrometallurgical treatment.
The developed process chain for battery recycling offers multiple advantages. Firstly, selective leaching ensures the recovery of lithium, a crucial metal for modern batteries, with high purity and minimal waste generation. Secondly, flotation enables efficient graphite recovery, addressing the increasing demand for this material. Lastly, smelting yields a valuable cobalt-nickel alloy and manganese is found in the produced slag, potentially opening up possibilities for further recovery.
The proof of concept presented in this work demonstrates the feasibility of the proposed recycling process chain for batteries. By integrating selective leaching, flotation, and pyrometallurgical treatment, this approach provides a comprehensive solution for recovering key battery materials. The successful extraction of lithium, graphite, cobalt-nickel alloy, and identification of manganese in the slag highlights the potential for resource sustainability and circularity in the battery industry.

2:45 PM EN09.02.04
Exploring Limits of Scale: Hydrothermal Relithiation for Direct Recycling MauraAppleberry and ZhengChen; University of California, San Diego, United States

Direct recycling is a promising alternative for low-cost and more environmentally friendly disposal of lithium-ion batteries. Hydrothermal relithiation is a method of direct recycling that uses an aqueous lithium hydroxide solution to infuse lithium back into cathode black mass at high temperatures and pressures. Despite recent attention and study, the limits of scaling the hydrothermal process are not understood. Our work has built on previous advancements of optimizing hydrothermal parameters, and demonstrated that the amount of aqueous solution can be significantly limited to still recover spent cathode materials. Through a study of lithium diffusivity at various states of delithiation, it is shown that minimal excess lithium is necessary to relithiate various lithium nickel cobalt manganese oxide (NCM) cathode materials. The improved solution-to-black-mass ratio maintains high cycling performance, fully restoring to pristine electrochemical capacity, thus paving the way for at-scale rejuvenation.

3:30 PM *EN09.02.05
Life Cycle Assessment for Cathode Active Material Recycling Processes ZhengLiu, YumengLi and PingfengWang; University of Illinois Urbana-Champaign, United States

With the growing demand of lithium-ion batteries for electric vehicles, handling the wasted lithium-ion batteries has become an intractable problem. Lithium-ion battery recycling has become a critical topic because of the increasing cost of mineral materials, environmental issues, and regulatory requirements. The lithium-ion battery components are separated through a pretreatment process to recycle lithium-ion batteries effectively. Among different components, cathode active material is the most valuable component. Thus, it attracts researchers' attention. However, most researchers focused on finding the optimal condition of a certain hydrometallurgical recycling process for cathode active material, and very few research comprehensively compared different hydrometallurgical recycling processes. In this study, life cycle assessment is adopted as the indicator to evaluate the environmental concerns, which is a major reason for using and recycling lithium-ion batteries, of different recycling processes for three widely used cathode active materials: NMC, LFP, and LCO. Based on the ISO 14040 standard, the life cycle impact assessment uses the ReCiPe method with standardized processes and unified reactors. As a result, the most effective recycling processes for different cathode active materials have been found. Moreover, an ultimate comparison between different cathode active materials is conducted, considering specific capacity and lifespan.

4:00 PM EN09.02.06
Exfoliation of $LiCoO_2$ into Nanosheets for Cobalt-Ion Extraction and Cathode Recycling Hsin JueiWang and CandaceK. Chan; Arizona State University, United States

In recent years, methods for recycling Li-ion battery cathode materials such as lithium cobalt oxide ($LiCoO_2$, LCO) have attracted more and more attention. Since the cobalt in LCO is a limited resource, developing better ways to extract and recycle cobalt from the cathode materials becomes a critical issue. Traditional methods include pyrometallurgy and hydrometallurgy, which involve high temperatures and reaction of spent LCO with acid, respectively. Here, a new approach investigates cobalt extraction from nanosheets of LCO based on the rationale that cobalt extraction is more facile from high surface area LCO nanosheets compared to bulk LCO particles. To obtain LCO nanosheets, two exfoliation methods are used: 1) an oxidation-reduction assisted method, and 2) proton-exchange assisted method. Both approaches are aided by the intercalation of bulky ammonium cations into the interlayer space of the LCO structure, which facilitates exfoliation of LCO to form nanosheet suspensions in water upon sonication. The last step is to mix the nanosheet suspensions with cation solutions with the goal of achieving ion exchange and extraction of cobalt. The process is dependent on the pH of the solution and the choice of cation used to exchange for cobalt. This process is also demonstrated for other Co-containing cathodes such as $LiNiMnCoO_2$ (NMC) and $LiNiCoAlO_2$ (NCA). The effectiveness of cobalt extraction and ion-exchange are characterized using Raman and X-ray photoelectron spectroscopy, electron microscopy, and inductively coupled plasma spectroscopic analysis. Further research will focus on different kinds of ion exchange and the reassembly of nanosheet backs into functional cathode materials.

4:15 PM EN09.02.07
From Lab Scale to Upscale Lithium Recovery Through Neutral Leaching of Black Mass DanielDotto Munchen and BerndFriedrich; IME - RWTH Aachen, Germany

In the next ten years, it is expected that the electric vehicles market will grow at least 20 % each year. Therefore, the manufacturing and usage of batteries, mostly of Lithium ion batteries, will rise. To avoid shortages in supply, the recycling of end-of-life batteries is the key for a complete circular economy. However, the recovery of lithium from the active material—so called black mass (BM)—lacks in a consolidated recycling route, especially concerning industrial scale. In hydrometallurgical treatment, water leaching with CO2 injection was developed to recover Li in an early stage based on solubility, which is an easy and low cost operation. With that in mind, this work aims on upscaling neutral leaching of BM from lab scale in terms of Li recovery efficiency. Firstly, lab scale trials were performed in a 1.5 L reactor, CO2 bubbling of 6 L/min, 60 min of leaching time, constant stirring rate of 350 rpm, and particle size < 63 µm. The parameters that varied were temperature (20 °C and 80 °C) and solid/liquid ratio (10 g/L and 70 g/L). Based on these results, the upscaling leaching was performed in a 100 L reactor, but with an intermediate solid/liquid ratio of 30 g/L. The lab scale Li recovery efficiency achieved up to 80 % in the conditions of 10 g/L and 80 °C, however at 10 g/L and 20 °C the recovery efficiency was only 3 % lower. The compounds that are expected to be formed are Li2CO3 as well as LiHCO3, which are soluble in water under such conditions. In contract, when 70 g/L was tested, the results in both temperatures showed Li recovery efficiency of only around 50 % because the solubility limit is reached. In addition, in all scenarios, less than 1 mg/L of other metals was found in solution. Maintaining lower consumption of energy by using 20 °C in the upscale and a slight higher S/L ratio of 30 g/L to better simulate industrial conditions, the Li recovery efficiency showed nearly 65 %, which clearly indicates that S/L ratio is the key factor. In summary, an early stage Li recovery with water and CO2 injection in upscale presents low cost and has potential to be further enhanced. The Li2CO3 in solution can be precipitated through evaporation with low grade of impurities, which is beneficial for the refinement of the raw material

for new batteries. Moreover, the filter cake after leaching contains Ni, Co, Mn, and Al. which can be further treated in hydrometallurgy, or even pyrometallurgically as an alloy.

4:30 PM EN09.02.08
Direct LiOH Production from Battery Cathode Leachate with Nanofiltration and Bipolar Membrane Electrodialysis TrentLee, LucyA. Kanias, Zi HaoFoo and JohnH. Lienhard; Massachusetts Institute of Technology, United States

With a growing global interest in environmental protection, the importance of lithium-ion batteries (LIBs) is rapidly increasing. As a result of their quick charging, longevity, and high power density, LIBs are the leading choice in powering portable devices like smartphones, laptops, and electric vehicles. Unfortunately, domestic supplies of lithium, cobalt and manganese are limited, and current extraction methods are energy-intensive and generate large volumes of chemical waste. Lithium can be secured from primary sources, such as solid ore mining—an environmentally harmful process—or from brine evaporation, which is a very time intensive procedure.
The supply of lithium, cobalt, and manganese can also be augmented through secondary sources, namely by recycling spent cathodes from LIBs. Battery recycling is the process by which valuable metals are recovered from spent LIBs to manufacture pristine LIBs. Lithium, cobalt, and manganese make up the cathode layer of the majority of LIBs. The prominent cathode chemical composition includes: $LiCoO_2$ (LCO), $LiMn_2O_4$ (LMO), and $LiNi_{0.33}Mn_{0.33}Co_{0.33}O_2$(NMC). Inorganic acid leaching—the process of soaking used batteries in inorganic acids like sulfuric acid and hydrochloric acid—is a highly effective method of recovering lithium, cobalt, and manganese from the spent cathodes. In this process, a highly concentrated acid leachate that comprises Li^+, Mn^{2+} and Co^{2+} is produced, and electrochemical reactions are commonly leveraged to reduce the metal ions into their respective solid forms.
In this work, we investigate membrane processes for direct LiOH production from battery cathode leachates. First, the battery leachate is pressurized and passed into a Donnan-enhanced nanofiltration process. Conventional polyamide nanofiltration (NF) membranes possess negative volumetric charge densities as a result of the high concentration of carboxyl moieties, leading to poor monovalent selectivity for cations. To enhance cation separations from battery leachates, a highly crosslinked layer of polyethyleneimine (PEI) is covalently bonded with the polyamide substrate through a condensation reaction between the perfluorosulfonic acid and amine moieties. The composite NF membrane acquires a positive zeta potential and exhibits passive selectivity for monovalent cations from the enhanced Donnan exclusion effect. Our preliminary results indicate that the Mn^{2+} and Co^{2+} rejections increase from 65% to 99%, between the experiments involving the pristine and composite NF membranes. Conversely, the Li^+ rejection only increased incrementally from 5% to 13%, and the Li product stream has purity rating of at least 98%.
Second, the Li-rich permeate stream from NF is used as the input to a bipolar membrane electrodialysis (BMED) process. In BMED, a bipolar ion exchange membrane facilitates water dissociation, while the inherent cation and anion exchange membranes inhibit co-ion transport. As a consequence, BMED produces a basic LiOH, an acidic HCl and a desalinated stream. Here, we leverage high current densities to promote efficient water dissociation, enabling highly concentrated (1M or greater) HCl and LiOH streams to be produced from the NF permeate. The HCl can be recycled for acid leaching of battery cathodes, reducing acid consumption and chemical waste generation while promoting a closed atom economy. The concentrated LiOH can be used as a feedstock for direct battery manufacturing.

4:45 PM EN09.02.09
Investigating the Greenhouse Gas Emissions of the Global Lithium Supply Chain for Batteries SiddharthShukla, MatthewRiddle and JarodKelly; Argonne National Laboratory, United States

The global demand for battery materials like lithium is increasing due to increased demand for battery-electric vehicles. Lithium is economically extracted from brine and spodumene ore resources, while clay resources are also gaining interest. These resources are diffusely spread across the globe. The greenhouse gas emissions of extracting lithium from these sources vary considerably due to the required processing energy and material inputs to the systems, along with the needs associated with the desired final products, namely lithium carbonate and lithium hydroxide. Also, different extraction and processing stages may occur in different countries leading to variability in grid electricity emissions and additional transportation emissions. Therefore, an accurate representation of the total greenhouse gas emissions from the global lithium supply chain is difficult to estimate. To fill this gap, the current work uses a novel framework to calculate the emissions from each step of the global lithium supply chain, accounting for the variability in lithium sourcing, additional material requirements, and processing locations. Further, the change in emissions due to possible supply disruptions is also investigated utilizing agent-based modeling of supply-demand flows. Overall, the results from this work can help identify carbon-intensive pathways in the global lithium supply chain and highlight pathways that lead to reduced emissions.

SESSION EN09.03: Poster Session: Lithium-Ion Battery Recycling and Reuse
Session Chairs: Kelsey Hatzell and Marta Hatzell

Electrochemical Properties of Recycled Battery Materials JianPeng[1], NeerajSharma[1] and StefanieMaslek[2]; [1]UNSW, Australia; [2]Mint Innovation, New Zealand

Owing to its high energy density and long cycle life, Lithium-ion batteries (LIBs) have been world-widely used for portable devices and electric vehicles in the past decade.[1] Typically, a LIB consists of cathode, anode, electrolyte, separator and sealing components. The graphite and $LiCoO_2$ (LCO) have been regarded as dominant materials for anode and cathode in commercial LIBs respectively, due to their cycling stability and relatively high energy density. The graphite anode is able to deliver a relatively high reversible capacity of approximately 370 mAh/g, while LCO exhibits a moderate capacity of about 140 mAh/g under the cutoff voltage of 4.2V.[2]

However, all batteries have a finite lifespan. According to the report, the waste of spent portable LIBs will reach 180,000 tons/annum by 2023, but less than 1% Li-containing waste can be well recycled globally.[3] This imbalance of battery waste and recycling/reused battery materials leads to plenty of research on how to effectively recycle transition metals (*e.g.*, Fe, Co, Ni, and Mn) and graphite from spent electrodes. In our study, we systematically investigated the electrochemical properties of recycled graphite powder as well as the LCO synthesized by recycled Co precursors. The capacity of recycled graphite can achieve 350.1 mAh/g at the current of 20 mA/g and capacity retention of 75.5% after 100 cycles. On the other hand, LCO powders synthesized by different Co precursors exhibit various electrochemical performance. The LCO synthesized by recycled $CoCO_3$ presents a capacity of 132.6 mAh/g at the first cycle but delivers the similar capacity after 100 cycles compared to that of commercial LCO powder. However, the LCO synthesized by recycled $Co(OH)_2$ only shows the capacity of about 120 mAh/g at the initial cycle.

In order to improve the electrochemical properties of recycled graphite, we have employed ball milling for 3h and 30h respectively to modify its particle size and surface morphology. Both Raman and scanning electron microscope (SEM) patterns indicates that ball milling successfully minimizes the number of defects in graphite particles, while surface area of particles enlarges with ball mill time. After 3h ball mill, these structural changes of graphite noticeably elevated the discharge capacity by 27% at the first cycle and 18.4% retention after 100 cycles. Whereas, regarding to 30h ball milled graphite a serious reaction between graphite and glass fibre separator was observed by SEM after 100 cycles, leading to a rapid capacity fading. It is unexpected that high surface area of graphite may cause the decomposition of glass fibre separator during cycling, which possibly induces safety issues of batteries. The electrochemical properties of ball milled graphite in full cells also implies that ball milling leads to unstable solid electrolyte interphase (SEI) on the graphite surface. Applying commercial LCO as the cathode, ball milled graphite presents a significant capacity fading with cycle number, with capacity decreases of 8.2% and 24.8% after 20 cycles for 3h ball milled and 30h ball milled graphite, respectively.

This work evaluated the electrochemical performance of recycled graphite and LCO synthesized by recycled Co precursors. The effect of ball mill on the electrochemical performance of recycled graphite has also been measured.

Design of a Hydrometallurgical Recycling Process for Polymer Solid-State Batteries using the Example of LFP Cathode Composite KirstinSchneider, DanielGoldmann and BengiYagmurlu; Technische Universität Clausthal, Germany

New battery technologies are constantly under research to meet the ever-increasing demands of electromobility imposed on lithium-ion batteries (LIBs). Solid-state batteries (SSBs) are

emerging as one of the promising next-generation battery technologies, offering higher energy density and improved safety compared to conventional LIBs. Naturally, SSBs have distinct differences than conventional liquid electrolyte LIBs, and therefore, it is crucial to design, adapt and uncover possible recycling routes since the development of SSBs is accelerating. This study investigates the hydrometallurgical recycling of LFP (lithium iron phosphate) in a polyethylene oxide (PEO) composite structure used in the cathode of polymer SSBs.
In this case study, we present a comprehensive analysis on the leaching of LFP cathode composite using sulfuric acid followed by an exploration of possible Fe and Li recovery routes. An important aspect of this investigation is to assess the impact of the PEO matrix on the hydrometallurgical process. To achieve this, a comprehensive characterization of the sample was conducted, including the determination of the particle size distribution, chemical composition, and molecular weight of the virgin polymer. Various process parameters are investigated in detail for the optimization of the recycling process.
The study findings showed that LFP was leached even with under stoichiometric addition of sulfuric acid at 25 °C within a short duration of 60 minutes. Notably, the water-soluble PEO predominantly influenced the storage stability of the leach solution. Moreover, strategies for iron removal and lithium recovery are also tested and proposed for a comprehensive design of the recycling process. The outcome of this case study offers valuable insights into the hydrometallurgical processing of LFP composites, particularly in the context of the recycling processes for next-generation SSBs. By understanding the leaching mechanism and the impact of the PEO matrix on the hydrometallurgical process, recycling processes can be strategically adapted to future material flows, thereby contributing to the advancement of the circular economy of batteries.

8:00 PM EN09.03.03
Analysis of R&D Investment and Performance Evaluation for Goverment-Funded R&D Programs in the Field of Lithium-Ion Batteries DongyoungKim, SeinKwon, JunhwanLee, SangwooLim and YeojinJeong; Korea Institute of S&T Evaluation and Planning, Korea (the Republic of)

This study aims to overview the current status of government-funded R&D programs in the field of lithium-ion batteries, analyze the evaluation indicators, suggest future directions for designing new research programs, and provide a guide for selecting indicators to study the feasibility and performance of the programs.
As of 2022, there are seven government R&D programs in the field of lithium-ion batteries, organized by the Ministry of Trade, Industry, and Energy. These programs, of which budget amount to 26.815 billion KRW(20.5 million USD), include studies on improving the performance of lithium-based rechargeable batteries, to enhance the reliability of rechargeable batteries through evaluation infrastructure, developing ESS technology using battery packs used in electric vehicles/ESS, and developing a battery-sharing platform for electric vehicles (EVs).
The performance evaluation indicators for the outcomes of these programs include indicators related to battery performance, patent, paper, revenue, technology standardization proposals, equipment establishment and operation rates, and conducting user satisfaction surveys.
Although the programs for analysis were selected based on specific criteria, the ratio for the field of rechargeable batteries seems to be relatively low compared to the Korean government's R&D budget of 29.8 trillion KRW(20.5 million USD). Basic research projects for battery material development were excluded, and further discussions are needed on the overall support scale and the direction of support in the field of lithium-ion batteries, both in terms of government support R&D and private sector R&D. Additionally, to improve the performance of R&D in the field of lithium-ion batteries, it is necessary to discuss the exploration of various evaluation indicators and data accumulation for performance evaluation, aiming to enhance R&D performances in the field of lithium-ion batteries.

8:00 PM EN09.03.04
Graphene Oxide (GO) as Chemical Anchor of Polysulfides for Li-S Batteries BalramTripathi[1,2], ClaudiaZuluaga Gomez[1], IvanCastillo[1], SunnyChoudhary[1], MohanBhattarai[1], RajeshKatiyar[1], GerardoMorell[1] and RamKatiyar[1]; [1]University of Puerto Rico, United States; [2]S S Jain Subodh PG College Jaipur, India

Lithium-sulfur (Li-S) battery is one of the most promising candidate for the next-generation rechargeable cell. In order to control the shuttle effect of dissolution lithium polysulfides (LIPSs), the chemical interactions between sulfur host and LIPSs on the performance of Li-S batteries has recently been highlighted. Herein, a facile strategy is proposed, which produces graphene oxide (GO) as an anchor to restrain LIPSs in Li-S batteries via chemical confinement by strong bonding interaction between GO and Li_2S_6. X-ray diffraction (XRD), Raman analysis & Scanning electron microscopy (SEM) of prepared composite material was done to study structural and morphological properties. Electrochemical performance of GO-S composite cathodes using LiTFSI electrolyte was studied by galvanostatic charge-discharge at various c-rates as well as via cyclic voltammetry & EIS measurements. The detailed results of the study will be discussed during the presentation of meeting.

8:00 PM EN09.03.05
Efficient Separation of Cathode Materials in Direct Recycling of Spent Lithium Ion Batteries Kwang BumKim and HunseokChoi; Yonsei University, Korea (the Republic of)

There is a growing demand of lithium ion batteries in consumer electronics, electric vehicles, and energy storage systems, which would eventually generate a huge number of spent lithium ion batteries. Spent lithium ion batteries should not be treated as waste but be considereded as a valuable resource rich in critical materials such as Co, Ni, Li and Cu. Recently, direct recycling process is being actively investigated to retrieve high value cathode materials which retains the original structure and morphology without chemical decompostion to metallic elements or metal ions. A major challenge for direct recycling is to efficiently separate cathode materials from aluminum foil because of the high adhesive bonding strength and chemical stability of polyvinylidene difluoride (PVDF) binder used in the production of lithium-ion batteries. In this regard, environmentally sustainable delamination process needs to be developed to efficiently recover cathode materials from cathodes. However, current procedures reportedly used toxic organic solvents to separate the active cathode materials from the aluminum foil. In this study, we report on the direct recycling of NCM cathode materials from spent lithium ion batteries, important delamination parameters and materials properties of delaminated NCM. More details will be discussed at the meeting.

8:00 PM EN09.03.06
Spent Cathode Materials Upgrading by Forming Nano-Coatings LanceYang[1,2], ZhiqianWang[1], JaredLiao[1], JerryXiang[1], JarettHoelzle[1] and BruceKoel[2]; [1]Princeton NuEnergy, United States; [2]Princeton University, United States

Lithium-ion batteries (LIBs) have emerged as the battery of choice for rapidly growing markets in electric vehicles (EVs) and grid electricity storage. This spurs a great demand for lithium, graphite, cobalt, and nickel that could outstrip the supply of virgin materials. Thus, there is an enormous interest in the development of new sustainable technologies for recycling and recovery of valuable materials from secondary resources, especially from used lithium-ion batteries. Compared to conventional high-temperature pyrometallurgical or hydrometallurgical methods, direct recycling of LIBs is a more desirable approach because it can directly regenerate the cathode materials by relithiation without destroying the LIB compounds. Additionally, direct recycling is a comparatively low-cost and less resource-intensive method of recovering LIB materials.
However, completely regenerating the full capacity and long-term performance of the original materials is still particularly challenging. For instance, cathode materials are often coated with a nanometer-thick protecting layer that is engineered to reduce the degrading effect on the cathode from direct contact with the electrolyte. Long-term charge-discharge cycling causes damage to this coating layer, and thus it needs to be repaired in order to recover the material performance. To address this challenge, we have developed a novel process that can regenerate and upgrade cathode materials from aged LIBs, as well as create a new coating layer to improve the performance of the cathode materials. In this presentation, we will provide a case study of the performance improvement of recycled lithium cobalt oxide (LCO) materials by forming an alumina coating layer on the surface. By controlling the thickness and sintering temperature, this surface alumina coating can be an effective way to improve the stability and cyclability of recycled LCO cathode materials.

8:00 PM EN09.03.07
Recycling and Upcycling Graphite Anode Materials YiPeng, MargaretWu, JaredLiao, TylerMcGivern-Jimenez, ZhiqianWang and LanceYang; Princeton NuEnergy, United States

Lithium-ion batteries (LIBs) have emerged as the battery of choice for rapidly growing markets in electric vehicles (EVs) and energy storage devices. Thus, there is an enormous interest in the development of new technologies for recycling and recovery of valuable materials from secondary resources, such as those from used LIBs. Finding ways to decrease the cost of recycling could thus significantly reduce the life cycle cost of LIBs, avoid material shortages, lessen the environmental impact of new material production, and provide low-cost active materials for new LIB manufacturing. In recent years, the recycling of spent LIBs has mainly been focused on the recycling of the cathode, while recycling of the graphite anode has only received limited attention due to its low value and complex recycling process. However, with the recent shortage of resources and the increase in production costs, recycling of graphite anode from spent batteries can no longer be ignored. There are several challenges associated with recovering spent graphite anodes – mainly, there are a variety of metal impurities in addition to surface solid electrolyte interface (SEI) and interior impurities which need to be removed. Conventional recycling methods are unable to solve this issue, especially in the purification process. Most current recycling systems use pyrometallurgical and/or hydrometallurgical methods, which necessitate multi-unit operation, high energy consumption, and high cost. Direct recycling, on the other hand, is a promising solution for overcoming the hurdles involved with recovering spent graphite anodes.
Princeton NuEnergy (PNE) has successfully developed a novel low-temperature plasma process to enable purification and direct repair of graphite anode materials from spent LIBs. We also demonstrated a simple but effective approach to upgrade the spent graphite to produce graphite-silicon composite with improved energy density. Spent graphite is an ideal choice for low-cost production of high-performance silicon-graphite composites because treated spent graphite presents a porous structure which can be well combined with silicon and effectively relieve volume expansion. The recycled graphite and upcycled graphite-silicon composite anode materials outperform the commercially available equivalent. The direct recycling/upcycling of graphite anode materials will increase the commercial viability of LIBs and reduce battery cost, thus accelerating the electrification of transportation and large-scale energy storage for renewable energy in the near future. In this presentation, the materials characterization and electrochemical performance of recycled/upcycled anode materials will be discussed.

8:00 PM EN09.03.08
Direct Recycling of NCM Cathode Materials from Spent EV Batteries JaredLiao[1], ChristopherBrooks[2], LyndonHuang[1], ZhiqianWang[1] and LanceYang[1]; [1]Princeton NuEnergy, United States; [2]Honda Research Institute USA, Inc., United States

Lithium-ion batteries (LIBs) have emerged as the battery of choice for rapidly growing markets in electric vehicles (EVs) and grid electricity storage. This spurs a great demand for lithium, cobalt, and nickel that could outstrip the supply of virgin materials. Thus, there is an enormous interest in the development of new technologies for recycling and recovery of valuable materials from secondary resources, especially those from used LIBs. Compared to conventional high temperature pyrometallurgical or strong acid hydrometallurgical methods, the direct recycling of LIBs shows great promise. Direct recycling regenerates the cathode materials without destroying the underlying compounds, while significantly reducing energy and chemical consumption.
Our low-temperature plasma-assisted separation (LPAS™) process has major reductions of adverse environmental impacts from mining/brine extractions of virgin metals, raw material transportation, and energy consumption. Direct regeneration of cathode materials using the this technology is far less costly and disruptive than virgin production. Cathode materials account for over 50% of typical LIB material value. As a result, recycling cathode materials is especially important for reducing battery costs. PNE's technology has proven versatile – capable of recycling and regeneration of a variety of cathode materials. In this presentation, we will present one typical case to demonstrate the successful regeneration of NCM cathode materials from spent EV batteries via our LPAS based direct recycling process.

8:00 PM EN09.03.09
Recycling of Solid-State Batteries - Influence of Different Solid Electrolytes on Mechanical Recycling Behaviour MarcoAhuis[1,2], PeterMichalowski[1,2] and ArnoKwade[1,2]; [1]TU Braunschweig, Germany; [2]Battery LabFactory Braunschweig, Germany

The growing use of lithium-ion batteries (LIBs) is leading to an increasing demand for raw materials, which may lead to raw material shortages and rising material costs in the future. In this context, solid-state batteries (SSBs) are promising next-generation batteries in which the liquid electrolyte of conventional LIBs is replaced by a solid-state electrolyte, offering advantages such as increased lifetime, energy density, and safety. To successfully establish the different SSB systems (e.g. polymer, sulfide, oxide and halide) in the market, material cycles need to be identified and closed to achieve lifecycle sustainability.
In this context, recycling and reuse of materials are essential elements of a climate-neutral and resilient energy system. Compared to the recycling of conventional LIBs, no drying or thermal step is required to recover the liquid electrolyte as it has been replaced by a solid electrolyte. However, the different SSB systems have different characteristics in terms of comminution and classification behaviour, so different process chains need to be developed taking into account the technological, safety, economic, and environmental properties of the materials used. [1]
This study examines the influence of the different solid electrolyte systems on mechanical recycling, specifically focusing on the comminution and classification behaviour. The comminution of **polymer SSBs** produces a foil fraction that cannot be further separated and requires additional processing. One possibility is solvent-based processing to separate the cathode active material. **Oxide SSBs**, due to the intrinsic properties of the solid electrolyte, are well suited to mechanical separation, allowing for subsequent hydrometallurgical processing, regardless of the active material used. High yields of oxide material can be achieved here, especially after thermal pretreatment. Due to the formation of hydrogen sulfide upon contact with water, **sulfide SSBs** require a process route to stabilise or inactivate the electrolyte before mechanical treatment. Initial studies with sulfur-based materials show that they can be recovered (up to 75 wt.-% yield) in a dry atmosphere and fed directly back into the production process. In order to evaluate each process, basic characterisation of the materials or intermediate and final products was carried out using various analytical methods such as TGA, ICP-OES and SEM-EDX.
The results of this work will indicate possible process routes for the recycling of solid-state batteries, paving the way for the development of efficient recycling processes even before SSB technology is ramped up. This establishes the foundation for creating closed, robust material cycles towards a CO_2-neutral energy system.

8:00 PM EN09.03.10
Ba Doped $SrTiO_3$ Perovskite as Anode for Li-Ion Batteries IvanCastillo, BalramTripathi, JeanR. Del Valle, ValerioDorvilien, DaniloG. Barrionuevo Diestra, SunnyChoudhary, RajeshKatiyar, GerardoMorell and RamKatiyar; UPR-RP, United States

In this study we are reporting the electrochemical performance of $Ba_{0.9}Sr_{0.1}TiO_3$ (BST) having polarization of 14.58 $\mu C/cm^2$ as an anode for Li-ion batteries. Perovskite structure (ABO_3) anode materials have received much attention because of their mixed electronic and ionic conduction behaviors that make the triple-phase boundary (TPB) extend to the entirely exposed anode surface. Among the variety of these oxides, $SrTiO_3$-based perovskite compounds are promising Ni-free anode candidates due to their high chemical stability at high temperatures under both oxidizing and reducing atmospheres, and strong resistance to carbon deposition. X-ray diffraction spectra confirm tetragonal symmetry (c/a=1.0073), Raman spectroscopic study confirms Raman modes ($A_1(TO_1)$, $A_1(TO_2)$, $A_1(TO_3)$ and $A_1(LO_3)$) of the tetragonal orientation for BST. SEM images confirm homogeneous surface of BST having grain sizes (1-1.5 μm). The carbon black was used as the conductive additive PVDF as binder, $LiPF_6$ as an electrolyte for charge-discharge performance and contribution to the electrochemical properties of the cell in terms of lithium intercalation and de-intercalation. At slow discharge rate, a capacity of approximately 240 mAh g^{-1} achieved. It is found that Ba on $SrTiO_3$ surface helps to facilitate electron transfer thereby improving the capacity and rate performance of BST as Li-ion battery anode material. The detailed results will be presented during the meeting presentation.

8:00 PM EN09.03.11
Optimization of the Discharge Process of Spent Li-Ion Batteries from Electric Vehicles for Direct Recycling HyunseokLee; Korea Battery Industry Association, Korea (the Republic of)

Since introducing electric vehicles 10 years ago, the disposal of spent LIBs generated from EVs has rapidly increased. The two main approaches for processing spent LIBs for EVs are reuse and recycling. Many studies have shown that the battery healthcare system can effectively estimate the spent batteries state of health for reuse. However, the spent LIBs must ultimately be recycled at the end of the reuse. Since the rare metals in spent LIBs are precious because they have limited reserves, researchers are investigating a systematic and safe recycling system. So far, three types of recycling methods for spent LIBs have been considered—pyrometallurgy process, hydrometallurgy process, and direct recycling. The pyrometallurgy process is widely used for the commercial recovery of cobalt. However, it has the disadvantages of high carbon emissions and difficulty in recovering Li. The hydrometallurgy process would be an alternative since it can recover more Li and Mn than the pyrometallurgy process. However, the hydrometallurgy process generates large amounts of wastewater and contaminated acid fumes, which can severely pollute the environment. Thus, research on direct recycling is recently gaining attention. Discharging spent LIBs is an essential process for direct recycling for the spent LIBs. By immersing the LIBs in the ionically conducting salt water to form the short circuit, the electrochemical discharge of LIBs in a conducting solution is introduced. Li et al. analyzed the chemical components of wastewater from the salt-water discharge process. Owing to salt-water discharge, they detected "high" levels of aluminum and iron and "moderate" levels of cobalt, lithium, copper, calcium, and manganese. In addition, considerable amounts of zinc, barium, and vanadium were also detected. The high concentrations of P were also observed, indicating that the corrosion of the metal collectors and sealing compartments causes the leakage of a certain amount of the electrolyte (i.e., LiPF6). Thus, a suitable discharge technology must be developed because the damage to LIB by salt-water discharge causes additional costs and steps in the recycling process.
In this study, we recovered spent LIBs used in two EVs and observed the state of the modules and cells through electrical discharge. Additionally, we performed a comparative experiment with the salt-water discharge of pouch-type LIBs because pouch-type LIBs are primarily used in EVs. After the discharge of the spent LIBs to various voltages, the crystal structures of the cathode and anode were analyzed. We examined problems caused by over-discharge based on the state of health and determined the appropriate discharge voltage. Swelling due to over-discharge became more rapid as SoH decreased. Cell volume expansion caused by swelling increases the internal pressure of the cell packaged in the module, leading to a risk of explosion. Therefore, it is essential to discharge pouch cells to an appropriate voltage that can prevent the pouch swelling of LIBs. The results of this study indicate the proper voltage for electrical discharge, which is adjudged applicable for environmentally friendly recycling processes.
As a spent LIB with a state-of-health of 66.8% was over-discharged, swelling significantly increased. Even after being discharged to 0 V, the voltage could recover to 2.689 V. We analyzed the discharged spent LIBs through X-ray diffraction, scanning electron microscopy, and electrochemical impedance spectroscopy, and confirmed the appropriate voltage for the discharge process is estimated to be 2.5 V. The proposed electrical discharge process will be suitable for the direct recycling of spent LIBs in the form of pouch cells.

8:00 PM EN09.03.12
Li Storage Performance of $LiMn_{1/10}Ni_{8/10}Co_{1/10}O_2$ Cathode for Li-Ion Batteries ShwetaShweta, BalramTripathi, SunnyChoudhary, MohanBhattarai, SatyamKumar, RajeshKatiyar, GerardoMorell and RamKatiyar; University of Puerto Rico, Puerto Rico

In this study we are reporting the electrochemical performance of $LiMn_{1/10}Ni_{8/10}Co_{1/10}O_2$ composite as cathode for Li-ion batteries. Spinel layered heterostructure by encapsulating layered lithium rich material with nanospinel mixture $LiNi_xMn_{2-x}O_4$. Spinel layer coating has been employed to tune the electrochemical performance of the layered composite cathode. The spinel layer coating contributes fast lithium ion transport of Li rich cathode. It is found that spinel content largely enhances the specific capacity, cycling stability and rate capability of Li rich cathode. XRD, Raman and SEM techniques has been used for structural, electronic & surface morphology of the fabricated layered composite cathodes. The detailed results will be presented

during the meeting presentation.

8:00 PM EN09.03.13
Crosslinked Zwitterionic Amphiphilic Copolymeric Membranes for Ion Separations AshleighB. Herrera and AyseAsatekin; Tufts University, United States

Lithium has become crucial for addressing the energy needs of the future. Current methods of lithium extraction are laborious, expensive, and environmentally damaging. Membrane technology offers an energy-efficient, simplistic, and scalable method for extracting lithium from aqueous sources. There has been recent progress showing the potential of membranes for recovering valuable mineral resources such as lithium and precious metals from wastewater, but many current membranes do not adequately address the selectivity, reliability, and fouling resistance these separations require. Recent work in our group has shown that thin film composite membranes with cross-linked zwitterionic amphiphilic copolymeric (x-ZACs) selective layers exhibit excellent fouling resistance coupled with exceptional ion selectivity. This ion selectivity is both size and charged based, separating like-charged ions such as chloride and fluoride. These x-ZACs readily self-assemble to form a network of nanochannels lined by the zwitterionic group. These channels are ~1 nm in size where the size is related to the degree of crosslinking. Previous work has suggested the ion selectivity is associated with selective interactions between the zwitterions lining the x-ZAC channels and the ions passing through. This effect appears to also be influenced by the confinement of the ions into the ~1 nm self-assembled nanochannels. However, to date, only one x-ZAC chemistry has been studied for ion separations. Current work expands on these findings to synthesize x-ZAC membranes that focus on other zwitterionic repeat units. The goal is to create membranes with cation-cation selectivity to use in various separations including lithium recovery from brines and lithium-ion battery waste solutions and selective extraction of valuable metal ions from wastewater and mine drainage. To accomplish this, we have synthesized x-ZAC membranes with different zwitterionic chemistries and analyzed the selectivity between cations. Preliminary studies have shown some selectivity between La+ and Na+ salts for a specific zwitterion chemistry. This work suggests that similarly sized and charged ions can be separated with pressure-driven membranes utilizing well-selected x-ZAC chemistries and crosslink densities, enabling more energy-efficient recovery of metal resources, especially lithium.

8:00 PM EN09.03.14
Simplified Solvent Extraction Process for High-Purity Ni/Co Mixed Solution for Lithium–Ion Batteries GogwonChoe[1], Young-JinLim[1], YounghyunKim[1], Go-GiLee[2] and Yong-TaeKim[1]; [1]POSTECH, Korea (the Republic of); [2]RIST, Korea (the Republic of)

The demands for Ni-based raw materials increase as Ni–Co–Mn ternary cathode materials become the main axis of the battery industry. Conventional hydrometallurgical process to produce raw materials from Ni ore for battery application is as follows: (i) leaching of metal ions by acid, (ii) solvent extraction process to extract target metals, and (iii) crystallization process to produce final single-metal compound as powder products. The conventional solvent extraction process is a three-circuit process comprising impurity removal, Co extraction, and Ni extraction circuits. Unlike conventional process, in this work, we suggest a simplified two-circuit process to simultaneously extract Ni and Co to produce Ni/Co mixed solution for cathode material precursor production which can also be applied to hydrometallurgical battery recycling process. Accordingly, the efficiency of site utilization can be maximized by reducing the investment cost for the manufacturing process and downsizing mixer-settler facilities. Further, ecofriendly effects such as reducing the consumption of titrants and cutting down the process costs and wastewater discharge can be realized.

Analysis of The Supply Chain Structure, Competitiveness and Risk in The Field of Lithium-Ion Batteries and Future Directions of The Government's Strategic R&D Policy SeinKwon and DongyoungKim; Korea Institute of S&T Evaluation and Planning, Korea (the Republic of)

The main purpose of this study is to analyze the supply chain structure, competitiveness, and risk factors in the lithium-ion battery sector, and to provide future directions for the government's R&D policy response to internal and external strategic environmental changes.
Traditionally, Raw material procurement in the lithium-ion battery supply chain is influential as the four core materials account for 75% of the cost. Recently, the importance of the recycling process has become more prominent due to the rapid growth of the market and the rise in raw material prices with black swans factors in the global supply chain. In the supply sector, three East Asian countries such as Korea, Japan, and China are leading the market. In particular, China's market dominance is overwhelming in the raw material mining and procurement sector. Meanwhile, due to the U.S.-China supply chain conflict, China is expected to promote internalization of the supply chain based on technological competitiveness and strategic assetization of key minerals. Therefore, the global supply chain structure also implies the possibility of uncertain change.
According to the results of the supply chain competitiveness analysis of 6 major countries, Korea has a relative competitive edge in design and cell manufacturing. Particularly, manufacturing companies are forming the mainstay of the industry by actively participating in R&D, and since many firms in the material and equipment sectors are participating in the supply chain network, the completeness of the domestic supply chain is robust. In contrast, It has low competitiveness in the demand and procurement process. Notably, there is a very high dependence on certain countries for raw material supply and demand. The material sector's dependence on China is 63.7%, with some of the LCO, PP/PE, and NCM accounting for 100% of the dependence.
In 2022, there are 7 government R&D programs led by the Ministry of Trade, Industry and Energy related to lithium-ion batteries, accounting for 0.09% of the total budget of 29.8 trillion KRW (20.5 million USD) for the Korean government's R&D programs. Most R&D programs focus on investing infrastructure of large-scale facility and equipment, and improving performance and developing innovative manufacturing technologies. Furthermore, The government has selected secondary batteries as the 12 major national strategic technologies and is focusing on developing safety-enhancing technologies for the four core materials through a five-year short-term strategy.
Even though Korea has a competitive edge in the design and manufacturing sector, it is necessary to diversify its supply chain to cope with the dependence on raw materials procurement concentrated in certain countries. In this regard, specific strategies for eco-friendly supply chain processes such as building strategic recycling hubs are required. In addition, the recycling-related R&D budget and programs are very insufficient, so it is necessary to plan new R&D programs and projects and promote investment in this field. In particular, financial support for initial investment in waste battery reuse and recycling demonstration projects, a standard system for safety and performance verification, and a professional training policy should be prepared to enhance technological competitiveness.

SESSION EN09.04: Lithium-Ion Battery Recycling and Reuse III

Achieving Low-Temperature Hydrothermal Relithiation by Redox Mediation for Direct Recycling of Spent Lithium-Ion Battery Cathodes XiaoluYu and ZhengChen; University of California, San Diego, United States

Lithium-ion battery (LIB) recycling is an urgent need to address the massive generation of spent LIBs from portable devices and electrical vehicles. However, the large-scale recycling is hampered by economic and safety issues associated with today's recycling processes. Here, we demonstrate a safe and energy efficient direct regeneration process based on low-temperature hydrothermal relithiation (LTHR) at low pressure for spent $LiNi_xCo_yMn_zO_2$ ($0 < x,y,z < 1$, $x + y + z = 1$, or NCM) cathode materials. A low concentration of low-cost redox mediator is employed to improve the relithiation kinetics of spent NCM materials, enabling full relithiation temperature to be reduced from 220 degree Celsius to 100 degree Celsius or below. Correspondingly, the pressure incurred in the relithiation process can be reduced from ~25 bar to 1 bar, offering significantly improved operation safety. Specifically, three NCM materials, including chemically delithiated NCM111, cycled (degraded) NCM111, and cycled NCM622, were successfully regenerated with complete recovery of composition, crystal structure, and electrochemical performance, achieving the same effectiveness as that achieved at high temperature process. Meanwhile, the total energy consumption of spent cell recycling and the greenhouse gas emission is also reduced. This work provides a facile and scalable way to more sustainable LIB recycling with high economic return, high operation safety and low cost.

9:15 AM EN09.04.02
End-Of-Life Lithium-Ion Batteries—Recycling and Upcycling of Cathode Materials RosieMadge[1,2], AbbeyJarvis[1,2], LauraL. Driscoll[3], PaulA. Anderson[1,2] and PeterSlater[1,2]; [1]University of Birmingham, United Kingdom; [2]Faraday Insitution, United Kingdom; [3]UKBIC, United Kingdom

Worldwide there has been an increase in the use of electric vehicles which has led to a consequent increase in the number of end-of-life lithium-ion batteries (LIBs) that need to be recycled. Recycling is commonly performed using pyrometallurgical and/or hydrometallurgical processes. These methods focus on the recovery of high value metals, such as Ni and Co, from the batteries. Alternative methods are therefore required to ensure that the entire battery is recycled and that the critical materials contained within the batteries are utilized in a meaningful way.

This work investigates recycling cathode material from an end-of-life Gen 1 Nissan Leaf (2011 model, 40,000 miles) which contains a mixture of $LiMn_2O_4$ (LMO) and

$LiNi_{0.8}Co_{0.15}Al_{0.05}O_2$ (NCA). LMO is combined with NCA to provide good thermal stability along with high capacity and long lifetime.[1,2] The use of such a blended cathode mixture increases the complexity of recycling as there are more components within the cathode that must be considered during recycling processes. A method has been developed which can selectively leach LMO from the cathode material using organic acids.[3] The separated LMO and NCA can then be regenerated and reused in new LIBs.

However, LMO is no longer favoured commercially, therefore this work investigates upcycling it into higher value materials. LMO has been upcycled to form a range of cathode materials, such as $LiMn_{1.5}Ni_{0.5}O_4$ (LMNO) and $Li_4Mn_2O_5$, a cation disordered rocksalt. These upcycled cathodes have been shown to have a comparable electrochemical performance to cathodes synthesised using pristine starting materials. This therefore demonstrates that end-of-life cathode materials can be upcycled to form new higher value cathode materials.

9:30 AM EN09.04.03
Recycling Valuable Metals from All Species of Spent Lithium-Ion Batteries using Non-Organic Solvents System Tzu MingCheng, Zheng YuChen and Chih-huangLai; National Tsing Hua University, Taiwan

Lithium-ion batteries have become the mainstream energy storage material in various industries due to their high energy density, high operating voltage, wide temperature range, and long lifespan. In recent years, the electric vehicle industry has flourished in an effort to reduce environmental pollution. Lithium-ion batteries, with their aforementioned advantages, have replaced traditional nickel-hydrogen batteries as the dominant power source for electric vehicles. This surge in demand for lithium-ion batteries is expected to generate a significant amount of waste batteries. Improper handling of these discarded batteries can pose serious risks to the environment and human health. Moreover, lithium batteries contain valuable metals such as lithium, cobalt, nickel, and manganese, which are vital and strategic resources. Developing suitable technologies to recycle and reuse these waste lithium-ion batteries can not only reduce environmental pollution but also enhance control over critical valuable metal resources, particularly since these metals are not domestically available and currently rely on imports. Mastering recycling techniques offers the opportunity to treat a large quantity of waste batteries as a valuable mineral deposit through urban mining. Therefore, lithium-ion battery recycling is poised to become a highly promising and profitable industry.
With the objectives of low cost, continuous operation, and scalability, we have developed an efficient, non-organic solvent recycling process for all species of lithium-ion batteries. Initially, we simulated the recycling scenario using simulated materials. The target elements including iron, phosphorus, and lithium, can be easily separated using pH control and therefore precipitants. However, the separation of nickel, cobalt, and manganese, which are closely positioned in the periodic table with similar physical and chemical properties, presents challenges in non-organic solvents system. To overcome this, we identified two aqueous phase precipitants, $KMnO_4$ and NaClO, combining with pH control, successfully separate these three elements without mutual interference. Ultimately, this method achieves high purity of recovered materials of all elements, with individual product purities reaching 98.72 wt% for iron phosphate, 92.97 wt% for manganese oxide, 98.06 wt% for cobalt oxide, 95.86 wt% for nickel hydroxide, and 96.76 wt% for lithium carbonate. This proposed process also provides high recovery yields which recovery yield reaching above 99% for valuable elements. To ensure the applicability of this technique to the industry, the real industrial black powder from a battery recycling plant was also applied for this research. Under the same process, we collected all the recycling products of above 90 wt% purity and the recovery yields reaching above 96% for valuable elements. Compared to existing lithium battery recycling technologies, this process offers a broader range of target products and provides an efficient recycling process with mass production potential.

9:45 AM EN09.04.04
A Novel Dry Powder Discharge Technique for Efficient and Environmentally Friendly Lithium Battery Recycling Zheng YuChen, Tzu MingCheng and Chih-huangLai; National Tsing Hua University, Taiwan

The demand of Lithium batteries has raising owing to the flourishing electronic industry. Therefore, an environment-friendly recycling method for lithium batteries is urgently needed, avoiding the environment pollution of lithium batteries disposal. The recycling process of lithium-ion batteries comprises two essential stages: pre-treatment and recovery of target products. Discharging is a crucial step to prevent the occurrence of short circuits and the associated risks of fire or explosion due to residual energy in discarded lithium batteries during collection, transportation, and pre-processing. Currently, common commercial methods for discharging involve submerging batteries in halogen-containing saline solutions or manually connecting large lithium battery modules to resistors for discharge. However, both of these discharge modes have their limitations. While resistor discharge does not cause corrosion and offers easy process control, it is not suitable for large-scale commercial operations due to the manual connection requirement for each battery. Solution immersion discharge, the most widely used method in commercial battery recycling, is prone to corrosion during the discharge process. Corrosion can damage the battery casing, and in severe cases, allow electrolytes to flow into the solution, resulting in significant waste producing which contaminated discharge solutions cannot be reused. Furthermore, corrosion negatively impacts subsequent battery sorting and refining processes.
Given the lack of an effective, non-corrosive, and cost-effective discharge method, our team has developed a novel dry powder discharge technique utilizing graphite powder as the discharge medium. Simply immersing the batteries in the powder and grounding the system enables efficient discharge. In our research, we investigated the influence of powder morphologies, particle sizes, discharging times and temperatures on discharge performance. Through optimization, we achieved even better discharge efficiency than traditional solution immersion discharge. Moreover, all batteries including common types such as ICR, IMR, NCR could be discharged safely below industry-specified limits (<0.5V) in 24 hours, meeting industry requirements. Unlike traditional solution discharge, our proposed method eliminates the corrosive reaction between the battery and the powder, ensuring a corrosion-free process without the generation of additional waste. The non-oxidizing nature of graphite powder allows for its reuse with almost negligible losses during the discharge process. These characteristics not only contribute to high discharge efficiency but also enhance environmental sustainability. We propose that this innovative dry powder discharge technique has the potential to replace traditional solution discharge, offering an efficient and eco-friendly solution for future lithium battery recycling.

Lithium-Ion Battery Recycling Facts and Opportunities IliasBelharouak, YaocaiBai and LuYu; Oak Ridge National Laboratory, United States

The growing demand is generating a huge number of spent lithium-ion batteries, thereby urging the development of cost-effective and environmentally sustainable recycling technologies to manage electrode scraps and end-of-life batteries. Lithium-ion battery recycling of end-of-life batteries is still in its infancy, with many fundamental and technological hurdles to overcome. The recycling rate of waste LIBs is projected to be much behind the rapid growth of the LIB market because of the complexity of the technology and its use cases. Several recycling strategies, including the pyrometallurgical process, hydrometallurgical process, and direct recycling approach, are being adopted on the market and are under further development by researchers. Here, we provide an overview of the current state of battery recycling by outlining and evaluating the incentives, key issues, and recycling strategies. A direct recycling strategy, which is developed in the US. Advanced Battery Recycling Consortium (ReCell) will be highlighted through a discussion of its benefits, processes, and challenges. Direct cathode regeneration seeks to recover the functional cathode particles without decomposition into substituent metals or salts along with other components such as graphite and current collectors. Perspectives on this important field's future energy and environmental science will also be discussed.

11:00 AM EN09.04.06
Selective Extraction and Upcycling of $LiMn_2O_4$ from used First Generation Lithium-Ion Battery Cathodes to Produce Mn-Based Conversion Anodes with Fascinating Electrochemical Properties BeatriceBrowning; University of Birmingham, United Kingdom

A multitude of cathode chemistries have been explored and utilised since the commercialisation of the Li-ion battery (LiB) in the 90s - including transition metal oxide chemistries (such as $LiCoO_2$, $LiFePO_4$, and $LiMn_2O_4$) and mixed transition metal oxide materials (such as NMC, $Ni_aMn_bCo_cO_2$, and NCA, $Ni_aMn_bAl_cO_2$). As electric vehicle adoption is rapidly increasing worldwide, the chemistry of Li-ion batteries used are heavily dictated by consumer demand. Customers expect fast-charging batteries with respectable range, factors which are dictated by the intrinsic electrode chemistry. High specific capacity cathodes that are thermally stable are preferable to consumers, as these features give rise to extended vehicle range and charging speeds. Current cathodes which meet these criteria are predominantly Ni-rich mixed TMO materials (such as NMC and NCA) and $LiFePO_4$.

As LiB technology has advanced over the years, initial cathode chemistries have become outdated with each generation of electric vehicle as companies race to ensure consumer demands are met. $LiMn_2O_4$ (LMO) is an example of a electrode material that was initially seen in electric vehicle batteries, often in conjunction with a layered Ni-rich phase. As subsequent generation vehicles have been released and their performance and energy densities have been enhanced to meet consumer demand, the LMO material has been phased out as the Ni-rich layered materials with high energy density have been prioritised.

When LiBs reach end-of-life the versatility of LiB cathode scrap pool (between manufacturers and between generations of EVs for the same manufacturer) has proven to be challenging for

battery recyclers. Selective extraction of materials is imperative to ensure recycling and upcycling of cathode material is feasible from such an assorted cathode scrap pool. Once selectively extracted, cathode material can be recycled in a closed-loop fashion to regenerate battery grade products. When extracting lesser used and redundant cathode chemistries from preliminary cell structures, it is vital that the maximum value of each product is obtained prior to extraction. Upcycling involves extracting and repurposing material to increase its value, and LMO is a key example of a lesser used material can be upcycled to form a variety of Mn-rich conversion anode materials with interesting properties.

Graphite is the main anode material used in LiBs, however graphite reserves are not infinite, nor are they evenly distributed globally - meaning reliance on other countries is great for this anode material and will only increase as reserves are depleted. There is no question that alternative anode materials are necessary to avoid the likelihood of bottlenecks in graphite supply. Through selective extraction and interconversion of LMO, an array of Mn-rich conversion anodes with fascinating electrochemical properties can be produced. Not only can Mn be extracted from redundant LMO cathode material, but Mn-reserves are cheap, non-toxic and abundant, and it is of great interest to explore these conversion anode materials and their characteristics.

Key electrochemical characteristics that are of great interest within this study include the anode capacities being several times greater than their theoretical capacities, and the increase in capacity that arises during cell cycling. The origin of the phemonena observed have been explored using an array of characterisation techniques, including in-situ Synchotron X-ray diffraction and Pair-distribution function (PDF) analysis, Raman spectroscopy, galvanostatic cycling, cyclic voltammetry, Inductively Coupled Plasma-Optical Emission Spectroscopy and scanning and transmission electron microscopy, to name a few.

11:15 AM EN09.04.07
Resynthesized Electrode Materials from Chemically and Biologically Recycled Li-Ion Batteries WitoldUhrynowski[1], MagdalenaWinkowska-Struzik[1], MaciejBoczar[1], MichalStruzik[2], ZbigniewRogulski[1], AndrzejCzerwinski[1] and DominikaA. Buchberger[1]; [1]University of Warsaw, Poland; [2]Warsaw University of Technology, Poland

Recently, a dynamic increase of interest in the possibilities of recycling and reuse of materials from lithium-ion batteries was observed. Along with the ever-increasing number of Li-ion cells powering new electric and electronic devices, the management of waste batteries and materials contained within them has become a more and more urgent problem to be solved. Due to the growing environmental awareness more stringent legislative means to control the matter are introduced. This includes the latest European Union directive on batteries which states that no less than 35% of Li and 90% of cobalt, nickel and manganese will need to be recovered from waste Li-ion cells. Based on those regulations, the new batteries produced after 2030 will need to contain, for example, at least 6% of recycled lithium. Although large-scale, proper processing of waste batteries is still an economical challenge, the changing global supply and demand dynamics, geopolitical events, technological advancements, and the aforementioned environmental regulations force stakeholders in the battery market to consider battery recycling not only necessary, but also potentially financially viable and sustainable practice.

The battery recycling process should be characterized by high efficiency and the lowest possible impact on the environment, and as such, needs to be optimized for every type of electrode material. For the purposes of this study lithiated nickel-manganese-cobalt oxide 6:2:2 (NMC622) material was chosen, due to its high energy and power density, relatively high resistance to subsequent cell charge/discharge cycles, as well as favorable economic and environmental parameters associated with decreased cobalt content. The electrode material, synthesized from supplier grade new substrates was subsequently recycled in a series of steps, including hydrometallurgical recovery of lithium, and transition metal ions recovery as (hydr)oxides. The leachates were further processed chemically and biologically, by means of selected bacterial consortia, to increase the yield of recycled materials and to lower the concentration of dissolved ions. The use of biological processes in the recycling of waste electrode material reduces the costs of the process, especially at low concentrations – where the load of the leachate is too low for effective and economic chemical recovery, but still to great for safe discharge of the effluents to ground waters. With the use of microorganisms, nearly complete removal of nickel, cobalt and manganese ions from the leachates can be obtained, and the resultant technical-grade waters may be reused in the cycle. Effective lithium recovery, however, still remains a challenge.

The obtained recovered lithium and transition metals were further used to resynthesize electrode materials. Crystallographic measurements were performed proving the structure and purity of the obtained recycled materials. The resynthesized NMC622 electrode material with 0 to 100% of recycled materials content were structurally and electrochemically investigated and compared with the "original" material. It was shown that the electrode materials made of recycled materials may perform in a comparable manner with the "original" materials. However, their endurance and stability in charge/discharge cycles is greatly affected by the purity of the recycled substrates.

Recovery of metals from waste batteries is important for economic and ecological reasons. The presented results indicate that optimization of the recycling process, though challenging, is promising, and the resynthesized materials may be a good additive or even an alternative for commercial ones.

SESSION EN09.05: Virtual Session

A Promising Solid-State Synthesis of $LiMn_{1-y}Fe_yPO_4$ Cathode for Lithium-Ion batteries JinliLiu[1,2]; [1]Nanjing University of Science and Technology, China; [2]Tsinghua University, China

$LiMn_{1-y}Fe_yPO_4$ (LMFP) is a significant and cost-effective cathode material for Li-ion batteries, with a higher working voltage than $LiFePO_4$ (LFP) and improved safety features compared to layered oxide cathodes. However, its commercial application faces challenges due to a need for a synthesis process to overcome the low Li-ion diffusion kinetics and complex phase transitions. Herein, we propose a solid-state synthesis process using LFP and nano $LiMn_{0.7}Fe_{0.3}PO_4$ (MF73). The larger LFP acts as a structural framework fused with nano-MF73, preserving the morphology and high performance of LFP. Our results demonstrate that the solid-state reaction occurs quickly, even at a low sintering temperature of 500 °C, and completes at 700 °C. However, contrary to our expectations, the larger LFP particles disappeared and fused into the nano-MF73 particles, revealing that Fe ions diffuse more easily than Mn ions in the olivine framework. This discovery provides valuable insights into understanding ion diffusion in LMFP. Notably, the obtained LMFP can still deliver an initial capacity of 142.3 mAh g^{-1}, and the phase separation during the electrochemical process is significantly suppressed, resulting in good cycling stability (91.2% capacity retention after 300 cycles). Our findings offer a promising approach for synthesizing LMFP with improved performance and stability.

10:45 AM *EN09.05.03
Solvent-Based Sequential Separation Processes for Direct Recycling of Lithium-Ion Batteries YaocaiBai, LuYu and IliasBelharouak; Oak Ridge National Laboratory, United States

The recycling of end-of-life lithium-ion batteries and the direct reintegration of the reclaimed materials into the battery supply chain are increasingly recognized as pivotal steps toward fostering a sustainable battery ecosystem. In a typical recycling process, the spent cells are discharged and shredded, followed by electrolyte recovery and component separation to remove/reclaim components like plastics, pouch material, and steel casing. As a result, a feedstock of anode and cathode on their current collectors is generated. This feedstock contains the most valuable components in a lithium-ion cell, including black mass (e.g., active cathode materials and graphite), Cu foils, and Al foils. To reclaim active electrode materials with high purity for direct regeneration, separation of electrode materials from their current collector as well as of anodes from cathodes is necessary. Current techniques require a complex set of separation processes to produce clean streams of material, resulting in lower recovery rates and higher costs. In this talk, solvent-based separation processes will be discussed to sequentially separate both anode/cathode and electrode/current collectors to recover cathode films, Al foils, anode films, and Cu foils. By circumventing a complex set of separation processes, the sequential separation method alone could fulfill the goal of reclaiming higher-purity materials, making recycling more profitable. The designed solution does not damage the active cathode materials nor corrode the metal foils. In addition, this process enables low-temperature separation in a cost-effective solution, reducing energy consumption and processing costs. The discussion will shed light on how environmentally sustainable and cost-effective sequential separation processes pave the way for direct recycling.

Liquid-Phase Electron Microscopy for Probing Electrocatalytic Material Interfaces VasoTileli; EPFL, Switzerland

The oxygen evolution half-reaction (OER) is responsible for the limited efficiency of water splitting devices for storing clean energy. A holistic understanding of the fundamental processes taking place during operation of catalysts in solution can be gained by using advanced operando techniques that can complement characterization pre and post operation. In particular, electrochemical liquid-phase transmission electron microscopy (TEM) can provide morphological, structural, and chemical information for these catalysts.
As an example, I will focus on OER oxide-based catalysts studied using liquid-phase TEM to investigate the solid-liquid interface in an alkaline solution [1]. The potential-dependent variation of the local contrast was associated to the modification of the alkaline liquid electrolyte and its wettability at the Co-oxide surfaces. At low applied potential, the hydrophobic character of the oxides was found to reduce due to electrowetting induced by OH^- accumulation at the interface. A distinct transition towards hydrophilicity was probed at the potential associated with the redox Co^{2+}/Co^{3+} reaction, which alters the interfacial capacitance. This leads to a relatively stable wetting character at intermediate potentials prior to the OER region where the oxide surfaces catalyse the adsorbed hydroxide ions at the solid-liquid interface to form molecular oxygen. Further operando measurements using electron energy loss spectroscopy (EELS) provided direct evidence of the evolution of molecular oxygen. Finally, similar experiments on IrO_2 particles reveal the possibility of facet-dependent production detections using EELS [2].
Overall, advanced electron diagnostics and characterization applied to electrocatalyst structures can provide valuable insights into solid/liquid/gas interfaces and can guide development of efficient devices.

11:00 AM EN10.01.02
Fundamental Understanding of Electrode-Electrolyte Interface in Hydrogen Evolution Reaction (HER) Kinetics AamirH. Shah and XiangfengDuan; University of California, Los Angeles, United States

The hydrogen evolution reaction (HER) is one of the most fundamental and critical reactions in renewable energy conversion. The recent advancement in various platinum (Pt) nanocatalyst designs has led to greatly improved HER activity. Identification of the exact active sites and understanding the structure-activity relationship are critical for rational catalyst design but remain elusive due to the lack of methods robustly resolving the role of different surface sites. Moreover, it is well recognized that the HER kinetics are drastically slower in alkaline media compared to acidic media, but the descriptors of the HER kinetics are still elusive. Specifically, in the presence of alkali metal cations and hydroxyl anions, the electrode–electrolyte (platinum–water) interface in an alkaline electrolyte is far more complex than that in an acidic electrolyte. The effects of different alkali metal cations (AM^+) and pH on these reactions are poorly understood due to a lack of suitable experimental methods. We are combining surface electrical transport spectroscopy (ETS) with other electrochemistry techniques and computational studies to probe and understand the fundamental role of different AM^+ and pH on the reaction kinetics of HER. Our study provides fundamental insights into how and why AM^+ and pH influence HER in

alkaline media. We expect that this research will provide the molecular-level understanding that will shed new insights into electrolyte engineering as an alternative pathway to control electrochemical reaction kinetics.

11:15 AM EN10.01.03
Modeling Electrochemical Reaction Rates at Fluid-Solid Interfaces RachelC. Kurchin; Carnegie Mellon University, United States

A detailed understanding of electrochemical reaction rates at interfaces between liquid electrolytes and a variety of solid electrodes is crucial in the engineering of next-generation electrochemical devices. In addition, it is becoming increasingly important to understand this behavior at higher overpotentials (where deviations from standard approaches such as Butler-Volmer are more likely) for applications such as fast charging of EV batteries. In this talk, I will introduce an extension to Marcus-Hush-Chidsey kinetics that explicitly accounts for the density of states of the electrode, and introduce several applications of it in a variety of systems, including twisted graphene structures.

Micelle-Like Structures in Localized High-Concentration Electrolytes and The Impacts on Electrolyte Performances BinLi[1,2]; [1]Oak Ridge National Laboratory, United States; [2]UTK-Oak Ridge Innovation Center, United States

A new class of electrolytes, localized high-concentration electrolytes (LHCE), have shown many benefits to high-capacity electrodes (Li-metal, Si, sodium, zinc, and potassium). These electrolytes combine high-concentration electrolytes (HCE) with salt and solvent with low-viscosity diluents. The dilutes were added to increase ionic conductivity while the locally highly concentrated salt-solvent clusters will facilitate stable solid-electrolyte interphase (SEI) formation while preventing metallic-dendrite formation. A ternary phase diagram for the design of LHCE is proposed based on salt-solvent solubility and solvent-diluent miscibility. Salt-solvent clusters in LHCE exhibit micelle-like behaviour. A salt concentration gradient naturally forms in a micelle-like cluster, through which the ion-pair aggregates get more localized due to accumulation of solvent as a surfactant at salt network/diluent matrix interfaces. The micelle-like structure is also influenced by the temperature. In an exemplary LHCE of LiFSI-1.2DME-2TFEO, a localized peak ratio of AGG+ is seen at 25 °C, confirmed with both Raman and MD simulations, inspired a formation protocol that improved initial SEI composition and morphology, and extended the cyclability. In the LiFSI-DMC-TTE system, an unprecedented CE above 99.5% is accomplished, optimized by compensating microstructures (e.g., micelle-like structures and network versus isolated clusters) with macroscale properties (e.g., ionic conductivity). This work proposes methods of controlling the micelle-like structure in LHCE, supported by SAXS and Raman characterization, MD simulations as well as electrochemical measurements, for higher performing practical batteries. From here, the impacts of electrolyte component choices in LHCEs to control salt-solvent cluster size, shape, and composition, as well as external parameters chosen during operation (e.g., temperature) can be optimized to extend anode stability and cyclability of high-energy batteries.

2:00 PM EN10.02.02
Uncovering the Electrochemically Active Surfaces in Polycrystalline NMC Battery Cathode Particles JinhongMin, RileyHargrave and YiyangLi; University of Michigan, United States

In battery electrodes, it is widely believed that the electrochemically active surface area equals the surface area of the particles. Based on this assumption, it has been generally believed that smaller particles have faster reaction and diffusion times than larger ones. In this study, we develop a new high-throughput, single-particle electrochemistry platform to test this belief for polycrystalline NMC battery particles. Surprisingly, we observed that the smaller particles have no shorter reaction and diffusion times than larger ones. To explain this unexpected relationship, we propose that electrolyte penetrates the grain boundaries of the secondary particle into the bulk. For this reason, the electrochemically active surface is not the area of the secondary particles, as typically believed, but the area of the primary particles. This work has substantial implications in accurate modeling and control of battery materials.

Electrode/Electrolyte Interface Control for Multivalent-Ion Batteries with High Stability and Reversibility ChangLi[1], RishabhD. Guha[2], AbhinandanShyamsuder[1], ZhuoYu[1], KristinA. Persson[3] and LindaNazar[1]; [1]University of Waterloo, Canada; [2]Lawrence Berkley National Laboratory, United States; [3]University of California – Berkeley, United States

Rechargeable multivalent-ion batteries (RMBs) are attractive as a “beyond lithium-ion battery” because of their multi-electron transfer and high abundance (eg. Zn^{2+} and Mg^{2+}), which principally provides higher volumetric capacity and better affordability. The development of highly reversible and stable RMBs is correlated to the multivalent feature of these ions, which poses great challenges to the design of functional electrode/electrolyte interfaces.
This presentation will include discussion of key obstacles for these interfaces, followed by tailored strategies to foster good performance. The main topics will cover two different approaches to stabilize the electrode/electrolyte interface by preventing interfacial side reactions in nonaqueous magnesium batteries with an operating potential of over 3.5 V. This includes **a)** a low-cost inorganic surface membrane that protects against the decomposition of an organoborate-based electrolyte to yield an ultra-stable Mg anode for high-power magnesium batteries; **b)** eliminating passivation on the Mg anode by tailoring commercially available electrolytes to achieve over 2500-hour Mg plating/stripping at 2 mA cm^{-2} and 2 mAh cm^{-2}. Brief highlights of interfacial optimization in aqueous zinc batteries will be also presented. Characterization of these designed and highly functional interfaces using depth-profiling high-resolution XPS, TEM and cryogenic-EM will be described.

2:30 PM EN10.02.04
Lithium Metal Anode Enabled by a Robust and Stable Artificial Surface Layer RidwanA. Ahmed, Ju-MyungKim, Ji-GuangZhang and WuXu; Pacific Northwest National Laboratory, United States

Lithium (Li) metal batteries have higher energy density than the state-of-the-art Li-ion batteries and the potential utilization in transportation devices. However, their practical application is still hindered by poor performance in terms of cycling stability and safety, especially at high current densities. This is due to a number of reasons among which are reactions between the Li metal and the liquid electrolyte, and formation of dendrites. In this study, we develop a robust and stable artificial solid electrolyte interface (aSEI), which consists of a surface treated (S_T) PEO – $Li_{6.4}Ga_{0.2}La_3Zr_2O_{12}$ composite polymer layer (CPL) on Li metal anode. The aSEI developed in this study is characterized by a good combination of electrochemical and mechanical properties. Benefitting from these characteristics, S_TCPL@Li||NMC811 cells with 4.7 mAh cm^{-2} cathode loading exhibit improved electrochemical cycling stability compared with the bare Li||NMC811 cells at high current densities of ~1.6 and ~2.4 mA cm^{-2}. A capacity retention of ~ 90% is obtained for S_TCPL@Li||NMC811 at ~1.6 mA cm^{-2} after 200 cycles compared with 60% for bare Li||NMC811. In addition, S_TCPL@Li||NMC811 demonstrates higher charge rate capacities at charge current densities compared with bare Li||NMC811. These findings suggest that S_TCPL is promising for high current density Li metal batteries.

Elucidating the Role of Prelithiation in Si-Based Anodes for Interface Stabilization ShuangBai and Y. ShirleyMeng; University of California, San Diego, United States

Prelithiation as a facile and effective method to compensate the lithium inventory loss in the initial cycle has progressed considerably both on anode and cathode sides. However, much less research has been devoted to the prelithiation effect on the interface stabilization for long-term cycling of Si-based anodes. An in-depth quantitative analysis of the interface that forms during the prelithiation of SiOx is presented here and the results are compared with prelithiaton of Si anodes. Local structure probe combined with detailed electrochemical analysis reveals that a characteristic mosaic interface is formed on both prelithiated SiOx and Si anodes. This mosaic interface containing multiple lithium silicates phases, is fundamentally different from the solid electrolyte interface (SEI) formed without prelithiation. The ideal conductivity and mechanical properties of lithium silicates enable improved cycling stability of both prelithiated anodes. With a higher ratio of lithium silicates due to the oxygen participation, prelithiated SiO1.3 anode improves the initial coulombic efficiency to 94% in full cell and delivers good cycling retention (77%) after 200 cycles. The insights provided in this work can be used to further optimize high Si loading (>70% by weight) based anode in future high energy density batteries.

Microscopic Insights into Ion Conduction at Solid-Solid Interfaces MiaofangChi; Oak Ridge National Laboratory, United States

Solid-state electrolytes are currently being investigated as a highly promising solution to overcome various challenges in battery technology. The ideal solid electrolyte material should exhibit high ionic conductivity while maintaining stability with metallic lithium. In recent decades, significant progress has been made in the development of solid electrolyte materials with high conductivity comparable to organic liquid electrolytes. However, a major limitation in practical applications of these materials is the unexpectedly high resistivity observed at grain boundaries and electrolyte-electrode interfaces. Elucidating the complexities of these interfaces is challenging due to spatial confinement, structural intricacies, and chemical complexities, posing obstacles for both experimental and theoretical approaches. In this talk, I will discuss our recent efforts to probe interfacial phenomena in solid electrolytes using advanced techniques such as in situ and atomic-resolution scanning transmission electron microscopy (STEM) and electron energy loss spectroscopy (EELS). Additionally, I will introduce 4D-STEM and vibration EELS, which enable the investigation of interfacial charge distribution and ion conduction behavior. Through these electron microscopy techniques, I aim to demonstrate their significant potential in providing valuable insights for the design and synthesis of high-performance solid-solid interfaces.

4:00 PM EN10.02.07
Thermodynamic Stability Dynamics during Delithiation of $LiCoO_2$SpencerDahl[1], LuelcCosta[2], JeffersonBettini[2] and RicardoCastro[3]; [1]University of California, Davis, United States; [2]National Center for Research in Energy and Materials - CNPEM, Brazil; [3]Lehigh University, United States

Cathode cycling leads to critical instabilities of the structures, being one of the most critical causes for battery failure. Interfacial properties are critical in this scenario, but there is a lack of fundamental experimental studies concerning the evolution of surface energies during delithiation and how to control them using thermodynamic strategies to improve cathode performance. Here we report experimental data on the thermodynamics of surfaces in nanocrystalline LiCoO2 using microcalorimetry and how it relates to stability against dissolution/degradation. By testing chemically de-lithiated states using microcalorimetry and EELS/HRTEM, we were able to quantify the thermodynamic changes between lithiated and delithiated states for a direct evaluation of driving force for growth and degradation. Further, we demonstrate how a dopant (lanthanum) designed to segregate to the surface lowers the excess energy of the interface, causing nano-LiCoO2 to show greater resistance to dissolution/growth/degregation founded on the dopant impact interface energies. Although LiCoO2 was used a model material, we discuss here the design principle behind interface stabilization to allow greater performance in liquid and solid state batteries.

4:15 PM EN10.02.08
Critical Deterioration Roots of Ni-Rich Cathode during Long-Term Cycling: Material Degradation, Diffusion Limit or Interfacial Instability?JiyuCai[1], NatashaChernova[2], BradPrevel[3], FengWang[1] and ZonghaiChen[1]; [1]Argonne National Laboratory, United States; [2]Charge CCCV, United States; [3]Primet Precision Materials, United States

Severe performance deterioration in long-term cycling is a long-standing challenge for practical applications of high-energy-density Ni-rich $LiNi_{1-x-y}Mn_xCo_yO_2$ (NMC, x+y < 0.5) cathodes at high potentials (>4.3V vs. Li/Li^+). Great efforts have correlated the performance deterioration to many physical observations, while the critical deterioration roots of Ni-rich cathode during long-term cycling are not well elaborated. Herein, we perform a systematic and in-depth investigation to probe the critical contributions from observed deterioration roots of Ni-rich $LiNi_{0.83}Mn_{0.1}Co_{0.07}O_2$ cathode in full cells with graphite anode after 1000 cycles at different upper potentials. Intriguingly, the severe capacity retention in electrochemical evaluation of recovered cathode half cells is contrail to the insignificant structural changes and transition metal loss via post-mortem characterizations of bulk material. GITT tests unveils that chemical diffusion limit is the dominant deterioration root of Ni-rich cathode at high potential. The severe chemical diffusion of Li^+ is strongly correlated to the exacerbated surface reconstructions at the cathode surface. Our study suggests that stabilizing the cathode interface and mitigating the surface reconstructions is the most crucial for enabling long lifespan of Ni-rich cathodes at high potentials.

4:30 PM EN10.02.09
Interfacial Aluminum Corrosion Reactions with Lithium Bis(fluorosulfonyl)imide (LiFSI) in Fluorinated and Non-Fluorinated Ether-Based Solutions for Li-Metal Batteries TaegyuJang and Hye RyungByon; KAIST, Korea (the Republic of)

Lithium-metal batteries (LMBs) have garnered significant attention as a potential replacement for graphite-based lithium-ion batteries due to their superior energy density. However, a critical challenge in LMBs is stabilizing the metallic lithium (Li) electrodes, which face continuous decomposition of the electrolyte solution and the formation of dendrites. It is crucial to develop a desired solid electrolyte interphase (SEI) that contains lithium fluoride (LiF) to protect the Li surface. For this purpose, the bis(fluorosulfonyl)imide (FSI^-) anion has been widely employed, as it readily forms abundant LiF through defluorination. However, the use of FSI^- is accompanied by the corrosion of aluminum (Al), the current collector in the positive electrode, which often leads to cell failures. Although recent studies reported mitigated Al corrosion through the use of fluorinated ethers and locally high concentrated electrolytes (LHCE), there is a lack of study on the interfacial reactions between these electrolytes and Al, as well as their ability to inhibit corrosion.
Herein we studied the Al corrosion with 1 M LiFSI in 1,2-dimethoxyethane (DME), tetraethylene glycol dimethyl ether (G4), 2,2,3,3-tetrafluoro-1,4-dimethoxybutane (FDMB), and LHCE comprising DME and 1,1,2,2-tetrafluorethylene 2,2,3,3-tetrafluoropropyl ether (TTE). The corrosion of Al was evaluated through chronoamperometry tests conducted from room temperature to 60 °C. The applied potential for each test was kept below the oxidation potential of the electrolyte solutions (4~4.3 V for DME and G4, and 4.5 V for FDMB and LHCE). In contrast to a significant increase in current observed with DME, the other electrolyte solutions exhibited low and stable leakage currents at room temperature. X-ray photoelectron spectroscopy revealed the formation of the $Al(FSI)_3$ complex on Al from G4 and LHCE, indicating a low solubility of $Al(FSI)_3$. On the other hand, AlF_3 was detected when FDMB was used, which was likely formed through the defluorination of FDMB, leading to the replacement of Li^+ coordination with Al^{3+} in the presence of LiFSI. At 60 °C, the leakage currents with DME, G4, and LHCE significantly increased, in the order of DME > G4 > LHCE. It is attributed to the increased solubility of $Al(FSI)_3$ and the exacerbation of Al corrosion. Open circuit potentials (OCPs) measured after tests were 0 to 0.3 V with DME, G4, and LHCE, indicating the significant dissolution of Al^{3+} that was deposited on the Li electrode. In comparison, FDMB with LiFSI provided a low and stable current even at 60 °C and 4.5 V. The OCP also remained above 3 V, suggesting the preservation of the Al_2O_3 surface and the mitigated Al corrosion. I will discuss the details of interfacial reactions between Al and electrolyte solutions in the presentation.

4:45 PM EN10.02.10
Ultrathin Semiconductor Interphase Regulated Electric Double Layer Enabling High-Stable Zinc Metal Anode YimeiChen; University of Alberta, Canada

The practical application of aqueous zinc-ion batteries for large-grid scale systems is still hindered by uncontrolled zinc dendrite and side reactions. Regulating the electrical double layer via the electrode/electrolyte interface layer is an effective strategy to improve the reversibility and stability of Zn anodes. Herein, the ultrathin zincophilic ZnS layer synthesized via a facile electrodeposition method is selected as a model regulator. At a given cycling current, the cell with Zn@ZnS electrode displays a lower potential drop over the Helmholtz layer across the electrode surface and a suppressed diffuse layer, indicating the regulated charge distribution and decreased electric double layer repulsion force. This protective layer also enables redistributed uniform electric fields and highly suppressed side reactions. Consequently, the cell with the ZnS protection layer exhibits a long cycling stability of around 3000 hours at 1mA cm^{-2}, accompanied by a high reversibility of 98.9% over 2500 cycles at 5mA cm^{-2}. When coupled with I_2/AC cathode, the cell demonstrates a high rate performance of 160 mAh g^{-1}at 0.1 A g^{-1} and long cycling stability of over 10000 cycles at 10A g^{-1}. The Zn||MnO_2 also sustains both high capacity and long cycling stability of 130 mAh g^{-1} after 1200 cycles at 0.5A g^{-1}.

SESSION EN10.03: Electrocatalysis I—From Single Atoms to Nanocatalysts

Single Metal Site Oxygen-Reduction Catalysts: From Atomic Active Site Structures to Fuel Cell Cathode Performance GangWu; University at Buffalo, SUNY, United States

Recently, scientists have identified the newly emerging atomically dispersed transition metal (M: Fe, Co, or/and Mn) and nitrogen co-doped carbon (M–N–C) catalysts as the most promising alternative to PGM catalysts. In this talk, I will provide a comprehensive review of significant breakthroughs, remaining challenges, and perspectives regarding the M–N–C catalysts in terms of catalyst activity, stability, and membrane electrode assembly (MEA) performance. The most considerable challenge of current M–N–C catalysts is the unsatisfied stability and rapid performance degradation in MEAs. Therefore, we further discuss practical methods and strategies to mitigate catalyst and electrode degradation, which is essential to make M–N–C catalysts viable in hydrogen fuel cell technologies.

9:00 AM *EN10.03.02
Nano Catalysts for Water Electrolysis: The Importance of Catalyst Layer Conductivity ShougoHigashi; Toyota Central R&D Labs., Inc./ Toyota Motor North America, United States

Humanity has been benefiting from the development of internal combustion engines for several decades. With the emergence and explosive increase of automobiles around 1980's, there has been a demand for environmental catalyst technologies to process exhaust gases such as CO (carbon monoxide), NO_X (Nitrogen oxides). Since then, a significant amount of knowledge about catalysts to reduce the usage of precious metal catalysts, which play a crucial role in automotive applications, has been obtained, leading to the current research and development of single-atom and few-atom cluster catalysts. We have seen that the chemical potential of the material can be modulated by tuning the size, shape, and introducing supporting oxides to achieve low-mass loading, high performance environmental catalyst. In the future, the roles played by batteries and catalysts will become increasingly important, and there is a need for next-generation electrochemical catalyst technologies to produce energy carriers, including hydrogen, at a low cost.
In this presentation, I will briefly review the knowledge of catalysts that we have accumulated since the rise of internal combustion engines and discuss the challenges and opportunities in electrochemical catalysis, with a specific focus on our research efforts in hydrogen production.

9:30 AM EN10.03.03
Enhancing Metal-Sulfur Batteries with Single Atom Catalysts and Graphitic Carbon Nitride: Addressing the Polysulfide Shuttle Effect AliakbarYazdani, JyotiPandey, VeronicaBarone, ValeriPetkov and BradleyFahlman; Central Michigan University, United States

Metal-sulfur batteries, including lithium-sulfur batteries, have attracted significant attention as promising energy storage systems. However, the presence of the polysulfide shuttle effect poses a major challenge, which leads to poor cycling stability and limited capacity retention. This research focuses on the exploration of novel strategies to overcome this issue and improve the performance of metal-sulfur batteries. One effective approach to mitigate this effect is the utilization of single atom catalysts. These catalysts have demonstrated promising results in enhancing the cell performance of metal-sulfur batteries, particularly in terms of higher C-rates and improved capacity retention. By providing active sites for polysulfide adsorption and conversion, single atom catalysts effectively trap and immobilize polysulfide intermediates, preventing their dissolution and subsequent migration between counter electrodes.
In this study, we investigated the incorporation of Fe, Co, and Ni single atom catalysts onto a carbon substrate for metal-sulfur batteries. Specifically, we explored the use of graphitic carbon nitride ($g\text{-}C_3N_4$) and reduced graphitic carbon nitride ($r\text{-}g\text{-}C_3N_4$) as suitable carbon substrates for sulfur and single atom catalysts. These materials possess desirable properties such as high surface area, excellent electrical conductivity, and good chemical stability, making them ideal candidates for enhancing the cathode performance of metal-sulfur batteries. Through systematic characterization and electrochemical testing, we will demonstrate the performance of metal-sulfur batteries that incorporate single atom catalysts and graphitic carbon nitride in the cathode. The effect of dispersed single atom catalysts in the suppression of polysulfide migration, as well as the cycling stability and prolonged capacity retention of metal-sulfur batteries, will be described.
Overall, our findings will highlight the potential of single atom catalysts and graphitic carbon nitride as effective strategies to address the polysulfide shuttle effect in metal-sulfur batteries. This research aims to contribute to the advancement of energy storage technologies, paving the way for the development of more efficient and sustainable battery systems.

9:45 AM EN10.03.04
Characterization and Modeling of Rhodium Single-Atom Catalysts on Porous Carbon Supports JyotiPandey; Central Michigan University, United States

Due to worldwide interest in expanding the electrification of the transportation sector, there is never-ending research carried out on the development battery materials. Sulfur being one of the least expensive elements, is an attractive choice for battery cathode but it comes with various limitations which includes the insulating behavior of polysulfides, poor reversibility and slow kinetics of the metal-S conversion reactions. The single-atom catalysts (SACs) open up a new avenue towards their use as catalysts and to increase the commercial applications. They are known to exhibit improved kinetics of metal-S conversion reactions through the redox kinetics. This work focusses on the characterization and modeling of Rh-SAC-functionalized porous carbon supports. Extended X-ray absorption fine structure (EXAFS) measurements were recorded on the Rh K-edge for the four different samples to study the coordination environment. An analysis of the EXAFS scattering contributions revealed that out of the four different samples, two of the samples, viz. Fibrous materials (CF) and carbon nano fibers (CNF) were explicitly possessing Rh single atoms dispersed on the carbon support. The other two samples, Carbon nano tube (CNT) and few layer graphene (FLG) were proven to possess Rh single atoms with some dimers/trimers, and Rh clusters, respectively. EXAFS fitting gives a good overlap between the DFT-optimized structures and the experimental spectra up to a range of around 3 Å around the scattering atoms. The insights gained from the characterization and modeling efforts will pave the way for improved understanding of the catalyst's behavior and facilitate the design of more efficient and effective catalyst systems. The outcomes of this study hold significant potential for enhancing the performance and commercial viability of sulfur-based batteries in the pursuit of widespread research in the field of cathode materials for the battery sector.

Catalytic Single-Site Co in Well-Define Metal Oxide Nanocrystal Surfaces for the Oxygen Evolution Reaction SenZhang and ChangLiu; University of Virginia, United States

Efficient electrocatalysts for the oxygen evolution reaction (OER) are paramount to the development of electrochemical devices for clean energy and fuel conversion. However, the structural complexity of heterogeneous electrocatalysts makes it a great challenge to elucidate the surface catalytic sites and OER mechanisms. This talk will be focused on our recent work on the interaction of single-site Co catalytic centers and inorganic coordination environments in the surface of doped metal oxide nanocrystals for the OER. The integration of controlled synthesis of nanocrystals, operando structural/catalytic characterization, and advanced theoretical calculation for electrocatalyst development will be discussed.

11:00 AM EN10.03.06
Active-Site Imprinting Towards Design and Understanding of Single Site Atomically Dispersed M-N-C Catalysts Tim-PatrickD. Fellinger; Bundesanstalt für Materialforschung und -prüfung (BAM), Germany

Atomically dispersed M-N-C catalysts such as Fe-N-Cs are very promising alternatives for precious metal-based catalysts for energy conversion reactions.[1-3] Early reports on such materials date back to the 1960s, when Jasinski pioneered the research based on tetrapyrrolic phthalocyanine macrocycles which were inspired by natural transition metal porphyrin complexes present in enzyme active sites.[3] For decades, the selective synthesis of these catalysts was complicated by the formation of side phases due to the harsh reaction conditions facilitating side phase formation. In 2018, we introduced a mild procedure, which is conservative toward the carbon support and leads to active-site formation at low temperatures in a wet-chemical step, essentially decoupling the preparation of the N-C backbone from the preparation of the active sites.[4, 5] The key concept therein is the so-called active-site imprinting into the N-C backbone using pyrolytic template ion reactions.[4][5] Using the same precursor that is used for the preparation of phthalocyanines, we were recently able to produce atomically-dispersed single-site M-N-Cs that consist of tetrapyrrolic M-N4 complexes.[6] The tetrapyrrolic Fe-N-C derivatives are highly active and extraordinary selective electrocatalysts for the oxygen reduction reaction. The well-defined and homogeneous active site structure allowed us to quantify the intrinsic catalytic activity of the materials and to reveal distinct degradation mechanism upon storage.[7] Herein, the general synthetic strategy for atomically dispersed catalysts will be discussed based on tetrapyrrolic Fe-N-C catalysts, which will be analyzed for their potential as fuel cell catalysts.

Photochemically Deposited Single Platinum Atoms Supported on Exfoliated WS_2 Nanosheets for Hydrogen Evolution Reaction Doo YoungKim, NadeeshaL. Kothalawala, TawaburRahman, ManishaGoonatilleke, NipunChandrasiri, BethS. Guiton and AronJ. Huckaba; University of Kentucky, United States

2-D transition metal dichalcogenides (TMDs) serve as an ideal platform for electro- and photo-catalysis. For example, TMDs can be interfaced with another layered material to constitute a heterojunction or can stabilize efficient catalysts (e.g., single atom catalysts) without chemical ligands. In this work, we report platinum single-atom-catalysts (Pt-SAC) decorated tungsten disulfide (WS_2) nanosheets for electrochemical hydrogen evolution reaction (HER). A green liquid-phase exfoliation method was employed to produce highly exfoliated (mono, bi- and few-layered) WS_2 nanosheets. This method involved a probe ultra-sonication in a low-boiling-point solvent mixture, water and ethanol, combined with a solvothermal process. These exfoliated

WS_2 nanosheets were crystalline and possess clean surfaces with high aspect ratio without any surface ligands or impurities. The synthesized nano sheets were predominantly semi-conducting hexagonal (2-H) phase.
We found that these exfoliated WS_2 nanosheets are an ideal support material to stabilize catalytic Pt-SAC. For the deposition of Pt-SACs on WS_2, H_2PtCl_6 precursor was photochemically reduced through a short exposure of high-energy Xe flash lamp. High-resolution scanning transmission electron microscopic (HR-STEM) images probed that the deposited Pt atoms were single- or nanoclustered. Pt-SACs demonstrate excellent performances for hydrogen evolution reaction. The mass activity (A/g_{Pt}) of Pt-SAC on WS_2 is ~ 20x higher than that of commercial platinum nanoparticle catalyst (Pt/C) in both acidic and alkaline electrolytes.

11:30 AM EN10.03.09
Predicting Catalytic Activity of Single Atom Catalysts in Oxygen Evolution Reaction via First-Principles Simulations and Symbolic Regression SatadeepBhattacharjee[1], SwetarekhaRam[1], Albert SLee[2] and Seung-CheolLee[1]; [1]Indo Korea Science and Technology Center, India; [2]Korea Institute of Science and Technology, Korea (the Republic of)

Efficient energy conversion and storage require the development of effective electrocatalysts for the oxygen evolution reaction (OER). In this regard, single-atom catalysts (SACs) with 100 % active sites for OER are promising [1-6]. This study investigates the OER activities of Co single atoms (CoSA) on metallic MXenes, namely $Ti_3C_2O_2$ and Mo_2CO_2, considering both stoichiometric and oxygen vacancy (Ov) configurations. Spin-polarized first-principles calculations were used to determine the rate-limiting step, the conversion of oxygen from hydroxyl species. The presence of oxygen vacancies resulted in decreased OER activity and higher overpotential for CoSA on $Ti_3C_2O_{2-\delta}$, while it increased OER activity for CoSA on Mo_2CO_2. Insights from the density of states, the variation of the charge density and the bonding analysis provide information about the observed results. Furthermore, the critical role of hybridization between the d states of CoSA and the transition metal sites of the catalyst bed (Ti/Mo) is demonstrated. Furthermore, we investigated the potential of designing SACs on Mo_2CO_2 MXenes for electrochemical OER using first-principles modeling simulations. The Electrochemical Step Symmetry Index (ESSI) method is used to fine-tune activity and identify optimal SACs, with both Ag and Cu showing potency in enhancing OER activity. Cu stands out among the chosen transition metals (TMs) as the best catalyst for reducing the overpotential, while Ag poses challenges in tuning its overpotential. Symbolic regression analysis is employed to identify key descriptors affecting catalytic efficiency, resulting in the derivation of mathematical formulas for the OER overpotential. This comprehensive investigation provides insights into the potential of SACs and MXenes in advanced electrocatalytic processes, offering prospects for improved OER activity and selectivity.

SESSION EN10.04/SF02.04: Joint Session: Crystallization at Electrochemical Interfaces
Session Chairs: Jingshan Du and Hua Zhou
Tuesday Afternoon, November28, 2023
Hynes, Level 3, Room 302

1:30 PM *EN10.04/SF02.04.01
Structure Stabilization in Layered Transition Metal Oxide Positive Electrodes for Sodium Ion Batteries DewenHou[1,2], EricGabriel[1,2], KincaidGraff[1], YifanDong[1], TianyiLi[2], YuziLiu[2], ChengjunSun[2] and HuiXiong[1]; [1]Boise State University, United States; [2]Argonne National Laboratory, United States

Sodium-ion batteries (SIBs) have stepped into the spotlight as a promising alternative to lithium-ion batteries (LIBs) for large-scale energy storage systems. However, the stability and performance of sodium ion battery electrode materials are lacking compared to their lithium counterparts as a consequence of the larger size of the Na^+ ion compared to Li^+. The layered transition metal oxide (LTMO) positive electrodes have attracted extensive attention for SIBs due to its favorable electrochemical performance. However, they suffer from complex and irreversible phase transitions during cycling, which leads to the chemomechanically-induced structural degradation and rapid capacity decay, limiting its practical applications. In this talk, we will discuss our recent progress in stabilizing LTMO structures during cycling and the origin of the phase interface's influence on the Na^+ storage and transport properties. *In situ*/operando spectroscopic techniques used in our work to track the phase transitions will also be discussed.

2:00 PM EN10.04/SF02.04.02
Engineering Multifunctional Interfaces for Forming and Recycling Composite Electrodes BoNie and HongtaoSun; The Pennsylvania State University University Park, United States

Lithium-ion batteries (LIBs) have emerged as the leading energy storage technology, dominating the market over the past decade. While significant progress has been made in developing high-performance electrode materials, the overall performance of LIBs is often compromised when including other passive components (e.g., 40-60 wt%) such as current collectors, separators, and packaging. This study demonstrates an alternative approach to achieve high performance at the device level by increasing the electrode thickness and reducing the weight percentage of passive components in LIBsystems.
We present an effective and sustainable manufacturing process for engineering multifunctional interfaces in thick composite electrodes (*e.g.*, $LiNi_{0.8}Co_{0.1}Mn_{0.1}O_2$). By integrating hybrid materials into artificial "grain boundaries (GB)," we can consolidate, densify, and recycle electrode active material powders to fabricate thick cathode composites with improved volumetric and areal performance. To this end, the cold sintering process (CSP) was employed to co-sinter all constituents into a highly dense form (2.7-3.2 g cm^{-3}) with good interfacial stability. Notably, the introduction of a transient solvent (e.g., 5 vol% DMF) enables the integration of distinct materials (*e.g.*, hybrids and NMC811 powders) under low processing temperature (120 deg C) and appropriate uniaxial pressure (300 MPa).
Moreover, the resulting artificial hybrid "GBs" consist of an electrically conductive network (e.g., carbon nanofiber and graphene) and an ionic conductive network (e.g., polymer-ionic liquid gel (PILG)), facilitating fast charge transport pathways. The co-sintered thick electrodes (550 µm) exhibit outstanding battery performance in gravimetric (194 mAh g^{-1}), volumetric (418 mAh cm^{-3}), and areal (23 mAh cm^{-2}) metrics. This improvement enables enhanced energy and power outputs while reducing the weight and cost of passive components. Furthermore, the polymer component (*e.g.*, PVDF-HFP) can be dissolved in a selective solvent, allowing for the collection and reforming/resintering of NMC powders from the sintered electrodes, enabling direct recycling.
In addition, in-situ electrochemical impedance spectroscopy was employed to monitor impedance information during both the densification of the sintering process and the evolution of artificial "GBs" during the lithiation/delithiation process. By combining the variables of the sintering process and the composite composition, a data-driven model was developed to successfully predict the dominant variables and their corresponding optimal value ranges, showing promise for optimizing the composite electrode design.
Overall, our interface engineering approach provides a sustainable solution to address critical challenges in the fabrication, efficient charge transports, and recycling of high-performance battery electrodes.

A Study of Lithiation-Delithiation Kinetics for Porous 1D Silicon-Based Anodes NancyChen[1], MihirParekh[1], MortezaSabet[1], YiDing[2] and ApparaoM. Rao[1]; [1]Clemson University, United States; [2]U.S. Army DEVCOM GVSC, United States

While today's lithium-ion batteries (LIBs) use graphite anodes, their limited specific capacity (372 mAh g^{-1}) has pushed researchers towards exploring alternative anodes with high specific capacity. Silicon (Si) anodes with a specific capacity of 4200 mAh g^{-1} offer an attractive solution, especially because of silicon's abundance in the earth's crust. However, high volume expansion (400%) during lithiation-delithiation leads to fracture and rapid capacity deterioration. This has limited the widespread adoption of Si-based anodes. We developed electrodes based on porous one-dimensional (1D) quill-like structures, aka Si nano-quills (SiNQ), to overcome these issues. Half cells equipped with SiNQ-graphite electrodes (containing 15 wt% SiNQ as the active material) exhibited an impressive initial reversible capacity of 527 mAh g_{Si}^{-1} at a current density of 90 mA g^{-1}, along with an outstanding capacity retention of 80.2% across 200 cycles. This starkly contrasts with anodes containing 15 wt% commercial Si nanoparticles, which could only manage an initial reversible capacity of 375 mAh g_{Si}^{-1} and a significantly lower capacity retention of 44.8% over the same number of cycles. Intrigued by this superior performance, we studied the lithiation-delithiation kinetics of SiNQ electrodes via the galvanostatic intermittent titration technique (GITT). GITT testing was performed between 0.01 V and 1 V with current pulses of 0.05C (210 mA g_{Si}^{-1}). Current pulses of 30 min duration were followed by a 6-hour rest period to allow the potential and built-up concentration gradients to relax. Unlike graphite intercalation electrodes, Si-based electrodes are phase transformation electrodes. So, lithiation-delithiation is accompanied by phase transformation in Si-based electrodes. While GITT-based models for phase transformation electrodes such as $LiFePO_4$ exist in the literature **[1]**, they do not account for electrode porosity and curvature. As a result, a novel model that accounts for the effects of phase transformation, electrode porosity, and electrode curvature on lithiation-delithiation kinetics was developed to fit the experimental data. Diffusion coefficients as a function of the state of charge were obtained and will be presented.

Controlling Electrochemical Deposition of 2D Zinc Metal Plates on Copper Substrates in Aqueous Electrolytes YingXia[1,2], JinhuiTao[2], JamesJ. De Yoreo[2,1] and JunLiu[1,2]; [1]University of Washington, United States; [2]Pacific Northwest National Laboratory, United States

Polyethylene glycol (PEO) is a commonly used polymer in the field of batteries for achieving flat and uniform electrodes to enhance the performance of batteries, such as lithium batteries and zinc (Zn) batteries. However, the impact of PEO on the electrochemical deposition of Zn metal on electrodes remains uncertain. In this study, we selected $ZnSO_4$ solution as electrolyte and copper (Cu) substrates as electrodes, which are widely applied in Zn batteries. We used *in situ* electrochemical atomic force microscopy (EC-AFM) to observe the nucleation and growth of Zn metal plates on the Cu substrate in the presence of different concentrations of $ZnSO_4$ and PEO additives. Our results indicate that PEO biases the crystallographic orientation of the initially deposited Zn metal nuclei, but does not have an obvious influence on subsequent growth. Based on our findings, we hypothesize that PEO primarily interacts with the Cu substrate to adjust the interfacial energy of the Cu-electrolyte interfaces. In contrast, due to the lack of apparent change in the Zn growth rate, we postulate that PEO has limited interaction with Zn^{2+} ions in the $ZnSO_4$ solution and thus does not strongly influence the activity coefficient of Zn^{2+} ions. The consistent aspect ratio of the Zn plates combined with the lack of an effect on growth rates further suggests that PEO does not interact significantly with the surface of the newly formed Zn plates. Our findings provide both insight into the underlying mechanism by which PEO promotes electrode flattening in Zn batteries and a standardized protocol for elucidating the impact of additives on the morphological evolution of interfaces during electrochemical deposition.

Directing Polymorph Specific Calcium Carbonate Formation with *De Novo* Protein TemplatesFatimaDavila-Hernandez[1], BiaoJin[2], PylesHarley[1], ShuaiZhang[1], ZhemingWang[2], TimothyF. Huddy[1], Chun-LongChen[2], JamesJ. De Yoreo[2] and DavidBaker[1]; [1]University of Washington, United States; [2]Pacific Northwest National Laboratory, United States

Biomolecules modulate inorganic crystallization to generate hierarchically structured biominerals, but the atomic structure of the organic-inorganic interfaces that regulate mineralization remain unknown. We hypothesized that heterogeneous nucleation of calcium carbonate could be achieved by a structured flat molecular template that pre-organizes calcium ions on its surface. To test this hypothesis, we designed helical repeat proteins (DHRs) displaying regularly spaced carboxylate arrays on their surfaces and found that both protein monomers and protein-Ca2+ assemblies directly nucleate nano-calcite with non-natural (110) or (202) faces while vaterite, which forms first absent the proteins, is bypassed. The nanocrystals then assemble by oriented attachment into calcite mesocrystals. We find further that nanocrystal size and polymorph can be tuned by varying the length and surface chemistry of the designed protein templates. Thus, bio-mineralization can be programmed using de novo protein design, providing a route to next-generation hybrid materials.

Interfacial Engineering of Catalyst and Battery Materials using Atomic Layer Deposition NeilP. Dasgupta; University of Michigan, United States

The ability to manipulate the properties of surfaces and heterogeneous interfaces using atomically-precise synthesis methods is of critical performance in electrochemical applications. In particular, the ability to "turn on" desirable properties (such as fast interfacial kinetics and stable activity), while "turning off" undesirable properties (such as chemical and/or morphological instability) is of increasing importance as the demands for high performance, long lifetimes, and stability continue to increase. To address these challenges, in this talk, I will describe key advances in the application of Atomic Layer Deposition (ALD) as an enabling technology platform for the atomically-precise modification of surfaces and interfaces for applications in two key electrochemical application spaces: electrocatalytic CO_2 reduction and rechargeable batteries.

I will demonstrate how ALD modifications can allow for rational control of interactions at heterogeneous interfaces, which can be used to tune the thermodynamic stability, kinetic activity, and mass transport properties of these integrated material systems. I will describe examples of the ALD process for conformal modification of gas diffusion electrodes and composite battery electrodes. I will also provide a perspective on challenges to scale-up design and manufacturing of these energy material systems at length scales ranging from atoms to meters.

4:00 PM EN10.04/SF02.04.07
Fabricating Dendrite-Free Porous Hosts of Li for Li-Metal Batteries via Electrodeposition. YifanMa and HailongChen; Georgia Institute of Technology, United States

Li metal anode is the ultimate choice for Li-chemistry-based batteries owing to its highest theoretical capacity (3860 mAh/g). Yet, the safety problems and low Coulombic efficiency resulting from Li dendrites are the remaining challenges for commercial applications.

Previously, we reported a 3D porous Cu current collector fabricated via a facile one-step electrodeposition method directly on commercial Cu foils. [1] This 3D porous Cu current collector showed stable long-term cycling with a high areal capacity up to 6 mAh/cm^2 without Li dendrites formation. However, for this one-step electrodeposition method, the thickness of the porous Cu layer is limited. Recently, we developed a new two-step electrochemical process to fabricate thick and porous Cu layers [2]. A thick Cu-Zn alloy was first electrodeposited on commercial Cu foil, and Zn was then removed electrochemically, leaving a thick and highly porous 3D Cu layer. Compared to our previous method, this 3D Cu layer has a high thickness of ~14 um and porosity of ~72%. This new 3D Cu current collector can achieve stable Li cycling up to 230 h at a high areal capacity of 10 mAh/cm^2 at a current density as high as 10 mAh/cm^2, demonstrating its high commercial application potential in Li-metal batteries. In situ XRD method was used to reveal the deposition of CuZn alloy and the electrochemical dissolution of Zn.

Computatonal Modeling of Nucleation at the Anode-Electrolyte Interface in Lithium Batteries MadisonMorey and EmilyRyan; Boston University, United States

The Lithium (Li) Metal Battery (LMB), which possesses a Li Metal anode has come to the forefront of many researchers' efforts to combat the energy storage limitations of the Li-Ion Battery (LIB). This is due to the large theoretical capacity that the Li metal anode (~3860 mA h g^{-1}) possesses in comparison with the graphite anode (~372 mA h g^{-1}) of the LIB. However, a main hindrance to the commercialization of these batteries is an unstable interface and uncontrolled dendrite growth, which pose serious safety concerns. While the growth process has been extensively studied, little is known about the nucleation process and how early nucleation effects dendrite growth throughout cycling. Due to the nature of the anode-electrolyte interface, it is difficult to study experimentally so we can use computational methods to resolve this interface and track the complex chemical and physical phenomena at this location. In this work we propose a computational model that uses a nucleation rate equation, stemming from Classical Nucleation Theory, to study how the electrochemical nucleation rate is impacted by varying parameters at the anode-electrolyte interface. The rate equation is then coupled with an extended, concentration dependent, Butler-Volmer equation to solve for the flux at the interface. Finally, the model is used to evaluate how surface energy impacts Li dendrite nucleation and growth.

4:30 PM EN10.04/SF02.04.09
***In Situ* Formation of Li^+ Ion Conductive Layers as the Solid Electrolyte Interphase (SEI) in Lithium Metal Batteries**DaewookKim and Hye RyungByon; Korea Advanced Institute of Science and Technology, Korea (the Republic of)

The desired solid electrolyte interphase (SEI) on metallic Li plays a crucial role in preventing continuous electrolyte decomposition and Li dendrite growth. Promising SEI components such as lithium fluoride (LiF), lithium nitride (Li_3N), lithium oxide (Li_2O), and lithium carbonate (Li_2CO_3) exhibit reasonable conductivity and mechanical robustness. In contrast, carbonaceous components are soluble and loosely cover the Li surface, leading to ongoing electrolyte decomposition. Typically, these inorganic and organic species are randomly mixed and form passivating films along with dead Li^0. Recent advancements have introduced localized high-concentration electrolytes or weakly coordinating solvents to establish inorganic-rich SEI composites. However, there is a lack of comprehensive studies on Li deposition and stripping processes over the SEI for long-term cycling, leaving the question of the cell-degradation process unanswered.
Herein, we demonstrate the formation of two passivating films by controlling 1,2-dimethoxyethane (DME)/1,3-dioxolane (DOL) ratios, while maintaining fixed concentrations of the lithium bis(fluorosulfonyl)imide (LiFSI) and $LiNO_3$ in Li|Li symmetric cells. The electrolyte solutions with a higher proportion of DME formed porous films after 30 cycles. Remarkably, continuous Li deposition was observed above these porous films, indicating their mixed ionic and electronic conduction properties. A passivating film grew as cycling proceeded, reaching a thickness of ~40 μm after 100 cycles. In contrast, the electrolytes with a higher proportion of DOL formed dense and particulate-shaped films. Interestingly, Li deposition occurred beneath these films, maintaining a thickness of < 15 μm. Thus, it is plausible that the dense film acted as a Li^+ ion conductor. X-ray photoelectron spectroscopy and titration gas chromatography revealed the presence of predominant dead Li, Li_2O, and Li_2CO_3 in both passivating films. However, the dense film exhibited a higher Li content and a lower carbon atomic ratio (less than 5 atomic %) than the porous film. We attributed the predominant DOL-based electrolyte with weak coordination properties to contribute to forming anion-derived inorganic components. Cell degradation started over 400 h, accompanied by increased carbon contents on the film surface and reduced Li contents. In the presentation, I will discuss the role of electrolytes in the formation of distinct passivating films and their impact on the overall performance of $LiFePO_4$-based full-cell configurations.

4:45 PM EN10.04/SF02.04.10
Electrodeposition of Conformal Ultrathin Functional Polymer Interphases JoergG. Werner, WenluWang, ZhaoyiZheng and RuiyangChen; Boston University, United States

Sub-micron interphases and coatings determine surface and interfacial properties of materials, which in turn are often dominant factors in defining their performance in applications and devices. Especially in electrochemistry, interfacial processes including charge and mass transfer depend on the nanometric environment around the electrode surface, which can be tailored with functional interphases. Polymer chemistry offers a large toolbox of molecular functionalities to create coatings and interphases with desired properties, but conformal deposition of uniform ultrathin films on micro- and nanostructured electrodes in batteries, fuel cells, and electrocatalytic systems remains elusive. Hence, new coating methods are required to achieve ultrathin uniform interphases that allow for tuning and tailoring of interfacial electrochemical processes in application-relevant electrodes. Here, we present a strategy to achieve conformal ultrathin coatings of functional polymers on porous and conductive materials with arbitrarily complex architecture through a novel electrodeposition paradigm. Our fabrication method separates the controlled deposition chemistry from the polymer properties through rational molecular design, making it agnostic and applicable to many polymer compositions and functionalities. We demonstrate how deposition and molecular parameters determine the interphase properties, including molecular permeability and thickness from 10s to 100s of nanometers, which in turn enables tunability over interfacial properties under electrochemical conditions such as modulation of the double layer and activation/passivation of molecular species. We envision our process to enable novel electrochemical material, composite, and device architectures with advanced performance characteristics, and serve as tailored model systems in mechanistic studies from electrocatalysis to energy storage.

Direct Observation of Lattice-Strain-Induced Oxygen Release in $LiCoO_2$ and Li_2MnO_3 Bypassing Electrochemical Cycling DonghoKim[1], JaejinHwang[2], PilgyuByeon[1], JaekwangLee[2] and Sung-YoonChung[1]; [1]Korea Advanced Institute of Science and Technology, Korea (the Republic of); [2]Pusan National University, Korea (the Republic of)

As the layered Li transition-metal oxides are a well-known material family for cathodes in Li-ion batteries, intensive studies have been carried out to elucidate the correlation between structural change and capacity/voltage fading. Among the several phenomena, the significant role of oxygen redox in enhancing the capacity of these cathode materials has brought critical issues of oxygen release with structural change and subsequent capacity fading, which should be addressed to improve electrochemical performance. Previous research predominantly employed electrochemically cycled cathodes, resulting in notable findings regarding cation migration, phase transformation, nanoscale voids/cracks formation, and even molecular O_2 trapped within the bulk during oxygen release. Despite recent studies focusing on the influence of microstrain to comprehend the correlation between structural degradation, oxygen loss, and voltage/capacity fading, the simultaneous integration of electronic, electrochemical, and mechanical factors presents a formidable task.

In this study, we examine the local variations of the atomic structure and oxygen content of single-crystalline layered Li transition-metal oxide model system to investigate the role of lattice strain in the oxygen release phenomena. In addition to mechanical surface polishing, the nanoindentation technique is also utilized to apply concentrated load to cathode materials. With intensive acquisition of conventional scanning transmission electron microscopy (STEM) and phase-contrast high-resolution electron microscopy (HREM) images at the atomic scale, we confirm that both types of mechanical strain induce local disordering of Li-*M* (*M* = Co, Mn) and subsequent amorphization. To establish the generality of this hypothesis, two single-crystalline layered oxide cathode materials, $LiCoO_2$ and Li_2MnO_3 were employed. Spectroscopic analyses also reveal a significant oxygen deficiency in the structurally altered regions, which is confirmed by the energy-dispersive X-ray spectroscopy (EDS) and electron energy loss spectroscopy (EELS) spectrum. Density functional theory (DFT) calculations further support the energetic preference of oxygen vacancy formation under shear strain compared to other types of strain. The most remarkable finding of this paper is that significant oxygen release can be induced solely by mechanical strain, even without electrochemical cycling. Moreover, this study highlights effective strain relaxation as a promising approach to enhance the structural stability of the anion framework in layered oxide cathodes.

8:00 PM EN10.07.02
Acid-and Gas-Scavenging Electrolyte Additive Improving the Electrochemical Reversibility of Ni-Rich Cathodes in Li-Ion Batteries ChaeeunSong[1], HyeongyuMoon[1], KyungeunBaek[2], ChorongShin[3], KwansooLee[3], Seok JuKang[2] and Nam-SoonChoi[1]; [1]Korea Advanced Institute of Science and Technology, Korea (the Republic of); [2]Ulsan National Institute of Science and Technology, Korea (the Republic of); [3]LG Energy Solution Ltd., Korea (the Republic of)

In view of their high theoretical capacities, nickel-rich layered oxides are promising cathode materials for high-energy Li-ion batteries. However, the practical applications of these oxides are hindered by transition metal dissolution, microcracking, and gas/reactive compound formation due to the undesired reactions of residual lithium species. Herein, we show that the interfacial degradation of the $LiNi_{0.9}Co_xMn_yAl_zO_2$ (NCMA, $x + y + z = 0.1$) cathode and the graphite (Gr) anode of a representative Li-ion battery by HF can be hindered by supplementing the electrolyte with *tert*-butyldimethylsilyl glycidyl ether (tBS-GE). The silyl ether moiety of tBS-GE scavenges HF and PF_5, thus stabilizing the interfacial layers on both electrodes, while the epoxide moiety reacts with CO_2 released by the reaction between HF and Li_2CO_3 on the NCMA surface to afford cyclic carbonates and thus suppresses battery swelling. NCMA/Gr full cells fabricated by supplementing the baseline electrolyte with 0.1 wt% tBS-GE feature an increased capacity retention of 85.5% and deliver a high discharge capacity of 162.9 mAh/g after 500 cycles at 1 C and 25 °C. Thus, our results demonstrate that the molecular aspect–based design of electrolyte additives can be efficiently used to eliminate reactive species and gas components from Li-ion batteries and increase their performance.

8:00 PM EN10.07.03
Modified Viologen-Assisted Reversible Bromine Capture and Release in Flowless Zinc–Bromine Batteries Seung HeeHan[1], SeoyoungKim[2], Hyeong YongLim[2], SewonPark[1], KyungjaeShin[1], SeungwonKim[1], Hee-TakKim[1], Sang KyuKwak[3], ChangdukYang[2] and Nam-SoonChoi[1]; [1]Korea Advanced Institute of Science and Technology, Korea (the Republic of); [2]Ulsan National Institute of Science and Technology, Korea (the Republic of); [3]Korea University, Korea (the Republic of)

Flowless Zn–Br_2 batteries exhibit considerable potential for energy storage system applications, which require the principal features of high safety, low cost, and long-term cycle stability. However, central challenges such as uncontrolled bromine crossover to anodes and aqueous electrolyte decomposition producing gases lead to a low cycle performance of batteries. Herein, we demonstrate that the introduction of bis(2-trimethylammonio) propyl viologen tetrabromide ($PV(Br)_4$) onto a graphite felt (GF) electrode ($PV(Br)_4$/GF) improves the cycle stability of flowless

$Zn–Br_2$ batteries comprising a 2.5 M aqueous $ZnBr_2$ electrolyte as the Zn and Br sources. During charging, $PV(Br)_4$ entraps corrosive and volatile Br_2 formed inside the GF electrode via favorable interactions with the four Br^- anions of $PV(Br)_4$, while polybromide anions are produced via an electrochemical-chemical growth mechanism. Furthermore, the $PV(Br)_4$ on the GF electrode reversibly releases Br^- into the electrolyte through the electrochemical reduction of entrapped polybromide anions during discharging. In addition, the spatially anchoring $PV(Br)_4$ on a GF electrode suppresses undesired oxidative decomposition of water by minimizing the physical contact with the electrode, thereby mitigating the depletion of the electrolyte during cycling. Suppression of O_2 evolution contributes to mitigation of inhomogeneous plating and vertical growth of Zn metal at the Zn anode. Consequently, a flowless $Zn–Br_2$ battery with a $PV(Br)_4$/GF electrode exhibits a high Coulombic efficiency of 95.6% over 400 cycles with a current density of 10 mA cm^{-2} and high areal capacity of 24.3 mAh cm^{-2}.

8:00 PM EN10.07.04
Single-Phase Perovskite $BaIrO_3$ Nanofibers as an Efficient pH Sensor Hee AhOh, KyungminKim, JuheeYang, YejinKim, SubinChoi, YoungmiLee and Myung HwaKim; Ewha Womans University, Korea (the Republic of)

pH sensors are utilized in various fields such as biomedical applications, food quality evaluation, and the nuclear and gas industries. Metal oxide pH sensors are extensively studied due to their biocompatibility. When a sensor is immersed in the analyte, water is adsorbed onto the surface, and this adsorbed water interacts with the hydronium ions of the analyte through proton hopping. Consequently, pH can be measured by monitoring the potential change on the sensor's surface. Among these sensors, IrO_x is recognized as the most efficient pH sensor due to its ability to be manufactured through electrodeposition, its wide range of stable reactivity, and its suitability for in vivo use. However, IrO_x is prohibitively expensive and has limitations for long-term use due to delamination. To address these issues, extensive researches are being conducted to reduce the unit price and improve sensitivity by alloying Ir with other metals. This study introduces $BaIrO_3$, a perovskite-structured material in which Ba and Ir are alloyed using electrospinning which is a well-known and facile method for synthesizing metal oxide nanofibers. The single-phase perovskite $BaIrO_3$ is then characterized using Field Emission Scanning Electron Microscopy (FE-SEM) and X-ray Diffraction (XRD) techniques, and it is compared with IrO_2. Subsequently, the pH sensitivity of $BaIrO_3$ is demonstrated potentiometrically, in comparison to IrO_2. The sensing performance of $BaIrO_3$ nanofiber was found to be comparable to IrO_2. It indicates that even with half of the amount of Ir, $BaIrO_3$ exhibits similar reactivity, making it much more cost-effective than using Ir alone. Additionally, $BaIrO_3$ demonstrated greater stability in extreme pH conditions. While further research is needed, these findings suggest that $BaIrO_3$ could be utilized as a pH sensor that is not only more economical but also highly stable. Subsequent studies will explore the commercial potential of $BaIrO_3$ for practical applications.

8:00 PM EN10.07.05
A Sustainable Cycle to Extract Valuable Metals and Green Hydrogen from Waste Brines DongqiYang[1], SaowalukSoonthornkit[1], AlvinChang[1], Chih-hungChang[1], KelseyStoerzinger[1], AstridLayton[2] and ZhenxingFeng[1]; [1]Oregon State University, United States; [2]Texas A&M University, United States

Driven by the global goal of achieving a net-zero emissions economy, green hydrogen (GH2) has emerged as a prominent solution for energy storage. However, its widespread adoption is hindered by high production costs. Similarly, the production of critical metals such as lithium has been limited in certain geographical locations, leading to uncertainty in the supply chain and the price increase. Additionally, the production of saline waste presents an environmental challenge, with potential damage amounting to over $1 million per 100 gallons per minute. To address these issues, a dual solution is proposed: coupling mineral desalination, such as Lithium extraction, with cost-effective GH2 production through water splitting. This integrated approach establishes a sustainable and circular process that extracts GH2 and value-added minerals from waste brines (e.g., seawater) while addressing environmental concerns.
Our project aims to create value by extracting Lithium and other valuable metals from the waste brines of desalination plants, oil or gas industries, and semiconductor companies. A significant portion of Lithium salt will be extracted and sent to companies for further processing, while the purified water will be produced simultaneously in this process. The purified water will be subjected to water splitting, generating green hydrogen that can be utilized in various sectors, including agriculture, transportation, and the electricity grid. The extraction of additional metals from brines is possible when combining membrane technologies. We will create a circular process for its self-sustainability and energy efficiency. A model that can extract 368 kg lithium per day from seawater via solar thermal energy was already under testing and a prototype of a small 4cm*4cm PEME using a double perovskite OER catalyst was under construction.

8:00 PM EN10.07.07
Interface Controlled Hybrid Carbon Bilayer Anode for Improved Ion Transport and Reaction Stability of Li Ion Battery Myoung-HoKim, MinsubOh, Hye-MiSo, Nigussh. Hatsey and SeungminHyun; Korea Institute of Machinery and Metals, Korea (the Republic of)

Li ion batteries (LIB) with high energy density and high power density are required due to the emerging market of electrical vehicles and other smart products. The dominant anode in current commercial LIBs is graphite owing to its low redox potential, good stability, and low cost. However, its effective capacity is drastically reduced owing to poor reaction rate during fast charge and discharge. To overcome this, graphite is mixed with other carbon materials, such as soft carbon (SC) and hard carbon (HC), as well as non-carbon materials. Carbon-based materials have a low cost and require relatively simple processing, and they are more chemically and mechanically stable than non carbon materials. They are the primary choices for mixtures with spherical crystalline graphite(SCG). Among carbon-based materials, SC is less expensive than HC and does not require high-temperature heat treatment. Although SC has a lower energy density than SCG, it allows for the rapid movement of ions through multiple edge planes. In this study we fabricated a novel bi-layered and patterned anode electrode to enhance the performance of the electrode by converging the idea of material blending, bi-layer structure, and patterned interface. The bilayer structure, which is different from that of the conventionally blended SCG/SC electrode, aims to stabilize the reaction with the electrolyte at the electrode surface while fully utilizing the bottom section of the electrode. Specifically, in our bilayer structure, the blended SC/SCG material was placed at the bottom and SCG alone was coated onto the top to maintain a stable electrode surface. The electrode pattern interfaces, which are optimized by controlling the pattern size, secure excellent mechanical adhesion and low internal resistance. The electrochemical performance of the bi-layered and patterned electrode was measured and compared with a single SCG electrode and with a conventionally blended SCG/SG electrode. The discharging current density, initial coulombic efficiency, and voltage plateau of these alternative structures were also compared by fabricating half cell. The improved performances of bi-layered and patterned electrode in the half-cell battery achieved high capacity retention of of 85.9% after 500 cycles at 1C. In addition, the full cell also attained and high energy density of 178.7.7Wh kg^{-1} at 10C, which is 2.3 times higher than that of the single-layer SCG electrode

8:00 PM EN10.07.08
Surface Stabilization of Single-Atom Catalyst on Metal Oxide Derived by Metal Hydroxide-Organic Frameworks SungyoonWoo; Korea Advanced Institute of Science and Technology, Korea (the Republic of)

Single-atom catalysts (SACs) have been attracted as promising sensitizers in gas sensors due to their high catalytic activity and efficient atomic utilization. To synthesize SACs-anchored materials, metal-organic frameworks (MOFs) have been widely employed as sacrificial templates owing to their structural flexibility and high surface area. However, in this approach, only carbon-based materials have been allowed as target products since structural deformation between ligand and metal nodes should be sufficiently minimized to stabilize SACs during the transformation. Herein, we propose a novel synthetic route to fabricate metal-oxide-supported SACs by utilizing metal hydroxide-organic frameworks (MHOFs) with noble metal chelated linkers as templates. Highly ordered metal hydroxide layers and numerous π-stacked MHOFs linkers provide stable binding sites for SACs during the complete transformation from MOFs to metal oxide. Thereby, a high concentration of SACs can be stabilized on metal oxide without aggregation and doping of catalysts. The resultant Pt SACs-anchored NiO showed enhanced activity for chemiresistive sensing of H_2S. Furthermore, the high structural diversity of MHOFs would allow the extension of this approach to other catalysts and metal oxides for targeting various analytes.

8:00 PM EN10.07.09
Dendrite-Free Zinc Anode Enabled by Buffer-Like Additive via Strong Cationic Specific Absorption ZiweiZhao; University of Alberta, Canada

Metallic zinc-based anodes suffer low reversibility from dendrite growth, hydrogen evolution reaction, and by-product generation during the Zn^{2+} striping/plating process. Herein, the novel electrolyte additive (histidine) was introduced into the conventional $ZnSO_4$ electrolyte. The strong cationic specific absorption between the additive molecule and zinc anode regulated the behavior of Zn^{2+} deposition and inhibited hydrogen evolution reaction. Significantly, the unique buffer-like amphoteric functional groups on histidine can further alleviate by-product generation by stabilizing electrolyte interphase pH value. With such an electrolyte additive, Zn||Zn symmetric cell can run for more than 3000 h under the current density of 2 mA cm^{-2}. When zinc anodes were coupled with an activated carbon cathode with a mass loading of 8 mg cm^{-2}, the powering device showed high reversibility. This strategy can give insight into developing zinc anode with high stability.

8:00 PM EN10.07.10
First Principles Modeling of Polaron Formation and Optical Signature on Titanium-Based Oxides for Oxygen Evolution Reaction Photocatalysis ShayMcBride[1], MichaelPaolino[2], TanjaCuk[2] and GeoffroyHautier[1]; [1]Dartmouth College, United States; [2]University of Colorado Boulder, United States

The exact mechanism and surface coverage present on (photo)-catalysts used for the oxygen evolution reaction (OER) remain elusive. Ultra-fast spectroscopy on model single crystal surfaces has started to clarify these questions but would benefit from more first principles theoretical support to facilitate the interpretation of the spectroscopic signatures. Here, we focus on the first principles modeling of the optical signature of polarons on OER intermediates on titanium-based photocatalysts (e.g., $SrTiO_3$ and TiO_2). The trapping of photo-generated holes by polarons on adsorbs at the catalyst surface is a key step in the photo-driven OER. We report from first principles on how the polarons formation process and optical signature changes with adsorbates

(OH_2, OH, O) on different surfaces and compare with experimental results when available. Our work is a first step towards a better connection between ultra-fast spectroscopy and first principles computations.

Co-Catalyst Optimization for Photoelectrochemical Hydrogen using Tandem III-V Semiconductors KeenanW. Wyatt[1,2], ToddG. Deutsch[2] and MichaelF. Toney[1]; [1]University of Colorado Boulder, United States; [2]National Renewable Energy Laboratory, United States

Direct photoelectrochemical (PEC) solar-to-hydrogen conversion on a III-V surface uses highly efficient photo absorbers for charge generation and separation. This route to hydrogen from sunlight and water can theoretically reach the highest conversion efficiencies. Pt and PtRu nanoparticles reduce the kinetic overpotential for water splitting and are deposited on the III-V surface via DC magnetron sputtering. The amount of co-catalyst balances kinetic improvements for the water splitting with photon absorption. Too many co-catalyst particles will begin to block light and degrade device performance. Here, we have optimized the amount sputtered co-catalyst for device efficiency and durability. Traditional PEC devices use p-type semiconductors as photocathodes however, our device structure adopts a buried pn junction with a wide bandgap window layer to eliminate surface recombination and a capping layer to protect the window layer from dissolution as it is Pourbaix unstable at every pH. We operate in a neutral electrolyte and have achieved over 100 hours of stability at short circuit with greater than 5% solar-to-hydrogen efficiency.

***In-Situ* AFM Observation of Solid Layer Formation at a Superconcentrated Electrolyte/Electrode Interface**AkitoKobayashi[1], TaketoshiMinato[2], KatsuyoshiIkeda[1] and KentaMotobayashi[1]; [1]Nagoya Insitute of Technology, Japan; [2]Institute for Molecular Science, National Institutes of Natural Sciences, Japan

1. Introduction
Lithium-ion batteries have high convenience and prevalence but have safety issues due to the volatility and flammability of organic electrolytes. Superconcentrated electrolytes have attracted considerable attention for their low volatility and flammability owing to extremely high electrolyte concentration in which all solvent molecules interact with Li^+ [1]. For reversible charge/discharge, solid layers on the electrode surfaces play important roles and are known to be produced by reductive decomposition of solvents for dilute electrolytes which limits the choice of available solvents [2]. On the other hand, reversible charge/discharge can be realized with various solvents for superconcentrated electrolytes [1], indicating different origin of the interfacial layers; however, details are still under discussion.
To elucidate the origin and formation process of the interfacial layers, we performed *in-situ* chemical and mechanical analysis of the superconcentrated electrolyte/electrode interface. Here we focus on potential-dependent mechanical properties of the interface analyzed by atomic force microscopy (AFM) combined with electrochemical techniques.

2. Experimental
Lithium bis(trifluoromethanesulfonyl)amide (LiTFSA) was dissolved in acetonitrile at concentration of 4.2 M to obtain the superconcentrated electrolytes. Au thin film deposited on a cleaved mica substrate (Au/mica), Pt mesh, and Pt wire were used as the working, counter and quasi-reference electrodes, respectively. Mechanical properties of the interface were analyzed through force curve measurements with AFM at 1024 points at each potential (4.0 V to 1.0 V vs Li/Li^+ where negligible Faradaic process was observed). All the measurements were carried out in an Ar atmosphere.

3. Results and Discussion
The Young's modulus of the interface derived from a force curve measurements were ~58 GPa at the potential more positive than 1.5 V, corresponding to that measured for bare Au/mica in air, and decreased to 30 GPa at more negative potentials. On the other hand, simultaneously derived adhesion force shows an increase at 1.5 V, suggesting an increase in local viscosity at the interface, and decreased again at more negative potentials. These results are compared with our model for solid layer formation based on the insights from interface-selective spectroscopy. At 1.5 V, Li^+ was attracted to the negatively charged electrode, and TFSA anions are also come to the vicinity of the electrode because of Li-TFSA interaction. Then, as a results of oversaturation, a solid salt layer of LiTFSA is deposited on the electrode surface. The change in the Young's modulus of the interface observed in this study is consistent with this model where bare Au surface is covered by solid salt layer at more negative potentials. Increase in local viscosity probably reflects the locally oversaturated solution on the electrode exists at the start of the solid layer deposition. Thus, the quantitative analysis of viscoelasticity using AFM combined with spectroscopic results enabled us to identify the formation process of the solid layer at the superconcentrated electrolyte/electrode interface.

Development of High Entropy Oxides for use in Solid Oxide Fuel Cells HakanYüce, BerkePiskin, FatihPiskin and GulhanCakmak; Muğla Sitki Kocman Universitesi, Turkey

In recent years, energy consumption has been increasing with technological and industrial developments. This leads to the search for clean, efficient, economical, and sustainable energy sources. Among these sources, ceramic-based solid oxide fuel cells, which are considered among the most efficient FCs, draw attention. The solid oxide fuel cell is an electrochemical energy conversion device that converts the chemical energy of the fuel directly into electrical energy, attracting great attention due to its high efficiency, fuel flexibility, and environmental friendliness. However, high operating temperatures (800°C− 1000 °C) cause the cells to be short-lived. Reducing the operating temperatures to 600°C − 800 °C is one of the effective approaches to solving this problem. $La_{0.7}Sr_{0.3}MnO_3$ LSM shows outstanding electronic conductivity, excellent electrocatalytic activity, and good stability for oxygen reduction in the temperature range of 800°C -1000 °C, but its electrochemical performance is significantly reduced at reduced operating temperature.
In recent years, high entropy oxides have received increasing attention. High entropy oxides usually contain 5 or more elements with small proportions of minor elements and have high mixing entropy. They can be easily synthesized, produced, and analyzed. ABO3-type perovskite oxide is of interest for solid oxide fuel cells due to its unique dielectric, ferroelectric, pyroelectric, and catalyst properties.
Many high entropy oxides have been found to improve thermal characteristics, magnetic properties, catalytic activity, and energy storage and conversion performance, but have less application in solid oxide fuel cells. In this study, the potential application of $La_{0.5}Sr_{0.5}Co_{0.25}Fe_{0.25}Ni_{0.25}Cu_{0.25}O_3$ perovskites in medium temperature solid oxide fuel cells was investigated LSCFNC powder was synthesized using the sol-gel method. As starting chemicals, nitrates of all of the considered cations were used: $La(NO_3)_3 \bullet 6H_2O$, $Sr(NO_3)_2$, $Co(NO_3)2 \bullet 6H_2O$, $Fe(NO_3)_3 \bullet 9H_2O$, $Ni(NO_3)_2 \bullet 6H_2O$,$Cu(NO_3)_2 \bullet 3H_2O$.
First, the stoichiometric amount of these nitrates was dissolved in distilled water, then citric acid was added to the solution. The molar ratio of all cations and citric acid in the mixture was 1:2. The solution was heated to 80°C with continuous stirring with the aid of a magnetic stirrer. The resulting gel was dried at 250°C for 2 hours to remove residual organics and nitrates. The dried gel was calcined at 700°C, 900°C, 1100 and 1300°C for 6 hours. The phase analysis of the powders was performed by using X-ray diffraction (Rigaku SmartLab X) using monochromatic Cu Ka radiation at 40 kV and 200 mA. The structures are refined using the Maud program to identify their crystal structure.
YSZ Synthesis
Yttria-stabilized zirconia (YSZ) with general formula $(ZrO_2)_{1-x}(Y_2O_3)_x$ and $0.08 \leq x \leq 0.1$, is the most studied electrolyte for SOFCs. The best conductivity value is obtained for the compound containing 8 mol% of yttrium oxide. In this study, zirconia powders stabilized with 8 mol% yttria were synthesized using the sol-gel process. $ZrO(NO_3)_2.xH_2O$ and $Y(NO_3)_3.6H_2O$ were dissolved in and mixed in ethylene glycol, citric acid, and purified water, respectively. Then, $Y(NO_3)_3.6H_2O$ was added to $ZrO(NO_3)_2.xH_2O$ solution drop by drop and mixed to make YSZ solution.
After mixing, the temperature was raised to 80°C and the pH was adjusted to 3.6 with HNO_3. The resulting suspension was mixed until homogeneous. This white and milky mixture was dried at 120°C and sintered at 1200°C for 2 hours.
The synthesis and analysis in this study are currently ongoing. In this circumstance, we will perform the analyses below:
1. A morphological analysis using a scanning electron microscope (SEM) and chemical analysis employing Energy Dispersive Spectroscopy (EDS) will be conducted to examine the physical characteristics and elemental composition of the samples.
2. Charge/discharge tests will be performed with symmetrical cell coating on YSZ.

***In Situ* X-Ray Absorption Spectroscopy Study of Monodispersed Cobalt Phthalocyanine on Carbon Nanotubes as Electrocatalyst for Carbon Dioxide Reduction to Methanol**MasonLyons[1], ConorRooney[2], HailiangWang[2] and ZhenxingFeng[1]; [1]Oregon State University, United States; [2]Yale University, United States

Carbon dioxide (CO_2) is accumulating in the atmosphere, causing entrapment of thermal energy and more chaotic weather. To sustainably decumulate the atmospheric CO_2 and sequester future emissions, it must be utilized in a circular economy. Upcycling of CO_2 to value added products such as hydrocarbons and alcohols requires the use of catalysts, among which molecular catalysts are the most promising due to their product selectivity and high utilization of metals. Unlike many other catalysts which primarily produce the undesired carbon monoxide (CO)

intermediate, cobalt phthalocyanine (CoPc) non-covalently anchored on carbon nanotubes (CNTs) exhibits preferential formation of methanol (MeOH) from CO_2 due to a modified Co electronic structure. To investigate the electronic and geometric arrangements of CoPc-CNTs during CO_2 reduction, *in-situ* X-ray absorption spectroscopy (XAS) was employed. The pre-edge peaks at 7710 eV related to orbital mixing increased while the 7715 eV peak related to bonding centro-symmetry decreased, when scanning from open circuit voltage to -1.1 V vs Reference Hydrogen Electrode (RHE) indicating a higher density of states in Co $3d_z^2$ and axial coordination from CNT as well as C adsorbate, respectively. An absorption edge shift associated with Co reduction to Co(I) was also observed and persisted at MeOH producing conditions, previously only reported for CO producing systems. Fitting of the extended X-ray absorption fine structure (EXAFS) spectra confirmed the CoPc coordination and bond lengths with theoretical calculations as well as the presence of a carbon adsorbate at potentials more negative than -0.5 V vs RHE, enabling further CO reduction to MeOH. The rich information from *in-situ* XAS elucidated the structure-property relationship of this catalyst to explain the superior performance of CoPc dispersed on CNTs for CO_2 upgrade.

Designing Bilayer Oxide Chemiresistors Consisting of Rh Nanoparticle Loaded TiO_2 Catalytic Overalyer ans SnO_2 Sensing Layer for Highly Selective and Sensitive Detection of Volatile Aromatic Compounds Young KookMoon; Korea Institute of Materials Science, Korea (the Republic of)

Oxide chemiresistors have mostly been used to detect reactive gases such as ethanol, acetone, formaldehyde, nitric dioxide, and carbon monoxide. However, the selective and sensitive detection of volatile aromatic compounds such as benzene, toluene, and xylene (BTX), which are extremely toxic and harmful, using oxide chemiresistors remains challenging because of the molecular stability of benzene rings containing chemicals. Moreover, the performance of the sensing materials is insufficient to detect trace concentration levels of BTX, which lead to harmful effects on human beings. Herein, novel bilayer sensors consisting of a SnO2 sensing layer and three different xRh-TiO2 catalytic overlayers (x = 0.5, 1, and 2 wt%) are designed for the selective detection, discrimination, and analysis of benzene, toluene, and p-xylene. The 2Rh-TiO2/SnO2 bilayer sensor shows a high selectivity and response toward trace concentration of benzene over a wide range of sensing temperatures. An array of three Rh-TiO2/SnO2 sensors can quantitatively discriminate aromatic compounds. The conversion of gases into more active species by gas reforming or into non-reactive forms by excessive catalytic promotion through the reaction with volatile armatic compoudns and nanosize noble metal catalysts are proposed as the reasons behind the enhancement and suppression of analyte gases, respectively. Analysis using proton transfer reaction-quadrupole mass spectrometer (PTR-QMS) is performed to verify the above proposals.

Polysulfide Chemisorption in Multiferroic Doped Sulfur/CNT Composite Cathode for High Energy Densities Li-S Batteries MohanK. Bhattarai[1], BalramTripathi[1,2], ShwetaShweta[1], RajeshKatiyar[1], ClaudiaZuluaga Gomez[1], BradWeiner[3], RamKatiyar[1] and GerardoMorell[1]; [1]University of Puerto Rico, Rio Piedras, United States; [2]S.S Jain Subodh PG College, India; [3]University of Puerto Rico, Río Piedras, United States

Herein, we are reporting the chemisorption effect of multiferroic doped sulfur/SWCNT cathode for Li-S batteries. Bismuth ferrite (BFO) is versatile multiferroic material having high polarization. We modified the composite cathode hydrothermally for the encapsulation of sulfur using SWCNT. The physical, morphological, and elemental analyses of cathode materials were studied using X-ray diffraction, Raman spectroscopy, SEM, EDX, and XRF techniques.
The electrochemical performance has been checked at various C -rates. In various C-rates conditions, we observed good cycle stability ~ 500 $mAhg^{-1}$ above 100 cycles at C/16 rate, and stable CE ~ 98% due to injection of BFO nanoparticles for chemisorption of polysulfide in the modified cathode. The detailed analysis will be presented during the meeting.
