Dislocation dynamics present a difficult simulation task for existing classical and ab initio methods due to the simultaneous accuracy and length-scale requirements for reliable simulation and comparison to experimental data. These limitations ultimately prohibit advanced understanding of plastic deformation (e.g. via edge and screw dislocations) of materials. Here, we develop a Bayesian machine-learned force field (MLFF) from first-principles training data that extends quantum-mechanical accuracy to large length-scale molecular dynamics simulations which permit direct observation of high-temperature and high-stress dislocation dynamics in Cu with atomistic resolution. In concert, a generalizable training protocol is defined for the construction of MLFFs for description of dislocations, which can be trivially employed for other metal and alloy systems of interest. The resulting FLARE MLFF provides excellent predictions of static bulk properties (e.g. bulk modulus and elastic tensor), stacking fault energies, and reliable, dynamic evolution of edge and screw dislocations, as well as cross-slip mechanisms that allow for non-planar movement of screw dislocations across a broad range of temperature and applied stress. Each of these observations from molecular dynamics simulations are then compared to experimental data, including the screw and edge stacking fault widths, edge dislocation mobility coefficient, and screw dislocation cross-slip activation energy, where FLARE provides the best agreement among the methods tested. Such simulations permit increased understanding of material responses to extreme conditions by direct atomistic insight at the mesoscale with near quantum mechanical accuracy.

Aniso-GNN: Physics-Informed Graph Neural Networks Generalizing to Anisotropic Properties of Polycrystals Guangyu Hu and Marat Latypov; University of Arizona, United States

We present Aniso-GNNs -- graph neural networks (GNNs) that generalize predictions of anisotropic properties of polycrystals to arbitrary loading directions without the need in excessive training data. To this end, we develop GNNs with a physics-inspired combination of node attributes and aggregation function. We further propose a new efficient training strategy leveraging fundamental symmetries of crystallographic orientations and textures as well as tensor properties of individual grains and polycrystals. We demonstrate the predictive power of Aniso-GNNs in modeling anisotropic elastic and inelastic properties of polycrystalline alloys in a wide range of loading directions without training data in those directions.

Efficient High-Throughput *Ab Initio* Prediction of Liquidus Curves Wenhao Sun; University of Michigan, United States

The liquidus curve captures the high-temperature eutectics, peritectics, congruent melting and incongruent melting regions of a phase diagram. Being able to predict liquidus curves would enable *ab initio* guidance of materials synthesis temperatures, as well as the design of materials stable under high-temperature operation conditions. Liquidus curves are available in databases like Thermocalc or SGTE, but the available chemical spaces in these databases lag far behind computational materials discovery efforts. Direct simulation of liquid free energies across broad chemical spaces is probably infeasible (even using machine-learned interatomic potentials) given the wide range of temperatures and compositions that must be sampled. Here, we

present a CALPHAD-inspired approach to reference liquidus curves from experimental ASM phase diagrams to DFT convex hulls from the Materials Project. Using this technique, we fit non-ideal liquid mixing free-energies on a 50x50 matrix of binary alloy phase diagrams. Using very simple machine-learning models, we can then predict liquid free energies in novel chemical spaces, including ternary or quaternary+ spaces, at a computational cost low-enough to be integrated with high-throughput DFT databases like the Materials Project. Our technique predicts liquidus curves, intermetallic melting temperatures, and three-phase invariant points (eutectics and peritectics) with surprisingly good accuracy, despite the known magnitude of formation energy errors in DFT convex hulls.

Identifying The Transition State in Structurally Unstable but Dynamically Stabilized Phases: A GPR-Assisted First Principles Methodology
Seyyedfaridoddin Fattahpour and Sara Kadkhodaei; University of Illinois at Chicago, United States

Numerous materials of technological importance feature high-temperature phases that exhibit phonon instabilities. Leading examples include shape-memory alloys, ferroelectric and refractory oxides, and some metal hydrides. I will introduce a new model for diffusion barrier calculation in these phases. Our model efficiently explores the system's diffusive transition path using the dimer scheme based on a Gaussian process regression (GPR) of the temperature-dependent energy surface. Our model simultaneously samples the temperature-dependent energy surface and converges the system towards the saddle point. Our method provides a useful alternative to methods such as molecular dynamics, which directly simulate diffusive hops. I present the application of this model for some example metals and oxides.

Machine Learning and Monte Carlo Simulations of The Gibbs Free Energy of The Fe-C System in a Magnetic Field
Ming Li[1], Luke Wirth[2], Ajinkya Hire[1], Stephen Xie[3], Michele Campbell[4], Dallas Trinkle[2] and Richard Hennig[1]; [1]University of Florida, United States; [2]University of Illinois at Urbana-Champaign, United States; [3]KBR, Inc., Intelligent Systems Division, NASA Ames Research Center, United States; [4]University of California-Merced, United States

To model the thermodynamics and kinetics of steels in response to high magnetic fields requires knowledge of the magnetic Gibbs free energy, which involves millions of energy evaluations for the potential energy landscapes as a function of the applied field in the configurational space. Although sufficiently accurate, density-functional theory (DFT) calculations would result in high computational cost, hindering its direct application.
To address this challenge, we take advantage of the ultra-fast force field (UF^3) method [1], a machine-learning potential that combines effective two- and three-body potentials in a cubic B-spline basis with regularized linear regression, to approximate the DFT energy landscape. We assembled a database by performing DFT calculations using the Vienna Ab initio Simulation Package (VASP). This DFT database focuses on the information of the energies and forces as a function of magnetic field for a series of bcc and fcc Fe(C) structures, throughout which both structural and magnetic configurations are varied. The UF^3 potentials are trained on this database to quickly evaluate the energies of ensembles based on the structural and spin configurations, and the accuracy of the resulting UF^3 models predicting energies and forces is validated.
Subsequent Monte Carlo simulations take place with these machine learning models implemented. Thermodynamic integration is utilized to combine the simulations at different temperatures to achieve the magnetic Gibbs free energy models for the two Fe(C) phases as a function of temperature, atomic fraction of carbon, and magnetic field. Our calculations aim to investigate the origin of the experimentally observed shift in the transition temperature of tens of kelvins under an applied field of 10 T [2].

Engineering Relative Stability in Four Dimensions with The Generalized Clausius-Clapeyron Relation
Jiadong Chen and Wenhao Sun; University of Michigan, United States

Sequential learning algorithms based on Bayesian optimization are routinely being deployed for materials stability optimization in high-parameter spaces. We anticipate these optimization methods would perform better if they were built upon stronger priors, for example, as derived from the fundamental thermodynamics underlying the equilibrium behavior of materials. Here, we present a thermodynamics-based technique to optimize the relative stability of a materials in high-dimensional thermodynamic space, based on a new derivation of a generalized high-dimensional Clausius Clapeyron relation. Using this thermodynamic infrastructure, we design several pathways to enhance the relative acid stability of Mn-oxides versus its dissolved states for potential electrochemical catalyst application. We construct a 4-D Pourbaix diagram with *p*H, redox potential *E*, particle radius 1/*R* and a chemical potential μ_K as axis. By exploring the gradients of the high-dimensional phase boundaries, we derive first-principles insights that nano-sizing (1/R) and certain doping ions (μ_K) can stabilize some metastable Mn-oxides polymorphs, where 1/R decreases acid stability and μ_K increases it. Our high-dimensional thermodynamic framework is a general method to engineer relative stability in parameter spaces that leverage multiple forms of thermodynamic work.

Rapid Discovery of Lightweight Cellular Crashworthy Solids for Battery Electric Vehicles using Artificial Intelligence and Finite Element Modeling
Edward J. Michaud[1,2] and Dayakar Penumadu[2]; [1]Volkswagen Group of America, United States; [2]The University of Tennessee, Knoxville, United States

Battery electric vehicles (BEVs) offer significant environmental benefits over traditional internal combustion engine (ICE) vehicles, including zero tailpipe emissions and improved energy efficiency. Despite this, typical BEV batteries can weigh up to 500kg, substantially heavier than a conventional vehicle's engine and fuel tank. This makes BEVs great candidates for lightweighting, offering improvements in driving range, acceleration, handling, and overall

efficiency. At the same time, these batteries must be protected from side-impact even further than a conventional ICE vehicle.
In this study, we aim to leverage computational modeling and artificial intelligence (AI) methods to lightweight the battery's protective structures beyond capabilities achievable by a typical human. Specifically, we focus on the methods necessary to fully train an artificial intelligence architectutre such that models can be rapidly generated and validated hundreds to thousands of times. Ultimately, this research will contribute to the development of more efficient and sustainable BEVs, which can help to mitigate climate change and reduce the environmental impact of transportation while maintaining or impmroving safety standards.

Chemical Environment Modeling Theory: Revolutionizing Machine Learning Force Field with Flexible Reference Points Xiangyun Lei, Weike Ye, Joseph Montoya, Tim Mueller, Linda Hung and Jens Hummelshoej; Toyota Research Institute, United States

This study introduces the Chemical Environment Modeling Theory (CEMT), a novel and powerful framework that generalizes the theory of machine learning force field (MLFF), which is widely used in atomistic simulations of chemical systems. The flexible and adaptable framework permits reference points to be positioned anywhere within the modeled domain rather than only atom centers, transcending this implicit constraint of traditional MLFFs, and enabling a diverse range of new model architectures. Leveraging Gaussian Multipole (GMP) featurization functions, several models with different reference point sets, including finite difference grid-centered and bond-centered models, were tested to analyze the variance in capabilities intrinsic to models built on distinct reference points. The results underscore the potential of non-atom-centered reference points in force training, revealing variations in prediction accuracy, inference speed, and learning efficiency. It clearly shows that the choice of reference points is an additional dimension of complexity that can be optimized for model performance, on top of environment featurization and model architecture. Finally, a unique connection between CEMT and real-space orbital-free finite element Density Functional Theory (FE-DFT) is established, and the implications include the enhancement of data efficiency and robustness by allowing the leveraging of intermediate results of DFT calculations. This framework could also serve as a cornerstone towards integrating known quantum-mechanical laws into the architecture of ML models.

5:00 PM MT01.09.03
A Self-Improvable Generative AI Platform for the Discovery of Solid Polymer Electrolytes with High Conductivity Weike Ye[1], Xiangyun Lei[1], Zhenze Yang[2], Daniel Schweigert[1], Ha-Kyung Kwon[1] and Arash Khajeh[1]; [1]Toyota Research Insitute, United States; [2]Massachusetts Institute of Technology, United States

This study presents a novel generative AI-based approach for the efficient discovery and design of high-performance solid polymer electrolytes, crucial for next-generation battery technologies. The platform integrates three core components: a conditioned generative model, a validation module, and a feedback mechanism, creating a self-improving system for material innovation. To optimize the conditional generative model, we have compared different architectures including both the GPT-based and diffusion-based models, and employed pertaining and fine-tuning training strategies to achieve faster convergence and superior data efficiency. The implementation of validation from full-atom MD simulation and the feedback mechanism allows the platform to refine the output iteratively. We demonstrate that this platform facilitates the generation of hundreds of thousands of novel, diverse, valid, and synthesizable polymers, and more importantly, the effectiveness of the platform is underscored by the identification of 19 polymer repeating units, each displaying a computed ionic conductivity surpassing that of Polyethylene Oxide (PEO).

Adaptive Loss Weighting for Machine Learning Interatomic Potentials Daniel Ocampo[1], Daniela Posso[2], Reza Namakian[1] and Wei Gao[1,1]; [1]Texas A&M University, United States; [2]The University of Texas at San Antonio, United States

For atomistic simulations, machine learning interatomic potentials (ML-IAPs) have proven to accurately represent potential energy surfaces, overcoming some limitations of empirical force-fields and their functional form. Training such potentials involves optimization of multipart loss functions typically composed of potential energies, forces and stress tensors. However, the contribution of each variable to the total loss is typically weighted using heuristic approaches that yield either iterative or sub-optimal results. Therefore, we implement an adaptive loss weighting algorithm based on a mathematically intuitive and computationally efficient scheme, in which the contribution of each term is dynamically recalculated based on its learning performance; optimizing the imbalance of the widely used, heuristic fixed loss weighting approaches. Additionally, by adding a stress term to the loss function and using high convergence criteria for density functional theory (DFT) calculations we show that a ML-IAP with accurate predictive stress capabilities must include stress information during training. This approach results in more automated neural networks networks that can learn effectively potential energies, forces and stresses from *ab initio* calculations, producing reliable ML-IAPs that are usable in simulations involving mechanical deformations, phase transformations, or other stress-dependent phenomena.

High-Accurate and -Efficient Potential for BCC Iron based on The Physically Informed Artificial Neural Networks Meng Zhang, Koki Hibi and Junya Inoue; The University of Tokyo, Japan

Atomic forces and energies, calculated by interatomic potential, are fundamental components of molecular dynamics (MD) and Monte Carlo (MC) simulations. Compared with traditional potential, machine learning (ML) potentials trained on extensive DFT databases offer enhanced accuracy in predicting physical and chemical properties of materials, but their transferability often faces constraints. To address this limitation, physically informed neural network (PINN) potentials have emerged. These models synergistically combine the strengths of ML with physics-based bond-order interatomic potentials, aiming for both improved accuracy and broader applicability. However, a major hurdle remains: the low performance of PINN potentials, hindering large-scale simulations. This work introduces a novel approach that significantly improves the performance of PINN potentials. The developed PINN potential for body-centered cubic (BCC) iron demonstrates exceptional accuracy in property predictions while boasting remarkable computational efficiency. Its performance overcomes both 12-MPI CPU-only ML potentials and GPU-accelerated ML potentials by achieving speedups of 168x and 22x, respectively. The proposed approach has a potential to provide a powerful way to develop high-performance and high-accuracy potentials even in the other systems.

Molecular Dynamics Simulation of HF Etching of Amorphous Si_3N_4 Using Neural Network Potential Changho Hong, Sangmin Oh and Seungwu Han; Seoul National University, Korea (the Republic of)

Dry etching plays a key role in the fabrication of semiconductor devices. Recently, the requirement of high aspect ratios (40–60) of deep-trench structures and the introduction of through-silicon vias for 3D circuit integration demand precise etching control. Traditional macroscale models, such as the level set and Monte Carlo-based methods, have been employed to predict the outcomes of process parameter optimization. However, phenomenological fitting of model parameters can result in inaccurate predictions of feature profiles due to the omission of detailed chemical processes. Molecular dynamics (MD)

simulations can offer a close look into atomic processes in ion etching, overcoming the trial-and-error approaches for parameter determination in macroscopic interaction models. Classical potentials are an option but have limitations in both availability and accuracy. Density functional theory (DFT), although highly accurate, is computationally prohibitive for large-scale simulations. Recent advances in machine-learning potentials (MLPs) have demonstrated their efficacy in simulations involving surface catalysis, physical sputtering, and surface oxidation processes. However, application of MLPs for etching reactions between ions and solid-state materials is currently lacking. This is attributed to the complexity of predicting chemical reaction pathways, which creates challenges in constructing training sets for MLPs.
In this study, we investigate the mechanisms underlying Si_3N_4 etching by HF ions using MD simulations driven by a neural network potential (NNP). The NNPs are trained using SIMPLE-NN package. The training set is constructed through manual curation of relevant atomic environments and an iterative training process. The basic constituents of atomic configurations are both crystalline and amorphous bulk structures, as well as their slab counterparts. Additionally, guided MD is employed to sample the chemical reactions between HF molecules and the Si_3N_4 substrate; here, hydrogen and fluorine are displaced toward nitrogen and silicon respectively based on the assumption of bond preference. Alongside guided MD, high-temperature MD of a slab is used to facilitate the sampling of diverse local atomic environments that may emerge during energetic ion collisions. Using manually curated training sets, NNPs are iteratively validated and refined. This refinement is achieved by incorporating structures from NNP trajectories that exhibit significant energy discrepancies when compared against DFT calculations. Utilizing this optimized NNP, we conduct etching simulations on 4 nm^2 amorphous Si_3N_4 substrates over a 5 ns timescale, and analyze characteristics such as etching yield and surface modification. Our results demonstrate a square-root dependence of the etching yield on the incident energy. Furthermore, we observe modifications at the topmost surface, where the ratio of Si to N is 1:1. This ratio is intriguingly similar to observations from experimental studies utilizing different reactive plasma species. The primary etch products at normal incidence are SiF_2, SiF_4, N_2, and NH_3. This behavior is attributed to chemical sputtering, in which the surface is significantly modified by incoming reactive species, becoming susceptible to chemical etching. In contrast, at high angles of incidence, the surface remains largely unmodified, with the primary etch products being lower-coordinated molecules of Si and N, along with N_2 molecules. This suggests that under these conditions, the etching is more affected by physical sputtering. Our methodology offers a cost-efficient approach to achieving DFT-level accuracy in MD simulations, thereby elucidating etching mechanisms and contributing to the optimization of the etching process.

5:00 PM MT01.09.07
Deep Potential Model for Analyzing Enhancement of Lithium Dynamics at Ionic Liquid and Perovskite ($BaTiO_3$) Interface Anseong Park, Sangdeok Kim, Chanui Park, Woojin Kang, Seungtae Kim and Won Bo Lee; Seoul National University, Korea (the Republic of)

Recently, ab-initio molecular dynamics (AIMD) based DeePMD (DPMD) potential has not only improved computational accuracy and speed but has also overcome the limitations of traditional force-field-based methods. In this study, we will discuss the technical details and considerations for utilizing this deep learning-based force field, particularly in multi-component systems such as ionic liquids. We will compare the results of structural & dynamical properties calculated from traditional force fields, scaled charge force fields, polarizable force fields, and DPMD force fields.
Finally, we will apply the DPMD force field to an ionic liquid and perovskite interface system, which is virtually impossible to simulate from using traditional force fields. Experiments have shown that the hybrid solid electrolyte (HSE), consisting of nanoscale perovskite particles mixed with an ionic liquid (IL), exhibits excellent flame retardancy, thermal stability, and improved ionic conductivity compared to pure IL electrolyte. We will analyze the structural and dynamical differences induced by the perovskite interface in comparison to bulk ionic liquid using DPMD force field simulations.

5:00 PM MT01.09.08
Autonomous AI generator for Machine Learning Interatomic Potentials Bowen Zheng and Grace Gu; University of California, Berkeley, United States

Machine learning interatomic potentials (MLIPs), which predict the system potential energy given an atomic configuration, have profoundly improved the accuracy and efficiency of molecular simulations. Learning from high-fidelity quantum chemistry-based data while interfacing with classical simulation frameworks, MLIPs inherit the quantum-level accuracy and the efficiency of classical molecular dynamics, achieving the best of both worlds. In recent years, MLIPs have witnessed great research efforts and various types of MLIPs have been proposed, tested, and documented. However, the development of MLIPs has largely been a manual, *ad hoc* process. Additionally, effective MLIPs are either scattered in online repositories such as Git-Hub or provided as supplementary materials of publications, making them difficult to locate and retrieve when needed. Here, we aim to create an autonomous AI generator for MLIPs, which consists of a Searcher, a Trainer, and an Evaluator. Given a request, for example, “generate an MLIP for Indium phosphide system”, the Searcher is first up to the task, looking for available MLIPs online via web scraping or APIs. If such MLIPs do not exist, the Trainer then performs the following tasks in sequence autonomously: select an MLIP template (such as a neural network or a SNAP MLIP, upon request or by certain criteria), generate DFT-MD training trajectories, and train the MLIP. For an MLIP returned either by the Searcher or the Trainer, the Evaluator calculates various accuracy metrics such as the mean absolute errors (MAEs) and R-squared values. It is also viable to request training multiple types of MLIPs and compare their performances. Lastly, we propose a large language model (LLM)-based agent named ChatMLIP which accepts textual user requests and delivers appropriate responses. By way of AI, the present work may accelerate the development of MLIPs and potentially benefit boarder research fields like carbon capture, protein engineering, drug discovery, among others.

5:00 PM MT01.09.10
Benchmarking, Visualization and Hyperparameter Optimization of UF_3 to Enhance Molecular Dynamics Simulations Pawan Prakash, Ajinkya Hire and Richard Hennig; University of Florida, United States

Ab initio methods offer great promise for materials design, but they come with a hefty computational cost. Recent advances with machine learning potentials (MLPs) have revolutionized molecular dynamic simulations by providing high accuracies approaching those of ab initio models but at much reduced computational cost. Our study evaluates the ultra-fast potential (UF_3), employing linear regression with cubic B-spline basis for learning effective two- and three-body potentials. On benchmarking, UF_3 displays comparable precision to established models like GAP, MTP, NNP(Behler Parrinello), and qSNAP MLPs, yet is significantly faster by two to three orders of magnitude. A distinct feature of UF_3 is its capability to render visual representations of learned two- and three-body potentials, shedding light on potential gaps in the learning model. In refining UF_3's performance, a comprehensive sweep of the hyperparameter space was undertaken, emphasizing finer granularity in zones indicative of optimal performance. This endeavor aims to provide insights into the smoothness of the UF_3 hyperparameter space, and offer users a foundational default set of hyperparameters as a starting point for optimization. While our current optimizations are concentrated on energies and forces, we are primed to broaden UF_3’s evaluation spectrum, focusing on its applicability in Molecular Dynamics simulations. The outcome of these investigations will not only enhance the predictability and usability of UF_3 but also pave the way for its broader applications in advanced materials discovery and simulations.

5:00 PM MT01.09.11
Generating Statistically Equivalent Thermal Spray Coatings Using Bayesian Optimization David Montes de Oca Zapiain, Anh Tran, Nathan W. Moore and Theron Rodgers; Sandia National Laboratories, United States

Thermal spray deposition is an inherently stochastic manufacturing process used for generating thick coatings of metals, ceramics and composites. The generated coatings exhibit complex internal structures that affect the overall properties of the coating. The deposition process can be adequately simulated using rules-based process simulations. Nevertheless, in order for the simulation to accurately model particle spreading upon deposition, a set of pre-defined rules and parameters need to be calibrated to the specific material and processing conditions of interest. The calibration process is not trivial given the fact that many parameters do not correspond directly to experimentally measurable quantities. This work presents a protocol that automatically calibrates the parameters and rules of a given simulation in order to generate the synthetic microstructures with the closest statistics to an experimentally generated coating. The protocol starts by quantifying the internal structure using 2-point statistics and then representing it in a low-dimensional space using Principal Component Analysis. Subsequently, our protocol leverages Bayesian optimization to determine the parameters that yield the minimum distance between synthetic microstructure and the experimental coating in the low-dimensional space.

5:00 PM MT01.09.12
Anisotropic Assembly of Nanoparticles Explored through Molecular Dynamics Simulations, Global Optimizations and Machine Learning Methods Yilong Zhou[1,2], Tsungyeh Tang[3], Sigbjorn L. Bore[3], Francesco Paesani[3] and Gaurav Arya[2]; [1]Lawrence Livermore National Laboratory, United States; [2]Duke University, United States; [3]University of California, San Diego, United States

Novel applications of polymer nanocomposites like plasmonics often require anisotropic organization of nanoparticles (NPs) in polymers. However, achieving unique anisotropic assemblies of NPs in polymers is challenging since NPs tend to self-assemble into three-dimensional close-packed aggregates. In this work, we tackle this challenge of achieving anisotropic NP assembly in polymers through a combination of molecular dynamics (MD) simulations, global optimization, and machine learning. First, we present a new strategy for assembling NPs into anisotropic architectures in polymer matrices, which leverages the interfacial tension between two mutually immiscible polymers forming a bilayer and differences in the relative miscibility of polymer grafts with the two polymer layers to confine NPs within 2d planes parallel to the interface.[1] Through coarse-grained (CG) MD simulations, we demonstrate this strategy, showcasing the assembly of NP clusters, such as trimers with tunable bending angle and anisotropic macroscopic phases, including serpentine and branched structures, ridged hexagonal monolayers, and square-ordered bilayers. The above MD simulations are however inefficient for determining the equilibrium structures of NP assemblies, particularly those involving many particles or complex unit cells. To address this issue, we adapt the efficient Basin-hopping Monte Carlo algorithm to locate the global minimum energy configurations of NPs at interface, allowing us to explore the full breadth of NP structures possible at interface and uncovering many unique NP structures.[2] While exploring the assembly of polymer-grafted NPs at polymer interfaces using explicit CG MD simulations, we observe that many-body effects play an important role in the formation of quasi-1d structures. However, explicit modeling of the polymer grafts and melt chains is highly computationally expensive, even using CG models. We thus introduce a machine learning approach to develop an analytical potential that can describe many-body interactions between polymer-grafted NPs in a polymer matrix. The developed potential reduces the computational cost by several orders of magnitude and thus allows us to explore NP assembly at large length and time scales. Overall, the anisotropic NP structures discovered in this study hold significant potential for applications in various fields, including plasmonics, electronics, optics, and catalysis, where precise and anisotropic NP arrangements within polymers are essential for achieving desired functionalities.

5:00 PM MT01.09.13
Differentiable Gaussian Process Force Constants Keerati Keeratikarn and Jarvist M. Frost; Imperial College London, United Kingdom

The finite temperature properties of matter requires understanding thermal motion. In crystals this can be described by representing the collective excitation of the centre of mass motion as a phonon. Phonon frequencies (Energies) in the harmonic approximation come from the second order force constants (FC) of the potential energy surface (PES). The standard approach is to use a finite displacement method (FDM). Anharmonic contributions (required for finite thermal conductivity) require higher order force constants. FDM-based calculations scale poorly both with the size of the system, and the order of the force constants[1]. As an alternative approach, we can use a more sophisticated surrogate potential energy surface model [2].
Gaussian processes (GPs) are a supervised machine learning method which can describe an arbitrary function. GPs are naturally Bayesian (probabilistic). Our reference data is the electronic structure from which conditions the model (training) [3, 4].
Due to the underlying Gaussian form of a GP, the model is infinitely differentiable [5, 6]. This allows the model to be trained directly on forces (the derivative of energy), reducing the number of calculations required for a given accuracy of PES evaluation [7-9]. This differentiation can be extended to compute the second and the third derivative of PESs (harmonics and cubic anharmonic FCs) by using automatic differentiation (AD). By performing linear operations between arbitrary derivative orders of the GP, the covariance functions among PESs, forces and those FCs can be calculated.
We implement this method in the Julia language, in our GPFC.jl package. We first use our technique of anharmonic property calculations of Si, NaCl and PbTe which their atomic environments are represented on atomic Cartesian coordinates. To impose their space group symmetry, phonon coordinate representations are then used to describe the environment of these three materials resulting in faster convergence of anharmonic properties. To further impose a three-dimensional rotation symmetry, we aim to use an SO(3) representation (such as spherical harmonics) with our GP method to achieve accurate FCs with less data [3, 10]. We compare our results to standard approach of FDM (in Phono(3)py.py) [2] and cluster expansion (HiPhive.py) [11].

Understanding The Interplay between Anion Dynamics and Proton Conduction in Solid-Acid Compounds Using Machine Learning Molecular Dynamics Menghang (David) Wang[1], Cameron J. Owen[1], Grace Xiong[2], Jingxuan Ding[1], Yu Xie[1], Simon L. Batzner[1], Albert Musaelian[1], Anders Johansson[1], Nicola Molinari[1], Ni Zhan[3], Ryan P. Adams[3], Sossina M. Haile[2] and Boris Kozinsky[1]; [1]Harvard University, United States; [2]Northwestern University, United States; [3]Princeton University, United States

Solid acid materials play a pivotal role as electrolytes for intermediate temperature hydrogen fuel cells. However, our current understanding of the relevant atomic motions that govern proton conduction remains incomplete, necessitating further investigation in different solid acid compounds. It is imperative to explore the atomic-scale correlation between anion and proton dynamics to design novel solid acid compounds with high proton conductivity.

In the superprotonic phase, solid acid proton conductors exhibit intricate behaviors, characterized by local proton hops in the O-H...O bond and anion reorientation. These phenomena comprise a two-step process necessary for long-range proton motion. Existing computational studies treat anion and proton dynamics as independent processes, while we find strong correlations between anion and proton dynamics in both CsH_2PO_4 (CDP) and $CsHSO_4$ (CHS) from machine learning molecular dynamics over nanosecond timescales. Achieving a nanosecond timescale is crucial to comprehensively study the diffusive regime. We observe that not all anion reorientations contribute to long-range proton motion, underscoring its multifaceted role in superprotonic behavior. Additionally, the contribution of anion reorientations to long-range proton motion exhibits distinctive characteristics in CDP and CHS. Furthermore, we confirm a significant O-H reorientation preceding the long-range proton motion, substantiating a previously hypothesized but unverified process. Our approach leverages machine learning interatomic force fields (MLFFs) developed through uncertainty-aware active learning [1] and equivariant neural networks [2]. By combining ab-initio precision with simulations of thousands of atoms over nanosecond timescales, our MLFFs support our findings on the correlations of anion dynamics and the long-range proton transfer with sufficient statistics.

This work bridges crucial knowledge gaps in the superprotonic behavior of solid acid proton conductors and has the potential to inform the design of advanced solid acid compounds for renewable energy technologies.

CRowdsourced Materials Data Engine for Unpublished X-Ray Diffraction Data Abhishek Daundkar, Mengying Wang, Hanchao Ma, Yiyang Bian, Alp Sehirlioglu and Yinghui Wu; Case Western Reserve University, United States

Modern multidisciplinary materials science routinely processes scientific workflows integrating different data resources (e.g., X-ray data, scripts, analytical results). This data resources are underutilized and sometimes tagged as ineffectual for the source problem. We propose to tackle the fundamental challenges of data-driven material science such as accessing extensive experimental data and relationship to the processing techniques of the discovered materials. Majority of machine learning models require significant number of training data that is not necessarily generated in materials research. Inspired by past work on discovery of high temperature piezoelectrics where the distributed nature of training and testing data was highlighted, we are creating CRUX, a CRowdsourced Materials Data Engine for Unpublished X-Ray Diffraction (XRD) to innovate and boost the utilization of this high-quality, unpublished material science data in collaboration with our industry partners and developer community. The core of CRUX is a materials knowledge graph (a semantic network of materials entities and their semantic relationships), build upon the materials data and materials ontology specifically developed to capture the processing meta-data. This knowledge graph represents abstract factual knowledge from XRD datasets, answers queries, and self-evolves to recommend newly shared datasets and facilitating the feature of querying itself to help users explore the underlying materials datasets. When working with materials research data the objective is to collect the most amount of critical data without overburdening the user submitting the information. We aim to enable a materials knowledge graph (KG) model, automatic data integration, and an exploratory query engine that support "Why" and "What-if" analysis for XRD analysis. As we expand on the experimental/modeling dataset we unleash the full potential of the data engine regardless of the state of model implemented for analysis. CRUX will enable an open, collaborative, and sustainable platform that can facilitate exchanging of unpublished XRD data and unlock new research problems (e.g., prediction of materials compositions with multi-phase data), and inspire the novel design of ML pipelines for data-driven materials science.

5:00 PM MT01.09.16
Do Computed Grain Boundary Energies Depend on Interatomic Potentials? Universal Trends Employing EAM-X Yasir Mahmood[1], Murray Daw[1], Michael Chandross[2] and Fadi Abdeljawad[3]; [1]Clemson University, United States; [2]Sandia National Laboratories, United States; [3]Lehigh University, United States

It is well established that grain boundaries (GBs) greatly influence the observable properties of a wide range of engineering and functional materials. Classical atomistic simulations employing the Embedded Atom Method (EAM) have emerged as a powerful technique to simulate GB phenomena. However, folded into such simulations is the dependency of GB structure and properties on the particular choice of EAM parameters. To address this question, we follow a direction of investigation that has not been generally explored, namely we simplify the EAM function space to a small but efficient set of parameters, called EAM-X [1]. Then, we study a set of GBs with various geometries and calculate their energies in the complete EAM-X parameter

space. We find that variations in GB energy with EAM parameters can be larger than variations due to GB geometry; an effect that has not been quantified before. The atomistic data are used to determine a fit of the GB energy in EAM parameter space, which can be used to obtain boundary energies in real FCC elements by selecting corresponding points in this parameter space. We find generally at best a moderate correlation between GB energy and shear modulii, and we discuss the relationship to prior work along these lines. Our work highlights the need to consider sensitivity to details of empirical potentials when performing quantitative studies of GB physics. *SNL is managed and operated by NTESS under DOE NNSA contract DE-NA0003525 (SAND2022-1056 A).*

5:00 PM MT01.09.17
Atomistic Modeling of Bulk and Grain Boundary Diffusion for Solid Electrolyte Li_6PS_5Cl Accelerated by Machine-Learning Interatomic Potentials Yongliang Ou[1], Yuji Ikeda[1], Sergiy Divinskyi[2] and Blazej Grabowski[1]; [1]University of Stuttgart, Germany; [2]University of Münster, Germany

Li_6PS_5Cl is a promising candidate for the solid electrolyte in all-solid-state lithium-ion batteries. For applications, this material is in a polycrystalline state with many grain boundaries (GBs) rather than an idealized single-crystalline state. Atomistic simulations of Li_6PS_5Cl with GBs, however, remain rare due to high computational cost. In this study, machine-learning interatomic potentials, specifically moment tensor potentials (MTPs) [1], are employed to accelerate the simulations while preserving the ab initio accuracy. In the initial stage, energies and forces of a small number of configurations are generated under the *ab initio* framework. MTPs are then fitted to the *ab initio* data, and active learning techniques are used to further stabilize the MTPs. The usage of MTPs enables molecular dynamics (MD) simulations in larger system sizes (up to 20 000 atoms) and longer time scales (several ns). Two tilt GBs Σ3[110]/(1-12), Σ3[110]/(-111) and one twist GB Σ5[001]/(001) are focused on, all of which show relatively low GB energies and an enhanced ionic conductivity for Li compared to bulk. Diffusion mechanisms specific to each GB are analyzed. This research offers new insights into the design of solid electrolytes through GB engineering and emphasizes the importance of considering GBs for materials modeling.

5:00 PM MT01.09.18
Exploring Reaction Pathways for Wet-Alkaline Etching of GaN with Machine-Learned Potential Purun-hanul Kim[1], Youngho Kang[2] and Seungwu Han[1,3]; [1]Seoul National University, Korea (the Republic of); [2]Incheon National University, Korea (the Republic of); [3]Korea Institute for Advanced Study, Korea (the Republic of)

Micro-sized light-emitting diodes (μLEDs) based on gallium nitride (GaN) are building blocks for the development of augmented reality and virtual reality displays in our hyperconnected society. However, owing to the high surface-to-volume ratio, μLEDs are susceptible to surface defects, resulting in significantly lower performance compared to bulk LEDs. The surface structure of μLEDs is profoundly influenced by wet-etching processes in alkaline environments which are essential for fabricating microscale GaN. Hence, understanding the etching mechanism is pivotal to establishing optimal etching processes for μLED production. However, it remains elusive because of difficulties in experimental characterization and analysis. While ab initio molecular dynamics (AIMD) based on density functional theory (DFT) have been widely employed to investigate chemical reactions at an atomic level, they have limitations in terms of the system size and simulation-time scale. As such, AIMD is inadequate to explore intricate and diverse chemical reactions occurring at an interface between the solution and GaN during wet etching.
Recently, Behler-Parrinello-type neural-network potential (NNP) based MD has emerged as an effective approach to overcome the limitations of AIMD. In this work, we explore wet etching of GaN using the NNP-MD simulation that is thousands of times faster than AIMD. To construct an accurate and reliable NNP for simulating etching processes, we generate a training set by sampling AIMD trajectories of GaN surface, KOH aqueous solution, and their interface models at wide ranges of temperature and pressure encompassing supercritical phase. Then, the NNP is trained using the in-house SIMPLE-NN code to reproduce the DFT energies, forces, and stress tensors. The generated NNP is thoroughly validated by comparing the results with DFT calculations. Afterward, we perform NNP-MD simulations to investigate the etching of GaN polar and nonpolar surfaces immersed in KOH solution applying a high-temperature and high-pressure to accelerate chemical reactions. Our simulation directly shows that an alkaline wet etching process transforms the slanted surface into the *m*-surface, which is consistent with experiments. Furthermore, the relative etching rates of different surface facets obtained from our simulations agree well with experiments. From the analysis of the atomic trajectories, we reveal the wet-etching mechanism of GaN surfaces in which the attachment of OH^- (*aq*) to surface Ga and subsequent passivation of a neighboring N dangling bond by H^+ (*aq*) are the key processes. By providing atomic-scale insights into etching processes and surface structures of GaN that cannot be obtained with conventional DFT methods, our work will help develop high-performance μLEDs.

5:00 PM MT01.09.19
Open Large Language Models in The Service of Material Science Vineeth Venugopal and Elsa O; Massachusetts Institute of Technology, United States

The application of Open Large Language Models (LLMs) in material science is revolutionizing the traditional methodologies employed in Named Entity Recognition (NER), classification, and information extraction tasks. This study aims to explore the expansive capabilities and performance limitations of LLMs in the realm of material science, underlining their role in the creation of automated databases via Retrieval-Augmented Generation (RAG) pipelines and probing their behavior through the examination of activation functions.
LLMs are increasingly being used to automate the extraction of valuable insights from the expansive corpus of material science literature. They demonstrate high efficiency in NER tasks, effectively identifying and categorizing terminologies, material properties, and synthesis parameters. These capabilities extend to classification tasks, where LLMs can sort documents or data points based on pre-defined categories, such as material type, structural characteristics, or application domains.
Despite these promising features, LLMs are not without their limitations. One critical issue pertains to their tendency to produce spurious or "hallucinated" outputs. To mitigate this, our study incorporates ensemble methods and evaluates the outputs through metrics like F1-score for classification tasks and ROGUE-L score for text generation tasks.
The RAG pipeline is a notable development, automating the database creation process by combining the strengths of both retrieval and generation modules. We particularly focus on the application of RAG in creating a high-throughput, structured database of material structure-property-processing parameters. The RAG pipeline leverages LLMs to encode text documents into a large vector database. Queries, specified in natural language, are transformed into vector embeddings, followed by a vector similarity search. The output is then aggregated and structured, serving as a robust database for further scientific research.
To deepen our understanding of LLM behavior, we also investigate the activation functions within these neural networks. By scrutinizing how different layers and nodes respond to specific input types, we gain valuable insights into the model's interpretability and reliability. This examination allows us to optimize the model's performance further and provides a diagnostic tool for understanding the complexities inherent in LLMs.
In conclusion, this study offers a comprehensive evaluation of the utility and limitations of Open Large Language Models in material science. It elaborates on their role in automating complex NER, classification, and information extraction tasks, their implementation in RAG pipelines for database creation,

and the insights gained from analyzing their activation functions. As material science stands to gain significantly from these advancements, understanding and optimizing LLMs can pave the way for more efficient and accurate research methodologies.

5:00 PM MT01.09.20
Developing and Optimizing an Ultra-Fast Force Field (UF3) for Modeling The Crystallization of Amorphous Silicon Nitride Jason B. Gibson[1], Tesia Janicki[2], Ajinkya Hire[1], Christopher Bishop[2], J. Matthew D. Lane[2] and Richard Hennig[1]; [1]University of Florida, United States; [2]Sandia National Laboratories, United States

Crystallization of amorphous silicon nitride, as observed experimentally, can alter material properties in microelectronics process conditions as a layer-stacked component. Understanding the crystallization mechanism mandates a multi-scale approach in which quantum simulations inform atomistic simulations, which further inform continuum scale simulations and subsequently, experimental work. This talk will detail the progress and challenges faced in developing an Ultra-Fast Force Field (UF3) specifically designed to bridge quantum and atomistic simulations for the Si-N material system. The UF3 integrates effective many-body potentials within a cubic B-spline framework with regularized linear regression, creating a fast and interpretable machine-learned potential (MLP). First, we will cover the nuanced requirements of the MLP's training data: it needs to be diverse enough to avoid overfitting to Si3N4 stoichiometry, while maintaining enough specificity to prevent unneeded generalizations across the entire Si-N compositional range. Following this, we leverage the interpretability of UF3's 2/3-body terms to understand the MLP's behavior and identify areas for improvement. The presentation will conclude by detailing the simulation results that were used to validate the MLP and an analysis of the simulated crystallization results of the final MLP.

Navigating Transition Path Sampling with Machine Learning Potentials: Insights and Challenges Nikita Fedik, Wei Li, Nicholas Lubbers, Benjamin Nebgen, Sergei Tretiak and Ying Wai Li; Los Alamos National Laboratory, United States

In the realm of molecular dynamics, capturing elusive transitions and unveiling potential energy landscapes is a paramount pursuit. Reactive events that lead a system from state A to state B through a transition path are often masked by an ensemble of energetically similar pathways. Transition path sampling (TPS) emerges as a potent tool to uncover these paths, although their infrequency in simulations due to high energy requirements and limited statistical occurrence remains a hurdle.
Machine learning potentials offer a promising avenue to model and discern these intricate transition paths, opening the door to new possibilities. The question that arises is: how do we select the right model and data?
Diverse machine learning potentials, such as HIPNN and ANI, have been shown to yield varying transition paths during sampling. An illustration is found in our exploration of alanine dipeptide, a system replete with multiple dihedral degrees of freedom. Intriguingly, even when accuracy metrics like mean absolute error (MAE) and root mean square error (RMSE) align, these static metrics assessed on a portion of the dataset may not suffice to identify the superior model. They serve as preliminary benchmarks, rather than comprehensive tests of model performance.
One avenue toward superior performance emerges through active learning sampling in the transition region. Our demonstrated approach significantly bolsters accuracy, reducing energy errors to a remarkable 0.5 kcal/mol. However, the path to progress is paved with caution when selecting transition paths for machine learning model testing. We emphasize this point using the example of azobenzene, a seemingly uncomplicated system with limited degrees of freedom, yet it poses a significant challenge for electronic structure calculations. Machine learning results may appear in perfect alignment with easily calculable paths, but this can be misleading if the unique open-shell nature of the transition state is overlooked. Establishing reliable benchmarks for machine learning, particularly in the context of transition path sampling, remains an intricate and ongoing endeavor.
Armed with these lessons of caution, our aim is to cultivate a deeper understanding of how to assess the accuracy of machine learning models in dynamical processes.

ChemChat | Conversational Expert Assistant in Material Science and Data Visualization Tim Erdmann, Sarathkrishna Swaminathan, Stefan Zecevic, Brandi Ransom and Nathan Park; IBM Research, United States

In recent decades, remarkable advancements have been made in the field of computational chemistry and machine learning (ML), yielding a plethora of sophisticated tools and artificial intelligence (AI) models. Despite their potential, these resources have yet to be fully harnessed due to their steep learning curves and their tendency to operate in isolation. Furthermore, the need for capabilities in programming and ML constitute access barriers to the targeted community – often experimental scientists. Concurrently, the advent of large-language models (LLMs) like (Chat)GPT has been revolutionizing various domains. Nevertheless, their efficacy in addressing chemistry-related challenges has been limited. Especially, these models lack knowledge about scientific workflows and the employed operations (e.g. in drug discovery), access to information sources providing up-to-date data, and the ability to accurately reference – but tend to hallucinate in their responses – what questions credibility, trust, and applicability. However, this crucial gap between AI and science can be overcome by integrating task-specific agents into the LLM-powered conversational application and allowing the LLM to reason over their appropriate usage based on provided instructions. It can be anticipated that this will result in a significant increase in the utilization of the developed cheminformatic tools and AI models and contribute to the scientific discovery overall.
Here, we present ChemChat, a web application and conversational assistant with a chatbot-driven user interface that is powered by non-GPT/OpenAI LLMs. Through the integration of existing cheminformatics tools and expert-developed AI models such as PubChem, CIRCA, RDKit, GT4SD, RXN, MolFormer and other knowledge sources the application is capable of assisting material scientists in tasks like property calculations, tailored design of molecules, retrosynthesis, forward reaction planning, data visualization, and literature research. Central to the talk we will be demonstrating use case-specific capabilities in comparison to related applications and the architecture and workflow behind ChemChat.

5:00 PM MT01.09.23
N-Body Fourier-Sampled Kernel for Machine Learning Potential Alexandre J. Dézaphie[1,2], Anruo Zhong[1], Clovis Lapointe[1], Alexandra Goryaeva[1], Jerome Creuze[2] and Mihai-Cosmin Marinica[1]; [1]CEA, France; [2]ICMMO, France

Irradiation induces the formation of vacancy and interstitial defects in crystalline materials, which can aggregate into larger clusters. The structure and mobility of self-interstitial clusters remain a largely unresolved issue. For the past 60 years, the scientific community has regarded the formation of interstitial clusters in metallic materials as an accumulation of mono-interstitials that, through diffusion, can aggregate into 2D dislocation loops with a well-defined Burgers vector, progressively growing to observable nanoscale sizes. Recently, we have shown that interstitial clusters in face centered cubic (FCC) metals can aggregate into 3D objects with a well-defined underlying crystallographic structure that ultimately dissociates into dislocation loops [1]. This results complete the puzzle of compact phase accumulation under irradiation, previously emphasized in body centered cubic metals (BCC) [2] and

seems to be a general phenomenon.
Further understanding the aging of these newly discovered nano-phases requires precise, large-scale molecular dynamics simulations. Studying the recombination mechanism of atomic scale defects into dislocations, as well as dislocation maturation, necessitates the development of new interatomic potentials. Machine learning potentials offer a compelling solution for atomistic simulations due to their unique ability to balance precision with computational efficiency. Therefore, we have embarked on the development of an innovative machine learning potential within the framework of kernel regression. The strength of our method is derived from: (i) introducing a novel descriptor that captures the many-body aspects of the metallic interatomic force fields, up to 5-body terms. To maintain invariance within the description of this local atomic environment, we employ and reformulate the permutation-invariant polynomials [3]. And (ii) solving the kernel regression in the descriptor space through the kernel-sampled Fourier transform method, avoiding the need for large matrix inversion. This force field was implemented in the Machine Learning Dynamics framework [4]. The intriguing aspect here is that while each of these approaches has previously existed independently, their integration marks a potential watershed moment, ushering in a new horizon of opportunities for atomistic simulations.
To investigate the mechanism governing the formation of compact clusters within FCC and BCC crystals, we conducted a series of simulations based on the newly developed interatomic potential. The kinetics of these processes were delineated through extensive molecular dynamics simulations at finite temperatures in Fe, Ni, and Al. Furthermore, we assessed the relative stability of these clusters through free energy calculations [5]. Lastly, we are actively engaged in the pursuit of intermediate states within the recombination mechanism of these nanophases. To achieve this, we will systematically explore the complex energetic landscape of these clusters at 0 K.

5:00 PM MT01.09.24
Data-Driven Crystal Growth Using Flux-Method Process Informatics Tetsuya Yamada[1,2] and Katsuya Teshima[1,2]; [1]Shinshu University, Japan; [2]Shinshu Univeristy, Japan

Crystallographic characteristics such as crystallinity, crystal outline, and size are one of important factors to determine material performance, since they relates to physicochemical phenomena occurring on the surface and inside of materials. The flux method, which grow crystals in molten salts (fluxes) is a powerful technique for development of high-performance crystalline materials. However, its growth guidelines are not well established due to multi-step growth process with various phenomena. Therefore, it is necessary to explore the optimal conditions in a huge experimental space based on various experimental factors, including flux species. Thus, it takes several years to develop crystals using flux method.
Recently, we have studies flux-method process informatics (FPI), which is a data-driven approach to effectively explore favorable experimental conditions based on crystal growth prediction in the flux method. There are many issues to be solved to achieve high-accuracy FPI system. For example, description manner of feature values, big-data collection, expansion of materials target, and also effectivity of this method itself. In this study, we constructed an adaptive design of experiments (ADOE) system that can be used for FPI and applied to an anisotropic perovskite-type oxides.
The ADOE system accords to a Bayesian optimization cycle consisting of (I) acquisition of experimental data, (II) modeling by Gaussian process regression, (III) conduction of virtual experiments over 10000 ways, and (IV) proposal of experimental conditions based on the acquisition function. In this time, a layered perovskite oxide $Ba_5Nb_4O_{15}$ (BNO) with an anisotropic crystal structure was selected as one of the model materials. As the explanatory variables, experimental conditions, including raw material amounts, flux species, and heating conditions were used. Two types of crystal sizes were used as the objective variables to describe anisotropic crystal shape of BNO. The number of training data was about 70.
Firstly, we evaluated the efficiency of FPI using already collected dataset. The all dataset was divided into 10 as a training data and others as a test data. A prediction model was created using the training data, and the test data with high-likelihood one was selected as the goal candidate. If the selected test data was different from the goal, the data was added to the training data and continued the exploration until finding the goal. The cycles of modeling were output per 1 trial and scored the efficiency of ADOE after 100 trials. Comparing 100 random experiments, the average number of cycles by ADOE was 6 times smaller, indicating the better efficiency of this system than human-driven approach. In this presentation, we will also discuss the experimental results after applying the ADOE system, and contributing mechanism of each factor on the crystal growth.

5:00 PM MT01.09.25
Semi-Automatic Image Analysis Tool for Cellulose Nanocrystal Particle Size Measurement from Atomic Force Microscopy Images Saba Karimi[1], Sezen Yucel[2], Robert J. Moon[3], Linda J. Johnston[4] and Surya R. Kalidindi[1]; [1]Georgia Institute of Technology, United States; [2]Intel Corporation, United States; [3]The Forest Products Laboratory, United States; [4]National Research Council Canada, Canada

Cellulose nanocrystals (CNCs) are rod-like nanoparticles with that exhibit a unique combination of attractive characteristics for many applications: abundance, renewability, biocompatibility, desirable mechanical and chemical properties, and cheap production potential. Given these desirable properties, a broad spectrum of applications has been demonstrated in the literature for CNCs, from biomedical to composites, and from adhesives to sensors. Among the obstacles to the commercial utilization of CNCs is producing consistent quality, optimizing process parameters and reliable characterization protocols. Particle size and particle size distribution are particularly important when optimizing performance in any given application, for example as a rheology modifier in fluids or as a polymer reinforcement phase. Moreover, to optimize manufacturing processes, standardizing particle analysis is a crucial step. Currently the state-of-the-art approaches for characterizing CNC particle morphology are to manually measure individual particle dimensions in transmission electron microscopy or atomic force microscopy (AFM) images. This approach is not only time-consuming but also inconsistent because of bias or fatigue by human analyst. To address these characterization issues, a semi-automated image analysis framework based on MATLAB, called SMART, has been developed that segments AFM microscopic images into background and CNC particles, and classifies the identified CNC objects into isolated and agglomerated. This talk briefly introduces SMART, how it is applied to AFM image analysis by measuring the length and height of each CNC and reporting their distribution. This talk shows how the results are validated with the results of an inter-laboratory comparison study by Bushell et al., that assessed CNC size distribution using a reference CNC material that was characterized in four different laboratories. This talk critically compares the differences between the results obtained from SMART and from the traditional manual approaches. The results indicated that, while SMART's measurements were in good agreement with the manual approach, its advantages are (a) significant reduction in analysis times of CNC characterization — from hours to minutes, and (b) employing a consistent approach as opposed to analyst subjectivity in manual measurements. This talk will discuss how

SMART will facilitate CNC morphology characterization and how it may improve quality control assessment process and particle size optimization for a given application.

High Throughput Virtual Screening of Polymer Electrolyes for Li-Ion Batteries with Molecular Dynamics Simulations Jurgis Ruza, Pablo A. Leon and Rafael Gomez-Bombarelli; Massachusetts Institute of Technology, Latvia

Developing high-power, high-density energy storage like lithium metal batteries is vital for sustainable, cost-effective electricity management in electric vehicles and intermittent renewables, reducing reliance on fossil fuels. Furthermore, lithium metal batteries have been proposed for high energy density applications to decarbonize the light- to heavy-duty vehicle sector, as well as for other applications with stringent energy density requirements. Unfortunately, the conventional carbonate-based liquid electrolytes used in lithium-ion batteries degrade both chemically and electrochemically when in the presence of solid lithium electrodes. Thus, alternative electrolyte systems are being investigated to increase diffusion kinetics and chemical stability to ultimately develop long-lasting batteries for electric vehicles and intermittent short-term renewable energy storage. Polymer electrolytes have been an interest in the field because of their enhanced electrochemical stability, increased safety as alternatives to liquid electrolytes.

We propose to use high-throughput molecular dynamics (MD) simulations to screen a large amount potential polymer electrolyte candidates for Li batteries. Using MD simulations for the screening of new materials accelerates the design and commercialization process and helps predict device-level performance using new candidates. However, the parameters historically used in interatomic potentials are inaccurate for new chemical systems, which limits the throughput of these simulations. Therefore, we use a machine learning pipeline to optimize interatomic potential parameters reproducibly for these species by using quantum chemistry simulations as training data across many unique polymer electrolyte systems. We show the capabilities of classical MD simulations with improved class I force fields are able to be used as a tool for ranking polymers based on their experimental conductivities and are able to simulate a large array of new polymer candidates, such as ether, ester, carbonate derivative as well as more different chemistries containing thiol, nitrile, and chemical groups.

Active Learning Protocols to Accelerate Galvanic Corrosion Predictions Aditya Venkatraman, Ryan Katona, Demitri Maestas, David Montes de Oca Zapiain and Philip Noell; Sandia National Laboratories, United States

The current of a galvanic couple is generally treated as a surrogate measure of its resilience to or extent of galvanic corrosion. Experiments to measure cathodic current or obtain cathodic polarization curves incur a very high cost due to the need to explore a wide range of temperatures, salt concentrations, and specimen geometries that are used in engineering applications. To reduce these costs, Finite Element (FE) simulations are used to assess the cathodic current output. However, these simulations use the cathodic polarization curves as boundary conditions, which can only be discerned by performing experiments. Therefore, a protocol to accelerate the assessment of the cathodic current output for different chemistries under in-service environmental conditions is desirable. In this work, we develop an active learning protocol to minimize the total costs associated with performing the experiments and the simulations. We first calibrate a low-cost gaussian process surrogate model for the cathodic current output as a function of the environmental and geometric parameters that characterize the galvanic cell. The surrogate model is calibrated on a dataset of FE simulations, and it is used to calculate an acquisition function that identifies specific additional inputs with the maximum potential to improve the current predictions. The identification of additional inputs for further exploration is accomplished with the help of a staggered two-step workflow – (i) the influence of the geometric parameters are marginalized to identify the best configuration of environmental conditions for discerning the polarization curves, following which (ii) the geometric inputs best capable of refining the current predictions are identified. We demonstrate the efficacy of this protocol by minimizing the number of simulations necessary to obtain accurate predictions of the current output of a AA7075-SS304 galvanic couple. The protocols developed and demonstrated in this work provide a powerful tool for screening various forms of corrosion under in-service conditions. This work was supported by the Laboratory Directed Research and Development program at Sandia National Laboratories. Exploring Multi-Type Crosslinked Architectures in Polymer Materials Using Graph Neural Networks Connor Leavitt and Mehdi Zanjani; Miami University, United States

Crosslinked polymer networks provide a promising route for developing novel material composites with a variety of applications in areas such as aerospace and biomedicine. These systems are typically made up of different combinations of backbone polymer chains and crosslinking agents of different kind. Understanding the relationship between the polymer network architecture and its properties is an important topic for design and development of new generation of polymer composites with on-demand functionality. While the study of crosslinked polymer networks has so far been mainly limited to systems with one or two types of crosslinkers, the existing synthesis techniques can readily be extended to devise more complex polymer networks with a larger number of crosslinkers and backbone chain types. However, the high-dimensional parameter space associated with such complex systems makes it difficult to predict the resulting architectures and properties of the materials developed through experimental trial and error.

In this work, we explore new designs for crosslinked polymer materials with multiple types of backbone chains and crosslinkers using a computational framework established based on graph theory (GT) and graph neural networks (GNNs). We demonstrate that including three or four types of backbone polymer chains can improve the mechanical behavior of the polymer composite provided that suitable structural features are established. We develop a graph representation of various polymer networks where graph edge features are defined according to the nature of crosslinking in the system, i.e. covalent or noncovalent bonds. We use a GNN framework to investigate the relationship between experimentally-controlled structural parameters, such as crosslinker density and type, and GT-based structural descriptors, such as graph connectivity and Wiener index. Following this step, we develop another GNN framework to study structure-property relationships using GT-based descriptors and mechanical properties obtained from Molecular Dynamics (MD) simulations. The trained GNNs will be used to predict the behavior of new potential structural morphologies in order to identify ‘best-performing’ configurations. The results of this work are aimed to be utilized for future experimental development of new crosslinked polymer composites.

SESSION MT01.10: Machine Learning and Simulations IX

The LAMMPS Particle Simulation Package: Bringing Together Innovative Physics Models, Machine-Learning Interatomic Potentials and Extreme-Scale Computing Resources Aidan P. Thompson; Sandia National Labs, United States

The molecular dynamics method (MD), as implemented in the LAMMPS[1] particle simulation code, is a powerful tool for explicitly sampling the phase space distribution of hundreds or billions of physically and chemically interacting atoms. It provides a wealth of information on how particular microscopic interactions lead to a vast range of emergent behaviors on much larger length and time scales, complementing theory and experiment. The overall usefulness of the method is sensitive to how well the chosen interaction potential approximates the true physical and chemical conditions. Over many decades, this has driven the emergence of many prominent interaction potentials that provifde a good tradeoff between accuracy and cost. At the one extreme of minimal complexity are well-established models for simple fluids (Lennard Jones particles), polymer melts (FENE chains), and metals (EAM). In the case of chemical reacting systems, both organic and inorganic, the ReaxFF reactive potential has proven quite effective. More recently, relatively expensive machine-learning (ML) potentials have been found to approach the accuracy of very expensive quantum methods. These are trained to reproduce the energy and forces of many small configurations of atoms obtained from quantum electronic structure calculations e.g. Density Functional Theory. Examples of ML potentials implemented in LAMMPS include Behler-Parinello, GAP, SNAP[2], the Atomic Cluster Expansion (ACE)[3], and ALEGRO. In this talk, I will give a general overview of LAMMPS capabilities, as well as the those the LAMMPS-integrated FitSNAP software [4] for generating quantum-accurate machine-learning interatomic potentials. I will describe several recent scientific applications of LAMMPS that combine innovative physics models, machine-learning interatomic potentials, and extreme scale computing resources.

Demystifying High Temperature/Pressure Material Synthesis through Physics-Informed Machine Learning Rebecca K. Lindsey; University of Michigan, United States

Design, discovery, and synthesis of new materials is a notoriously challenging problem, due largely to the massive associated design space and complex underlying phenomena. Simulations can provide a powerful means of navigating this problem space by providing both a capability for pre-screening and extracting otherwise inaccessible atomistically-resolved information on the underlying phenomena, but efforts are often limited by a lack of models exhibiting the necessary balance of accuracy and computational efficiency. In this presentation, we discuss recent efforts to overcome these challenges through development and targeted application of ChIMES, a physics-informed machine-learned interatomic model (ML-IAM) and supporting computational framework. We will present recent efforts to address grand challenges in ML-IAM development and application, e.g., toward reproducibility, reliability, and training efficiency as well as applications to high temperature/pressure nanocarbon synthesis.

10:30 AM MT01.10.03
Molten Salt Crystallization studied by Machine-Learned Potentials Zhao Fan[1], Michael Whittaker[1], Piotr P. Zarzycki[1] and Mark Asta[1,2]; [1]Lawrence Berkeley National Laboratory, United States; [2]University of California, Berkeley, United States

Molecular dynamics (MD) simulations based on accurate interatomic force-fields are employed to calculate solid-liquid phase diagrams and investigate mechanisms of crystallization at the atomic level. The work is motivated by the potential relevance of molten salts in the context of lithium extraction. We report on the development of efficient and robust machine learning (ML) potentials for three unary salts (LiF, NaF and KF), three binary mixtures (LiF-NaF, LiF-KF and NaF-KF) as well as the ternary mixture of LiF-NaF-KF in the framework of Atomic Cluster Expansion and with the training datasets generated using density functional theory (DFT) with the strongly constrained and appropriately normed (SCAN) functional. We demonstrate that simulations based on these potentials produce properties consistent with DFT and available experimental data, including lattice constant, liquid density, melting point and latent heat of melting. The phase diagrams for the three binary mixtures and the ternary mixture calculated based on our ML potentials will be presented. In addition, we discuss results of simulations for homogeneous crystal nucleation, with focus on the crystallization pathways and role of metastable polymorphs. These studies are enabled by the attention paid in the potential development to accurate description of competing crystal phases, such as those with wurtzite, zinc blende and CsCl-prototype structures. The atomic-level mechanism of homogeneous melting of the rocksalt structure of LiF, NaF and KF will also be illustrated.

10:45 AM MT01.10.04
Tracing Molecular Reactions and Decomposition Using Machine Learning Force Fields and Active Learning Julia Yang[1,1], Whai Shin Amanda Ooi[2], Zachary Goodwin[1], Yu Xie[3], Ah-Hyung Alissa Park[4] and Boris Kozinsky[1,1]; [1]Harvard University, United States; [2]Columbia University, United States; [3]Microsoft Research, Germany; [4]University of California, Los Angeles, United States

Molecular reactivity spans extended length and time scales, making them costly to simulate using ab initio approaches or limited in chemical transferability/scope using reactive force fields. In this work, we describe how simulations of liquid structure and dynamics of organic molecules undergoing thermal decomposition reactions can be achieved using hybrid density functional theory (DFT), active learning [1], and machine learning force fields (MLFF) [2]. Active learning is essential for several reasons: 1) The overall computational cost of hybrid DFT is reduced dramatically as the uncertainty-aware force field collects only sufficiently-uncorrelated DFT frames; 2) High-temperature configurations with radicals or free gases, which are potential decomposition products, can also be collected on-the-fly; 3) The approach is useful in situations where classical force fields are either unavailable or lacking in expressivity.

When the training data from active learning are fed into a data-efficient equivariant neural network, molecular decomposition and reaction pathways can be traced with first-principles, all-atom resolution by identifying reaction pathways to product formation. We apply the approach to study the thermal decomposition of a “green” solvent used in battery recycling and validate our results against experimental characterization.

11:00 AM *MT01.10.05
Rational Design of Machine-Learned Interatomic Potentials Megan J. McCarthy; Sandia National Laboratories, United States

The predicative capability of a molecular dynamics simulation is determined by how accurately the chosen interatomic potential (IAP) captures a material's bonding characteristics. Integrating machine learning techniques into IAP development has led to powerful improvements in that accuracy, while also introducing new levels of complexity to the training process. The choice of model (hyper)parameters, training set structures, validation tests, and whether and how to use tools such as active learning is frequently a material-specific, highly empirical process. To accelerate development and usage of machine-learned IAPs, new approaches to promote reproducibility and rational design of IAP are needed, ideally ones that are consistent with FAIR (Findable, Accessible, Interoperable, Reusable) research practices. In this talk, I will discuss promising developments in this area, amongst them software tools and techniques our group has developed while training machine-learned IAPs for multicomponent, chemically-complex materials used in extreme environments.

11:30 AM MT01.10.06
In Search of a More Perfect Forcefield: Considerations and Strategies for Parameterizing Complex Interatomic Potentials for Molecular Dynamics Aravind Krishnamoorthy; Texas A&M University, United States

Molecular Dynamics (MD) simulations are an increasingly vital tool to understand molecular processes in a variety of material systems across mechanical, materials, and biological engineering. MD simulations require parameterized interatomic forcefields that capture complex interatomic interactions in materials. However, forcefield parameterization is a non-trivial global optimization problem involving quantification of forcefield variables in large-dimensional search spaces.

This talk will discuss currently used strategies to parameterize reactive and non-reactive interatomic potentials and will identify opportunities for improving these strategies through newly developed algorithms and software for performing multi-objective and global optimization, as well as schemes inspired by AI and ML training. Using EZFF, a Python package for parameterization of several types of interatomic forcefields using single- and multi-objective optimization techniques, I will describe a meta-analysis of the performance of forcefields for complex multi-phase materials generated using different strategies such as force-matching, energy-fitting and direct parameterization against dynamical properties. Approaches for parameterization of new forcefields against sparse ground truth data from experiments or expensive simulations will also be analyzed.

SESSION MT01.11: Machine Learning and Simulations X

Friday Afternoon, April 26, 2024
Room 320, Level 3, Summit

1:30 PM *MT01.11.01
Machine Learning-Enhanced Physics-Based Modeling of Materials: From Atomistics to Microstructure-Property Relationships Alejandro Strachan; Purdue University, United States

The synergy between principles-based modeling and data science is increasingly important in materials science and engineering. In addition to accelerating the design of new materials, there is significant interest in using machine learning (ML) tools to extract physical laws and structure-property relationships that govern materials' behavior from data. I will discuss recent progress by my group on machine learning applied to multiscale modeling and in the development of interpretable models that balance accuracy with parsimony.
I will discuss recent work on reactive ML interatomic potentials for materials at extreme conditions using an iterative approach to address the challenge of generating training data and the stochastic nature of NN training. The next step of the multiscale ladder is coarse-graining atomistic simulations, and I will discuss two applications. First, the use of dimensionality reduction techniques to extract physically interpretable collective variables from reactive MD simulations which are used to derive reduced-order chemical kinetics models. Finally, I will discuss our recent work on convolutional neural networks to develop models capable of mapping the initial microstructure of a composite material to the 3D temperature field induced by a shockwave.

2:00 PM MT01.11.02
Extracting Catalytic Reaction Mechanisms from Large-Scale Simulations Accelerated by Machine Learning Interatomic Potentials Anders Johansson, Cameron J. Owen and Boris Kozinsky; Harvard University, United States

Machine learning interatomic potentials (MLIPs) have become a prevalent approach to bridging the gap between slow-but-accurate ab initio calculations and fast-but-inaccurate empirical potentials for molecular dynamics. Among MLIPs, there is a pareto front of models with different tradeoffs between accuracy and speed. The FLARE interatomic potential aims to push the boundary of scalability and performance, while maintaining sufficient accuracy to study complex, reactive systems.

In our recent work [1], we demonstrated the ability of FLARE to simulate heterogeneous catalytic reactions in systems of up to 0.5 trillion atoms using 27336 GPUs, with an accurate Bayesian MLIP efficiently trained using active learning. With the exceptional speed of FLARE on modern HPC architectures, we can combine the atomistic resolution of molecular dynamics simulations with the large length and time scales required for realistic simulations and sufficient sampling of rare catalytic events, while providing the near-quantum level of accuracy provided by the MLIP. In this talk, we will showcase how this combination of scales and accuracy enables new insights into chemically complex processes such as heterogeneous catalysis through high-resolution measurements of reaction rates and residence times.

2:15 PM MT01.11.03
Understanding Complicated Chemistry of Organic Materials Using Machine Learning Interatomic Potential Cong Huy Pham[1], Nir Goldman[1], Laurence Fried[1] and Rebecca K. Lindsey[2]; [1]Lawrence Livermore National Laboratory, United States; [2]University of Michigan–Ann Arbor, United States

Understanding the chemical reactivity of organic materials under extreme conditions is important in many fields, such as chemistry, materials science, pharmaceutical, astronomy. Molecular dynamics simulations have become a powerful method that can provide insights into the detailed chemistry at the atomistic level. However, its accuracy depends strongly on the interatomic potential. Here, we present our effort to develop a quantum accurate Chebyshev Interaction Model for Efficient Simulation (ChIMES) many-body reactive potential to study the complicated chemistry of 1,3,5-Triamino-2,4,6-trinitrobenzene (TATB) under a shockwave. We discuss the techniques to control model accuracy and transferability as well as minimal training data selection. Our ChIMES potential has capability of reproducing the structural properties and chemistry of TATB at high accurate quantum level for a wide range of thermodynamic conditions. The shock simulations of TATB using ChIMES show good agreements with available experimental data.

2:30 PM MT01.11.04
Bayesian Interatomic Potentials for Thermodynamics Stability Predictions of Icosahedral Boron Crystals Hao Deng and Bin Liu; Kansas State University, United States

Elemental boron and icosahedral boron compounds (IBCs) are of surging interest due to their superior and versatile properties. For instance, boron suboxide (B_6O) and boron subphosphide ($B_{12}P_2$) derived from the α-rhombohedral boron lattice have extreme hardness and unusual electrical properties. These compounds display an extraordinary self-healing ability to repair the lattice defects generated from exposure to high-energy irradiation. Synthesis and control of the stoichiometry of IBCs are critical technical challenges. Computational tools, including Density Functional Theory (DFT) and molecular dynamics (MD) simulation, provide pathways to decipher the phase stability of IBCs. However, the structural and chemical complexity of IBCs hinder accurate DFT calculations and large-scale MD simulations.
In this talk, we report a unified sparse Gaussian process (SGP), a machine learning interatomic potential, for the phase stability predictions of boron allotropes (i.e., α-B, β-B, and γ-B). To account for the variety of lattice structures, on-the-fly training was employed for precise training set generation. The trained SGP yielded good agreement with DFT on predictions of structural, thermodynamics, and vibrational properties. Insights were gained from the generated P-T diagram and free energy composition analyses. The verified SGP training strategy is also employed in the phase stability prediction of B_6O. Factors affecting the phase stability of B_6O, including defect concentration and elemental composition, were investigated using SGP interatomic potentials implemented in large-scale MD simulations. We anticipate this computational approach will aid the understanding of the phase transition of complex crystals in future studies.

2:45 PM MT01.11.05
Benchmarking Anharmonicity in Machine Learned Interatomic Potentials Sasaank Bandi[1], Chao Jiang[2] and Chris A. Marianetti[1]; [1]Columbia University, United States; [2]Idaho National Laboratory, United States

Machine learning (ML) approaches have recently emerged as powerful tools to probe structure-property relationships in crystals and molecules. Specifically, ML interatomic potentials have been shown to predict ground state properties with near density functional theory (DFT) accuracy at a cost similar to conventional interatomic potential approaches. While ML potentials have been extensively tested across various classes of materials and molecules, there is no clear understanding of how well the anharmonicity of any given system is encoded. Here, we benchmark popular ML interatomic potentials using third and fourth order phonon interactions in flourite crystals. An anharmonic hamiltonian was constructed from DFT using our highly accurate and efficient irreducible derivative methods, which was then used to train three classes of ML potentials: Gaussian Approximation Potentials, Behler-Parrinello Neural Networks, and Graph Neural Networks. We evaluate their accuracy in not only reproducing anharmonic interaction terms but also in observables such as phonon linewidths and lineshifts. We then present the results of the models trained on a DFT dataset, showing good and reasonable agreement with the DFT computed third and fourth order interactions, respectively. Finally, we discuss strategies to leverage anharmonic terms in the training procedure to improve the accuracy of ML interatomic potentials.

Data-Driven Approaches to Facilitate Inorganic Materials Discovery and Synthesis Chris Bartel; University of Minnesota, United States

Machine learning is playing an increasingly prominent role in computational materials discovery. Recent advances in (universal) machine learning interatomic potentials allow practitioners to optimize the structure and compute the energy of inorganic crystals for arbitrary material compositions. These computed energetics can then be used as inputs to the convex hull analysis to determine if a hypothetical material is thermodynamically stable against potential competing phases. While stability is an important property for a candidate material, it does not determine if or how that material can be made in the lab. Whereas stability (at some set of conditions) is an intrinsic property of a material, synthesizability is not a similarly straightforward binary – it depends on experimental choices such as precursors, temperature, synthesis approach, etc. This talk will discuss recent efforts to use machine learning in the context of synthesis “recipe” generation, assessment, and optimization.

4:00 PM *MT01.11.07
Robust Machine Learning allows Accurate Modeling of Thermodynamics of Catalysts and Bulk Materials Daniel Schwalbe-Koda; UCLA, United States

Recent advances in machine learning (ML) interatomic potentials (IPs) allow density functional theory (DFT) calculations to be bypassed with models that balance high accuracy and relatively low computational cost. However, MLIPs can be unreliable in regions of the configuration space not represented in the training data, which often hinders their use as universal predictors when modeling high-complexity systems. In this talk, I will describe how understanding robust generalization in ML can improve the development of next-generation ML models for materials simulation. First, I will demonstrate how extrapolation in atomistic systems can be rigorously defined in a model-free approach, thus without surrogate metrics such as variance of predictions. Then, I will describe how deep learning theory can be used to improve the generalization of MLIPs. These results are used to model several problems in materials simulation, from the thermodynamic of phase transformations to coverage effects in catalysis. In combination with automated workflows for combinatorial data generation, robustness in ML models can help drive the field towards the development of universal MLIPs towards length and time scales not accessible by ground truth calculations.

4:30 PM MT01.11.08
General Protocol for Training Machine Learning Interatomic Potentials for Ionic Liquids and Battery Solvents Zachary A. Goodwin, Nicola Molinari, Julia Yang, Albert Musaelian, Simon L. Batzner and Boris Kozinsky; Harvard University, United States

We develop machine learning force fields (MLFFs), based on the equivariant graph neural networks with NequIP/Allegro [1,2], for representative ionic liquids and conventional battery solvents. As capturing the complex intermolecular interactions are subtle, and the dynamics of these electrolytes/solvents are quite slow, training a potential for these systems is not always straightforward. We develop a general, automatable protocol for training MLFFs for

complex, multicomponent liquids, which efficiently samples representative structures, to collect diverse, uncorrelated molecular configurations for training. This approach is shown to yield reliable simulations in the NVT ensemble, but not always in the NPT ensemble, where we find densities significantly lower than expected from our DFT calculations. We develop an approach to remedy this issue, and test it on a number of electrolytes/solvents to ensure it is a robust method. In addition, we study the question of model transferability, the effect of long-range interactions and uncertainty of the model.

4:45 PM MT01.11.09
Deep Learning-Assisted Analysis of Molecular Dynamics Simulations of LiTFSI/PYR_{14}TFSI Ionic Liquid Electrolyte Chanui Park, Sangdeok Kim, Anseong Park, Seungtae Kim, Woojin Kang and Won Bo Lee; Seoul National University, Korea (the Republic of)

Over the past decades, significant research has been conducted to understand microscopic behavior of ionic liquid electrolytes (ILEs) through molecular dynamics (MD) simulations. The development of polarizable force fields is one of the most remarkable achievements as they predict structural and dynamical properties of ionic liquid-based systems very accurately. However, even with the help of polarizable force fields, one cannot analyze atomic dynamics of a system in detail because most of the properties are evaluated by "averaging" individual atomic or molecular properties. A deep learning technique called Graph Dynamical Networks (GDyNets) has been suggested to learn atomic scale dynamics from MD simulations. GDyNets trains local environments around a specific target atom and classify them into states in an unsupervised manner. The classification model is trained in the direction where the VAMP loss decreases. The classification results are combined with conventional analysis techniques to calculate state-wise properties which can describe the system according to each state. Using this method, we analyzed MD trajectories of LiTFSI/PYR_{14}TFSI ILE with a range of lithium mole fractions, where the trajectories were generated under the APPLE&P polarizable force field. Li^+ ions were treated as target atoms and classified into 3 local configurational states. State-wise radial distribution function, coordination number, spatial distribution function were defined and calculated to identify each state. The identified states were a Li^+ ion coordinated by 2 and 3 $TFSI^-$ ions, and a cluster composed of multiple Li^+ and $TFSI^-$ ions. Also, a transition matrix based on the Markov state model was generated from the classification results. With this matrix, dynamical properties of the states and transitions between states were measured to reveal which state or transition dynamics is faster than others. Finally, a design rule for ILEs with faster Li^+ ion conduction was suggested.

Small Data Challenge for Materials Research in Battery Manufacturing Krishna Rajan; University at Buffalo, The State University of New York, United States

The harnessing of data driven methods for materials design in battery manufacturing, demands the linking of data associated with the fundamentals of materials chemistry through to battery performance. A critical limitation of applying current informatics methods is that available data captures only small parts of the materials information spectrum. In this presentation we explore approaches to address this issue to track linkages between multiscale data regimes that allows one to explore connections between crystal chemistry to device performance.

11:00 AM *MT02.01.02
A Strategic Approach to Building a Secure Domestic Battery Supply Chain Venkat Srinivasan; Argonne National Laboratory, United States

As the world embarks on widespread decarbonization, the supply chain crunch for batteries has become front and center around the world. In the United States, the issues are widespread, from material availability to the lack of cell and pack manufacturing. Recycling, which could bridge the supply gap, is still in its early stages. With the expected growth in the storage market, tactical approaches to solve the challenges will not suffice. What is needed is a comprehensive strategy that brings a holistic approach to solve the battery supply chain issues. This includes the search for alternative materials to the presently-constraints materials (such as nickel, cobalt, and lithium), examining opportunities for clean extraction of battery minerals, and recycling. In addition, an important part of the strategy is to examine leapfrogging materials and manufacturing methods that can enable deep decarbonization of transportation and grid sectors. The talk will examine the status of battery technology, and the opportunities for enabling widespread electrification with a sustainable and secure supply chain.

11:30 AM *MT02.01.03
Guiding New Battery Material Scale Up Through Automated Information and Relation Extraction Elsa Olivetti[1], Kevin Joon-Ming Huang[1], Mrigi Munjal[1], Thorben Prein[2] and Jennifer L. Rupp[2]; [1]Massachusetts Institute of Technology, United States; [2]TU Munich, Germany

Improving the performance of novel electrode materials will enable competition with mature technologies like lithium-ion batteries (LIBs) at scale. To some extent novel electrode active materials can leverage the well-established manufacturing knowledge of lithium-ion batteries. However, several materials synthesis and performance challenges for electrode materials must be addressed for them to mature from lab to industrial scale. We employ natural language processing (NLP) tools to extract challenges from battery literature in the performance and synthesis of active battery materials. The tools also systematically review corresponding mitigation strategies. These selected mitigation strategies are then evaluated among a broad set of pre-existing lab-proposed mitigation strategies. These derived insights enable engineers in research and industry to navigate a large number of proposed strategies.

1:30 PM *MT02.02.01
How Argonne's MERF Can Help Advance Your New Materials Krzysztof Pupek; Argonne National Laboratory, United States

Rechargeable batteries are among the critical technologies in the decarbonization effort of increasingly expanded transportation and power grids. The demand for safer, longer-lasting, durable energy storage continues to fuel the need for battery innovation. This need, in turn, requires designing new materials, understanding how they function, and developing scalable processes to manufacture them. Electric vehicles (EVs) powered by lithium-ion batteries (LIBs) represent the most advanced and readily available energy storage technology to help the decarbonization of the world. There is an increased interest in deploying sustainable EVs powered by the new generation of rechargeable batteries, making energy storage scientists explore new, safer, cheaper, and earth-abundant materials to lower costs and dependence on foreign sources. The challenges ahead of battery researchers are complex, and it may take decades to convert the discoveries into full commercial adoption. These materials or better-performing new materials can quickly become a new quest for scientists. The current proven technologies to produce these materials most often may not work when the chemical composition and particle morphology requirement changes.
The Materials Engineering Research Facility (MERF) is a part of the Applied Materials Division at Argonne National Laboratory. Established in 2009, remodeled, and expanded in 2020, the MERF is a 28,000-square-foot research facility equipped with state-of-the-art instrumentation. It employs 40 researchers, engineers, and support technicians, with all key staff having an extensive industrial background. The facility is a home for Process R&D and Scale-up Group. It is a vital component of Argonne's Materials Manufacturing Innovation Center (MMIC), a significant, multi-year investment of discretionary laboratory resources to extend the Laboratory leadership in accelerating scalable materials synthesis and process development.
The presentation will familiarize the audience with MERF capability, including traditional process R&D technologies as well as a suite of emerging manufacturing technologies like Tailor Vortex Reactors, Hydro/Solvothermal Synthesis, Flame/Ultrasonic Spray Pyrolysis, and Continuous Flow Reactors. We will use systematic, data-driven approaches to develop efficient manufacturing processes and scale up the new materials to make sufficient amounts to support further research, prototyping, and industrial validation.
The team of researchers and engineers behind MERF aims to streamline the conversion of your discovery into commercial products.

2:00 PM *MT02.02.02
Linking Failure Mode Analysis and Machine Learning to Accelerate Life Prediction Eric Dufek; Idaho National Laboratory, United States

Batteries continue to see rapid advancement both in materials selection and in emerging use cases. In all cases as new options for battery use and design arise there is a need to validate performance and to understand failure modes. Traditionally validation processes would require years of testing and immense use of resources to reach acceptable certainty that a new battery would function in an intended use case. Recent emergence of the use of combining failure mode analysis with machine learning and other advanced data analytics provides the opportunity to dramatically reduce the time needed for validation and to more quickly bring new discoveries and uses cases from the bench top to the consumer.

In this discussion several different approaches to reducing the time needed for perfromance validation will be discussed. This includes both the importance of appropriate and targeted data collection as well as the data analytic methods that can support rapid validation. The key to both the advanced analytics and data collection is the need to ensure a link to physical processes which aids in battery failure mode identification. The link also allows extended data sets to be generated using different modeling or synthetic data approaches to be used for enhanced training purposes.

Using a combination of experimental and synthetic data it will be shown that enhanced predictions are possible and that the time and resources needed to make predictions can be dramatically reduced. As an example set different predictions for graphite/NMC batteries used in standard and fast charge conditions will be highlighted.

2:30 PM *MT02.02.03

Data-driven Research for Aqueous Organic Redox Flow Batteries Wei Wang; Pacific Northwest National Laboratory, United States

Aqueous organic redox active materials have recently shown great promise as alternatives to transition metal ions as energy-bearing active materials in redox flow batteries for large-scale energy storage due to their structural tunability, cost-effectiveness, availability, and safety features. However, development to date has been limited to a small palette of aqueous soluble organics. This presentation will provide an overview of a data-driven approach to accelerate the discovery and development of aqueous organic redox-active molecules for flow batteries, including database curation, structure-property correlation, and automated property characterization and performance testing developed in PNNL's ARES (Automated Robotics for Energy Storage) lab.

3:30 PM *MT02.02.04
DigitalDNA: Synchronizing Molecules to Machines to Build Smart Gigafactories Shailesh Upreti; Charge CCCV LLC C4V, United States

Lithium-ion battery (LIB) market size will grow at the compounded annual growth rate of +16%, surpassing 165 billion USD in revenue by 2030. While most of this growth is enabled by innovations in battery chemistry and performance, safety hazards remain a primary concern and a major restrain to market expansion. Safety incidences often results from errors introduced during high-volume manufacturing that, through a chain of events, leads to a thermal runaway and fire. C4V has teamed with leading Machine Learning (ML) and Artificial Intelligence (AI) experts to address the issue by developing tools that can not only track and minimize or eliminate manufacturing defects in the battery cells, but can warn users of an incipient catastrophic event ahead of time, thus preventing any damage to property or loss of life. The first generation of the DigitalDNA (DDNA) software is able to automatically capture key electrochemical data from cell cyclers installed at iM3NY, a New York based gigafactory that produces 50Ah prismatic cells. 2 DDNA automatically curates and analyse data generated at the production floor, and create actionable outputs for operator to take corrective measures in near real-time. DDNA is designed to be platform agnostic and can capture data in multiple formats. The next-generation of DDNA, with an in-built advanced data analytics algorithms can easily access and use these large data sets to train the ML models and implement AI to provide predictive insights and enable continuous improvements in electrochemical performance of LIBs. In addition, with a recent release of the Supply Chain module, DDNA can perform a full inventory control and management of +30 components that are required for battery cell production. With this module, DDNA can also track the progress of C4V's extensive raw material qualification program currently underway for more than 50 vendors globally. By integrating best-practices in laboratory information and data management systems, DDNA enables a high level of information flow control during the 5 discrete stages of phasegate qualification process starting with a preliminary assessments in a coin cell to a full scale evaluation in the commercial cell. When integrated with the warehouse management system and highlevel business systems such as ERP, the predictive capability of the software can use the raw material utilization data intelligently to create sourcing and procurement scenarios to achieve full inventory and cost optimization. By leveraging the fully digitized future gigafactories and the IIoT ecosystems, the future-generations of DDNA will seamlessly integrate with manufacturing execution systems to collect data at each step of the manufacturing process. By tapping into the real-time visualization of process and equipment performance data, the ML and AI analytics will be able to detect anomalies ahead of time. This ability to predict failure and perform preventive maintenance will increase equipment availability and performance and reduce disruptions and costly repairs. More importantly, DDNA will interface with the numerous in- or at-line quality control instruments implemented in a roll-to-roll process. Together with feedback control loop, access to statistically significant anomaly data set and advanced descriptive analytics, DDNA will enable processes that will reduce waste and improve yields. By quickly detecting and eliminating any debilitating defects at every step, DDNA will afford a highly reliable and safe battery products. We envision that DDNA will mature into a comprehensive software platform that will enable Smart gigafactories and predictive manufacturing and will make intelligent decisions informed by data gathered over the entire value chain of LIB from molecules (mines) to machines (vehicles and Energy Storge Systems).

Exploratory Perspectives on Artificial Intelligence Enabled Autonomous Manufacturing Yuepeng Zhang[1], Noah H. Paulson[1], Santanu Chaudhuri[1,2] and Jie Xu[1]; [1]Argonne National Laboratory, United States; [2]University of Illinois Chicago, United States

Manufacturing spans complex materials properties and process variables. Currently, process development relies on empirical analysis, trial-and-error, and ex-situ characterization, limiting production efficiency and yield. Recently, artificial intelligence (AI) coupled with in-situ, in-line metrology has enabled autonomous characterization, data analysis, and rapid development of process-property correlations — necessary components in a future accelerated manufacturing paradigm. In this report, we share perspectives on applying AI and machine learning (ML) to roll-to-roll (R2R) coating of formulated inks — a scalable high-throughput manufacturing process used for many energy storage and conversion technologies including lithium-ion battery (LIB) electrodes and fuel cell and water electrolyzer membrane electrode assemblies (MEAs).

4:30 PM *MT02.02.06
High-Throughput Approach to High Energy Lithium-Ion Cell Roadmap Development Gang Cheng, Ye Zhu, Ram Deivanayagam and Hui Wang; Wildcat Discovery Technologies, United States

As EV adoption has grown, there has been an increased focus in the battery industry on the development and implementation of high-nickel cathodes from 80% Ni to now 95 and above with increasing Si% in the anodes. These materials can deliver improved energy density relative to today's materials but suffer from poor lifetime and durability. Variations in electrode composition can impact the performance of the material. This presentation highlights Wildcat high-throughput strategy that can accelerate implementation of high-nickel cathodes paired with high Si% of anodes in applications. The presentation focuses on approaches other than compositional changes to the high nickel NMC/Si-C cells to improve cycle life in high-loading electrodes.

10:30 AM MT02.05.02
3D Printed Flexible Lithium-Ion Batteries with Improved Cycling Performance Xin Hu[1,2], Yimin Chen[1,2], Baozhi Yu[1,2] and Ying Chen[1,2]; [1]Deakin University, Australia; [2]ARC Research Hub for Safe and Reliable Energy, Australia

3D printing technology, one of the additive manufacturing techniques, has shown remarkable promise in creating flexible and tailor-made high-performance batteries, which are in high demand for the upcoming era of intelligent and widespread energy usage. Nonetheless, a notable performance disparity, particularly in terms of cycling stability, still persists between 3D-printed electrodes and traditional counterparts, severely constraining the practical utility of 3D-printed batteries. This presentation discusses the development of a range of 3D-printed electrodes based on thermoplastic polyurethane (TPU) using fused deposition modeling for high-performance, flexible, and customizable lithium-ion batteries. The TPU-based electrode filaments are produced in significant quantities through a straightforward extrusion method. Consequently, the electrodes are printed with precision, offering excellent dimensional accuracy, flexibility, and mechanical stability. Notably, 3D-printed TPU-LFP electrodes demonstrate an impressive capacity retention of 100% after 300 cycles at 1C, representing one of the most robust cycling performances among all reported 3D-printed electrodes. This exceptional performance can be attributed to the outstanding stress-absorbing characteristics of the TPU-based electrodes, which effectively accommodate the volume changes during cycling and thus substantially prevent the collapse of the 3D-printed electrode structures. These findings not only open up new possibilities for creating adaptable and flexible batteries but also pave the way for bridging the performance gap between 3D-printed and traditional lithium-ion batteries.

10:45 AM *MT02.05.03
Sustainable $LiFePO_4$ and $LiMn_xFe_{1-x}Po_4$ (x=0.1 to 1) Cathode Materials for Lithium-Ion Batteries: A Systematic Approach from Mine to Chassis Atiyeh Nekahi, Anil Kumar Madikere Raghunatha Reddy, Karim Zaghib, Xia Li and Sixu Deng; Concordia University, Canada

We conducted a comprehensive literature review for $LiFePO_4$ (LFP) and $LiMn_xFe_{1-x}PO_4$ (x=0.1 to 1) (LMFP)-based lithium-ion batteries (LIBs), focusing primarily on electric vehicles (EVs), which account for approximately 90% of LIB consumption. Although numerous individual research studies exist, a unified and coordinated review that covers the subject from mine to chassis is notably absent. Accordingly, our review encompasses the entire LIB development process, starting with *I)* initial resources, including lithium (Li), iron (Fe), manganese (Mn), and phosphorous (P), their global reserves, mining procedures, and their demand in LIB production. Then, we examined *II)* the main Fe- and Mn-containing precursors of Fe^0, Fe_xO_y, $FePO_4$, $FeSO_4$, and $MnSO_4$, focusing on their preparation methods, employment in LIBs, and their effect on the electrochemical performance (EP) of the final active cathode materials (ACMs). These two steps are followed by *III)* utilizing these precursors in synthesizing ACMs. Specific attention is paid to the pioneering synthesis methods in olivine production lines, particularly hydrothermal liquid-state synthesis (LSS), molten-state synthesis (MSS), and solid-state synthesis (SSS). Afterward, we described *IV)* electrode engineering and design and optimization of electrolytes and *V)* the production of cells, modules, and packs. Finally, *(VI)* our review underscored the challenges associated with the widespread utilization of olivines in LIBs, emphasizing safety, cost, energy efficiency, and carbon emission. In conclusion, our review offers a comprehensive overview of the entire trajectory involved in the fabrication of LFP/LMFP-based LIBs, spanning from the initial elements in the mine to the assembly of final packs that power EVs.

11:15 AM *MT02.05.04
Circular Manufacturing of Next-Generation Lithium-ion Battery Cathode Materials with R2R Molten Salt Electrodeposition Heng Yang; Xerion Advanced Battery Corporation, United States

For the past few years, Xerion has been developing a roll-to-roll (R2R) molten salt electrodeposition technology (DirectPlate™) for circular manufacturing of lithium-ion battery cathodes. Cathode materials such as $LiCoO_2$, $Li(Ni_xM_yCo_z)O_2$, and $Li_xMn_yO_z$ are demonstrated with good electrochemical properties. DirectPlate™ cathodes are distinctly different from conventional slurry-cast electrodes combining several notable properties: they are very dense with less than 10% porosity, free of additives (carbon and polymer binder), and their crystal orientation can be accurately controlled, enabling high-rate operation at or beyond state-of-the-art areal capacity loading (3-4 mAh/cm^2). As Li^+ diffusion primarily occurs through the single crystalline domains aligned vertically to the current collector, DirectPlate™ $LiCoO_2$ cathodes delivers good electrochemical properties in a solid-state cell without the need to infiltrate electrolyte into the cathode. We further demonstrate that end-of-life DirectPlate™ cathodes can be efficiently re-lithiated and repaired with a short molten salt treatment; or they can be upcycled into another cathode material with a completely different composition. Finally, we demonstrate that the DirectPlate™ cathode can be employed as a redox membrane for direct lithium extraction from various lithium-containing solutions. Integrating the collective mineral refinement, electrode fabrication and recycling capabilities into the R2R DirectPlate™ platform enables next-generation circular battery manufacturing with much lower energy and environmental cost.

SESSION MT02.06: Data-Driven Battery Optimization and Health Prognosis
Session Chairs: Eric Dufek and Alejandro Franco

Room 321, Level 3, Summit

1:30 PM MT02.06.01
Behind the Coulombic Efficiency Zonghai Chen, Jiyu Cai and Yingying Xie; Argonne National Laboratory, United States

Lithium-ion batteries have been widely adopted as the most practical energy storage technology for powering portable electronics and electric vehicles. Portable electronics generally require a battery calendar life of 2 years or less, which can be easily fulfilled by most state-of-the-art lithium-ion technologies. However, this is not the case for the emerging application in EVs, which generally require a substantially longer calendar life for 10 years or more. The assurance of calendar life must rely on certain mathematical prediction, such as multivariant regression and machine learning. On the other hand, coulombic efficiency has been generally used as an empirical indicator of cell performance, but the quantitative use of coulombic efficiency for prediction of cell life is not achieved yet. This talk will focus on the chemical and physical processes behind the measurement of the coulombic efficiency of lithium-ion cells, as well as its implication on the cell life prediction.

1:45 PM *MT02.06.02
AI Performance and Health Prognosis for Degradation-Aware Battery Development Noah H. Paulson, Joseph Kubal, Logan Ward, Saurabh Saxena, Wenquan Lu and Susan Babinec; Argonne National Laboratory, United States

Battery development requires extensive experimental trials ranging from benchtop materials discovery, to scale up trials, to full production optimization, incurring costs that may exceed hundreds of millions of dollars. One principal barrier to a more efficient and accelerated development process is the requirement to consider the degradation of batteries with use, the experimental evaluation of which requires 12 to 18 months of laboratory cycling experiments to reach failure. Physics-based simulations of battery degradation are rapidly advancing, but the diversity and complexity of coincident degradation mechanisms precludes the complete replacement of experimental trials. Data-driven methods, however, do not require exhaustive description of degradation mechanisms, and in recent years have shown strong performance in predicting battery degradation and remaining useful life (RUL). In this presentation, we share recent work in predicting battery RUL from limited cycling for a dataset of 300 Li-ion pouch cells representing 6 cathode chemistries and a variety of anode and electrolyte compositions. RUL prognosis was performed with a mean absolute error of ~100 cycles for a model trained on all available cathode chemistries, and useful predictions were made for unseen chemistries. Furthermore, we present timeseries prognosis of a multivariate battery state of performance and health including capacity, energy, efficiency, resistance, and open circuit voltage quantities.

2:15 PM MT02.06.03
Harnessing AI: Accurate Predictions of Battery Capacity Fade and Battery Cycle Life Jordan Crivelli-Decker[1], Marc Cormier[2], Shivang Agarwal[1], Ty Sours[1], Steffen Ridderbusch[1], Dan Zhao[1], Stephen Glazier[2], Brian Wee[1], Don Fiander[2] and Ang Xiao[1]; [1]SandboxAQ, United States; [2]Novonix, Canada

Predicting battery degradation is pivotal for advancing material research and unlocking opportunities in battery design, utilization, testing, and recovery. This enables better battery management and ensures the maintenance of desired performance characteristics over an extended period including both up and downstream manufacturing processes such as material selection, design qualification, technology/cell selection (battery management), and warranty, etc. However, traditional models and machine learning techniques often fall short in capturing these characteristics.

Lithium-ion cells typically show a gradual capacity degradation up to a certain point, known as the knee-point, beyond which the degradation accelerates rapidly, leading to the cell's End-of-Life. SandboxAQ's collaboration with NOVONIX has resulted in a robust method to predict long-term cell capacity fade from early-life cycling data. The approach begins with extracting early-life current, voltage, and capacity data collected on NOVONIX's world-class Ultra-High Precision Coulometry (UHPC) cycler systems. Electrochemically relevant metrics are then combined with advanced feature engineering and sophisticated data transformations are employed to construct features conducive for machine learning.

Proprietary machine learning and deep learning models were trained on several comprehensive, but limited datasets. Despite limited training data, these models demonstrate a remarkable ability to accurately classify the cells with and without catastrophic failure at a given point in time, predict the cycle number at which 80% of cell's initial capacity remains, and estimate the remaining useful life of the cell, which provides key indicators of cell health and longevity.

One of the standout features of these models is their flexibility. They are designed to seamlessly incorporate new data as it becomes available, ensuring that the predictions remain relevant and accurate over time. This approach not only provides a more cost and time-efficient alternative to long-term experiments traditionally used to estimate battery life but also opens avenues for more dynamic and responsive battery management strategies.

In summary, our solution leverages AI to rapidly make accurate, physics-based, end-of-life predictions using early-life electrochemical data. We leveraged comprehensive manufacturing cell data to deliver custom machine learning and deep learning models that were able to reliably predict cycle life only from high fidelity early-life data. The models are designed to easily integrate any future data, offering a cheap and efficient alternative to lengthy benchtop experiments.

3:30 PM *MT02.07.01
Data-Driven Battery Analysis with Machine Learning: From Laboratory to Field Application Weihan Li; RWTH Aachen University, Germany

Machine learning has emerged as a pivotal force within the battery industry, spanning research endeavors from the material level to the system level, encompassing both production processes and practical applications. Recent advancements in machine learning and data-driven methodologies have enabled innovative solutions for complex problems, particularly those scenarios where conventional physics-based models have fallen short.

In my talk, I will delve into our latest endeavors in the realm of data-driven battery analysis, encompassing both laboratory experimentation and real-world application in electric vehicles and stationary energy storage systems. Our research is centered on the development of deep learning models designed to augment and denoise CT images for in-depth battery electrode analysis. Additionally, we are actively engaged in harnessing machine learning and statistical learning techniques to scrutinize data from various testing and field sources, thereby improving aging diagnostics in the cloud.

This talk aims to offer a comprehensive overview of the diverse array of machine learning approaches employed in battery-related analyses while also shedding light on the unique challenges faced and the abundant prospects awaiting exploration.

4:00 PM MT02.07.02
Incorporating Domain Knowledge in Statistical Machine Learning to Efficiently Navigate Parameter Space and Test Durability for Energy Storage Maher Alghalayini, Marcus M. Noack and Stephen J. Harris; Lawrence Berkeley National Lab, United States

Given the urgency of addressing global warming and the need for sustainable energy solutions, the importance of efficient energy storage devices cannot be overstated. Of particular interest are the long-duration storage systems that are paramount for the integration of these sustainable sources, like renewables, in the power grid. Long-duration storage systems are designed to capture surplus energy during periods of high production and low demand, subsequently releasing it during periods of low production and high demand.

Developing such systems requires efficiently exploring their parameter spaces and assessing durability. Traditionally, this exploration process has been haphazard and inefficient, resulting in time and resource wastage, and an inadequate assessment of durability and failure probabilities. Machine learning and artificial intelligence are revolutionizing most aspects of science and engineering, including parameter space exploration, but adopting those advancements has been slow in the energy-storage community. The reasons are the expense of battery testing and the associated sparsity of datasets, the need to extrapolate instead of interpolate, the inherent stochasticity of the problem, and the deep connection between failure mechanisms and physical and chemical processes. All of this causes a purely data-driven approach to be suboptimal. In this study, we present an innovative method that harnesses statistical and machine learning techniques, specifically Gaussian Process regression and the expected information gain from future experiments, to streamline the exploration of energy storage systems parameter space. By incorporating the expertise of domain specialists to tailor our prior mean, kernel function, and noise model, our approach minimizes the need for extensive experimentation while accurately quantifying the failure probability distribution. Our results show that this method can, in fact, efficiently explore the parameter space and approximate failure distributions early in the testing process. In short, this work holds promise for expediting the development and optimization of energy storage, facilitating renewable energy integration, and contributing to a more sustainable future.

4:15 PM MT02.07.03
Exploring Secondary Phase Formation at The Solid-Electrolyte/Cathode Interface using Machine-Learning Interatomic Potential Wonseok Jeong, Brandon Wood and Liwen Wan; Lawrence Livermore National Laboratory, United States

All-solid-state Li-ion batteries are attractive next-generation energy-storage devices, offering improved safety, energy density, and durability compared to conventional Li-ion batteries. A critical challenge in these batteries is the occurrence of side reactions at the solid-electrolyte/cathode interface, particularly at elevated temperatures during co-sintering. These reactions have the potential to result in the undesired formation of secondary phases that impede the transport of lithium ions. The dynamic formation of these secondary phases at the atomic scale and the conditions governing their emergence remain unclear.
In this work, we explore the nucleation and evolution of secondary phases, such as La-Co-O, at the interface between the $Li_7La_3Zr_2O_{12}$ (LLZO) solid electrolyte and the $LiCoO_2$ (LCO) cathode. Our investigation comprises three main components that employ atomistic simulations driven by a machine-learning potential (MLP) for accelerated and comprehensive analysis. Firstly, we utilize a crystal structure prediction algorithm in conjunction with an MLP to accelerate the identification of potential secondary phases that may form at the interface. Secondly, we conduct MLP-driven metadynamics simulations to investigate the relationship between local structural features and the energy landscape associated with the nucleation of secondary phases. This exploration helps us understand the conditions leading to the formation of bulk-like secondary phases. Finally, we perform large-scale MLP molecular dynamics simulations to directly observe the formation of secondary phases in a model interface structure.
Through this multi-level investigation, we offer a holistic understanding of the formation of secondary phases at the LLZO/LCO interface. This insight is critical for understanding battery degradation resulting from interface reactions.

This work was sponsored by the Office of Energy Efficiency and Renewable Energy, Vehicle Technologies Office and was performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344. A portion of this research was performed using computational resources sponsored by the Department of Energy's Office of Energy Efficiency and Renewable Energy and located at the National Renewable Energy Laboratory.

4:30 PM MT02.07.04
Reveal The Active Components of Crystalline Li-Nb-O and Li-Ta-O Coatings Hengning Chen[1], Zeyu Deng[1], Yuheng Li[1] and Pieremanuele Canepa[1,2]; [1]National University of Singapore, Singapore; [2]University of Houston, United States

As widely applied coating materials for high-voltage positive electrode materials, niobate and tantalate materials can mitigate the interfacial reactivities in Li-ion and all-solid-state batteries. Although crystalline $LiMO_3$ (M=Nb, Ta) coatings show substantial enhancements in the battery electrochemical performances, there exists an apparent contradiction between the low Li-ion conductivity of crystalline $LiMO_3$ coating and the good rate capabilities achieved in these cells.[1,2] This contradiction needs to be well understood to optimize the functional properties of crystalline niobates and tantalates. Leveraging a combination of density functional theory, empirical bond valence mapping, nudged-elastic band calculations, and machine learning molecular dynamics, we reveal the multiphasic nature of Li–M–O coatings, containing mixtures of $LiMO_3$ and Li_3MO_4. The concurrence of several phases in Li–M–O modulates the type of stable native defects in these coatings. Li–M–O coating materials can form favorably lithium vacancies and antisite defects combined into charge-neutral defect complexes. Even in defective crystalline $LiMO_3$, we reveal poor Li-ion conduction properties. In contrast, Li_3MO_4 introduced by high-temperature calcinations can provide adequate Li-ion transport in these coatings. However, the occurrence of intrinsic defects in niobates (and tantalates) remains conditional to the coexistence of $LiMO_3$ and Li_3MO_4 at synthesis conditions, which regulates the availability of Li vacancies. Our in-depth investigation of the structure-property relationships in the important Li–M–O coating materials helps to develop more suitable calcination protocols to maximize the functional properties of these niobates and tantalates.[3]

4:45 PM MT02.07.05
Data-Driven Electrolyte Design for Lithium Metal Batteries Solomon Oyakhire[1,2], Sang Cheol Kim[1], Yi Cui[1] and Stacey F. Bent[1]; [1]Stanford University, United States; [2]University of California, Berkeley, United States

Enhancing Coulombic efficiency (CE) plays a pivotal role in facilitating the adoption of high-energy-density lithium metal batteries. While liquid electrolyte engineering has emerged as a promising strategy for improving CE, its inherent complexity makes performance prediction and electrolyte design challenging. In this two-part presentation, we introduce machine learning methods and workflows that enable us to predict electrolyte performance, guide the design of new high-performing electrolytes, and extract important scientific insights.

In the first part, we introduce a novel workflow that combines principles of feature engineering, feature selection, and machine learning model assessment. This workflow allows us to extract insights that guide the design of five new, high-performing electrolytes. Leveraging simple features, such as elemental composition that encodes pertinent physics within the electrolytes, we constructed interpretable models using linear regression, random forest, and bagging techniques. Through the results derived from these interpretable models, we identified crucial electrolyte features that are instrumental in achieving high battery efficiency. One such feature is the atomic fraction of oxygen in the solvent, highlighting the significance of reducing solvent oxygen for achieving

high Coulombic efficiency (CE). Equipped with this insight and a few others, we formulated five new electrolyte compositions with fluorine-free solvents, one of which attains a high CE of 99.70%.

In the second part, we employ data segmentation in conjunction with machine learning methods to discern crucial performance descriptors within distinct electrolyte efficiency classes. Through this approach, we made a surprising discovery. Common electrolyte performance descriptors like lithium morphology, ionic conductivity, solid electrolyte interphase chemistry, and lithium-electrolyte reactivity, **do not** explain performance variations in electrolytes beyond a Coulombic Efficiency (CE) of 98%. By utilizing new machine learning model assessment techniques, interpretable machine learning models, correlation analysis, and rigorous spectroscopy and electrochemistry characterizations, we unveil the pivotal role of **galvanic corrosion** in accounting for performance disparities within high CE (>98%) electrolytes.

This work underscores the potential of data-driven approaches in expediting the discovery of high-performance electrolytes for lithium metal batteries.

SESSION MT02.08: Poster Session

5:00 PM MT02.08.01
Image Enhancement and Feature Extraction for Battery Electrodes with Deep Learning Thorsten Tegetmeyer-Kleine, Adrian Mikitisin, Dirk Uwe Sauer and Weihan Li; RWTH Aachen University, Germany

In the field of battery material science, the use of advanced imaging techniques is paramount for a comprehensive understanding of electrode materials. Computed Tomography (CT) has become an invaluable tool, offering insights into the internal structures of battery components. However, the challenges of low-contrast materials and small feature sizes inherent to battery electrodes necessitate innovative approaches for image enhancement and feature extraction. In this study, we explore the application of a machine learning approach, i.e., UNets, for enhancing CT images and employ a Variational Autoencoder (VAE) for feature extraction and clustering.

Our focus centers on a graphite-silicon composite electrode, chosen due to its relevance in battery materials and the complex imaging challenges it presents. Notably, the smallest features, such as carbon black and chipped graphite flakes, exist at nanometer scales, contributing to a heterogeneous structure. Moreover, the materials, including graphite and carbon black binder, share similarities in their core charge numbers, leading to low signal contrast, making their distinction challenging.

The study primarily addresses three key aspects:
Image Enhancement: We utilize UNets to enhance CT images of the graphite-silicon composite electrode. These neural networks excel in denoising and super-resolution, improving the visibility of small features and enhancing the overall image quality. The application of UNets leads to clearer, more informative images, aiding researchers in the analysis of battery materials in a faster way.
Feature Extraction: Through the implementation of a VAE, we perform feature extraction and clustering on the CT images. This technique enables the identification and isolation of important structural features within the electrode, offering insights into the material's composition and distribution. The extracted features can be instrumental in understanding the electrode's behavior during battery aging.
Applications: We discuss the practical applications of enhanced CT images and feature extraction in battery material science. The enriched images facilitate the accurate characterization of small-scale structures and the spatial distribution of materials within the electrode. This information can be used in the development of battery materials and manufacturing processes, contributing to enhanced performance, safety, and longevity.

Our study underscores the potential of utilizing cutting-edge image enhancement techniques and feature extraction methods in battery material science. By enhancing the quality of CT images and extracting relevant features, researchers can gain deeper insights into the intricate structures of battery electrodes. This research bridges the gap between imaging technology and materials science, offering valuable tools for advancing the development and manufacturing of high-performance batteries.

5:00 PM MT02.08.02
Coral-Like Metal Oxide/C Hybrid Microspheres comprising a Porous Yolk and a Hollow Thin-Shell for Anodes in Li Ion Batteries Jung Sang Cho; Chungbuk National University, Korea (the Republic of)

Nowadays, innovative anodes are in demand owing to the requirement for improvement in the performance of Li ion batteries (LIBs). Although yolk–shell structured transitional metal oxides (TMOs) with various compositions have been studied as anodes for LIBs thus far, their long-term cycle properties are unsatisfactory in practical implementation. In order to solve this problem, hybrids of TMOs and C could be a effective strategy, but with the traditional synthetic process for the yolk–shell structure, it is difficult to prepare the yolk-shell structured TMO/C hybrid. In this study, we introduce a novel synthetic strategy for the yolk-shell structured TMO/C hybrids. The yolk shows a coral-like structure with interconnected mesopores. The synergetic effects of the coral-like yolk-shell structure with well-defined interconnected mesopores and a highly conductive C content result in advanced anodes with excellent Li^+ ion storage properties. The detailed formation mechanism of the structure and its electrochemical properties as anodes for LIBs were investigated, in detail.

5:00 PM MT02.08.03
A Novel Machine Learning Approach for Surface Roughness Quantification and Optimization of Cast-On-Strap Lead-Antimony Alloy via Two-Point Correlation Function Nageh K. Allam; American University in Cairo, Egypt

Surface roughness has a negative impact on the materials' lifetime. It accelerates pitting corrosion, increases effective heat transfer, and increases the rate of effective charge loss. However, controlled surface roughness is desirable in many applications. The automotive lead-acid battery is very sensitive to such effects. In our case study, the cast-on-strap machine has the largest effect on the surface roughness of the lead-antimony alloy. In this regard, statistical correlation functions are commonly used as statistical morphological descriptors for heterogeneous correlation functions. Two-point correlation functions are fruitful tools to quantify the microstructure of two-phase material structures. Herein, we demonstrate the use of the two-point correlation function to quantify surface roughness and optimize lead-antimony poles and straps used in the lead-acid battery as a solution to reduce their electrochemical corrosion when used in highly corrosive media. However, we infer that this method can be used in surface roughness mapping in a wide range of applications, such

as pipes submerged in seawater as well as laser cutting. The possibility of using information obtained from the two-point correlation function and applying the simulated annealing procedure to optimize the surface micro-irregularities is investigated. The results showed successful surface representation and optimization that agree with the initially proposed hypothesis.

5:00 PM MT02.08.04
First-Principles Investigations of FeP@Graphene as Anode Material for Sodium-Ion Batteries Qi-Jing Hong; National Central University, Taiwan

In recent years, numerous strategies have been proposed to tackle the challenges of large volume changes and capacity decay in conversion-type electrodes. Most studies have focused on experimental investigations, and only a few have centered on simulation studies. This research aims to apply density functional theory to study FeP and its modifications, which are one of the most widely recognized conversion-type electrodes in experimental studies due to its low cost and high theoretical capacity. Experiments have shown that combining FeP with graphene (FeP@graphene) can be a promising way to alleviate the volume variation issue. Furthermore, Cu doping in FeP has been reported to enhance conductivity and capacity.
The FeP@graphene model was constructed based on experimental results of X-ray diffraction (XRD), thermogravimetric analysis (TGA), and scanning electron microscopy (SEM), followed by a geometry optimization calculation using density functional theory (DFT). We conducted calculations on the adsorption energy of single sodium atom under various conditions, including distance from the graphene sheet and the nearest Fe and P of the FeP cluster. The results indicate that the adsorption energy is unaffected by whether Na is near Fe or P, while adsorption away from the FeP cluster results in weaker interaction, i.e., lower adsorption energy. The effect of Cu doping in FeP on material conductivity was studied by performing electronic structure analysis. The calculation results of the partial density of states (PDOS) did not exhibit substantial differences between models with and without Cu doping in FeP, but the adsorption energy of a single Na atom was significantly lower in the Cu doping system.
Analyses of electron density difference maps (EDDM) and partial atomic charges are performed to further discern the distinctions between FeP@graphene with and without Cu doping. Climbing image-nudged elastic band (CI-NEB) calculations are conducted to investigate the diffusion behavior of Na in the FeP@graphene structure.

SESSION MT02.09: Data-Driven Materials and Process Design II

Thursday Morning, April 25, 2024
Room 321, Level 3, Summit

8:00 AM *MT02.09.01
Data-Driven Analysis on The Dynamics and Heterogeneity of Particle Network in Composite Electrodes of Li-Ion Batteries Kejie Zhao; Purdue University, United States

We use a data-driven approach to assess the heterogeneous electrochemistry and mechanics in composite cathodes. We visualize the morphological defects at multi-scales ranging from the macroscopic composite, particle ensembles, to individual single particles. Particle fracture and interfacial debonding are identified in a large set of tomographic data. The mechanical damage of active particles is highly heterogeneous. The difference originates from the polarization of the electrolyte potential, various local conducting environments, and thus the non-uniform distribution of the activation energy for the charge transfer reaction. We model the kinetics of intergranular fracture and interfacial degradation to assess the heterogeneous mechanical damage in composite electrodes using microstructure-informed mechanics modeling. We quantify the influence of the mechanical damage on the metrics of battery performance. More interestingly, the interfacial failure reconstructs the conductive network and redistribute the electrochemical activities that render a dynamic nature of electrochemistry and mechanics evolving over time in the composite electrodes.

8:30 AM MT02.09.02
Navigating Phase Diagram Complexity to Optimize The Robotic Synthesis of Battery Cathodes and Solid-State Electrolytes Jiadong Chen and Wenhao Sun; University of Michigan, United States

There are a plethora of computationally-predicted battery 'wonder' materials, but only a limited number of them can be successfully synthesized. Efficient synthesis recipes are essential to accelerate the realization and manufacturing of theoretically-predicted electrodes. Oftentimes the solid-state synthesis of multicomponent oxide electrodes is impeded by undesired byproduct phases, which can kinetically trap reactions in an incomplete non-equilibrium state. We present a thermodynamic strategy to navigate high-dimensional phase diagrams in search of precursors that circumvent low-energy competing byproducts, while maximizing the reaction energy to drive fast phase transformation kinetics. Using a robotic inorganic synthesis laboratory, we perform a large-scale experimental validation of our precursor selection principles. For a set of 35 target quaternary oxides with chemistries representative of intercalation battery cathodes and solid-state electrolytes, we perform 224 reactions spanning 27 elements with 28 unique precursors. Our predicted precursors frequently yield target materials with higher phase purity than when starting from traditional precursors. Robotic laboratories offer an exciting new platform for data-driven experimental synthesis science, from which we can develop new fundamental insights to guide both human and robotic chemists.

8:45 AM MT02.09.03
Cathode Upcycling for Direct Recycling Using a Rapid Coprecipitation Approach Eva M. Allen[1], Jessica Macholz[1], Feng N. Wang[1], Mansi Porwal[2], Tim Fister[1], Denis Keane[3], Michael Guise[3], Viktor Nikitin[1], Jordi Cabana[2] and Albert Lipson[1]; [1]Argonne National Laboratory, United States; [2]University of Illinois at Chicago, United States; [3]Northwestern University, United States

In line with carbon neutrality goals by 2050, the Li-ion battery market has surged. To enhance battery sustainability and circularity, direct recycling methods aim to recover intact cathode materials. However, end-of-life cathode materials are typically 15-20 years old and often have lower energy density compared to current cathode materials. In response, we have developed a rapid coprecipitation process to boost energy density by converting low Ni-compositions, $LiNi_{0.33}Co_{0.33}Mn_{0.33}O_2$ (NMC111), into higher Ni-compositions (NMC622). This process forms a Ni-rich coating that diffuses into the core, increasing compositional homogeneity upon high-temperature relithiation. Our technology leverages existing infrastructure, offering low capital cost and minimal additional chemical input. Through ex-situ tomographic transmission X-ray microscopy (TXM) and XANES, we quantify Ni:Co:Mn elemental ratios and Ni valence state, confirming that elemental content evens at the secondary particle level, but elemental gradients remain at the primary particle level upon relithiation. Ex-situ high-resolution and in-situ wide-angle X-ray diffraction reveals concurrent structural changes during the relithiation process. These findings guide further improvements in synthesis for increased initial capacity and retention.

9:00 AM *MT02.09.04
In Situ Insights into Cathode Calcination: A multimodal Assessment of the Crystallization Process of $LiNiO_2$ Akhil Tayal[1], Pallab Barai[2], Hui Zhong[1], Xiaohui Qu[1], Jianming Bai[1] and Feng N. Wang[2]; [1]Brookhaven National Laboratory, United States; [2]Argonne National Laboratory, United States

Calcination is a crucial step in the solid-state synthesis of metal oxides, finding applications not only in manufacturing of cathode materials for batteries but also across various industrial sectors. However, the inherent complexity associated with the process, involving elusive kinetic intermediates, hindering in-depth understanding and predictive control over the production of high-performance metal oxide materials. In this presentation, we report our in-situ analysis of the calcination process of LiNiO2, a potential high-performance cathode for Li-ion battery, to assess the course of crystallization and phase progression vs temperature and time. The composition phase evolution diagrams derived from quantitation Rietveld analysis over in-situ XRD patterns, extracted with multivariate curve resolution (MCR) fitting of the in-situ XAS data, simulated with a phase-field based continuum model, and constructed by using a cosine similarity based automated data analysis as an in-line tool for process monitoring, are examined individually and compared with each other to draw new insights over the calcination process in order to establish optimized processing parameters.

9:30 AM *MT02.09.05
PyBOP: A Python Framework for Battery Model Optimisation and Parameterisation Brady Planden, Nicola Courtier and David Howey; University of Oxford, United Kingdom

To maximise the benefits of battery models, we need to parameterise them accurately from materials and electrochemical data. However, this remains a significant challenge [1] due to the need for expert knowledge in experimental data acquisition, processing, and system identification. In response, we introduce a systematic software framework, PyBOP [2], to establish and formalise novel parameterisation workflows for various continuum battery models. We present initial results from synthetic open-source battery datasets for benchmarking our model parameter identification efforts, comparing traditional deterministic methods with advanced Bayesian inference techniques. We will also highlight PyBOP's capabilities for optimising cell design by discussing an electrode optimisation study on a high-voltage LNMO cathode and silicon-graphite composite anode cell. Throughout this work, we demonstrate PyBOP's ability to accommodate different levels of proficiency in model parameterisation and optimisation, including llustrative workflows tailored towards researchers or industrial users.

SESSION MT02.10: AI/ML for Materials and Process Modeling I
Session Chairs: Deyu Lu and Feng Wang
Thursday Morning, April 25, 2024
Room 321, Level 3, Summit

10:30 AM *MT02.10.01
Nanoscale structures in battery cathodes from theory, ML, and microscopy/spectroscopy experiments Maria K. Chan; Argonne National Laboratory, United States

The determination of nanoscale structural evolution in battery materials during synthesis and cycling is of importance in order to understand battery performance and degradation. The integrated use of first principles density functional theory (DFT) modeling, machine learning (ML), together with microscopy (e.g. STEM), diffraction/scattering, and spectroscopy (e.g. XANES and EELS) measurements, has enabled more in depth understanding of such structural evolution. In this talk, we will discuss how this combination of techniques has allowed us to determine oxygen instability and reactivity, map local cation and defect concentrations, and determine intermediate phases in lithium battery cathode materials.

11:00 AM MT02.10.02
Designing 2D Janus MXene Zr_2CXT (X, T =O, S, Se, and Te) for Lithium-Ion Batteries using Computational Approaches Yu-Ting Lin and Szu-Chia Chien; National Central University, Taiwan

Lately, 2D MXenes have drawn significant attention owing to their potential applications in energy storage, optoelectronics, sensors, etc. Among various types of 2D MXenes, transition metal carbides with a general chemical formula of $Mn_{n+1}X_nT_x$ where M represents a transition metal atom, such as Ti, V, and Zr, X represents a C or N atom, and T represents the surface termination atom including S, O, Se, and Te, have become promising materials for electrodes in Li-ion batteries (LIBs) due to its high electrical conductivity and low diffusion barrier[1,2]. Through chalcogen functionalization, the MXenes with higher capacity and relatively low diffusion barrier energy can be obtained[3,4]. On the other hand, by functionalizing different surface elements on the two opposite sides of a single layer MXenes, instinct materials properties can be linked together, facilitating the realization of versatile functions and the expansion of various applications.

Janus Zr-based MXenes, Zr_2CXT, was recently found to possess excellent structural, elastic, electronic, and optical properties[5,6], making them promising materials in LIBs applications. It is of great interest to search for potential Janus 2D Zr_2CXT for broader applications. However, precise control of the functionalization on the MXenes surface by experimental methods is indeed very challenging. Therefore, this work aims to apply density functional theory (DFT) calculations to explore the promising Janus Zr-based MXenes for electrode materials in Li-ion batteries. Various $Zr_2CXT$with surface atoms, including O, S, Se, and Te are studied. The essential properties of suitable anode materials, such as the dynamical stability, electronic properties, and diffusion barrier, are calculated. Furthermore, the adsorption energy of the Li on the Zr_2CXT surface is also calculated, as well as the capacity. It is anticipated that this work will provide insights into designing good 2D Janus MXenes for LIBs applications.

AI-assisted X-ray absorption spectral analysis: Data reproducibility, database, and machine Learning Deyu Lu; Brookhaven National Laboratory, United States

X-ray absorption spectroscopy (XAS) is a premier element-specific experimental technique widely used for materials characterization in battery research. XAS encodes rich local structural and chemical information around X-ray absorbing species, however such information is convoluted in an abstract form, making it very difficult and time consuming to analyze. In this talk, we will discuss the emerging opportunities in AI-assisted XAS analysis, which leverages first-principles theory, high-throughput computing and data analytics. Specifically, we will highlight key areas in this approach, including pipelines to ensure data quality and reproducibility, spectral database development, and machine learning applications. The AI-assisted analysis pipeline can enable real-time feedback in high-throughput studies and autonomous experimentation.

11:30 AM MT02.10.04
Robust Machine Learning Inference from X-Ray Absorption Near Edge Spectra through Featurization Yiming Chen[1,2], Chi Chen[2], In-Hui Hwang[1], Michael J. Davis[1], Wanli Yang[3], Chengjun Sun[1], Shyue Ping Ong[2] and Maria K. Chan[1]; [1]Argonne National Laboratory, United States; [2]University of California, San Diego, United States; [3]Lawrence Berkeley National Laboratory, United States

Machine learning (ML), used in conjunction with materials modeling, is reshaping the way that researchers analyze and interpret materials characterization data by greatly accelerating the process and providing underlying physics [https://link.springer.com/article/10.1557/s43577-022-00446-8]. One notable application is the extraction of essential materials properties, such as oxidation states and structural information, from X-ray absorption spectroscopy (XAS) data. Traditional ML models typically utilize raw spectral intensities as the model input, with limited exploration on transforming the spectra intensities to potentially boost model performance. In this presentation, we will compare and assess the effectiveness of both reduced-dimensional features and overcomplete representations to discover the optimal representation of x-ray absorption near edge structure (XANES) data. Our system of interest is $LiNi_xMn_yCo_zO_2$ (NMC), a typical cathode material for Li-ion batteries. This material presents challenges in studying detailed changes during electrochemical cycling due to the complexity arising from transition metal mixing. We will evaluate various input transformations for XAS through regression and classification tasks to demonstrating how such feature engineering improves prediction accuracy and interpretability of ML models. Furthermore, we will discuss model validation using unseen experimental datasets, illustrating the transferability and robustness of the feature. A thorough explanation will also be provided to elucidate why certain features outperform others, aiding in the data analysis of experimental spectra [arXiv preprint arXiv:2310.07049].

11:45 AM MT02.10.05
Atomistic Modeling of Chemomechanics at Electrified Interfaces Veerendra Naralasetti, Himanshu Shekhar and Aravind Krishnamoorthy; Texas A&M University, United States

As the world moves to a more electrified future, addressing several mechanical and tribological challenges in electric systems ranging from electrical energy storage to electric vehicle powertrains requires a more fundamental understanding of chemomechanics of electrified interfaces. More detailed insights into the reactivity of surfaces under mechanical contact are needed to design novel materials/lubricants that are needed to improve the efficiency of electro-mechanical systems. In this study, we performed ab initio density functional theory (DFT) calculations and reactive molecular dynamics (RMD) simulations to understand the surface reactivity and evolution of tribolayers in surfaces under electrified and non-electrified contact. Atomistic simulations of Polyalphaolefin (PAO) lubricants on naturally-oxidized steel surfaces reveal the formation of amorphous non-stoichiometric iron-carbide tribolayers that are non-protective and contribute to surface wear, consistent with experimental observations. Reactive MD simulations, performed using a specially parameterized ReaxFF forcefield, were used to predict surface passivity and tribological performance at extreme conditions of temperature, pressure and electrification encountered near asperities in surfaces under mechanical loading and thus derive new design rules for surface structures and lubricants for electrified applications.

SESSION MT02.11: AI/ML for Materials and Process Modeling II
Session Chairs: Deyu Lu and Feng Wang
Thursday Afternoon, April 25, 2024
Room 321, Level 3, Summit

1:30 PM *MT02.11.01
Tackling Ion Transport and Interfacial Evolutions in Solid-State Batteries through “Intelligent” Machine-Learning Zeyu Deng[1], Abhishek Panchal[2], Xie Weihang[1], Sai Gautam Gopalakrishnan[3] and Pieremanuele Canepa[2,1]; [1]National University of Singapore, Singapore; [2]University of Houston, United States; [3]Indian Institute of Science, India

Computational material science is crucial to establishing a firm link between complex phenomena occurring at the atomic scale and macroscopic observations of functional materials, such as energy materials for solar cells, fuel cells, and rechargeable batteries. Storing and distributing green energy is

central to the modernization of our society. Rechargeable batteries, including lithium (Li)-ion batteries, contribute substantially to shifting away from oil and other petrochemicals. The 2019 Nobel Prize in Chemistry awarded to John Goodenough, Stanley Whittingham, and Akira Yoshino resulted in the Li-ion battery as a mainstream technology powering millions of portable devices, electric vehicles, and stationary applications.
Commercial Li-ion batteries suffer from stability issues. All-solid-state batteries utilizing solid-electrolyte “membranes” separating the distinct chemistries of the electrode materials appear to be a safer alternative. Nevertheless, stabilizing solid-solid “buried” interfaces in all-solid-state batteries remains a poorly understood aspect. In my talk, I will showcase the power of simulations to inform the complex reaction mechanisms, which take place at these complex interfaces. My talk will address two main aspects: 1) The advancement of first-principles kinetic Monte Carlo to study transport in fast-ion conductors. 2) I will showcase how machine-learned potentials can bring insight into the metal-anode/sulfide electrolyte interfaces, such as that of Li-metal/Li_6PS_5Cl.

2:00 PM MT02.11.02
Graph Neural Networks for Accurate Prediction of Ionic Transport Properties of Solid-State Electrolytes Cibrán López Álvarez[1,2], Edgardo Saucedo[1,2] and Claudio Cazorla[1,2]; [1]Polytechnic University of Catalonia, Spain; [2]Barcelona Research Center in Multiscale Science and Engineering, Spain

In the pursuit of energy-efficient and environmentally friendly energy storage devices, solid-state electrolytes (SSE) have emerged as promising candidates due to their substantial stability and performance. The discovery of new materials with enhanced ionic diffusion is essential for the advancement of SSEs. To address this challenge, we introduce a novel approach based on Graph Convolutional Neural Networks (GCNNs) to predict the ionic diffusion coefficient of materials in large datasets such as the Materials Project database.

Our GCNN model is trained on a large and diverse database of density functional theory ab initio MD (DFT-AIMD) simulations [1,2], comprising several families of SSE and tens of millions of atomic configurations, what allows extracting valuable insights from the underlying crystallographic and structural relationships.

The predictive power of our GCNN-based approach is demonstrated through extensive validation on the dataset, showcasing its ability to accurately forecast the electrolyte behavior of both known and yet to discover materials. The integration of GCNNs into the materials discovery pipeline holds great promise for the development of next-generation SSEs technologies, introducing here a framework which allows predicting on any desired dataset.

The scripts resulting from this study have been made publicly available as a Python package, that is user-friendly and easily adaptable [3] to any desired target database.

Calcination of Lithium-Ion Battery Cathode Materials: Addressing Scale-Up Challenges using Multiscale Modeling Techniques Pallab Barai, Feng N. Wang, Tiffany Kinnibrugh, Ozgenur Kahvecioglu, Xiaoping Wang, Mark Wolfman, Tim Fister, Juan C. Garcia, Hakim Iddir, Krzysztof Pupek and Venkat Srinivasan; Argonne National Laboratory, United States

Rapid electrification of the automotive industry requires the synthesis of battery cathode materials at large scale, where the high temperature calcination is considered to be the most energy consuming and expensive process. Oxidation and lithiation of the transition metal cathode precursors occur at elevated temperatures (around 700°C – 1000°C) during the calcination process. The various physicochemical processes that occur during the calcination process can be summarized as dehydration, oxidation, lithiation, layering, and sintering induced grain growth. Transport of reactants, removal of reaction byproducts, and maintaining uniformity of temperature within the reaction zone, are of significant importance for successful scale-up of the calcination processes. A multiscale computational methodology is developed, where the kinetics of chemical reactions are extracted at the smaller length scale, and the mass and energy transport related issues are addressed at the larger length scale. Collaboration with in situ characterization using X-ray diffraction (XRD) techniques provide experimental data required for the model development activities. Atomistic simulations are conducted to extract further insights regarding the energetics of the evolution of different phases during the high temperature calcination process. Overall, the developed modeling capability is able to help with the optimization of calcination protocols during their scale up procedure.

Beyond Predictions: An Interpretable Machine Learning Approach for Battery Performance Forecasting Injun Choi[1], Jieun Kim[1,2] and Inchul Park[1,2]; [1]Research Institute of Industrial Science & Technology, Korea (the Republic of); [2]POSCO NEXT Hub, Korea (the Republic of)

This presentation will discuss our recent study on the application of machine learning to predict the electrochemical behavior of batteries, a key aspect in the field of battery management systems and fast charging technologies. In a distinct departure from existing utilization-based degradation models, this research offers a fresh perspective that emphasizes material-focused performance prediction.

The core of this study is the extensive analysis of data from tens of thousands of charge-discharge cycles of Li-rich layered oxide in a single cell setup. This approach allows for a more focused study of material properties, while avoiding the complexities often introduced by cell configurations. A key achievement of the research is the application of deconvolution techniques to extract intrinsic material properties from the extensive dataset, a critical step in achieving improved prediction accuracy and understanding of material properties.
An integral part of this research is the detailed monitoring of these intrinsic properties over time. This enables not only broad trend predictions, but also a detailed understanding of the dynamic electrochemical behavior of the material. In addition, insights into the material's elemental composition ratios contribute to both performance prediction and a deeper understanding of its intrinsic properties.
The study demonstrates a high accuracy of over 98% in predicting battery performance, confirming the efficiency of the machine learning models and the robustness of the dataset. In addition, the research extends its applicability beyond LLO materials, suggesting its potential across different battery materials. This broad relevance underscores the significant impact of the study on battery material design and performance optimization.
In summary, this research represents a significant advancement in the application of machine learning to battery performance prediction. By focusing on intrinsic material properties and leveraging an extensive, detailed dataset, the study not only achieves high prediction accuracy, but also establishes a scalable model for materials analysis in battery technology. The methods and results introduced can lead to more efficient, reliable, and adaptable energy storage solutions for future battery technology.

3:30 PM MT02.11.05
AI + Quantum Chemistry: A Paradigm Shift in Lithium Battery Development - An Assessment of Potential Contributions Jie Liu[1,2]; [1]Hong Kong Quantum AI Lab, Hong Kong; [2]The University of Hong Kong, Hong Kong

The global lithium-ion battery market, achieving a shipment volume of 958 GWh in 2022 with an estimated average commercialized energy density of ~170 Wh/kg, is on the brink of a significant transformation. This equates to an annual consumption of approximately 6.38 Mt of battery materials, underscoring the substantial resource usage and the sustainability challenges facing industry growth. The global effort towards more efficient, resource-saving, and eco-friendly energy storage systems has positioned AI and Quantum Chemistry as key drivers in battery manufacturing and R&D, with their full potential impact yet to be completely realized.

In this study, we provide a comprehensive assessment of the potential contributions of AI and Quantum Chemistry to the future development of lithium batteries, with a focus on material efficiency and cost savings. Anticipating a compound annual growth rate of 22.8% over the next eight years (as per EV-Tank's forecast), lithium-ion battery shipments are projected to reach 4,952 GWh by 2030. We analyzed two scenarios of energy density improvements: a conservative estimate of a 3% annual increase, in line with traditional development pathways, leading to an energy density of 215 Wh/kg by 2030, and an optimistic projection incorporating AI, Quantum Chemistry, and Automation in R&D. This advanced integration could potentially elevate annual improvement rates from 3% to 5.1%, achieving an estimated commercial battery energy density of 234 Wh/kg by 2030. Such advancements could result in a significant variations in the required material volume, estimated at 23 Mt/year and 21.21 Mt/year by 2030, respectively. This approach could potentially lead to cumulative material savings of 4.3 Mt from 2023 to 2030, translating into substantial cost savings of approximately 41 billion USD over this period.

A sensitivity analysis was conducted to provide a more accurate reflection of these projections, taking into account different annual improvement rates and market dynamics. The findings underscore the significant advantages, both economically and in terms of resource conservation, of accelerating lithium battery R&D. There is a compelling case for seizing the opportunity to integrate AI and Quantum Chemistry in lithium battery R&D. This integration not only promises enhanced energy densities but also marks a significant stride towards more sustainable and cost-effective battery production, potentially yielding returns far greater than the current investments in these cutting-edge technologies.

3:45 PM MT02.11.06
Machine Learning Workflow to Track Degradation Mechanisms in Industrial Lithium Ion Battery Cells Amina El Malki[1,2], Mohamed Ati[2], Mark Asch[3] and Alejandro A. Franco[1,4,5]; [1]Laboratoire de Réactivité et Chimie des solides (LRCS), UMR CNRS 7314, Université de Picardie Jules Verne, Hub de l'Energie, France; [2]Renault SA, France; [3]LAMFA, CNRS UMR 7352, Université de Picardie Jules Verne, France; [4]Réseau sur le Stockage Electrochimique de l'Energie (RS2E), FR CNRS 3459, Hub de l'Energie, France; [5]ALISTORE-European Research Institute, FR CNRS 3104, Hub de l'Energie, France

The degradation of lithium-ion battery (LiB) cells is a complex process resulting from the interaction of multiple phenomena. Understanding LiB cell aging requires tracking measurable effects of different degradation mechanisms, known as degradation modes. These include the loss of active material in the electrodes, loss of lithium inventory, and conductivity loss. The aging mechanisms are directly correlated with electrochemical cycling protocols and operation conditions of the LiB cell, such as parameters related to the type and rate of current in the charge and discharge, voltage cutoff conditions, temperature, break periods, state of charge, and cycle number.

Using machine learning techniques to uncover the interrelations between aging conditions/protocols and mechanisms can trigger tremendous progress in designing battery management systems capable of extending cell lifetime in Electric Vehicle (EV) applications [1]. In this work, we introduce a novel workflow that combines various machine learning techniques with electrochemical LiB cell state of health diagnostic analysis, facilitating the discovery of the impact of a broad set of cycling conditions/protocol parameters on aging modes [2]. This approach allows for deriving the possible aging mechanisms that might manifest in each distinct condition.

While numerous studies have employed machine learning techniques on LiB cell datasets, they often focus on a limited number of cycling stressors (e.g., C-rate for charge and discharge), and the datasets typically originate from tests conducted in academic laboratories. In this study, a comprehensive industrial dataset, encompassing a broad range of cycling conditions and protocols to simulate real-world usage of LiB cells in Electric Vehicles (EVs), is utilized. We explore how more than 10 stressors impact the aging modes of cells and identify the predominant degradation mechanisms based on cycling conditions. The analytical capabilities of our machine learning tool are demonstrated through various application examples, and strategies for mitigating aging in automotive applications are discussed. Finally, we consider how our machine learning workflow holds the potential to propel current battery management systems in EVs to the next level.

Room 322, Level 3, Summit

10:30 AM *MT03.01.01
Autonomous Experimentation for Materials Research Benji Maruyama; Air Force Research Laboratory, United States

The current materials research process is slow and expensive; taking decades from invention to commercialization. The Air Force Research Laboratory pioneered ARES™, the first autonomous experimentation system for materials development. A rapidly growing number of researchers are now exploiting advances in artificial intelligence (AI), autonomy & robotics, along with modeling and simulation to create research robots capable of making research progress orders of magnitude faster than today. We will discuss concepts and advances in autonomous experimentation in general, and associated hardware, software and autonomous methods.

We will distinguish between non-iterative AI/ML approaches that use large data sets (e.g., CNN, LLM) and small data, iterative approaches that strive to identify & confirm scientific hypotheses using AI reasoning.

We consider the impact of autonomous experimentation on human scientists and the scientific enterprise: Changing roles for humans and robots, expectations. In the future, we expect autonomous experimentation to revolutionize the research process, and propose a "Moore's Law for the Speed of Research," where the rate of advancement increases exponentially, and the cost of research drops exponentially. We also consider a renaissance in "Citizen Science" where access to online research robots makes science widely available.

11:00 AM *MT03.01.02
Polybot: Accelerating Electronic Polymer Discovery through AI/ML and Automation Henry Chan[1], Jie Xu[1], Aikaterini Vriza[1] and Yukun Wu[2,1]; [1]Argonne National Laboratory, United States; [2]Purdue University, United States

The increasing demand for flexible, wearable, and smart electronics has propelled the exploration of electronic polymers. To unleash their full potential, understanding the complex relationships between processing, structure, and properties is crucial, along with the development of scalable methods for producing high-quality thin films and devices. This task is particularly challenging due to the intricate interactions between processing parameters, including solution formulation, rheological behavior, and post-treatment procedures. In this presentation, we introduce Polybot, an advanced Autonomous Materials Acceleration Platform (MAP) that seamlessly integrates AI/ML, robotics, and automated characterization techniques for expediting the discovery and optimization of electronic polymers. Polybot exemplifies its prowess through closed-loop studies, demonstrating simultaneous enhancements in polymer processability and performance within a high-dimensional experimental parameter space. Furthermore, we delve into the intriguing realm of small data, addressing the integration of literature-derived insights and physics-based simulations within MAPs. Our discussion will illuminate both the challenges and the promising prospects associated with this integration, showcasing how it enriches the efficacy and robustness of the materials discovery process.

11:30 AM MT03.01.03
High-Throughput Structural Investigation of Block Copolymer and Conjugated Polymer Co-Assemblies Karen Li, Kiran Vaddi and Lilo D. Pozzo; University of Washington, United States

Conjugated polymers (CPs) have garnered much interest as semi-conducting materials for organic electronics. The properties of conducting polymers can be affected from induced long-range order. Block copolymers (BCPs) are commonly used as templating materials due to their ability to self-assemble into many crystalline structures. Blending structure directing BCPs and relatively rigid CPs may lead to materials with enhanced properties due to the formation of highly ordered structures. Thus, it is essential to understand the phase behavior of these co-assembled blends. The shape and order of these structures are also affected by many parameters including temperature, concentration, molecular weight, side chains, shear, etc. High-throughput characterization and analysis will be required to effectively investigate these factors. To demonstrate this, hydrogel blends of BCP polyethylene oxide-polypropylene oxide-polyethylene oxide and conjugated polyelectrolyte poly[3-(potassium-4-butanoate)thiophene-2,5-diyl] were prepared at varying concentrations with an open-source liquid handling robot. The polymer blends were structurally characterized through high-throughput small angle x-ray scattering (HT-SAXS), utilizing a custom cartridge system that can enable thousands of measurements per day at a synchrotron. In addition, various temperatures and shear conditions were applied to the polymer blends to produce monolithic oriented gels and measured via small angle neutron scattering (SANS). A statistical analysis tool, *autophasemap*, was developed in our group to automatically generate phase maps that provide a hierarchical summary of the HT-SAXS experiments. This is accomplished by measuring the similarity between sampled profiles and data-based template functions and clustering the profiles based on this similarity. Multiple ordered phases of the polymer blends were then identified through the presence and position of Bragg peaks in 1D profiles and Bragg spots in 2D profiles.

11:45 AM MT03.01.04

Development of a High-Throughput Electrochemical Device for Data-Driven Electrolyte Materials Discovery Yangang Liang; Pacific Northwest National Laboratory, United States

Data-driven research in the field of electrolyte discovery for energy storage applications is growing rapidly. However, current characterization techniques struggle to analyze large numbers of samples accurately and efficiently. To address these limitations, we propose an innovative electrochemical measurement system to integrate with robotic platforms. This high-throughput system provides highly reliable and repeatable conductivity measurements, facilitating fast screening of battery materials and establishing materials-electrochemical property relationships. Our research contributes to advancing electrolyte materials for energy storage and demonstrates the potential of high-throughput characterization technologies in accelerating materials discovery.

SESSION MT03.02: Machine Learning for Experiments II

Tuesday Afternoon, April 23, 2024
Room 322, Level 3, Summit

1:30 PM *MT03.02.01
Machine Learning Accelerated Electrolyte Discovery for Batteries Chibueze Amanchukwu; University of Chicago, United States

Battery chemistries with high energy densities are required for long duration energy storage. Moving away from intercalation to electrodeposition endows lithium metal batteries (LMBs) with energy densities that surpass conventional lithium-ion. However, there are no electrolytes to date that can enable efficient electrodeposition and dissolution of lithium metal without significant degradation and lithium dendritic growth. Therefore, electrolyte discovery holds great promise for lithium metal batteries. Unfortunately, current approaches to electrolyte discovery have focused primarily on trial-and-error. In our work, we pursue a data-driven approach. We curate the largest dataset of important properties for small molecule electrolytes – ionic conductivity, oxidative stability, and Coulombic efficiency. We build machine learning models capable of predicting these properties and show that the models are consistent with known chemical principles and intuition. Deploying these models on large unlabeled datasets allowed us to identify new and promising electrolytes that have never been explored for LMBs. Our data science driven approach for electrolyte discovery is a paradigm shift that addresses challenges facing electrolytes in a wide range of electrochemical devices.

2:00 PM *MT03.02.02
Machine Learning Defect Properties of Semiconductors Arun Kumar Mannodi-Kanakkithodi; Purdue University, United States

Defects and impurities in semiconductors heavily influence their performance in optoelectronic applications. Quick predictions of defect properties are desired in technologically important semiconductors, but complicated by difficulties in assigning measured levels to specific defects and by the expense of large-supercell first principles computations that involve charge corrections and advanced functionals [1]. We address this issue by combining high-throughput density functional theory (HT-DFT) with machine learning (ML) to develop predictive models for defect formation energies (DFE) and charge transition levels (CTL) of native defects and functional impurities in Group IV, III-V, and II-VI zinc blende (ZB) semiconductors. Using an innovative approach of sampling dozens of metastable polymorphs each from defect configurations in thousands of distinct DFT computations, we generate one of the largest known computational defect datasets, containing many types of vacancies, self-interstitials, anti-site substitutions, impurity interstitials and substitutions, and defect complexes [2,3].

Two distinct types of ML methods are applied: (a) random forest, Gaussian process, and neural network regression models based on manual descriptors encoding the defect atom's elemental properties, coordination environment, and "unit cell" defect data [2,3], and (b) crystal Graph-based Neural Networks (GNNs) trained using entire defective structures as input [4], specifically using three established GNN techniques, namely Crystal Graph Convolutional Neural Network (CGCNN) [5], Materials Graph Network (MEGNET) [6], and Atomistic Line Graph Neural Network (ALIGNN) [7]. Root-mean square errors (RMSE) in predicting DFE are as high as 1 eV with the former, while ALIGNN yields errors of ~ 0.3 eV or less which represents a prediction accuracy of 98% given the range of values within the dataset, improving significantly on the state-of-the-art. While the first set of models yield only optimized energies based on a smaller dataset of ~ 1500 points, the GNN models are trained on > 15,000 data points and can be applied to predict accurate unoptimized, partially optimized, or fully optimized DFE values corresponding to any defective structure. The best models are eventually applied to perform screening across hundreds of thousands of hypothetical single defects/dopants and defect complexes to find stable defects which may or may not create energy levels within the band gap and affect the semiconductor's performance in optoelectronic devices. We also demonstrate that GNN models can be used as an effective surrogate for DFT computations to obtain low energy defective structures for any semiconductor-defect combination, which is very promising for screening over large chemical spaces without the need for expensive DFT.

Analyzing The Impact of Design Factors on Solar Module Thermomechanical Durability Using Interpretable Machine Learning Xin Chen[1,2], Todd Karin[3] and Anubhav Jain[1]; [1]Lawrence Berkeley National Lab, United States; [2]University of California, Berkeley, United States; [3]PVEL, United States

Solar modules in utility-scale PV systems are anticipated to maintain a prolonged lifetime to effectively rival conventional energy sources. However, the

durability of these modules is often compromised by cyclic thermomechanical loading, emphasizing the need for a proper module design to counteract the detrimental effects of thermal expansion incompatibility. Given the complex composition of solar modules, isolating the impact of individual components on overall durability remains a challenging task. In this work, we constructed a comprehensive data set, capturing bill-of-materials and post-thermal cycling power loss from over 250 distinct module designs. Utilizing the data set, we developed a machine learning model to correlate the design factors with the degradation and applied the Shapley additive explanation to provide interpretative insights into the model's decision-making, investigating the impacts of design factors like the busbar number, wafer thickness, and others. Our analysis reveals that the type of silicon solar cell, whether monocrystalline or polycrystalline, predominantly influences the degradation, and monocrystalline cells present better durability. This finding was further substantiated by statistical testing on our raw data set. We also demonstrate that the thickness of the encapsulant remains another important factor, with thicker encapsulants correlated with reduced power loss. The study here provides a blueprint for utilizing explainable machine learning in an intricate material system and can potentially steer future research on optimizing solar module design.

2:45 PM MT03.02.04
Machine Learning Enhanced Optical Characterization of Hexagonal Boron Nitride Thickness on 300-nm Oxide Substrate Kirsten L. Lina[1,2] and Masahiro Ishigami[1,2]; [1]University of Central Florida, United States; [2]NanoScience Technology Center, United States

This study integrates optical techniques with machine learning to achieve precise characterization of hexagonal boron nitride (hBN) thickness on 300-nm silicon oxide substrate. Conventional methods for interpreting large volumes of microscopy data are labor intensive, time consuming, and faulted by human subjectivity. The aim of this work is to mitigate these challenges by employing a regional convolutional neural network (R-CNN) to perform image segmentation and object detection on optical microscopy images, enabling real-time processing capabilities for thickness identification. The Mask R-CNN architecture featuring the ResNet101 backbone network, region proposal network, classification and mask subnets with bounding box regression generates feature maps to identify graphical features including shapes, flake sizes, contrast, and color. Initially, a robust theoretical mapping of hBN flake colors in the standard red, green, blue (sRGB) color space was developed, accounting for the oxide thickness. Theoretical RGB values corresponding to specific hBN thickness align remarkably well with those extracted from optical images, validating the use of colors as a reliable standard for hBN thickness identification. Our trained R-CNN predicts thickness of hBN flakes based on their mapped expected color variations with remarkable accuracy. This material characterization approach accelerates initial characterization of hBN while also holding potential for enhancing production efficiency across various 2D materials in nanoscience research.

Engineering Soft-Matter with Agent-Driven High-Throughput Experiments Lilo D. Pozzo, Maria Politi, Brenden Pelkie, Kiran Vaddi, Huat Thart Chiang, Karen Li and Kacper J. Lachowski; University of Washington, United States

Artificial intelligence (AI), when paired with laboratory automation, can greatly accelerate materials optimization and scientific discovery. For example, it can be used to efficiently map a phase-diagram with intelligent sampling along phase boundaries, or in ‘retrosynthesis’ problems where a material with a target structure is desired but a synthetic route is not known. These approaches are especially promising in soft matter and polymer physics, where design parameters (e.g. chemical composition, MW, topology, processing) are vast and where properties and function are intimately tied to molecular design features. However, for AI algorithms to operate efficiently in these spaces, they must also be ‘encoded’ with relevant domain expertise specific to the problems being tackled. This talk will cover recent advances in hardware and software tools for accelerated materials optimization for polymers and soft matter systems. Finally, it will outline remaining challenges in practical implementations and identify future opportunities for research.

4:00 PM MT03.02.06
Accelerated Development of Ga_2O_3 Thin-Film Epitaxial Growth by AI Approaches with FAIR Data in NOMAD Andrea Albino[1], Ta-Shun Chou[2], Hampus Näsström[1], Amir Golparvar[1], Theodore Chang[1], Alvin Noe Ladines[1], Lauri Himanen[1], Mohammad Nakhaee[1], Andreas Popp[2], Jose Marquez Prieto[1], Sebastian Brückner[2,1], Markus Scheidgen[1], Claudia Draxl[1] and Martin Albrecht[2]; [1]Humboldt-Universität zu Berlin, Germany; [2]Leibniz-Institut für Kristallzüchtung, Germany

Data-driven material science has the potential to transform the way we design and develop materials. This emerging field represents a significant departure from traditional trial-and-error methods and empirical approaches that have characterized materials science for decades. Experiments in this area involve a multidimensional parameter space, making analysis challenging and time-consuming. Finding predictive empirical relations that allow for precise control over various aspects of the synthesis process has posed a challenge to human cognitive abilities alone. This becomes even more complex when combining datasets from different labs or from different scientists due to the lack of established standards for data models and methods to capture the large number of experimental details, including elaborate workflows and a large diversity of instruments for characterization. It requires a radical shift in how information is handled and research is performed. Experiment data must be complemented with its rich-metadata context, also covering ontologies and workflows according to the FAIR (findable, accessible, interoperable, reusable) principles [1].
Opening new perspectives towards finding structure, correlations, and novel information with data-analysis and AI tools, therefore, is intimately connected to the challenge of integrating this information into a FAIR infrastructure [2].

Here we present growth optimization of β-Ga_2O_3 thin films by metalorganic vapor phase epitaxy (MOVPE) on (1 0 0) β-Ga_2O_3 semi-insulating substrates which is a successful example of applying ML/AI approaches in materials synthesis. Improving the efficiency of this synthesis is highly relevant due to the wide range of electronic device applications based on Ga_2O_3. Applying AI modeling on the experimental data related to thin film growth, we effectively improved the growth rate and prediction of doping level in MOVPE-grown Si-doped β-Ga_2O_3 [3,4].

We will present the implementation of this use case in NOMAD (nomad-lab.eu) [5] and discuss the functionalities developed to digitize the entire data lifecycle in crystal growth and epitaxy, with the ultimate goal of FAIR data for materials growth. We developed and deployed Electronic Laboratory Notebooks (ELN) to document all relevant synthesis procedures. We will show how structured data opens up the potential to create tools that facilitate and automate data management, and the sustainable application of AI-based analytics, dedicated to process optimization in synthesis.

Explainable Materials Informatics for Coherent Phonon Transport in 2D Heterostructures by Self-Learning Entropic Population Annealing
Wenyang Ding[1], Jiang Guo[1], Koji Tsuda[1,2,3] and Junichiro Shiomi[1,1]; [1]The University of Tokyo, Japan; [2]National Institute for Materials Science, Japan; [3]RIKEN Center for Advanced Intelligence Project, Japan

The exploration of coherent phonons demands flawless interfaces to circumvent phonon phase disruptions and inter-phonon interactions, a formidable challenge to achieve in practice. Van der Waals (vdWs) heterostructures, created through the precise layering of diverse two-dimensional materials, offer an optimal foundation for exploring coherent phonon transport because of their seamlessly integrated interfaces. Over the past decade, the comprehension of coherent phonon transport within superlattices has significantly advanced, propelled by the sophisticated field of materials informatics (MI) driven by machine learning techniques. Bayesian optimization, known for its efficiency in recommending structures with desirable properties, is a commonly adopted MI method. However, it's a black-box method with the potential for converging to local minima and limited representation of the entire sample space. In contrast, entropic population annealing (SLEPA) extended from entropic sampling with a machine learning model by Li et al. [1], efficiently captures the density of states, enabling comprehensive thermal conductivity assessments for vdWs heterostructures while evaluating few candidates without missing optimal results.
In this study, we obtain thermal conductivity distribution of graphene/WS_2 heterostructure in a candidate space of tens of thousands by combining SLEPA and atomistic Green's functions. Though analysis, we identified two factors that have a significant negative impact on the thermal conductivities of heterostructures: the average distance of WS_2 from the center of the heterostructure and the presence of specific sequences, such as '1 0 0 1', where '0' represents graphene and '1' represent WS_2. Moreover, by using mode-resolved atomistic Green's function (AGF), the underlying mechanism under these two factors are investigated. The findings reveal that, as the average distance of WS_2 from the center of the heterostructure decreases, there is an increase in the transmission of high-frequency phonons at oblique angles. Additionally, an increase in the number of '1 0 0 1' leads to higher transmission of low-frequency phonons that are normally incident. The combination of these two factors can suppress phonon transmission across a broad spectrum of frequencies and angles of incidence, leading to the optimized heterostructure with remarkably low thermal conductivity.

4:30 PM MT03.02.08
Machine-Learning Minimization of Amorphous Heat Conduction by High-Throughput Deposition Process in The Loop
Kunihiko Shizume[1], Ryohei Nagahiro[1], Michiko Sasaki[1,2], Masahiro Goto[2] and Junichiro Shiomi[1]; [1]The University of Tokyo, Japan; [2]National Institute for Materials Science, Japan

In Material Informatics, material exploration *via* high-throughput experiments has gained traction. This study utilizes a specially equipped combinatorial sputtering system and thermoreflectance method to explore amorphous materials with TC ~0.1 W/mK. There is a significant demand for solid-like thermal insulation materials combining mechanical strength, which can be applied to heat-mediated sensing devices and heat shields. Amorphous materials are promising candidates for dense thermal insulator since the disordered structure strongly suppress propagation of the vibrational modes. Their metastable nature can result in varied structures depending on the fabrication process. For instance, our prior research demonstrated that TC of amorphous Si (a-Si) and Ge (a-Ge) films varies with the deposition temperature during sputtering. This implies that amorphous structures can be modulated using sputtering process parameters (PP). Due to challenges in identifying structures, optimizing properties of amorphous materials has not been studied much. In this study, while treating the structure and the composition as a black box, we use the sputtering PPs as the explanatory variables and TC as the target variable to be minimized through Bayesian optimization. This high-throughput experiment also works as a materials screening process to identify interesting materials for the characterization analysis. It allows efficient experimental data accumulation on the relationships between the thermal conductivity and the characteristics of amorphous. As a further objective of this study, we also plan to implement machine learning to interpret the gathered data and enhance our comprehension of heat transfer in amorphous materials, which is not yet fully understood.
Samples were prepared using Combinatorial Sputter Coating System (COSCOS), which can deposit the target material with four arbitrarily controlled PPs: mixed gas composition, total gas pressure, sputtering power, and sample-target distance. The multiple holders enable automated deposition of 14 samples under a unique set of PPs, in a single batch. We prepared 40 of a-SiO_x, 35 of a-SiN_x, and 12 of a-$Si_aGe_bSn_c$ films with a thickness between 30-200 nm and measured the TC. Here, a-SiO_x and a-SiN_x were measured by frequency-domain thermoreflectance (FDTR) and a-$Si_aGe_bSn_c$ was measured by time-domain thermoreflectance (TDTR). Moreover, for the a-SiN_x, deposition was performed under 26 new conditions, as suggested by Bayesian optimization.
32 out of the 40 a-SiO_x films exhibited similar TC ranging from 0.6 to 0.9 W/mK except for the remaining 8 films with TC between 1.4-2.2 W/mK, likely due to contaminations of iron clusters from the equipment during sputtering. In contrast, a-SiN_x exhibited TC ranges from 0.6 to 1.5 W/mK with a wide-tailed distribution. This indicates the broader TC modulation range for a-SiN_x, compared with a-SiO_x. Among 26 of a-SiN_x films prepared under PPs suggested by Bayesian optimization, the one with the lowest TC achieved 0.5 W/mK. This result ensures the efficacy of our strategy to reduce TC. For a-$Si_aGe_bSn_c$ films, the lowest TC was 0.2 W/mK, lower than the reported TC of similar materials like a-$Ge_{39}Si_5Sn_{1.3}O_{36}$ (0.4 W/mK). TDTR also confirmed decreases in speed of sound as Sn content increases which contributes to the TC reduction. As a result, a-$Si_aGe_bSn_c$ emerges as a promising candidate for further optimization. Various characteristics like density and structure, beyond merely composition, might be modulated through the depositions across diverse PPs.
To enhance the experimental throughput, we employed the masking mechanism of COSCOS for multi-point deposition on a single substrate and FDTR/TDTR mapping measurements. This experimental scheme should facilitate data accumulation on the order of 100 samples per single deposition batch. We are currently continuing our material exploration in the a-$Si_aGe_bSn_c$ system and will report on these results in our presentation.

4:45 PM MT03.02.09
Accelerating The Development of Thin Film Photovoltaic Technologies: An Artificial Intelligence Assisted Methodology Using Spectroscopic and Optoelectronic Techniques
Victor Izquierdo-Roca[1], Robert Fonoll[1], Enric Grau-Luque[1], Ignacio Becerril-Romero[1], Jacob Andrade-Arvizu[1], Pedro Vidal-Fuentes[1], Alejandro Perez-Rodriguez[2] and Maxim Guc[1]; [1]IREC, Spain; [2]Departament d'Enginyeria Electrònica i Biomèdica, IN2UB,, Spain

Thin film photovoltaic (TFPV) materials and devices present a high complexity with multi-scale (from nm to μm), multi-layer and multi-element structures and with complex fabrication procedures. To deal with this complexity, the evaluation of the compositional, structural, morphological, optical, and electrical properties, among others, of TFPV devices is critical to generate a model that allows pushing forward their development and optimization, especially in terms of PV performance. However, the intrinsic complexity of TFPV materials and devices requires approaching their research in a holistic way. This involves the performance of a holistic characterization approach which presents three main challenges: 1) performing a systematic combinatorial characterization (using different characterization techniques) of materials and devices, 2) automating characterization (data acquisition) for generating a statistically relevant amount of information (big data), 3) generating automatized, fast, and multidimensional data processing strategies.

In this work, an approach to solve these three challenges is presented through the creation of a modular and highly customizable automatized characterization platform and methods that provide a fast, holistic, and non-destructive characterization of complex material and devices. The above-

mentioned challenges are faced up by the platform in the following way:

1) Systematic heterogeneous characterization – integrating dedicated sensors for the evaluation of composition, morphology, crystal structure, thickness, and optoelectronic parameters by different techniques (X-ray fluorescence, Raman, photoluminescence and UV-Vis-NIR reflectance spectroscopies, visual imaging, elastic light scattering, I-V, EQE, electroluminescence).
2) Automatize data acquisition – developing dedicated software and protocols for systematic and automatized data acquisition and a data storage structure for efficient data analysis.
3) Automatized and fast multidimensional data processing – developing flexible methodologies and algorithms to automatize data conditioning and processing using statistical and AI-assisted data analysis using machine learning algorithms to accelerate the big data analysis and identify correlation patterns and processes to push forward the development of the TFPV technologies.

A real case for the accelerated research of $Cu_2ZnSnSe_4$-based TPV (CZTSe) devices is then used as practical example for the proposed platform. More than 20 samples (with 5x5 cm^2 size) are systematically studied as the initial step for large-scale production of CZTSe based PV devices. The devices have Glass/Mo/MoSe2/CZTSe/CdS/i-ZnO/ITO structure and small controlled and non-controlled fabrication processes variations are included in the samples. Each samples is discretized in 3x3 mm^2 individual solar cells (up to 196 cells per sample), which allows achieving a complete data library that aids obtaining a considerable amount of cell-by-cell information to implement statistically relevant analyses. A systematic characterization combining optical and optoelectronic techniques as described above is performed in each cell. The analysis of the data obtained allows correlating the physicochemical properties of the TFPV materials with variations in device performance. This knowledge provides key information to understand the role of different materials and layers properties, their interrelations and, finally, the current technology limitations. This information is strongly relevant for the future development of the CZTSe technology towards high efficiencies and its future industrialization. Moreover, the proposed platform opens a way for the development of a process monitoring tool for controlling the production of TFPV devices that is easily adaptable to other optoelectronic technologies.

SESSION MT03.03: Poster Session: Machine Learning, Data, Software

5:00 PM MT03.03.01
Mara - An Autonomous Synthesis System for Energy Materials Clara N. Tamura, Arthur Chong and Shijing Sun; University of Washington, United States

The discovery and development of energy materials are crucial tasks to tackle the ongoing progression of climate change. Current research has focused on the exploration and synthesis of such materials, but current methods are time-consuming and do not allow for a larger scale of exploration and depth investigations. With the recent advancements in machine learning and robotics, autonomous synthesis and analysis to accelerate material discovery has become possible, allowing for widespread exploration and rapid prototyping.2 Still, the field of autonomous laboratories is young, and integrating machine learning with robotics is yet to be explored.1 At the UW Sun Lab, we are developing a fully autonomous materials synthesis system with AI instructing robots to make new materials. We are developing “Mara,” an autonomous synthesis system consisting of an Opentron-OT2 liquid-handling robot, a microplate reader (96-well), and a camera system for monitoring the robotic movement and automated image analysis to create solar materials such as halide perovskite synthesized by drop-casting. Ultimately, Mara will autonomously synthesize material with desired properties, such as optimal absorption, without the need for human intervention. We set up the whole system from scratch in two months, and the Mara system is driven by the Python API commands. This will demonstrate the effective use of robotics and machine learning to accelerate material discovery and development, allowing a faster response to climate change.

PV-VISION: An Deep Learning based Package for Automated Solar Module Inspection Xin Chen[1,2] and Anubhav Jain[1]; [1]Lawrence Berkeley National Lab, United States; [2]University of California, Berkeley, United States

Solar photovoltaic (PV) modules are susceptible to manufacturing defects, mishandling problems or extreme weather events that can limit energy production or cause early device failure. Trained professionals use electroluminescence (EL) images to identify defects in modules, however, field surveys or inline image acquisition can generate millions of EL images, which are infeasible to analyze by rote inspection. We developed an open-source computer vision package PV-VISION to automatically process the EL images using deep learning models, covering automatic image preprocessing, cell defect detection and crack feature extraction. We demonstrated the functions of PV-VISION on two tasks: investigating fire impacts on solar farms by inspecting 2.4 million cells and quantifying crack growth in solar modules under mechanical aging tests. We anticipate that PV-VISION can offer a supportive platform for researchers in the solar field, facilitating a more efficient and data-driven approach to EL image analysis.

5:00 PM MT03.03.05
AI-Predicted Synthesis of Vertically Aligned Nanocomposite Structures Jianan Shen, Tinghan Yang, Jiayi Liu, Benson Tsai, Yizhi Zhang, Chang Liu, Shiyu Zhou, Nirali Bhatt, Zedong Hu, Lizabeth Quigley, Jialong Huang, Jennifer Neville and Haiyan Wang; Purdue University, United States

The fabrication of self-assembled two-phase nanocomposite thin films through a one-step pulsed laser deposition process has garnered significant research interest. These films exhibit a wide range of functionalities, including ferromagnetic, ferroelectric, magnetoresistive, and multiferroic properties, as well as unconventional optical behaviors like plasmonic and hyperbolic properties. Typically, these nanocomposites self-assemble into two distinct structures: particles-in-matrix (PIM) nanostructures or vertically aligned nanocomposite (VAN) nanostructures with embedded nanopillars within the matrix phase. In rare instances, a solid solution structure emerges. Among these structures, VAN stands out due to its unique features, including vertical strain control and

highly anisotropic structure, which enable the epitaxial growth of materials with significant lattice mismatch. However, the successful synthesis of VAN structures has been challenging, often relying on time-intensive trial-and-error approaches due to the intricate underlying mechanics. Therefore, it is imperative to develop a predictive method capable of determining the most likely synthesis recipe for VAN structures. In this context, harnessing the capabilities of state-of-the-art artificial intelligence (AI) technology, we have created an automated pipeline tool helping predict the synthesis route of VAN structures. Our pipeline incorporates an automated data extraction process that leverages an advanced large language model (LLM) to extract information from our paper repository and combines it with laboratory-collected data to construct a comprehensive database. Subsequently, this database is utilized by a custom machine learning model for binary classification, distinguishing between VAN and non-VAN structures. The model achieves an impressive accuracy rate of 95%, validated through rigorous evaluations employing metrics such as precision, recall, and F1 scores. Furthermore, the model incorporates elements of a graph neural network, enabling it to comprehend the crystalline characteristics of materials and exhibit strong generalizability across a variety of materials, including metals, oxides, and nitrides, etc. The effectiveness of this model has been verified across multiple material systems in our laboratory. Looking ahead, we envision that researchers in this field can utilize our model to assess the likelihood of success for their VAN growth recipes, significantly reducing time and cost expenditures in experimental setups. In summary, our utilization of AI technology has yielded a robust tool for predicting VAN structure synthesis, highlighting the potential of AI in material science research.

5:00 PM MT03.03.06
Optimization of Bistable Clamp for Aerospace Thermal Systems Russell Laudone, Matthew Nakamura and Joseph Brown; University of Hawaii at Manoa, United States

Large spacecraft, launch vehicles, and hypersonic craft use a thermal protection system (TPS) consisting of tiles to mitigate potential thermal hazards while traveling through the atmosphere at high velocities. Historically, these tiles have been attached via silicone adhesive that mates tiles to the craft permanently. The proposed mechanism is a macroscale interlocking bistable compliant clamp that securely houses and rapidly exchanges thermal tiles attached to the TPS. Compliant mechanism design presents a significant learning curve due to large deflections requiring nonlinear mechanics models, and unexplored design space for analysis of deflection of flexible links and mechanisms. Despite their design challenges, compliant mechanisms present many desired characteristics not found in traditional multi-joint rigid-body components, including lower part cost, scalability, precise motion, zero off-gassing, and reduction in weight and friction. Here we report methodology, designs, and results that demonstrate use of optimization techniques to autogenerate revised compliant structures by comparing them against a specified fitness metric. This proposed method is less time-consuming and more efficient than traditional computational or “trial-and-error” methodology and exports parameterized structures in manufacturable file format. This paper's proposed bistable compliant clamp was fabricated in polylactic acid (PLA), assessed with finite element analysis (FEA), and mechanically cycled on a tensile tester. Results identified preliminary performance metrics regarding stress concentrations, retention force, and input force. It was theorized that these metrics depend on seven geometric parameters and could be optimized to maximize retention force and minimize input force, while keeping acceptable material-based stress concentrations and bistable characteristics. The design methodology implemented topology optimization techniques to identify potential parameter solutions that improve one or more of the defined performance metrics. Redesigned models were fabricated and tested against the original prototype to validate the algorithm's ability to enhance mechanisms' performance. The proposed compliant mechanism serves as a solution for a re-attachable TPS tile system and a methodology to optimize compliant structures that do not require extensive expertise in compliant design theory. This result also demonstrates optimal design of unit cells that may be tessellated to form an adhesive metasurface.

5:00 PM MT03.03.07
Machine Learning for Experimental Design of Ultrafast Electron Diffraction Mohammad Shaaban; Texas A&M University, United States

In the field of nanomaterials research, this study presents a groundbreaking approach to overcome the challenges associated with Ultrafast Electron Diffraction (UED) data analysis. We introduce convolutional neural network (CNN) models that enable real-time analysis of UED data, unveiling dynamic material processes and identifying signs of damage. Moreover, Generative Variational Autoencoder (G-VAE) models are introduced to interactively optimize experimental parameters. These machine learning techniques showcase their potential for self-correcting UED experiments and can be readily extended to other characterization methods. By using CNNs to classify UED images and C-VAEs for dimensionality reduction, this study identifies defect formation, lattice distortions, and phase transformations in real-space, offering a transformative shift in materials research. Transfer learning techniques are also demonstrated for practical application on experimental UED patterns, promising advancements in materials science experimentation.

5:00 PM MT03.03.08
Development of a Photovoltaics Research and Development Ontology Michael Goette[1], Tobias Roeschmann[1], Jens Hauch[2], Ulrich Paetzold[3], Eva Unger[1] and Thomas Unold[1]; [1]Helmholtz-Zentrum Berlin, Germany; [2]HI-ERN, Germany; [3]Karlsruhe Institute of Technology, Germany

Current efforts in energy materials research produce large quantities of data, most of which, however, are not published or stored according to FAIR principles. This can be an impediment to progress and makes it difficult to cooperate, reproduce results and enable machine-learning on these data sets. Ontologies provide a common syntactic and semantic framework for research domains and have been widely applied in many fields, such as finance and biomedics. Coupling ontologies with databases containing FAIR data can unlock the power of machine-learning across a whole research field. So far only few ontologies have been developed and applied in energy materials research and development, and to our knowledge no publicly shared ontology for photovoltaic materials and devices exists at present. We will present an ontology a thin film photovoltaic materials and devices which is based on the basic formal (BFO) top level ontology (https://matportal.org/ontologies/TFSCO). As a first use-case the PV ontology is used to integrate high-throughput research in halide perovskite photovoltaics at several research groups/institutes of the Helmholtz-Gemeinschaft in Germany, but could be in the future expanded to encompass further research and development areas in photovoltaics.

Bayesian Optimization for Customizable Hierarchical Kirigami Piezo-Transmittance Strain Sensor Designs Jimin Gu[1], Bowen Zheng[1], Jihyeon Ahn[2], Inkyu Park[2] and Grace Gu[1]; [1]UC Berkeley, United States; [2]Korea Advanced Institute of Science and Technology, Korea (the Republic of)

The significance of IoT systems incorporating green and sustainable energy sources has grown exponentially. Simultaneously, the demand for sensing

systems integrated with low-powered and self-powered capabilities has emerged. Piezo-transmittance strain sensors, which operate on the optical transmittance change induced by mechanical deformation of the functional film, have demonstrated remarkable potential for in self-powered soft sensing applications integrated with solar cells. These sensors are notable for their reliability, rapid response, and long-term stability. While soft sensing systems offer advantages because of their compliance and stretchability, their suitability for vertical sensing platforms varies depending on the mechanical properties of the target objects. Consequently, there is a growing need to develop customized sensor characteristic optimization procedures within this field. The utilization of a kirigami structure in piezo-transmittance sensors addresses two benefits. First the repeated unit-cell pattern across the film area ensures sensor uniformity. Additionally, it offers design flexibility, allowing for the accommodation of predicted mechanical deformations within the pre-designed structure. In this research, we optimized a hierarchical kirigami-based structure, focusing on sensor sensitivity within different working ranges, as the functional film for piezo-transmittance strain sensors. First, we utilize the results obtained from finite element simulations as a training dataset to build a neural network surrogate machine learning model. This model accepts geometric variables as input and furnishes data regarding the desired performance metrics, thereby substituting the requirement for more costly physical simulations, facilitating the optimization process. The Bayesian optimization and the cross-entropy method were used to optimize the sensor's geometric structure, and a comprehensive analysis of the geometric factors was conducted through sensitivity analysis. Through sensitivity analysis, we can identify the major geometric factors that affect the sensor's performance. Additionally, in contrast to auxetic behavior, the sensor's performance is better in a simpler model, specifically at hierarchical level 1. Furthermore, through experimental testing, we can validate the superior performance of the designed kirigami piezo-transmittance strain sensors.

Physics inspired Machine Learning of Eliashberg Spectral Function for High-Throughput Screening of Novel Superconductors Ajinkya Hire, Jason B. Gibson, Benjamin Geisler, Philip Dee, Oscar Barrera, Peter Hirschfeld and Richard Hennig; University of Florida, United States

The Eliashberg spectral function (α^2F) is at the core of understanding the electron-phonon superconducting properties of a material. But calculating α^2F from ab initio methods for a large number of materials is expensive, impeding the high-throughput search of novel superconductors. With machine learning models gaining prominence over the past decade for material properties, our work harnesses this potential for α^2F prediction. In this presentation, I will present our expansive database of theoretically calculated high-quality α^2F and introduce our state-of-the-art equivariant neural network models trained using it. This talk also elucidates the nuances of training models for predicting continuous properties such as α^2F, focusing on innovative physics-inspired node embeddings to bolster model performance. For the α^2F-derived properties like the electron-phonon coupling λ, and two moments of the frequency ($\langle \omega_{log} \rangle$, and $\langle \omega^2 \rangle$), our base model, relying solely on crystal structure, achieves a Pearson correlation coefficient of 0.3, 0.7, and 0.8. In comparison, integrating moderately expensive node embeddings increases the Pearson correlation coefficients of 0.5, 0.8, and 0.9 on the derived properties. An intriguing power-law relationship between model loss and training dataset size is observed, emphasizing the imperative for community-collaborated expansion of α^2F databases.

AI Accelerated Computational Design of The Freeform Solar Cell Structures Ruiqi Guo[1,2], Wenqing Wang[1,2], Masahito Takakuwa[2], Kenjiro Fukuda[1] and Takao Someya[1,2]; [1]RIKEN, Japan; [2]The University of Tokyo, Japan

Artificial intelligence generated configurations (AIGC) have emerged as a game-changing approach for inverse design, demonstrating remarkable potential in the realm of free-form device structures. This innovation is especially valuable in the context of thin-film solar cell (SC) devices, where patterned meta-surfaces offer the potential to enhance both their electrical and optical properties.

Traditional human-designed periodic meta-surfaces, while effective, are inherently constrained by topological limitations and a limited set of parameters. The advent of free-form design liberates us from these constraints, allowing for the creation of intricate and unconventional shapes, as well as the exploration of a vastly expanded design landscape. This newfound design freedom holds the promise of unlocking unprecedented functional capabilities, potentially surpassing human intuition. Nevertheless, the efficient exploration of this expansive design space presents a significant computational challenge.

One of the primary obstacles to realizing high-throughput free-form designs is the computational cost associated with conventional numerical simulations. In our study, we tackle this challenge head-on by introducing a fully automated system that harnesses the power of high-speed Deep Learning (DL) surrogate solver alongside intelligent configuration optimizer. Compared to standard numerical methods, our DL surrogate model accelerates the prediction of outcomes by 22,700 times, resulting in a 98.47% reduction in computation costs, all while maintaining an average accuracy of approximately 99%.

Our extensive evaluation, encompassing a dataset of 600,000 configurations generated by the intelligent configuration optimizer, has led to the discovery of an optimized SC device design boasting a power conversion efficiency of 17.58%. This performance greatly surpasses the 14.70% baseline efficiency of SC device lacking patterns on the substrate layer. These findings underscore the immense potential of AIGC techniques in efficiently enhancing the performance of photovoltaic devices, paving the way for a brighter future in renewable energy applications.

9:00 AM MT03.04.04
Machine Learning to Construct Process-Structure-Property Relations of hBN Thin-Films Dokwan Kook and Satish Kumar; Georgia Institute of Technology, United States

Hexagonal Boron Nitride (hBN) is a 2D material with high in-plane thermal conductivity and low out-of-plane thermal conductivity. Due to its anisotropic properties, hBN films have high potential for the thermal management of next-generation electronics. The thermal conductivity of hBN film depends on the processing conditions and its thickness. The construction of Process-Structure-Property (PSP) relations of hBN film can help in accelerating the synthesis of hBN films with desired thermal properties. Machine learning (ML) techniques can help in utilizing both measurements and simulations to develop reliable PSP relations to guide the synthesis process. In this presentation, we will discuss how Gaussian Process Regression (GPR) can be applied to experimental and simulation data to construct PSP relations. Pulsed laser deposition (PLD) is used for the extraction of experimental data, and molecular dynamics simulations is used for the extraction of simulation data. The PSP relations will be constructed using SEM images as structure data and out-of-plane thermal conductivity as property for various process conditions.
A significant challenge is dimensionality mismatch which occurs from the large size of the structural data compared to process conditions and properties, e.g., SEM images are 2D images of a 3D structure, while process conditions or properties are typically 1D. Dimensional mismatch makes the ML model difficult to learn. To resolve this problem, we will apply two-point correlations and principal component analysis. Two-point correlations preserve spatial statistical information of the SEM images. This will allow original structural data from the samples to be converted into similar shapes, allowing the ML model to be trained efficiently. Applying principal component analysis will allow the structure data to be expressed as a linear combination of orthogonal vectors. The data will be represented by the matrix of coefficients of orthogonal vectors, which will be much smaller than an SEM image itself.
Experimental data have high fidelity but low quantity, while simulation data can be produced in larger volume. Simulation data will be included with the

experimental data during the training of ML model to accelerate PSP relations and the model will identify process conditions corresponding to high thermal conductivities accurately.

MaterialEyes – Looking into Renewable Energy Materials with Theory- and AI-Guided Characterization Maria K. Chan; Argonne National Laboratory, United States

The understanding and design of materials for sustainability -- such as photovoltaics, optoelectronics, and energy storage materials -- rely on measurements not just of the functional properties, but also of fundamental structural and electronic properties. Data driven approaches such as machine learning (ML) for interpreting these measurements via microscopy and spectroscopy rely on labeled, reliable, balanced training data. We will discuss the use of AI including computer vision and large language models (LLMs) to obtain such training data from literature, and also the use of theory-guided AI approaches to interpret new microscopy and spectroscopy data. We will also discuss the use of generative AI to understand interfaces and structural evolution in renewable energy materials.

Physics and Uncertainty-Aware Ensemble-Based ML-Models for Interatomic Potentials and Prediction of Reaction Networks and Cell-Level Performance Tejs Vegge; Technical University of Denmark, Denmark

Understanding the dynamic processes at solid-liquid interfaces in electrochemical devices like batteries is key to developing more efficient and durable technologies for the green transition. Fundamental and performance-limiting interfacial processes like the formation of the Solid-Electrolyte Interphase (SEI) [1] and dendritic growth [2] span numerous time- and length scales. Despite decades of research, the fundamental understanding of structure-property relations remains elusive. Ab initio molecular dynamics (AIMD) generally provides sufficient accuracy to describe chemical reactions and the making and breaking of chemical bonds at these interfaces [3]. Still, the cost is prohibitively high to reach sufficiently long time- and length scales to ensure proper statistical sampling [4]. Machine learning (ML) potentials offer a potential solution to this challenge. Still, training ML-based potentials capable of handling activated processes in organic or aqueous electrolytes remains a fundamental challenge since the potential must capture both intra- and intermolecular interactions in the electrolyte and during chemical reactions at the interface [4]. Here, we present new approaches using phase field models [2], graph neural networks [5] and new transition state training sets [6] for chemical reaction networks, and machine/deep learning models to predict the spatio-temporal evolution of electrochemical interphases [3]. We also discuss the development of methods like symbolic regression to learn the laws of electrolyte transport [8], the predictions of energy and forces with calibrated uncertainty quantification for interatomic potentials using neural network ensemble models [8,9]. Finally, we discuss how such models trained on multi-sourced and multi-fidelity data from multiscale computer simulations, operando characterization, high-throughput synthesis, and testing, to provide uncertainty-aware and explainable ML for early prediction of, e.g., of degradation trajectories for battery cells [10].

Machine Learning Prediction of Electronic Structure for High-Throughput Inverse Design of Functional Organic Materials Reinhard Maurer; University of Warwick, United Kingdom

Materials for electronic devices such as organic light emitting diodes need to have tailored optoelectronic properties and be synthetically viable. As devices are composed of organic thin films with different functionality, the optoelectronic properties of materials need to be designed in concert and the role of the interfaces between thin films must be understood. Computational high-throughput screening of molecular excited states can greatly facilitate this complex multi-objective design problem. I will present our recent work on deep machine learning models that are able to predict structure, electronic structure, and excited states of organic molecules and materials in general. Our models predict optical excitations, the fundamental gap, electron affinity and ionisation potential for large organic molecules of diverse composition. [1] While the models are trained on first principles electronic structure data, the prediction process requires no recourse to computationally expensive ab initio calculations. The accuracy and transferability of the models can be assessed against photoemission spectroscopy data. I will further showcase how such models can be used in combination with generative machine learning to discover novel organic compounds that satisfy specific optoelectronic properties. [2] We explore different applications with our approach from the design of organic electronics to plasmonic sensors and tailored nanoparticles. [1] Chem. Sci. 12, 10755-10764 (2021), [2] Nature Comp. Sci. 3, 139–148 (2023);

Proposal of Bayesian Framework for Inverse Inference to Predict Material Properties from Microstructures Satoshi Noguchi[1] and Junya Inoue[2]; [1]JAMSTEC, Jamaica; [2]The University of Tokyo, Japan

This presentation introduces a Bayesian framework designed for inverse inference to predict material properties or process parameters from microstructure images. The basic strategy of the proposed framework is the integration of Bayesian inference methodologies with machine learning techniques. This enables us to not only predict target properties but also quantify the uncertainty associated with these predictions. Specifically, our focus lies on the development of a Bayesian framework based on generative networks which recently have received much attention in the field of computational material science. The integration could contribute to the examination of the prediction uncertainty.

In this presentation, we will explain the fundamental concepts of our framework and the outcomes of its application of this to a specific case study. Our chosen case is the prediction of material properties from artificial dual-phase steel microstructures. Also, we will discuss the comparison between our proposed Bayesian framework and a conventional inference method based on convolutional neural networks. By the end of this presentation, you will gain insights into the novel Bayesian approach and its potential advantages over conventional methods, providing a powerful tool for more robust predictions in the field of computational material science.

11:30 AM MT03.04.10
Physics-Informed Pre-Training of Graph Neural Networks for Materials Property Predictions Shuyi Jia, Fan Shu, Akaash Parthasarathy, Chandreyi Chakraborty and Victor Fung; Georgia Institute of Technology, United States

Pre-training of machine learning models, particularly in the form of self-supervised learning, is now an ubiquitous approach for improving model performance and robustness which has featured prominently in the fields of natural language processing and computer vision. To apply these similar concepts to the materials sciences, new domain-aware pre-training strategies need to be developed. We introduce a series of physics-informed pre-training strategies which align well to materials data and can be applied towards the widely used graph neural network class of machine learning models. We demonstrate the effectiveness of this approach on a wide range of benchmarks across multiple materials systems and properties. We discuss the benefits of pre-training for situations where datasets are limited in size and robust out-of-distribution performance is needed, as well as potential implications of pre-training towards developing foundational models for the materials sciences.

11:45 AM MT03.04.11
Using Domain Specific Languages to Enable Artificial Intelligence for Polymer and Catalyst Design Nathan Park[1], Jannis Born[2], Matteo Manica[2], James Hedrick[1], Tim Erdmann[1] and Pedro Arrechea[1]; [1]IBM Almaden Research Center, United States; [2]IBM Research-Zurich, Switzerland

Traditional research workflows in polymer chemistry, which often rely heavily on trial-and-error, stand to be profoundly reshaped through continued advances in automated experimentation and artificial intelligence (AI). However, the seamless integration of these advances within daily research activities still faces significant hurdles. To overcome these obstacles, we have focused our efforts in key areas which would be impactful for experimentalists. First, we have developed new systems and software for facilitating automated synthesis using readily available lab equipment, both for polymerization in continuous-flow reactors as well as small molecules in flow to batch systems. Second, we show how the use of a domain-specific language (DSL) can solve a host of issues surrounding experimental data representation and management—facilitating more straightforward development of AI models. Finally, we demonstrate how experimental data represented in a DSL can be utilized to develop effective generative models for materials and catalyst design.

SESSION MT03.05: Machine Learning for Computation: High-Throughput Computing

Wednesday Afternoon, April 24, 2024
Room 322, Level 3, Summit

1:30 PM MT03.05.01
Computational Design of Dual-Atom Catalysts for Sustainable Energy Conversion Guoxiang (Emma) Hu; Georgia Institute of Technology, United States

Dual-atom catalysts (M_1M_2-N-C) are emerging as promising candidates for electrochemical reactions (e.g., oxygen reduction reaction) which are critical for clean and sustainable energy devices. However, due to the large chemical design space, myriad possible structural configurations, and dynamic structure evolutions of the metal centers under reaction conditions, the design of dual-atom catalysts has been challenging and cost-prohibitive for both experiments and computations. Here, using high-throughput density functional theory (DFT) calculations combined with machine learning, we rapidly and efficiently evaluate over 20000 dual-atom catalysts for oxygen reduction reaction. We first generate a DFT database of a subset of the dual-atom catalysts, and validate our computational predictions of the structure, stability, and catalytic activity with experimental data where available. With this benchmarked database, machine learning models based on neural networks were trained and applied to identify promising dual-atom catalysts in the search space which possess higher durability and activity than the state-of-the-art Pt and Fe-N-C single-atom catalysts. Furthermore, additional DFT calculations were performed on selected catalysts to reveal the origin of their improved catalytic performance and establish structure-property-performance relationships. The computational framework developed in this work can be generally extend to other important electrochemical reactions including carbon dioxide reduction reaction and hydrogen evolution reaction for sustainable energy conversion.

1:45 PM MT03.05.02
Sub-Trillion-Scale Atomic Data Integrated Deep Learning Approach for Predicting Thermal Transport Properties of 60,000 Inorganic Perovskites Ming Hu; University of South Carolina, United States

Although first-principles based anharmonic lattice dynamics method coupled with the phonon Boltzmann transport equation has been developed to obtain the phonon properties including lattice thermal conductivity at highest accuracy ever, the costly and time-consuming nature of the required interatomic force constants calculations renders high-throughput infeasible when facing tens of thousands of new materials. Here, a high-dimensional multi-element deep neural network with sub-trillion-scale atomic data is trained, dubbed Elemental Spatial Density Neural Network Force Field (Elemental-SDNNFF), achieving a competitive force root mean square error and a speed-up of 4 to 5 orders of magnitude in comparison to first principles. The effectiveness and precision of the Elemental-SDNNFF approach is demonstrated on a set of 150,000 inorganic crystalline structures spanning 63 elements in the periodic table by prediction of complete phonon properties such as phonon dispersions and lattice thermal conductivity. We then use our trained neural network model to predict and screen full phonon properties of 60,000 single and double perovskite structures. Due to the inherent structural feature of dynamical disorder, the perovskite structures have shown diverse thermodynamic and phonon transport properties. Dynamic stability of all 60,000 perovskite structures is predicted by screening negative frequencies in the Brillouin zone. Four-phonon scatterings and two-channel thermal transport are also analyzed and screened. The underlying mechanism is analyzed in deep at the electronic level. This study demonstrated that our algorithm is very powerful for predicting phonon properties of large-scale inorganic crystals and is also promising for accelerating high-throughput search of novel phononic materials for emerging applications.

2:00 PM *MT03.05.03
Understanding and Mitigating Bias in Autonomous Materials Characterization and Discovery Jason R. Hattrick-Simpers; University of Toronto, Canada

Since the publication of the Mission Innovation Materials Acceleration Platform, AI is increasingly responsible for driving automated experimental and computational tools. There have been multiple case studies for which autonomy was demonstrated to successfully drive materials optimization or discovery

problem and the world of scientific robots has moved from science fiction to reality. However, within the broader AI community it is well known that AI's carry with them their creators' biases and this has serious implications on model development and deployment. Using several case studies, I will illustrate how biases can arise in materials science and specific steps that can be taken to remove them. Specifically, I will discuss some of our recent work in (1) reducing human bias in label generation by applying robust statistics to spectroscopic data analysis, (2) identifying and mitigating search space bias through model disagreement, and (3) circumventing the big data bias loop by illustrating how to the presence of information redundancy in large computational datasets and (4) how construct an optimally informative dataset for model training.

2:30 PM BREAK

3:30 PM *MT03.05.04
Predicting The Structure and Properties of Bulk and Surface Perovskite Oxides with Machine Learning and Simulations Rafael Gomez-Bombarelli, James K. Damewood, Jessica Karaguesian, Jaclyn Lunger, Jiayu Peng and Xiaochen Du; Massachusetts Institute of Technology, United States

Ceramics based on multicomponent oxides are a promising platform for catalysis and electronics. By controlled doping of multiple elements, it may be possible to tune electronic and transport properties of oxide materials towards high performance applications. This opens an exciting and high-dimensional design space for choosing the most promising choices and stoichiometric ratios of elements that fine tune desired properties.

Here we will describe how machine learning models, powered by electronic structure simulations can address property prediction and design in multicomponent space. In particular, we will explore how perovskite oxides, which can support quaternary or even more complex compositions, can be engineered in silico.

We will describe the use of elemental and electronic descriptors to predict whether perovskite oxide materials will exhibit chemical ordering when synthesized, we will evaluate the use of per-site deep learning models to predict atomically-project properties such as magnetic moments of catalytic side activity, the use of machine learning interatomic potentials to relax perovskite structures and to create surface phase diagrams, and the ability of equivariant models to capture symmetry-breaking relaxation and properties from idealized, unrelaxed prototypes.

These tools put together, alongside machine learning models for synthesis planning, will support the development of bottom-up data-driven design pipelines for multicomponent oxide materials with tailored properties.

4:00 PM *MT03.05.05
Fantastical Training Data and How To Generate It Martijn Zwijnenburg; University College London, United Kingdom

In an ideal world we would train machine learning models for organic materials on training data generated using coupled-cluster singles-doubles-triples-quadruples or something similar and fully take into account the environment of the molecules. In practice this is impossible considering the number of training points required for most models. As a result, we have to make choices. Even more so when we want our model not to predict ground state energies and/or geometries but excited state properties, such as optical excitation energies or electron affinities/ionisation potentials, as well as to be transferable. Models that could accurately predict excited state properties for a wide range of organic materials would be very useful in virtual high-throughput screening of materials for organic LEDs, photovoltaics and photocatalysts.

In my contribution I'll discuss our work and that of others on training data generation for excited-state properties of organic materials. I'll consider which properties to aim for, what the best possible training data might look like and how hybrid schemes based on tight-binding methods calibrated to higher-level methods can be exploited.

4:30 PM MT03.05.06
Experiment Versus Computation, Physics Versus Machine Learning in The Inverse Design of Photovoltaic Materials Andrea Crovetto; Technical University of Denmark, Denmark

As a practical case study to advance methods for the inverse design of photovoltaic (PV) materials, my group has been given the following task for the next 5 years: Identify and synthesize the best PV absorber out of the space of all inorganic materials containing sulfur and phosphorus (phosphosulfides). Within this family of materials ~10 compounds have already been considered as potential PV materials, ~260 have previously been synthesized, ~420 are present in the Materials Project database, and 200,000 phosphosulfide compounds from ternary and quaternary systems are chemically plausible according to charge-neutrality arguments.

To try to solve this puzzle within a 5-year timeframe, we have set up a multi-faceted inverse design platform. This platform includes:

1. High-throughput/high versatility modular synthesis apparatus for combinatorial growth of any inorganic phosphosulfide thin films, so that there are no excuses for excluding certain elements from experimental work. This includes sulfur- and phosphorus partial pressure control (both at atmospheric and low total pressures), separate chambers for volatile metal incorporation, and creation of perpendicular combinatorial gradients in the metal-to-metal ratio as well as in the S/P ratio.

2. High-throughput characterization apparatus, focusing on the properties that are expected to be correlated with the final PV performance and are difficult to simulate with sufficient accuracy.

3. A tiered approach to material property simulation, with a focus on complementing (rather than reiterating) the information available from experiment. The simulation tools can be roughly divided into first-principles quantum mechanical methods, semiclassical methods, and classical "rule-of-thumb" methods.

4. A data management tool to accommodate both experimental and simulation data.

5. Various artificial intelligence tools to be used both for decision-making in the lab and for understanding complex composition-structure-process-property-performance relationships.

6. Public access to the data generated by the tools listed above.

To make the presentation more concrete, I will discuss two practical examples that highlight the importance of a diversified methodological toolkit in

modern materials research. The first example is the integration of computational and experimental approaches in the process of discovering new materials with new compositions and unknown crystal structures. The second example is the balance between physical soundness and statistical performance in the machine-learning-aided development of a phenomenological figure of merit to evaluate the quality of a generic PV material.

SESSION MT03.06: Data, Autonomy and Algorithms I
Session Chairs: Shijing Sun and Steven Torrisi
Thursday Morning, April 25, 2024
Room 322, Level 3, Summit

8:00 AM *MT03.06.01
Supervised and Unsupervised Machine Learning Applied to Challenging and Rapid Diffraction and Structural Problems Simon J. Billinge; Columbia University, United States

Development of next generation materials for applications in sustainable energy and beyond require us to study the structure of real materials in real devices even as they operate: for example, putting operating batteries in the beam, studying spatially resolved labs-on-chip, doing real-time autonomous experiments and using computed tomography to see diffraction from cross-sections of bulk samples. These developments, powered by wonderful synchrotron and neutron source and detector developments, present major challenges on the data analysis side. Now we are putting heterogeneous devices in the beam and getting signals from different parts of them. We have bad powder averages (spotty data) because we can't spin the battery, and single crystal spots coming from some component in the setup that happens to be in the way of the beam. We have unknown and unexpected phases coming and going, and want to extract tiny signals from large backgrounds. I will present some of the data analysis, algorithmic and computational developments that are helping us to overcome these challenging situations and not only recovering from 'bad data', but also turning bad data into good data. Spotty powder patterns have more information in them than smooth powder rings. I will describe some new approaches, algorithmic, statistical, machine learning and otherwise, that are helping us move the goalposts in this domain, which can open up new opportunities for studying complex heterogeneous samples with hard x-rays.

8:30 AM *MT03.06.02
Designing Vitrimer Polymers with Molecular Dynamics and Machine Learning Aniruddh Vashisth; University of Washington, United States

Vitrimers are a new class of self-healing polymers that can heal by rearranging their molecular structure via dynamic covalent bonds. These polymers offer promise for improving the circular life-cycle and sustainability of various polymeric systems that are used in our day-to-day life ranging from fiber composites to electronics. A recently developed framework called Accelerated ReaxFF, uses the "bond boost" approach to speed up the MD simulations by providing reactive sites in the reactants with boost energy equivalent or slightly larger than the energy reaction barrier to overcome the cross-linking process barrier and form desired products. This approach avoids unwanted high-temperature side reactions while allowing for rejection of high-barrier events. This method can be employed not just for virtual characterization of vitrimer polymers but also to understand the rearrangement reactions in epoxy-acid vitrimer polymer chemistries. Further, using coupled molecular dynamics and machine learning, we design new vitrimer chemistries with targeted applications. This includes collecting a dataset of glass transition temperature of various vitrimer chemistries calculated through molecular dynamics (MD). This data is then used to train a latent space and property predictor . Finally, a search is performed within the latent space to uncover vitrimer chemistries with desired properties.

9:00 AM *MT03.06.03
Taming The Complexity of Materials Degradation with Machine Learning Brett M. Savoie; Purdue University, United States

Limited stability and unacceptable degradation products are common reasons for otherwise promising materials to fail technological translation. The enduring state-of-the-art for establishing these properties essentially remains make-and-break testing, which is costly and provides information only at the end of the materials development process. The complexity of the reaction networks that govern degradation and the difficulty of data analysis pose tremendous obstacles to predictive approaches, however recent advances in automated reaction prediction and machine learning are increasingly making it possible to tractably describe and even predict degradation phenomena. In this talk I will highlight our group’s recent work developing methods for predicting reaction outcomes and how they have been applied to several different materials classes. The second half of the talk will discuss machine learning approaches to the closely related problem of identifying degradation products on the basis of typical spectral information sources.

9:30 AM *MT03.06.04
Materials Cartography: The Role of Materials Representation Steven B. Torrisi; Toyota Research Institute, United States

Within materials science, practitioners are concerned with modeling time and length scales that span many orders of magnitude, presenting differing challenges across the atomistic, mesoscale, and device levels. Moreover, problems where data are scarce pose challenges for applying machine learning in many scientific fields. When designing, training, and applying a model, the representation of input features can be just as important as the target and architecture of the model itself. Finding the appropriate way to represent a material of interest is not always straightforward and remains an active area of research. In this talk, I will highlight recent work which explores the concept of materials representation in applications ranging from materials and device-level informatics to molecular dynamics, highlighting intruiging results as well as lessons learned that may be useful for practitioners in diverse subfields of materials science.

10:00 AM BREAK

10:30 AM *MT03.06.05
Learning from Data and Distributions to Accelerate Engineering of Energy Materials and Devices Rachel C. Kurchin; Carnegie Mellon University, United States

Whether or not we take an explicitly probabilistic perspective, and whether or not we are using black-box models or traditional physics-based ones, learning from and with distributions (of data, probability, and/or parameters) is an important tool in the data-driven modeler’s toolbox. In this talk, I’ll present two stories from my group’s work emphasizing why this is important.
First, I’ll discuss some past and present work in using Bayesian parameter estimation to characterize materials and interfaces in photovoltaic devices. In

this work, we use a drift-diffusion solver to simulate current-voltage curves with a variety of different materials properties for both the layers and the interfaces within the device. By comparing these simulated curves to measured data we can effectively "invert" the device model to get posterior distributions reflecting our knowledge about the input parameters to the model as a function of measurements corresponding to the output.
Next, I'll shift to focus on some ongoing work utilizing diffusion models (the same type of machine learning model behind generative image tools such as DALL-E and Midjourney) to generate realistic microstructures of solid-oxide cell electrodes for use in device degradation simulations. A key aspect of validating these models is running their outputs through software that computes various microstructural properties of interest, including phase fractions, interfacial areas, and triple phase boundary densities. In particular, we examine the distributions of these properties in the generated data as compared to the training data and investigate whether, as has been reported in other work, diffusion models are less prone to issues such as mode collapse compared to other types of generative models such as generative adversarial networks.
In both of these stories, understanding how we can learn from and with both data and distributions is paramount. The insights that we have on how physical processes in our systems of interest should affect values and distributions in our datasets are critically important to incorporate in the way we analyze and learn from that data.

11:00 AM MT03.06.06
Algorithmic Design and Implementation of an Automated Synthesis Platform for Rare and Exceptional Materials Discovery Alexander E. Siemenn[1], Armi Tiihonen[1,2], Basita Das[1], Eunice Aissi[1], Fang Sheng[1], Sebastian De Jesus[1], Lleyton Elliott[1], Sharil Maredia[1], James Serdy[1], Hamide Kavak[1,3] and Tonio Buonassisi[1]; [1]Massachusetts Institute of Technology, United States; [2]Aalto University, Finland; [3]Cukurova University, Turkey

Discovery of exceptional materials that have high-performance properties, such as perovskite materials with ideal band gaps and high stability, stands as an imperative challenge for developing sustainable electronic devices to tackle decarbonization and address the larger climate crisis. However, these exceptional materials are rare – existing only in narrow hypervolumes of vast and high-dimensional material search spaces, similar to a needle-in-a-haystack. With the rise in self-driving labs, it has become tractable to search larger volumes of these high-dimensional search spaces. However, current high-throughput self-driving labs are limited by their algorithmic performance in discovering needle-in-a-haystack exceptional materials as these labs are often guided using standard Bayesian optimization methods that inherently smooth over these regions containing exceptional materials within the search space. In this contribution, we present the design of DiSCO ([Di]scovery, [S]ynthesis, [C]haracterization, and [O]ptimization), an autonomous and high-throughput platform designed specifically to target the discovery of exceptional materials for sustainable electronic device applications. We highlight the following key contributions of DiSCO: (1) design of a zooming-based Bayesian learning with hypervolume penalization to maximize the number of exceptional materials discovered per unit time and (2) vectorization of the predicted exceptional materials for ultra-high-throughput synthesis and automated characterization within high-dimensional materials search spaces.

The DiSCO platform uses a method of ultra-high-throughput inkjet gradient deposition that synthesizes up to 100 unique material compositions within 20 seconds. Each material gradient is suggested by a custom Bayesian learning algorithm, entitled ZoMBI-Hop ([Zo]oming [M]emory [B]ased [I]nitialization). ZoMBI-Hop drives the discovery of exceptional materials within DiSCO by iteratively zooming the search bounds into regions of high-reward, in turn, capturing the true rough, non-convex nature of the needle-in-a-haystack optimum, rather than smoothing it over. Furthermore, ZoMBI-Hop jumps between high-reward basins in the search space, such that once an optimal region has been discovered, then that hypervolume becomes penalized for future iterations, resulting in only new high-reward regions being searched. Using this approach, we demonstrate the targeted discovery of up to 10x more exceptional materials from 6D materials search spaces, relative to previous ZoMBI implementations, given the same number of experiments. Each optimum suggested by ZoMBI-Hop is transformed from a single point into a vector that spans the extents of the search bounds using the angle of highest predicted cumulative reward along the vector. This vectorization of a single point generates a gradient of compounds that can be tractably synthesized in an ultra-high-throughput manner using DiSCO, hence, further increasing the resolution of the search space around each predicted exceptional material. In this version of DiSCO, the implemented reward function is derived from the optimization of band gap, computed autonomously for each deposited material using computer-vision-guided hyperspectral imaging. Future implementations will contain additional reward metrics such as electrical conductivity and stability. This automated characterization of band gap takes approximately 3 minutes to compute the band gap for every 100 uniquely synthesized material compositions. Overall, with the design of this DiSCO platform, it becomes tractable to acquire voluminous experimental data of exceptional materials as well as the regions surrounding those exceptional materials, resulting in the ability to confidently down-select optimal candidates with high precision for full electronic device scaled-up and testing. Discovery of high-performance band gap perovskite materials results in progress.

Atomistic Structure Search of Nanoscale Systems Using Generative Modeling and Evolutionary Algorithm Venkata Surya Chaitanya Kolluru, Nina Andrejevic and Maria K. Chan; Argonne National Laboratory, United States

Knowledge of the exact atomistic structure is crucial for computational analysis of unknown phases observed in experiments and for discovering novel materials. We previously developed the FANTASTX (Fully Automated Nanoscale To Atomistic Structure from Theory and eXperiments) package, a multi-objective evolutionary algorithm to determine atomistic structure from experimental characterization data. This approach relies on sampling the potential energy landscape of thermodynamically stable structures to find the best match between the simulated phase and observed experimental data. In this work, we develop a method for efficient sampling of candidate structures based on generative modeling.

Using a variational autoencoder (VAE), we transform the original, structure-oriented search space to a low-dimensional, property-oriented one. Structures are represented using an invertible point-cloud representation, and an auxiliary network is used to steer the latent space distribution according to the desired property. In this talk, we will discuss key components of this approach, including network optimization and sampling of the resulting latent space. We report the results of preliminary tests performed on CdTe and IrOx datasets, which utilize molecular dynamics and density functional theory for structure relaxation, respectively. This VAE-augmented approach enables more efficient sampling by refining the search space to meet expected property criteria, such as energy or mismatch to experimental data.

Advancements in Multimodal Emotion Sensing for Enhanced Human-Machine Interaction Anand Babu[1], Isabelle Dufour[2], Dipankar Mandal[1] and Damien Thuau[3]; [1]Institute of Nano Science and Technology, India; [2]Université de Bordeaux, France; [3]Bordeaux INP, France

Achieving effective human-machine interaction hinges on the recognition and response of machines to human emotions. However, the integration of emotions into robotics is a formidable challenge, primarily due to the intricacy and subjectivity of human emotional experiences. To enable the development of cognitive robotics capable of simultaneously perceiving and responding to human emotions, it is essential to make significant strides in emotional sensors driven by artificial intelligence (AI) and machine learning algorithms capable of accurately interpreting and responding to emotional cues. In this study, we introduce a novel approach to multimodal emotion sensing by harnessing non-invasive data collection of physiological indicators, including heart rate pulse, breathing patterns, and voice signatures. We utilize wearable printed organic piezoelectric sensors that offer rapid response times and are highly sensitive response a wide spectrum of force waveforms, frequencies, and pulse-width modulation. The responses obtained from these

wearable sensors are fed into a long short-term memory neural network algorithm, achieving remarkable classification in distinguishing various emotional states.
To further demonstrate the feasibility of transferring emotions to robotics, we have implemented Q-learning, demonstrating the effective training of a robotic model. By harnessing these multifaceted signals, our AI-driven emotional sensors aim to redefine the landscape of human-machine interaction. We envision a future in which machines possess the capability to discern and dynamically adapt to the diverse spectrum of human emotional states, fostering more seamless and responsive interactions between humans and machines.

Customized Acquisition Function Design for Materials Disovery Using Bayesian Algorithm Execution Sathya R. Chitturi[1,2], Akash Ramdas[1,2], Yue Wu[2], Brian Rohr[2], Stefano Ermon[1], Jennifer A. Dionne[1], Felipe H. da Jornada[1,2], Mike Dunne[2,1], Willie Neiswanger[1], Christopher Tassone[2] and Daniel Ratner[2]; [1]Stanford University, United States; [2]SLAC National Accelerator Laboratory, United States

The development of advanced materials requires precise and efficient search through a vast range of possible material candidates and conditions to find the select few which satisfy highly customized or specific experimental goals. We focus on the area of AI-based sequential decision making where, at each step, the next candidate material is suggested based on previous accumulated data. We develop and extend the recently proposed concept of Bayesian Algorithm Execution to allow users to automatically convert a complex, targeted experimental goal into an adaptive data collection strategy, resulting in substantially improved performance compared to state-of-the-art methods.

SESSION MT03.07: Data, Autonomy and Algorithms II
Session Chairs: Janine George and Shijing Sun

1:30 PM MT03.07.02
High-Throughput Methods for Lead-Free Halide Double Perovskites: Computation and Experiment Marina Selana Günthert[1], Oleksandr Stroyuk[2], Bernd Meyer[1] and Christoph J. Brabec[1]; [1]Friedrich-Alexander Universität Erlangen-Nürnberg, Germany; [2]Forschungszentrum Jülich GmbH, Germany

Lead-free halide double perovskites (LFHDP) have been an emerging material class for various applications in the field of optoelectronics over the last couple of years. In contrast to their lead-based counterparts they possess not only tunable optoelectronic properties but environmental friendliness and exceptional stability.[1-2] Nevertheless only a small number of those perovskites have been evaluated up until today. The material class can be enlarged even further by substituting the Pb^{2+} ion not only with one M^{1+} and one M^{3+} ion but with two of each resulting in a total number of six ions in the material.[3-5] This adaption increases the number of possible materials immensely and gives rise to the demand for a different approach in material investigation: high-throughput (HTP) screening.
HTP screening aims to analyze a vast material range in a reasonable time by applying automation techniques and the restriction to swift measurement methods. Overcoming this issue can be done by applying not only HTP experimental methods but also HTP computational methods. Density functional theory (DFT) is able to examine a perfectly controlled range of material compositions for complementary features.
The combination of these strategies is a promising approach towards a HTP screening in novel materials discovery and is shown to be applicable on the example of $Cs_2Ag_xNa_{(1-x)}Bi_yIn_{(1-y)}Cl_6$. DFT has access to features like e. g. the lattice parameter, elastic properties and electronic properties whereas experimental methods investigate e. g. optical and vibrational material properties. By combining these two screening approaches a wider picture of the full material properties can be achieved.
Additionally DFT is not restricted by synthesis conditions and can therefor give an indication of what to expect of materials on the composition map which are not easily synthesizable or just reducing the time consumption of a certain measurement if only a random sample of the material range is measured and those measurements are then used as a calibration for the density functional data received for the whole composition map.
Using the variety of ion combinations in this LFHDP structure with interchangeable ion ratios opens up a whole new field of materials which can be evaluated by the methods developed on the example of $Cs_2Ag_xNa_{(1-x)}Bi_yIn_{(1-y)}Cl_6$ and therefor to build up a database. Using machine learning algorithms on this database can lead to a deeper understanding of the coupling between the ion exchange and macroscopic material properties.

Materials Informatics for Polymer Materials: Experiments in The Loop Junichiro Shiomi[1,2]; [1]The University of Tokyo, Japan; [2]RIKEN, Japan

Materials informatics (MI) is to develop or study materials with an aid of informatics or machine learning. A typical approach is to train a black box model that relates basic descriptors (structure, composition, etc) and FoM (target properties) and predict or design a material with the largest FoM. At Thermal Energy Engineering Lab at University of Tokyo, together with the collaborators, we have been working on MI for heat transfer since 2015. One of the initial works was to design binary multilayered nanostructure to minimize or maximize thermal conductance by coupling thermal transport calculation and Bayesian optimization, which showed excellent efficiency. Later, the search space has been greatly expanded by utilizing quantum annealing. We have applied the methodology to computationally design and experimentally realize aperiodic superlattice that optimally impedes coherent thermal transport and multilayer metamaterial with wavelength-selective thermal radiation [1-8].
More recently, we have extended the machine-learning approach to that for polymers, aiming to functionalize them in terms of the thermal and dielectric properties. When molding or compounding polymers, the final properties are quite sensitive to the process parameters, therefore, the above approach of

serially connecting optimal design and experimental realization of materials is not sufficient. To this end, we have been developing a semi-automated MI system, where experimental fabrication and measurement are included in the optimization loop. This allows us to efficiently enhance the polymer properties. The MI optimization with experiments in the loop gives rise to various conceptual and practical questions; for instance, how to design and develop a robotic system that is adoptable to the existing material-development instruments and protocols, how to couple the property simulations and database with automated experiments, or how to appropriately define the search space for process parameters, etc. These aspects will be discussed in the talk.

Toward Accelerated, Experimental-Theoretical Closed-Loop Discovery Austin Mroz, Rebecca L. Greenaway and Kim E. Jelfs; Imperial College London, United Kingdom

Novel chemical systems are necessary to fully address the major global challenges facing humanity, including the climate emergency, resource scarcity, and energy consumption needs. Traditional chemical discovery initiatives are founded on intuition-guided, “trial-and-error" processes. Here, small, iterative changes to chemical structure and experimental conditions are made by the researcher.[1] This is significantly resource and time intensive; after each small modification, the molecule must be synthesized (often a trial-and-error process in itself) and properties measured. As a result, these workflows are associated with long timescales (~20 years) and high costs.[2,3] Recently, computation has accelerated this process via atomistic simulations and data-driven approaches.[4,5] Yet, present applications of computation are largely often to post-rationalization of experimental observations or high-throughput screening of manually-curated databases of hypothetical systems.[1]
The full utility of computation in the chemical discovery pipeline is only realized with the close integration of experiment and theory.[6] This could be achieved via closed-loop, experimental-theoretical workflows, which are poised to efficiently identify high-performing candidate compounds for target applications. Here, AI-driven theoretical predictions guide high-throughput, automated experiments and these experimental results are used to improve the accuracy of the predictive models in an iterative process, which is repeated until convergence criteria are met. Often this process is directed using data-driven optimization strategies.
Despite the initial success of AI in closed-loop chemical discovery workflows, there still exist major challenges in their scalable implementation – the major bottlenecks being i) the degree of human intervention needed and ii) lack of methods to manage the number and quality of initial data points. This is further complicated by the necessary integration and accommodation of i) varying metadata formats, ii) non-compatible, proprietary characterization software, and iii) hands-on robotic platform calibration and manipulation, among others. Each of which needs to be explicitly addressed to realize coherent, automated closed-loop chemical discovery. Thus, data-driven solutions and supporting software are imperative to seamlessly close-the-loop in experimental-theoretical discovery workflows.
We address these bottlenecks and present an integrated, experimental-theoretical workflow that leverages high-throughput, automated experiments, and abstract computational models with data-driven optimization strategies to drive towards viable supramolecular materials for gas storage and separation applications.

New Opportunities for Data-Driven Chemistry and Materials Science Through Automation Janine George[1,2]; [1]Federal Institute for Materials Research and Testing (BAM), Germany; [2]Friedrich-Schiller-Universität Jena, Germany

In recent years, many protocols in computational materials science have been automated and made available within software packages (primarily Python-based).[1] This ranges from the automation of simple heuristics (oxidation states, coordination environments)[2] to the automation of protocols, including multiple DFT and post-processing tools such as (an)harmonic phonon computations or bonding analysis[3]. Such developments also shorten the time frames of projects after such developments have been made available and open new possibilities.

For example, we can now easily make data-driven tests of well-known rules and heuristics or develop quantum chemistry-based materials descriptors for machine learning approaches. These tests and descriptors can have applications related to magnetic ground state predictions of materials relevant for spintronic applications[4] or for predicting thermal properties relevant for thermal management in electronics.[5] Combining high-throughput *ab initio* computations with fitting, fine-tuning machine learning models and predictions of such models within complex workflows is also possible and promises further acceleration in the field.[6]

In this talk, I will show our latest efforts to link automation with data-driven chemistry and materials science.

Accelerated (Re)Design of Sustainable Formulations with The Autonomous Formulation Lab Tyler Martin, Duncan Sutherland and Peter Beaucage; National Institute of Standards and Technology, United States

Industrial liquid formulations from electronics to nanoparticle coatings to drug delivery vehicles are often strikingly complex, with large numbers of components (10-100), complex multistep processing, and a wide variety of design requirements for a functional, sustainable, regulatory compliant product. This complexity often precludes physics-informed mapping between component fractions, processing, structure, leaving most formulation design to empirical trial-and-error or design of experiments strategies. I will discuss recent efforts by the Autonomous Formulation Laboratory (AFL) team at NIST to use machine learning driven, highly automated characterization to rapidly and intelligently map formulation phase space using structural characterization tools such as small-angle x-ray and neutron scattering (SAXS/SANS) together with secondary measurements, e.g. optical imaging, UV-vis-NIR and capillary viscometry. Our initial studies have resulted in an order of magnitude reduction in the time needed to map a model phase diagram and rapid cross-learning between model petroleum-based and biobased formulations. Other systems of interest from our personal care, biopharmaceutical, and alternative energy industrial collaborators will also be highlighted, including recent results on multimodal cooperative active learning.

4:00 PM MT03.07.07
A Low-Cost, Closed-Loop Nanomaterials Synthesis Automation Platform Maria Politi, Brenden Pelkie, Blair Subbaraman, Fabio Baum, Kiran Vaddi, Nadya Peek and Lilo D. Pozzo; University of Washington, United States

Conventional nanomaterials synthesis schemes can be labor- and time-intensive, which significantly impedes the pace of new materials discovery and their applications. Semi-automated and fully automated platforms, in combination with data-science principles and artificial intelligence, have become an emerging paradigm for accelerated materials discovery. The combination of high-throughput experimentation and minimal human interactions with the system have allowed faster material synthesis, characterization, and analysis. However, many of these initiatives are still too costly to be implemented. In this context, open hardware principles have made the use of laboratory automation more accessible and more easily implemented for a variety of applications. We have demonstrated the use of a versatile automatic tool-changing platform (Jubilee) configured for automated ultrasound application, a liquid-handling robot (Opentrons OT2) and a well-plate spectrometer for the synthesis of CdSe nanocrystals. A total of 625 unique sample conditions were prepared and analyzed in triplicate with an individual sample volume of as little as 0.5 mL, which drastically reduced chemical waste and experimental time. Furthermore, we coupled the high-throughput workflow to a data-driven approach for the interpretation of the results provided a holistic view of the design space investigated. While successful, the previous study relied on three different instruments to conduct the workflow. Further improvements have allowed for integrating all the synthesis, processing, and characterization tools onto the same Jubilee platform for a closed-loop experimental campaign. This new ecosystem uses a simple Python API and allows for new tools to be easily integrated and interfaced, for simpler experimental orchestration. Thanks to the high-throughput capabilities of this low-cost and open-hardware platform, the ease in scalability of the system, and the modularity of the protocol, the overall workflow was adapted to study a variety of nanocrystal design spaces.

4:15 PM MT03.07.08
Understanding Design Rules of Colloidal Self-Assembly Using Autonomous Phase Mapping Kiran Vaddi, Huat Thart Chiang, Sage Scheiwiller, Karen Li and Lilo D. Pozzo; University of Washington, United States

Automation in many experimental pipelines at laboratory and central facilities has shifted the bottleneck to autonomously driven data analysis and decision-making. Exponential growth in tools available for data-driven modeling resulted in the advent of self-driven laboratories (SDL) that aim to automate and accelerate the entire workflow starting from synthesis to characterization and device integration for emerging technologies and energy needs. Platforms based on solution-processible materials (polymers, colloids, and nanoparticles) are amenable to automation both at the synthesis and characterization levels. Techniques such as scattering and spectroscopy provide faster high-throughput alternatives to capture a signal of the underlying structure allowing us to construct composition-structure phase maps. However, one of the common goals in ‘phase mapping’ a system is to accurately identify phase boundaries that can have materials with interesting structures and properties. In the realm of SDL, the problem of mapping phase boundaries is tackled using a combination of Bayesian active learning and data clustering. These techniques however cannot predict the phase map by ‘filling’ in the unexplored space that can provide information about the type of phase transition a boundary represents. We address this problem by reformulating the closed-loop phase mapping as a Bayesian active learning of a surrogate model that predicts measurement curves (spectroscopy, diffraction, or scattering). We apply the proposed approach to several classes of nano-scale colloidal and polymeric materials to learn phase maps that can be effectively used in understanding design rules to engineer colloidal self-assembly.

10:30 AM NM01.01.01
High-Yield and High-Throughput Delamination of Multilayer MXene via High-Pressure Homogenization Alex Inman[1], Kateryna Shevchuk[1], Joseph Capobianco[2] and Yury Gogotsi[1]; [1]Drexel University, United States; [2]USDA ARS, United States

Two-dimensional (2D) MXenes are a large family of materials with unique properties and numerous potential applications. They are typically produced by selective chemical etching of MAX phase precursors, which is a top-down approach allowing for scalable manufacturing. Multilayer MXenes are then further processed by chemical intercalation and delamination to produce a stable dispersion of 2D flakes in water. The current process of delamination requires multiple time-, energy-, and waste-intensive steps and still fails to delaminate some MXenes. Herein, we demonstrate a method of high-energy delamination called high-pressure homogenization (HPH) that combines high shear, cavitation forces, and impact forces to delaminate MXene without any post-process refinement steps or chemical intercalants. HPH-delaminated MXene can be made at scale with high throughput and yield with virtually no waste. We demonstrate the viability of this process by fabricating free-standing films with the material for use as electrodes for energy storage and as an effective antimicrobial coating where any residual lithium is undesirable. HPH-MXene electrodes demonstrated comparable capacitance to that of lithium-delaminated films with better rate capability. HPH-MXene coatings proved effective as antimicrobial coatings with over a two-log reduction in pathogenic microbes without the concern of chemical leaching by the coating. We anticipate that this method will decrease the cost of MXene manufacturing and be applicable to a variety MXenes, including those that cannot be currently delaminated via intercalation.

10:45 AM NM01.01.02
A-Modified MXenes: Interlayer Incorporation of A-Elements into MXenes via Selective Etching of A' from $M_{n+1}A'_{1-x}A''_xC_n$ MAX Phases Alexander Sinitskii; University of Nebraska -Lincoln, United States

MXenes are a large family of two-dimensional materials with a general formula $M_{n+1}X_nT_z$, where M is a transition metal, X = C and/or N, and T_z represents surface functional groups. MXenes are synthesized by etching A elements from layered MAX phases with a composition of $M_{n+1}AX_n$. As over 20 different chemical elements were shown to form A layers in various MAX phases, we propose that they can provide an abundant source of new MXene-based materials [1]. The general strategy for A-modified MXenes relies on the synthesis of a $M_{n+1}A'_{1-x}A''_xX_n$ MAX phase, in which the higher reactivity of the A' element compared to A'' enables its selective etching, resulting in A''-modified $M_{n+1}X_nT_z$. In general, the A'' element could modify the interlayer spaces of MXene flakes in a form of metallic species or oxides, depending on its chemical identity and synthetic conditions. We demonstrate this strategy by synthesizing Sn-modified $Ti_3C_2T_z$ MXene from $Ti_3Al_{0.75}Sn_{0.25}C_2$ MAX phase, which was used as a model system. Although the incorporation of Sn in the A layer of Ti_3AlC_2 decreases the MAX phase reactivity, we developed an etching procedure to completely remove Al and produce Sn-modified $Ti_3C_2T_z$ MXene. The resulting MXene sheets were of high quality and exhibited improved environmental stability, which we attribute to the effect of uniform Sn modification. We demonstrate a peculiar electrostatic expansion of Sn-modified $Ti_3C_2T_z$ accordions, which may find applications in MXene-based nanoelectromechanical systems. Overall, these results demonstrate that in addition to different combinations of M and X elements in MAX phases, an A layer also provides exciting opportunities for the synthesis of new MXene-based materials. Synthetic approaches to MXenes modified with A-elements other than Sn, as well as applications of such materials, will also be discussed.

11:00 AM NM01.01.03
Synthesis and Electronic Transport of Ultrathin Single Crystal WC and W_2C Alexander J. Sredenschek, David Sanchez, Jiayang Wang, Da Zhou, Le Yi, Morteza Kayyalha, Susan B. Sinnott and Mauricio Terrones; The Pennsylvania State University, United States

The transition metal carbide (TMC) family has historically been studied and applied for their high hardness, chemical stability, and electrocatalytic activity. Initially studied in bulk, non-layered morphologies, TMCs have received renewed interest with the development of novel top-down and bottom-up approaches to isolate layered TMCs (MXenes)[1] and ultrathin, non-layered TMCs (UThTMCs)[2], respectively. The MXene family is large, but challenges persist in phase control and isolation of tungsten carbide owing to the lack of appropriate precursor material.[3] Following recent works in bottom-up synthesis of UThTMCs[4,5], we show the isolation of two tungsten carbide phases using a liquid-metal-assisted chemical vapor deposition (LMCVD). Moreover, in the tungsten carbide system, little attention has been given to the influence of diffusion barrier and reactive gas ratios on the thickness, morphology, and phase of the crystalline products.
In this work, we report the synthesis of WC (P-6m2) with copper/tungsten foil stacks, and W_2C (Pbcn) from gallium/tungsten substrates. We identify the phase of these compounds using a combination of X-ray diffraction and planar/cross sectional selected area electron diffraction. The chemical compositions of WC and W_2C are investigated by planar energy dispersive X-ray spectroscopy (EDX) in the scanning transmission electron microscope. Moreover, we probe the dependence of crystal morphology with changes in growth temperature as well as methane/hydrogen (CH_4/H_2) ratios. Another

aspect of the synthesis that we have investigated are byproducts in the synthesis of WC/Cu/W and W_2C/Ga/W by combination of scanning electron microscopy, EDX, and Raman spectroscopy. We find that an increase in the CH_4/H_2 ratio promotes the formation of graphene in both systems, yielding irregular shaped W_2C nanoplates with large thickness, and polycrystalline WC nanoplates. In the W_2C/Ga/W system, we also find that crystalline Ga_2O_3 is formed during the synthesis and can be limited using higher H_2 concentrations.
To explain how these distinct phases are isolated, we carried out a density functional theory study to probe thermodynamic properties of the WC and W_2C systems. We find that the carbon concentration and atomic terminations at the surface of WC and W_2C are critical to the preferential isolation of W_2C on Ga/W substrates. Finally, we report the electronic transport measurements of UThTMCs single crystals of WC and W_2C. In particular, we find that semimetallic WC does not enter a superconducting state down to 10 mK, while W_2C enters a superconducting state below 2.85 K. We then compare in-plane and out-of-plane magnetic field measurements to assess the dimensionality of this superconducting state.

Exploration of Stacked MXenes as Precursors to Ultra-High Temperature Ceramics Kat Nykiel, Brian Wyatt, Babak Anasori and Alejandro Strachan; Purdue University, United States

Ultra-high temperature ceramic (UHTC) vacancy-ordered zeta phases are critical for applications over 2000°C due to their high melting temperatures, oxidation resistance, and fracture toughness. However, the synthesis of zeta phase systems typically requires high temperature processing at >1400°C with high pressures, making alternative synthesis pathways to UHTC phases highly desirable. In this work, we investigate the potential of layered 2D MXenes as nanoceramic building blocks for nanolamellar carbide and nitride zeta-like phases. Stacked MXenes can expand the domain of zeta-like phases via their large space of interfacial combinations. We employed density functional theory (DFT) to investigate the thermodynamic stability of stacked MXenes as UHTC precursors, with sequential quasi-random structures to study non-stoichiometric nanolamellar carbides. We identify both stoichiometric and non-stoichiometric nanolamellar carbides below the established convex hull. Furthermore, we use a workflow that combines DFT simulations and machine learning to predict key UHTC features, such as melting temperature and elastic constants. Our findings show that by using stacked MXenes the UHTC domain can be expanded beyond vacancy-ordered zeta phases and traditional UHTC transition metals via a lower-temperature synthesis pathway.

Two-Dimensional Materials from Large-Scale Computations and Selective Etching of Laminated Solids Johanna Rosen; Linkoping University, Sweden

In 2011, the synthesis of 2D materials through selective etching of specific layers in laminated 3D precursors was demonstrated, leading to the discovery of MXenes. Since then, the quest for 2D materials via etching has relied primarily on experimental methods, given the lack of accurate and efficient computational protocols. We here present the first steps towards a general theoretical approach for predicting 2D materials formed by selective etching under acidic conditions. Among ~60,000 3D materials, we identify ~100 potentially exfoliable candidates, including several material families. We corroborate the existence of well-established materials such as both TMD and MXene. Furthermore, and as a proof-of-principle, we selectively etch Y from a Ru-based compound, resulting in freestanding 2D sheets of Ru-based material Our discoveries hold promising implications for experimental realizations and further advancements in theoretical investigations.

Synthesis Science between MAX phases and MXenes Christina S. Birkel[1,2] and Rose Snyder[1]; [1]Arizona State University, United States; [2]Technische Universität Darmstadt, Germany

The synthesis of MAX phases and their two-dimensional siblings MXenes, especially when pushing beyond Ti-based compounds, is far from trivial. Our group uses diverse preparation techniques to access new versions of these intriguing types of materials, recent examples include Cr_2GaC in the shape of carbonaceous microwires,[1] hollow and full microspheres[2] as well as hitherto unknown carbonitride phases, such as $Cr_2GaC_{1-x}N_x$ and $V_2GaC_{1-x}N_x$.[3] We specialize in non-conventional methods, such as sol-gel chemistry[4–6] and microwave heating[7] to synthesize the MAX phases.
In this talk, I will highlight two of our recent projects: (i) Our work on a unique "514" MAX phase $(Mo_{0.75}V_{0.25})_5AlC_4$, its structural investigation and transition to the respective MXene including its electrocatalytic properties. (ii) The transition from a MAX-like "221" compound Mo_2Ga_2C to the fully exfoliated MXene Mo_2CT_x as well as Mn-doped variants. All materials are structurally characterized by diffraction and microscopy techniques and a deeper understanding of their chemical composition, formation mechanism and stability is obtained through spectroscopy and thermogravimetric methods.

2:00 PM NM01.02.02
Synthesis of High-Quality Monolayers of $Cr_2TiC_2T_x$ MXene, Their Mechanical Properties, *p*-type Electrical Transport and Positive Photoresponse Saman Bagheri[1], Michael J. Loes[1], Alexey Lipatov[1,2], Haidong Lu[1], Alexei L. Gruverman[1] and Alexander Sinitskii[1]; [1]University of Nebraska-Lincoln, United States; [2]South Dakota School of Mines and Technology, United States

In the rapidly growing family of MXenes, $Cr_2TiC_2T_x$ is one of the most intriguing materials as an ordered double-transition-metal MXene with peculiar magnetic properties. In this work, we developed a synthetic procedure for high-quality $Cr_2TiC_2T_x$ and produced monolayer sheets with lateral sizes exceeding 15 μm for single-flake measurements. The results of such measurements on $Cr_2TiC_2T_x$ further establish it as a unique material among the MXenes experimentally tested so far. Field-effect electrical measurements on monolayer $Cr_2TiC_2T_x$ flakes reveal an average conductivity of 66.18 S cm^{-1} and *p*-type transport properties, while established MXene materials, such as $Ti_3C_2T_x$ and $Nb_4C_3T_x$, demonstrated *n*-type behavior in similar studies. The

experimental data are corroborated by DFT studies, showing that Cr vacancies are the major contributing factor to the p-type behavior of $Cr_2TiC_2T_x$. When illuminated with visible or infrared light, the $Cr_2TiC_2T_x$ devices exhibit *positive* photoresponse in contrast to the *negative* photoresponse that was recently reported for $Ti_3C_2T_x$ monolayers. Nanoindentation measurements of monolayer $Cr_2TiC_2T_x$ membranes yield a respectable value of effective Young's modulus of 220±22 GPa. This work provides access to large high-quality $Cr_2TiC_2T_x$ flakes that can find numerous applications due to their attractive mechanical characteristics and transport properties that are complementary to other established MXene materials.

2:15 PM NM01.02.03
Evidence of Metallic Conductivity in $Ti_3C_2T_x$ by Temperature-Dependent Resistivity Measurements. Alexey Lipatov[1], Saman Bagheri[2] and Alexander Sinitskii[2]; [1]South Dakota School of Mines & Technology, United States; [2]University of Nebraska - Lincoln, United States

$Ti_3C_2T_x$, the most popular MXene to date, is widely regarded as a metallic material based on numerous theoretical predictions and the results of experimental studies. Yet, despite this general consensus on the metallic nature of Ti3C2Tx, there have not been reports on its temperature-dependent resistivity (ρ) measurements that would demonstrate the expected increase of resistivity with temperature with $d\rho/dT > 0$ in a wide temperature range. Instead, all ρ(T) data reported so far, mainly collected on macroscopic films of percolating $Ti_3C_2T_x$ flakes, demonstrate dependences with minima, which were observed in the range of 90-250 K in different measurements. In this work, we fabricated electronic devices based on individual high-quality $Ti_3C_2T_x$ flakes and measured their temperature-dependent resistivity. The resistivity of flakes was found to increase with temperature in the entire 10-300 K range, and the resulting ρ(T) dependences can be accurately fitted by the Bloch–Grüneisen formula for the temperature dependence of resistivity of metals, confirming the metallic nature of $Ti_3C_2T_x$. We also demonstrate that oxidation of a $Ti_3C_2T_x$ monolayer transforms a monotonically increasing ρ(T) curve into a dependence with a minimum that looks similar to the previously reported results for percolating MXene films. We also demonstrate that multilayer $Ti_3C_2T_x$ flakes retain their purely metallic $d\rho/dT > 0$ behavior even after annealing in air, suggesting that the outer layers of multilayer flakes effectively protect the core layers from oxidation. This result suggests that certain applications may benefit from multilayer flakes' improved environmental stability.

2:30 PM BREAK

3:00 PM NM01.02.04
Bottom-Up Synthesis of Two-Dimensional Transition Metal Carbides and Nitrides (MXenes) Mark Anayee, Rahul Rao, Nicholas Glavin, Benji Maruyama and Dhriti Nepal; Air Force Research Lab, United States

MXenes represent the largest and fastest growing family of 2D transition metal carbides and/or nitrides, which exhibit unique combinations of properties, including metallic conductivity, hydrophilic surface chemistry, redox-active surface, and plasmonic behavior that make them attractive as electrodes for pseudocapacitive energy storage to coatings for electromagnetic interference shielding, transparent conducting displays for optoelectronics, conductive yarns for functional textiles, implantable electrodes for medicine, and many other applications. MXenes are typically derived via topochemical etching of atomically thick layers from precursor layered MAX phases using corrosive aqueous etchants. However, the chemical etching process leads to various atomic defects, contaminants, and inhomogeneity in surface chemistry. Herein, we explore bottom-up growth of MXenes using thermal and laser assisted Chemical Vapor Deposition (CVD). We conduct experiments using gradient samples (composition, film thickness, etc.) to demonstrate a combinatorial approach towards optimization of MXene synthesis and exploration of new MXene compositions. This work demonstrates the need to utilize high-throughput automated synthesis to investigate material systems with a vast chemical space such as MXenes. It also enables fabrications of MXene films with ordered morphologies that would not be possible using solution based deposition techniques.

3:15 PM NM01.02.05
Synthesis of Three Families of Titanium Carbonitride MXenes Teng Zhang, Christopher E. Shuck, Kateryna Shevchuk, Mark Anayee and Yury Gogotsi; Drexel University, United States

Layered MAX phases and 2D MXenes derived from them are among the most studied materials due to their attractive properties and numerous potential applications. The tunability of their structure and composition allows every property to be modulated over a wide range. Particularly, elemental replacement and forming a solid solution without changing the structure allows fine-tuning of material properties. While solid solutions on the M (metal) site have been studied, the partial replacement of carbon with nitrogen (carbonitrides) has received little attention. By applying this concept, herein we report the synthesis of three families of titanium carbonitride $Ti_{n+1}Al(C_{1-y}N_y)_n$ MAX phases and $Ti_{n+1}(C_{1-y}N_y)_nT_x$ MXenes with one, two and three C/N layers. This greatly expands the variety of known MAX phases and MXenes to encompass 16 titanium carbonitrides with tunable X-site chemistries and different 2D layer thicknesses, including MXenes in the $Ti_4(C_{1-y}N_y)_3T_x$ system, which have not been previously reported. We further investigated the relationship between the composition, structure, stability, and synthesis conditions of the MXenes and their respective Al-based MAX phases. This range of materials will enable fundamental studies of the N:C ratio effect on optoelectronic, electromagnetic and mechanical properties of MXenes, as well as tuning those properties for specific applications.

3:30 PM *NM01.02.06
Organic and Inorganic Surfact Chemistry of MXenes Dmitri V. Talapin[1,2], Young-Hwan Kim[1], Chenkun Zhou[1] and Di Wang[1]; [1]University of Chicago, United States; [2]Argonne National Laboratory, United States

Two-dimensional (2D) transition-metal carbides and nitrides (MXenes) show impressive performance in supercapacitors, batteries, electromagnetic interference shielding, and electrocatalysts. These materials combine the electronic and mechanical properties of 2D inorganic crystals with chemically modifiable surfaces, and surface-engineered MXenes represent an ideal platform for fundamental and applied studies of interfaces in 2D functional materials.
The comprehensive understanding of MXene surfaces is required for prescriptive engineering of their physical and chemical properties. We discuss general strategies to install and remove surface groups by performing topotactic substitution and reductive elimination reactions. Successful synthesis of MXenes with halido-, oxo-, imido-, thio-, seleno-, or telluro- terminations, as well as bare MXenes (no surface termination) can be synthesized both by traditionally (from MAX phases) and directly synthesized MXenes. We also successfully synthesized a series of hybrid organic-inorganic MXenes by covalently attaching dense carpets of organic surface groups. Since organic and inorganic materials are, in many aspects, complimentary to each other, organic-inorganic MXenes open a pathway to merge the benefits of both worlds into a hybrid matter that combines engineerability of molecules with the electronic, thermal, and mechanical properties of inorganic 2D materials. The description of MXene surface structure and reactivity requires a mix of concepts from the fields of coordination chemistry, self-assembled monolayers and surface science. MXene surface groups control biaxial lattice strain, phonon frequencies, electrochemical performance, the strength of electron-phonon coupling, making MXene surfaces not spectators but active contributors to conductivity, superconductivity, and catalytic activity.

About the structure, chemistry and stability of MXenes Per O. Persson; Linköping University, Sweden

The properties and tailoring ability of MXenes has inspired research efforts across the globe, and the number of researchers, publications and applications associated with these materials is steadily accelerating. Despite this enormous and collective effort, fundamental properties, related to the MXene structure and the surface terminations remain unexplored.

At Linköping University, we have explored the structure and chemistry of individual MXene sheets, since the very first MXene publication. The method of choice for this purpose is advanced scanning transmission electron microscopy and spectroscopy methods with sub-atomic resolution.

In this talk I will review the current understanding of the structure, atomic defects and surface terminations. I will discuss which methods are available to generate, modify and tailor these through interaction with and exposure to the ambient environment. I will also review the current understanding of the stability of the structure, the surface chemistry, and how MXene interacts with water. For this I will provide in situ and ex situ results obtained using a number of different microscopy methods, microscopes, and special environmental holders.

8:45 AM NM01.03.02
Tuning The Microenvironment of Water Confined in $Ti_3C_2T_x$ MXene by Cation Intercalation Mailis Lounasvuori[1], Teng Zhang[2], Yury Gogotsi[2] and Tristan Petit[1]; [1]Helmholtz-Zentrum Berlin, Germany; [2]Drexel University, United States

The local microenvironment, which is often tuned by adding alkali metal cations to the electrolyte, has recently been found to play a major role in the electrocatalytic activity of nanomaterials.(1) Modulating the microenvironment can be used to either suppress hydrogen or oxygen evolution, thereby extending the electrochemical window of energy storage systems, or to tune the selectivity of electrocatalysts. MXenes are a large family of two-dimensional transition metal carbides, nitrides and carbonitrides that have shown potential for use in electrochemical energy storage applications. Due to their negatively charged surfaces, MXenes can accommodate cations and water molecules in the interlayer space. Nevertheless, the nature of the aqueous microenvironment in the MXene interlayer remains poorly understood. Here, we apply Fourier transform infrared (FTIR) spectroscopy to probe the hydrogen bonding of intercalated water in $Ti_3C_2T_x$ as a function different intercalated cation and relative humidity. Being highly sensitive to different H-bonding states of water confined within the MXene layers,(2,3) especially in the O-H stretching mode region, FTIR spectroscopy enables the direct characterization of the H-bonding network of water and gives information on the relative amounts of water present in the samples. Because anions do not intercalate into MXene,(4) we are able to probe the hydration shell around isolated cations in a 2D confined environment. Strong changes in the hydrogen-bonding of water molecules confined between the MXene layers is observed after cation exchange. Furthermore, the IR absorbance of the confined water correlates with resistivity estimated by 4-point probe measurements and interlayer distance calculated from XRD patterns. This work demonstrates that cation intercalation strongly modulates the confined microenvironment, which can possibly be used to tune the activity or selectivity of electrochemical reactions in the interlayer space of MXenes in the future.

9:00 AM *NM01.03.03
MXene Reactivity and Its Role in Development of Applications Vadym Mochalin; Missouri University of Science and Technology, United States

A large family of two-dimensional transition metal carbides and nitrides (MXenes) raises interest for many applications due to their high electrical conductivity, mechanical properties [1], potentially tunable electronic structure [2], nonlinear optical properties [3], and the ability to be manufactured in the thin film state [4]. However, their chemistry that is key to development of these applications, still remains poorly understood [5,6]. In this presentation we will discuss recent progress in understanding fundamental MXene chemistry and harnessing it for suppressing unwanted reactions and prolonging stability of these materials.
For example, suppressing oxidation and hydrolysis at high pH was demonstrated as an effective way to prolong shelf-life and stability of MXene aqueous colloids [7]. Use of polyphosphate also has been shown to improve chemical stability of MXene aqueous colloids [8].
Other selected examples illustrating connections between understanding MXene chemistry and development of their applications will also be considered.

9:30 AM BREAK

10:00 AM NM01.03.05

Defect Engineering of MXenes at Elevated Temperatures Brian Wyatt[1], Matthew G. Boebinger[2], Paul Kent[3], Zachary D. Hood[4], Shiba Adhikari[4], Kartik Nemani[1], Murali Gopal Muraleedharan[3], Annabelle Bedford[1], Wyatt Highland[1], Raymond R. Unocic[2] and Babak Anasori[1]; [1]Purdue University, United States; [2]Center for Nanophase Materials Sciences, United States; [3]Oak Ridge National Laboratory, United States; [4]Argonne National Laboratory, United States

The chemically diverse family of 2D MXenes have been widely adopted in areas such as energy storage, conversion, and electronics. From the ceramic perspective, MXenes uniquely enable the atomic control of its structure at the ~1 nm scale. In this presentation, we demonstrate the defect engineering of $Mo_2TiC_2T_x$, $Ti_3C_2T_x$, $Mo_2Ti_2C_3T_x$, and Nb_2CT_x MXenes at elevated temperatures using alkali cations. We demonstrate the improved phase stability of MXenes and control of formed carbide phases using *in situ* x-ray diffraction and scanning transmission electron microscopy techniques. Further, we present evidence for the role of partial occupation of alkali cations in defective sites in MXenes using computational methods paired with *in* and *ex* situ methods. Overall, this cation-based engineering of defects in 2D MXenes demonstrates the potential for improving their stability and further develops the tools for researchers to apply MXenes as a diverse and tunable family of nanoceramics for high temperature applications.

10:15 AM *NM01.03.06
Achieving Environmental Stability of MXenes in Air, Water and Electrolytes Asaph S. Lee, Mark Anayee, Mikhail Shekhirev and Yury Gogotsi; Drexel University, United States

MXenes display extraordinary electrical, optical, chemical, and electrochemical properties. There is a perception though that MXenes are unstable and degrade quickly in ambient environment, limiting potential applications and requiring specific storage conditions to last for a long time. However, significant developments in MXenes' synthesis, processing, and understanding of its chemistry led to dramatic increases in their environmental stability. Herein, we analyze delaminated $Ti_3C_2T_x$ MXene flakes in solution and on a substrate, electrodes in acidic electrolyte as well as free-standing films aged up to a decade. Structural, chemical and morphological characterization along with electronic conductivity measurements reveal the effect, or lack thereof, of prolonged storage under ambient conditions. Up to 90% conductivity was retained after 5 years of storage by the films dried after synthesis. Further, we show that decrease in electronic conductivity over time is largely caused by uptake of water by the hydrophilic surfaces of MXenes, and its effect can be, at least partially, reversed by vacuum drying at elevated temperature. MXene supercapacitor electrodes performed well over 500,000 cycles at 20 mV/s. The effects of $Ti_3C_2T_x$ stoichiometry, surface chemistry, defects, intercalants, interlayer spacing and storage condition on oxidation and hydrolysis are discussed. While no systematic data is available for other MXenes, we demonstrate that the same principles are applicable to V_2C, Nb_4C_3 and other 2D carbides.

10:45 AM NM01.03.07
Raman Spectroscopy Characterization of 2D Carbide and Carbonitride MXenes Kateryna Shevchuk[1], Asia Sarycheva[1,2], Christopher E. Shuck[1,3] and Yury Gogotsi[1]; [1]Drexel University, United States; [2]Lawrence Berkeley National Laboratory, United States; [3]Rutgers, The State University of New Jersey, United States

The first step to wider adoption of two-dimensional (2D) materials is understanding their fundamental properties by employing characterization methods, among which Raman spectroscopy plays a unique role, being a fast and nondestructive tool. The number, frequencies, and intensities of the modes (or bands) in the Raman spectrum have been used to identify the 2D materials' crystal lattice, bonding, and even the number of layers. MXenes, 2D transition metal carbides, nitrides, and carbonitrides, span diverse chemistries and structures, but only a few Raman spectra have been reported. This work is the first systematic experimental Raman spectroscopy study of the MXene family. We explore the vibrational spectra and provide peak assignments for ten MXenes with varying structures (from 2 to 4 atomic layers of transition metal) and compositions - Ti_2CT_x, Nb_2CT_x, Mo_2CT_x, V_2CT_x, $Ti_3C_2T_x$, $Mo_2TiC_2T_x$, Ti_3CNT_x, $Nb_4C_3T_x$, $V_4C_3T_x$, and $Mo_2Ti_2C_3T_x$ (terminated with –F, –OH, and =O) based on the experimental results and previously reported computational studies. We discuss the effects of MXene layer thickness, surface terminations, and MXene's metallic properties on Raman scattering. Additionally, we employ polarized Raman spectroscopy to identify out-of-plane vibrations and explain the higher frequency region of the spectra, and computational predictions to assign the peaks to the Raman-active modes. By creating the Raman spectra library of the most frequently used MXenes, we open the door for the use of Raman spectroscopy for fingerprinting of various MXenes.

11:00 AM *NM01.03.08
Insights into the MXene interfaces from simulations De-en Jiang; Vanderbilt University, United States

First principles molecular dynamics simulations of the MXene/water interfaces and the organic groups on the MXene surfaces will be presented. First, we will show how the proton transport across the interface and in confined water layers for MXenes and MXene/graphene heterostructures. Second, we will discuss the reactivity of MXene with water, to address the stability issue, including how the defects in the MXene layer impacts its reactivity with water. Hydrogen bond network, water dipoles, and Ti-water interaction are found to play important roles in the processes examined. Last, we will look at some organic groups on the MXene surface to examine the unique inorganic-organic interface on MXenes.

SESSION NM01.04: Synthesis and Characterization IV
Session Chairs: Alex Inman and Stefano Ippolito
Wednesday Afternoon, April 24, 2024
Room 330, Level 3, Summit

1:30 PM NM01.04.01
Local Surface Chemistry of $Ti_3C_2T_x$ MXenes in Aqueous Electrolyte Monitored by *In Situ* Scanning Transmission X-Ray Microscopy Peer Bärmann, Namrata Sharma, Faidra Amargianou, Tianxiao Sun, Markus Weigand and Tristan Petit; Helmholtz Zentrum Berlin, Germany

The pseudocapacitive behavior of $Ti_3C_2T_x$ MXenes promises high power and energy densities thanks to redox reactions occurring during the (de-)protonation of the MXene surface in acidic electrolyte. Nevertheless, local electrochemical processes occurring at the MXene-electrolyte interface and the associated changes of the MXene surface chemistry are currently largely unexplored. To this aim, soft X-ray spectroscopies are particularly relevant as they enable the selective characterization of either the electrolyte or the material of interest thanks to their element specificity.[1] Furthermore, the high spatial resolution (<30 nm) offered by X-ray Microscopy can provide precious information about local inhomogeneities at the nanoscale,[2] enabling the characterization of single MXene flakes. In this talk, the chemical bonding of Ti atoms in single few-layered $Ti_3C_2T_x$ MXene flakes was monitored in different electrolytes using synchrotron-based *in situ* Scanning Transmission X-ray Microscopy (STXM) at the Ti L-edge. Significant changes of the Ti

chemical environment are observed between acidic and neutral Li^+-containing aqueous electrolyte and sub-flake inhomogeneities in the MXene surface chemistry was evidenced. Finally, potential-induced changes of MXene local surface chemistry will be discussed. *In situ* STXM will open new perspectives on the characterization of electrochemical processes in MXenes that can be monitored down to the single flake level.

1:45 PM NM01.04.02
A Mechanistic Study of MXene Current Collectors for Lithium-Metal-Based Batteries Ruocun Wang[1,2], Raymond R. Unocic[3], Jaehoon Choi[4], Yan Burets[1,2], Mark Anayee[1,2], Geetha Valurouthu[1,2], Wan-Yu Tsai[3] and Yury Gogotsi[1,2]; [1]A.J. Drexel Nanomaterials Institute, United States; [2]Drexel University, United States; [3]Oak Ridge National Laboratory, United States; [4]University of Picardie Jules Verne, France

Lithium metal is widely investigated as a high-energy-density anode replacement for graphite in lithium-ion batteries. It is important for next-generation lithium-metal-based battery technologies. However, lithium dendrites tend to grow during deposition and stripping, resulting in poor battery life or short circuits. Literature shows that using MXene instead of copper as the current collector can mitigate lithium dendrite growth. Two mainstream hypotheses for dendrite suppression include forming a hexagonal close-packed structured lithium layer and a homogeneous growth of solid-electrolyte interphase (SEI) on the surface of MXene. However, there is a lack of experimental evidence to support those hypotheses. Here we used a suite of characterization techniques, including cryo-transmission electron microscopy (cryo-TEM), X-ray photoelectron spectroscopy (XPS), *in situ* Raman spectroscopy, scanning electron microscopy (SEM), and *operando* optical microscopy to investigate the crystal structure, SEI, and morphology of lithium nucleated on $Ti_3C_2T_x$ MXene at different rates and capacity.

2:00 PM *NM01.04.03
Photoactive MBenes: the next generation of MXene-like 2D structures Agnieszka M. Jastrzebska; Warsaw University of Technology, Poland

MBenes family is a novel member in the flatland and a recent derivative of ternary MAB phases. However, MBenes differ from MXenes in many ways. Compared to MXenes, MBenes' structure is more complex due to multiple lattice arrangements. At the same time, boron opens the door to the rich structural chemistry of MBene, excellent reactivity, and energy harvesting abilities, to mention a few. In this talk, I will present a new synthetic approach to Mo_2B_2 MBene from its parental MoAlB phase, supported by theoretical calculations. In addition, I will demonstrate the tremendous photocatalytic potential of MBene compared to MXene. While research interest is rapidly accelerating, practical applications require better control over MBene's surface terminations and oxidation. MBene's vast compositional space and versatility provide almost limitless potential for designing structural variants with tailored optical and electronic properties. However, further research is needed to fully understand these novel materials and unlock their exotic light-driven phenomena. In summary, I expect MBenes to boost the fundamental research toward exploring their catalytic features in the next decade and develpment of MBene-based technologies that can manipulate light like never before.

A Systematic Study of MXenes for Hydrogen Evolution Reaction Anupma Thakur and Babak Anasori; Purdue University, United States

Two-dimensional (2D) transition metal carbides and nitrides (MXenes) are a large family of earth-abundant materials with more than forty compositions synthesized since 2011, such as Ti_2CT_x, Nb_2CT_x, $Ti_3C_2T_x$, and $Mo_2Ti_2C_3T_x$. MXenes have emerged as promising candidates for catalytic energy storage and conversion due to their electrochemically active surfaces combined with hydrophilicity, high electrical conductivity, and affinity to bond to molecules and nanomaterials to form hybrid structures. The ease of production of MXenes and their earth-abundant elements can overcome one of the major obstacles to the large-scale implementation of durable and efficient catalysts. In this talk, we will discuss the control of MXene transition metals and their surfaces to tune their electrocatalytic behavior. Specifically, we present a systematic study of 20 different MXenes, including novel compositions such as $W_2TiC_2T_x$ and $Mo_2Nb_2C_3T_x$ and high-entropy MXenes, and discuss how we achieve low overpotential for hydron evolution reaction (as low as ~160 mV).

SESSION NM01.05: Applications I

$Ti_3C_2T_x$ *MXene*-Based Electrochemical Sensors for Phosphate Detection Thiba Nagaraja, Shiseido Robinson, Rajavel Krishnamoorthy and Suprem R. Das; Kansas State University, United States

The recent surge of the Internet of Things (IoT) has left an indelible mark on the global sensor market, spurring further research in a similar direction. At the heart of any sensor lies the sensing material and its intrinsic characteristics that define the key sensor metrics such as selectivity, sensitivity, limit of detection and dynamic range. Electrochemical sensors, known best for their dominance in rapid detection, cost efficiency and accuracy, are no exception to this paradigm. To date, many nanomaterials, including two-dimensional (2D) graphene, have been discovered and used as electrochemical sensing platforms for various biomedical and environmental applications. 2D transition metal carbides/nitrides (also known as *MXenes*), with their unique structure and presence of transition metals, have demonstrated large surface to volume ratio, high electrical conductivity, ease of functionalization and solution processibility. However, their electrochemistry and electrochemical stability have received limited exploration. Recently, there has been a growing focus on delving deeper into these aspects. Phosphate ions are intriguing molecules with significant relevance in environmental and biomedical applications. Understanding its detection in a solution environment using *MXene* as a sensing electrode will unveil *MXene*'s outstanding properties for unique applications as a phosphate sensor. Herein, we studied the performance of $Ti_3C_2T_x$ *MXene* on a standard glassy carbon electrode in detecting phosphate ions in an electrochemical setup in the presence of molybdenum in an acidic media. The quality of $Ti_3C_2T_x$ *MXene* was extensively characterized prior to serving as the sensing material in the electrochemical system. The proposed method demonstrated high selectivity in the presence of common interfering ions. The $Ti_3C_2T_x$ *MXene* sensor also exhibited low detection limit and high sensitivity towards phosphate ions along with a large linear detection range

with reliable performance. This research lays the groundwork for the advancement of $Ti_3C_2T_x$ *MXene*-based phosphate sensors, promising future applications in environmental monitoring and sensing.

A Wide Look at MXene-Based CO_2 Reduction Electrocatalysts: Pioneering Pathways for Green Formaldehyde Production Sixbert P. Muhoza[1], Shiba Adhikari[1], Anupma Thakur[2], Babak Anasori[2] and Zachary D. Hood[1]; [1]Argonne National Laboratory, United States; [2]Purdue University, United States

Transition metal carbides, oxy-carbides, nitrides, and carbonitrides (MXenes) constitute an ever-growing class of two-dimensional materials with unique properties, including high conductivity and surface area as well as versatile and tunable surface chemistry.[1–3] Such a wide-ranging array of properties primes MXenes for various applications and, hence, provides them with the potential to tackle some of the most pressing challenges faced by our planet. Climate change is one such challenge, and the electrochemical CO_2 reduction reaction (CO_2RR) provides a potent pathway to alleviate the effects of CO_2 emission on the environment.[4] The maturation of electrochemical CO_2RR, however, will require the development of electrocatalysts that maximize the value gained from converting the CO_2 feedstock. For this reason, we have developed a novel class of MXene-based electrocatalysts that leverage the unique properties of MXenes to convert CO_2 to formaldehyde. Formaldehyde is a key ingredient in manufacturing many value-added products, including resins, coatings, and vehicle components.[5] However, formaldehyde is not typically generated with traditional electrocatalysts, indicating that the herein introduced MXene catalysts drive CO_2RR through new reaction pathways. This work highlights the behavior of a wide array of MXenes: ranging from single-layered traditional MXenes ($Ti_3C_2T_x$, $Mo_2TiC_2T_x$, and $W_2TiC_2T_x$) to multi-layered MXene/metal heterostructures ($Ti_3C_2T_x$/CuM, M = Ag, Sn, Zn, Ru, Ni, Fe). The $Ti_3C_2T_x$/CuM heterostructures were developed through a novel electroless deposition of the bimetals onto the surface of MXenes by oxidizing the Ti moieties of the $Ti_3C_2T_x$ MXene. The reduction potential of the adsorbed metals dictated this process, with the strongly oxidizing metals reaching their lowest oxidation states while the weakly oxidizing metals were only partially reduced. In all cases, formaldehyde was generated and the highest efficiencies were achieved at low, industrially relevant, cell potentials (between -1.4 V to -2.2 V). These results, as they pertain to pioneering green formaldehyde production and favorability for industry adoption, warrant further exploration of the MXene-based CO_2RR electrocatalysts.

9:30 AM *NM01.05.03
MXene-based membranes for water-treatments Tae Hee Han; Hanyang University, Korea (the Republic of)

Seawater desalination presents a tremendous opportunity to utilize abundant water resources as approximately 70% of the Earth's surface is covered by the ocean. A recent advancement in the field involves an innovative approach that integrates reverse osmosis (RO) with feed heating through membrane distillation (MD), creating a hybrid thermal–membrane process to vaporize hot saline water and transport it through the pores of the hydrophobic membrane. However, this hybrid process still faces practical limitations, primarily due to the necessity of introducing an external heater, resulting in increased energy loss and thermal inefficiency. In this talk, I introduce a novel strategy to overcome these limitations by incorporating surface heating MD systems with MXene-based membranes. Specifically, MXene, known for their excellent electroconductivity, makes it an efficient material for Joule-heating. Additionally, surface-modified MXene exhibited remarkable oxidation stability and corrosion resistance. Ultimately, our MXene-based membrane demonstrated superior desalinating performance, achieving a high permeate flux and an outstanding heat utilization efficiency, all while maintaining excellent material stability.

10:30 AM *NM01.05.04
Advancing wearable MXene bioelectronics to human translation. Flavia Vitale; University of Pennsylvania, United States

Wearable bioelectronics are widely adopted in clinical, research, and consumer electronics for health and fitness tracking. MXenes, and $Ti_3C_2T_x$ in particular, have emerged as ideal materials for soft, conformal, and multimodal wearable interfaces for sensing and modulating different body functions. In this talk, I will discuss our most recent works on designing, fabricating, and translating wearable MXene bioelectronics for use in humans. First, I will review how *ad hoc* manufacturing schemes allow leveraging the remarkable electronic, electrochemical, and magnetic properties of $Ti_3C_2T_x$ MXene at the molecular scale, while enabling full customization of the device functionality, geometry, and area coverage. Then, I will present examples of application of MXene wearables for non-invasive brain monitoring in outpatient clinical settings and neuromuscular diagnosis and rehabilitation in Achilles tendinopathy patients.

11:00 AM NM01.05.05
Hydrogel-Encapsulated MXene-Graphene Transistor for SARS-CoV-2 and E. Coli Bacteria Biosensing: Gel Gating and Transport Control Jiaoli Li[1], Jiabin Liu[2], Xinyue Liu[2], Shaoting Lin[2] and Chenglin Wu[1]; [1]Texas A&M University, United States; [2]Michigan State University, United States

Field-effect transistor (FET) biosensors have attracted huge interest in the multi-discipline, due to their effortless, time-saving, and label-free properties. However, its development is greatly restricted by its bare sensing surface and the liquid electrolyte, which will increase the nonspecific biomarkers absorption in complex environments. In this work, hydrogel encapsulation was applied to the MXene-graphene-based FET to detect SARS-CoV-2 and E. coli. Specific detection was also conducted to evaluate the feasibility of specific detection on our sensors. It demonstrated that hydrogel encapsulation

could achieve both gel gating and biomarker transport control and signal enhancement besides sensor encapsulation, which shows great advantages over the normal bare sensors. The investigation on the hydrogel encapsulated sensors shows great potential in the application of in-vivo monitoring and detection.

11:15 AM *NM01.05.06
Multispectral Electromagnetic Shielding Capabilities of 2D MXenes Chong Min Koo; Sungkyunkwan University, Korea (the Republic of)

The increasing prevalence of advanced electronics, mobilities, telecommunication, and medical devices operating across a wide range of EM waves (from ultralow kHz-level to high THz-scale frequencies) necessitates the development of EMI shielding materials operating in multispectral EM bands. MXenes, a class of two-dimensional materials comprising transition metal carbides, nitrides, and carbonitrides, have emerged as cutting-edge functional EMI shielding materials since their initial report in 2016. This is attributed to their exceptional metallic conductivity, expansive surface area, numerous surface terminations, and excellent solution processability. Here, this presentation aims to demonstrate that MXenes can deliver outstanding multispectral EMI shielding capabilities against radio-frequency (RF) waves, GHz-range microwaves, and THz/infrared (IR)-frequency waves, all achieved with minimal thickness and in various structural forms. Pristine MXene films with nanometer-scale thickness effectively interact with EM waves across the RF, GHz, and THz frequency ranges, while simultaneously demonstrating remarkably low IR emissivity. This low IR emissivity is a critical characteristic for applications such as selective thermal management, IR camouflage, stealth, and anti-counterfeiting measures. Through this exploration, we aim to highlight the versatility and efficacy of MXenes in addressing the evolving demands of EMI shielding across a wide range of electromagnetic frequencies and applications.

11:45 AM NM01.05.07
Integration of Mxene (Ti3C2Tx)-PVA-PAA Composite into Hanji: A Multifunctional Smart Fabric for Energy Harvesting, Thermoregulation, and EMI Shielding Yong Choi, Jiheon Kim and Byungseok Seo; Korea University, Korea (the Republic of)

Multifunctional smart fabrics have attracted a lot of attention due to the rapid downsizing of numerous electronic components and the emergence of wearable devices. One of the most advanced functions in such fabrics is energy harvesting in operating environments, while other multiple performances in terms of thermoregulation and electromagnetic interference (EMI) shielding would be desirable. Currently, heat, pressure, and triboelectricity are major energy sources that can be used with typical smart multifunctional materials. Herein, we report a novel smart fabric integrating energy harvesting using human perspiration and ambient moisture, as well as zonal heating for body temperature regulation and EMI shielding performances. In the smart fabric design, a blend of Mxene(Ti3C2Tx)-PVA-PAA is integrated into the environmentally friendly, traditional Korean paper, 'Hanji'. This composite exhibits high flexibility, oxidation resistance, hydrophilicity, and electrical conductivity. A precipitate of the mixture is obtained through ultrasonic treatment at room temperature, and then the asymmetric coating is applied to both sides of 'Hanji' using a vacuum filtration process. When the working fluid contacts the opposite side of the coated fabric, it rapidly penetrates through the coated interface of ‘Hanji’ and generates electricity through negatively charged nanofluidic channels. The introduction of hydrophilic polymer modulates the spacing of Mxene layers and prevents oxidation due to fluid exposure. The synergy between conductive Mxene and resistive hydrophilic polymer leads to achieving outstanding EMI shielding performance. Remarkably, even at low voltages, this composite shows efficient electricity-to-heat conversion and serves as a zonal heating element. The hydrophilic functional groups in the coating also provide humidity-sensing capabilities. The developed multipurpose smart fabric in this work will contribute to rationally designing multifunctional yet efficient energy harvesters using multiple sources.

SESSION NM01.06: Applications II

Tailoring MXene Synthesis and Assembly for Enhanced Performance in Diverse Applications Yeonjin Baek[1], Kiandokht Pakravan[1] and Majid Beidaghi[2]; [1]Auburn University, United States; [2]The University of Arizona, United States

Two-dimensional (2D) MXenes have garnered significant attention in recent years due to their exceptional properties and wide-ranging potential applications. This presentation showcases our group's recent research dedicated to optimizing the synthesis process and assembly techniques to enhance MXenes' electrochemical, mechanical, and membrane performance. The synthesis of MXenes plays a pivotal role in shaping their properties, including electrical conductivity and mechanical strength. Our studies reveal that the details of the synthesis process have a profound impact on MXene morphology, defect concentrations, and surface chemistry, ultimately influencing their electrical, electrochemical, and mechanical properties. Given the substantial impact of synthesis on MXene properties, the development of standardized synthesis protocols is imperative, as is the establishment of consistent performance reporting protocols across various fields of application. Furthermore, the performance of MXene-based devices is greatly influenced by how 2D MXene flakes are assembled into 3D structures. This presentation illustrates our research findings pertaining to the formulation of strategies aimed at enhancing MXene-based device performance through innovations in MXene assembly.

2:00 PM NM01.06.02
Exploiting Properties of MXenes to Improve Performance of Dry Reforming Catalysts Placidus B. Amama, Joshua Ighalo, Ahmed Al Mayyahi and Haider Almkhelfe; Kansas State University, United States

The development of efficient catalysts for dry reforming of methane (DRM) is critical for the sustainable production of syngas, an essential precursor for many industrial processes. DRM is known to have a high energy penalty due to the intrinsic chemical stability of the CO_2 molecule. The mechanism suggests that CO_2 is activated at the metal-support interphase while methane is activated on the surface of the active metals. Therefore, the reaction can be significantly improved by designing new catalysts that maximize the metal-support interactions (MSI) and consequently facilitate CO_2 activation. In this work, MXene ($Ti_3C_2T_x$) is used as support for Ni catalysts to address their low deactivation resistance during DRM. Wet impregnation was used to synthesize MXene-supported Ni catalysts ($Ni/Ti_3C_2T_x$) and a reference catalyst (γ-Al_2O_3-supported Ni) with 10 wt% loadings. The morphology and composition of the catalysts and the tailored surface functional groups of the MXenes obtained from electron microscopic and spectroscopic techniques have been correlated with their catalytic activity during dry reforming at atmospheric pressure. Simulations using Aspen Plus have been used to compare the experimental conversion with the thermodynamic benchmark by the Gibbs free energy minimization method.

2:15 PM NM01.06.03
Novel MXene-Based Electrified Air Filters for Enhanced Antiviral Airfiltration Performance Marina Sefen; New Jersey Institute of Technology, United States

The COVID-19 pandemic has heightened concerns in public health regarding the transmission of airborne viruses. Many existing air purification methods primarily rely on physical barriers and filtration to arrest the spread of pathogens, but they often fall short in completely neutralizing microbiological agents. This deficiency poses the risk of secondary pollution and continued human infection. In this research, we developed MXene-coated non-woven air filters and achieved efficient antiviral air filtration at a low voltage of < 2V over the 4 x 4 cm2 area. Uniform MXene coatings on commercial air filter membranes were fabricated by the spray coating of Ti3C2Tx MXene colloidal solution with varied loading amounts from 0.13 to 1.5 mg/cm2. Under a voltage of 5 V, the current passing through an area of 2x2 cm2 area was measured as 70 mA at 0.12 mg-MXene/cm2 and 1500 mA at 0.75 mg-MXene/cm2, much higher than the 2 mA for 1.5 mg/cm2 graphene loading. This much-improved conductivity for the MXene-coated air filters can be ascribed to their excellent electrical conductivity. The antiviral air filtration tests revealed that the virus (MS2) removal rate was increased from ~50% for commercial air filters to ~75% for 0.12 mg/cm2 and to >99% for 0.75 mg/cm2 MXene coatings. Negligible pressure drop was achieved for MXene coatings up to a loading amount of 0.75 mg/cm2. Notably, our findings indicated that the MXene-coated air filter exhibited significantly improved virus removal efficiency, surpassing the performance of graphene-based coatings. The affordability of MXene surface coatings further underscores their potential as a cost-effective solution for addressing critical public health concerns.

2:30 PM BREAK

3:00 PM NM01.06.04
$Ti_3C_2T_x$ Co-Catalyst on CuO: Size Effects on Enhanced Photocatalytic Activity Lu Chen[1,2], Taotao Qiang[1], Matyas Daboczi[2], Yasmine Baghdadi[2] and Salvador Eslava[2]; [1]Shaanxi Univresity of Science and Techonolgy, China; [2]Imperial College London, United Kingdom

Co-catalysts play a crucial role in photocatalytic reactions, and titanium carbide ($Ti_3C_2T_x$) is a promising alternative to expensive noble metal co-catalysts. However, size effects and charge transfer mechanisms of $Ti_3C_2T_x$ co-catalysts on semiconductors for photocatalytic water splitting remain under-researched. Herein, we coupled copper (II) oxide (CuO) semiconductor with either $Ti_3C_2T_x$ nanosheets (T2D) or $Ti_3C_2T_x$ quantum dots (T0D) to create composite photocatalysts: T2D/CuO and T0D/CuO. The effects of size, morphology, and energetics of $Ti_3C_2T_x$ were investigated and hydrogen production rates were tested. The results show that T0D are better co-catalysts for photocatalytic hydrogen production in comparison to T2D. The optimal T0D/CuO sample achieved a hydrogen production rate of 2174 $\mu mol\ g^{-1}\ h^{-1}$, which is 19 times that of the optimal T2D/CuO samples, and more than 100 times that of pure CuO. The size of T2D in the composites is 200 nm, whereas the size of T0D is only 7 nm. This difference serves to decrease light obstruction and parasitic light absorption. Simultaneously, the surface area increases from 29 cm^2/g for T2D/CuO to 43 cm^2/g for T0D/CuO, indicating a higher abundance of active sites. This study highlights the impact of the size effects of $Ti_3C_2T_x$ co-catalysts on photocatalytic performance and lays the foundation for the research of other quantum dot sized co-catalysts.

3:15 PM NM01.06.05
MXene Iontronics for Neuromorphic Computers and Actuators Max M. Hamedi; KTH, Sweden

2D materials and in particular MXenes can not only form passive metallic or supercapacitive structures but can also become active structures in which their optoelectronic or structural properties change as a function of doping. We term these materials 2D mixed ionic electronic materials (MIEC) or iontronics. Here we highlight two specific MXene MIECs devices that we have developed:

1) A component for in memory computers called **MXene electrochemical random-access memories (ECRAMs).** The MXene ECRAM components has a channel like a conventional transistor, where the channel comprises a multi-layered MXene film formed using a highly accurate layer-by-layer self-assembly method developed by us.[1] In the ECRAM, however, an electrolyte between the channel and gate is used instead of the dielectric used in a solid-state field-effect transistors (FET). As a result, we can electrochemically switch the redox state of the MXene MIEC material using a gate electrode. Conducting polymer ECRAMs were until now the only shown ECRAMs but can not be integrated into silicon chips because organic materials burn at the high temperatures used in CMOS fabrication. The multilayers of titanium carbide MXene[1] can form ECRAMs with promising metrics for in-memory computation (also termed neuromorphic computers)[2] and can withstand high temperatures for integration. In recent studies we analyze these components and describe their characteristics using equation derived for organic electrochemical transistors.[3]
We think our work paves the way for ECRAM based computers and MXene electrochemical transistors.

2) We recently developed an MXene based actuators that we call **Electrochemical Osmotic (ECO) actuators.**[4] These actuators are formed from bulk composite electroactive hydrogels, fabricated from cellulose nanofibrils from trees, and 2D MXenes.[5] These nanoparticles self-assemble into an anisotropic composite networks with an open mesoporous structure that can hold lots of water and be highly permeable to substances in their surroundings, while being mechanically very strong. The anisotropy of the network allows high expansion in one direction while maintaining very high strength and high electric conductivity in the other. The electrochemical charge/discharge of the MXene in the hydrogels controls the internal salt concentration and consequently their osmotic swelling. This allows direct electrically controlled actuation where around 700 water molecules expand/contract the structure for each ion/electron pair inserted/de-inserted at only ±1 volt, resulting in 300% electroosmotic expansion, with very high pressures reaching 1 MPa. This mode of electronic actuation has not been shown before, and has emergent properties not present in any previously known soft material. ECOs allow for monolithic integration of sensors and other functions into one composite, rendering a new form of smart soft material not achieveable with other materials systems.

3:30 PM NM01.06.06
Increased Sensitivity of Zero-Bias-Operated MXene via Lignin Hybridization for Chemiresistive Sensor I Ketut Gary Devara, Dhananjay D. Kumbhar, MiJi Kwon, Su-yeon Cho, Dong Jun Kwon and Jun Hong Park; Gyeongsang National University, Korea (the Republic of)

High-sensitive and accurate environmental monitoring devices are essential to match the appropriate gas sensors to particular applications and requirements as global urbanization drives population density. MXenes is one of the 2D materials used as the active layer in chemical sensors. Since the bare MXene is nearly conductor, the dynamics of electric response upon chemical stimulation are not comparable to other solid-state chemiresistive devices. This work aims to enhance the sensitivity of chemiresistive sensors with different $CO_{2(g)}$ and $NO_{2(g)}$ gas concentrations without bias by reconfiguring the functional groups of MXene via hybridization lignin. Therefore, compared to MXene, MXene/lignin hybridization significantly showed better sensitivity. Besides that, it displayed a higher response and good repeatability for the target gases with various concentrations at room temperature. Under zero bias operation, the MXene chemiresistive sensor's sensitivity to $NO_{2(g)}$ and $CO_{2(g)}$ significantly enhanced with lignin hybridization at 15 ppm. In addition, the hybridized MXene/lignin was also applied on a curved composite substrate to determine the possibility for application in curvature objects. The MXene/lignin sensor bent shows a similar response and sensitivity to the value without curved, as exposure to 15 ppm of $NO_{2(g)}$ and $CO_{2(g)}$ gas at room temperature under zero gate bias operation. In addition, these chemical responsibilities of hybrid composite sensors are maintained after 50 bending cycles, consistent with mechanical stability. Consequently, MXene/lignin could be an attractive candidate sensing material for room temperature and zero bias $NO_{2(g)}$ and $CO_{2(g)}$ gas detection. The MXene/lignin hybridization sensor can be a model system for application in the advanced solid states sensory platform for curvature structure.

3:45 PM NM01.06.07
When MXenes Meet Machine learning: A Promising Initiative Towards Data-Intensive Scientific Revolution Moses A. Bokinala; University of Barcelona, Spain

Addressing the global challenge of sustainability and improving the quality of life for a growing population requires the development of advanced technologies, such as water-splitting devices, fuel cells, and rechargeable batteries. These technologies rely on materials that are both environmentally friendly and cost-effective. However, the path to discovering innovative materials faces a bottleneck due to complex trade-offs among material properties and challenges in optimizing high-dimensional spaces. Artificial intelligence (AI), employing data mining and machine learning (ML) tools, revolutionizes material discovery by automating and streamlining processes, empowering researchers to reveal hidden trends, and accelerating screening through efficient exploration of chemical space in vast materials datasets. Particularly, exploration of recently developed transition metal carbides/nitrides (MXenes), distinguished by their distinctive physical and chemical characteristics, has gathered widespread attention of material scientists, engineers, and chemists. Given the practical constraints of synthesizing the vast array of possible MXenes, a holistic approach that combines experimental and computational methods with ML gains prominence. This presentation highlights the pivotal role of ML in extracting knowledge from existing MXenes by using implicit data patterns and intricate correlations, providing intelligent guidance for purposeful MXene's development. Emphasizing the importance of SMART (specific, measurable, attainable, relevant, and timely) targets, the presentation illustrates how these objectives strategically shape the selection and transformation of data, promoting a comprehensive understanding of the challenges at hand. Subsequently, our recent work is showcased, featuring a versatile multistep procedure employing various supervised ML algorithms to develop well-trained data-driven models capable of predicting the hydrogen evolution reaction (HER) activity across a dataset comprising 4,500 MXenes configurations. A notable achievement in this exploration of ML modelling is the outstanding performance of the Gradient Boosting Regressor (GBR), demonstrating accurate and rapid prediction of the Gibbs free energy associated with hydrogen adsorption (ΔG_H). A detailed analysis of feature importance sheds light on key descriptors influencing HER performance, including d-band center variance, electron affinity, and the number of valence electrons in terminating groups. Overall, the adeptly trained ML model not only matches the predictive accuracy of DFT calculations but also exposes the factors shaping HER activity, opening up a coherent avenue to explore diverse configurations of MXenes.

5:00 PM NM01.07.01
Multifunctional Single Component Epoxy System and MXene/Epoxy Composite with Polymeric Imidazole Latent Curing Agent Sungmin Jung and Chong Min Koo; Sungkyunkwan University, Korea (the Republic of)

A single-component epoxy system is necessary for industrial applications because of the convenience, productivity, and cost. Thus, there is a need for a latent curing agent that secures storage stability, while simultaneously triggering an immediate curing reaction above a certain temperature. Herein, we synthesize copolymers consisted of imidazole and furan groups in different ratios using controlled radical polymerization. Then, a microbead-type latent curing agent for epoxy resin is fabricated in an oil-in-water emulsion followed by Diels-Alder (DA) reaction between furan groups of copolymer and maleimide groups of bismaleimide (BMI) molecule at 40 °C. Compared to bare imidazole, the fabricated microbeads are able to effectively suppress reactivity due to the simultaneous operation of chemical modification and physical protection effect by DA network for 3 months at 60 °C. In addition, compared to epoxies made with imidazole, flame retardancy is secured by blocking heat and oxygen due to the high char residue formed by polymerization of BMI. Also, the increase in stiffness of specimen due to the rigid segment in the DA network results in the improvement of tensile, shear and impact strength. Lastly, as a proof-of-concept application, we incorporate fuctionalized-$Ti_3C_2T_x$ MXene into epoxy to fabricate composite since MXene has received much consideration as a filler in polymer systems due to its remarkable electrical, electromagnetic interference shielding and flame-retardant properties. This proof-of-concept study demonstrate that MXene successfully endows the developed composites with high electrical conductivity and electromagnetic interference shielding and flame-retardant properties.

5:00 PM NM01.07.02
Ag-Ti_3C_2 MXene: A Promising Sorbent for Iodine Gas Capture in Nuclear Waste Karamullah Eisawi[1], Michael Naguib[1] and Brian Riley[2]; [1]Tulane University, United States; [2]Pacific Northwest National Laboratory, United States

The capture and disposal of radioactive iodine gas, a byproduct of used nuclear fuel, are increasingly critical in the nuclear industry to ensure the sustainability of nuclear energy. There is a need for novel materials to capture such radioactive waste efficiently. MXenes, a family of 2D transition metal carbides, nitrides, and carbonitrides, exhibit intriguing physical and chemical properties, including customizable surface terminations, tunable interlayer spacing, high surface area, and excellent electronic conductivity. Their remarkable performance extends across diverse applications, encompassing energy storage, catalysis, water purification, and coating materials. In this study, we present a novel application for MXene hybrids, utilizing silver-MXene (Ag-$Ti_3C_2T_x$), as an effective sorbent for iodine gas at operating temperature of 150 °C. The hybrid was synthesized using a straightforward reduction of $AgNO_3$ to produce Ag nanoparticles that grow on the surfaces of $Ti_3C_2T_x$ MXene layers. Our research demonstrates a notable iodine capture capacity in Ag-

$Ti_3C_2T_x$, surpassing widely reported iodine sorbents like silver zeolite (AgZ)[1] and Ag-aerogel[2]. Specifically, the iodine loading in Ag-$Ti_3C_2T_x$ reached 0.62 $g_{iodine}/g_{sorbent}$, outperforming AgZ and Ag-aerogel, which recorded 0.22 $g_{iodine}/g_{sorbent}$ and 0.56 $g_{iodine}/g_{sorbent}$ respectively. These findings highlight the potential of this synthesized hybrid material as effective sorbent for capturing iodine gas.

Design of an amperometric glucose oxidase biosensor with added protective and adhesion layer Rongwei Gao; KU Leuven, Belgium

Electrochemical enzyme sensors have attracted tremendous attention due to their incomparable properties, such as specific selectivity, fast response, low cost, and easy miniaturization. Over the last decades, various electrochemical enzyme sensors have been reported, from simple test strips to wearable devices and implantable systems. Yet, only a few electrochemical enzyme sensors have practical application due to the instability and easy inactivation of enzyme. It is well known that immobilized enzymes display higher activities and stabilities compared to free enzymes, thus numerous works have focused on enzyme immobilization. Specifically, a total of 8398 documents was retrieved from the Web of Science when searching the keyword "Enzyme immobilization" over the past five years. Although many enzyme sensors have been reported in the literature, only a few that have been applied in various industries, such as blood glucose meters and pregnancy tests. In addition to the effective immobilization of enzymes, other factors may restrict the practical application of enzyme sensors and, thus, require further investigation.
Generally, enzyme sensors require a period of storage between preparation and use, which can affect their stability. Enzyme contamination denaturation and loss of activity can also cause sensor failure. Since the test system is inseparable from the liquid for both intrusive and non-invasive sensors, poor enzyme immobilization can cause the enzyme to leach from the immobilized layer or the entire modified layer to peel off the electrode into the test solution, resulting in detection failure. On the other hand, the electrochemical sensing process generally includes enzymatic reactions and heterogeneous electron transfer reactions. The key aims of this process are to achieve effective contact and accelerate the reaction kinetics between enzymes and detection molecules. Thus, it is pertinent to maintain the enzyme activity during the storage period, so that the active layer does not separate from the electrode surface under liquid operating conditions. The rapid realization and effective collection of the response signal of the enzyme toward target molecular are also highly important.
Herein, we propose an effective synergistic strategy to improve the stability and sensitivity of the enzyme sensor by combining the surface protective layer, intermediate reaction layer, and basic adhesion layer. Sodium hyaluronate (SH) is employed as the permeable protective film to protect enzymes from pollution and water loss, which is also beneficial to the diffusion of glucose towards the sensor's interface. The reaction layer is constructed with MXene-Ti_3C_2/GOD, in which MXene-Ti_3C_2 can ensure the highly dispersed loading of GOD. The adhesion layer consists of CS/rGO, whereby the large specific area of rGO strengthens the bond between the modification layer and current collector, preventing the sensing surface from peeling off the collector during the test. CS not only helps to bind MXene-Ti_3C_2 with rGO organically but also ensures high biocompatibility of the sensor. During the reaction, glucose passes quickly through the protective film (SH) into the reaction layer (MXene-Ti_3C_2/GOD) and reacts on the surface of GOD. Then, electrons are quickly released and effectively collected by the rGO-modified current collector. Results demonstrate that the repeatability of our designed sensor increased by 73.3% after improving the adhesion between the reaction layer and the current collector and that its response ability was greatly enhanced. Moreover, the long-term stability of the electrode surface with SH protective film proved to be superior than that without protective film, which suggests that this design can effectively improve the overall performance of the enzyme biosensor. This work proposed a multi-tier synergistic approach for improving the reliability of enzyme sensors.

A novel Zn single atom anchored $Ti_3C_2T_x$@ZIF-67 nanocomposites for effective deterioration of recalcitrant Mohammed Askkar Deen F and Selvaraju Narayanasamy; Indian Institute of Technology Guwahati, India

Single atom catalyst (SAC) have garnered much attention owing to their atomic utilization efficiency, superior catalytic selectivity as well as engineerable catalytic sites. Despite this promising potential of SAC, the major challenge arises in their synthesis. Since SAC require chemically stable and high thermal substrates to stabilize metal atoms without sintering. Metal-Organic Frameworks (MOFs) offer vast surface area and enormous pore structure to be an immaculate template for synthesizing nanomaterials. However, its tendency to form nanoclusters during the synthesis renders them low mass transfer rate and poor catalytic activity. Hence, a pertinent substrate is required to enhance the MOFs stability, thereby regulating its electronic structure for optimized catalytic performance. MXene, a 2D nanomaterial with phenomenal conductivity, tunable surface terminations and remarkable mechanical pliability, exemplifies exceptional catalytic activity that can serve as a substrate for MOFs to exert a synergistic effect. Herein we developed a stable Zn single atom anchored $Ti_3C_2T_x$@ZIF-67 (Zn-SA/MXene/MOF) nanocomposites. The synthesized nanocomposites resulted in enhanced oxidation stability than pristine $Ti_3C_2T_x$ MXene. Additionally, the nanocomposites exhibited a superior catalytic activity towards recalcitrant deterioration.

MXene Enabled Wearable Energy Storage Solutions Alex Inman, Magdalena Zywolko, Lingyi Bi, Tetiana Hryhorchuk, Kyle Matthews and Yury Gogotsi; Drexel University, United States

E-textiles can create new user experiences and provide comfortable monitoring of patient vitals. To realize their potential, there is a need for textile-based energy storage. However, devices reported in the literature don't store enough energy to power the electronics necessary to realize this vision. MXenes are conductive 2D materials with an electrochemically active surface and high energy storage capacity that can be integrated into textiles, making them an ideal candidate for textile-based energy storage. We demonstrate the use of MXenes in two different textile-based devices to power fully programable microcontrollers capable of motion tracking and environmental sensing for extended times.

5:00 PM NM01.07.08

Stability of Pseudocapacitive Energy Storage in $Ti_3C_2T_x$ MXene in a Wide Temperature Range Ruocun Wang[1,2], Mark Anayee[1,2], Muhammad Nihal Naseer[3], Teng Zhang[1,2], Yuan Zhang[1,2], Mikhail Shekhirev[1,2], Kateryna Shevchuk[1,2], Yong-Jie Hu[2] and Yury Gogotsi[1,2]; [1]A.J. Drexel Nanomaterials Institute, United States; [2]Drexel University, United States; [3]University of Picardie Jules Verne, France

Pseudocapacitors have the potential to achieve high energy and high power density simultaneously, a holy grail for electrochemical energy storage. However, one obstacle facing pseudocapacitors is their shorter lifetime than commercial supercapacitors using the double-layer charge storage mechanism. In MXene-based pseudocapacitors, this concern is pronounced particularly at high temperatures due to the limited stability of the active material in aqueous solutions. This work shows that $Ti_3C_2T_x$ MXene thin-film electrodes in 5 M H_2SO_4 possess excellent rate capabilities from -50 °C to 70 °C but also a sufficient lifetime at 70 °C using a float test holding at -0.9 V vs. Hg/Hg_2SO_4. Post-mortem characterization using X-ray photoelectron spectroscopy and Raman spectroscopy showed negligible signs of oxidation in the bulk of the film. This work suggests sufficient stability of $Ti_3C_2T_x$ MXene as a negative electrode in protic aqueous electrolytes across a wide temperature range rooted in thermodynamics, making it promising for pseudocapacitor energy storage.

5:00 PM NM01.07.09
Colorful MXene inks for multifunctional textiles Lingyi Bi, Danzhen Zhang, Kseniia Vorotilo, Richard Vallett, Genevieve DIon and Yury Gogotsi; Drexel University, United States

Textiles are the ultimate wearables, providing 24/7 next-to-skin coverage of large areas of our body. They present large surface areas to host sensing devices. Great effort has been made to impart electronic properties - movement tracking, biological signal monitoring and actuation functions for haptic interactions– by incorporating conductive materials into traditional textiles. However, these metal and carbon-based conductive materials not only limit the hues to silver, black and grey but also require a large amount to be deposited for sufficient electrical conductivity – an approach that makes these textiles dull and harsh, deviate from the vibrant and comfortable textiles we love and experience every day. MXenes could pose a solution. MXenes are a family of two-dimensional transition metal carbides and nitrides with the highest electrical conductivity among solution processible nanomaterials. MXenes exhibit distinct colors from green, blue to purple, gold of different shades depending on the transitional metal(s) present (e.g., Ti, V, Nb, Mo, and Cr) and on their structuring. Moreover, the functional groups on the surfaces of MXenes allow them to establish strong interactions with the substrates, making them ideal conductive additives for durability and scale. Here, screen printing—a widely adopted technique in the textile industry—was demonstrated as an economical method for not only faithfully replicating MXene colors and achieving high conductivities on fabrics but also for carefully placing and combining MXenes for many electronic functions.

Annealing Ti3C2Tz MXenes to control surface chemistry and friction Kailash Arole, Hong Liang, Miladin Radovic, Jodie Lutkenhaus and Micah Green; Texas A&M University, United States

Although surface terminations (such as =O, -Cl, -F, -OH) on MXene nanosheets strongly influence their functional properties, synthesis of MXenes with desired types and distribution of those terminations is still challenging. Here, it is demonstrated that thermal annealing help to remove much of the terminal groups of molten salt-etched multi-layered (ML) Ti3C2Tz .In this study, the chloride terminations of molten salt etched ML-Ti3C2Tz were removed via thermal annealing at elevated temperatures under an inert (argon) atmosphere. This thermal annealing created some bare sites available for further functionalization of Ti3C2Tz . XRD, EDS, and XPS measurements confirm the removal of much of the terminal groups of ML-Ti3C2Tz . Here, the annealed ML-Ti3C2Tz were re-functionalized by -OH groups and 3-aminopropyl triethoxysilane (APTES), which was confirmed by FTIR. The -OH and APTES surface-modified ML-Ti3C2Tz are evaluated as a solid lubricant, exhibiting ~70.1% and 66.7% reduction in friction compared to steel substrate, respectively. This enhanced performance is attributed to the improved interaction or adhesion of functionalized ML-Ti3C2Tz with the substrate material. This approach allows for effective surface modification of MXenes and control of their functional properties

5:00 PM NM01.07.11
Graphene Quantum Dots enhanced MXene/Rare-earth Metal Oxide Nanohybrids based Printed Electrochemical Biosensor for Detection of Biogenic Amine Neurotransmitters Sudip Das, Arghya Chakravorty, Aarcha A.M. and Vimala Raghavan; Vellore Institute of Technology, Vellore, India, India

With the expansion of science and technology, the healthcare business is flourishing with cutting-edge trends and innovations. Moreover, progress in the development of portable, real-time smart healthcare devices based on nanotechnological routes is of great collaborative interest between research and industry. Neuroscience is one such complicated, fascinating, but concerning genre of research in this current decade. Abnormal neurotransmitter levels and distributions can induce incurable disorders involving descending or ascending modulatory circuits or defective organs, according to neuroscience. One of the most promising methods for diagnosing brain illnesses is the detection of aberrant biogenic amine neurotransmitter levels. Hence, in this research, we have developed a novel graphene quantum dot enhanced MXene ($Ti_3C_2T_x$) and rare earth metal oxide-based (Gd_2O_3) printed electrochemical biosensor for simultaneous detection of Dopamine and Epinephrine. The nanocomposite has been characterized by some sophisticated characterization techniques like scanning electron microscopy, UV-vis spectroscopy, Fourier-transform infrared spectroscopy, energy dispersive x-ray spectroscopy, and powder x-ray diffraction. Cyclic voltammetry is employed for studying the chemical kinetics and absorbance of the nanocomposite, while differential pulse voltammetry, Linear sweep voltammetry, and electrochemical impedance spectroscopy have been performed to find out the lower-range detection limit of the analyte and wide linear range of the neurotransmitters present in the different biological fluids.

5:00 PM NM01.07.12
Efficient Delamination and Dispersion of 2D MXenes in Organic Solvents for Fabrication of Polymer Nanocomposites James FitzPatrick and Yury Gogotsi; Drexel University, United States

MXenes, a family of two-dimensional (2D) transition metal carbides and nitrides, have attracted significant attention in recent years for their unique optical, electronic, and chemical properties, to name a few. These nanomaterials have a general formula of $M_{n+1}X_nT_x$ where M is a transition metal, X is carbon and/or nitrogen, and T_x represents a variety of surface terminations. MXenes can be tailored for an incredibly broad array of applications, but are still often hindered by manufacturing, stability, and mechanical challenges. Many of these challenges can be overcome by integrating the 2D material into polymer matrices, leading to composites with distinct properties that can serve specific or multiple functions. To date, only a small portion of MXene research has been focused on polymer composites. Several hurdles exist for crafting high performance composites, including uniform distribution of flakes and interfacial compatibility with certain polymers, specifically hydrophobic ones. Current methods for compositing nanoparticles with polymers typically involve blending the two materials in an organic solvent, but dispersing the MXene in this medium either involves complex processing or lengthy sonication that can greatly reduce the average flake size and deteriorate properties. Herein, a more efficient approach to delaminating multilayer $Ti_3C_2T_x$ MXene in an organic solvent is proposed, forming stable colloidal solutions that can be used to process composites with highly uniform flake distribution. This delamination method requires little more work than typical methods for obtaining single-layer MXene flakes and does not require any sonication or

surface functionalization to improve interfacial compatibility and dispersion in a hydrophobic polymer matrix. Certain organic solvents such as propylene carbonate are highly effective in forming stable MXene solutions as well as enhancing formation of electroactive crystalline phases in polymers like PVDF. The properties of MXene-PVDF composites made through this process are examined through several characterization techniques, and potential applications of similar composite structures are explored.

5:00 PM NM01.07.13
Photoelectrochemical application of $MoSe_2$ decorated Ti_3C_2 MXene derived 2-D TiO_2 photoelectrode for simultaneous wastewater treatment and hydrogen generation Pooja .[1,2] and Pooja Devi[1,2]; [1]Academy of Scientific and Innovative Research (AcSIR), Ghaziabad- 201002, India, India; [2]Materials Science and Sensor Application, Central Scientific Instruments Organisation, Chandigarh-160030, India

To address the rising global energy demand, the world is transitioning to renewable sources, with hydrogen emerging as a clean and sustainable fuel option. While water is abundant, but availability of fresh water is very limited, and alternatively untreated wastewater can also be a source of pollution. Thus, using polluted/low quality water for hydrogen production presents a dual solution: managing wastewater while generating clean fuel. Photoelectrochemical (PEC) water splitting using photoelectrodes offers a promising approach. In this work hydrogen production from dye-contaminated water (utilizing methylene blue as a model pollutant) using $MoSe_2$-decorated Ti_3C_2 MXene derived TiO_2 photoelectrode in a PEC water-splitting system is demonstrated. The 2-D TiO_2 was synthesized from hydrothermal treatment of Ti_3C_2 MXene. Characterization confirms improved optical and structural properties of MXene derived 2-DTiO_2 as compared to commercial TiO_2. The 2-D TiO_2 hybrid electrode achieves better photocurrent density of as compared to P25-TiO_2. The condition will be optimized to yield remarkable dye degradation efficiency, and will be compared to $MoSe_2$ and TiO_2 alone. The optimized electrodes will also be studied for real waste water degradation by analysing the TOC and COD removal along with H_2 generation via gas chromatography investigation.

MXene as Electrochemical Sensing Chip for On-site Heroin Detection – New Era in Forensic Illicit Drug Monitoring Vimala Raghavan, Arghya Chakravorty, Sudip Das and Aarcha A.M.; Vellore Institute of Technology, India

In developing nations as well as across the globe, the abuses of narcotics are increasing drastically. In 2019, 1.3 million Europeans were heroin-addicted, while heroin production worldwide was 509-739 tons in 2022. Thus, a need arises to develop sensors that will lead to the detection of drugs even at lower concentrations. In this research study, we have fabricated titanium carbide MXene/Pt/Au nanocomposite on carbon paste screen printed electrode for developing a user-friendly, cost-effective sensing chip to detect illicit drug heroin. Scanning electron microscopy (SEM), X-ray powder diffraction (XRD), BET surface area analysis, and energy dispersive X-ray spectroscopy (EDX) are used for the characterization of composition and morphology of MXene/Pt/Au nanocomposite, demonstrating its high specific surface area of the synthesized material. The synthesized MXene possesses wall thicknesses of about 17 nm, nanoparticles' size was less than 70 nm on average. The mentioned properties provided rapid electron transfer and large electrochemically active surface area and assisted in the discrimination of analytes that reduce or oxidize under the same potentials. The enhanced electrode demonstrated appropriate sensing ability to heroin after performing fixation of MXene/Pt/Au nanocomposite. Kinetic factors charge transfer coefficient, standard heterogeneous electron transfer rate constant, and other different electrochemical factors are predicted using voltammetry methods. At a glance, the developed electrochemical chip ensures a unique LOD for device making and a wide linear range during detecting heroin. In addition, the mentioned suggested a suitable potential for profiling of heroin with appropriate long-term stability, repeatability, and reproducibility. The excellent efficiency for the measurement of real samples demonstrated the most significant future perspectives of this sensor.

5:00 PM NM01.07.15
MXene-Derived Sodium Titanate Nanoribbon/Lanthanum Composite as High-Performance Electrochemical Point-of-Care Sensor – A Step towards Achieving One Health Arghya Chakravorty, Aarcha A.M., Sudip Das and Vimala Raghavan; Vellore Institute of Technology, India

One Health is an approach to designing and implementing programs, policies, legislation, and research in which multiple sectors communicate and work together to achieve better public health outcomes. The One Health approach is critical to addressing health threats in the animal-human-environment interface. Among global health problems, antimicrobial resistance (AMR) is the one that best illustrates the One Health approach. In this context, the antibiotic enrofloxacin plays an important role in terms of therapeutic drug monitoring in humans, and administration in poultry, animals, and aquaculture, which includes the threat to food as well as environmental safety. Thus, a need arises to develop sensors that will lead to the detection of enrofloxacin even at lower concentrations in versatile real matrixes. In this research study, we have fabricated titanium carbide MXene-Derived Sodium Titanate Nanoribbon/Lanthanum nanocomposite on carbon paste screen printed electrode for developing a user-friendly, cost-effective sensing chip to detect illicit drug heroin. Scanning electron microscopy (SEM), X-ray powder diffraction (XRD), BET surface area analysis, and energy dispersive X-ray spectroscopy (EDX) are used for the characterization of the composition and morphology of MXene-Derived Sodium Titanate Nanoribbon/Lanthanum nanocomposite, demonstrating its high specific surface area of the synthesized material. The synthesized nanoribbon possesses wall thicknesses of about 15 nm, nanoparticles' size was less than 50 nm on average. The mentioned properties provided rapid electron transfer and large electrochemically active surface area and assisted in the discrimination of analytes that reduce or oxidize under the same potentials. The enhanced electrode demonstrated appropriate sensing ability to heroin after performing fixation of the nanocomposite. Kinetic factors charge transfer coefficient, standard heterogeneous electron transfer rate constant, and other different electrochemical factors are predicted using voltammetry methods. At a glance, the developed electrochemical chip ensures a unique LOD for device making and a wide linear range during detecting enrofloxacin in different real matrixes, viz. milk and food samples; human blood serum, and urine; waste water, and pharmaceutical industry effluents. In addition, the mentioned suggested a suitable potential for profiling of enrofloxacin with appropriate long-term stability, repeatability, and reproducibility. The excellent efficiency for the measurement of real samples demonstrated the most significant future perspectives of this sensor.

5:00 PM NM01.07.16
First-principles investigation of surface functionalization and CO_2 adsorption in MXenes Michelle Becerra and Cormac Toher; The University of Texas at Dallas, United States

Ever-increasing amounts of carbon dioxide (CO_2) are being expelled into the atmosphere, and without some type of countermeasure the environmental consequences will be dire. Motivated by the fact that CO_2 generators are a fixed part of our technological society which may be reduced, but not fully removed; research efforts have been directed towards utilizing these high concentrations of atmospheric CO_2 as a sustainable resource. Carbon capture, specifically post-combustion, captures CO_2 from a single source, removing it from the air and allowing further operations to be performed later. 2D early transition metal carbides and nitrides known as MXenes are investigated as an effective sorbent material thanks to their diverse composition, chemically active surface stemming from surface functionalizations and overall versatile and tunable nature. The computational characterization of MXene surface functionalizations, both the native surface inherited from synthesis and non-native surface groups introduced afterwards, are being systematically explored through calculated adsorption energies from density functional theory (DFT) as well as material optimization via machine learning (ML) methods. Molecules and surfaces being modeled are: pristine surfaces (Ti_3C_2, Mo_3C_2), attaching molecules (CO_2, H_2O, O_2, N_2, SO_2), native surface functional groups

(F, O_2, O, OH, Cl and H), non-native surface functional group (NH_2) and the interactions between them. The characterizations so far have shown that when adsorbing to a pristine Ti_3C_2 surface, single ions of F, O, OH, Cl and attaching molecules CO_2, H_2O and O_2 all preferred binding to hollow sites, while ions of H and NH_2 favored the bridge site before relaxing into a hollow site. Single fluorine ions bound to the surface were more thermodynamically stable when H_2O adsorbed, when compared to CO_2 and O_2, but saturation of the surface with fluorine resulted in CO_2 and H_2O having similar adsorption energies. The unknowns revolving around MXenes and their surface functionalizations is a knowledge gap that is preventing MXenes from being fully utilized in the field of sustainable chemistry. The characterizations and MXene designs generated by this research will not only fill in the divide between MXenes and carbon capture, but also unite industries and our environment through more accessible carbon capture methods.

5:00 PM NM01.07.18
Enhanced SERS Sensing via 3D Microstructures Hybridized with 2D MXenes Shehua C. Thor[1], Zihao Lin[1], Sodam Choi[2], Chiwon Ahn[2] and Jeong-Hyun Cho[1]; [1]University of Minnesota, United States; [2]Korea Advanced Institute of Science & Technology (KAIST), Korea (the Republic of)

Surface-Enhanced Raman Spectroscopy (SERS) is an analytical technique that can be used to detect target particles on a plasmonically enhanced surface. This has applications in fields such as medicine and environmental pollution. The advantage of SERS detection is that it can be used to detect very small amounts of a sample and it is noninvasive. However, traditional SERS requires that the target particles be in contact with the plasmonic materials on the sensing surface. For the detection of very low concentration target particles in a liquid, traditional SERS techniques are limited by the diffusion limit. More specifically, it can take hours for nanoscale target particles in a liquid at very low concentrations to diffuse to the sensing surface for detection. In this study, we address the diffusion limitation by merging MXenes, a 2D material, with a 3D microstructure, establishing a micro-scaled surface optimized for detecting minute concentrations of target particles in a liquid. The 3D configuration composed of SU-8 is a self-assembled twin-tubular microstructure that creates a nanogap at the center curvature. When fluid is flown through this tubular structure, an enhanced Raman signal can instantly be obtained. As fluid is flown from one end of the twin tubular structure to the other end, some fluid will flow between the center curvature (a nanogap). At this center curvature, some of the analytes will be caught in between the nanogap of the center curvature. Furthermore, both sides of this nanogap have MXenes. Hence, the analytes will be in contact with the plasmonic surface and be ready for instant Raman measurement. Furthermore, this Raman signal demonstrates two levels of enhancement. The first level of enhancement is from the MXenes. MXenes can be used as a plasmonic material that can enhance the Raman signal. The second level of enhancement is from the proximity of the two MXenes surfaces at the center of the twin tubular 3D microstructure. This proximity is a function of the twin tubular structure. The twin tubular structure curves itself into a shape where there is a nanogap at the center between the two tubes. At this nanogap, there is also MXenes on both sides of the gap. This nanogap is the plasmonic surface where the enhanced Raman measurement will be taken. Capitalizing on the combined advantages of 3D structures and low-dimensional (0D, 1D, and 2D) materials, which counterbalances the limitations of 2D materials like MXenes, the approach of fusing 3D microstructures with these low-dimensional materials offers broad application possibilities.

5:00 PM NM01.07.19
The fabrication and characterization of a water treatment system incorporating activated carbon, graphene nanoplatelets, and Ti3C2-based composite nanofiltration matrix: towards the development of multifunctional nanofiltration systems for targeted removal of emerging contaminants Prakhyat Gautam[1], Parshwa Khane[1], Derek Xiong[1], Edbertho Leal-Quiros[2], Saquib Ahmed[3,3] and Sankha Banerjee[1,4]; [1]California State University, Fresno, United States; [2]University of California, Merced, United States; [3]Buffalo State College, United States; [4]University of California, Davis, United States

Researchers are exploring various strategies to address water scarcity, and one such approach involves the application of nanotechnology in water treatment and purification. There is also a great need for the targeted removal of Polyfluoroalkyl Substances (PFAS) and the recovery of useful nutrients from different wastewater sources. The ongoing research focuses on creating and refining a water purification system that combines activated carbon with graphene, and Ti3C2-based composite nanofiltration matrix. This system was tested using five different concentrations of methylene blue and deionized water solutions, which underwent filtration in three separate cycles. For potential consumer-level use, a cost-effective, small-scale water filter was developed. It utilizes activated carbon and graphene nanoplatelets, with filter paper serving as the medium to retain a mixture of these materials within the filter. To assess the water quality, measurements were taken for conductivity, total dissolved solids (TDS), and pH in both the untreated feed water and the processed water. These measurements were carried out using an Oakton PC2700 Benchtop Meter. A UV-Vis spectrometer was employed to gauge solution absorption. Additionally, scanning electron microscopy was used to observe the microstructure of the composite filtration matrix and the distribution and adsorption of dye particles.

5:00 PM NM01.07.20
Delamination of uniformly terminated MXene produced using the molten salt etching Teng Zhang, Kateryna Shevchuk and Yury Gogotsi; Drexel University, United States

MXenes produced by molten salt of MAX phases have attracted attention of the community due to their controllable surface chemistry. However, their delamination is challenging due to the hydrophobicity of multilayer MXene and strong interactions betweel halogen-terminated MX sheets. The current delamination method involves dangerous chemicals such as N-Butyllithium or NaH, making scale-up difficult and limiting practical application. In this work, we present a low-cost, sustainable, and eco-friendly methodology for the delamination of molten salt synthesized MXenes while maintaining their surface chemistry. We demonstrate successful delamination. MXene films produced from the delaminated MXene had a conductivity of 8,000 S/cm and it didn't change after exposure to 95% humidity conditions for a week. This validation of successful delamination, preservation of inherent surface properties, and stability under high-humidity conditions broadens the range of potential applications of MXenes. This research marks a significant leap towards the sustainable and economical production of two-dimensional materials.

Enhanced Gas Sensing Performance of M_2CT_x/MO (M = Ti, V, Nb, Mo) Nanocomposites M S Bhargava Reddy and Shampa Aich; Indian Institute of Technology Kharagpur, India

Gas sensors are in high demand across various fields, from disease diagnosis through breath analysis to ensuring environmental safety and enhancing food and agriculture processes. The continuous discovery of new materials drives advances in gas sensor technology. Notably, 2D materials have gained significant attention for gas sensing due to their remarkable electrical, optical, and mechanical properties. Among them, 2D MXenes have emerged as compelling candidates due to their high specific area and their rich surface functionalities with tunable electronic structure make them compelling for sensing applications. MXenes are generally represented by $M_{n+1}X_nT_x$, in which M represents an early transition metal, X denotes either carbon or nitrogen or carbonitrides or oxy-carbides, T_x signifies surface terminations (T_x = -OH, -O, -F, -Cl), and *n* can be 1-4. M_2CT_x MXenes, in particular, show promise for VOC/gas detection based on theoretical calculations. However, research has predominantly focused on $Ti_3C_2T_x$ MXenes due to their established status, leaving limited exploration of other MXene variants as gas sensors. By altering the transition metal in MXenes, selectivity for specific gases can be achieved. Our research involves synthesizing MXenes from parent precursors (MAX and non-MAX phases) and conducting thorough property characterizations. We employ optimized synthesis methods to obtain single-/few-layered MXenes via selective etching and delamination. However, when comes to practical applications, pristine MXene-based gas sensors have low sensitivity, significant baseline drift, susceptibility to cross-interference, and a narrow band gap, which limits gas reaction and responsiveness. The self-stacking of MXene layers also impedes the diffusion of gas molecules and hinders surface-active sites, restricting the gas sensor response and limiting the detection of low-concentration gases [1]. To enhance gas sensing capabilities (response and stability), we fabricate M_2CT_x/MO (M = Ti, V, Mo, Nb) nanocomposites, introducing multiple in-situ Schottky barriers through surface oxidation to enhance VOC sensing capabilities. The MXene/MO nanocomposites were prepared by using the concept of in-situ conversion using MXene surfaces as reactants. MXene layers expose metallic atomic layers on their outer basal planes, which are highly oxophilic and prone to surface reactions like oxidation (e.g., Ti to TiO_2 in Ti_2CT_x or $Ti_3C_2T_x$). The MXene surface is transformed partially, to form MO material in these processes. This approach lays the foundation for understanding the surface-sensitive behavior of MXenes in gas sensing by investigating the impact of surface chemistry. It represents a critical step towards expanding the scope of MXene-based gas sensors beyond $Ti_3C_2T_x$ and advancing the field of gas sensing technology.
Keywords: $Ti_3C_2T_x$; M_2X MXenes; surface chemistry; gas sensing; in-situ Schottky barriers.

Two-Dimensional Graphene and MXene Electrodes for Stretchable Displays Huanyu Zhou, Hyun-Wook Kim, Shin Jung Han and Tae-Woo Lee; Seoul National University, Korea (the Republic of)

Two-dimensional (2D) materials, exemplified by graphene and MXenes, hold immense potential for various flexible display applications. Nevertheless, the practical use of these materials has been hampered by the high charge injection barrier at the interface between stretchable electrodes and organic layers. In this study, we innovatively introduced a 2D graphene layer onto silver nanowire percolation networks, creating a comprehensive two-dimensional contact stretchable electrode (TCSE). This graphene layer effectively tailored the work function, facilitated charge distribution, and acted as a barrier against the ingress of oxygen and moisture. Our breakthrough enabled the development of intrinsically stretchable organic light-emitting diodes (ISOLEDs) boasting a remarkable efficiency of 20.3 cd/A. To further enhance electrode solution processability, we designed an environmentally stable MXene conductive electrode characterized by outstanding conductivity and a work function (WF) of 5.84 eV. Implementing the MXene electrode in ISOLEDs resulted in a substantial boost in current efficiency over 25 cd/A. These pivotal advancements not only establish a robust foundation but also offer a comprehensive blueprint for the creation of highly-efficient stretchable displays.

MXenes as Hydrogen Storage Materials Yi Zhi Chu[1,2] and Kah Chun Lau[1]; [1]California State University Northridge, United States; [2]Michigan Technological University, United States

The ever-increasing need for electricity will require foremost increased efficiency in the uses of electric energy, more secure and sustainable energy resources and storages. To be better tailored to these challenges, novel materials for electrochemical and chemical energy storages that can efficiently store and deliver electric energy is highly important. In this case, hydrogen fuel stands out as a promising energy solution, and able offering a clean alternative to conventional energy sources while exhibiting the highest specific energy among many alternatives. Due to their high aspect ratio and tunable surface, slit-shape ion/mass transport channels, MXenes is a promising candidate in hydrogen storage materials. To address this issue, I will share with you our recent efforts based on theoretical studies with experimental supports from our collaborators. Based on our findings, some key avenues for future research that may help overcome the challenges and enable MXenes materials attain its full potential in this problem will be discussed.

Engineering 2D Mo-Based MXenes and Application in Ammonia Synthesis Amanda Sfeir[1], Christopher E. Shuck[2], Maya Marinova[3], Jean-philippe Dacquin[1], Yury Gogotsi[2], Said Laassiri[4] and Sébastien Royer[1]; [1]Université de Lille, CNRS, ENSCL, Centrale Lille, University Artois, UCCS-Unité de Catalyse et de Chimie du Solide, France; [2]Drexel University, United States; [3]Université de Lille, CNRS, INRA, Centrale Lille, Université Artois, IMEC – Institut Michel-Eugène Chevreul, France; [4]Chemical & Biochemical Sciences, Green Process Engineering (CBS), Mohammed VI Polytechnic University, Morocco

Ammonia, which is one of the most important chemicals for synthesis of dyes, pharmaceuticals, and fertilizers, is conventionally produced by the reaction of molecular hydrogen with nitrogen, over an iron-based catalyst at 400-500 °C under pressure of over 200 bar, the Haber-Bosch process. While the H-B process is credited for providing a simple and cost-effective route for nitrogen-based fertilizer production, it is highly energy-intensive, accounting for ~ 2 % of the world's energy production, and as it relies on fossil-based resources, resulting in a staggering emission of 2.5% of global CO_2 annually. Decreasing the temperature and pressure of this century old, highly energy intensive process, would greatly decrease the energy consumption in the world and reduce carbon emissions. Fundamentally, producing ammonia at lower pressures is not thermodynamically prohibited, providing that the reaction takes place at temperatures below 300 °C. However, due to the high energy barrier for the activation/dissociation of the strong triple covalent NN bond (945 kJ mol^{-1}), most developed catalysts, including the industrial H-B catalyst, operate at temperatures over 400 °C. Consequently, high-pressure operation is

required to increase ammonia yields to acceptable industrial production (15% conversion per cycle). In this work, for the first time in the literature, we engineered Co decorated Mo_2CT_x MXene multilayers as catalysts for ammonia synthesis under mild conditions. The MXene functionalized by Co showed catalytic activity for ammonia synthesis from H_2 and N_2 at temperatures as low as 250°C, without any pre-treatment. The developed catalyst was highly active for ammonia synthesis, demonstrating a high rate up to 9500 μmol $g^{-1}_{active\ phase}$ h^{-1} at 400 °C under ambient pressure in steady state conditions, and did not suffer from any deactivation after 15 days of reaction. The apparent activation energy (E_a) was found to be in the range of 68 to 74 kJ mol^{-1} which aligns with the value reported for highly active catalysts such as Li-MT, Mn_4N-BaH_2, $Ru/C_{12}A_7{:}e^-$, and $BaTiO_{2.5}H_{0.5}$. This improved catalyst may decrease the energy consumption in synthesis of ammonia and its derivatives, as well as facilitate the use of ammonia as a hydrogen carrier for renewable energy storage. Numerous characterization techniques were used to analyze the catalysts including, XRD, SEM, TEM, H2-TPR, XPS, EPR and ICP to understand their unique properties. Post-reaction analysis revealed partial substitution of lattice carbon with nitrogen, as well as partial reduction of Co^{2+} during ammonia synthesis. The catalytic activity profiles, supported by post-reaction catalysts characterization, suggest that active sites generated upon reaction might be cobalt decorated carbonitrides Co-$Mo_2C_{1-\delta}N_\delta T_x$. Upon reaching the steady state, the activity becomes stable upon cycling between low- and high-temperature conditions with no induction time. The results reported in this work demonstrate the appropriate modification of Mo_2CT_x resulted in a high-performance ammonia synthesis catalyst capable of operating under mild reaction conditions in the intermittent regime.

MXene Nanosheet-Derived N, S-Codoped Quantum Dots for Ultrasensitive Detection of 3-Nitro-*L*-Tyrosine in Biological Fluids Nguyen Thi Ngoc Anh, Van Thanh Nguyen and Ruey-An Doong; National Tsing Hua University, Taiwan

3-Nitro-L-tyrosine (3NT) is an oxidative stress metabolite of neurodegenerative diseases, and the rapid and effective detection of 3NT in human fluids for early diagnosis is important. Herein, for the first time, the nitrogen, sulfur co-doped graphene quantum dots derived from nitrogen-doped Ti3C2Tx MXene nanosheet via the hydrothermal method in the presence of mercaptosuccinic acid was synthesized as an optical sensing probe to detect 3NT in human serum. Tetramethyl ammonium hydroxide, the nitrogen source and delamination agent, was used to prepare nitrogen-doped MXene nanosheets via one step at room temperature. The as-prepared NS-MXene QDs (NSMQDs) are uniform with an average size of 1.2 ± 0.6 nm, and can be stable in aqueous solution for at least 90 d to serve as the fluorescence probe. The N atoms in N-MXene reduce the restacking and aggregation of MXene nanosheets, while the sulfur dopant in NSMQDs increases the quantum yield from 6.2 to 12.1% as well as enhances the selectivity of 3NT over the other 12 interferences via coordination interaction with nitro group in 3NT. A linear range of 0.02 – 150 μM in PBS and 0.05 – 200 μM in human serum with a recovery of 97 – 108% for 3NT detection is observed. Moreover, the limit of detection can be lowered to 4.2 and 7 nM in PBS and 1× diluted human serum, respectively. Results obtained clearly indicate the potential application of the N-Ti3C2Tx derived NSMQD for effective detection of 3NT, which can open a window for the synthesis of doped MQDs via 2D MXene materials for ultrasensitive and selective detection of other biometabolites and biomarkers of neurodegenerative diseases in biological fluids.

Thermoplastic Polyurethane (TPU) Reinforced with $Ti_3C_2T_x$ MXene: Synthesis, Characterization, Properties and Computational Modelling Rodrigo M. Ronchi, Rafael K. Nishihora, Jeverson T. Arantes and Sydney F. Santos; Universidade Federal do ABC, Brazil

Thermoplastic polyurethanes are block copolymer consisting of alternating sequences of hard and soft segments (or domains). These materials are widely employed in industry for a wide range of applications which demands for high mechanical properties and wear resistance, good chemical stability, high formability at low temperatures, and high damping properties. Despite of these interesting properties, further improvements are still necessary to expand the use of TPU. In this context, the development of polymer based nanocomposites of TPU reinforced with MXenes appears as an attractive strategy to produce high-performance advanced materials with enhanced mechanical and tribological properties. Nanocomposite films of $Ti_3C_2T_x$ / TPU with concentrations 0, 0.25, 0.5, 0.75 and 1.0 wt% of MXene were produced and characterized by XRD, FTIR, XPS, SEM, DSC and TGA. Mechanical and tribological properties were assessed by nanohardness and nanotribological tests. Better results for mechanical properties and tribological behavior were found for the nanocomposites containing 0.5 and 0.75 wt.% of MXenes, respectively. In order to deeper understand the interaction between the TPU and $Ti_3C_2T_x$, the matrix / reinforcement interface was investigated by by first principles calculation through DFT. The obtained results showed that the TPU adsorption on the surface of $Ti_3C_2T_x$ MXene is strongly affected by the surface functional groups and adsorption sites. While fluorine and hydroxyl terminations favored the interaction with the polymer, oxygen terminated MXene was unstable in three of the four configurations simulated. These results indicate the relevance of MXenes surface chemistry to the properties of these composites.

10:45 AM NM01.08.08
A Search for The Long-Duration Storage Medium of Ti_2CTx MXene Chiranjit Roy; Technical University of Denmark, Denmark

Recently, a new family of 2D transition metal carbides and nitrides named MXenes has gained significant attention due to their excellent electrochemical and mechanical properties. But, poor chemical/ oxidation stability of MXene acts as a barrier in its widespread application. To date, oxidation stability of $Ti_3C_2T_x$ MXene has been mostly studied among all Ti-based MXene, due to its excellent capacitance and metallic conductivity. The lightest Ti_2CT_x MXene has secured less attention in the research field, although it has comparable physiochemical properties. It also degrades rapidly over time in ambient conditions, limiting its widespread implementation. In this regard, we have resolved the two challenging tasks to broaden the application of the most unstable Ti-based Ti_2CT_x MXene: the improvement of oxidation stability and the prolongation of their shelf life for further practical applications. To solve these problems, we have dispersed the Ti_2CT_x MXene in different solvents (organic and water) for an extended period of time (3 months) under ambient as well as freezing conditions and observed how it affects the oxidation stability. Finally, the results suggest that the suitable medium to store Ti_2CT_x MXene for 3 months is IPA or DMSO at -20°C or Water at -80°C. This work is suitable for a wide range of readers working on synthesis, stability and characterization of Ti_2CT_x MXene to explore its application in the field of Supercapacitors, Li-ion batteries (LIBs), EMI shielding and Hydrogen storage etc.

11:00 AM NM01.08.09
Voronoi Inspired Conductive and Healable Covalent Adaptable Thiourethane MXene Nanocomposites Michael Carey[1,2]; [1]Air Force Research Laboratory, United States; [2]Riverside Research Institute, United States

A novel thiourethane vitrimer (TUV) chemistry is presented, along with a method to directly produce micron sized vitrimer powders through a simple precipitation polymerization. These TUV powders can then be passed through a colloidal suspension of conductive 2D MXene, $Ti_3C_2T_x$. With pH adjustment, electrostatic attractions allow for conformal MXene coatings on these TUV powders. Neat and composite bulk samples are produced by hot-pressing non-coated or MXene coated TUV powders into panels or thin sheets with minimal processing intensity. The unique Voronoi inspired microstructure obtained by the fusing of these TUV particles is characterized by micro and nano computed tomography (CT), scanning electron microscopy (SEM), electron dispersive spectroscopy (EDS) and transmission electron microscopy (TEM), revealing the presence of MXene at the boundaries between thiourethane rich domains. This microstructure facilitates conductive composites with a very low percolation threshold, a 275% increase in Young's modulus, and a 50% increase in toughness compared to the control vitrimer. This re-healable, conductive, and mechanically robust

platform has great potential for a next-generation smart composite for various advanced applications.

11:15 AM NM01.08.10
Vacancy and Growth Modulation of Cobalt Hexacyanoferrate by Porous MXene for Zinc Ion Batteries Aiping Yu and Maiwen Zhang; University of Waterloo, Canada

Prussian blue analogues (PBAs) featuring with three-dimensional open framework are recognized as promising cathode candidates for Zinc-ion batteries, but unsatisfactory active site utilization, low conductivity and abundant structural vacancies have impeded fulfillment of their potential. In this work, a highly conductive in-plane porous MXene is for the first time adopted as a multifunctional host material to enhance cobalt hexacyanoferrate (CoHCF) growth and crystallinity. Particularly, the uniform MXene surface charges are identified to induce anisotropic and highly crystalline CoHCF, which are critical to alleviating the practical drawbacks commonly associated with the PBA family. Empowered by the targeted modification, the CoHCF nanotube on porous MXene composite realizes high surface area and low defectiveness, achieving a high capacity of 197 mAh g^{-1} at 0.1 A g^{-1} and robust capacity retention of 94.4% even over 3000 cycles of operation at 2.0 A g^{-1}. This composition strategy, utilizing MXene as a multifunctional template, enhances PBAs' surface area, conductivity, and crystallinity, optimizing cathode capacity and stability for ZIBs, and showcasing the potential for large-scale energy storage.

Keywords: Zinc-ion battery, Porous MXene, Prussian blue analogues, induce growth, low vacancy

11:30 AM NM01.08.11
Strategy for Highly Absorption-Dominated Electromagnetic Interference Shielding through Electrical Polarization and Triboelectrification Synergistic Effect in Surface-Patterned Ferroelectric Poly[(vinylidenefluoride-co-trifluoroethylene)-MXene] Composite Sol Lee and Junghyo Nah; Chungnam National University, Korea (the Republic of)

Extensive utilization of electronic devices and wireless equipment require human to take affirmative measures to weaken unwanted electromagnetic wave radiations. Herein, a ferroelectric poly[(vinylidenefluoride-co-trifluoroethylene) (P(VDF-TrFE)-MXene]-poly(3,4-ethylenedioxythiophene) (PEDOT) multilayered film is developed that can increase electromagnetic interference (EMI) shielding performance through electrical polarization. The MXene is encapsulated by a P(VDF-TrFE) matrix, which inhibits oxidation, and a highly conductive MXene is created conductive network resulting in enhancement EMI shielding effectiveness (EMI SE). Furthermore, the surface pattern inducing multiple scattering and PEDOT layer contributes to the increasing absorption due to the electrically conductive PEDOT. Thanks to the electrically polarized and negatively charged P(VDF-TrFE)-MXene, the composite film demonstrates superior EMI SE and absolute EMI SE (SSE_t) are exhibited remarkable ≈61 dB and 15230 dB cm^2g^{-1} with high absorptivity (0.87) at thickness of 120 μm in X-band. Additionally, P(VDF-TrFE)-MXene composite film is applicable to motion and thermo-resistive sensor due to the negatively charged P(VDF-TrFE) and thermo-resistive property of PEDOT, respectively, for multifunctionality. This work provides a feasible avenue for flexible absorption dominant EMI shielding materials via electrical polarization with remarkable EMI shielding performance.

Mxene Doped Supramolecular Composite Hydrogels for Antioxidant and Photothermal Antibacterial Studies Zakia Riaz; Shanghai Jiao Tong University, China

Bacterial infections and the harm caused by various reactive oxygen species (ROS) present a significant danger to human health. There is a strong need to discover an ideal biomaterial system with wide-ranging antibacterial and antioxidant abilities. This study introduces a novel supramolecular hydrogel composite with both antibacterial and antioxidant properties. The composite is created using a chiral L-phenylalanine-derivative matrix (LPFEG) and Mxene ($Ti_3C_2T_x$) as a filler material. Fourier transform infrared and circular dichroism spectroscopy confirm the existence of noncovalent interactions (such as hydrogen bonding and π-π interactions) between LPFEG and Mxene, along with a reversal in the chirality of LPFEG. Rheological analysis reveals that the composite hydrogels possess enhanced mechanical properties. This hydrogel system also exhibits a photothermal conversion efficiency of 40.79%, enabling effective broad-spectrum photothermal antibacterial activity against both Gram-positive (Staphylococcus aureus) and Gram-negative (Escherichia coli, Pseudomonas aeruginosa) bacteria. Additionally, Mxene contributes to the hydrogel's exceptional antioxidant capabilities by efficiently scavenging free radicals like DPPH, ABTS, and OH. These findings suggest that the Mxene-based chiral supramolecular composite hydrogel, with improved rheological, antibacterial, and antioxidant properties, holds significant promise for biomedical applications.

8:15 AM NM01/NM03.02
Synthesis of Chromium Carbide MXene nanosheets and its electrochemical analysis for energy storage application Shavita Salora[1,2], Suman Singh[1,2] and Amit Lochan Sharma[1,2]; [1]CSIR-Central Scientific Instruments Organization, Chandigarh, India, India; [2]Academy of Scientific and Innovative Research (AcSIR), India

MXene, a well known 2D transition metal carbide or nitride based material has been proved to be promising material for energy storage application. This material has gained significant attention due to their mechanical, electrical properties. In our study, the potential of chromium carbide MXene as an electrode material for energy storage applications has been investigated. The Chromium Carbide MXene opens up new avenues for energy storage owing to its electrical conductivity, mechanical properties, and high surface area.
Chromium MXene was synthesized by using $FeCl_3$, well known etchant to etch Al layer for Cr_2AlC and Ascorbic acid was used for the removal of by-products. Delamination of the layers was done by sonication the sample in DMSO. A comprehensive characterization of chromium carbide MXene, including structural, morphological and electrochemical has been performed to understand this material. Electrochemical performance is evaluated as an electrode material for Supercapacitor application in different electrolyte i.e. acidic, basic and neutral medium. Cyclic voltammetry and galvanostatic charge-discharge studies demonstrated energy storage capabilities of synthesized chromium carbide MXene with capacitance 188 F/g and energy density of 26.11Wh/Kg, excellent rate performance, and stability. This study sheds light on the potential of chromium carbide MXene as an electrode material for energy storage applications. The demonstrated electrochemical performance and the insights gained from this research pave the way for the design of MXene-based electrode materials, contributing to the development of energy storage devices.

8:20 AM NM01/NM03.03
Demonstration of Spin Hall Angle in Monolayer Xenes: A Proposed Template Swastik Sahoo[1], Satadeep Bhattacharjee[2] and Bhaskaran Muralidharan[1]; [1]IIT Bombay, India; [2]Korea Institute of Science and Technology, India

The capability of high-speed computing for spintronics has led to its development in the last two decades. The paramount acumen of controlling spin transport properties in non-magnetic materials is the usage of spin-orbit coupling (SOC). We propose a model to calculate the spin hall angle (SHA) for the elemental monolayers of group 4 with a buckled honeycomb structure, namely, silicene, germanene, and stanene. This model is based on Landauer-Buttiker formalism for quantum transport [1], and the device is introduced to some manual defects, manual dislocations, and interface-induced spin-orbit coupling. The SHA of these devices also illustrates the mesoscopic fluctuations, which can be a comparative measure for graphene and other metal devices. Further, the deviation of SHA of these Xenes follows the universal relationship regarding the longitudinal conductivity, which establishes the usefulness of the Xenes in the context of graphene. To validate our outcomes, we compare our results with experimental data and numerically exact real-space simulation results based on the nearest-neighbor tight binding (NNTB) model. This work will be a template to calculate spin-hall conductivity for all the elemental monolayers [2], considering the intrinsic scattering mechanism. Also, we look forward to calculate the spin transport parameters by taking heterostructures of monolayer Xenes, as mentioned above, with suitable materials like MoS2 [3]. This work can be further extended to explore the possible spintronics applications for extrinsic scattering, which includes side-jump and skew-jump [4] scattering processes.

Synthesis of Graphene Quantum Dots from Waste Material for Sustainable Application Dharmveer Yadav, Jyotiraman De, Saumaya Kirti, Sumit Saxena and Shobha Shukla; Indian Institute of Technology Bombay, India

As a 2D wonder material, graphene has excellent physical, chemical, and mechanical properties, leading to vast applications in electronics, water filtration, medicine and healthcare. Graphene quantum dots (GQD) can significantly enhance graphene's optical and electronic properties due to their size, expanding the scope of application in sensing, imaging, energy storage, and catalysis. However, their large-scale production often involves resource-intensive methods. Therefore, this study explores an innovative and eco-friendly method for synthesizing GQDs using waste materials as a carbon source. In this research, waste materials, such as biomass-derived precursors, are converted into high-quality GQDs through controlled pyrolysis to tailor the size, morphology, and surface functionalization of the GQDs. The resulting GQDs were characterized using advanced analytical techniques, confirming their structural and chemical properties. The sustainable GQDs obtained from waste materials demonstrated excellent performance in diverse water applications, including filtration and sensing of contaminates. Developed GQDs have been incorporated into polymer membranes to enhance membrane performance in terms of permeability and separation efficiency. Moreover, using waste materials as feedstock reduced the environmental impact and contributed to waste valorization and resource efficiency. The utilization of waste materials for GQD synthesis aligns with the principles of green chemistry and supports the transition towards a circular and sustainable economy. As the demand for GQDs continues to grow, this research provides a novel and eco-conscious approach to meet this demand while minimizing the environmental footprint.

High-Dimensional Approaches for Immune Profiling of 2D Materials Lucia G. Delogu; Unviersity of Padua, Italy

We recently depicted the “Nano-immunity-by-design” where the characterization of 2D materials is not solely based on their physical-chemical parameters but also on their immuneprofiling. [1] The immune-profiling can be revealed on its complexity by unique, informative ways: high dimensional approaches. [2,3] We exploited high-dimensional approaches, such as single-cell mass cytometry and imaging mass cytometry on graphene and other novel two dimensional materials, such as transition metal carbides/carbonitrides (MXenes). [4-6] We revealed that the amino-functionalization of graphene oxide increased its immunocompatibility. [4] Moreover, we combined graphene with AgInS2 nanocrystals, enabling its detection by single-cell mass cytometry on a large variety of primary immune cells. [5] Recently, we reported the immune modulation of specific MXenes, and their label-free detection by single-cell mass cytometry and other high dimensional approaches. [6-7] Together with our published works, I will present unpublished results on a wider variety of novel 2D materials, Mxenes, MoS2, WS2, and bismuthene. Our results conceptualize that chemical and immnological designs of 2D materials offer new strategies for their safe exploitation in biomedicine.

9:20 AM NM01/NM03.06
Multiwalled Carbon Nanotubes and CuO Nanoparticles Composite based H_2S Sensors Sumit Kumar and Mahesh Kumar; Indian Institute of Technology Jodhpur, India

H_2S is an extremely hazardous air pollutant that harms the human respiratory system and world ecosystems. The main sources of H_2S emissions are sewage, petroleum industries, and natural gas. The demand for some sensing mechanism to monitor its emissions is paramount. Herein, we demonstrate CuO nanoparticles and multiwalled carbon nanotubes (MWCNTs)-based H_2S sensors. The conventional chemical vapor deposition technique (CVD) is used for growing MWCNTs. The optimal amount of MWCNTs and CuO nanoparticles in the composite enhanced the H_2S sensor response. The experimental data confirmed that the bare CuO sensor response ($\Delta R/R\%$) for 1 ppm H_2S was 31%; further MWCNTs/CuO heterojunction sensor responses reached 53%. The enhanced sensing characteristics are a result of the formation of nano-heterojunctions between MWCNTs and CuO nanoparticles, which enhance the chemical and electronic sensitization properties. In addition, the heterojunction sensor demonstrated excellent H_2S selectivity over other

oxidizing and reducing gases.

9:25 AM NM01/NM03.07
New Mechanics in Cell-Nanomaterial Interactions: Boron Nitride Nanosheets Inducing Water Channels Across Lipid Bilayers Xuliang Qian[1], Matteo Andrea Lucherelli[2], Wenpeng Zhu[3], Paolo Samorì[4], Huajian Gao[1], Alberto Bianco[2] and Annette von dem Bussche[5]; [1]Nanyang Technological University, Singapore; [2]CNRS, Immunology, Immunopathology and Therapeutic Chemistry, France; [3]Sun Yat-sen University, China; [4]University of Strasbourg, France; [5]Brown University, United States

Understanding the interaction between two-dimensional (2D) materials and cell membranes is pivotal for nanomedicine and safe nanotechnology applications. In this study, we investigate how hexagonal boron nitride (hBN) interacts with the cell membrane by combining molecular dynamics (MD) simulations and in vitro experiments. Our MD simulations reveal that sharp hBN wedges can penetrate lipid bilayers, forming cross-membrane water channels along their exposed polar edges, a behavior not exhibited by round hBN sheets. We hypothesize that such water channels can facilitate cross-membrane transport, potentially leading to lysosomal membrane permeabilization. To test this hypothesis, we prepared two types of hBN nanosheets, the former with a cornered morphology and the latter with a round morphology, and exposed human lung epithelial cells to both hBN nanosheets. The cornered hBN with exposed polar edges resulted in a dose dependent cytotoxic effect, whereas round hBN did not cause significant toxicity, thus confirming our hypothesis. These results highlight the significance of 2D materials in facilitating nanoscale water and molecular transport across lipid membranes and have substantial implications for the design of hBN-based drug delivery systems and safe design of future advanced hBN containing composites and devices.

Low Temperature Electron Transport study on Inkjet Printed Ti3C2Tx and Filtrated Ti3C2Tx-Ti3AlC2 Nanosheet Thin Films Mi-Jin Jin; Institute for Basic Science, Korea (the Republic of)

Ti3C2Tx, most common structure of MXenes tunably show semiconductor behavior in their percolated thin-film structure. Magnetoconductance studies of thin-film MXenes are important to understanding their electronic transport properties and charge carrier dynamics, and also to appraise their potential for spintronics and magnetoelectronics. Also, it is desirable to develop deposition strategies such as inkjet printing, filtration that would enable direct patterning with complex structures/networks. Here, we investigate the extrinsic negative magnetoconductance of inkjet printed Ti3C2Tx MXene thin films and simply filtrated Ti3C2Tx-Ti3AlC2 nanosheet thin film. Both of inkjet-printing and filtration process has advantage for simple patterning of a device. Importantly, we report a crossover from weak anti-localization (WAL) to weak localization (WL) near 2.5K for both thin-film system but shows strong scale dependence for different materials element system. The WAL is consistent with strong, extrinsic, spin orbit coupling. From the magnetoconductance analysis, we estimate that the printed MXene thin-film has a strong spin orbit coupling field. Our results and analyses offer detailed understanding into microscopic charge carrier transport in Ti3C2Tx, and Ti3C2Tx-Ti3AlC2 nanosheet thin films

Optical Hyperpolarization of Nuclear Spins in Nanodiamonds Fedor Jelezko; Ulm University, Germany

Dynamic nuclear spin polarization allows to enhance signals in NMR and MRI by orders in magnitude. We show that electron spin of NV centers in diamond can be used as efficient source of nuclear spin polarization allowing to orient nuclear spins associated with ^{13}C in nanodiamonds. We show that coherent control tools allow to realize efficient polarization transfer in randomly oriented nanodiamonds including isotopically engineered diamond nanoparticles. Efficient hyperpolarization together with long spin lattice relaxation time of diamond nuclear spins has the potential for applications in magnetic resonance imaging. Furthermore, hyperpolarized nanodiamonds can be employed as spin batterie for polarization transfer to external nuclear

spins.

11:00 AM *NM02.01.02
Engineering Nanodiamonds for Quantum-Enhanced Bio-Sensing Philip Hemmer; Texas A&M University, United States

Diamond color centers like the nitrogen-vacancy (NV) have shown much promise for nanoscale sensing of magnetic and electric fields and temperature. So far however the quantum properties of the NV have not been used to full advantage, for example quantum entanglement of NV qubits has rarely been used for sensing. In this talk I will review recent advances in the fabrication of NVs, and other magnetic color centers in diamond, and in the growth of high quality nanodiamonds. Combining these advances, I will discuss the future prospects of engineering quantum-enhanced sensors in nanodiamonds.

11:30 AM *NM02.01.03
Long Spin Coherence and Relaxation Times of Nitrogen-Vacancy Centres in Nanodiamonds Gavin W. Morley; University of Warwick, United Kingdom

The negatively charged nitrogen-vacancy center (NVC) in diamond has been utilized in a wide variety of sensing applications. The long spin coherence and relaxation times (T_2*, T_2 and T_1) of the center at room temperature are crucial to this, as they often limit sensitivity. Using NVCs in nanodiamonds allows for operations in environments inaccessible to bulk diamond, such as intracellular sensing. We report long spin coherence and relaxation times at room temperature for single NVCs in isotopically purified polycrystalline ball-milled nanodiamonds. Using a spin-locking pulse sequence, we observe spin coherence times, T_2, up to 786 ± 200 μs. We also measure T_2* times up to 2.06 ± 0.24 μs and T_1 times up to 4.32 ± 0.60 ms.

We also magnetically levitate micron-sized diamonds in vacuum towards putting them into a superposition of being in two places at once. This provides a platform for testing fundamental physics which could include, in time, a test of the quantum nature of gravity.

SESSION NM02.02: Biological Applications of Nanodiamond Sensors
Session Chairs: Yuen Hui and Alexander Shames
Tuesday Afternoon, April 23, 2024
Room 338, Level 3, Summit

1:30 PM *NM02.02.01
Diamond Quantum Sensing Microscopy of Spin Crossover and Cytochrome C Molecules Abdelghani Laraoui[1], Suvechhya Lamichhane[1], Rupak Timalsina[1], Kayleigh McElveen[1], Cody Schultz[1], Adam Erickson[1], Ilja Fescenko[2], Kapildeb Ambal[3], Shuo Sun[1], Yinsheng Guo[1], Sy-Hwang Liou[1] and Rebecca Lai[1]; [1]University of Nebraska-Lincoln, United States; [2]University of Latvia, Lao People's Democratic Republic; [3]Wichita State University, United States

Diamond Quantum sensing (DQS) microscopy based on nitrogen vacancy (NV) centers has become a unique tool to probe weak static and fluctuating magnetic fields with an excellent combination of spatial resolution and magnetic sensitivity, opening new routes to study solid-state [1] and biological materials [2]. In this work, we present two examples of using DQS in wide-field geometry to probe nanoscale magnetic phenomena in molecules.
First, we discuss DQS wide-field microscopy measurements on individual $Fe(Htrz)_2(trz)](BF_4)$] (Fe triazole) spin-crossover (SCO) nano-rods of size varying from 20 to 1000 nm. Fe triazole SCO molecules show thermal switching between low spin (LS) and high spin (HS) states which are applicable in thermal sensors and molecular switches. While the bulk magnetic properties of these molecules are widely studied by bulk magnetometry techniques, their properties at the individual level are not yet explored. Scanning electron microscopy (SEM) and Raman spectroscopy are performed to determine the size of the nano-rods and to confirm the spin state (LS vs HS) of the Fe triazole molecule respectively [3]. The stray magnetic fields produced by individual nano-rods are imaged by DQS microscopy as a function of temperature (up to 150 ^{0}C) and applied magnetic field (up to 350 mT) and correlated with SEM and Raman. We found that in most of the nanorods the LS state is slightly paramagnetic, probably originating from the surface oxidation and/or the greater Fe^{+3} presence along the nanorods' edges. NV measurements on the Fe-triazole LS state nanoparticle clusters revealed both diamagnetic and paramagnetic behaviors [3].
Then, we show DQS wide-field microscpy measurements on cytochrome C (Cyt-C) nanoclustered molecules. Cyt-C is an iron-containing biomolecule that plays an important role in the electron transport chain of mitochondria [4]. Under ambient conditions, the heme group remains in the Fe^{+3} paramagnetic state [5]. Initially, we performed NV T_1 relaxometry measurements on a carboxylated diamond chip doped with 8-nm thick NV-layer without any Cyt-C, which revealed a relaxation time T_1 of ~ 1.2 ms. Subsequently, we varied the concentration of Cyt-C from 6 mM to 54 mM and show a reduction of the NV relaxation time T_1 from ~ 800 μs to 150 μs respectively, explained by the spin noise generated from the intracellular iron spins in the Cyt-C molecules [6]. Additionally, we performed magnetic relaxometry imaging of Cyt-C proteins on a nanostructured diamond substrate by which we estimate the density of adsorbed iron from 1.44×10^6 to 1.7×10^7 per μm^2 [6]. 2:00 PM *NM02.02.02
On The Optimal Chemical Interface of Diamond for Quantum Biosensing Petr Cigler; Institute of Organic Chemistry and Biochemistry of The CAS, Czechia

Non-perturbing sensing techniques applicable to biological systems are currently of central interest in the biosciences. Nanodiamond (ND) is a highly biocompatible nanomaterial for construction of nanosensors, which can accommodate nitrogen-vacancy (NV) centers. The NV spin properties can be read optically, which enables design of various probes based on quantum mechanical interactions. NDs can be exposed to biological environment and report sensitively on the spin-related processes occurring in a close vicinity of the particle employing for example the NV spin relaxometry measurements. ND relaxometry however reaches its limitations in terms of poor colloidal stability in physiological environment and non-specificity to detect only the magnetic field originated from the spins of interest.

To ensure colloidal stability in biologically-relevant environment we stabilize ND probes using thin polymer coatings that can be further modified to allow sensing of specific physical quantities or targeted molecules. To that end, we design molecular transducers for transposing the presence of particular analytes to a selective and unambiguous readout. Different types and concepts of surface architectures including those for selective measurements of pH, temperature, redox potential, and ascorbate concentration under physiological conditions will be discussed. Additionally, our recent developments of ND probes for detection of biomolecules using relaxometry together with a proof-of principle results will be presented.

3:00 PM NM02.02.03
Detection of Alzheimer's Disease Through Fluorescent Nanodiamonds-Based Spin-Enhanced Lateral Flow Immunoassay Stefanny Angela[1], Wesley Wei-Wen Hsiao[1], Gianna Fadhilah[1], Trong-Nghia Le[2], Huan-Cheng Chang[2] and Wei-Hung Chiang[1]; [1]National Taiwan University of Science and Technology, Taiwan; [2]Academia Sinica, Taiwan

Fluorescent nanodiamond (FND) has recently been regarded as a superior alternative reporter for lateral flow immunoassays (LFIA). The negatively charged nitrogen-vacancy (NV^-) center in FND is a point defect with unique magneto-optical properties, giving outstanding characteristics to detect biomarkers of diseases. Alzheimer's disease (AD) is the most common form of dementia, characterized by decreased memory, thinking, cognition, behavior, personality, and ability to conduct everyday duties, which might result in complete brain failure and, eventually, death. The two most commonly used detection techniques to detect changes in the brain caused by AD are brain imaging (CT, MRI, PET) and lumbar puncture. However, while brain imaging is costly and time-consuming, lumbar puncture is controversial since 30% of patients get severe headaches followed by nausea and vomiting lasting more than a week. To this end, we have developed a Spin-Enhanced Lateral Flow Immuno-Assay (SELFIA) for non-invasive AD diagnostics utilizing the spin properties of the NV^- centers in FND to achieve background-free ultrasensitive detection. In addition, to enhance sensitivity and specificity, we employed a sandwich assay of SELFIA to further noncovalently conjugate FND to anti-pTau antibodies toward detecting pTau protein (a critical AD biomarker involved in AD pathology), while the capture antibody immobilized on the membrane. Note that we have a comparable result with Enzyme-Linked Immunosorbent Assay (ELISA), as our FND-based SELFIA only requires approximately 30 minutes to reach a detection limit of 7 pg/mL for pTau (the sensitivity/specificity threshold is 15 pg/mL in plasma). Hopefully, this study will contribute to developing a safe, simple, and accurate AD detection platform that can identify this illness in its earliest stages and might also be applied to other diseases in precision health.

3:15 PM *NM02.02.04
Intracellular Thermometry with Fluorescent Polymer Sensors and Nanodiamonds Yoshie Harada; Osaka University, Japan

Intracellular temperature fluctuations are thought to be closely related to higher order cellular phenomena. We have developed a method for imaging the temperature distribution in single living cells using a fluorescent polymer thermometer and fluorescence lifetime imaging microscopy to study the effects of intracellular temperature on cellular physiological activity. Previous experiments using the developed method have shown that during the G1 phase, the temperature of the nucleus is approximately 1°C higher than the temperature of the cytoplasm, as well as some mitochondria and centrosomes. The mechanisms that maintain this intracellular temperature heterogeneity and its physiological significance are not well understood. Recently, however, the mechanisms of physiological phenomena caused by fluctuations in intracellular temperature have begun to be elucidated. We hypothesized that intracellularly generated heat is not only a product of reactions, but also drives cellular responses. To test this hypothesis, we focused on cell differentiation, in which cells dramatically change their protein expression patterns. Using the neuronal model cell PC12, we investigated the relationship between neuronal differentiation and intracellular temperature. The results showed that intracellular temperature is involved in neuronal differentiation and associated neurite outgrowth. In addition to the aforementioned fluorescent polymer temperature sensor and fluorescence lifetime imaging microscopy, we also measured temperature using fluorescent nanodiamond particles containing negatively charged nitrogen vacancy centers as temperature sensors. We have previously shown that fluorescent nanodiamonds are able to measure temperature independent of external environmental influences such as pH, salt, and viscosity. To measure intracellular thermal conductivity, we also fabricated nanoparticles coated with polydopamine, which generates heat when exposed to light, around fluorescent nanodiamonds. Although the intracellular thermal conductivity has been assumed to be the same as the thermal conductivity of water, whether this is true or not was verified by actually measuring the intracellular thermal conductivity using the fabricated hybrid particles of polydopamine and fluorescent nanodiamonds. The results showed that, although the data were very uneven, on average the thermal conductivity inside the cell was several times smaller than the conductivity of water. In the present study, it is clear from microscopic observations that the hybrid particles are present inside the cell, but it is not known where in the cell they are localized. The variability of the data suggests variations in thermal conductivity depending on the location within the cell. Future work will use techniques to chemically modify the surface of the polydopamine-fluorescent nanodiamond hybrid particles, such as localizing the particles in mitochondria and nuclei, to measure thermal conductivity at different local positions in the cell to clarify what exactly produces such low thermal conductivity.

3:45 PM NM02.02.05
Diamond-Based Quantum Sensing of Free Radicals in Migrating Human Breast Cancer Cells Claudia R. Reyes San Martin[1], Arturo Elias-Llumbet[1,2], Marcia Manterola[2], Aldona Mzyk[3] and Romana Schirhagl[1]; [1]University Medical Center Groningen, Netherlands; [2]University of Chile, Chile; [3]Technical University of Denmark, Denmark

Cell migration is a crucial parameter for disease progression in cancer. It is known that ROS levels are involved in the regulation of the migration process, however, the exact role of free radical generation and where it occurs is unknown. Here we use a diamond-based quantum sensing technique to detect free radical generation during cancer cell migration in real time with subcellular resolution. We investigated highly metastatic MDA-MB-231 human breast cancer cells and observed free radical formation after 16 hours of starvation and 24 h of migration under low-serum conditions. Intracellular diamond dynamics was monitored at different migration points (0, 12, and 24 h), and cell morphology was evaluated. Additionally, the number of focal adhesions was analyzed as an indicator of the migratory potential of the cells. All the parameters were addressed using a homemade script on the FIJI platform. We further measured free radical generation under NOX2 inhibition by apocynin. We found that free radical levels decreased after 24 h treatment with 36 µg/mL apocynin while the levels of ROS increased and also the migratory capacity of the cells. Our results evidence the complexity of the redox regulation in migrating cancer cells and offer a novel approach to specifically and locally interrogate pivotal players of the oxidative network behind metastatic success.

Synergistic Effects of Nanoparticle Geometric Shape and Post Curing on Nanodiamond-Reinforced Epoxy Nanocomposites: Characterization, Microstructure and Mechanical Properties Dawei Zhang, Ying Huang and Xingyu Wang; North Dakota State University, United States

Nanodiamond, a significant member of carbon-based nanoparticles, is characterized by a spherical geometric shape and typically classified as a 0-D material due to the extremely small diameter of individual nanoparticles. The unique characteristics of nanodiamonds distinguish them from other carbon-based nanoparticles and have gained considerable interest in the fields of medicine, electronics, sensors, and particularly as nanofillers in polymeric

nanocomposites. One of the primary challenges associated with nanoparticle-reinforced nanocomposites is achieving a homogeneous and consistent dispersion of the nanoparticles within the polymer matrix. Compared to other commonly used carbon-based nanoparticles such as cylindrical carbon nanotubes and planar graphene, the enormous differences in shape and dimension may inevitably lead to notable variations in dispersion, which further greatly influences the overall properties of reinforced nanocomposites. This study explores the dispersion characteristics of nanodiamond in epoxy nanocomposites and examines the resulting effects on viscosity, microstructure, and mechanical properties of the epoxy nanocomposites. Systematic comparisons are made between nanodiamond along with carbon nanotube and graphene, while also considering the synergistic effects with post curing of epoxy. Experimental results indicate that the nanodiamond-reinforced epoxy nanocomposite exhibit a more homogenous nanoparticle dispersion, lower viscosity, reduced porosity, and stronger pull-off adhesion, while the graphene-reinforced epoxy nanocomposites achieve a higher lap shear strength. Although post curing is effective in reducing porosity and improving adhesion properties of the nanocomposites, its impact became less pronounced with the addition of nanoparticles.

Photophysical Characterization of Non-Covalently Bound Porphyrin-Nanodiamond Assemblies in Water William A. Maza, Daniel Ratchford, Adam D. Dunkelberger and Jeffrey C. Owrutsky; US Naval Research Laboratory, United States

Photoinduced charge transfer dynamics between nanodiamond, ND, particles and adsorbed dyes can potentially provide the necessary driving force to induce chemical reactions. We present steady-state and time-resolved fluorescence and UV-visible absorption data of self-assembled aggregates of the free-base porphyrin meso-(tetracarboxyphenyl)porphyrin, H_2TCPP, and surface modified ND. Surface modification of H-terminated nanodiamond was carried out by the laser ablation method in water which has been reported to result in a OH-rich surface of ND, OHND. Interactions between H_2TCPP and OHND in water result in a bathochromic shift of the porphyrin Soret band and a quenching of both the porphyrin singlet and triplet state. The results are discussed in the context of what is known regarding the energetics of ND in solution and a model of porphyrin quenching by OHND is proposed.

Improving The Creation of SiV Centers in Diamond via Sub- Pulsed Annealing Treatment Yan-Kai Tzeng; SLAC National Accelerator Laboratory, United States

Silicon-vacancy (SiV) centers in diamond are emerging as promising quantum emitters in applications such as quantum communication and quantum information processing. Here, we demonstrate a sub- pulsed annealing treatment that dramatically increases the photoluminescence of SiV centers in diamond. Using a silane-functionalized adamantane precursor and a laser-heated diamond anvil cell, the temperature and energy conditions required to form SiV centers in diamond were mapped out via an optical thermometry system with an accuracy of ± 50 K and a 1 temporal resolution. Annealing scheme studies reveal that pulsed annealing can obviously minimize the migration of SiV centers out of the diamond lattice, and a 2.5-fold increase in the number of emitting centers was achieved using a series of 200-ns pulses at 50 kHz repetition rate via acousto-optic modulation. Our study provides a novel pulsed annealing treatment approach to improve the efficiency of the creation of SiV centers in diamond.

Carbon Dots: Visible Light Activated Antimicrobial Functions and Their Property-Function Correlations Liju Yang[1], Yongan Tang[1] and Ya-Ping Sun[2]; [1]North Carolina Central University, United States; [2]Clemson University, United States

Carbon dots (CDots), generally defined as small carbon nanoparticles (CNPs) with various surface passivation schemes, represent the nanoscale carbon allotrope at zero-dimension. Attributed to the π-plasmon-associated electronic transitions, CDots have remarkable broad optical absorptions in the entire visible spectrum, extending into both near-UV and near-IR, making them excellent visible light-excitable agents.
In recent years, a large number of studies have provided strong evidence to support the establishment of CDots as a new class of effective and efficient visible/natural light-activated antimicrobial agents. Experimentally, our teams have demonstrated the highly effective photoactive antimicrobial activities of CDots against various bacteria and viruses, ranging from laboratory model bacteria (*E. coli, Bacillus subtilis*), pathogenic foodborne pathogens (*Listeria, Salmonella*), to multi-drug resistant (MDR) nosocomial pathogens (*Enterococcus*), and biofilms, as well as various viruses (model MS2 virus, vesicular stomatitis virus (VSV), marine norovirus (MNV), and norovirus virus-like-particles (VLPs).
Mechanistically, upon photoexcitation on CDots, there are rapid charge transfers and separation to form electrons and holes redox pairs, followed by the radiative recombinations of the separated redox pairs resulting in emissive excited states, which are responsible for the bright fluorescence as well as the photodynamic production of classical reactive oxygen species (ROS). It is the combined action of the initially separated redox pairs and the generated classical ROS that are responsible for the observed uniquely effective photoactivated antimicrobial function of CDots. Associated oxidative damages in CDots-treated bacterial cells have been confirmed, including elevated levels of lipid peroxidation, increased membrane permeability, and cytoplasmic structural disruptions. Degradation in viral proteins and genomic RNAs have also been confirmed.
The presentation will also include the insights on property-function correlations in CDots for their photoactivated antimicrobial activities . Extensive experimental results have revealed that the optical properties, the surface functional groups and charges, the passivation layers of CDots, as well as the synthesis processes, are highly correlated with their photoinduced antimicrobial functions. Such correlations make CDots to be excellent tunable and expandable material platforms for further improvement in their desirable functions. Along with their non-toxic nature, CDots open up new opportunities for the development of highly potent carbon-based non-traditional photodynamic antimicrobial agents.

Mechanical Properties of 2D Hexagonal Diamond Fabricated by Electrodeposition Daniel Choi and Mohammed Afif; Khalifa University of Science and Technology, United Arab Emirates

Hexagonal Diamond is also popularly known as Lonsdaleite in an honor of Kathleen Lonsdale. Hexagonal diamonds are naturally occurred when meteorites strike surface of earth at very high velocities, due to high temperature and pressure of impact some parts of graphite present in meteorites turns in to hexagonal diamond. These hexagonal diamonds are unique and possess exceptional physical and electronic properties. Fabrication of hexagonal diamond using anodized aluminum oxide (AAO) nanoporous template is performed by two steps electrodeposition process. Initially, cobalt nanowires are deposited in the nanocavities of AAO template by applying constant current (galvanostatic) across the electrodes. Subsequently, hexagonal diamonds are deposited over cobalt nanowires by applying constant voltage (potentiostatic). Acetonitrile and methanol of 1:1 ratio homogeneous solution was used as an electrolyte in second stage diamond deposition process. The yield of diamonds was increased by keeping the crystallography of cobalt nanowires similar to crystal structure of hexagonal diamond by altering the pH of cobalt sulphate aqueous solution. HRTEM and STEM-EDS experiments were initially performed on the samples deposited. HRTEM with probe corrector, at operating voltage of 300 kV was used to analyze all the samples, occasionally. An elemental analysis was performed on AAO crystals and hexagonal diamond particles, spectrum from AAO and hexagonal diamond particles. HRTEM bright field and diffraction studies were performed on Individual Hexagonal diamond particles and acquired diffraction patterns are indexed with Lonsdaleite diffraction data obtained from crystallographic database. The ZA [001] of diffraction data matched with the experimental data and d-spacing of high-order reflections of experimental diffraction pattern matched with standard data with minimum deviation. Investigation of mechanical and electrical properties by Atomic Force Microscopy (AFM) is in progress. As preliminary results, the elastic modulus and thin-film resistivity of hexagonal diamond are found to be 800-900GPa and 10-100 GW·m, respectively.

9:15 AM NM02.04.05
Imaging and Sensing Extreme Ultraviolet Radiation with Nanodiamonds containing Nitrogen-Vacancy Centers Yuen Y. Hui[1], Teng-I Yang[2] and Huan-Cheng Chang[1]; [1]Academia Sinica, Taiwan; [2]National Applied Research Laboratories, Taiwan

Extreme ultraviolet (EUV) radiation with wavelengths ranging from 121 nm to 10 nm has been applied for photolithography to fabricate nanoelectronic devices. This study demonstrates that Fluorescent NanoDiamonds (FNDs) containing Nitrogen-Vacancy (NV) centers as scintillators to image and characterize EUV radiations. The FNDs employed are ∼100 nm in size; they form a uniform and stable thin film (∼1 μm in thickness) on an indium−tin−oxide-coated slide by electrospray deposition. The film is non-hygroscopic and photostable and can emit bright red fluorescence from the neutral NV centers when excited by EUV light. An FND-based imaging device has been developed for beam diagnostics of 50 nm and 13.5 nm synchrotron radiations respectively, achieving a spatial resolution of 30 μm. The noise equivalent power density is 29 $\mu W/(cm^2\ Hz^{1/2})$ for the 13.5 nm radiation. Our method can be extended to the imaging of Vacuum Ultraviolet radiation and soft X-ray.

Shape Induced Enhanced Fluorescence in Fluorescent Nanodiamond revealed by Correlative Transmission Electron Microscopy and Photoluminescence Microscopy Shery Chang; University of New South Wales, Australia

Fluorescent nanodiamonds (FNDs) are diamond nanoparticles containing color centers that emit visible light at room temperature. Among the color centers in FNDs, the nitrogen-vacancy centers (NV) have drawn the most attention due to its exceptionally stable optical properties and great prospect in sensing and biomedical diagnostic applications.

The current understanding of the optical properties of the FNDs relies largely on the optical measurement methods from either ensemble of materials or from few single particles. As most of the FND fabrication is a top-down process where larger diamond crystals are milled to desired nanometer size, FNDs generally have broad size distribution and irregular shapes. Therefore understanding of FNDs structure-property relationship using ensemble measurements only is insufficient.
We have developed a new method based on correlative transmission electron microscopy and photoluminescence (TEMPL)[1]. TEMPL allows a direct correlation of the fluorescence brightness and three-dimensional size and shape of individual nanoparticles. PL provides optical information with exquisite energy resolution, and TEM provides structural information with exquisite spatial resolution. Unsupervised machine learning (ML) with the generalized 3D shape descriptors, is used to analyse correlations between the PL brightness and 3D shape of FND particles. The automation provided by machine learning allows TEMPL to be applied to large sample areas (2-3 orders of magnitude larger than a typical TEM field of view) containing a statistically significant number of particles.
Using this new method, we directly reveal that the volume-averaged PL brightness of thin, flake-like nanodiamond particles is up to several times greater than that of three-dimensional-shaped, thicker particles provided the particle diameter is less than the sub- wavelength limit. With the assumption that the number of NVs within a particle is proportional to its volume, this implies that individual NVs within thinner particles are brighter. This experimental observation is supported by the theoretical simulations on simplified particle geometries on a range of supporting substrate and surrounding medium. The simulations indicates that the comparative brightness of thinner particles, either on a thin supporting substrate or in a low- index medium, is attributable, at least in part, to the constructive interference of partial light waves in these particles. With increasing particle thickness, such an effect becomes damped. The sub-wavelength dimension of the substrate plays an important role, as it results in higher effective reflectivity comparable to diamond particles in a low-index medium (e.g., a low- index solution).
In addition to correlative PL with TEM, we have also carried out correlative SEM and AFM for the study of FNDs supported on bulk substrate. Our overall results help to guide new routes of enhancing fluorescence brightness of FNDs for broad sensing applications.

9:45 AM NM02.04.07
Control of Synthesis and Structural Analysis of Poly(glycerol) Functionalized Nanodiamonds Masahiro Nishikawa[1,2], Ming Liu[1], Taro Yoshikawa[1], Hidekazu Takeuchi[1], Naoyoshi Matsuno[1] and Naoki Komatsu[2]; [1]Daicel Corporation, Japan; [2]Kyoto University, Japan

Poly(glycerol) (PG) functionalization is one of the most common surface functionalization methods for a variety of nanoparticles (NPs). The hyperbranched hydrophilic polymer on NP surface gives advantageous features; dispersibility in aqueous media with high ionic concentration and

extensibility for further functionalization through abundant -OH group. In addition, PG layer suppresses the adsorption of serum proteins in physiological environment to evade immune response or other non-specific interactions.
For PG functionalized nanodiamonds (ND-PG), to enable material and process design more quantitatively, we conducted the analyses of PG functionalization reaction, in which ring opening polymerization of glycidol (GD) on ND surface is done in ethylene glycol (EG) as a solvent, and structure of ND-PGs. As a result, we found that the amount of PG can be precisely controlled by the reaction conditions, use amount of GD and EG, and properties of ND core, oxygen content and particle size. In the structural analysis, the abundance ratios of substructures of glycerol unit in PG chain and the thicknesses of PG layer in dispersion for ND-PGs of different PG amounts and ND cores were elucidated by NMR, TGA and DLS.

Paramagnetic Defects in e-Beam Irradiated and Annealed Polycrystalline Nanodiamonds Produced by External Shock-Wave Detonation Synthesis Alexander I. Shames[1], Frederick T. So[2,2,3], Takuya F. Segawa[4], Shinobu Onoda[3], Hideaki Takashima[2,5], Takeshi Ohshima[3,6], Shigeki Takeuchi[2], Masahiro Shirakawa[2,3] and Norikazu Mizuochi[2,2]; [1]Ben-Gurion University of the Negev, Israel; [2]Kyoto University, Japan; [3]National Institutes for Quantum Science and Technology, Japan; [4]ETH Zurich, Switzerland; [5]Chitose Institute of Science and Technology, Japan; [6]Tohoku University, Japan

PolyCrystalline NanoDiamonds (PCNDs), manufactured by an external shock-wave detonation (the DuPont method), are among directly synthesized diamond nanoparticles which attract growing interest to their use in biomedical and quantum sensing application. In contrast to detonation nanodiamonds (DNDs), origin and evolution of paramagnetic defects in PCNDs induced by various treatments such as thorough purification, irradiation, annealing were beyond the scope of diamond community. We report on results of room temperature electron paramagnetic resonance (EPR) experiments done on a series of PCND samples undergone purification and e-beam irradiation at increasing fluences up to 1×10^{19} e^-/cm^2 followed by standard annealing at 800 ºC. The paramagnetic defects' pool in all samples consists of high abundant primary defects (mostly of $S = 1/2$) and low abundant triplet ($S = 1$) defects [1]. The total content of primary defects in the pristine PCND sample reaches 1280 ppm whereas the content of triplet NV^- centers does not exceed 35 ppb. Boiling acid treatment of the non-irradiated and non-annealed sample PCND-BA causes significant reduction of primary defects (down to ~780 ppm) but does not really affect triplet centers. Annealing of that sample retains the content of all defects untouched, however causes prolongation of spin-lattice relaxation times of primary defects. Deconvolution of the intense singlet quasi-Lorentzian line of primary defects into broad and narrow components allowed attributing these components to dangling bonds (broad) and exchange coupled P1 centers (narrow) [2]. The content of dangling bonds in the annealed PCND-BA sample was estimated as ~620 ppm and that of P1 of ~160 ppm. E-beam irradiation (fluences 1×10^{18}, 3×10^{18}, 5×10^{18} and 1×10^{19} e^-/cm^2) increases the total content of primary defects at that contribution of the broad component practically does not change, the increase occurs due to the narrow one (up to ~400 – 500 ppm). At the same time content of the triplet centers in e-beam irradiated PCND-BA samples remains at the same low level. The PCND-BA sample irradiated with 1×10^{19} e^-/cm^2 fluence was further undergone the annealing treatment. It was found that annealing reduces total amount of primary defects (to ~400 ppm) due to reduction of both broad (~310 ppm) and narrow (~90 ppm) components. Some insignificant growth of NV^- content (up to 50 ppb) was observed as well. The observed findings allow attributing the increase of the content of defects contributed to the narrow component in e-beam irradiated samples to appearance of radiation-induced paramagnetic V^- centers. Annealing of these samples causes diffusion and recombination of V^- centers accompanying by formation of a certain amount of radiation induced NV^- centers. Surprisingly, the effect of NV^- centers formation in PCND samples by e-beam irradiation and annealing was found to be at least on the order of magnitude weaker than that in both NDs obtained by nanonization of HPHT diamonds and DNDs. In strong contrast, DNDs show an NV^- concentration of ~100 ppb in pristine sample, which increases up to ~500 ppb under identical electron irradiation and annealing condition [3]. This specificity of PCND samples is discussed within the framework of models recently proposed in the Ref. [3].

Excitation and Charge Transfers in Functionalized Nanodiamonds in Water Arsène Chemin[1], Ronny Golnak[1], Jie Xiao[1], Andreas Weisser[1], Benjamin Kiendl[2], Anke Krueger[2] and Tristan Petit[1]; [1]Helmholtz-Zentrum Berlin, Germany; [2]Institut fur Organische Chemie, Germany

Generating solvated electrons from sunlight using diamond material has been proposed as a promising strategy to achieve CO2 or N2 reduction in liquid phase [Zhu, D. et al, Nat. Mater (2013), Zhang, L. et al. Angew. Chem. (2014)]. The high conduction band energy and negative electron affinity of diamond surfaces facilitate easy electron transfer to water. Despite the diamond's large band gap (5.47 eV), reports have demonstrated CO2 photo(electro)chemical reduction using visible light [Knittel, P. et al. *ChemCatChem*. (2020)] as well as the emission of solvated electrons from nanodiamonds [Buchner, F. et al. *Nanoscale* (2020)]. Our recent investigation of the sub-bandgap excitation on diamond materials has demonstrated the implication of the surface states in the photon absorption and the charge transfers in air [Chemin, A et al. *Small Methods* (2023)] by combining surface sensitive X-ray absorption spectroscopy (XAS) to surface photovoltage. However, ex-situ measurements have shown limitation in explaining charge transfers in liquid.

In this work, we investigate *in-situ* the nanodiamond-water interface to unravel the charge transfers and excitation process of detonation nanodiamonds functionalized with Ru complex, which showed promising photoelectrocatalytic properties [Kiendl, et al. Preprint (2022)]. While XAS characterisation is easily performed into vacuum, measurement in water is much more challenging due to the short penetration depth of soft X-ray in liquid. A recently introduced detection mode for XAS in liquid [Schön, D. et al. *J. Phys. Chem. Lett*. (2017)], performed at BESSY II synchrotron in Berlin, is used to characterize the unoccupied states at the nanodiamond surface as well as the structure of the water molecules at the interface with nanodiamonds. By comparing this measurement to XAS in vacuum, we determined that the interaction with the liquid lead to strong modification of the surface states. By coupling this information with UV-Vis absorption spectroscopy and photocurrent spectroscopy, we discuss further the impact of the water interface in the possible excitation path and charge transfer of the functionalized nanodiamonds.

This project has received funding from the European Commission under the Horizon 2020 grant agreement 665085 (DIACAT) and Volkswagen Foundation under the Freigeist Fellowship No. 89592.

11:00 AM NM02.04.10
Phonon Green's Function Method for Multiscale Modeling of Color Centers in Nanodiamonds Vinod K. Tewary and Edward J. Garboczi; National Institute of Standards and Technology, United States

Nanodiamonds are materials of strong topical interest because of their unusual properties and diverse potential applications in biomedical, communications, and sensing devices. Their dimensions range from a few to several hundred nanometers. There is special interest in color centers in nanodiamonds, which give them unique photonic and spin characteristics. These characteristics are useful for their applications in optical and quantum devices.
Color centers are lattice defects such as vacancies. A lattice defect causes a break in the translation symmetry of the lattice. Consequently, it causes a distortion or strain in the lattice, which also distorts the electronic wave functions and perturbs the associated energy levels. This effect is likely to be a serious material issue, which can affect the reliability and the performance of the finished device based upon the use of nanodiamonds. It is, therefore, of paramount importance to develop modeling and measurement techniques of the lattice distortion/strain field due to a color center in nanodiamond, which is the objective of this work.
A unified theory for lattice defects in nanodiamonds is a challenging problem because the nanodiamonds can be too small or too big for a conventional theoretical treatment. A 5 nm nanodiamond is too small for a standard bulk material continuum model to be accurate. One must use a discrete lattice theory such as molecular dynamics (MD). On the other hand, modeling a 100 nm nanodiamond, containing up to a billion atoms, using ordinary MD will be a formidable task, even with modern computer.
Further, in addition to variations in the size, there is also a need for seamless linking of the length scales in the same nanodiamond. Lattice distortion is a discrete function expressed as the displacement of atoms from their positions of equilibrium and needs to be calculated by accounting for the atomistic structure of the lattice. On the other hand, strain is a continuum model parameter defined in terms of the derivatives of the continuous displacement field. The inherent assumption in a continuum model is that the discrete lattice distortion is smeared out into a continuum, which is valid only at distances much larger than the interatomic separations. For the final results to be physically realistic, the near field and far field formulation must be seamlessly linked.
We describe a Green's function (GF) method for modeling a color center in a nanodiamond of arbitrary size. The model is computationally efficient and can simulate even several hundred million atoms on an ordinary computer. It links the different length scales smoothly and seamlessly so can be used to estimate the nanodiamond size effect. We calculate the lattice GF by using a simple Born-von Karman model, in which each atom interacts with up to its second neighbor atoms. We also assume the harmonic approximation and the adiabatic approximation.
In this model, the main parameters are the interatomic force constants. These are given by the derivatives of the total potential energy, evaluated at the positions of equilibrium for each atom. In practice, the force constants are treated as adjustable parameters, which are determined phenomenologically by fitting them to elastic constants and phonon dispersion. Hence, an explicit knowledge of the interatomic potential is not needed. Our selected set of the force constants correctly reproduces the measured elastic constants of bulk diamond and gives a reasonable agreement with the observed phonon spectrum over the first Brillouin zone.
Numerical results will be presented for the strain field due to a color center, specifically a single vacancy, in a nanodiamond. The size effect on the strain field and the limitations and applicability of our model to interpretation of measurements will be briefly discussed.

11:15 AM *NM02.04.11
Real Effect of Size on The Raman Spectrum of sub-5 nm Nanodiamonds Stepan Stehlik[1,2]; [1]Institute of Physics, AS CR, Czechia; [2]University of West Bohemia in Pilsen, Czechia

Nanodiamonds (NDs) hold promise for a vast range of various distinct applications including drug delivery, cellular labeling and imaging, quantum sensing (such as thermometry and magnetic field/spin sensing), selective biomolecule binding or energy harvesting, and (photo)catalysis - to name a few. Although researchers employ nanodiamonds in all these applications, due to the great variety of this nanomaterial, the actual nanoparticles used can differ substantially. Sometimes to the extent that they could be defined as a different material.
In this contribution, specifics of the two most common ND types, detonation NDs (DNDs) and high-pressure high-temperature (HPHT) NDs will be highlighted. We will review recent experimental advances in the preparation of sub-5 nm NDs of both detonation and HPHT origin, including the HPHT NDs synthesized from molecular precursors (E. Ekimov et al., *Nanomaterials* 2022, 12, 351). The presentation aims to critically compare these two ND types from the Raman spectroscopy point of view as this technique is broadly used to assess not only the ND phase composition (C-sp^3 and C-sp^2 content) but also the ND size. We show that the Raman spectra of DND and HPHT NDs on the 3-5 nm scale are size-insensitive yet significantly different from each other which limits the application of the current phonon confinement models for the ND size distribution analysis (S. Stehlik et al., *J. Phys. Chem. C* 2021, 125, 5647−5669). The diamond structural quality, and temperature (in)stability caused by laser irradiation during the measurement are the key features reflected in the NDs' Raman spectrum. The first time observed low-frequency (20−200 cm^{-1}) Raman scattering signals may correspond to "breathing-like" modes of NDs as these signals exhibit clear size dependence. The low-frequency Raman scattering may thus provide another way for size distribution analysis of nanodiamonds (A. Vlk et al., *J. Phys. Chem. C* 2022, 126, 6318−6324).

11:45 AM NM02.04.13
Size Sorting of Highly Crystalline High-Pressure High-Temperature Nanodiamonds Marie Finas, Hugues A. Girard and Jean-Charles Arnault; CEA Paris Saclay, France

Due to their excellent crystalline quality, recent studies exhibited that milled high-pressure high-temperature nanodiamonds (MND) behave electronic properties very close to those of bulk diamond, with similar dependence on surface chemistry [1]. Those characteristics make them excellent candidates for photocatalysis applications. However, it is well known that particle size have a great influence on nanomaterial's properties, and HPHT nanodiamonds are no exception. Depending on nanodiamond size, modifications are expected especially dealing with specific area, spectroscopic signatures and electronic properties. According to literature, proton affinity is strongly facet-dependent [2] and thermal stability and structural properties are proved to be size-dependent in the range from 1 to 8 nm [3]. Moreover, the smaller the nanodiamonds, the greater the surface-to-volume ratio, which would influence the photocatalytic properties. Therefore, as MND exhibit a large polydispersity, it is crucial to fractionate them into different size ranges to assess their specific size-dependant properties.

Our strategy consists in implementing a density gradient made of mixtures of ethylene glycol and water in a vertical container, where MND will sediment with different velocities depending on their size during centrifugation [4]. This method was previously explored to fractionate with success detonation nanodiamonds and remove clusters [5]. We applied it for the first time to MND. To determine optimal separation conditions, experimental parameters like the centrifugation time, the MND initial size range and the fractionation values were tuned. By this mean, we succeeded to isolate larger MND (15-40 nm) from the smaller ones (< 15 nm). We used UV-Vis spectrophotometry to measure MND concentration after centrifugation, and DLS and SEM to evaluate size-sorting efficiency. The sorted MNDs were then characterized by FTIR, Raman and XPS to investigate the size influence on their surface properties.

SESSION NM02.05: Characterization and Processing of Nanodiamond Materials
Session Chairs: Petr Cigler and Yuen Hui
Wednesday Afternoon, April 24, 2024
Room 338, Level 3, Summit

1:30 PM *NM02.05.01
New Techniques of Depositing Detonation Nanodiamonds onto Substrates and Their Applications Taro Yoshikawa[1,2], Akira Kaga[1] and Tomoaki Mahiko[1]; [1]Daicel Corporation, Japan; [2]Kanazawa University, Japan

Detonation nanodiamonds (DNDs) are considered exciting candidates for various applications, such as lubricant additives, semiconductor quantum dots, magnetic mapping sensors, protein mimics, and initial seeds for chemical vapor deposition (CVD) of diamond thin films on heterogeneous substrates. Essentially, these potential applications can be categorized into two groups: solution-based applications that use DND colloidal suspensions, and solid-state applications based on systems of DNDs supported by substrates, tips/probes, etc. The former applications have shown tremendous progress toward practical realization over the past decades. This progress is the result of thorough investigations and technological development in material preparation, including disassembling tightly bound aggregates, isolated/separated dispersion through graphitization or oxidization of surfaces, annealing in a hydrogen atmosphere, insertion of appropriate surfactants, surface functionalization with organic molecules, and stirred-media milling with ceramic or zirconia microbeads. Meanwhile, development of the latter applications has been primarily hindered by the technical challenge of depositing/coating DNDs on the surfaces of solid-state materials with the desired layer thickness, particle density, and surface roughness.
Recently, we have established two new techniques for depositing DNDs onto substrates. One technique involves the nanometer-scale ordered arrangement of DNDs on substrates. The signs of surface charges, i.e., zeta potentials, of substrate surfaces are locally inverted through a combination of electron beam lithography and surface functionalization with 3-aminopropyltriethoxysilane. As a result, selective electrostatic deposition of DNDs onto the substrates is performed with line-and-space and dot array patterns at a length scale of ≥20 nm. Another technique involves the electrostatic layer-by-layer deposition of DNDs onto substrate surfaces using DND colloidal suspensions with different zeta potentials. By treating substrate surfaces in DND colloidal suspensions with positive and negative zeta potentials alternately, DNDs are deposited homogeneously on the substrate surfaces layer-by-layer.
During the presentation, these techniques are introduced in detail, along with specific applications we have recently demonstrated. The nanometer-scale ordered arrangement technique is tested for the patterned growth of nanocrystalline diamond films. This could contribute to the manufacture of smaller diamond-based micro/nano electromechanical system devices through a bottom-up process, rather than the conventional top-down method that requires costly polishing and etching of the diamond films. Meanwhile, the electrostatic layer-by-layer deposition technique is applied to fabricate diamond photocatalytic electrodes, enabling CO_2 reduction with visible light irradiation. The results indicate that the DND layer thickness of the electrode strongly affects the photosensitivity of the CO_2 reduction reaction.

2:00 PM *NM02.05.02
Fluorescent Diamond Particles for Bioimaging and Quantum Sensing Olga A. Shenderova[1], Marco Torelli[1], Nicholas Nunn[2,1], Alex I. Smirnov[2] and Ashok Ajoy[3]; [1]Adamas Nanotechnologies, United States; [2]North Carolina State University, United States; [3]University of California, Berkeley, United States

Diamond nanoparticles containing fluorescent color centers exhibit a favorable combination of optical properties including photostability that outlasts quantum dots and molecular probes, a broad emission color palette, and excellent biocompatibility. Fluorescent nanodiamonds containing nitrogen-vacancy (NV) color centers enable unique quantum sensing capabilities by reporting on nearby analytes, such as free radicals and other paramagnetic species, by decoding fluctuating magnetic fields induced by these external spins. This information can be conveniently imaged optically by adapting conventional microscopes or via hyperpolarized magnetic resonance methods. For the latter, quantum sensing is based on hyperpolarizing ^{13}C nuclei in nanodiamond particles by optical pumping of NV centers and then imaging chemical information by ^{13}C NMR scanners at high resolution. In this presentation, material developments for quantum sensing applications will be highlighted. The progress of several projects on quantum sensing with a biological scope under development by our team will be presented, with a more detailed focus on a near-term application such as using nanodiamond particles as sensors of paramagnetic species in biological media.

High Pressure High Temperature Synthesized Diamond Particles with Controlled Nitrogen Content Nicholas Nunn[1,2], Sergey Milikisiyants[1], Marco Torelli[2], Alexander Healey[3], Roy Styles[3], Brett Johnson[3], Philipp Reineck[3], Christopher Long[4], Timothy Dumm[4], Adam Dalis[4], Takeshi Ohshima[5], Emmanuel Druga[6], Ashok Ajoy[6], Alexander I. Shames[7], Alex I. Smirnov[1] and Olga Shenderova[2]; [1]North Carolina State University, United States; [2]Adamas Nanotechnologies, Inc., United States; [3]RMIT University, Australia; [4]Hyperion Materials & Technologies, United States; [5]National Institutes for Quantum and Radiological Science and Technology, Japan; [6]University of California, Berkeley, United States; [7]Ben-Gurion University of the Negev, Israel

Diamond particles hosting nitrogen vacancy centers is a platform material for potential use in emerging nano and microscale sensing technologies. These envisioned quantum sensors are based on optical manipulation and readout of NV centers in response to external environmental stimuli (e.g., temperature, electromagnetic fields, mechanical strain). The important prerequisites for such measurement protocols are NV centers with suitable spin properties such as long coherence and relaxation times. While such properties are observed in bulk diamond crystals of suitable quality, the properties of diamond particles are often severely degraded by the presence of paramagnetic defects such as electronic spins associated with surface defects and other paramagnetic centers (primarily nitrogen P1 centers). Here we demonstrate HPHT grown microparticulate diamond with good crystal quality and a controlled nitrogen content in the range of *ca.* 5-50 atomic ppm. A resultant improvement in NV electronic spin coherence times by approximately 3-fold is directly observed by pulsed electron paramagnetic resonance (EPR) across the range of nitrogen concentration studied. These results may provide a foundation for the production of the next generation of fluorescent diamond particles, which thus far have relied exclusively on particulate diamond with nitrogen contents of ca. 100 atomic ppm.

3:45 PM NM02.05.04
Catalytic, Photocatalytic and Electrochemical Properties of Surface-Treated Nanodiamond and of Multifunctional Gold Decorated Nanodiamond Systems Emanuela Tamburri, Riccardo Salvio, Laura Micheli, Rocco Cancelliere, Giorgia Magnante, Emanuele Rea and Silvia Orlanducci; University of Tor Vergata, Italy

The unique surface properties of detonation nanodiamonds, such as their stability, high surface area, and the ability to be easily functionalized, make them a versatile and promising material for various catalytic applications. The large surface area and diverse surface functional groups on detonation nanodiamonds can promote heterogeneous catalysis and they can be used in a variety of reactions, including hydrogenation, reduction, oxidation, and other industrial processes. Here are some ways, developed in our laboratory, to modulate catalytic activities of ND by surface functionalization or by decorating ND with gold nanoparticles (AuNP). Gold nanoparticles and nanodiamonds are indeed remarkable nanomaterials with unique properties and a wide range of potential applications. The teamwork between AuNP and ND is related to the ability to control the shape and size of gold nanoparticles on the surface of nanodiamonds, modulate the colloidal properties, and the interactions with their surroundings. The hybrid system can exhibit unique catalytic and sensor activities, as both components contribute to these properties. In this communication, we will explore the use of AuNP-ND system as a platform for immobilizing enzymes and antibodies on electrode surfaces and test them in electroanalytical applications. Finally modified ND will be investigated as a catalyst in the reductive degradation of pollutants (nitrophenols class) and as enzyme mimics in the transesterification reaction. In summary, the combination of gold nanoparticles and nanodiamonds offers a powerful platform for a wide range of applications in various fields. Their unique properties, surface chemistry, and biocompatibility make them highly versatile, and the synergy between these two components can lead to innovative solutions in the areas of imaging, drug delivery, biosensing, and beyond. Research continues to explore and develop these hybrid systems to unlock their full potential for practical applications.

4:00 PM NM02.05.05
Surface Modification of Fluorescent Nanodiamond for Quantum Sensing Marco Torelli[1], Nicholas Nunn[1,2], Gary McGuire[1] and Olga Shenderova[1]; [1]Adamas Nanotechnologies Inc, United States; [2]North Carolina State University, United States

Developments in quantum sensing which surpass the capabilities of classical measurements will improve the understanding of complex events in molecular disease biology and enable new modalities for drug and biomarker discovery. The negatively charged nitrogen-vacancy (NV) center in fluorescent nanodiamond can sense local electromagnetic fields, free radicals, temperature, and pH with nanoscale resolution. However, charge transfer and electromagnetic noise from the particle's surface destabilize negatively charged NV^- emitters and convert them to non-sensing, neutral NV0 centers. This effect is important because sensing has a strong dependence on distance, and thus the quality of shallow NVs relates to sensing characteristics. Additionally, at small particle sizes the fraction of destabilized NV centers near the surface becomes significant. Here we report results for conversion and stabilization of NV^- by plasma surface modification with fluorine and nitrogen groups to provide enrichment and stabilization of NV^-. The treatment is shown to be suitable for particles of differing sizes and initial surface chemistries, allowing for scalable production of nanodiamond particles adapted for quantum sensing applications.

4:15 PM NM02.05.06
Group-IV Split Vacancy Nanodiamonds Synthesized via High-Pressure High-Temperature Techniques for Enhanced Quantum Sensing Chaman Gupta, Elena P. Pandres, Brittany P. Bishop, Alexander Bard, Christopher E. Woodburn, Alexey Soldatenko, Vincent C. Holmberg and Peter Pauzauskie; University of Washington, United States

Rapid strides in quantum sensing have necessitated the development of robust, scalable, and efficient nanodiamond materials with well-defined point-defect microstructure. This research presents a novel method to further this pursuit by synthesizing nanodiamonds doped with group-IV elements (Si, Pb, Sn, Ge), aiming to harness the unique properties of their split vacancies in nanodiamonds for a range of quantum sensing and quantum communication applications. A chemical bottom-up approach was employed, where 4.5 nM of tetraethylorthoxysilane (TEOS) and 4.5 nM of tetraphenylgermane (TPG) were added as the dopants for Si and Ge, respectively, while trace amounts of organometallic Sn and Pb were included in the processing of carbon aerogel target materials. The doped resorcinol-formaldehyde (RF) gels were pyrolyzed to obtain the group 4-doped carbon aerogels. Subsequent laser heating to 1260 K ± 10 K in high-pressure environments of 22 GPa ± 0.2GPa using diamond anvil cells yielded nanodiamond samples doped with group-IV point defects. Photoluminescence characterization showcased distinct zero-phonon lines (ZPLs) stemming from NV- (638 nm), SiV- (720 nm), SnV (620 nm), and Pb-related centers at ambient conditions. The observed shift in SiV ZPL with increasing pressure (0.85 meV/GPa) was in excellent alignment with existing density functional theory (DFT) calculations (0.83 meV/GPa). Further, we conducted lifetime measurements of the SiV centers at ambient conditions post nanodiamond recovery, resulting in a lifetime of ~1.25 ns ± 0.03 ns, which matches very closely with the literature. A significant advancement of this research lies in its potential to modulate the relative concentration of dopants, enabling the precise ratio control of various quantum sensors in the resultant nanodiamonds. This study contributes to the development of the synthesis of nanodiamonds with split vacancy without damage induced by ion implantation. With future development, these group-IV split vacancies hold promise for quantum sensing and quantum communication applications.

8:30 AM NM03.01.01
Growth of Carbon Nanotubes (CNTs) using Catalyst Stabilizers for Extended Growth Michael J. Bronikowski; University of Tampa, United States

Recent results will be reported from investigations into Carbon Nanotube (CNT) growth using metal catalyst particles composed of catalytic metals such as iron mixed with heavy refractory catalyst stabilizers. The heavy refractory metals, which include high-melting-point elements such as tungsten, ruthenium and hafnium, act to slow down the erosion and Ostwald ripening of the nano-particles of catalytic metals from which the CNTs nucleate and grow, thereby allowing the particles to remain active for longer times and thus to grow longer CNTs. A number of different combinations of catalyst metal and heavy refractory stabilizer are investigated. Ethylene (C_2H_4) is used as the carbon source gas for nanotube growth, and growth parameters including temperature, pressure, and gas flow composition and rate, are varied for best CNT growth. Discussion will include implications for growth of CNTS to lengths great enough (tens of cm or more) for application in materials applications such as ultra-high-strength wires and cables.

8:45 AM NM03.01.02
Nanoconfinement Facilitates The Precipitation of Iron Hydroxides in Porous Amorphous Aluminum Oxides Xiaoxu Li, Jianbin Zhou, Sebastian T. Mergelsberg, Xin Zhang and Kevin Rosso; Pacific Northwest National Laboratory, United States

In nature, nanoscale spaces where molecules are confined are ubiquitous, including within nanoparticle aggregates, biofilms, and fractures in rocks, leading to unique size-dependent chemical and physical interactions. Nanoconfinement also offers unique opportunities to manipulate and control reaction pathways and the properties of materials and substances in energy storage and conversion, carbon capture, catalysis, water purification and nanoelectronics. The well known tendency of nanoconfinement to lower the dielectric constant of water and limit diffusive mass transport rates leads to a common assumption that reactions are slower compared with their counterparts in bulk solution. Here, we report that the nanoconfinement can instead promote mineral replacement reactions. We examined the proton-promoted dissolution rate of porous amorphous aluminum oxide matrices of varying pore diameter when contacted with ferric chloride solution at acidic pH. Consumption of protons within the pores coupled to Al^{3+} release leads to oversaturation with respect to ferric hydroxides. Consequently, 2-5 nm Al-doped ferrihydrite and akageneite nanoparticles heterogeneously nucleated on the dissolving surfaces of aluminum oxides pores, based on various solid characterization including SEM-EDS, TEM-EDS, XRD, and Mossbauer spectroscopy. Furthermore, the surface area normalized dissolution rates of the pores coupled to precipitation of ferric hydroxides exhibit an exponential increase of two orders of magnitude as pore diameter linearly decreases from 200 nm to 30 nm. This increasing rate trend of dissolution-reprecipitation with decreasing pore size aligns quantitively with the principle of heterogenous nucleation of ferric hydroxides on curved surfaces. These results underscore the notion that nanoconfined space can accelerate dissolution-reprecipitation reactions by reducing the energy barrier to heterogenous nucleation of secondary phase, primarily due to the smaller pore size. Our results shield light on the underestimated and significant role of confined spaces in mineral replacement reactions that occur across a wide range of natural and materials synthesis environments.

9:00 AM *NM03.01.03
Nanofluidics under Extreme Confinement in 1D and 2D Channels Aleksandr Noy[1,2]; [1]Lawrence Livermore National Laboratory, United States; [2]University of California Merced, United States

Extreme spatial confinement in narrow fluidic channels strongly influences their transport properties and enables unconventional selectivity mechanisms that can often mimic some of the selectivity and transport characteristics of biological membrane channels. Modern nanomaterials have enabled experimental platforms that can recreate such extreme confinement in a range of 1D and 2D channels with defined geometry and controllable electronic properties. I will discuss several of these nanomaterials-based channel systems and show how confinement phenomena, coupled with the different electronic effects and dynamic charge equilibria in these channels can shape their transport properties and ion selectivity characteristics. Overall, these observations can pave the way for developing a new generation of precision separation platforms for biomedical and industrial use.

9:30 AM NM03.01.04
Mechanistic Study of Electroosmotic Pumping through Atomically Smooth Carbon Nanotube Membranes with Application in Programmed Drug Delivery Bruce Hinds; University of Washington, United States

Mechanistic study of electroosmotic pumping through atomically smooth carbon nanotube membranes with application in programmed drug delivery
An important challenge for the membrane community is to mimic natural protein channels that outperform, by orders of magnitude, man-made systems based on pore size and coarse chemical selectivity. To mimic protein channel pumping on a robust engineering membrane platforms, applied bias can be used to actuate charged gatekeepers and induce ionic pumping. Carbon nanotubes have three key attributes that make them of great interest for novel membrane applications 1) atomically flat graphite surface allows for ideal fluid slip boundary conditions and extremely fast flow rates [1,2] 2) the cutting process to open CNTs inherently places functional chemistry at CNT core entrance for chemical selectivity and 3) CNT are electrically conductive allowing for electrochemical reactions and application of electric fields gradients at CNT tips. The CNT membrane, with tips functionalized with charged molecules, is a nearly ideal platform to induce electro-osmotic flow with high charge density at pore entrance and a nearly frictionless surface for the propagation of plug flow [3,4]. Use of the electro-osmotic phenomenon for responsive/programmed transdermal drug delivery devices for nicotine addiction [5]. Our recent work [6] shows highly energy efficient electroosmotic pumping of nicotine with optimal power consumption/flux efficiency of 111(μW/cm2)/μmoles/cm2/h. This allows watch-battery lifetimes of 7-62 days for conventional treatment dosing regimens. On/off nicotine flux ratios of 68 were achieved allowing programmed delivery between therapeutically relevant nicotine patch and nicotine gum levels. By varying degree of chemical functionalization at CNT tips and pH control of ionic/neutral species ratio, the relative contribution of electroosmosis and electrophoresis within atomically smooth CNT conduits was quantified. More recent work with the direct measurement electroosmotic flow in a capillary flow cell shows the enhancement is due to atomic smoothness of CNTs, as seen the reversable stopping of flow by benzyl alcohol adsorption but no effect by H-bond chain disrupter NaSCN. Increased cation size had minimal improvement in EO pumping through DWCNT conduits.

9:45 AM BREAK

10:15 AM NM03.01.05
Nanofluidic Ion and Molecule Transport in Boron Nitride Nanotube Porins Zhongwu Li[1] and Aleksandr Noy[1,2]; [1]Lawrence Livermore National Laboratory, United States; [2]University of California Merced, United States

Biological membrane channels, which exhibit excellent efficiency and selectivity in ion and molecule transport, have sparked considerable interest in the development of their synthetic analogues. Numerous artificial nanochannels that can be integrated into lipid membranes have been designed and synthesized over the past decade, e.g., the remarkable one-dimensional carbon nanotube porins that exhibit exceptional nanofluidic transport properties. However, there is still a need to diversify the nanotube porin family to include nanochannels made of different materials that provide access to different geometries, surface properties, and electronic structure.

Here, we present the fabrication and nanofluidic transport studies of boron nitride nanotube (BNNT) porins. With the combination of liposome transport measurement and Cryo-EM imaging, we show that BNNT porins can insert into lipid membranes to form functional channels. Ion transport studies, which used the droplet interface bilayer setup, reveal distinct ion conductivity profiles and scaling behaviors at high ion concentrations. The ion transport also exhibits an inverted U-curve dependency on pH with the highest conductance at the neutral pH value. Reversal potential measurements suggest that BNNT porins have a high cation/anion selectivity. We attribute these observations to the strong ion interactions and pronounced surface adsorptions in the highly charged and extremely confined nanotubes. Furthermore, we present evidence of the ability of these BNNT porins to transport DNA molecules. Our findings position BNNT porins as a promising biomimetic platform for the investigation of nanofluidic transport and the development of membranes and biosensors.

10:30 AM NM03.01.06
Decoupling Entrance and Inner Resistances in CNT Channels Melinda L. Jue, Steven F. Buchsbaum, Sei Jin Park, Kathleen E. Moyer-Vanderburgh and Francesco Fornasiero; Lawrence Livermore National Laboratory, United States

Due to their high transport rates, a great deal of attention has been recently given to 2D materials and slippery 1-D nanochannels as promising building blocks for next generation membranes. While in 2-D materials high flux is expected because of the classical inverse scaling of the flow rate with the pore thickness, in smooth channels such as carbon nanotubes (CNT), orders of magnitude rate enhancements with respect to classical theories are attribute to a vanishing friction at the pore wall. Irrespectively of the high flux origin, in both atomically thin and thicker but slippery nanopores, the flow rates are largely dictated by the entrance/exit hydrodynamic resistance.

For CNT channels, experimental quantification of the magnitude of end and inner resistances is still lacking despite its importance for both practical applications and fundamental understanding. This has led to inaccuracy and disagreement in the calculation of slip lengths and flow rate enhancements from experimentally measured permeation rates, since often entrance/exit resistances are neglected altogether, or an arbitrary magnitude is assumed. Here, we quantified these resistances for both gases and liquids in CNT channels by fabricating membranes with controlled CNT length and known number of open pores. We found that the end resistance dominates the total resistance. For liquid water, measured viscous energy dissipation at the nanotube ends is quantitatively described by Sampson equation. For 2.4 nm wide single-walled CNTs, measured slip lengths approach several microns. A prevailing contribution of the end resistance was also found in pressure-driven gas transport, and recorded flow rate enhancements with respect to Knudsen theory appear to be independent of the gas type. These findings further advance the community understanding of the peculiar and often unusual CNT fluidic properties and may help reconciliating “conflicting” literature reports on the subject.

Engineering Tunable Macrocyclic Subnanometer Pores as Biomimetic Channels for Ångstrom-Precision Separation Yuhao Li[1] and Jiachen Feng[1,2]; [1]Lawrence Livermore National Laboratory, United States; [2]The University of Nebraska Medical Center, United States

Efficient and selective membranes are essential for advancing sustainable water treatment processes, with the potential to address the separation of problematic contaminants and reduce environmental waste. The present landscape of conventional membrane fabrication techniques falls short in achieving the required solute-solute selectivity at the molecular level. Traditional approaches, such as interfacial polymerization for thin-film composite (TFC) membranes, were developed to enhance water-solute selectivity but lack precise control over local pore structures and chemical properties.
Herein we demonstrate by using triangular macrocyclic hosts as biomimetic channels, offering a remarkable degree of tunability. By merely substituting the bridging groups, we can directly influence local pore size and structure, resulting in enhanced selectivity and efficiency. This innovation offers the possibility of a bottom-up approach to membrane fabrication that can be customized for specific separation needs, providing an array of advantages. These include precise control over sub-nanometer pore structures, size, and chemical environments through subcomponent modifications, excellent processability, and simplified assembly of subcomponents, thus offering a promising solution for advanced membrane fabrication.

Dynamic Memory Effects in Aqueous Ion Transport through 2D Nanopore Arrays Yechan Noh[1,2] and Alex Smolyanitsky[1]; [1]National Institute of Standards and Technology, United States; [2]University of California, Berkeley, United States

Nanofluidic ion-conducting devices with built-in memory are gaining attention as potential components for brain-mimetic computing systems. Here we present examples of the dynamic memory effects in the aqueous ion transport through 2D nanopore membranes under alternating bias voltages. In the first example, we explore the transport of KCl and NaCl salt mixtures through arrays of graphene-embedded crown-like pores, known to selectively trap aqueous K^+ ions. In this system, trapped K^+ ions act as pore cloggers, while Na^+ ions are the main charge carriers. We demonstrate that the dynamically

changing state of the system defined as the ratio of pores *unblocked* by K^+ (and thus the number of conductive paths available to Na^+) is marked by a basic time delay. This delay is shown to result in distinct memristive ion transport under alternating voltage bias.
In the second example, we investigate capacitive transport of water-dissociated RbCl in the presence of sub-nm pore arrays in hexagonal boron nitride (hBN). In contrast to the first example, the pores are impermeable to Rb^+ and such a system behaves as a capacitor with a built-in chemical barrier, causing current spiking. The external bias voltage is shown to induce ordered adsorption of Rb^+ on one side of the membrane, representing the charging phase. Alternating the voltage direction triggers rapid ion discharge, leading to current spikes with current polarity dependent on the prior input.
The physical processes described in this work are remarkably illustrative, potentially extending beyond the presented examples. By focusing on the mechanisms, we provide a clear insight into the design of nanofluidic systems capable of memristive and spike ion transport within realistic timescales.

Exploring Confinement-Dependent Alkaline Silicon Etching in Nanochannels and Nanotrenches: Origins and Solutions Yiding Zhong, Dohyun Park and Chuanhua Duan; Boston University, United States

Alkaline etching of silicon (Si) is one of the most fundamental processes for the semiconductor industry. Although its etching kinetics on plain substrates has been thoroughly investigated, the kinetics of Si wet etching in nanoconfinements has yet to be fully explored despite the practical importance of three-dimensional (3-D) semiconductor manufacturing. Herein, we report the systematic study of potassium hydroxide (KOH) wet etching kinetics of amorphous-silicon (a-Si) filled two-dimensional (2-D) planar nanochannels with heights ranging from 11 nm to 120 nm and polysilicon (poly-Si) filled 2-D vertical nanotrenches with widths ranging from 20 nm to 285 nm. We found that, while there is a positive correlation between the etching rate and the KOH etchant concentration similar to bulk Si etching, the etching rate would increase with the increase in nanochannel height/nanotrench width before reaching a plateau, indicating a strong nonlinear confinement effect. To investigate the fundamental mechanisms of the confinement effect, we further conducted Si wet etching using etching solutions with different ionic strengths and/or different temperatures. Our results show that both electrostatic interactions and hydration layer inside the nanoconfinement contribute to the confinement-dependent etching kinetics. To address the challenge of non-uniform etching rates in nanoconfinements of varying dimensions, we implemented various active or passive methods to modify nanochannel surface-etchant interactions, including DC bias gating, diffusiophoresis, and etchant additives. Notably, we discovered that adding certain polymers and organic solvents resulted in excellent etching rate uniformity in poly-Si nanotrenches with spanning widths from 27 nm to 205 nm. These results provide new insights into the kinetic study of reactions in nanoconfinements and will shed light on etching process optimization in the semiconductor industry.

11:30 AM NM03.01.10
Controlled Ionic Transport and Electrical Sensing of DNA using Van der Waals Heterojunction Nanopores Sihan Chen[1], Siyuan Huang[1], Jangyup Son[1], Edmund Han[1], Kenji Watanabe[2], Takashi Taniguchi[2], Pinshane Y. Huang[1], William P. King[1], Arend M. van der Zande[1] and Rashid Bashir[1]; [1]University of Illinois at Urbana-Champaign, United States; [2]National Institute for Materials Science, Japan

Sequencing the human genome has helped to improve our understanding of disease, inheritance and individuality. Solid-state nanopores could potentially meet the demand for even cheaper and faster genome sequencing, owing to their superior mechanical, chemical and thermal robustness and durability, and potential for integration into high-density electronic arrays.[1] Despite the promise, solid state nanopores have yet to demonstrate DNA sequencing. Two key challenges remain, i.e., achieving few-base spatial resolution and slowing the translocation of the DNA molecule. 2D materials such as graphene[2] and MoS_2[3] have emerged as attractive possibilities, since the thickness of these films is in the range of a few nucleotides. However, atomic membranes alone are not robust in fluid under an electric field.[4] 2D materials sandwiched within dielectrics could provide a stable platform,[5] but the resulting stack thickness limits the spatial resolution. Resolving these challenges requires new sensing mechanisms beyond ionic currents and translocation control.

This work reports a novel solid state nanopore sensor that has the desired sub-nanometer spatial resolution, integrated electrical sensing, and can potentially control the translocation of the DNA molecule. In this architecture, the nanopore is drilled through a vertical 2D heterostructure consisting of n-type MoS_2 and p-type WSe_2 using focused electron beams. The heterostructure forms an atomically thin out-of-plane p-n diode. The diode is passivated by atomic layer deposition (ALD) of HfO_2 for electrical insulation. We demonstrated modulation of ionic current by the interlayer potential of the van der Waals heterostructure diode. Ionic current modulation is more effective with smaller pores and lower salt concentrations, and thus is not caused by leakage or edge electrochemistry. Modulation of ionic transport is also more effective under forward bias than under reverse bias, as a larger fraction of in-plane bias drops across the vertical p-n junction under forward bias.[6] Finally, we obtained signatures of DNA translocation in ionic and diode channels simultaneously. DNA translocation in 10 mM KCl resulted in current increase in ionic channel, as well as current increase in diode channel. Overall, this heterojunction architecture represents a new paradigm for nanopore mass transport control with simultaneous electrical sensing, which could be applied to applications such as gated molecular sieving and slowing translocation for molecular identification with solid-state nanopores.

High-Performance Hemofiltration via Molecular Sieving and Ultra-Low Friction in Carbon Nanotube Capillary Membranes Piran Ravichandran Kidambi; Vanderbilt University, United States

Conventional dialyzer membranes typically comprise of unevenly distributed polydisperse, tortuous, rough pores, embedded in relatively thick ≈20–50 μm polymer layers wherein separation occurs via size exclusion as well as differences in diffusivity of the permeating species. However, transport in such polymeric pores is increasingly hindered as the molecule size approaches the pore dimension, resulting in significant retention of undesirable middle molecules (≥15–60 kDa) and uremic toxins. Enhanced removal of middle molecules is usually accompanied by high albumin loss (≈66 kDa) causing hypoalbuminemia. Here, the scalable bottom-up fabrication of wafer-scale carbon nanotube (CNT) membranes with highly aligned, low-friction, straight-channels/capillaries and narrow pore-diameter distributions (≈0.5–4.5 nm) is demonstrated, to overcome persistent challenges in hemofiltration/hemodialysis. Using fluorescein isothiocyanate (FITC)-Ficoll 70 and albumin in phosphate buffered saline (PBS) as well as in bovine blood plasma, it is shown that CNT membranes can allow for significantly higher hydraulic permeability (more than an order of magnitude when normalized to

pore area) than commercial high-flux hemofiltration/hemodialysis membranes (HF 400), as well as greatly enhance removal of middle molecules while maintaining comparable albumin retention. These findings are rationalized via an N-pore transport model that highlights the critical role of molecular flexing and deformation during size-selective transport within nanoscale confinements of the CNTs. The unique transport characteristics of CNTs coupled with size-exclusion and wafer-scale fabrication offer transformative advances for hemofiltration, and the obtained insight into molecular transport can aid advancements in several other bio-systems/applications beyond hemofiltration/hemodialysis.

Pushing The Limits of Size-Selectivity in Nanoscale Solute Separations Feng Gao[1], Wen Chen[1,2], Jamila Eatman[1,2], Paul Nealey[1,2] and Seth Darling[1,2]; [1]Argonne National Laboratory, United States; [2]The University of Chicago, United States

Transport of a spherical solute through a cylindrical pore has been modeled for decades using well-established hindered transport theory, predicting solutes with a size smaller than the pore to be rejected nonetheless because of convective and diffusive hindrance; this rejection mechanism prevents extremely sharp solute separations by a membrane. While the model has been historically verified, solute transport through near-perfect isoporous membranes may finally overcome this limitation. We achieve encouraging solute rejections using nanofabricated, defect-free, thin silicon nitride isoporous membranes. The membrane is challenged by a recirculated feed of dextran molecules to increase the opportunity for interactions between solutes and the pore array. Results show the membrane completely rejects solutes with greater size than the pore size while effectively allowing smaller solutes to permeate through. A steep size-selective rejection curve takes shape in distinct contrast to the conventional S-shape rejection curve predicted by hindered transport theory. With this traditional hurdle overcome, there is new promise for unprecedented membrane separations through judicious process design and extremely tight pore-size distributions.

Soft Artificial Tissues based on Droplet Interface Bilayers and Their Application as Membranes for Electrically Driven Separations Aida E. Fica Conejeros[1], Harekrushna Behera[1], McKayla Torbett[2], A. Derya Bakiler[1], Elisabeth Lloyd[3], Robert Hickey[3], Berkin Dortdivanlioglu[1], Stephen A. Sarles[2] and Manish Kumar[1]; [1]University of Texas at Austin, United States; [2]The University of Tennessee, Knoxville, United States; [3]The Pennsylvania State University, United States

Soft tissue-like materials mimicking biological tissues' functionality, responsiveness, and reconfigurability hold immense potential for revolutionizing robotics, sensing, computing, biomanufacturing, and separations. Key features involve replicating cell structure by compartmentalizing aqueous environments with lipid membranes and incorporating membrane proteins for ion and solute transport. Droplet interface bilayers (DIBs) emerge as a promising platform, forming cell-like compartments enclosed by lipid membranes, serving as building blocks for 2D and 3D soft, responsive tissues. Conductive pathways are established by associating membrane proteins with lipid bilayers, providing tunable transport properties.

A rapid, scalable protocol combining emulsification and centrifugation has been devised for creating artificial tissues based on DIBs. This process successfully produces tissues from lipids, and polymers, and integrates ion channels like self-inserting peptides, integral membrane proteins, and artificial channels. Additionally, a platform has been designed to employ these tissues as membranes for electrically driven separations. The process hinges on three main components: an aqueous solution, hydrophobic media, and a bilayer-forming amphiphile as the emulsifier. Emulsification leads to aqueous droplet formation enclosed by a monolayer. Centrifugation creates a tightly packed system and displaces the excess oil. The contact of monolayer-enclosed droplets creates a bilayer, forming a network of communicating water compartments. This process enables the formation of tissues from microliter to liter scale, with resulting material exhibiting exceptional properties including high electrical resistance, viscoelasticity, and self-healing behavior.

Modifications to the process can significantly alter tissue's electrical properties. By incorporating ion channels during emulsification, the tissue can become electrically conductive. This enables the creation of biomimetic membranes that replicate and amplify channel properties, such as selectivity and pore size exclusion. The system allows for the incorporation of various natural or artificial channels, as they self-arrange in the monolayer/bilayer due to the hydrophobic effect. Channels like gramicidin (self-inserting peptide), Outer Membrane Protein (OmpF), Ammonium Transporter Protein (AmtB), and artificial channels like LAP5n10, a highly selective lithium channel, have been successfully incorporated through this method.

The use of DIB-based artificial tissues as membranes for water treatment has been proposed and demonstrated at the laboratory scale. To fabricate the membrane, the tissue is placed in a glass or plastic container, separated by two hydrogel layers on each side, which are in contact with an aqueous media. The assembly order is aqueous solution/hydrogel/tissue/hydrogel/aqueous solution. Applying voltage between the two aqueous solutions drives the transport of charged molecules or ions across the membrane through ion channels. The membrane's selectivity is controlled by the tissue's width and the selectivity of the channels used, as each layer of droplets acts like a membrane. For example, two layers of droplets containing a channel with 90% selectivity for a specific molecule will behave like two 90%-selectivity membranes in series, yielding an overall 99% selectivity provided all droplets contain the selective channel. This feature allows fine-tuning of membrane selectivity even when using low-selectivity channels. Overall, this innovative platform for fabricating soft membranes holds tremendous promise for advancing water treatment separations.

Computationally Guided Study of Cross-Linked Covalent Organic Frameworks for Membrane Applications Alathea E. Davies, Michael J. Wenzel, Cailin L. Brugger, Jordan Johnson, Bruce A. Parkinson, John Hoberg and Laura de Sousa Oliveira; University of Wyoming, United States

Two-dimensional covalent organic frameworks (2D-COFs) exhibit characteristics that are favorable for membrane applications including, but not limited to, their high stability and well-ordered nanopores. A challenge with fabricating these materials into membranes, however, is that membrane wetting leads to flake dispersion and increased interstitial flow of particles. Cross-linking, or "chemically stitching" two layers of the COF together has been shown to significantly improve the membrane performance. This work seeks to investigate the stability of cross-linked 2D-COFs via computational modelling coupled with synthesis, characterization, and membrane permeance testing. A quinoxaline-based COF was computationally modeled and cross-linked with oxalyl chloride (OC) and hexafluoroglutaryl chloride (HFG). Cohesive energy calculations indicate that both cross-linking moieties increase the intramolecular bond strength of the COF, thereby increasing the stability of the material. Based on enthalpy of formation, it was concluded that HFG is a marginally more favorable cross-linking moiety. This was attributed to the length of HFG which allows it to cross-link with the COF in more configurations than OC. Cross-linking with HFG was synthesized and characterized with Fourier transform infrared (FTIR) spectroscopy, X-ray diffraction (XRD), and water contact angles. The presence of HFG cross-linking was confirmed and it was concluded via membrane permeance testing that varying the amount of cross-linking reagent during synthesis had not changed the amount of cross-linking occurring. This was also supported by thermogravimetric analysis with differential scanning calorimetry (TGA-DSC). Enthalpy of formation and cohesive energy calculations suggest that reduced cross-linking has a negligible effect on framework stability, and *ab-initio* molecular dynamics also agreed with the temperature range of stability from TGA-DSC.

Measurement of Liquid Transport in a Single Diatom Frustule via *In-Situ* Optical Microscopy Omer R. Caylan[1], Carlos D. Diaz[1], Suchitra Ambudipudi[2], Sunghwan Hwang[2], Jihoon Park[2], Joseph Flanagan[2], Ken Sandhage[2] and Lenan Zhang[1]; [1]Massachusetts Institute of Technology, United States; [2]Purdue University, United States

Diatoms are a type of microscopic phytoplankton that exist in various aquatic environments (oceans, lakes, rivers). They are unicellular organisms enclosed in intricate, silica-rich microshells known as frustules. Notably, diatom frustules can possess multilevel hierarchical 3-D pore patterns with the smallest pore sizes down to a few tens of nanometers. Such unique 3-D multiscale features cannot be easily achieved with state-of-the-art cleanroom fabrication techniques. For this reason, diatom frustules have attracted attention in a wide range of applications, from nanotechnology to biotechnology (e.g., for drug delivery, wastewater treatment, biomolecule, and gas sensors). To support these crucial applications, it is essential to possess a comprehensive understanding of the fundamental principles governing liquid transport within diatom frustules. However, characterizing liquid transport through the hierarchical pores in a single microscopic diatom frustule is fundamentally challenging. To overcome these challenges, we developed a microfluidic test rig equipped with high-resolution optical microscopy. This characterization apparatus is capable of detecting liquid propagation from multiple angles with high spatial resolution and with a high frame capture rate. We have used this apparatus to identify microscopic features affecting liquid transport in *Coscinodiscus wailesii* diatom frustules and, for the first time, obtained key liquid transport characteristics of such frustules (including capillarity, wickability, and permeability). The optical metrology-based test rig developed in this work can be a useful platform for evaluating microfluidic behavior in various complex structures. This study is based on work supported by the Air Force Office of Scientific Research under Award Number FA9550-23-1-0055.Diatoms are a type of microscopic phytoplankton that exist in various aquatic environments (oceans, lakes, rivers). 3:30 PM NM03.02.06
Multimodal Characterization of Separation Membranes in Three Dimensions using Scanning Transmission Electron Microscopy (STEM) Tomography and Electron Energy Loss Spectroscopy (EELS) Matthew J. Coupin[1,2]; [1]The University of Texas at Austin, United States; [2]Texas Materials Institute, United States

For decades, thin film composite membranes, in particular those employing an aromatic polyamide active layer, have become the dominant technology for the purification of water by nanofiltration and reverse-osmosis [1]. The extreme physical and chemical requirements demanded of these membranes (selectivity, permeability, fouling resistance, mechanical strength) combined with unique difficulties in studying their structure-property relationships on the nanoscale, have largely frustrated efforts to develop viable membranes based off new technologies. After more than 40 years, synthetic polymer membranes, many of which were discovered serendipitously, remain state-of-the-art. As the world confronts a changing climate, growing demand for water, and a transition away from fossil energy it is increasingly important that new effective, energy-efficient separation technologies be developed [2]. This will require advances in computational modeling and synthesis, informed by new and improved methods of material characterization.

TEM has long been a powerful tool for the nanoscale characterization of membranes; however, all TEM methods fundamentally produce some sort of two-dimensional projection of the sample. Although there can be great value in 2D top-down and cross-sectional imaging of membranes [3], the structure of a membrane must be studied in more than two dimensions to fully describe its function. Unlike conventional TEM-tomography methods, which have been successfully employed to study 3D morphological properties of separation membranes [4] high angle annular darkfield scanning transmission microscopy (HA-ADF STEM) scans a focused probe over the sample and is capable of producing images at the highest achievable resolutions whose contrast is proportional to sample density and thickness. Further, each scan line can be acquired with a different defocus, allowing large areas of the sample to be kept in-focus even at high tilt angles [5]. Taken together, these qualities allow for three-dimensional images that accurately reflect the sample's scattering density to be computed from the HA-ADF tilt series data.

In this presentation I will discuss how HA-ADF STEM tomograms can be collected, calculated, and combined with electron energy loss spectroscopy data to produce three-dimensional images of chemistry and sample density to inform water transport simulations [6] and membrane synthesis. Particular emphasis will be given to the experimental and geometrical limitations on quantitativeness, such as the limited range of angles from which a membrane can

be viewed in TEM, and how optimization and machine-learning techniques can be employed improve quantitativeness beyond the current state-of-the-art. Last, prospects for a 'closed-loop' unifying synthesis, characterization, and computational design will be discussed.

Advanced Chemical Characterization of Sub-Nanometer Pores in 2D Hexagonal Boron Nitride Dana O. Byrne[1,2], Aleksandr Noy[3,4], Alex Smolyanitsky[5], Jim Ciston[2] and Frances I. Allen[1,2]; [1]University of California, Berkeley, United States; [2]Lawrence Berkeley National Laboratory, United States; [3]Lawrence Livermore National Laboratory, United States; [4]University of California, Merced, United States; [5]National Institute of Standards and Technology, United States

Understanding and controlling the local chemistry and structure of vacancy defect clusters (i.e. nanopores) in 2D materials is essential for the development of advanced membranes that leverage the unique transport properties of these systems. In particular, nanopores in solid state 2D membranes can be designed to finely control ion selectivity and molecule permeability, and are thus of great interest for advanced applications in filtration and molecular sensing. Recent theoretical work and simulation has demonstrated strain-modulated ion transport behavior in graphene-embedded crown ethers, where oxygen termination of the pore edges forms $C^{\delta+}$-$O^{\delta-}$ dipoles radially aligned toward the center of each pore [1]. To investigate this mechanosensitivity effect experimentally, we turn to the heteroatomic 2D material hexagonal boron nitride (hBN). This is because geometric (specifically, triangular) nanopores can be fabricated in 2D hBN with radially oriented dipoles by default, eliminating the need for additional chemical functionalization steps.
To fabricate nanopores in 2D hBN with controlled shape and size, we use ion beam [2], electron beam [3], and combined ion and electron beam methods [4]. The ion irradiation is performed using an ion beam microscope, whereas the electron beam manipulation is carried out in a transmission electron microscope (TEM) with in-situ imaging at atomic resolution to track the pore growth process. Although we have control over nanopore size and shape using the TEM, dangling bonds present on the nanopore edges will be susceptible to chemical changes. Environmental effects are thus expected to alter the nanopore transport properties, since ion transport is heavily dependent on the electrostatic and steric interactions inside the pore. Therefore, it is essential that we elucidate the chemical structures of the nanopores in order to understand how they behave in a real system.
We survey the local chemistry of our nanopores using monochromated electron energy loss spectroscopy (EELS) in the TEM, probing local bonding and chemical composition based on variations in the fine structure of the boron K-edge signals. We find that oxygen dopant defects are present in varying amounts in a range of hBN nanopore samples and that the local chemistry of the nanopores is susceptible to change both inside the vacuum environment of the microscopes as well as upon exposure to air. Furthermore, we find that nanopore stability in air is greatly affected by the presence of hydrocarbon surface contaminants. These results highlight the importance of thoroughly characterizing the chemical structure of 2D nanopores when they are exposed to different environments in order to enable accurate simulation and interpretation of ion transport data.

Defect-Healed Carbon Nanomembranes for Enhanced Salt Separation: Scalable Synthesis and Performance Zhen Yao[1], Pengfei Li[1,2], Kuo Chen[1,2], Yang Yang[1], André Beyer[1], Q. Jason Niu[3] and Armin Goelzhaeuser[1]; [1]Bielefeld University, Germany; [2]China University of Petroleum (East China), China; [3]Shenzhen University, China

Ultrathin carbon nanomembranes (CNMs), fabricated from crosslinking self-assemblies of molecular precursors, are 2D membranes that possess well-defined physical and chemical properties.[1] Featuring a high density of sub-nanometer channels, CNMs enable superior salt separation performance compared to conventional membranes.[2] However, defect occurrence during synthesis and transfer processes impedes their technical realization on a macroscopic scale.
Here, we introduce a practical and scalable interfacial polymerization method to effectively heal defects while preserving the sub-nanometer pores within CNMs. Defects in CNM composites were successfully repaired by interfacial polymerization of polyamide using m-phenylenediamine as the aqueous phase monomer and trimesoyl chloride as the oil phase monomer. The defect-healed CNMs exhibit exceptional performance in forward osmosis (FO), achieving a water flux of 105 L m^{-2} h^{-1} and a specific reverse salt flux as low as 0.1 g L^{-1} when measured with 1M NaCl as draw solution. This water flux is ten times higher than commercially available FO membranes. Through successful implementation of the defect-healing method and support optimization, we demonstrate the scalable synthesis of fully functional, centimeter-scale CNM-based composite membranes, showing a water permeance comparable to commercial membranes and a salt rejection of ~99.8%. Our defect-healing method presents a promising pathway to overcome limitations in CNM synthesis, unlocking their potentials for practical salt separation applications.

Interlayer-Shifting and Functionalization of 2D COF Membranes for Controlled Transport Sui Zhang; National University of Singapore, Singapore

2D COF membrane is a versatile platform for the understanding and control of ion/molecular transport with its microporosity, interlayer spacing and rich space of chemistry.

In the first part of our work, we attempted to regulate the interlayer alignment of 2D COF membranes by the use of different catalyst. In contrast to traditional acid, the Lewis acid is able to accelerate the polymerization of imine-based COF and drives the interlayer shifting between adjacent layers, thereby resulting in pore redistribution and reduced pore size. The membrane exhibits high permeance and reasonable selectivity for H2/CO2 separation.In the 2nd part of our work, we functionalized the COF with sulfonate groups and observed interesting coordination-facilitated ion transport in the mixed ion environment. While single ion tests do not show much selectivity towards divalent and monovalent ions, the ion transport is much accelerated in the mixed ion solution, enabling high Mg2+/Li+ selectivity.

Novel Copper-Nickel Pc-Por-Based Electrocatalysts for Highly Selective CO2 Reduction and Multi-Carbon Compound Synthesis Abebe B. Workie; National Taiwan University of Science and Technology, Taiwan

Efforts are focused on developing an efficient strategy to combat global warming while also advancing the electrochemical conversion of carbon dioxide (CO2) into multi-carbon compounds and improving C-C coupling processes. For accelerating the transformation of CO2 into high-value chemicals, Metallomacrocyclic compounds have shown great potential among the many materials under investigation. However, they have thus far run across issues including low current density, limited catalytic activity, poor product selectivity, and stability worries. In this work, we present a novel achievement in the form of stable and conductive ultrathin dimeric Copper-Nickel Pc-Por-based electrocatalysts, synthesized through a solvent-assisted strategy. The manipulation of electron polarization between metal atoms is made feasible by adjusting the functionality and size of ligands, which enhances catalytic activity. This, in turn, leads to heightened atom utilization efficiency, customized catalytic behaviors, and exceptional selectivity, surpassing the benchmarks in C-C coupling and multi-carbon product formation. Our electrocatalyst exhibits remarkable selectivity for acetylene production, as demonstrated in an H-type cell. When operating in a 0.5 M KHCO3 solution, it achieves outstanding Faradaic efficiencies (FEs) for CO2 reduction at 0.61 V (vs. RHE), yielding over 94% acetylene with a current density exceeding 85 mA cm2. These results surpass the performance of the majority of previously reported CO2 electrocatalysts. This study introduces a practical approach for designing future generations of cost-effective, efficient, and selectivity electrocatalytic reduction of carbon dioxide, offering potential solutions to mitigate global warming.

5:00 PM NM03.03.02
Separation of High-Purity C_2H_2 from Binary C_2H_2/CO_2 with Robust Al-Based MOFs Constructed with Nitrogen(N)-Containing Heterocyclic Dicarboxylate Se Min Jeong[1,2], Donghyun Kim[1,3], Ji woong Yoon[1], Su-Kyung Lee[1], Jong Suk Lee[2], Donghui Jo[1], Kyung-Ho Cho[1] and U-hwang Lee[1]; [1]Korea Research Institute of Chemical Technology, Korea (the Republic of); [2]Sogang University, Korea (the Republic of); [3]Yonsei University, Korea (the Republic of)

The separation of acetylene (C_2H_2) from carbon dioxide (CO_2) holds considerable industrial importance, primarily in acetylene purification. Indeed, the conventional distillation process poses significant energy-consuming due to the similar physicochemical properties, such as kinetic diameters and boiling points of these two gases. In this research, we investigate the potential of three aluminum-based metal-organic frameworks (Al-MOFs), namely Al-L_1, Al-L_2, and Al-L_3, built by nitrogen (N)-containing organic linkers for separating C_2H_2 from C_2H_2/CO_2 mixtures. Among these Al-MOFs, Al-L_3 shows the highest C_2H_2/CO_2 selectivity (4.86) owing to its relatively greater adsorption capacity for C_2H_2 (7.90 mmol g^{-1}) and lower adsorption capacity for CO_2 (2.82 mmol g^{-1}) compared to the other two Al-MOFs. In dynamic breakthrough experiments with an equimolar binary C_2H_2/CO_2 gas mixture, Al-L_3 demonstrates superior separation performance by yielding high-purity C_2H_2 (>99.95%) of 3.73 mmol g^{-1} through a simple desorption procedure with helium (He) purging at ambient condition. Also, computational simulations employing canonical Monte Carlo and dispersion-corrected density functional theory (DFT-D) methods are conducted to explore the distinctive pore structures of Al-L_1 and Al-L_3. The results emphasize the changes of affinity from variations in the positions of N atoms within pyridine and secondary amine (H–N) groups of three different Al-MOFs. Consequently, Al-L_3 is considered a promising adsorbent for separating high-purity C_2H_2 from binary C_2H_2/CO_2 gas mixtures, and we expect to effectively address challenges related to gas separation in both industrial and scientific fields.

5:00 PM NM03.03.03
Single-Step Ethylene Purification from Ternary C_2 Hydrocarbon Mixtures in a Scalable Metal–Organic Framework Donghyun Kim[1,2], Bao Nguyen Truong[1], Donghui Jo[1], Ji woong Yoon[1], Su-Kyung Lee[1], Youn-Sang Bae[2], Kyung-Ho Cho[1] and U-hwang Lee[1]; [1]Korea Research Institute of Chemical Technology, Korea (the Republic of); [2]Yonsei University, Korea (the Republic of)

Single-step purification of the ternary C_2 hydrocarbon mixture to produce ethylene (C_2H_4) directly using adsorption-based technologies is desirable for reducing large energy consumption. However, it is challenging to develop an appropriate adsorbent, having preferential adsorption characteristics toward ethane (C_2H_6) and acetylene (C_2H_2) rather than C_2H_4 coupled with high adsorption capacity owing to their similar physicochemical properties. Herein, we present a highly stable, cheap, and scalable CAU-23 adsorbent, which enables single-step production of high-purity C_2H_4 (>99.9%) from the ternary C_2 hydrocarbon mixture. CAU-23 exhibited higher uptake capacity of C_2H_6 (4.0 mmol g^{-1}) and C_2H_2 (4.7 mmol g^{-1}) compared to that of C_2H_4 (3.8 mmol g^{-1}). Further, it showed the reasonable selectivity for both C_2H_6/C_2H_4 (1.54) and C_2H_2/C_2H_4 (1.5) with an equimolar binary mixture, indicating that the separation performance of CAU-23 is comparable to the benchmark porous materials for separating C_2 ternary gas mixture. The breakthrough experiments

demonstrated its capability to produce high-purity C_2H_4 (>99.9%) with various $C_2H_6/C_2H_4/C_2H_2$ compositions at 298 K and 1 bar with high recyclability. The origin of the separation performance was further explored by using computational simulations of the grand canonical Monte Carlo (GCMC) and density functional theory (DFT).

5:00 PM NM03.03.04
Metal-Organic Framework (MOFs)-Derived Carbon Nanotubes (CNT) Intercalated into Ultrathin Polyamide Selective Layers to Improve Ethanol Purification Performance Lei Jiang, Pengrui Jin and Bart Van der bruggen; KU Leuven, Belgium

With the growing severity of the energy crisis, the development of renewable and clean energy sources that can replace fossil fuels has become a hot research topic. Biofuel ethanol, mainly derived from biomass through processes like saccharification and fermentation, with a volume concentration of over 99% anhydrous ethanol, has emerged as a promising alternative energy source due to its natural abundance and non-toxic properties. Utilizing membrane separation technology to purify ethanol offers a more efficient alternative to traditional distillation techniques, significantly reducing overall production costs. The selective layer for the membrane is prepared through interfacial polymerization using d-sorbitol (DST) and trimesoyl chloride (TMC). DST is chosen for its higher number of hydroxyl groups, which provide a denser separation layer with the thickness less than 100 nm. Its linear structure reacts well with TMC, enhancing crosslinking and improving separation performance. Metal-organic framework (MOFs)-derived carbon nanotubes (CNTs) are a novel carbon material with the diameter of 10 nm obtained by high-temperature calcination of ZIF-67. During the pyrolysis process, there is no aggregation, and embedding MOFs-derived CNTs in the thin-film nanocomposite (TFN) membrane selective layer can create mass transport channels to increase the TFN membrane's flux without compromising separation efficiency.
Therefore, post-treatment using MOFs-derived CNT intercalated into ultrathin polyamide selective layers can further enhance the flux and keeping a stable separation efficiency of TFN membranes with a stable performance over a long period of time.

5:00 PM NM03.03.05
Effect of Voids on Nanoscale Charge Transport Through 2D Networks Consisting of 1D Nanoscale Wires Sara Alzahrani, Devendra Kumar Gorle, Andrew Qiu and Ant Ural; University of Florida, United States

Two-dimensional (2D) networks consisting of one-dimensional (1D) nanoscale wires, such as carbon nanotubes, metal nanowires, and graphene nanoribbons, are promising candidates for many applications including nanoscale mass transport membranes, transparent conductive electrodes, flexible electronics, wearable systems, electronic skin, biosensors, and neuromorphic computation.
The nanoscale charge transport in 2D nanowire networks is governed by percolation, which deals with the formation of long-range connectivity in random networks. As a result, Monte Carlo simulations need to be utilized in order to compute the charge transport properties of these networks. Understanding the impact of voids, which could be present due to lack of control in the deposition/fabrication process or introduced intentionally, on nanoscale charge transport phenomena in nanowire networks is critical for many applications.
In this work, we study the effect of voids on nanoscale charge transport through nanowire networks. We generate two-dimensional square nanowire networks with square voids located at the center of the nanowire network. We define the relative void size as the ratio of the length of the side of the void to the length of the side of the nanowire network. We first study the impact of voids on networks consisting of randomly oriented and straight nanowires. We compute the percolation probability in these networks as a function of nanowire density for different relative void sizes ranging from 0 (i.e., a network without a void) to 0.8. Assuming a Gaussian percolation probability density function (PDF), we find that both the mean and standard deviation of the PDF increase with increasing relative void size. We then compute the relative conductivity change as a function of nanowire density for different relative void sizes and find that it increases approximately linearly with relative void size.
The conductivity of a nanowire network is found to exhibit a power-law dependence on nanowire density as predicted by percolation theory. In order to study the effect of voids on this dependence, we extract the local power-law critical exponent as a function of nanowire density for different relative void sizes. We find that the critical exponent approaches 2 at high density for all relative void sizes, in agreement with previous observations for junction-resistance dominated networks without voids.
Furthermore, we generate curvy nanowires using third order Bezier curves characterized by the curviness angle and aligned nanowires using an orientation characterized by the alignment angle. Using the same procedure as randomly oriented and straight nanowires, we then investigate the impact of voids on the nanoscale charge transport through networks consisting of curvy and aligned nanowires. We compute critical phenomena such as the percolation probability, mean and standard deviation of the percolation probability density function, relative conductivity change, and nanowire density critical exponent.
Our results demonstrate the impact voids have on nanoscale charge transport through 2D networks consisting of 1D nanoscale wires, such as carbon nanotubes, metal nanowires, and graphene nanoribbons. These results also show that Monte Carlo simulations are an essential predictive tool for providing insights into nanoscale charge transport in nanowire networks, which are promising candidates for a wide range of applications such as nanoscale mass transport membranes, transparent conductive electrodes, flexible electronics, wearable systems, and neuromorphic computation.

SESSION NM03.04: Graphene Membranes I

8:30 AM NM03.04.01
Ion-Selective Membranes for Critical Materials Seperation Van T. C. Le, Quy Nguyen, Hien Duy Mai, Bin Wang and Ngoc Bui; The University of Oklahoma, United States

This study aims at the design and fabrication of an emerging adsorptive membrane platform for transition metal ion capture. Specifically, the membrane composes of a selective layer built from stacks of zinc imidazole salicylaldoxime (ZIOS) crystalline nanosheets on a polyvinylidene fluoride (PVDF) supporting layer pretreated with polydopamine and polyethyleneimine. The dimensional and morphological textures of ZIOS layers were tuned by varying the concentrations of poly(vinyl alcohol) (PVA, Mw = 146,000-186,000 g/mol) in the reaction media. Additionally, textural properties (e.g., morphology, crystal size, particle orientation, and uniformity) and the adhesion of the ZIOS selective layer to the PVDF-PDA-PEI supporting substrate were controlled by tuning the synthetic conditions. Our results show that these ZIOS/PVDF-PDA-PEI membranes feature distinct ion transport and adsorption efficiency, which are critical for selective metal ion capture. The Cu2+/Ni2+ separating factor was calculated to be 193. We use in-situ Raman spectroscopy to elucidate the underlying mechanisms governing the preferential metal ion uptake by the adsorptive membranes, of which the ZIOS layer functions as a selective layer in discriminating the guest metal cations. Coupled with first-principles calculations, results from this study synergistically provide insight

into mechanistic understanding of metal ion separating behaviors of an emerging membrane platform based on ZIOS, a crystalline adsorbent system that we designed specifically for copper/nickel separation.

Self-Assembled 3D Graphene-Based Framework for Supercapacitor Xiaojun Ren[1], Tongxi Lin[1], Bing Sun[2], Sophia Gu[2], Tobias Foller[1] and Rakesh Joshi[1]; [1]School of Materials Science and Engineering, UNSW Sydney, Australia; [2]UNSW Sydney, Australia

Numerous interests have been attracted to establishing graphene-based materials for energy storage applications in the past decades [1, 2]. Constructing 3-dimensional graphene-based architectures provides a promising conductive skeleton and surface area for surface charge transfer and storage [3]. Herein, we report a simple self-assembled approach utilising surface electrostatic force between graphene oxide (GO) and trimolecular layered double hydroxide (LDH) nanoparticles to construct a hybrid 3D functionalised graphene framework via freeze-drying method for supercapacitor. Surprisingly, the synthesised GO-LDH hybrid material exhibits a typical electro-double layer capacitor (EDLC) rather than a battery electrochemical profile contributed by LDH material [4]. Our experimental study confirmed that the GO-LDH hybrid presents a relatively high specific capacitance of 278 F/g at 1 A/g and impressive rate capability (77.6%) at a high current density of 50 A/g in the aqueous working environment. We further investigated the surface structure to discuss the unexpected electrochemical profile of the material. This work provides a new insight into the fabrication and understanding of the GO-LDH hybrid 3D framework. A simple synthesis method, high reproducibility, and effective energy storage performance open a broad potential pathway for further applications.

CO2 Capture using Functionalized Graphene Oxide Dogukan Yazici and Michael Bozlar; The University of Texas at Arlington, United States

In this work, we aim to address the urgent global issue of increasing CO2 levels. We conduct a comprehensive study that integrates both experimental and theoretical chemistry. Using Density Functional Theory (DFT) first-principle calculations, we determine the positions of functional groups on the graphene lattice. Furthermore, we investigate the nature of interactions between functionalized-Graphene Oxide and CO2 molecules, from first principles. We synthesize various types of functionalized-graphene membranes for CO2 capture and perform physical and chemical analyses using X-ray Diffraction (XRD), Proton Nuclear Magnetic Resonance (H-NMR), and Fourier Transform Infrared Spectroscopy. Our results demonstrate effective CO2 capture using amino-functionalized graphene under stationary conditions, consistent with theoretical predictions.

9:15 AM *NM03.04.04
Graphene Oxide Membranes for Purification and Separation Rakesh Joshi, Tobias Foller, Xinyue Wen, Dali Ji and Xiaojun Ren; UNSW Sydney, Australia

We report graphene oxide (GO) based membranes with proper control of structure, in-plane pores and morphology for water purification, selective gas separation and moisture adsorption. We have investigated the water transport in cation-intercalated graphene oxide membranes and observed that cations act as water-attracting impurities on the channel walls. Via controlled water transport experiments, we show that the slip length of the nanochannels decays exponentially with the hydrated diameter of the intercalated cations. In collaborative projects with industries, we have successfully employed our GO membrane to remove natural organic matter and chlorine from water while maintaining high water flux. In addition, we introduce a straightforward electrochemical method utilising the angstrom confinement of laminar reduced graphene oxide (rGO) nanochannels to obtain a centimetre-scale network of atomically thin (0.4 nm) 2D transition metal oxides.

9:45 AM BREAK

10:15 AM NM03.04.05
Electrophoretically Deposited Graphene Oxide on Acid-Washed Nickel Foam Substrate for High-Performance Capacitive Ion Desalination Jyotiraman De, Arun Kumar Singh, Sumit Saxena and Shobha Shukla; Indian Institute of Technology Bombay, India

Graphene Oxide (GO) comprises unique features that make it a potential material for capacitive deionization (CDI) of brackish and saline water such as Graphene Oxide's increased surface area provides more ion adsorption sites, chemical stability of Graphene Oxide across a wide pH and ionic strength range contributing to the longer operational time of the CDI electrodes, possibility of modification of the Graphene Oxide with various surface functional groups in order to alter the selectivity of CDI electrode for ions and easy dispersibility of Graphene Oxide in various aqueous media and solvents. However, the method of loading the Graphene Oxide as an active material on the current collector to prepare an electrode and the preparation of a current collector before loading of the active material affects the desalination performance. Hence, exploring an efficient loading method of Graphene Oxide on a high charge transfer capable current collector is required that would inherit a higher electrochemical performance along with higher salt removal capacity. In order to mitigate the drawbacks of currently employed materials and methods, here we report a facile, scalable, and efficient method of preparing CDI electrodes by electrophoretic coating of GO on acid-washed Nickel foam. The nickel foam as a current collector was subjected to acid washing with various concentrations of acid, and simultaneous material and electrochemical characterization were conducted to optimize the acid concentration. Further, the Deionised (DI) water and acid-washed Nickel foam current collectors were dip-coated and electrophoretically coated with Graphene Oxide which on performing the physiochemical and electrochemical characterization displayed the specific capacitance and current density in the order electrophoretically coated GO on acid-washed Nickel foam > dip-coated GO on acid-washed Nickel foam > electrophoretically coated GO on DI-washed Nickel foam > dip-coated GO on DI-washed Nickel foam. In comparison to the dip-coated GO on DI-washed Nickel foam, electrophoretically coated GO on acid-washed Nickel foam demonstrates a multi-fold increase in the specific capacitance and current density. The use of three-dimensional electrophoretically coated GO on acid-washed Nickel foam electrodes in a CDI device contributed to the efficient charge transfer ability of the CDI and resulted in a substantial increase in salt adsorption capacity with excellent recyclability and efficient regeneration of the electrodes.

10:30 AM *NM03.04.06
Nanoscale Transport of Water and Molecules within 2D Materials and Its Impact on Nanofluidic Circuitry Slaven Garaj; National University of Singapore, Singapore

The study of molecular transport within nanometer-scale confinements is a fundamental challenge in materials science, underpinning the rational design of advanced materials for diverse applications and novel nanofludics circuitry. Two-dimensional (2D) materials, renowned for their atomically clean interfaces, sub-nanometer control over geometry, and precise manipulation of surface properties, present an exceptional model system for unravelling the intricate phenomena of molecular transport at the nanoscale.
Here we present a comprehensive exploration of the transport of water and molecules within atomically smooth 2D nanochannels and self-assembled laminar nanodevices. This investigation unveils distinct flux patterns for individual components of binary organic and ionic aqueous solutions, enabling a systematic investigation of the interplay between geometric factors, material properties and molecular correlations. Furthermore, our inquiry delves into the mechanical interplay between confined liquids and the channel walls, resulting in the intriguing phenomenon of elastocapillary-driven channel collapse, colloquially referred to as "switching." Armed with a comprehensive theoretical framework and a deep understanding of switching dynamics, we have engineered novel active nanofluidic components, specifically nanoswitches and nanocapsules. Notably, nanocapsules have demonstrated the remarkable ability to reversibly seal zepto-liter volumes of liquids, mirroring the volumes found within viruses.

11:00 AM NM03.04.07
Permeation Behavior of Stretchable Graphene-Based Films for High Performance Gloves Zidan Yang[1], Robert Hurt[1], Aidan Stone[1], Jiaman Wang[1], Aicha Sama[1], Rebecca Martin-Welp[1], Indrek Kulaots[1] and Francesco Fornasiero[2]; [1]Brown University, United States; [2]Lawrence Livermore National Laboratory, United States

Graphene-based ultra-thin films are gaining attention for their exceptional performance as molecular barriers. Understanding how water vapor and hazardous organic molecules permeate these films is key to applications in for personal or product protection. We propose the use of pre-wrinkled graphene-oxide-based nanosheet films as high-performance coatings on gloves due to their stretchability, breathability and strong barrier performance for many organic molecules. Graphene oxide films, however, lack water stability and sufficient mechanical strength for the glove application. To address this, we explore three alternative stabilization methods: high-loading GO-polymer composites, embedded "sandwich" structures, and textured stretchable GO-based coatings. We fabricated these three types of barrier architectures, studied their behaviors under bending, tensile stress, stretching and water immersion, and measured their permeability to water, hexane and toluene as model molecules of widely varying polarity. This work identified several film formulations that show promising barrier properties in combination with breathability and mechanical/immersion stability suitable for glove applications.

11:15 AM *NM03.04.08
Mass Transport Phenomena in Low-Dimensional Space Hyung Gyu Park; Pohang University of Science and Technology, Korea (the Republic of)

Membrane technology poses the potential to bring process intensification to various industrial processes, such as energy-efficient separation of chemicals and energy storage. Membrane-based separation can enhance its efficacy if the membrane materials' selectivity, permeation, and durability can be rendered optimal. In this regard, understanding molecular transport phenomena under extreme confinement provided by low-dimensional materials can help understand and engineer the selective transport in the membrane interior, with which to innovate the pore design. This talk introduces the transport phenomena of molecules across 0D-, 1D-, and 2D-confined space that atomically thin orifices, nanotubes, and laminated 2D materials provide. As the confinement dimension increases, mass permeation tends to decrease from ultimate permeation to fast transport to molecular conduction, whereas chemical selectivity can be endowed to this space by engineering the confining material properties. From the perspective that one may tailor actual chemical selectivity through proper pore design and architectural modification, thus obtained knowledge and pore architectures could lay the cornerstone of advancing membrane transport properties toward process intensification.

11:45 AM NM03.04.09
PH-Dependent Water Permeability Switching and Its Memory in MoS2 Membranes Chengyi Hu[1,2,3], Amritroop Archari[1,2], Kun Huang[1,2] and Rahul Raveendran Nair[1,2]; [1]National Graphene Institute, United Kingdom; [2]The University of Manchester, United Kingdom; [3]Xiamen University, China

Intelligent transport of molecular species across different barriers is critical for various biological functions and is achieved through the unique properties of biological membranes. Two essential features of intelligent transport are the ability to (1) adapt to different external and internal conditions and (2) memorize the previous state. In biological systems, the most common form of such intelligence is expressed as hysteresis. Despite numerous advances made over previous decades on smart membranes, it remains a challenge to create a synthetic membrane with stable hysteretic behaviour for molecular transport. Here we demonstrate the memory effects and stimuli-regulated transport of molecules through an intelligent, phase-changing MoS_2 membrane in response to external pH. We show that water and ion permeation through 1T′ MoS_2 membranes follows a pH-dependent hysteresis with a permeation rate that switches by a few orders of magnitude. We establish that this phenomenon is unique to the 1T′ phase of MoS_2, due to the presence of surface charge and exchangeable ions on the surface. We further demonstrate the potential application of this phenomenon in autonomous wound infection monitoring and pH-dependent nanofiltration. Our work deepens understanding of the mechanism of water transport at the nanoscale and opens an avenue for the development of intelligent membranes.

Covalently Linked Fullerene Membranes for Gas and Water Transport De-en Jiang; Vanderbilt University, United States

It is extremely challenging to create long-range-ordered sub-nanometer pores in carbon materials. Recent breakthroughs in synthesis of covalently linked fullerene networks in gram scales provide a great opportunity to realize 2D and 3D ordered sub-nanometer pores at the interstices among linked C60 units. Here we show from both first principles and molecular dynamics simulations that the square-latticed monolayer fullerene membranes based on the experimental quasi-tetragonal phase of the fullerene 2D network possess the pore size, shape, and geometry promising for gas separations and water

transport. Our simulation results suggest that there is a great potential in using covalently-linked-fullerene membranes for separations.

2:00 PM *NM03.05.02
Mechanistic understanding of oxidation of graphitic lattice for gaining control over the incorporation of Å-scale pores in graphene Kumar Varoon Agrawal; EPFL, Switzerland

Porous two-dimensional (2D) selective layer hosting zero-dimensional pores is attractive for molecular differentiation because one can tune molecular selectivity (by tuning pore size) and molecular flux (by tuning pore density). Porous graphene is an attractive candidate for this given that single-layer graphene can be conveniently synthesized in single-layer polycrystalline film morphology by chemical vapor deposition. Several promising results towards molecular separation have been demonstrated by incorporating pores in graphene by a variety of methods including physical etching (bombarding lattice with energetic beams) and oxidative etching.

In this presentation, I will highlight the important role of oxidative etching of graphene in highly scalable and easy-to-implement porosity incorporation in graphene with excellent control in the incorporation of Å-scale pores. I will discuss our recent efforts in understanding the mechanism of incorporation of these pores in the graphene lattice, starting with a single oxidation event, followed by cooperative assembly of the chemisorbed oxygen (epoxy) into clusters which then regulate the final pore size. I will discuss how clusters have ordered superlattice of O (against expectations of amorphous structure), which then leads to a series of sequences resulting in the incorporation of pores. I will discuss further examples of oxidation reactions that allow one to tune the size of pores in a highly controllable manner. Finally, I will discuss recent activities in scaling up graphene membranes, thanks to a highly scalable graphene oxidation chemistry.

2:30 PM *NM03.05.03
Cascaded Compression of Size Distribution of Nanopores in Monolayer Graphene Chi (David) Cheng[1], Jiangtao Wang[2] and Jing Kong[2]; [1]The University of New South Wales, Australia; [2]Massachusetts Institute of Technology, United States

Monolayer graphene with nanometre-scale pores, atomically thin thickness and remarkable mechanical properties provides wide-ranging opportunities for applications in ion and molecular separations, energy storage and electronics. Because the performance of these applications relies heavily on the size of the nanopores, it is desirable to design and engineer with precision a suitable nanopore size with narrow size distributions. However, conventional top-down processes often yield log-normal distributions with long tails, particularly at the subnanometre scale. Moreover, the size distribution and density of the nanopores are often intrinsically intercorrelated, leading to a trade-off between the two that substantially limits their applications. In this talk, we report a cascaded compression approach to narrowing the size distribution of nanopores with left skewness and ultrasmall tail deviation, while keeping the density of nanopores increasing at each compression cycle. The formation of nanopores is split into many small steps, in each of which the size distribution of all the existing nanopores is compressed by a combination of shrinkage and expansion and, at the same time as expansion, a new batch of nanopores is created, leading to increased nanopore density by each cycle. As a result, high-density nanopores in monolayer graphene with a left-skewed, short-tail size distribution are obtained that show ultrafast and angstrom-size-tunable selective transport of ions and molecules, breaking the limitation of the conventional log-normal size distribution. This method allows for independent control of several metrics of the generated nanopores, including the density, mean diameter, standard deviation and skewness of the size distribution, which will lead to the next leap in nanotechnology.

3:30 PM *NM03.05.04
Nanoporous Graphene Based Nanofluidics, From Mechanisms to Applications Luda Wang; Peking University, China

Nanofluidics has not only drawn significant research interest due to its abnormal behavior compared to bulk fluids, but also has numerous applications such as separation, sensing, and energy conversion. Graphene provides an ideal two-dimensional platform to investigate the transport of nanofluids owing to its ordered structure, chemical stability, and easy modification.
Nanopores in graphene membranes provide 0D confined spaces to study transport mechanisms. Controlling the pore size in graphene membranes is a prerequisite, as even a small variation in pore size can result in a significant difference in transport properties. By decoupling defect site nucleation and defect growth with two successive plasma treatments, we achieved a narrow pore size distribution from gas-selective sub-nanometer pores to a few nanometers in size for small molecule separation. Moreover, we used a new strategy and achieved high solvent flux via organic solvent forward osmosis. After the precise introduction of the confined space, we then focus on designing functional groups, which provide a new degree of freedom. Through controlled nitrogen plasma, a highly proton-selective membrane was fabricated. By controlling the grain boundary density, proton permeance can be tuned within a range of 2 orders of magnitude with high selectivity and high proton conductivity. Through the synergistic regulation of the pore size and chemical properties of *in-situ* covalent modification, asymmetric ion transport behaviors and efficient sieving of monovalent metal ions (K^+/Li^+ selectivity ~ 48.6) can be achieved. Meanwhile, it also allows preferential transport for cations. The resulting membranes exhibit a K^+/Cl^- selectivity of 76 and an H^+/Cl^- selectivity of 59.3. The synergistic effects of steric hindrance and electrostatic interactions impose a higher energy barrier for Cl^- or Li^+ to cross nanopores, leading to ultra-selective H^+ or K^+ transport.
Besides the proof-of-concept experiments, we tried to bridge the gap between theory and reality to utilize graphene membranes in specific applications. For large-scale production, decimeter-scale ($\sim 15 \times 10$ cm^2) large-area nanoporous single-layer graphene membranes and stability-enhanced double-layer graphene membranes were fabricated. An application paradigm of graphene in a membrane-based precision instrument with higher precision and better stability was achieved. One step further, regarding realizing the module of graphene membrane, the poor resistance to deformation under tension and bending of composite membrane is the limit. We designed a large-area nanoporous graphene separation membrane supported by a fiber-reinforced structure, which exhibits excellent tensile and bending capabilities. The fracture stress, fracture strength, and tensile stiffness have been increased by 1-2 orders of magnitude compared to existing research. It can maintain stability under different curvature conditions and remain intact after 10,000 repeated bends, laying a foundation for the long-term development of graphene films in practical separation applications.

Anti-Arrhenius Passage of Gaseous Molecules through Nanoporous Two-Dimensional Membranes Petr Dementyev and Armin Goelzhaeuser; Bielefeld University, Germany

The passage of molecules through membranes is known to follow an Arrhenius-like kinetics, i.e. the flux is accelerated upon heating and vice versa. There exist though stepwise processes whose rates can decrease with temperature if, for example, adsorbed intermediates are involved. In this study, we perform temperature-variable permeation experiments in the range from -50 to +50 °C and observe anti-Arrhenius behaviour of water and ammonia permeating in two-dimensional freestanding carbon nanomembranes (CNMs). The permeation rate of water vapour is found to drop manyfold with warming, while the passage of ammonia molecules strongly increases when the membrane is cooled down to the dew point. Liquefaction of isobutylene shows no enhancement for its transmembrane flux which is consistent with the material's pore architecture.

The Parameter Space for Scalable Integration of Atomically Thin Graphene with Nafion for Proton Exchange Membrane (PEM) Applications
Piran Ravichandran Kidambi; Vanderbilt University, United States

Selective proton permeation through atomically thin graphene while maintaining impermeability to even small gas atoms *i.e.* He or hydrated ions, presents potential for advancing proton exchange membranes (PEMs) across a range of energy conversion and storage applications. The incorporation of graphene into state-of-the-art proton conducting polymers *e.g.* Nafion can enable improvements in PEM selectivity as well as mitigate reactant crossover. The development of facile integration approaches are hence imperative. Here, we systematically study the parameters influencing the integration of monolayer graphene synthesized *via* scalable chemical vapor deposition (CVD) on polycrystalline Cu foils with a model proton conducting polymer (Nafion) *via* a facile hot-press process. The hot-press time (*t*), temperature (*T*) and pressure (*P*) are found to not only influence the quality of graphene transfer but can also introduce additional defects in the CVD graphene. Graphene transfers to Nafion performed below the optimum temperature (T_{opt} ~ 115 °C) remain patchy with ruptures, while transfers above T_{opt} showed defect features, and transfers near T_{opt} show minimal ruptures and defect features. We demonstrate Nafion|graphene|Nafion sandwich membranes using the optimal transfer conditions that allow for ~50% reduction in hydrogen crossover (~0.17 mA cm^{-2}) in comparison to Nafion control membranes (~0.33 mA cm^{-2}) while maintaining comparable proton area specific resistance < 0.25 Ω cm^2 (areal conductance ~ 4–5 S cm^{-2}), that are adequate to enable practical PEM applications such as fuel cells, redox flow batteries, and beyond.

Programmable Synthesis of Atomically Precise Nanoporous Graphene Materials Mamun Sarker[1], Christoph Dobner[2], Percy Zahl[3], Axel Enders[2] and Alexander Sinitskii[1]; [1]University of Nebraska-Lincoln, United States; [2]University of Bayreuth, Germany; [3]Brookhaven National Laboratory, United States

The bottom-up synthesis is a powerful approach for fabricating graphene-based nanomaterials (GNMs) with atomic precision. This approach relies on well-defined chemical reactions between specially designed molecular precursors that dictate the structure of the resulting GNMs. Therefore, preparing a new GNM generally requires the design and synthesis of a new molecular precursor, which is often very challenging and laborious. In this work, we demonstrate a family of molecular precursors based on 7,10-dibromo-triphenylenes that can selectively produce different varieties of atomically precise GNMs, porous nanographenes (pNGs), and porous graphene nanoribbons (pGNRs), using different synthetic environments. More specifically, we show that upon Yamamoto polymerization of these molecules in a solution environment, the free rotations of the triphenylene units around the C-C bonds result in forming cyclotrimers at high yields. In contrast, in the case of on-surface polymerization of the same molecules on Au(111), these rotations are impeded, and the coupling proceeds toward forming long polymer chains. These chains can then be converted into pGNRs by annealing. Correspondingly, the solution-synthesized cyclotrimers can also be deposited onto Au(111) and converted into pNGs via a thermal treatment. Thus, both processes start with the same molecular precursor and end with an atomically precise GNM on Au(111), but the product type, pNG or pGNR, depends on the specific coupling approach. We also produced extended nanoporous graphenes (NPGs) through the lateral inter-ribbon cyclodehydrogenation of highly aligned pGNRs at high coverage. All synthesized products were atomically precise, including the NPGs, which were shown to be deterministic in terms of the nanopore shape and size and contain only [18]annulene nanopores if occasional defects are not considered. We demonstrate the generality of this approach by synthesizing two varieties of 7,10-dibromo-triphenylenes that produced six GNM products with different dimensionalities. By constructing different GNMs from the same building blocks, it is possible to tune the band gap in a wide range. The basic 7,10-dibromo-triphenylene is amenable to structural modifications, potentially providing access to many new GNMs. The fact that the synthesized GNMs possess atomically precise nanopores suggests using these materials for fundamental studies of the nanopore effect on the electrical and mechanical properties of graphene and their potential use for electronic, optoelectronic, and molecular sieving applications.

Nonlinearities and High-Harmonic Generation with Strongly Coupled Photon-Matter Prineha Narang; University of California, Los Angeles, United States

The ability to generate and control light at increasingly short time scales impacts wide-ranging areas of science and technology ranging from the investigation of material properties to the development of optical frequency combs suitable for metrology. Ultrafast light sources are often limited in terms of achievable photon energies though various techniques aimed at generating high harmonics of input light from solid-state materials have been pursued to push the upper energy limit to the extreme ultraviolet or x-ray regime. In this context, I will discuss a cavity-mediated approach to break the inversion symmetry allowing for highly tunable even-order harmonic generation naturally forbidden in such systems. This relies on a quantized treatment of the coupled light-matter system, similar to the driven case, where the molecular matter is confined within an electromagnetic environment and the incident (pump) field is treated as a quantized field in a coherent state. When the light-molecule system is strongly coupled, it leads to two important features: (i) a controllable strong-coupling-induced symmetry breaking, and (ii) a tunable and highly efficient nonlinear conversion efficiency of the harmonic generation processes. Both of these have implications for molecular quantum architectures. At the same time, being able to control molecules at a quantum level gives us access to degrees of freedom such as the vibrational or rotational degrees to the internal state structure. Towards this, we explore the role an excited cavity mode plays in the generation of entanglement between molecules in a strongly coupled cavity setup and the potential for generating non-classical states of light due to the strong interaction between the molecules and cavity field. Finally, I will present an outlook on connecting ideas in cavity control of matter and nonlinearities in such systems with quantum information science.

Probing Solid-State Matter with High-Order Harmonic Generation Spectroscopy Andrea Annunziata[1,2,3], Cristian Soncini[2], Nicolas Tancogne-Dejean[3], Monica Bollani[2], Giovanni Isella[1], Umberto De Giovannini[3], Hannes Huebener[3], Michele Devetta[2], Angel Rubio[3], Salvatore Stagira[1,2], Alberto Crepaldi[1], Eugenio Cinquanta[2], Caterina Vozzi[2] and Davide Faccialà[2]; [1]Politecnico di Milano, Italy; [2]Istituto di Fotonica e Nanotecnologie, Consiglio Nazionale delle Ricerche, Italy; [3]Max Planck Institute for the Structure and Dynamics of Matter, Center for Free Electron Laser Science, Germany

When an intense mid-infrared (MIR) laser pulse interacts with matter, photons with energies that are integer multiples of the incident photon's energy are emitted. This process, known as High-order Harmonic Generation (HHG), was first discovered in noble gases[1,2], and then applied to molecules[3], solids[4], and liquids[5].Focusing on solid-state HHG, this process was described as a sequence of three steps. In the first step, the interaction of the material with the driving field promotes an electron in the conduction band, leaving a hole in the valence band. In the second step, electrons and holes are accelerated in the respective bands by the external driving field. Due to the non-linearity of the band dispersion, intra-band harmonics are emitted. In the third and last step, electrons and holes can recombine, thus generating inter-band harmonics.
This highly non-linear phenomenon conveys information about the originating medium, making high-order harmonic generation spectroscopy (HHGS) a powerful technique for probing matter in solid state. Significant examples are provided by all-optical band structure reconstruction and Berry phase measurement[6,7]. HHG can also be used as a probe of electronic and lattice dynamics initiated by a secondary pump pulse preceding the HHG driving field. This time-resolved HHGS (tr-HHGS) approach has the capability to probe phase transition and phonon dynamics with unprecedented spatial and temporal resolution[8].
In our work, we applied HHGS and tr-HHGS for the characterization of two semiconductor materials, germanium, and tellurium.
We performed HHGS measurements in bulk germanium (001) driven by a linearly polarized MIR field centered at 3.2 μm. By focusing an intense linearly polarized MIR field, and collecting the harmonics generated in reflection, we observed harmonics up to the 15th order and we fully characterized the harmonic yield as a function of the crystal axis direction. All the harmonics reflect the cubic symmetry of the material but show very different behavior as a function of the driving field intensity and polarization direction. This is a signature of the non-linear dynamics taking place during the process. Moreover, we fully characterized the polarization state of the emitted harmonics up to the 7th order as a function of the crystal axis direction, showing that it can significantly diverge from the driving field polarization and demonstrating the emission of light at specific wavelengths having strong ellipticity. This could be attributed to the interference of different harmonic emission pathways, which can allow us to extract information about the complex sub-cycle ultrafast electron dynamics in germanium when it undergoes strong field interactions.
Furthermore, we used tr-HHGS for probing phase transitions in tellurium, an elemental semiconductor with *chiral* crystal structure. Preliminary results show how the extreme sensitivity of HHGS can be used for tracking the lattice and electron dynamics induced by the pump.

New Routes for Label-Free Super-Resolution Microscopy and Attosecond Science via Transient High-Harmonic Generation Peter Kraus[1,2]; [1]Advanced Research Center for Nanolithography, Netherlands; [2]Vrije Universiteit Amsterdam, Netherlands

While the upconversion of infrared driving lasers into soft-X-ray pulses by high-harmonic generation (HHG) *in gases* has become an established technique for attosecond science and nanoscale imaging [1-3], HHG *in solids* is less explored. Gas-phase HHG is highly sensitive and thus controllable with regards to the microscopic generation mechanism, and the macroscopic buildup of emission via phase matching [4,5]. Parallels between solid and gas-phase HHG suggest that solid-state HHG may be controlled in similar manners, which would enable a generally applicable all-optical light switch with wide application potential.

In this talk I will introduce femtosecond resolved solid-state HHG and highlight the applications of solid-state HHG for metrology, spectroscopy and imaging with recent examples from our group.
On the nanoscale, we controlled HHG via engineering the surface topography of solids, which in turn demonstrates how solid HHG can be used for metrology on surfaces and tailored as a light source [6].
On the femtosecond time scale, we used the sensitivity of HHG to electronic band structure to follow ultrafast phase transitions in strongly correlated materials [7], and photocarrier dynamics in perovskites [8].
While the first set of measurements mentioned above showed nanoscale sensitivity, the second set of experiments demonstrated that photoexcitation can be used to control light emission via solid-state HHG.
Combining both efforts, I will outline and show first results how ultrafast control of solid HHG enables harmonic deactivation microscopy (HADES) - a label-free super-resolution microscopy below the diffraction limit of light [9].

Thinking ahead, the development of these techniques may enable resolution on the nanometer and femto- to attosecond scale fitted into a regular microscopy setting, with application potential ranging from strongly correlated materials to semiconductor metrology, photosynthetic processes, and medical imaging.

Advances in Hands-Off Femtosecond Parametric Amplifiers for Solid-State Materials Investigation Stefan Piontek, Valdas Maslinskas, Jonas Berzinš and Marco Arrigoni; Light Conversion, Lithuania

Time-resolved and static nonlinear optics (NLO) experiments at surface and bulk of advanced solid-state materials require agile femtosecond and picosecond tunable sources with high peak power and excellent stability. Repetition rate agility, ease of use and a compact footprint enhance experimental productivity and eliminate the need for an “expert” laser user. Typical experimental set-ups for study of interfaces and bulk material properties on meso- and nanoscale include two-dimensional infrared (2D-IR)[1], sum- frequency generation (SFG) [2, 3], as well as transient absorption (TA)[4] spectroscopy. Until recently, these experiments required titanium-sapphire amplifiers with repetition rates of 1-5 kHz, or mode-locked lasers at 80 MHz with limited energy and tuning ranges.<!--![endif]---->
<!--[endif]---->With technological advancements provided by flexible Yb-based regenerative amplifiers, experiments can now be realized at 100 kHz-1 MHz repetition rates with significant improvements in signal-to-noise ratio[1,5]. While for most experiments on solid-state samples, laser pulse energies in the microjoule range are perfectly adequate, some other benefits from higher energies that are now achievable in the latest generation of Yb amplifiers. After briefly describing recent advances in amplifiers, we will describe state-of-the-art tunable parametric amplifiers ranging from 190 nm to 16000 nm, allowing seamless access to most of the chemically relevant frequencies of interest[6-8]. We will provide application examples that benefit from technological improvements including sealed, hands-off configurations, enhanced efficiency and short pulse generation.

SESSION QT01.02: Ultrafast Dynamics in 2D Materials I
Session Chairs: Veronica Policht and Ursula Wurstbauer
Tuesday Afternoon, April 23, 2024
Room 420, Level 4, Summit

1:30 PM *QT01.02.01
Manipulation and Non-Linear Propagation of Excitonic Complexes in 2D Materials Alexey Chernikov; Technische Universität Dresden, Germany

Two-dimensional transition metal dichalcogenides offer an excellent platform to study non-linear dynamics of tightly-bound exciton quasiparticles. The properties of the excitons and their optical response change drastically in the presence of free charges, leading to emergence of many-body states described as trions or Fermi polarons. The physics of such Bose-Fermi quasiparticle mixtures have attracted a lot of interest in the scientific community and motivated the development of methods to control them on ultrafast time-scales. In addition, excitonic complexes are known to be mobile both in monolayers and heterostructures, with the transport of optical excitations playing a central role from both fundamental and technological perspectives. The first part of the talk will be focused on the use of intense THz pulses to transiently modify light-emission of exciton-electron ensembles in a monolayer semiconductor. We demonstrate a near complete, THz-induced trion-to-exciton conversion by monitoring time resolved photoluminescence after optical

excitation. It offers new pathways to manipulate exciton-electron mixtures in monolayer semiconductors, triggering a non-linear optical response by low-energy photons on picosecond timescales. In the second part, I will discuss linear and non-linear propagation of interlayer excitons in atomically reconstructed heterobilayers for an extended density range up to the Mott transition. Key results include demonstration of rapid exciton diffusion in absence of disorder- and Moiré-induced localization, role of the exciton-exciton interactions, and effectively negative diffusivity in the regime of dissociated excitons and dense electron-hole plasma.

2:00 PM QT01.02.02
Disentangling Many-Body Effects in The Coherent Optical Response of a 2D Semiconductor Chiara Trovatello[1,2], Florian Katsch[3], Qiuyang Li[1,4], Xiaoyang Zhu[1], Andreas Knorr[3], Giulio Nicola Felice Cerullo[2] and Stefano Dal Conte[2]; [1]Columbia University, United States; [2]Politecnico di Milano, Italy; [3]Technische Universität Berlin, Germany; [4]University of Michigan–Ann Arbor, United States

Monolayer transition metal dichalcogenides (1L-TMDs) have received increasing attention because of their enhanced light-matter interaction, strongly bound excitons, exciton Rydberg states and many-body effects[1]. Transient absorption spectroscopy has been extensively used to study exciton scattering processes on an ultrafast timescale. While it has been shown that on a ten- to hundred-ps timescale, the exciton decay dynamics is dominated by thermal effects[2], **the physical origin of exciton dynamics on a ps and sub-ps timescale is still under debate**. In this temporal window, many-body effects lead to a renormalization of the bands, inducing a transient energy shift of the excitonic resonance. Simultaneously, the increase of the electronic temperature after photo-excitation, due to multiple electronic scattering events, broadens the excitonic linewidth. Broadening and shift of the excitonic peak overlap in time with an abrupt absorption reduction due to phase-space filling effect[3]. All these processes are difficult to disentangle, and their dynamical interplay determines the complex shape of the transient absorption spectra of TMDs across the bandgap at early pump-probe delays. Transient exciton energy shifts have been roughly estimated from pump-probe measurements with contrasting results, e.g., blue vs red shift, and values from meV to tens of meV.

In this work, we measure the transient optical response of 1L-WS_2 on SiO_2 across the A and B excitonic resonances. The sample is photoexcited on- and out-of-resonance with the A exciton, and at variable pump fluences below the exciton-Mott transition. In order to capture the origin of the different transient signal shapes for both excitations, we disentangle absorption reduction, energy shift and broadening of the excitonic peak from the transient optical response, using Kramers-Kronig constrained variational analysis. From the measured transient reflectivity ($\Delta R/R$) of 1L-WS_2 we retrieve the absorbance spectrum as a function of pump-probe delay.
When the sample is photo-excited the pump induces a dramatic change of the A exciton, resulting from several concomitant effects: a quenching of the exciton oscillator strength, a blue energy shift and an asymmetric lineshape broadening. All the spectra are well reproduced by a fitting function made by the sum of two Lorentz oscillators on top of a polynomial background. The transient energy shift persists over a timescale much longer than the temporal overlap of pump and probe pulses, excluding the possibility that it originates from optical Stark effect.

Microscopic calculations based on excitonic Heisenberg equations of motion quantitatively reproduce the non-linear absorbance spectra of the material. All the lorentzian parameters show a linear dependence with rising excitation power for both the pump photon energies, and many-body effects are strongly enhanced for resonant excitation, resulting in a transient blue shift of the A exciton. The shift progressively decreases as the pump is detuned from the resonance and turns into a small red shift when the energy of the pump is close to the B excitonic resonance. The energy shift originates from Coulomb-induced bandgap renormalization while the asymmetric broadening is related to excitation induced dephasing mechanism[4].

In conclusion, we provide a complete picture of the transient optical response of 1L-WS_2 which can finally explain the strong differences observed in the pump-probe spectra following on- and off-resonant excitation [4]. Our combined experimental and theoretical studies give important insights into the complex interplay between many-body correlations and excitonic interactions determining the non-equilibrium response of 1L-TMDs.

2:15 PM *QT01.02.03
Ultrafast Charge Transfer Dynamics in Van der Waals Heterostructures Ermin Malic; Philipps University Marburg, Germany

Van der Waals heterostructures built by vertically stacked transition metal dichalcogenides (TMDs) exhibit a rich exciton energy landscape including spatially separated interlayer states, momentum-dark intervalley states, and hybrid exciton states. Recent experiments have demonstrated an ultrafast charge transfer in TMD heterostructures. However, the nature of the charge transfer process has remained elusive. Based on a microscopic and material-realistic exciton theory combined with time-resolved ARPES measurements, we reveal that phonon-mediated scattering via strongly hybridized dark intervalley excitons governs the charge transfer process [1,2]. We track the time-, momentum-, and energy-resolved relaxation dynamics of optically excited excitons and determine the temperature- and stacking-dependent charge transfer times for different TMD bilayers.

Furthermore, we demonstrate how the Coulomb interaction between the correlated electron- and hole-components of intra- and interlayer excitons facilitates the study of the ultrafast hole transfer mechanism in a twisted WSe_2/MoS_2 heterostructure. Intriguingly, we find an increase of the photoelectron energy in the ARPES spectrum upon the hole transfer process across the interface. This is surprising at first, because the electron remains rigid in the conduction band during the hole transfer process, and also because any relaxation mechanism is typically expected to cause an overall decrease of the measured electronic energies. However, we do not observe a free photoelectron, but the blue-shift is a direct consequence of the correlated nature of the Coulomb-bound electron-hole-pair.

Compared to the electron transfer occuring on a timescale of sub-100fs, we find both in experiment and theory that the hole transfer is considerably slower and occurs rather on a timescale of a few picoseconds. This can be traced back to different relaxation pathways: In the case of the electron transfer, optically excited intralayer excitons are subject to a relaxation cascade via layer-hybridized $K\Lambda$ excitons to the lowest interlayer exciton states. In contrast, the hole transfer occurs via layer-hybridized ΓK excitons. Since the Λ valleys are three-fold degenerate, while there is only one Γ valley, the density of states for the electron transfer pathway is more efficient. Furthemore, the exciton energy difference between the initial optically excited intralayer exciton and the final interlayer exciton is roughly 200 meV larger in the case of the hole transfer, further contributing to a slower transfer dynamics of holes.

The provided insights present an important step forward in microscopic understanding of the technologically important charge transfer process in van der Waals heterostructures.

Ultrafast Coherent Control of Valley Polarization in a 2D Semiconductor Francesco Gucci[1], Mattia Russo[1], Franco V. A. Camargo[2], Rui E. F. Silva[3,4], Misha Ivanov[4,5,6], Álvaro Jiménez-Galán[4,7], Stefano Dal Conte[1] and Giulio Cerrulo[1,2]; [1]Politecnico di Milano, Italy; [2]IFN-CNR, Italy; [3]Centro Superior de Investigaciones Científicas, Spain; [4]Max Born Institute, Germany; [5]Humboldt-Universität zu Berlin, Germany; [6]Imperial College London, United Kingdom; [7]National Research Council of Canada and University of Ottawa, Canada

Today's information processing technology relies on electronics, with transistor switches reaching speeds as high as 800 GHz yet appearing to approach their limits. The next disruptive step in increasing speed of information processing should come from driving electronic response in two-dimensional materials with ultrafast controlled lightwaves. This so-called lightwave electronics aims to use ultrashort pulses of light to switch electric currents and can potentially operate at nearly PHz rates. Lightwave valleytronics targets a new degree of freedom for information processing offered by excitons in two-dimensional materials with broken inversion symmetry: the valley pseudospin. The valley pseudospin is associated with the occupation of energy degenerate, but distinct valleys K and K'.
The optical selection rule, which couples the valleys with circularly polarized light, provides important implications for the development of valleytronics-based devices[1]. However, to this day, the short valley lifetime (i.e. few picoseconds) has prevented any practical implementation of valleytronics.
Recently, the realization of a translating-wedge based identical pulses encoding system (TWINS) enabled the generation of phase-locked collinear pulses with a delay controlled on a sub-fs scale[2]. Exploiting this technology, we experimentally prove a new all-optical coherent ultrafast protocol to manipulate the valley polarization in two-dimensional semiconductors[3]. In our experiment, a couple of delayed phase-locked ultrashort laser pulses with perpendicular polarization enables us to induce a positive or negative valley polarization in a WS2 monolayer. Our findings show that by making sub-cycle adjustments to the delay, we can continuously switch from exciting one valley to exciting the other.
Then, exploiting four phase-locked pulses, we realize an ultrafast switch of the valley polarization at room temperature: by carefully controlling the delays between the excitation pulses we quench and amplify the valley polarization on a sub-100 fs temporal scale. Our measurements also allow us to extract the excitonic dephasing time. Our experimental findings are validated by theoretical simulations calculated from first principles.
Our results demonstrate the possibility to control the valley polarization in two-dimensional semiconductors on a ultrafast timescale, opening a new route for ultrafast information processing with low-power few-cycle light pulses available today. We also provide a novel approach to investigate the properties of these materials.

Ultrafast Switching of Trion Emitters in Monolayer $MoSe_2$ Marzia Cuccu[1], Tommaso Venanzi[2], Xiaoxiao Sun[3], Takashi Taniguchi[4], Kenji Watanabe[4], Manfred Helm[3,1], Stephan Winnerl[3] and Alexey Chernikov[1]; [1]Technische Universität Dresden, Germany; [2]Istituto Italiano di Tecnologia, Italy; [3]Helmholtz-Zentrum Dresden-Rossendorf, Germany; [4]National Institute for Materials Science, Japan

Excitons in two-dimensional transition metal dichalcogenides emerged as a unique nanoscale platform offering strong light-matter coupling, spin-valley locking and exceptional tunability. Moreover, their properties and optical response change drastically in the presence of free charges, leading to the formation of new quasiparticles known as trions or Fermi polarons. The physics of such Bose-Fermi quasiparticle mixtures have attracted considerable interest in the scientific community. However, there are limitations to how fast the optical response of these states can be manipulated, restricting the majority of applications to a static regime.

Here, we show how to overcome this challenge by using low-energy photons in the THz frequency range. We demonstrate the conversion of trions into excitons in two-dimensional materials on ultrafast timescales of a few picoseconds by applying short THz pulses after the optical excitation. Monitoring the time-resolved photoluminescence dynamics, a strong quenching of the trion population induced by the THz radiation is observed, accompanied by a simultaneous increase of the exciton emission. The process is highly sensitive to the energy of the THz photons, that has to match the trion binding energy of the material. Furthermore, the observed switching is found to be highly reproducible when both the THz power and the time delay between optical and THz pulses are tuned. Our results provide a promising experimental tool for fundamental research of light-emitting excitation mixtures and offer pathways towards technological developments of nanophotonic devices based on atomically thin materials.

Ultrafast Processes in Atomically Thin Semiconductors Stefano Dal Conte; Politecnico di Milano, Italy

Two dimensional (2D) transition metal dichalcogenides (TMDs) have received increasing attention because of their optical and electronic properties, including enhanced light-matter interaction, strongly bound excitons, exciton Rydberg states, multiparticle excitonic complexes, and valley-selective circular dichroism [1]. Some of these properties are exploited in the realization of prototypical optoelectronic devices with improved performances and decreased size. Multiple layers of TMDs can also be stacked to form vertical heterostructures (HS) with tailored electronic and optical properties. Most of TMD-based heterobilayers have type II band alignment leading to fast charge separation and formation of interlayer excitons (ILX) characterized by ultra-long population recombination and twist angle dependence [2].
In my talk, I will report on the non-equilibrium optical response of 2D TMDs and their related HS measured by pump-probe optical spectroscopy techniques. In the first part of the talk, I will describe exciton formation and relaxation processes occurring on a sub-ps regime in isolated TMDs [1] focusing on the interplay between many-body and Coulomb correlation effects and excitonic population effects [3,4]. In the second part of talk, I will focus on the ultrafast processes occurring in TMD HS. I will show that it is possible to simultaneously detect interlayer hole and electron transfer processes on a 100 fs timescale [5] while the formation dynamics of ILX bleaching signal shows a distinct picosecond delayed growth dynamics significantly longer than that of intralayer excitons. Theoretical calculations based on microscopic Heisenberg equations of motion find that the delayed formation is mainly related

to phonon-assisted interlayer scattering of photo-excited carriers that give rise to finite-momentum (i.e. optically dark) hot ILX which quickly exchange energy and momentum with phonon population and become bright [6].

Quantum Dynamics of Fermi Polarons in Doped Semiconductor Monolayers Xiaoqin E. Li; The University of Texas at Austin, United States

In doped semiconductors, optically excited electron-hole pairs (i.e. excitons) can be treated as an impurity coupling to a Fermi sea. Atomically thin semiconductors provide a rich playground to explore the Fermi polaron problems where the electrons and excitons further acquire a valley index. The attractive interaction between the exciton and Fermi sea leads to an energetically favorable state --- the attractive polaron --- as well as a higher energy repulsive polaron, a metastable state that eventually decays into attractive polarons. Here, we study the emergence and evolution of attractive polarons and repulsive polarons in $MoSe_2$ and WSe_2 monolayers as the electron doping density increases. Using two-dimensional coherent electronic spectroscopy (2DCES), we follow the changes in resonant energy, oscillator strength, and quantum decoherence of the AP and RP branches. Because of their different band structures, polarons in $MoSe_2$ and WSe_2 monolayers exhibit distinct quantum quantum dynamics and coupling mediated by valley index. Because of the large oscillator strength associated with quasi-particles, their intrinsic dephasing dynamics occur on sub-picosecond time scales. On the other hand, long-lived population and valley dynamics have been reported in previous experiments. We attribute such dynamics from a few hundred picoseconds to a few nanoseconds to dark-to-bright exciton conversion processes.

Z-Scan Spectroscopy of $BaFeGaO_4$ Mark Swift, Orrin Clarke-Delgado, Jordan Palmer, Leroy Salary and Doyle Temple; Norfolk State University, United States

There have been reliable methods in the past for determining the nonlinear optical properties of materials (i.e. nonlinear absorption and nonlinear refraction) that can be used for multiple applications such as optical limiting, multi-photon polymerization, and optical switching. Of these methods, z-scan, which was developed by Eric Van Stryland [1] is found to be the optimal method for determining the third order optical susceptibility of a material.

The goal of my Masters project was to build a z-scan system for nonlinear optical measurements of materials fabricated in the NSF CREST Center for Research and Education in Quantum-leap Science (CREQS) at Norfolk State University (NSU). The optical system uses 100 fs pulses emitted at a repetition rate of 1 kHz from a Spectra Physics Solstice regenerative amplifier. These pulses at 800 nm are converted to visible wavelengths using a Spectra Physics TOPAS Prime optical parametric amplifier. The wavelength used in this study was 650nm. Pulses were detected using standard silicon photodiodes that were amplified and fed into an AD converter for input into the computer. Labview was used to monitor all detectors and control the position of the sample using a Newport Corp. precision translator.
The sample used for system development was a BaTiO3 crystal grown at NSU. The data was analyzed using a Mathcad Prime computer model of the z-scan process that was written as part of this project. This semester this includes computer modeling the z-scan technique using the computer program Mathcad, to determine the experimental parameters for building the Z-Scan system.
Preliminary results are consistent with the z-scan model but further refinements in the optical and detection system are underway and will be reported at the conference.

Laguerre-Gaussian Laser Beam Shaping for Control of Optical Angular Momentum in Ultrafast Laser Spectroscopy of Quantum Materials
Alecia Gulledge and Doyle Temple; Norfolk State University, United States

The project's main goal is to develop an optical system for generating and controlling laser pulses with desired states of Optical Angular Momentum (OAM) needed for experiments that will study spin states in quantum materials. A beam of light has a linear momentum which depends on the spatial distribution of an Optical Field (E) where E represents a specific electric field distribution which in this case is a Gaussian distribution. The specific OAM that’s being desired is modeled using a helical mode in which the wavefront of the momentum is shaped like a helix.
The first step was to use MathCAD Prime to model the 2D patterns or filter needed to transform the Gaussian beam into the desired OAM wavefront. The point of this is to control the energy distribution of the laser wavefront so when it interacts with a material so that we can model the interaction of electron spins in the material with the OAM wave using quantum mechanics.
Second, we implemented the 2D patterns calculated using Mathcad on a spatial light modulator (SLM). An ultrafast laser beam was expanded to a diameter of 3 cm and passed through the SLM resulting in an OAM that could be observed by interfering the OAM beam with a plane wave beam split off from the original laser beam. Finally, the patterns generated in the experiment were compared with the modeled patterns and the results shows promise for future use in experiments of spin states in materials.
Future work includes refining the model used to generate the patterns on the SLM and implementing the system in the study of quantum materials which is

the subject of my PhD thesis.

5:00 PM QT01.03.03
Nanocavity-Mediated Purcell Enhancement of Er in TiO_2 Thin Films Grown via Atomic Layer Deposition Cheng Ji[1,2], Michael Solomon[1,2], Gregory Grant[1,2], Koichi Tanaka[1,2], Muchuan Hua[2], Jianguo Wen[2], Alan Dibos[2] and Supratik Guha[1,2]; [1]University of Chicago, United States; [2]Argonne National Laboratory, United States

Trivalent erbium (Er^{3+}), typically embedded as an atomic defect in the solid state, has widespread adoption as a dopant in telecommunications devices and shows promise as a spin-based quantum memory for quantum communication. In particular, its natural telecom C-band optical transition and spin-photon interface make it an ideal candidate for integration into existing optical fiber networks without the need for quantum frequency conversion. However, successful scaling requires a host material with few intrinsic nuclear spins, compatibility with semiconductor foundry processes, and straightforward integration with silicon photonics.

Here, we present Er-doped titanium dioxide (TiO_2) thin film growth on silicon substrates using a foundry-scalable atomic layer deposition (ALD) process with a wide range of doping control over the Er concentration (from sub-ppm to a few percent). Even though the as-grown films are amorphous, after oxygen annealing at 400C, the anatase TiO_2 lattice structures can form and the embedded Er ions exhibit the characteristic optical emission spectrum from anatase TiO_2. Critically, this growth with an annealing process introduces the poly-crystalline grains of a few hundred nanometers, while maintaining the low surface roughness required for nanophotonic integration. This ALD process also offers potential advantages over other methods, such as molecular beam deposition of doped films and implantation of erbium ions in undoped films, in terms of translation to industry because of lower cost and increased scalability.

Furthermore, our optical measurements revealed distinct optical transitions and a substantially narrower homogeneous linewidth upper bound for the characteristic emission peaks around 1532 nm for the annealed films. Additionally, the films with low Er concentration exhibited a natural optical lifetime greater than 1 ms, typical of Er in anatase TiO_2. Finally, we interface Er ensembles with high-quality factor Si nanophotonic cavities via evanescent coupling and demonstrate a large Purcell enhancement (~ 300) of their optical lifetime. This enhancement plays a crucial role in achieving more efficient and controlled light-matter interactions.

Overall, our findings demonstrate a low-temperature, non-destructive, and substrate-independent process for integrating Er-doped materials with silicon photonics. To emphasize, this ALD deposition with annealing at 400C process is CMOS compatible, which ensures industrial scalability and can potentially lead to many applications in the integrated silicon photonics industry. For example, at high doping densities, this platform can enable integrated photonic components such as on-chip amplifiers and lasers, while dilute concentrations can realize single ion quantum memories.

5:00 PM QT01.03.04
Phase Dependent Ultrafast Light-Matter Interaction in Two-Dimensional Silver Matthew Liu, Arpit Jain, Chengye Dong, Joshua Robinson and Kenneth Knappenberger; The Pennsylvania State University, United States

Atomic-level control of two-dimensional materials provides a novel platform for nanoscale photonics and optoelectronics. Two-dimensional silver (2D-Ag) is stabilized via silver intercalation in epitaxial graphene on SiC. Two phases of 2D-Ag, termed $Ag_{(1)}$ and the $Ag_{(2)}$, have been distinguished through 1) in-plane phonon shear modes: $Ag_{(1)}$ at 17 cm^{-1}, and $Ag_{(2)}$ exhibiting two modes at 66 and 92 cm^{-1} and 2) linear extinction: $Ag_{(1)}$ with two absorption peaks centered around 460 and 650 nm, and $Ag_{(2)}$ with a single band centered around 570 nm. Control of graphene chemistry enables the formation of single phase 2D-Ag, allowing us to explore the inherent differences between $Ag_{(1)}$ and $Ag_{(2)}$. The symmetry breaking at the SiC/2D-Ag interface creates an out-of-plane axial dipole, resulting in strong nonlinear optical (NLO) responses. Second harmonic generation microscopy is implemented to investigate the symmetry and second order susceptibility $\chi^{(2)}$ of $Ag_{(1)}$ and $Ag_{(2)}$. Both phases exhibit point group symmetry *3m*, verifying the epitaxial growth of the Ag layer on the modified SiC surface. The $\chi^{(2)}$ of $Ag_{(2)}$ is orders of magnitude greater than that of $Ag_{(1)}$. The carrier dynamics of 2D-Ag is studied with near-degenerate transient absorption (TA) spectroscopy. Both phases are excited near the resonance frequencies of 2D-Ag, setting pump wavelengths at 575 and 650 nm. Rapid decays (~2 ps) following the initial bleach are observed in the time-resolved TA spectra for both phases. The difference in coherent oscillations between $Ag_{(1)}$ and $Ag_{(2)}$ is attributed to electron-phonon coupling corresponding to the in-plane shear mode of each phase as confirmed with correlated Raman spectroscopy. The results suggest that we are able to tailor the NLO properties and carrier dynamics of 2D-Ag through phase engineering at the atomic level.

SESSION QT01.04: Ultrafast Magnetism in Quantum Materials
Session Chairs: Alberto De la Torre and Ursula Wurstbauer
Wednesday Morning, April 24, 2024
Room 420, Level 4, Summit

8:45 AM QT01.04.01
Terahertz Field-Driven Nonlinear Magnonics in Antiferromagnets Zhuquan Zhang[1], Frank Gao[2], Edoardo Baldini[2] and Keith A. Nelson[1]; [1]Massachusetts Institute of Technology, United States; [2]The University of Texas at Austin, United States

Coherent excitations of magnetically ordered materials, referred to as spin waves and their quanta, magnons, have emerged as prominent candidates for interference-based signal processing technologies. Despite growing interest in manipulating magnonic states beyond thermodynamic equilibrium, elucidating and inducing coherent couplings between distinct magnon modes remains a formidable challenge. By developing and employing a novel two-dimensional (2D) terahertz (THz) polarimetry technique facilitated by single-shot detection, we successfully uncover correlated magnonic states at the sum and difference frequencies of the two modes, as well as a second-order magnon upconversion response. These findings not only expand the domain of nonlinear magnonics by incorporating antiferromagnets but also lay the groundwork for further advancements in the ultrafast control of magnetism.

9:00 AM QT01.04.02
Terahertz Parametric Amplification of a Coherent Magnon Mode Zhuquan Zhang and Keith A. Nelson; Massachusetts Institute of Technology, United States

Parametric amplification is a ubiquitous process in nonlinear systems where a specific parameter can be varied to amplify a coupled degree of freedom. In

condensed matter systems, parametric amplification of collective excitations allows one to study non-equilibrium order-parameter physics and potentially control material properties. In this study, we use a pair of intense terahertz (THz) pulses to sequentially excite two distinct coherent magnon modes in an antiferromagnet and find that the lower frequency magnon mode is amplified by driving the higher frequency mode. The nonlinear excitation pathway of this parametric downconversion process is confirmed by two-dimensional THz spectroscopy measurements. Our work provides crucial insights into nonlinear magnonics in antiferromagnets, extending the frontiers of spintronics and magnonics into the ultrafast nonlinear regime.

9:15 AM QT01.04.03
Light Driven Spontaneous Phonon Chirality and Magnetization in Paramagnets Yafei Ren[1], Mark Rudner[2] and Di Xiao[2]; [1]University of Delaware, United States; [2]University of Washington, United States

Spin-phonon coupling enables the mutual manipulation of phonon and spin degrees of freedom in solids. In this study, we reveal the inherent nonlinearity within this coupling. Using a paramagnet as an illustration, we demonstrate the nonlinearity by unveiling spontaneous symmetry breaking under a periodic drive. The drive originates from linearly polarized light, respecting a mirror reflection symmetry of the system. However, this symmetry is spontaneously broken in the steady state, manifested in the emergence of coherent chiral phonons accompanied by a nonzero magnetization. We establish an analytical self-consistent equation to find the parameter regime where spontaneous symmetry breaking occurs. Furthermore, we estimate realistic parameters and discuss potential materials that could exhibit this behavior. Our findings shed light on the exploration of nonlinear phenomena in magnetic materials and present possibilities for on-demand control of magnetization.

9:30 AM ^QT01.04.04
Coherent Magnon-Exciton Coupling in Magnetic Semiconductors Youn Jue Bae; Cornell University, United States

Two-dimensional (2D) magnetic semiconductors possess tightly bound excitons with large oscillator strength and long-lived coherent magnons due to the presence of bandgap and spatial confinement. While magnons and excitons are energetically mismatched by orders of magnitude, their coupling can lead to efficient optical access to spin information. The ability to overcome energy mismatch between magnon and exciton combined with optical excitation and detection renders 2D magnetic semiconductors attractive candidates for quantum transducers. In this presentation, I will discuss strong magneto-electronic and magnetoelastic coupling and implications of these couplings in the 2D van der Waals antiferromagnetic semiconductor, CrSBr. Because of both magnetic and semiconducting properties in CrSBr, excitons are highly sensitive to spin environments. Optical excitation of coherent spin waves can dynamically modulate the dielectric environment and excitons can sensitively detect these changes. I will also discuss strong magnetoelastic coupling in CrSBr that induces transient strain fields to selectively launch a narrow range of wavevector and frequency of both coherent magnons and acoustic phonons.

10:00 AM BREAK

10:30 AM QT01.04.05
Extreme Nonlinear Opto-Magnonic Effects in a Layered Magnetic Semiconductor Geoff Diederich[1], John W. Cenker[1], Jordan Fonseca[1], Sinabu Pumelo[1], Youn Jue Bae[2], Daniel Chica[3], Xiaoyang Zhu[3], Xavier Roy[3], Di Xiao[1,1], Yafei Ren[4] and Xiaodong Xu[1,1]; [1]University of Washington, United States; [2]Cornell University, United States; [3]Columbia University, United States; [4]University of Delaware, United States

The nonlinear dynamics of collective excitations offer both intriguing fundamental phenomena and significant practical applications. A prime illustration is the field of nonlinear optics, where diverse frequency mixing processes are central to advancing photonic technology. Demonstration of these frequency mixing processes in magnons holds considerable potential for practical applications in magnonics, an emerging frontier of spintronics and an important platform for developing quantum transducers and wave-based computing beyond traditional paradigms. In this talk, I will demonstrate the optical generation and detection of abundant magnonic frequency mixing processes in the antiferromagnetic semiconductor CrSBr by employing above-gap pump pulses to launch coherent magnons and optically measuring them via strong magnon-exciton coupling. The data shows a series of magnon sidebands arising from high-harmonic generation and, when breaking the system symmetry, the mixing of discrete magnon modes to produce sum and difference frequency generation (SFG & DFG). Further, we demonstrate control over the DFG in CrSBr by rotating an external magnetic field to tune its frequency over a broad range. This tuning allows us to push the DFG mode into resonance with one of the fundamental magnon modes, where we can controllably induce parametric amplification. These findings herald the opening of a new domain in nonlinear opto-magnonic coupling, offering innovative functionalities for hybrid quantum magnonics.

10:45 AM *QT01.04.06
Thermally Driven Ultrafast and Deterministic Reversal of Magnetization in Ferrimagnets upon Single Pulse Photo-Excitation Unai Atxitia; Instituto de Ciencia de Materiales de Madrid, Spain

The discovery of an ultrafast and deterministic reversal of magnetization upon single pulse excitation[1] in GdFeCo, dubbed as all-optical switching (AOS), holds promise for faster and more energy-efficient data storage. Followed by this discovery, a growing body of research has unveiled other magnetic systems exhibiting AOS, and has triggered extensive theoretical and experimental research efforts.

Although several micro- and macroscopic models have reproduced AOS, complete understanding of the role of electrons, lattice and spin sublattices, and their mutual interactions has remained a challenge. The existing criteria for switching rely on the existence of two antiferromagnetically coupled magnetic sublattices showing a distinct dynamical response to femtosecond laser photoexcitation, which heats the electron system at elevated temperatures. This allows the two sublattices to decouple and to dissipate angular momentum on their own time scales. While in single-species ferromagnets such as 3*d* transition metals, relaxation of angular momentum occurs via dissipation into other degrees of freedom in two-sublattice magnets; additionally, relaxation can occur via angular momentum exchange between sublattices— exchange relaxation. By driving the spin system into a nonequilibrium state where exchange relaxation dominates, a nonequilibrium ultrafast reversal path opens. One of the most outstanding open questions is about the conditions or criteria for the onset of the exchange-dominated relaxation regime.

In this talk, I present a general theoretical framework for the description of single-pulse switching of ferrimagnets[2]. I provide explicit expressions for the relativistic and exchange relaxation parameters as a function of microscopic material parameters. This allows to uncover the criteria for the onset of the exchange-dominated relaxation regime and switching. In particular, I demonstrate that the magnetization dynamics transits from a relativistic relaxation path to an exchange-dominated regime due to the strong enhancement of the exchange relaxation under highly non-equilibrium situations. We demonstrate that switching occurs when the sublattice magnetization reaches a threshold value. Notably, this threshold scales inversely proportional to the number of exchange-coupled nearest neighbours considered in the model, which in the simplest case is directly linked to the underlying lattice structure. This dependence is related to the enhancement of the non-equilibrium spin fluctuations, which opens the door for a more efficient reversal in magnetic 2D ferrimagnets[3].

Notably, by using the general theoretical framework, we have been able to guide experiments of AOS in ferrimagnets. First, to approach terahertz frequency of write/erase cycles with a minimum pulse to pulse separation of 7 ps[4].Second, to determine that the minimum size for AOS in GdFe alloys, induced by a nanoscale periodic excitation, is around 25 nm and that this fundamental limit is governed by ultrafast lateral heat diffusion of electrons and by the threshold for optical damage.

Light Control of Magnetism in Quantum Materials Andrea Caviglia; Université de Genève, Switzerland

We will discuss light control of magnetism in van der Waals antiferromagnets and oxide interfaces and surfaces, focusing on the role of orbital angular momentum. In the first example, we will consider the control of magnetic ordered states using light. We will show that light-driven phonons can be utilized to coherently manipulate macroscopic magnetic states. Intense mid-infrared electric field pulses, tuned to resonance with a phonon mode of the antiferromagnet DyFeO3, induce ultrafast and long-living changes of the fundamental exchange interaction between rare-earth orbitals and transition metal spins. [1-3]. In the second example we will discuss the emission and detection of a nanometre-scale wavepacket of coherent propagating magnons in the antiferromagnetic oxide dysprosium orthoferrite using ultrashort pulses of light [4]. In the third example we consider experimentally the relative merits of electronic and vibrational excitations for the optical control of zero orbital angular momentum magnets, focusing on a limit case: the antiferromagnet manganese phosphorous trisulfide (MnPS3), constituted by orbital singlet Mn2+ ions. We study the correlation of spins with two types of excitations within its band gap: a bound electron orbital excitation from the singlet orbital ground state of Mn2+ into an orbital triplet state, which causes coherent spin precession, and a vibrational excitation of the crystal field that causes thermal spin disorder [5].

11:45 AM QT01.04.08
Photoexcited Electron Spin Resonance Properties of CrSrBr Lovia Ofori[1], Eric Walter[2], Luis Martinez[1], Xavier Roy[3] and Srinivasa Rao Singamaneni[1]; [1]The University of Texas at El Paso, United States; [2]Pacific Northwest National Laboratory, United States; [3]Columbia University, United States

The recent discovery of two-dimensional (2D) magnets offers excellent opportunities for the exploration of low-dimensional magnetism and for the development of novel magnetoelectric, magneto-optic, and spintronic devices. CrSrBr is an air-stable antiferromagnetic semiconductor and gained a great deal of attention in the community for its novel magneto-optical properties. In this work, we present our recent findings on the electron spin resonance (ESR) properties of quasi-2D CrSrBr upon photoexcitation as a function of temperature and time across the magnetic phase transition. We noticed that ESR spectral properties (line shape, g-factor, line width, and signal intensity) are strongly modified upon photoexcitation which infers the tunability of magnetic interactions. Our work demonstrates the unique importance of employing photons in tuning the magnetic properties and interactions of 2D van der Waals magnets.

SESSION QT01.05: Light-Matter Coupling in Quantum Materials I

Wednesday Afternoon, April 24, 2024
Room 420, Level 4, Summit

1:30 PM *QT01.05.01
Light-Matter Control of Quantum Materials Michael Sentef[1,2]; [1]University of Bremen, Germany; [2]MPSD Hamburg, Germany

Advances in time-resolved pump-probe spectroscopies have enabled us to follow the microscopic dynamics of quantum materials on femtosecond time scales. This gives us a glimpse into the inner workings of how complex, emergent functionalities of quantum many-body systems develop on ultrafast time scales or react to external forces. The ultimate dream of the community is to use light as a tuning parameter to create new states of matter on demand with designed properties and new functionalities, perhaps not achievable by other means. In this talk I will discuss recent progress in controlling and engineering properties of quantum materials through light-matter interaction [a,b]. I will highlight work on Floquet engineering — the creation of effective Hamiltonians by time-periodic drives — on sub-cycle time scales [1,2] combining theory and pump-probe experiments at the limits of energy and time resolution. I will then showcase recent theories on inducing superconductivity with light by employing enhanced light-matter interaction in the near-field involving polaritonic excitations [3,4].

Mapping The Ultrafast Transient Response of Cavity-Embedded WS_2 Monolayers with High Angular Resolution Veronica Policht[1], Jose J. Fonseca Vega[2], Samuel W. LaGasse[2], Nicholas Proscia[2], Jeremy T. Robinson[2], Cory D. Cress[2] and Paul D. Cunningham[2]; [1]NRC Postdoc Associate residing at U.S. Naval Research Laboratory, United States; [2]US Naval Research Laboratory, United States

The behavior of Exciton-Polaritons (EP), arising from strong coupling between the photon mode of a high-quality microcavity and excitonic states in an embedded semiconductor material, have been of intense recent interest[1]. EPs of cavity-coupled excitons in Two-Dimensional Transition Metal Dichalcogenides (TMD) are of particular interest due to promising potential applications including low threshold lasing[2] as well as the opportunity to study many-body physics at ambient temperatures[3]. Compared to the excitons in bare TMDs, TMD EP states show enhanced oscillator strengths, longer of excitonic and valley coherence times[4], and may also mediate mixing between otherwise distinct excitonic species[5]. Despite recent progress towards TMD EP-based technologies, there remains significant ambiguity in our understanding of EP dynamics at early times, due in part to the ultrafast timescales (~100s fs) of EP relaxation. Additionally, previous studies of ultrafast EP dynamics have had limited angular resolution due to the use of microscope objectives which average over a large angle range and therefor obscure the EP response.

We study the ultrafast response of a WS_2 monolayer embedded in a metallic cavity measured with a transient reflectance technique with high angular resolution achieved in part through the use of large-area WS_2 monolayer flakes. With this approach, we are able to incisively pump and probe different EP branches as a function of the in plane angular momentum, k, with <1° angular resolution. We generate pseudo-dispersion maps as a function of k and photon energy for a given pump-probe delay time. We use this new approach to provide insight on the source of various nonlinear EP dynamics reported for cavity-coupled TMDs in literature and in particular resolve clear differences in the WS_2-cavity response under different pump energy conditions.

First-Principles Machine-Learning Quantum Dynamics at 0K in SrTiO3: Light-Induced Ultrafast Ferroelectric Transition Francesco Libbi[1], Lorenzo Monacelli[2], Anders Johansson[1] and Boris Kozinsky[1]; [1]Harvard University, United States; [2]EPFL, Switzerland

Low temperature nonequilibrium quantum dynamics in crystals is extremely challenging, and has not been possible to perform on materials of realistic complexity. In this work we develop a novel technique, the time-dependent self-consistent harmonic approximation (TDSCHA [1]), and use it to simulate the quantum dynamics in SrTiO3 at 0K. We combine TDSCHA with state-of-the-art machine learning force fields to accelerate calculations by multiple orders of magnitude compared to first principles dynamics.
We study the light-induced ferroelectric transition in SrTiO3, where nuclear quantum fluctuations play a major role in stabilizing the paraelectric phase at low temperatures.
Our approach allows for an unprecedented description of the light-induced ferroelectric transition due to the absence of ad-hoc parameters, paving the way to the development of next-generation ultrafast nonvolatile memories.

Exploring Electronic Band Structure of 2D and Quantum Materials by Time- and Angle-Resolved Photoemission Spectrocopy and KISS Exfoliation Method Antonija Grubisic-Cabo; University of Groningen, Netherlands

The fundamental physics of solids, including two-dimensional (2D) materials, is inherently linked to their electronic band structure. The investigation of the electronic band structure is therefore of paramount significance for understanding, tailoring and discovering new states of matter. In the case of 2D materials, such as graphene and single layer transition metal dichalcogenides, control of the electronic structure can be achieved by altering their surroundings, as the electronic structure of 2D materials is highly sensitive to the surrounding environment. However, robust methods for the determination of the electronic structure are required to ascertain the effects of those alterations. In this talk, I will present time- and angle-resolved photoemission spectroscopy (TR-ARPES) as a technique for the electronic structure studies on the ultrafast, femtosecond scale [1], and as means to achieve control over 2D materials by light [2].
Furthermore, I will introduce an innovative preparation method for 2D materials, kinetic *in situ* single-layer (KISS) method [3]. Using KISS method, exfoliation of 2D materials can be performed directly in ultra-high vacuum, and large flakes of excellent crystallinity and purity can be obtained. Multiple semiconducting and metallic transition metal dichalcogenides were exfoliated onto Au, Ag and Ge substrates, showing the versatility of the technique, and characterised by ARPES. Importantly, the proposed method is straightforward, simple, and does not require any specialised equipment. This technique is ideally suited for the electronic structure research of air-sensitive 2D materials since the sample preparation process happens entirely in ultra-high vacuum.

Probing Exciton Dynamics and Dispersion in C_{60} Using TR-ARPES Rysa J. Greenwood[1,2], Alexandra Tully[1,2] and Sarah Burke[1,2]; [1]Quantum Matter Institute, Canada; [2]The University of British Columbia, Canada

In organic semiconductors, photoexcitation generates strongly bound excitons which recombine quickly (generally 10's – 100's of femtoseconds). To achieve efficient charge separation in these materials it is necessary to drive the dissociation of the exciton prior to recombination. This is one of the limiting factors for organic photovoltaic (OPV) devices today. The mechanisms that result in efficient charge separation in these materials are still not well understood. Therefore, to better advise device design it is necessary to gain a deeper understanding of both the dynamics and delocalization of excitonic states that occur post- photoexcitation with femtosecond resolution.

While the ultrafast response of organic semiconductors have been studied using all-optical techniques for a number of years [1], a lack of momentum resolution has limited understanding of their delocalization and symmetry. Time-resolved, angle-resolved photoemission spectroscopy (TR-ARPES) is a powerful technique that allows a user to visualize the energy-momentum landscape of a material and monitor how the material responds to photoexcitation with femtosecond resolution. Recent developments in TR-ARPES (or similar techniques) are enabling investigation of organic semiconductors because of its capability to directly map the momentum dependent dispersion of the excitonic states with high temporal resolution [2-4].

Here, I show the capability to probe the fate of excitonic states in C_{60}, a prototypical OPV material, using TR-ARPES pumped with 3.1eV light. We have been able to track the dynamics of the excitonic states which decay into each other with lifetimes ranging from hundreds of femtoseconds to tens of picoseconds. Constant energy contours show momentum-space structure of each state across the first Brillouin zone which disperses energy. With this improved angular resolution, we aim to access the extent of delocalization of the excitons in the C_{60} lattice.

Rare earth nickelates display insulator-metal transition which is accompanied by a magnetic transition, charge ordering, and a crystal structure change. Laser-excitation drives the transition at ultrafast timescales providing an avenue to understand the role of coupled transitions in causing the transition. We utilized time-resolved x-ray diffraction to study the structural dynamics of epitaxial NNO thin film by observing the photoinduced changes in the (002) Bragg peak. The out of plane lattice parameter contracts for low fluences and expands for high fluences after laser excitation. A thermal model explains experimental trends revealing the potential for controlling structural dynamics via heteroepitaxial strain. Similar recovery timescales of structural and magnetism dynamics indicate a strong magneto-structural coupling is prevalent in the ultrafast recovery process. The change in integrated intensity and FWHM of the (002) peak indicate photoinduced domain dynamics which corroborates an ultrafast conductivity study proposing recovery via nucleating and growth in NNO. We present direct evidence of phase separation using time-resolved nanodiffraction. Spatiotemporally resolved characterization clearly shows the spatial heterogeneity of the structural dynamics in nickelates.

4:30 PM *QT01.05.07
Dynamic Control of Macroscopic Phases via Thermal Quench in 1T-TaS_2 Alberto De la Torre; Northeastern University, United States

In materials with competing order parameters, quenching across a phase transition can lead to the system being trapped in a long-lived metastable phase, even if it is not the global free-energy minimum. Examples of this phenomenology can be found over multiple energies and length scales - from the evolution of the known Universe to supercooled liquids [1]. 1T-TaS_2, a layered dichalcogenide, is a unique platform for studying dynamic phase transitions in quantum materials [2]. Upon quenching 1T-TaS_2 after excitation with an ultrafast laser pulse, a low-temperature metallic metastable phase (H-CDW) emerges [3], which is different from any of the charge density wave (CDW) phases characterizing its thermodynamic phase diagram. I will show that a new metastable insulating phase with similar scattering signatures to the H-CDW [4] can be stabilized by intermediate quenching rates [5]. I will discuss the implications of this new phase in the controversy surrounding the presence of Mott physics and the role of c-axis correlations [6] in the equilibrium ground state of 1T-TaS_2.

A Molecular Dynamics of Photo-Excited Ligand Exchange Dynamics in Tungsten-Complexes Kamrun N. Keya[1], Yulun Han[2], Wenjie Xia[1], Bakhtiyor Rasulev[2], Svetlana V. Kilina[2], Wenfang Sun[3] and Dmitri Kilin[2]; [1]Iowa State University, United States; [2]North Dakota State University, United States; [3]The University of Alabama, United States

Transition-metal complexes (TMCs) play a pivotal role in areas such as optoelectronics, solar energy conversion, and biomedical applications. In this

study, we delve deep into the dynamics of ligand exchange reactions in six distinct $W(CO)_4$(bpy) complexes using time-dependent excited-state molecular dynamics (TDESMD) based on Rabi oscillations between ground and excited states under optical irradiation. Our objective is to explore the mechanism of how the photo-induced charge transfer dynamics facilitates the mechanistic pathway in which a mix of $W(CO)_6$ and bipyridine (bpy) transforms into a $W(CO)_4$(bpy) complex. Preliminary findings suggest that the photoreactions are facilitated by excited states corresponding more closely to ligand-to-metal charge transfer (LMCT) character. It is this photoactivation, particularly of the LMCT type, that weakens the W-C bonds, thereby facilitating the subsequent dissociation of CO ligands. Consequently, this gives rise to the reactive $W(CO)_5$ radical, which then establishes a coordination bond with the nitrogen of the bpy ligand. At the next stage, second CO ligand desorbs allowing for formation of two stable coordination bonds between tungsten and bpy. Several approaches have been committed to explore the possibility of the subsequent formation of $W(CO)_2(bpy)_2$ and $W(bpy)_3$ complexes. Our study enables the exploration of the pathways of photoactivated reaction dynamics and assessment of the intermediates formed during the reaction and the transition states along this path. Such insights are instrumental in interpreting synthetic endeavors, aiming for an efficient exploration of near-infrared (NIR) emitters composed of earth-abundant metals and a variety of organic ligands.

Wearable Health Monitoring with Ultrathin Self-Powered Heavy-Metal-Free Cu-In-Se Quantum Dot-Photodetectors Jae Hong Jang[1], Shi Li[2], Jiwoong Yang[2] and Moon Kee Choi[1]; [1]Ulsan National Institute of Science and Technology, Korea (the Republic of); [2]Daegu Gyeongbuk Institute of Science and Technology, Korea (the Republic of)

Photodetectors (PDs), that transform light signals into electronic signals, are essential components in wearable electronics, finding wide-ranging applications in biological imaging, optical communication, and health monitoring. In particular, wearable health monitoring devices utilizing photoplethysmography (PPG) technology, which employs a light source and PDs to measure blood circulation variations, offer significant potential for non-invasive, cost-effective, and continuous real-time monitoring of vital signs and cardiac function. To enable effective real-time vital sign monitoring, PDs must exhibit high specific detectivity (D^*), rapid response time, and high mechanical deformability. Consequently, the development of mechanically deformable PDs with superior device performance and response times has been a paramount objective. While prior research advanced flexible and stretchable PDs, challenges endure, including limited deformability with thick inorganic films and reduced performance in organic PDs. Furthermore, most photodetectors rely on external power sources to generate photocurrent, restricting the evolution of point-of-care type wearable systems capable of independent, wireless, and sustainable operation.

Colloidal quantum dots (QDs) are highlighted for PDs, boasting size-tunable electrical and optical properties, high photo-absorption coefficients, narrow emission and absorption bandwidth, and robust photo- and air-stability. Nevertheless, the practical application of QD-PDs in wearable electronics faces challenges. Existing QD-PDs exhibit limited mechanical deformability due to their relatively thick light absorption layers (typically several hundreds of nanometers). Furthermore, the conventional use of toxic heavy-metal-containing QDs, including lead, mercury, and cadmium chalcogenide QDs, raises concerns about impact on human health.

Recently, heavy-metal-free Cu-In-Se (CISe) QDs been highlighted as a promising material for eco-friendly optoelectronic devices. CISe QDs offer advantageous characteristics, including a direct-bandgap structure, high absorption coefficient, broad absorption range spanning from ultra-violet to near-infrared, stable phase structure, cost-effectiveness, and nontoxicity. However, a dearth of research exists regarding the selection of optimal charge transport materials, specifically for the electron transport layer (ETL) and hole transport layer (HTL) materials, tailored to CISe QD-PDs. The electron mobility of typical ETLs is generally three orders of magnitude higher than that of general HTLs, causing the charge imbalance and recombination of photogenerated electrons and holes, leading to poor device performance. Therefore, the development of high-quality HTLs is essential to achieve high-performance CISe QD-PDs.

In this study, we present ultrathin self-powered CISe QD-PDs for the wearable PPG-based health monitoring system. We constructed PDs with CISe QDs capped with iodide ions as ultrathin light absorption layers (~40 nm), *p*-type colloidal MoS_2 nanosheets blended with poly(3,4-ethylenedioxythiophene):poly(styrenesulfonate) as HTLs, and *n*-type ZnO nanoparticles as ETLs. Fabricated ultrathin PDs (~120 nm except electrodes) feature high D^* of 2.10×10^{12} Jones, linear dynamic range of 102 dB, and spectral sensitive region from 250 to 1,050 nm at 0 V bias. These PDs utilize built-in potential created through the photovoltaic effect, facilitating the efficient separation and transfer of photogenerated electron−hole pairs without requiring an external power source. Their performance rivals that of conventional QD-PDs employing thick Pb-chalcogenide QD layers and typical self-powered PDs from previous researches. Furthermore, PDs fabricated on flexible substrates exhibit outstanding mechanical flexibility and device performance, surpassing that of flexible PDs employing alternative semiconductor materials. This realize skin-attachable PPG sensors capable of real-time vital sign monitoring.

Ultrafast Dynamics of Quantum Emitters in hBN Steffen Michaelis de Vasconcellos; University of Münster, Germany

Key challenges in the development of quantum networks and communications include the availability of efficient and robust quantum light sources and their optical coherent control. Recently, single-photon sources in atomically thin transition metal dichalcogenides and other 2D van der Waals materials joined the family of solid-state quantum light emitters [1]. In the 2D insulator hexagonal boron nitride (hBN), optically active states in the band gap have been discovered, efficiently emitting single photons even at room temperature. The wide variability of the emission wavelength, narrow emission lines and tunability makes this emitter particularly compelling for quantum sensing and wavelength division multiplexed quantum communications.

The quantum emitters in hBN can be found in commercially available nanocrystals, making them ideal for creating large arrays of single-photon emitters using the capillary assembly technique with high positioning yields up to 95% [2]. This method opens the way for systematic optical characterization of easily addressable single-photon emitters and offers the possibility of deterministically fabricating photonic nanostructures around individual emitters. Notably, photonic microstructures and components can be created using 3D direct-laser writing. This technique allows the printing of polymer microlenses in various shapes to effectively collect and direct light from embedded emitters. However, the auto-fluorescence of commercially available photoresins limits the application in quantum optics. To address this issue, we have developed an ultra-low-fluorescence photoresin for 3D direct laser writing. We demonstrate the 3D-printing of microlenses that effectively collect quantum light emission from the emitters and collimate the single photons into a low-

divergent beam [3].
Furthermore, we demonstrate the coherent state manipulation of a single hBN quantum emitter with ultrafast laser pulses using a double-pulse experiment [4]. The coherence properties of the two-level system are detected by measuring the emitted photons as a function of the pulse delay. Our joint experiment-theory study reveals the effects of different sources of spectral jitter on the ultrafast coherence dynamics. We also demonstrate that coherent control can not only be exerted resonantly on the optical transition but also phonon-assisted, provides profound insight into the internal phonon quantum dynamics. We find that increased decoherence rates in optical phonons are due to dephasing processes of the phonon states, partly due to their anharmonic decay. Similarly, dephasing induced by acoustic phonon generation results in a rapid decrease in coherence when propagating phonon wave packets are emitted. Our experiments on phonon-assisted coherent control of individual hBN color centers are a significant step towards hybrid quantum technologies that combine electronic and phononic excitations.

Controlling The Ultrafast Optical Properties of Graphene with Ionic Liquid Gating Eva A. A. Pogna; CNR-IFN, Italy

Single-layer graphene is endowed with broadband optical absorption, largely dependent on the Fermi energy. Ionic liquid gating allows to tune the Fermi energy to hundreds of eV and control its optical response in the near-infrared and THz ranges. Transient absorption measurements in the near-infrared reveal that also the out-of-equilibrium optical properties can be largely tuned using ionic gating. By varying the Fermi energy via electrostatic gating, the sign of the transient optical response of graphene is switched while the recovery dynamics significantly slows down due to the quenching of the relaxation of the hot electrons through the emission of optical phonons. The electrostatic control of the recovery dynamics and of the sign of differential transmission, opens intriguing perspectives for applications of graphene as a tunable saturable absorber for generation of tunable near-infrared pulses or alternatively as optical limiter or logic gate. Moreover, ionic gating is exploited to conceive compact optoelectronic devices acting in the THz range as amplitude modulators, saturable absorber mirrors and frequency tuners. The large control of the THz optical response is used to compensate the cavity dispersion of a multimode THz quantum cascade laser and induced stable operation as frequency comb for metrological applications.

10:30 AM QT01.08.02
Ultrafast Exciton Dynamics in 2D Van der Waals Nanostructures: Probing The Hot Exciton Relaxation of Size-Controlled & Well-Dispersed Graphene Nanoflakes Elsa Cassette[1], Sébastien Quistrebert[1], Daniel Medina-Lopez[2], Stéphane Campidelli[2] and Jean-Sébastien Lauret[1]; [1]LuMIn - Université Paris-Saclay, ENS Paris-Saclay, CNRS, CentraleSupelec, France; [2]NIMBE/LICSEN - Université Paris-Saclay, CEA, CNRS, France

Graphene nanostructures, such as graphene quantum dots (G-QDs), graphene nanoribbons (G-NRs) and carbon nanotubes (C-NTs), combine the unique mechanical and electronical transport properties of sp^2- hybridized carbon materials and the optical properties of direct semiconductors provided by the optical gap resulting from the reduction of dimensionally. Among them, the recent developments within the well-known synthesis of G-QDs though bottom-up approach [1] have led to exceptionally well-controlled nanostructures in terms of size, shape and dispersion [2]. The resulting graphene nanoflakes provide tunable emission in the red range, with fluorescence quantum yield close to one. Furthermore, these nanostructures have revealed to be promising stable emitters of single photons, as shown in our laboratory [2-5].
Here we use transient absorption of 30 fs temporal resolution with polarization-controlled configuration to probe the hot exciton relaxation (internal conversion, $S_n \rightarrow S_1$) in rectangular G-QDs of various lateral lengths. The nanoflakes are composed of exactly 96, 114 and 132 conjugated carbons (respectively 2.30, 2.71 and 3.11 nm). While the ultrafast electronic dynamics in graphene nanostructures are often being blurred by large broadband photo-induced absorption signals [6-8] (in particular involving triplet states, $T_1 \rightarrow T_n$), here the suppressed aggregation in the studied graphene nanoflakes allows a clear observation and identification of the discrete ground state bleaching (GSB) and photo-induced emission (PIE) signals.
We selectively excite the different samples at the second optically active electronic transition and, thought the appearance of a PIE signal at the energy corresponding to the bandedge and red-shifted vibrational replica (*i.e.* at the position of the steady-state photoluminescence peaks), the dynamics of relaxation were unveiled. The resulting relaxation times range from 100 fs to 175 fs. These results allowed to discuss the mechanism of relaxation, with the effect of the length of the graphene nanoflakes and of the fluence excitation [Quistrebert *et al.*, in preparation].

Hot Carrier Cooling and Trapping in Atomically Thin WS_2 Probed by Three-Pulse Femtosecond Spectroscopy Tong Wang[1], Tom Hopper[1,2] and Artem Bakulin[1]; [1]Imperial College London, United Kingdom; [2]Stanford University, United States

Transition metal dichalcogenides (TMDs) have shown outstanding semiconducting properties which make them promising materials for next-generation optoelectronic and electronic devices. These properties are imparted by fundamental carrier-carrier and carrier-phonon interactions that are foundational to hot carrier cooling. Recent transient absorption studies have reported ultrafast timescales for carrier cooling in TMDs that can be slowed at high excitation densities via a hot-phonon bottleneck (HPB), and discussed these findings in the light of optoelectronic applications. However, quantitative descriptions of the HPB in TMDs, including details of the electron-lattice coupling, and how cooling is affected by the redistribution of energy between carriers, are still lacking. Here, we use femtosecond pump-push-probe spectroscopy as a single approach to systematically characterize the scattering of hot carriers with optical phonons, cold carriers, and defects in a benchmark TMD monolayer of polycrystalline WS_2. By controlling the interband pump and intraband push excitations, we observe, in real-time (i) an extremely rapid 'intrinsic' cooling rate of ~18 ± 2.7 eV/ps, which can be slowed with increasing hot carrier density, (ii) the deprecation of this HPB at elevated cold carrier densities, exposing a previously undisclosed role of the carrier-carrier interactions in mediating cooling, and (iii) the interception of high energy hot carriers on the sub-picosecond timescale by lattice defects, which may account for the lower photoluminescence yield of TMDs under above band-gap excitation condition.

11:00 AM *QT01.08.04
Revealing Ultrafast Phonon-Mediated Inter-Valley Scattering by Simulating Transient Absorption and High Harmonic Spectroscopies Aaron Kelly; Max Planck Institute, Germany

Processes involving ultrafast laser driven electron-phonon dynamics play a fundamental role in the response of quantum systems in a growing number of situations of interest, as evidenced by phenomena such as strongly driven phase transitions and light driven engineering of material properties. In this presentation we will discuss how these processes can be captured in real-time from a computational perspective, focusing on simulating the transient absorption spectra and high harmonic generation signals associated with processes such as valley selective excitation under strong driving, and phonon-mediated intra-band charge carrier relaxation. We will show that the multi-trajectory Ehrenfest dynamics approach, implemented in combination with real-time time-dependent density functional theory and tight-binding models, offers a simple and efficient method to study ultrafast electron-phonon coupled phenomena in solids under diverse pump-probe regimes which can be easily incorporated into the majority of real-time *ab-initio* software packages.

11:30 AM +QT01.08.05
Quantum Floquet Engineering with an Exactly Solvable Tight-Binding Chain in a Cavity Dante Kennes; RWTH Aachen University, Germany

Recent experimental advances enable the manipulation of quantum matter by exploiting the quantum nature of light. However, paradigmatic exactly solvable models, such as the Dicke, Rabi or Jaynes-Cummings models for quantum-optical systems, are scarce in the corresponding solid-state, quantum materials context. Focusing on the long-wavelength limit for the light, here, we provide such an exactly solvable model given by a tight-binding chain coupled to a single cavity mode via a quantized version of the Peierls substitution. We show that perturbative expansions in the light-matter coupling have to be taken with care and can easily lead to a false superradiant phase.
Furthermore, we provide an analytical expression for the groundstate in the thermodynamic limit, in which the cavity photons are squeezed by the light-matter coupling. In addition, we derive analytical expressions for the electronic single-particle spectral function and optical conductivity. We unveil quantum Floquet engineering signatures in these dynamical response functions, such as analogs to dynamical localization and replica side bands, complementing paradigmatic classical Floquet engineering results. Strikingly, the Drude weight in the optical conductivity of the electrons is partially suppressed by the presence of a single cavity mode through an induced electron-electron interaction.

Exciton Multiplication and Dynamics in Two-Dimensional Transition-Metal Dichalcogenides Suman Kalyan Pal, Ashish Soni and Bhuvan Upadhyay; Indian Institute of Technology Mandi, India

Two-dimensional (2D) transition-metal dichalcogenides (TMDs) have attracted considerable attention due to their notable optical, electrical, and mechanical characteristics [1]. Their potential for investigating many-body interactions at room temperature is rooted in the robust Coulomb interaction and diminished screening effects [2]. In recent years, ultrafast optical techniques have been employed to directly examine the many-body processes in 2D TMDs [3]. Our research has showcased effective multiple exciton generation (MEG) in monolayer MoS_2, discerned through the tracking of carrier dynamics at varying excitation photon energies. Our findings not only disclosed a low threshold energy for MEG but also highlighted a high MEG efficiency (86%) [4]. Furthermore, I will delve into the impact of vanadium (V) doping on the electronic structure and carrier dynamics of monolayer MoS_2 [5]. Our observations indicate that carrier recombination decelerates in V-doped samples, leading to prolonged charge carrier survival. To conclude the discussion, I will emphasize a distinctive aspect of our research involving the efficient dissociation of excitons at the interface of a WS_2/2D perovskite heterostructure. The electron transfer from WS_2 results in the formation of a longer-lived interlayer exciton in this van der Waals heterostructure. The experimental insights gleaned from our research bear significant implications for advancing mechanically flexible and highly efficient next-generation solar cells and photodetectors.

Microscopic and Spectroscopic Study on the Superfluorescence of Quasi-2D Perovskite Aaron Wildenborg[1], Ryan Munter[1], Francisco Freire Fernandez[2], Teri W. Odom[2] and Jae Yong Suh[1]; [1]Michigan Technological University, United States; [2]Northwestern University, United States

Halide perovskites have seen a surge in interest in optoelectronic devices beyond their uses in solar cells and batteries. By using buffer molecules in fabrication, it is possible to inhibit the growth of perovskites along one dimension, creating a few layers thick film called quasi-2D perovskite. With a sufficiently high excitation power at room temperature, quasi-2D perovskite exhibits the phenomenon of superfluorescence in which emitters undergo cooperative spontaneous emission. Our quasi-2D perovskite thin-films have shown pulsed emission of enhanced decay rate, an indicator of superfluorescence. Moreover, we perform scanning transmission electron microscopy on the samples to corroborate the quadratic dependence of output intensity on the number of emitters. We find that the formation of a superlattice plays a significant role in generating the superfluorescence of quasi-2D perovskite.

Bidirectional Phonon Emission in Two-Dimensional Heterostructures triggered by Ultrafast Charge Transfer Archana Raja; Lawrence Berkeley National Laboratory, United States

Atomically thin van der Waals crystals like graphene and transition metal dichalcogenides allow for the creation of arbitrary, atomically precise heterostructures simply by stacking disparate monolayers without the constraints of covalent bonding or epitaxy.While these are commonly described as nanoscale LEGO blocks, many intriguing phenomena have been discovered in the recent past that go beyond this simple analogy. In this talk, I will describe how we use ultrafast electron diffraction to uncover the role of layer-hybridized electronic states as a powerful route to control ultrafast energy transport across atomic junctions [1]. We measure the simultaneous heating of both WSe2 and WS2 in a WSe2/WS2 heterobilayer on a picosecond timescale after selective excitation of the WSe2 monolayer. This observation cannot be explained purely by phonon transport across the interface. Through first-principles calculations, we identify electronic states hybridized across the heterostructure that allow phonon-assisted interlayer transfer of photoexcited electrons, which leads to bidirectional phonon emission and simulatneous heating of both the layers.

10:00 AM QT01.10.01
Unveiling The Efficient Charge Transfer Cascade in Band-Tailored Two-Dimensional WS_2/ Ni Doped $CsPbI_3$ Heterosystem Himanshu Bhatt[1], Tanmay Goswami[1] and Hirendra N. Ghosh[2]; [1]Institute of Nano Science and Technology (INST), Mohali, India; [2]National Institute of Science Education and Research (NISER), India

Band structure modulation in heterostructure has emerged as a highly effective strategy for fabricating advanced optoelectronic devices. In this work, we have designed a $CsPbI_3$-WS_2 (CPI-WS_2) heterosystem and employed transient absorption (TA) spectroscopy to gather a comprehensive understanding of charge carrier dynamics. TA study demonstrated the charge delocalization at the interface of CPI and WS_2. Due to the quasi-type II integration of CPI and WS_2, the charge separation in this heterosystem is not very effective, which would restrict their utilization in photovoltaic applications. To further improvise the charge separation, Ni atoms were introduced as dopants into CPI nanocrystals. Ultraviolet electron spectroscopy (UPS) suggested that the homovalent doping elevated the band positions of CPI and resulted in a type II band configuration with WS_2. TA analysis revealed the spontaneous carrier's separation in band-modulated heterosystem due to the isolation of electrons and holes in discrete semiconductors. These spectroscopy findings were correlated with the optoelectronic performance of heterostructure-based devices. Enhanced charge separation within a doped heterosystem leads to superior optoelectronic performance compared to undoped heterosystems. Our findings showed that the band level of engineering encourages the segregation of charge carriers at the hetero-interface, which would be extremely impactful for designing heterostructure-based optoelectronic systems.

Light Control of Charge Transport and Phase Transitions Sheng Meng; Chinese Academy of Sciences, China

Photoexcitation is a powerful means in distinguishing different interactions and manipulating the properties of matter, especially for charge transport and phase transitions in complex quantum systems.
Here we show that laser-controlled coherent phonon excitation enables orders of magnitude enhancement of carrier mobility via accelerating polaron transport in a prototypical material, lithium peroxide (Li2O2). The selective excitation of specific phonon modes, whose vibrational pattern directly overlap with the polaronic lattice deformation, can remarkably reduce the energy barrier for polaron hopping. The strong nonadiabatic couplings between the electronic and ionic subsystem play a key role in triggering charge transport. These results extend our understanding of charge transport dynamics to the nonequilibrium regime and allow for optoelectronic devices with ultrahigh on-off ratio and ultrafast responsibility competitive with those of state-of-the-art devices. We also investigate photoexcitation induced ultrafast phase-transition dynamics in two-dimensional materials, where we identify a laser-induced collective pathway from 2H phase to 1T phase in MoTe2 that is significantly different from thermal phase transitions. Our results provide insights from a new perspective on the coherent electron and lattice quantum dynamics in materials upon photoexcitation.

Light-Matter Coupling with Bound States in The Continuum in Van der Waals Metasurfaces Luca Sortino[1], Stefan A. Maier[2,3] and Andreas Tittl[1]; [1]Ludwig-Maximillians-University Munich, Germany; [2]Monash University, Australia; [3]Imperial College London, United Kingdom

The extraordinary properties of layered van der Waals (vdW) materials, like hexagonal boron nitride (hBN) and Transition Metal Dichalcogenides (TMDCs), make them an appealing platform to investigate and engineer light-matter interactions at the nanoscale. When reduced to atomically thin monolayers, they display attractive characteristics, such as strongly bound excitons and optically addressable spin defects, while in their bulk form they exhibit significant optical anisotropy and possess high refractive index values greater than 4, surpassing common semiconductor materials. This makes vdW materials highly desirable for achieving low-loss optical resonances and for vertically stacking different materials for developing novel all-dielectric nanophotonic structures.
Here, we exploit the concept of quasi-bound states in the continuum (qBIC) to create high-quality optical resonances in dielectric metasurfaces made of hBN and TMDCs. Our method is entirely monolithic, using only van der Waals materials, and achieves optical resonances with Q factors exceeding 10^2 through a two-step fabrication process. We demonstrate spectral tuning across the entire visible spectrum in hBN qBIC metasurfaces [1], and enhance light-matter coupling with intrinsic spin defects in hBN [2]. We observe a remarkable 25-fold increase in photoluminescence intensity and spectral narrowing of defect emissions, with a linewidth below 4 nm full width at half-maximum. Furthermore, our platform offers exciting possibilities for strong light-matter coupling, as seen in the distinct anti-crossing behavior between qBIC resonances and intrinsic excitons in monolithic TMDC WS_2 metasurfaces, achieving Rabi splitting values up to 116 meV under ambient conditions [3]. Our results illustrate how combining qBIC photonic metasurfaces with van der Waals materials paves the way for novel hybrid nanophotonic platforms and room temperature polaritonic devices.

Optical Imaging of Ultrafast Phonon-Polariton Propagation through an Excitonic Sensor Shan-Wen Cheng[1], Ding Xu[1], Haowen Su[1], James M. Baxter[1], Luke N. Holtzman[2], Kenji Watanabe[3], Takashi Taniguchi[3], James Hone[2], Katayun Barmak[2] and Milan Delor[1]; [1]Department of Chemistry, Columbia University, United States; [2]Columbia University, United States; [3]National Institute for Materials Science, Japan

Hexagonal boron nitride (hBN) hosts phonon polaritons (PhP), hybrid light-matter states that facilitate electromagnetic field confinement and exhibit long-range ballistic transport. Extracting the spatiotemporal dynamics of PhPs usually requires tour-de-force experimental methods such as ultrafast near-field infrared microscopy. Here, we leverage the remarkable environmental sensitivity of excitons in two-dimensional transition metal dichalcogenides to image PhP propagation in adjacent hBN slabs. Using ultrafast optical microscopy on monolayer WSe2/hBN heterostructures, we image propagating PhPs from 3.5 K to room temperature with sub-picosecond and few-nanometer precision. Excitons in WSe2 act as transducers between visible light pulses and infrared PhPs, enabling visible-light imaging of PhP transport with far-field microscopy. We also report evidence of excitons in WSe2 co-propagating with hBN PhPs over several microns. Our results provide new avenues for imaging polar excitations over a large frequency range with extreme spatiotemporal precision, and new mechanisms to realize ballistic exciton transport at room temperature.

Polaron Dynamics of The Photo-Induced Hidden Metallic Phase in $La_{2/3}Ca_{1/3}MnO_3$ Shiyu Fan[1], Feng Jin[2,3,4], Umesh Kumar[5], Brandon Yalin[1], Jiemin Li[1], Taehun Kim[1], Vivek Bhartiya[1], Yanhong Gu[6], Valentina Bisogni[1], Sobhit Singh[7], Wenbin Wu[3,4,2] and Jonathan Pelliciari[1]; [1]Brookhaven National Laboratory, United States; [2]University of Science and Technology of China, China; [3]Anhui Key Laboratory of Condensed Matter at Extreme Conditions, China; [4]Hefei National Research Center for Physical Sciences at the Microscale, China; [5]Rutgers, The State University of New Jersey, United States; [6]The University of Tennessee, Knoxville, United States; [7]University of Rochester, United States

Creating new "hidden" phases that have no analog in thermodynamic equilibrium is becoming increasingly important in condensed matter physics. The use of ultrafast laser with femtosecond pulse width to trigger such quantum phase transition is appealing as some of the hidden phases can be long-lived, with a lifetime of hours or weeks, and reversible with temperature sweeping or extra laser pulses. However, investigating and understanding the microscopic interactions in those hidden phases are still on the early stage due to the lack of high-end spectroscopic techniques that are sensitive to all degrees of freedom, precluding the development of designing high performance devices. Here, by combining the femtosecond ultrafast laser as a switching knob with the state-of-the-art ultrahigh-resolution resonant inelastic X-Ray Scattering as a probe, we reveal the phonon and polaron dynamics, as well as the evolution of crystal-field excitations across the insulating to photoinduced hidden metallic phase transition in a strained $La_{2/3}Ca_{1/3}MnO_3$ thin film. Upon the ultrafast excitation, the Jahn-Teller distortion is suppressed due to the strain relaxiation induced by the increasing itinerancy of the Mn e_g electrons. This renormalizes the energies of the polaron and Mn *dd* excitations, ultimately leading to the formation of a metastable long-lived ferromagnetic metallic phase. Our results demonstrate that the electronic properties of the mesoscopic photoinduced hidden phase evolve with laser fluence, as an evidence of the systematic softening of the polaron binding energy and Mn *dd* excitations, consistent with the trend extracted from the bulk phase comparision. However, the spectral weight of the phonon and polaron is different compared to the metallic as-grown film, proving that the photo-induced phase is unique and distinct from the bulk metallic phase. Our findings indicate the strength of electron-phonon coupling plays the key role to determine the conductivity of manganites.

First-Principles Quantum Electrodynamics Theory of Light-Matter Interactions at All Coupling Strengths Yu Zhang and Xinyang Li; Los Alamos National Laboratory, United States

This presentation introduces VT-QEDHF, a novel first-principles quantum electrodynamics method developed to understand light-matter interactions at any coupling strength. The intersection of QED with materials science has catalyzed significant advancements in manipulating materials properties.

Traditional computational approaches, while effective, have been limited by their applicability to specific coupling regimes. Our work breaks away from the limitations of conventional approaches, offering a universal and efficient way to study light-matter interactions across various coupling regimes. Our findings open up new possibilities for researching and manipulating material properties via light-matter couplings.

11:45 AM QT01.10.07
A Composite Electrodynamic Mechanism to Reconcile Spatiotemporally Resolved Exciton Transport in Quantum Dot Superlattices Rongfeng Yuan[1,2], Trevor Roberts[1], Rafaela M. Brinn[1], Alexander Choi[1], Ha Park[1], Chang Yan[1,3], Justin Ondry[1,4], Ke Xu[1], Paul Alivisatos[1,4] and Naomi S. Ginsberg[1]; [1]University of California, Berkeley, United States; [2]The Hong Kong University of Science and Technology (Guangzhou), China; [3]Shanghai Jiao Tong University, China; [4]The University of Chicago, United States

Quantum dot (QD) solids are promising optoelectronic materials; further advancing their device functionality depends on understanding their energy transport mechanisms. The commonly invoked near-field Förster resonance energy transfer (FRET) theory often underestimates the exciton hopping rate in QD solids, yet no consensus exists on the underlying cause [1–3].
We elucidate a mixed near-field FRET and far-field emission/reabsorption mechanism excitonic energy transport by combining time-dependent exciton energy and exciton diffusivity measurements in a heterogeneous QD superlattice (QDSL) [4]. We first quantitatively characterize the heterogeneous energetic landscape of CdSe:Te/CdS QDSL monolayers by extracting inhomogeneous and intrinsic spectral components of QDs by single-particle emission spectroscopy [5]. We next track the time-dependent decay of the mean exciton energy by time-resolved emission spectra (TRES) upon QDSL photoexcitation. The enhanced dynamic redshift occurring in the QDSLs relative to the solution phase QDs immediately following excitation indicates excitons, on average, sample progressively lower-energy QDs as they explore the spatioenergetic landscape. Finally, we measure exciton transport by monitoring the spatiotemporal expansion of an exciton population after a local photoexcitation in QDSL monolayers with time-resolved ultrafast stimulated emission depletion (TRUSTED) microscopy [6]. The result is that the data may be fitted to a simple model of the TRUSTED protocol [6] to determine migration parameters, such as diffusivity.
We use all three types of experimental results to constrain parameters in a kinetic Monte Carlo simulation, and we find that FRET theory is incompatible with the TRUSTED and TRES results simultaneously. This approach is unique because we connect the exciton energy and diffusion dynamics directly, which puts stringent test on the existing FRET theory. We show that only by introducing far-field emission/reabsorption terms that allows hops well beyond the nearest neighbors, can the model reproduce both all three experimental results. Our inclusion of far-field coupling was inspired by Andrews *et al.* [7], who originally wrote down how the energy transfer rate between donor and acceptor TDM can most generally be written as a dipole-dipole coupling expansion, , where represents the FRET rate and dominates in the near-field. The far-field term (scales with r^{-2}) dominates when r is much greater than $\lambda/2\pi$.
The explanation of our own multimodal study also addresses a longstanding paradox in exciton transport within QD solids, i.e., the typically-employed FRET near-field model has repeatedly fallen short of explaining experimental results despite being perpetuated as a standard. We furthermore showed how our model reconciles the original report of this paradox from Tisdale and co-workers [1]. Overall, this work yields a much-needed unified framework in which to characterize transport in QD solids and new principles for device design.

SESSION QT01.11: THz Dynamics in Quantum Materials
Session Chairs: Youn Jue Bae and Nicolò Maccaferri
Friday Afternoon, April 26, 2024
Room 420, Level 4, Summit

2:00 PM QT01.11.01
Time-Resolved THz-TDS Nanoscopy for Probing Carrier Dynamics in 2D Materials with Femtosecond Temporal and Nanometer Spatial Distribution Tobias Gokus[1], Jonas Albert[1], Artem Danilov[2] and Andreas Huber[1]; [1]Attocube Systems AG, Germany; [2]Attocube Systems Inc, United States

THz imaging and spectroscopy is attracting attention as a tool for contact-free characterization of free charge carriers and their dynamics in nano-electronic devices [1]. However, the optical resolution of traditional THz microscopy is restricted by the diffraction limit of light. Scattering-type scanning near-field optical microscopy (s-SNOM) surmounts the diffraction limit by focusing light to a metallic scanning tip and collecting and analyzing the tip-scattered light [2]. Deep subwavelength spatial resolution down to sub-15 nm ($\lambda/8000$) was recently demonstrated for s-SNOM measurements in the THz frequency range [3].

In this work we demonstrate THz-TDS based s-SNOM imaging and spectroscopy in combination with time-resolved THz-TDS spectroscopy based on a fully integrated pump-probe THz-TDS near-field optical microscope system. To illustrate these capabilities, we perform NIR pump – THz probe near-field imaging and spectroscopy of a MoS_2 flake with a thickness of about 250 nm deposited on a gold coated Si substrate.

Delivering broadband THz pulses (0.1 – 5 THz) for tip illumination, micron sized terraces with varying thickness on the MoS_2can be well distinguished based on their characteristic near-field contrast, highlighting the capability of the system to achieve deep subwavelength spatial resolution. Further, a pronounced contrast is observed in the THz image between the MoS_2 and the highly reflective Au substrate.

Optical pumping of the flake with femtosecond laser pulses (center wavelength, 780nm (1.59 eV), pulse duration < 150fs) at photon energies larger than the direct/indirect bandgap of MoS_2 results in a general increase of the THz amplitude signal across the flake. Interestingly, the magnitude of the near-field

THz signal on the flake is now almost the same as for the gold substrate, indicating that the increase in THz signal of the MoS_2 flake originates from modification of the refractive index. Obviously, upon photoexcitation with the 780 nm pump pulse, the terahertz conductivity increases due to absorption by the photoinduced charge carriers [4,5]. It is to note, that the magnitude of the THz-near-field signal of the gold substrate remains unaltered during NIR laser illumination.

THz transients are measured by varying the timing between the NIR optical pump and THz probe pulses. The transients were recorded on two different areas on the flake separated only by a few microns. The decay of the THz near-field amplitude signal is on the order of a couple of hundreds of picoseconds with notably slower decay for the location with larger thickness. The observed long carrier relaxation dynamics up to the >100 ps time scale might result from slow carrier relaxation processes in the crystal [6].

Scattering type near-field microscopy is a powerful tool for optical investigation of nanoscale structures with wavelength-independent resolution < 20 nm. Its applicability has been successfully extended to the THz frequency range. Furthermore, we have expanded these capabilities successfully to enable time-resolved VIS/NIR pump and THz probe spectroscopy for studying the dynamics of photoexcited carriers in semiconductors. We envision even further opportunities for the investigation of low energy optical excitations in novel materials and their dynamics by implementing time-resolved THz-TDS spectroscopy to cryogenic s-SNOM microscopes.

2:15 PM QT01.11.02
Terahertz Emission Spectroscopy to Probe Ultrafast Spin to Charge Conversion at Perovskite/Ferromagnet Interfaces Yifan Dong[1], Matthew Hautzinger[1], Andrew Comstock[2], Aeron McConnell[2], Dali Sun[2] and Matthew C. Beard[1]; [1]National Renewable Energy Laboratory, United States; [2]North Carolina State University, United States

Understanding spin-to-charge conversion (SCC) allows efficient control and manipulation of the spin degree of freedom, which can pave the way for next generation spintronic devices. Unlike conventional transport-based measurements, terahertz (THz) emission spectroscopy offers great advantages including the capability of measuring transient charge currents with sub-picosecond time resolution. Using THz emission spectroscopy, we observed the ultrafast spin current injection at the interface between a ferromagnetic (FM) material and a chiral two-dimensional (2D) perovskite via inverse Rashba-Edelstein effect. In summary, we observed strong magnetic field- and polarization-dependence in both phase and intensity of the emitted THz signal, implying the great tunability in these chiral 2D perovskites for spintronic application. These results present a promising way to control charge and spin interconversion at perovskite/ferromagnetic interfaces and future spintronics devices. The unique asymmetry in THz emission due to SCC at chiral 2D perovskite/FM (i.e. $(R\text{-}MBA)_2PbI_4$/NiFe and $(S\text{-}MBA)_2PbI_4$) interface distinguishes them from three-dimensional perovskite materials which only exhibiit symmetric THz emission. In this talk, I will discuss the measured THz emission signals including both the forward and backward THz emission (reflected at the air/substrate interface). The forward emission signal exhibits a π-phase shift when the in-plane magnetic field flips its sign, whereas the backward signal exhibits no phase shift at all. In addition, I will also discuss the asymmetry in THz emission intensity. Specifically, the THz emission intensity of the forward emission signal decreases by almost two-fold when the in-plane magnetic field reverses, while the backward emission signal increases by two-fold when the field direction reverses. Such asymmetry in THz emission can be explained with an in-plane momentum shift of the Rashba bands induced by the ultrafast laser pump.

3:00 PM *QT01.12.02
Quantum Material Research through Femtosecond Electron Crystallography, Spectroscopy and Microscopy Chong-Yu Ruan; Michigan State University, United States

The major potential advantage in using electron scattering data, compared to X-ray, is that electrons can be focused using an electromagnetic lens; thus, both images and diffraction patterns can be utilized for structural analysis under the same platform. Importantly, the different modalities are controlled by the post-specimen optics and aperture placement with additional sets of lenses. The lens combination offers great flexibility in creating either image, diffraction, or even spectroscopic signals from a large field of view or data for the microanalysis of small regions. Injecting ultrafast time resolution into the typical TEM modalities will not only allow ultrafast imaging and diffraction patterns to be obtained for studying material processes, but also the delicate control of timing between the pump and probe pulses can create a new contrast mechanism at various stages of the material's responses. Especially, the recent successful implementation of high precision control of electron probe dynamics enables the technologies to perform in the 10s femtosecond regime, opening new possibility of studying control-feedback mechanism.

We will discuss the uses of dynamical contrast to enhance the imaging and crystallography capabilities for the understanding of the evolutionary processes set forth from different types of laser pulse initiations in quantum materials. The evolutionary processes are probed through combined approach of ultrafast spectroscopy, diffraction, and microscopy that are conducted in situ to piece together information. Using vanadium dioxide nanocrystals and transition-metal dichalcogenide (TMDC) thin layers as examples, we demonstrate how the multi-modality ultrafast electron platform may provide useful new information regarding quantum material state evolution at different spatial and temporal scales. Through joint structure and spectroscopy probes we identify the common presence of nanoscopic transition intermediate as the cornerstone for the system's successful descend into the eventual state and adopting its functionality.

In the studies of TMDC (TaS_2, $TaSe_2$) first focusing on the dynamics on the ps and sub-ps timescale with time-domain contrasts over the optical signals and selected Bragg peaks, we observe that under different pump conditions different types of phonon modes in the hosting lattice of the charge-density-wave materials may be activated. Upon entering the phase transition regime, these phonon modes are hybridized with the emerging density-wave state observed through the dynamical crystallographic patterns. The transition becomes stepwise with the formation of nanoscopic domains that lock the emergent order with the host lattice in various formation. Remarkably, upon varying the pump power, the timescale for the multi-stage evolutions can be tuned by more than one order of magnitude. In the case of VO_2, multi-critical behavior also emerges but here we show the thermal and non-thermal controls manifest in different types of behavior. For the nonthermal control, in which, the initial step of ultrafast spectroscopic insulator-to-metal transition is observed over sub-100 fs timescale where the emergence of a nanoscopic excitonic polaron domain is simultaneously captured by the diffraction signals. Such evolution is different from the insulator-metal transition obtained under the thermal regime of control where no such polaronic domain is identified. These results indicate that the functional controls in correlated electron crystals may be more nuanced due to their sensitivity to more than one type of control parameter and our multi-perspective results may shed insight to address some highly debated open questions regarding these materials.

The work was funded by the U.S. Department of Energy, Grant DE-FG0206ER46309. The experimental facility was supported by U.S. National Science Foundation, Grant DMR 1625181.

3:30 PM QT01.12.03
Spatiotemporal Imaging of Waveguide Nonlinear Optics Ding Xu and Milan Delor; Columbia University, United States

Non-linear optical conversion is an essential aspect of modern photonic applications, and major efforts target the realization of efficient nonlinear processes in compact waveguides for miniaturization. Van der Waals structures, renowned for their pronounced light-matter interactions and nonlinear susceptibilities, have emerged as promising platforms to realize such nonlinear waveguides, but optimization requires precise knowledge of their linear and nonlinear optical properties, which are notoriously difficult to extract in highly anisotropic microstructures. I will describe an approach we developed to extract the optical properties and phase-matching conditions of nonlinear materials by directly imaging light propagation and harmonic conversion within van der Waals waveguides with extreme spatiotemporal resolution. Although it is generally assumed that waveguided light remains out the reach of far-field microscopy, our approach, based on far-field ultrafast microscopy, leverages strong light-matter interactions to track light fields even beyond the total internal reflection barrier, an unprecedented feat. We focus on slab waveguides of 3*R*-MoS2, which were recently found to exhibit highly efficient second harmonic generation. We show that spatiotemporal imaging of both fundamental and second harmonic waves provides several self-consistent methods to determine the phase-matching angle, mode profiles, harmonic generation efficiency and losses in nonlinear waveguides without any a priori knowledge of material properties. Our approach thus enables rapid identification of promising materials and optimization of waveguide structures for efficient harmonic generation and optical modulation in nanophotonic architectures.

Ultrafast Infrared-Light-Driven Symmetry Control in Crystalline Materials Zhiren He and Guru Khalsa; University of North Texas, United States

The interplay between structure, symmetry, and function is a fundamental and long-standing paradigm in materials physics. It dictates how we access physical properties, reveals hidden order, and guides both the search for, and the engineering of, new physical phenomena. Recent technological advances have enabled sub-picosecond manipulation of structure through the far-from-equilibrium drive of phonons — the mechanical modes of crystalline materials — using mid- and far-infrared light. How can we leverage these structural changes to induce new symmetries and functionalities?

In this talk, I will discuss our theoretical exploration of light-driven control of symmetry in crystalline materials via direct excitation of phonons. Focusing on strategies for tailored optical control of elusive symmetries and orders, I will demonstrate that new symmetries and length scales can emerge, that chemical environments not observed near equilibrium can be prepared, and that known or hidden phase boundaries may be traversed.

Quantum Defects in 2D Materials for Terahertz Technologies Su Ying Quek; National University of Singapore, Singapore

The emergence of stable terahertz (THz) sources and other THz optical components has spurred the development of many applications. However, THz technologies have thus far not been well integrated into the quantum regime. In this work, we predict that transition metal substitutional defects in two-dimensional transition metal dichalcogenides (TMDs) can serve as quantum defects for terahertz technologies. Central to this prediction is the finding that the zero field splittings between the spin sublevels in these defects are in the sub-terahertz to terahertz range. These zero field splittings are orders of magnitude larger than those found in other common quantum defects, due to the large spin-orbit coupling in these TMD systems. Based on the symmetries of the quantum states as well as first principles calculations of the optical transition energies, we identify defects that can serve as spin qubits, either through resonant excitation or through intersystem crossing channels. Such spin qubits are expected to have a longer spin coherence time compared to spin qubits with smaller zero field splittings. We further propose defects that can potentially be tunable quantum sources of terahertz radiation. Our research broadens the scope for advancements in quantum computing and information science, and lays a foundation for their integration with THz technologies.

THz Driven Ultrafast Processes in Quantum Materials Shovon Pal; National Institute of Science Education and Research Bhu, India

Quantum materials – a category of condensed matter systems – display strong electronic correlations where the very notion of electrons as non-interacting entities fails. The properties of quantum materials with the so-called strongly correlated states are, instead, determined by the collective interaction of many electrons via their charges and spins [1,2]. The complexity that arises from such interactions gives rise to emergent phenomena in a multitude of quantum materials, like high-T_c superconductors [3], heavy-fermion materials [4,5], ferroelectrics [6], topological materials [7], and multiferroics [8]. Because of the

multi-particle nature, microscopic understanding of their ground states with such strong-correlation phenomena is a demanding task and requires going away from the ground state and studying the nonequilibrium dynamics of such systems. In general, equilibrium studies ignore the temporal evolution of a physical process, and most importantly, neglect local fluctuations in the systems. In contrast, the non-equilibrium descriptions explain the roles of such fluctuations both in time and space. As the dynamics of many-body processes get even more critical in various quantum materials, we need to understand how the temporal evolutions of specific processes affect the underlying correlations between charge, spin, lattice and orbital degrees of freedom. In this talk, I will provide an overview on how the THz light has been used to drive quantum materials out of equilibrium and gain information on the associated correlation processes and the dynamics of low-energy excitations [9].

Non-Linear Light-Matter Interactions in Quantum Materials Su Ying Quek; National University of Singapore, Singapore

Non-linear optical phenomena are at the heart of many important technologies and spectroscopic techniques. In order to fundamentally understand, and predict, non-linear optical properties in quantum materials, it is necessary to incorporate the physics of excitons, or bound electron-hole pairs. In this work, we develop and implement a theory for the second-order optical susceptibility that takes into account excitonic effects with a first principles GW-Bethe-Salpeter-Equation (GW-BSE) approach. Using this theory, we elucidate the impact of excitons on sum-frequency generation and spontaneous parametric down-conversion in niobium oxydihalides ($NbOX_2$, X = Cl, Br, I) [1], a material of significant current interest in non-linear optics [2]. We also predict difference-frequency generation effects in quantum materials. In addition to shift current effects (the zero-frequency response), we consider the generation of terahertz pulses due to difference frequency mixing from incoming laser pulses. Our work provides a framework to predict and understand the non-linear effects arising from continuous-wave and ultrafast laser light incident on quantum materials.

Ultrafast Thermodynamic Phenomena Involving Photons, Electrons and Phonons in (Twisted) Quantum (Meta)Materials Klaas-Jan Tielrooij[1,2]; [1]Eindhoven University of Technology, Netherlands; [2]Catalan Institute of Nanoscience and Nanotechnology, Spain

Quantum materials exhibit several exciting ultrafast physical phenomena that are moreover potentially technologically useful. This is particularly true for quantum materials with massless Dirac electrons, such as graphene and topological insulators. When light is absorbed in these materials, electron heating occurs through electron-electron interactions on a 10-100 fs timescale, followed by electron cooling, typically involving the emission of phonons on a picosecond timescale. We have exploited these ultrafast thermodynamics, and the heat-induced decrease in terahertz (THz) absorption, to generate harmonics in the THz regime [1]. This THz harmonic generation is particularly efficient in quantum metamaterials that consist of a quantum material and a metallic grating [2]. Thanks to an efficient “Coulomb cooling” mechanism between surface and bulk electronic states in topological insulators [3], we have recently demonstrated that the ultrafast thermodynamics can give rise to third-order terahertz harmonic generation approaching the milliwatt regime [4]. These results establish quantum (meta)materials as an excellent material platform for nonlinear terahertz photonics, with possible applications in next-generation wireless communication systems, among others.

Whereas these ultrafast thermodynamics in graphene and topological insulators are relatively well understood, this is not the case for twisted bilayer graphene near the magic angle. Using time-resolved photocurrent measurements, we have studied these ultrafast dynamics and found that the electron cooling dynamics in twisted bilayer graphene near the magic angle is very distinct from the dynamics in monolayer or non-twisted bilayer graphene. Specifically, the cooling time in near-magic twisted bilayer graphene is a few picoseconds all the way from room temperature down to 10 K, where non-twisted bilayer graphene becomes increasingly slow for lower temperatures. We ascribe this ultrafast cooling in magic-angle twisted bilayer graphene to Umklapp-assisted electron-phonon cooling, facilitated by the moiré pattern in twisted bilayer graphene [5]. Whereas Umklapp scattering is a very common phenomenon for phonons, it is very rare to observe such scattering processes for electrons. These results establish twist angle as control knob for steering the cooling dynamics and flow of electronic heat, and have possible implications for the development of ultrafast detectors operating at cryogenic temperatures, among others.

10:30 AM *QT02.01.01
Graphene Nanostructures 3.0: Nanoelectronics, Quantum Phenomena and Properties Xinliang Feng[1,2]; [1]Max Planck Institute of Microstructure Physics, Germany; [2]Technische Universität Dresden, Germany

With the advances in emergent quantum technologies, such as quantum computing, quantum communications, etc., graphene nanostructures provide a unique molecular toolbox for accessing their unprecedented quantum phenomena and properties. In this lecture, we will introduce our recent efforts towards the precision graphene nanostructures as the defined quantum entities for the spin-spin coupling. Both in-solution and on-surface synthesis approaches will be discussed that provide synthetic access to this class of unique graphene nanostructures with controlled spin-orbital coupling behavior. Individual open-shell graphene molecules (Kekuléne, non-Kekuléne and concealed non-Kekuléne structure motifs) with controlled singlet, triplet, as well as high-spin states, will be developed. Next, we will discuss the collective carbon magnetisms in the dimers of open-shell graphene molecules. Spin-chains with fractional edge excitations will also be presented. In the final section, we will also present our recent efforts towards graphene nanoribbon-based nanoelectronics. Various robust graphene nanoribbons with controlled edge structures and topologies will be synthesized and demonstrated to show their unique electronic and optoelectronic properties. The integration of single graphene nanoribbons into the nanoelectronic devices will be particularly highlighted.

11:00 AM QT02.01.02
Chemical Exfoliation of 1-Dimensional Antiferromagnetic Nanoribbons from a Non-Van der Waals Material Mulan Yang[1], Guangming Cheng[2], Nitish Mathur[1], Ratnadwip Singha[1], Fang Yuan[1], Nan Yao[2] and Leslie Schoop[1]; [1]Princeton University, United States; [2]Princeton Materials Institute, United States

As the demand for increasingly varied types of 1-dimensional (1D) materials grows, there is a greater need for simple and scalable methods to synthesize these materials. Chemical exfoliation is commonly used to make 2-dimensional (2D) materials, often in a way that is both straightforward and suitable for making larger quantities, yet this method has thus far been underutilized for synthesizing 1D materials. In the few instances when chemical exfoliation has been used to make 1D materials, the starting compound has been a van der Waals material, thus excluding any structures without these weak bonds inherently present. We demonstrate here that ionically bonded crystals can also be chemically exfoliated to 1D structures by choosing $KFeS_2$ as an example. Using chemical exfoliation, antiferromagnetic 1D nanoribbons can be yielded in a single step. The nanoribbons are crystalline and closely resemble the parent compound both in structure and in intrinsic antiferromagnetism. The facile chemical exfoliation of an ionically bonded crystal shown in this work opens up opportunities for the synthesis of both magnetic and non-magnetic 1D nanomaterials from a greater variety of starting structures.

11:15 AM QT02.01.03
Using High-Pressure Conditions to Access Novel Structures and Engender Magnetic Control in Layered Lanthanide Materials Alison Altman, Ebube Oyeka and Ryan O'Shea; Texas A&M, United States

A rational approach to designing the next generation of quantum magnetic materials requires hypothesis-driven synthesis. Yet, the complex phase space of solid-state systems and the small energy scales that determine magnetic order are such that subtle changes in composition can drastically change the structure and properties of the resulting material. In comparison, pressure provides an incrementally tunable vector, serving to increase orbital overlap and leading to more significant covalent and metallic interactions. In this work, we describe our multimodal approach combining high-pressure synthesis with spectroscopy and calculations to bring new chemical insight into the discovery of layered materials containing lanthanides primed to exhibit exotic magnetic behaviors. To realize promising synthetic targets, we turned to both traditional solid-state techniques as well as high-pressure experiments in diamond anvil cells. We note an established tendency towards layered structures in lanthanides halides that depends on the formal valence state of the lanthanide metal. Crucially, dimensionality is known to be sensitive to applied pressures, and can be harnessed to tune the structure of lanthanide systems to promote low-dimensional motifs. We will discuss our burgeoning chemical intuition for structure formation and metastability in this space, as well as present our ongoing efforts towards correlating new structures with magnetic properties both at ambient pressures and under high-pressure synthesis conditions.

11:30 AM *QT02.01.04
Antagonistic Pairs: A Pathway to The Discovery of New Quasi-Low Dimensional Materials Tyler Slade; Ames Laboratory, United States

A foundational goal of materials chemistry is to develop general design principles for synthesizing materials with targeted structural motifs and physical properties. We propose that pairs of strongly immiscible elements, referred to here as antagonistic pairs,[1] can be used to reliably produce ternary compounds with low or quasi-reduced dimensionality intrinsically built into their crystal structures. Many pairs of elements offer essentially no miscibility, of which examples are Co-Pb, Cr-La, and Fe-Ag. The heart of our work is to leverage third elements that are mutually compatible with any given immiscible pair to form stable ternary compounds containing that pair. When such ternary compounds can be made, we discuss how the strong immiscibility of the antagonistic pair is remarkably preserved in the ternary crystal structures, with the third element separating the immiscible atoms into spatially separated substructures. Quasi-low dimensional structural units, such as chains or sheets, are the natural consequence of the immiscible atoms seeking to avoid close contact in the solid-state. Finally, we present the growth and characterization of single crystals of several new, 3*d* transition metal containing, ternary compounds based on antagonistic pairs and which feature quasi-2D structural motifs, concluding with an overview of their magnetic and transport properties.

Room 421, Level 4, Summit

1:30 PM *QT02.02.01
Helical Light Emission from a Moiré Chern Magnet Xiaodong Xu; University of Washington, United States

Twisted $MoTe_2$ bilayer is an emergent fractional Chern insulator with spontaneous time reversal breaking. As semiconducting transition metal dichalcogenides famously exhibit spin-valley locking and circularly polarized valley-optical selection rules, a natural question arises as to how the interaction induced ferromagnetism couples to the optical response. Here, we demonstrate that the degree of circular polarization (DOCP) in the trion photoluminescence at zero magnetic field reaches near unity in the anomalous Hall metal phase, with the helicity controlled by the magnetization direction. Spin-valley Hall response is shown to tune the emission helicity, establishing the electric current as an additional control of the PL helicity. We further show that the PL DOCP is a sensitive probe of the integer and fractional quantum anomalous Hall effects, the putative zero-field composite fermi liquid state, as well as their electric field-driven topological quantum phase transitions. The unprecedented optical properties of this system promise to have profound implications for spintronics, valleytronics, and topological-optoelectronic devices.

2:00 PM QT02.02.02
Optics as a Probe and Control of Spin/Valley Order in Topological Moiré Magnet $MoTe_2$ Eric Anderson[1], Xiaodong Xu[1], Jiaqi Cai[1], Heonjoon Park[1], Di Xiao[1], Ting Cao[1], Liang Fu[2], Wang Yao[3], Kenji Watanabe[4] and Takashi Taniguchi[5]; [1]University of Washington, United States; [2]Massachusetts Institute of Technology, United States; [3]The University of Hong Kong, Hong Kong; [4]National Institute for Materials Science, Japan; [5]Kyoto University, Japan

In the past year, near-AA stacked homobilayer moiré $MoTe_2$ has been established as a robust, gate-tunable ferromagnet upon hole doping of the first moiré valence band. The system's spontaneous time reversal symmetry breaking enables the realization of an effective Haldane model and flat, topologically nontrivial bands. These unique characteristics of the moiré $MoTe_2$ system led to observation of quantum anomalous Hall and, for the first time, fractional quantum anomalous Hall states. Here, I discuss our optical measurements of tunable magnetic and topological states in the moiré superlattice. Additionally, I present our more recent studies leveraging the magnetic order in the system to control helical optical emission at zero applied magnetic field. The strong correspondence between the spin, valley, and optical degrees of freedom these results establish suggests that optics is not only a powerful probe of moiré $MoTe_2$, but could also be promising control knob for the magnetic states. Beyond the implications for spintronics, valleytronics, and magneto-optical devices, the link between magnetic order and topological index of the FQAH states presents a new path forward in the study of anyon physics – and perhaps, one day, towards topological qubits.

2:15 PM *QT02.02.03
Electrical Switching of The Edge Current Chirality in Quantum Anomalous Hall Insulators Cui-Zu Chang; The Pennsylvania State University, United States

A quantum anomalous Hall (QAH) insulator is a topological state of matter, in which the interior is insulating but electrical current flows along the edges of the sample, in either a clockwise (right-handed) or counter-clockwise (left-handed) direction dictated by the spontaneous magnetization orientation. Such chiral edge current (CEC) eliminates any backscattering, giving rise to quantized Hall resistance and zero longitudinal resistance. In this work, we fabricate mesoscopic QAH sandwich (i.e. magnetic topological insulator (TI)/TI/magnetic TI) Hall bar devices and succeed in switching the CEC chirality through spin-orbit torque (SOT) by applying a current pulse under a suitably controlled gate voltage. The well-quantized QAH states before and after SOT switching with opposite CEC chiralities are demonstrated through four- and three-terminal measurements. Our theoretical calculations show that the SOT that enables the magnetization switching can be generated by both bulk and surface carriers in QAH insulators, in good agreement with experimental observations. Finally, I will briefly talk about the SOT switching-induced topological phase transition between the QAH and axion insulator states.

This work is supported by ARO award (W911NF2210159), AFOSR grant (FA9550-21-1-0177), DOE grant (DE-SC0023113), and Gordon and Betty Moore Foundation's EPiQS Initiative (Grant GBMF9063 to C.-Z.C.).

2:45 PM QT02.02.04
Observation of Fractional Quantum Anomalous Hall Effect Heonjoon Park[1], Jiaqi Cai[1], Eric Anderson[1], Yinong Zhang[1], Jiayi Zhu[1], Xiaoyu Liu[1],

Chong Wang[1], William Holtzmann[1], Chaowei Hu[1], Zhaoyu Liu[1], Takashi Taniguchi[2], Kenji Watanabe[2], Jiun-Haw Chu[1], Ting Cao[1], Liang Fu[3], Wang Yao[4], Cui-Zu Chang[5], David Cobden[1], Di Xiao[1] and Xiaodong Xu[1]; [1]University of Washington, United States; [2]National Institute for Materials Science, Japan; [3]Massachusetts Institute of Technology, United States; [4]The University of Hong Kong, Hong Kong; [5]The Pennsylvania State University, United States

The interplay of topology, magnetism, and strong correlation leads to intriguing quantum states of matter. A prominent example is the quantum anomalous Hall effect (QAHE), which displays integer quantum Hall effect at zero magnetic field due to topologically nontrivial bands and intrinsic magnetism. Realizing a similar analogue of the fractional quantum Hall effect at zero field, known as the fractional quantum anomalous Hall effect (FQAHE), has long posed a challenge due to stringent constraints in electron-electron interaction and quantum geometry. Here, we present the experimental observation of FQAHE and electrically tunable topological phase transition in twisted MoTe2 bilayer using electrical transport measurements. In addition, an anomalous Hall state emerges near the filling factor -1/2. Its behavior mirrors that of the composite Fermi liquid in the half-filled lowest Landau level of a two-dimensional electron gas under high magnetic fields. The direct observation of the FQAH and associated effects opens the door to exploring charge fractionalization and anyonic statistics at zero magnetic field.

3:00 PM BREAK

SESSION QT02.03: Emerging Kagome and Magnetic Materials
Session Chairs: Zhong Lin and Andrew F. May
Tuesday Afternoon, April 23, 2024
Room 421, Level 4, Summit

3:30 PM *QT02.03.01
Topology and Correlation in Kagome Lattice Metals Linda Ye; California Institute of Technology, United States

The two-dimensional kagome lattice comprised of corner-shared triangles is theoretically expected to host multiple exotic band features such as Dirac points, van Hove singularity and flat bands in its tight-binding model. The intricate interplay of these band features with spin-orbit coupling and electron-electron interactions renders the kagome lattice an exceptionally promising platform for the realization of topological and correlated electronic states. Recently, a growing family of transition metal-based intermetallic materials, known as "kagome metals," has been found to faithfully realize the anticipated model kagome electronic structure. In this talk, we will focus on the ongoing advancements in the pursuit of topological and correlated phases in binary kagome metals; in particular, we will highlight the band topology in the ferromagnetic phase, the emergence of flat bands as well as non-Fermi liquid behavior in these kagome metals.

Above Room-Temperature Ferromagnetism in Van der Waals Material Fe3GaTe2 Chaowei Hu, Jiayi Zhu, Sanae Tominaga, Jordan Fonseca, Yuzhou Zhao, Xiaodong Xu and Jiun-Haw Chu; University of Washington, Seattle, United States

The emergence of two-dimensional van der Waals magnets has introduced new prospects for vdW heterostructure and spintronic applications in the past decade. Recently a new member Fe3GaTe2 was found and stood out for its persistent ferromagnetism above room temperature. In this presentation, we will discuss our successful synthesis of single-crystalline Fe3GaTe2, as well as the following bulk characterization, transport, and magneto-optical measurements performed on our single crystal and exfoliated thin flakes. The magnetization and transport studies on the bulk Fe3GaTe2 crystals reveal a high Curie temperature of 355K and the thermodynamic investigations suggest the presence of a strong electron-electron correlation. Layer-dependent magneto-optical studies on thin Fe3GaTe2 flakes further unveil its robust ferromagnetism for room-temperature applications in 2D limits. Our work illuminates the remarkable magnetic properties of Fe3GaTe2, establishing it as a suitable vdW platform for realizing controllable 2D magnetism and spintronic applications in everyday environments.

4:15 PM *QT02.03.03
Kagome and Van der Waals Magnetic Topological Materials Roland K. Kawakami; The Ohio State University, United States

Materials and heterostructures combining magnetic order and band topology are important for science and technology ranging from quantum anomalous Hall effect (QAHE) to highly efficient spin-orbit torque switching. Kagome lattice metals and van der Waals (vdW) heterostructures are two classes of materials that are particularly promising in this regard. The 2D kagome lattice has topological flat bands and Dirac cones inherent in its band structure and these features persist in compounds with layered kagome lattices. Meanwhile, vdW materials encompass 2D magnets and topological insulators that manifest the QAHE, most notably Cr-doped $(Bi,Sb)_2Te_3$ and $MnBi_2Te_4$. Our research has focused on the atomic layer-by-layer synthesis of kagome and vdW materials by molecular beam epitaxy and their characterization through magneto-optics, angle-resolved photoemission spectroscopy (ARPES), and magnetotransport. For kagome metals, we investigated spin-orbit torque effects in Fe_3Sn_2 by magneto-optic methods [1,2] and flat bands in CoSn by ARPES [3]. Recently, we demonstrated the first thin film growth of rare-earth kagome magnets (RMn_6Sn_6, R = rare-earth Tb, Er), which are prospective QAHE materials. For vdW materials, we developed thin films of layered antiferromagnetic topological insulator $MnBi_2Se_4$ [4], which cannot be stabilized in bulk vdW crystal form, and Fe_3GeTe_2/Bi_2Te_3 heterostructures. The latter are heterostructures combining topological insulators and 2D magnets, where the Curie temperature has been raised to above room temperature by varying growth conditions [5].

4:45 PM QT02.03.04
Half-Magnetization Plateau in The Kagome-Stripe-Lattice $Na_2Co_3(VO_4)_2(OH)_2$ Yiqing Hao[1], Megan Smart[1], Jie Xing[1], Rongying Jin[2], Joseph Kolis[3], Duminda Sanjeewa[4] and Huibo Cao[1]; [1]Oak Ridge National Laboratory, United States; [2]University of South Carolina, United States; [3]Clemson University, United States; [4]University of Missouri–Columbia, United States

Magnetization plateaus often signify quantum magnetic states arising from geometric frustration and/or quantum fluctuations. Here, we report a half-magnetization plateau in the kagome-stripe lattice (KSL) material, Na2Co3(VO4)2(OH)2. Our susceptibility measurements reveal the half-magnetization plateau under the applied field perpendicular to the quasi-one-dimensional stripe direction. To unravel the origin of the magnetization plateau, we used single crystal neutron diffraction to investigate the evolution of magnetic structures with field. At zero field, the ground state magnetic structure is a non-collinear antiferromagnetic order with reduced ordered-magnetic moments on both Co sites. Increasing the magnetic field flips the spins on one of the Co sites to ferromagnetic order, while the spins on the other Co site remain small to zero ordered-magnetic moments despite the strong magnetic field. Such robustness in reducing ordered-magnetic moments indicates strong magnetic frustration and/or quantum fluctuations in this KSL material. Furthermore, aided by the local magnetic susceptibility method using polarized neutrons, we concluded that the resulting ground state and the half-magnetization plateau are likely caused by the Dzyaloshinskii-Moriya (DM) interactions between spins on two Co sites and the strong quantum fluctuations within the 1D Co-spin chain.

The research was supported by the U.S. Department of Energy (DOE), Early Career Research Program Award KC0402020 and used resources at the High Flux Isotope Reactor, a DOE Office of Science User Facility operated by ORNL.

SESSION QT02.04: Emerging 2D Magnetic Materials II
Session Chairs: Dmitry Ovchinnikov and Tyler Slade
Wednesday Morning, April 24, 2024
Room 421, Level 4, Summit

8:30 AM *QT02.04.01
Next Level Two-Dimensional Quantum Materials Xavier Roy; Columbia University, United States

Two-dimensional (2D) materials have received widespread attention in the past two decades due to their remarkable physical, mechanical and chemical properties, and our ability to integrate them into devices. In this seminar, I will present our recent work in the development of the next generation of 2D materials. I will first discuss how magnetic order strongly couples to optical transitions in a new magnetic semiconductor developed in my laboratories, CrSBr. I will then introduce the synthesis and characterization of the first *f*-electron-based heavy fermion metal, CeSiI, that is also a 2D van der Waals (vdW) material. Conceptually, our synthetic design takes a traditional 3D intermetallic heavy fermion compound and slices it into atomically-thin vdW sheets by incorporating iodine into the structure. The resulting material is cleavable and effectively 2D electronically, even in bulk crystals.

9:00 AM QT02.04.02
Intercalation-Induced Magnetic Properties of Quasi-2D $Fe_{3-x}GeTe_2$ Van der Waals Magnet Srinivasa Rao Singamaneni and Daniel Rascon; The University of Texas at El Paso, United States

Among several well-known transition metal-based compounds, cleavable van der Waals (vdW) $Fe_{3-x}GeTe_2$ (FGT) magnet is a strong candidate for use in two-dimensional (2D) magnetic devices due to its strong perpendicular magnetic anisotropy, sizeable Curie temperature (T_C ~ 154 K), and versatile magnetic character that is retained in the low-dimensional limit. While the T_C remains far too low for practical applications, there has been a successful push toward improving it via external driving forces such as pressure, irradiation, and doping. Here we present experimental evidence of a novel room-temperature (RT) ferromagnetic phase induced by the electrochemical intercalation of common tetrabutylammonium cations (TBA+) into quasi-2D FGT. We obtained Curie temperatures as high as 350 K with chemical and physical stability of the intercalated compound. The temperature-dependent Raman measurements in combination with vdW-corrected *ab initio* calculations suggest that charge transfer (electron doping) upon intercalation could lead to the observation of RT ferromagnetism. This work demonstrates that molecular intercalation is a viable route in realizing high-temperature vdW magnets in an inexpensive and reliable manner, and has the potential to be extended to bilayer and few-layer vdW magnets.

Room Temperature Néel-Type Skyrmions in a Van der Waals Ferromagnet Revealed by Multi-Modal Lorentz Electron Microscopy Yu-Tsun Shao[1], Hongrui Zhang[2], Xiang Chen[2], Zhen Chen[3], Robert Birgeneau[2], Ramamoorthy Ramesh[4] and David A. Muller[5]; [1]University of Southern California, United States; [2]University of California, Berkeley, United States; [3]Institute of Physics, Chinese Academy of Sciences, China; [4]Rice University, United States; [5]Cornell University, United States

Two-dimensional van der Waals (2D vdW) magnets offer a promising platform for exploring magnetic and topological phases, owing to their unique layered structure and crystallographic symmetries sensitive to stacking order. Real-space topological spin textures, such as magnetic skyrmions consisting of swirling spin configurations, are often stabilized by an antisymmetric Dzyaloshinksii-Moriya interaction (DMI) present in materials with broken inversion symmetry. Among the vdW materials for studying 2D magnetism, the Fe_NGeTe_2 (FGT, N=3-5) system is exceptional due to its tunability of magnetic properties with chemical doping and the existence of ferromagnetism above room temperature.

Here, we explore the chemically driven structural and magnetic phase transitions in $(Fe_{1-x}Co_x)_5GeTe_2$ (FCGT) using a combination of atomic resolution imaging, energy dispersive x-ray spectroscopy (EDS) mapping, and Lorentz four-dimensional scanning transmission electron microscopy (4D-STEM) along with an electron microscopy pixel array detector (EMPAD). Upon Co-doping, we find that the FCGT undergoes both structural and magnetic phase transitions from an antiferromagnetic, centrosymmetric AA-stacking (x=0.46) to a ferromagnetic, polar AA'-stacking (x=0.50). This structural phase transition is accompanied by a change in Fe and Co ordering as revealed by atomic resolution STEM-EDS. More interestingly, room temperature Néel-type skyrmions emerge in the AA' phase as revealed by Lorentz 4D-STEM. In summary, our work paves the way for studying structural and magnetic phase transition in vdW magnetic materials.

Magnetism in The Square Lattice Compounds $YbBi_2IO_4$ and $YbBi_2ClO_4$ Andrew F. May, Pyeongjae Park, Gabriele Sala, Thomas Proffen, Matthew Stone and Andrew Christianson; Oak Ridge National Laboratory, United States

The square lattice affords a simple platform to study quantum effects in two-dimensions (2D). This is because a two-interaction square lattice system is frustrated when the interactions are antiferromagnetic, with the phase diagram including the quantum spin liquid state. $YbBi_2IO_4$ and $YbBi_2ClO_4$ possess well-isolated layers containing square lattices of Yb^{3+} and are thus good candidates for realizing quantum effects on a square lattice. Here, we examine the magnetism and crystal field levels in the title compounds through a combination of specific heat, magnetization and inelastic neutron scattering measurements on polycrystalline samples. The results reveal that these materials host well-isolated Kramer's doublet ground states, with quasi-2D magnetic behavior as well as evidence for magnetic frustration. $YbBi_2IO_4$ and $YbBi_2ClO_4$ are therefore interesting candidates for future studies of 2D quantum magnetism.

Expanding The Portfolio of Two-Dimensional Magnetic Materials and Their Applications from First Principles Marco Gibertini[1,2]; [1]Università degli Studi di Modena e Reggio Emilia, Italy; [2]CNR-NANO, Italy

We have performed an extensive high-throughput screening of known inorganic materials, to identify those that could be exfoliated into novel two-dimensional (2D) monolayers [1]. The screening protocol based on density-functional theory simulations has identified a portfolio of close to 2,000 inorganic materials that appear either easily or potentially exfoliable [2], which has recently almost doubled [3] with further data ingestion and now provides an extensive pool to investigate promising properties. Specific interest has been devoted to the determination of the magnetic ground state [4], potentially considering supercells to accomodate non-trivial magnetic structures and systematically probing the energy landscape by effectively controlling and exploring the orbital occupation matrices of magnetic atoms through the Robust Occupation Matrix Energy Optimiser (ROMEO) workflow [5]. Among the possible applications of these novel 2D magnets, we have considered the possibility of creating heterostructures where the topological character and the dissipationless transport of the edge modes can be controlled by the magnetization direction [6].

Structural and Magnetic Properties of Entropy-Engineered Vanadium Rich 2D Thiophosphates Patricia E. Meza, Abishek Iyer, Roberto dos Reis, Mercouri G. Kanatzidis and Vinayak P. Dravid; Northwestern University, United States

Metal thiophosphates (MPX_3) have gained recent prominence for their intrinsic magnetic properties. These materials feature a layered, van der Waals structure with $[P_2X_6]^{4-}$ bipyramid anion units surrounded by octahedrally coordinated metal cations. By incorporating different metal cations, a diverse range of magnetic phases can be induced, making MPX_3 compounds promising subjects for condensed matter research into magnetic phases. Remarkably, V-based thiophosphates are comparatively understudied despite exhibiting the most stable antiferromagnetic ground state for the homogenous family of compounds, characterized by its large exchange parameter. [1] This is largely due to the difficulty of synthesizing the monometallic phase due to the formation of a parasitic V_xS_y species. Utilizing a flux method, [2] we have stabilized V in the MPS_3 structure by alloying with Mn, Fe, Co, or Ni. These V-rich compounds are expected to maintain the large exchange parameter while possibly exhibiting magnetic frustration.

Herein, we present a thorough investigation of novel $V_{0.56}FeP_2S_6$, and $V_{0.56}(MnFeCoNiZn)P_2S_6$ thiophosphates including a study of structure, vanadium oxidation state, and chemical homogeneity. Elemental studies have confirmed the single crystal stoichiometry of these mixed cation systems. This is corroborated by structural refinement showing lattice expansion with increased alloying. Other mixed bimetallic thiophosphate systems demonstrate an inhomogeneous distribution of cations, resulting in heterostructures in the case $CuInP_2S_6$ or large composition fluctuations between exfoliated flakes in $FeCoP_2S_6$.[3], [4] Conversely, electron energy loss spectroscopy (EELS) of $V_{0.56}(MnFeCoNiZn)P_2S_6$ reveals a remarkable homogenous solid solution which is preferred for future magnetic susceptibility measurements to determine magnetic moment alignment. Additionally, we were able to clarify the oxidation state of V in these materials using bulk and nanoscale spectroscopy techniques. We confirm a mixed V^{2+} and V^{3+} state and observe a trend towards increasing V^{2+} as the system is alloyed from bimetallic to high entropy. Finally, we present synthesis techniques to grow phase pure V-rich thiophosphate powders and centimeter scale crystals to target both catalysis and magnetic measurements. Our findings highlight entropy engineering as a useful method towards stabilizing vanadium rich thiophosphates and provide in-depth chemical characterization which is vital for applications of V-rich thiophosphates in next generation electronic devices.

Magnetic-Electronic Coupling in The Van der Waals Metal-Phosphorous-Trichalcogenides Efrat Lifshitz; Technion-Israel Institute of Technology, Israel

The recent discovery of magnetic van der Waals materials- opens a new paradigm in solid-state research, offering an exploration of magnetism at the nearly atomistic limit, with an impact on the development of newly emerging spintronics, memory and information devices. In particular, antiferromagnetic (AFM) materials are catching special attention at the current time, due to their low stray magnetic field, and fast spin response (in the THz). The talk will include a thorough investigation of the fundamental magnetic properties and their coupling to the electronic nature of two representative materials: $MnPS_3$ and $FePS_3$. With a single AFM layer, the metals are positioned in a honeycomb arrangement. The AFM character is generated via a spin-exchange interaction among metal next neighbours (NNs), when the metal spins are mainly oriented normally to the layer plane arranged either in Nèel or zigzag configurations. It is important to note that second and third NNs intralayer interactions are not negligible in the MPX_3 layers, governed by super-exchange

AFM coupling through the metal(d)-chalcogen(p) bonding. An interlayer interaction adds small tuning with weak super-super spin-exchange interaction, which despite being weak, may change the magnetic properties by having either AFM or FM stacking or by inducing a magnetic torque.
A $MnPS_3$ layer with a Nèel magnetic configuration and lack of spin-orbit coupling was a suitable platform for examining the contribution of the long spin-exchange interaction. The study implemented dilution of the Mn content (forming alloyed compounds with the general chemical formula MnxZn1-xS_3), examining the sustain of AFM arrangement down to a composition of x=0.5, hence, supporting the weight of 2nd and 3rd spin-exchange coupling to the long-range magnetic ordering. A $FePS_3$, having a zigzag magnetic configuration, represents a case with a pronounced distortion of the honeycomb symmetry, due to local distortion around a metal site by a strong spin-orbit coupling. The two examples mentioned here showed a strong correlation between the magnetic ordering and the optical transitions, showing obvious changes in the photoluminescence at the Nèel temperature (a point possessing a magnetic transition from AFM to paramagnetic phase), as well as an optical polarization character along the magnetic directionality. It was mainly distinct in the appearance of an exceptionally sharp emission line in the $FePS_3$ single layer with a strong linear polarization along the zigzag direction.
The accompanied DFT calculations simulated the spin-exchange coupling process and its impact on the electronic band structure (will be shown at the presentation by a short movie). Furthermore, the theoretical calculations exposed a fundamental character in which the electronic transitions show a hybrid property between local metal transitions and band-edge transitions. The exploration of these fundamental points is an ongoing process at the current moment.

Growth of 2D Magnets and Dielectrics Zdenek Sofer; Institute of Chemical Tech, Czechia

The recent progress in methods of high quality and low defect 2D magnetic materials will be discussed. Beside the group of transition metal halides and chalcogens also the rapidly growth family of mixed halogen-chalcogenides will be introduced. The dominantly explored material, chromium sulfo-bromide adopt FeOCl structure and possess A type antiferromagnetic ordering at low temperature. By various methods of exfoliation or defect formation, this material can be converted to ferromagnetic state. The chemistry of CrSBr including doping and possible covalent and non-covalent functionalization and its effect on magnetic and optical properties will be presented together with possible applications in electronic devices.
Beside the two dimensional magnets, the 2D dielectric exhibit important group of materials with crucial rule in device fabrication. The broad spectra of novel high-k 2D dielectric materials growth and applications will be presented together with large scale crystal growth of hexagonal boron nitride at atmospheric pressure using various metal flux.

Magnetic Dilution in The Magnetic Topological Insulators Derived from $MnBi_2Te_4$ Ekaterina Kochetkova[1,2], Manaswini Sahoo[1], Laura T. Corredor[1] and Anna Isaeva[2,1]; [1]Leibniz Institute for Solid State and Materials Research Dresden, Germany; [2]University of Amsterdam, Netherlands

Magnetic topological insulators were recently shown to host the quantum anomalous Hall effect (QAHE), albeit in a low-temperature range which is not yet technologically relevant. Extrinsically doped Bi_2Te_3 and $(Cr,V)Bi_2(Se,Te)_3$ heterostructures demonstrate the QAHE below 1 K [1], whereas the intrinsically magnetic van der Waals material $MnBi_2Te_4$ sustains it up to 6.5 K [2]. Bulk $MnBi_2Te_4$ is an A-type antiferromagnet with T_N = 25 K, and its isostructural analogue $Mn_{1+x}Sb_{2-x}Te_4$ exhibits a ferri- or ferromagnetic ground state with an increased T_C up to 58 K [3] depending on the amount x of Mn excess.
Our combined x-ray and neutron studies of the Mn and Sb(Bi) distribution in $MnSb_2Te_4$ and $MnBi_6Te_{10}$ [4] highlight the importance of the Mn(II) distribution pattern in the crystal stucture for the resulting magnetic ground state. Even subtle details of the atomic intermixing appears to influence the magnetic properties greatly.
In this talk, I will discuss our latest studies of the Mn-Ge-Sb-Te and Mn-Ge-Se-Te systems with the focus on how the site disorder of Mn(II) in the periodic crystal structure impacts the long-range magnetic order.

Near Room-Temperature Intrinsic Exchange Bias in an Fe Intercalated $ZrSe_2$ Spin Glass Zhizhi Kong and Kwabena Bediako; University of California, Berkeley, United States

Exchange bias is a magnetic phenomenon commonly manifested as the hysteresis-loop shift when a system hosting certain magnetic heterointerfaces is cooled under an applied external magnetic field. Despite the extensive use of the exchange bias effect, particularly in magnetic multilayers, for the design of spin-based memory/electronics devices, a comprehensive mechanistic understanding of this effect remains a longstanding problem. Recent work has shown that disorder-induced spin frustration might play a key role in exchange bias, suggesting new materials design approaches for spin-based electronic devices that harness this effect. Here, we design a spin glass with strong spin frustration induced by magnetic disorder by exploiting the distinctive structure of Fe intercalated $ZrSe_2$, where Fe(II) centers are shown to occupy both octahedral and tetrahedral interstitial sites and to distribute between $ZrSe_2$ layers without long-range structural order. Notably, we observe behavior consistent with a magnetically frustrated and multidegenerate ground state in these $Fe_{0.17}ZrSe_2$ single crystals, which persists above room temperature. Moreover, this magnetic frustration leads to a robust and tunable exchange bias up to 250 K. These results not only offer important insights into the effects of magnetic disorder and frustration in magnetic materials generally, but also highlight as design strategy the idea that a large exchange bias can arise from an inhomogeneous microscopic environment without discernible long-range magnetic order. In addition, these results show that intercalated TMDs like $Fe_{0.17}ZrSe_2$ hold potential for spintronic technologies that can achieve room temperature applications.

2D Heisenberg Ferromagnetism in Fe_3GeTe_2 Ankita Tiwari[1], Hyobin ahn[2], Jyoti Saini[1], Pawan K. Srivastava[3], Budhi Singh[3], Changgu Lee[2,3] and Subhasis Ghosh[1]; [1]Jawaharlal Nehru University, India; [2]SKKU Advanced Institute of Nanotechnology (SAINT), Sungkyunkwan University, Korea (the Republic of); [3]School of Mechanical Engineering, Sungkyunkwan University, Korea (the Republic of)

The van der Waals ferromagnets, such as CrI_3, $CrTe_2$, $Cr_2X_2Te_6$ (X = Si and Ge) and Fe_3GeTe_2 provide an excellent platform to investigate ferromagnetism in two dimension (2D) which is otherwise forbidden for short ranged exchange interaction mediated ferromagnetism, according to Hohenberg-Mermin-Wagner (HMW) theorem[1,2]. 2D van der Waals ferromagnets are being touted seriously as the materials for future spintronic devices. In particular, Fe_3GeTe_2 and Fe_5GeTe_2 are being investigated vigorously due to the exceptional tunability of their magnetic properties and high Curie temperature, which is near or above room temperature [3]. Short-ranged exchange interaction, such as 2D Ising and 2D XY driven phase transition, has been observed in $Cr_2X_2Te_6$ and CrI_3, respectively. However, the 2D-Heisenberg ferromagnet has not yet been observed in accordance with the HMW theorem. The presence of long-range (LR) interaction changes the scenario completely [4]. LR interactions have been shown to be responsible for (i) interesting finite temperature transitions, (ii) new critical phenomena, and (iii) continuously varying critical exponents in spin 1/2 Heisenberg systems in 2D systems. Though it is realized that LR-driven ferromagnetism is essential for circumventing the HMW theorem in 2D, but experimental realization remains elusive in condensed matter systems. Here, we show that Fe_3GeTe_2 is a 2D Heisenberg ferromagnet by breaking the limit of the HMW theorem. This has been possible due to the presence of both itinerant and local-moment magnetism in Fe_3GeTe_2 [5]. Temperature dependence of magnetization with the signature of 2D magnons, Rhodes-Wohlfarth (RW) and generalized RW-based analysis [6] established that Fe_3GeTe_2 is a 2D ferromagnet with itinerant magnetism which can be tuned by the magnetic field. So far, critical phenomena and second-order phase transition have been dealt with renormalization group theory. However, the same in the presence of long-range interaction is nontrivial [4]. Here we present an improvised method to deal with phase transition and critical phenomena mediated by long Heisenberg interaction in 2D in the presence of long-range Ruderman-Kittel-Kasuya-Yusida (RKKY). We show that critical exponents, in this case, can vary with external parameters. The critical exponents cross from the mean-field universality class to the 2D Heisenberg universality class as the field increases. We argue that variable critical exponents is the key signature for 2D Heisenberg ferromagnetism, as emphasized by recent theoretical calculations [7]. Fe in Fe_3GeTe_2 has two inequivalent charge states, i.e. Fe^{2+} and Fe^{3+}, which lead to multi-orbital paths for different spin-spin interactions. In the case of a hexagonal crystal field, as in Fe_3GeTe_2, the five 3d orbitals of the Fe atom split into three groups of orbitals with differing localization is responsible for underlying long-range ordering for both itinerant and local-moment ferromagnetism.

2. Department of Physics and Astronomy, Michigan State University, East Lansing, MI, 48824
3. Division of Materials Science, Ames Laboratory, Ames, IA, 50010

$SmCrGe_3$ was reported in the polycrystalline, which has ferromagnetic order occurring at 155 K [1]. To study the magnetic behaviors of $SmCrGe_3$, herein, the single crystals of $SmCrGe_3$ were grown using high temperature flux method. According to the single crystal X-ray diffraction, SmCrGe3 crystallizes in the hexagonal $LaCrGe_3$-type structure with Cr linear chain along the *c*-axis, which forms the face-sharing Cr-centered octahedra aligned along the *c*-axis. Compared with itinerant magnet $LaCrGe_3$, $SmCrGe_3$ offers the opportunity to understand the interaction between localized 4*f* election and itinerant electron in this quasi-one-dimensional system and the role of interaction played in domain pining changing [2], which may explain “one domain” behavior in $LaCrGe_3$ single crystal. Transport, magnetization, and specific heat measurements are taken. $SmCrGe_3$ behaves as a hard ferromagnetic material, which is different from other *RE*$CrGe_3$ (*RE* = La - Nd). Coercivity as the function of temperature and field-dependent pinning change are given, and the results will be discussed in detail.

4:00 PM QT02.06.02
Unravelling Quantum Phases in The Shastry-Sutherland Lattice Huibo Cao[1], Kyle Ma[1], Brianna Billingsley[2], Madalynn Marshall[1] and Tai Kong[2]; [1]Oak Ridge National Laboratory, United States; [2]The University of Arizona, United States

The Shastry-Sutherland lattice consists of a two-dimensional orthogonal arrangement of spin dimers. By varying the ratio of intra-dimer and inter-dimer

interactions, the rich phase diagram can emerge, encompassing various exotic quantum states. Single-ion and exchange magnetic anisotropies can further diversify the phased diagram and give rise to quantum states beyond the traditional antiferromagnetic Heisenberg Shastry-Sutherland lattice model. Neutron scattering is an important technique for characterizing magnetic states. Here, I will introduce our recent studies using neutron scattering to unravel the quantum states of spin dimers in the rare-earth (RE) Shastry-Sutherland lattice compound $BaRE_2ZnS_5$ (RE=Nd, Ce, and Pr).

The research was supported by the U.S. Department of Energy (DOE), Early Career Research Program Award KC0402020 and used resources at the High Flux Isotope Reactor, a DOE Office of Science User Facility operated by ORNL.

4:15 PM *QT02.06.03
Structural and Electronic Phases of 2D Transition Metal Dichalcogenides Oleg Yazyev; Ecole Polytechnique Federale de Lausanne, Switzerland

Layered transition metal dichalcogenides (TMDs) of chemical composition MX_2 (M = transition metal; X = S, Se, or Te) represent a broad family of materials with diverse electronic properties, including metals, insulators, as well as more complex states such as the charge-density-wave (CDW) and superconducting phases. More recently, the possibility of realizing single- and few-layer TMDs has brought the two-dimensional (2D) forms of these materials into the spotlight of prospective application in electronics, optoelectronics and beyond [1]. In my talk, I will review the "periodic table" of TMDs attempting to reveal systematic trends and develop chemical intuition across this family of 2D materials. Using a Wannier function approach, I will address the relevance of the crystal and ligand fields in determining the relative stability of 1T and 1H polymorphs as a function of the filling of the d-shell in 2D TMDs [2]. Then, I will present a unified picture of lattice instabilities in metallic TMDs that describes both the CDW phases and the strong-coupling scenario resulting in the formation of metal-metal bonds (as e.g. in the dimerized 1T' phases) [3]. In the rest of my talk, I will focus on topological and magnetic phases of TMDs. The 1T'-phase of Mo and W TMDs that have recently been shown to host the topologically non-trivial quantum spin Hall (QSH) insulator phase. The robustness of the QSH phase as well as the topological edge states [4] and interface states at the well-ordered 1T'-1H lateral heterojunctions will be discussed in conjunction with recent experiments on 1T'-WSe_2 [5]. I will also cover our recent discovery of magnetic ordering and magnetoresistive switching in metallic few-layer and insulating single-layer $PtSe_2$ [6,7].

Probing The Local Properties of Co-Honeycomb Magnets as an Avenue to Understanding Their Complex Magnetic Behaviour Megan R. Rutherford[1], Dalmau Reg-i-Plessis[2], Daniel Shaw[3], Austin Ferrenti[4], Solveig S. Aamlid[1], Graham King[5], Tyrel McQueen[4], Kate Ross[3], Kenji Kojima[6,1] and Alannah Hallas[1]; [1]The University of British Columbia, Canada; [2]ETH Zürich, Switzerland; [3]Colorado State University, United States; [4]Johns Hopkins University, United States; [5]Canadian Light Source, Canada; [6]TRIUMF, Canada

In the field of frustrated magnetism, the relationship between the crystal structure of a material and its magnetic properties has been a fruitful area of research for decades. A problem that has tormented materials scientists for an equal length of time, is the effect of small structural perturbations on the overall magnetic behaviour of a sample. An example of the interconnectedness of disorder sensitivity with rich magnetic phase spaces can be seen in well-studied examples of honeycomb magnets like ��-$RuCl_3$, where large differences in its physical characteristics emerge from subtle variations in stacking. A less well-understood example of this type of phenomena can be seen in the material $BaCo_2(PO_4)_2$ where the Co^{2+} ions form a highly frustrated, undistorted honeycomb lattice of Co^{2+} that are well separated by Ba and PO_4 spacer layers, hence this material is highly 2-dimensional. Neutron diffraction of $BaCo_2(PO_4)_2$ reveals not one, but two distinct short range ordered magnetic states that develop over two successive transition temperatures. In contrast, $BaCo_2(AsO_4)_2$, which is isostructural to the phosphate, long range orders into a single well-defined magnetic ordered state at low temperatures. Muon spin relaxation (μSR) is a local probe that is uniquely suited to the investigation of multiple coexisting, competing magnetic phases. A comprehensive μSR study has been performed on both the phosphate, and the arsenate for comparison, to determine how these competing magnetic phases develop with changing temperature across the temperature range of interest. The local structure of the material has also been investigated using total x-ray scattering techniques in an attempt to elucidate the origin of the unique magnetic behaviour of $BaCo_2(PO_4)_2$. The combined evidence from these local proves leads us to conclude that this phase coexistence in $BaCo_2(PO_4)_2$ is likely a result of synthesis-sensitive polymorphism.

SESSION QT02.07: Poster Session

Flex Hall C, Level 2, Summit

5:00 PM QT02.07.01
The Effect of Pr Doping and Sintering Temperature on The Structural, Magnetic and Transport Properties of $La_{1-x-y}Pr_yCa_xMnO_3$ (y = 0.30, 0.35, 0.40; x = 0.40) Nanocrystals Dharmendra S. Raghav[1], Hari K. Singh[2] and Ghanshyam D. Varma[3]; [1]Invertis University, India; [2]CSIR-National Physical Laboratory, India; [3]Indian Institute of Technology Roorkee, India

Among the doped rare earth manganites, $La_{1-x-y}Pr_xCa_yMnO_3$ (LPCMO) has been recognised as the prototypical of the phase separated doped rare-earth manganites. LPCMO perovskite manganites still attract the interest of materials, chemistry and physics communities. The structural, microstructural, magnetic and electrical transport properties have been correlatively studied to decipher the complex consequences of variation of intrinsic parameter, the average La-site cationic radii and extrinsic particle size on the magneto-electrical phase coexistence in $La_{1-x-y}Pr_yCa_xMnO_3$ (y = 0.30, 0.35, 0.40; x = 0.40). Magnetization measurements show sequential paramagnetic (PM)-antiferromagnetic (AFM)-ferromagnetic (FM) transitions on lowering the temperature. The AFM-FM transition exhibits (i) pronounced hysteresis between field-cooled cooling (FCC) and field-cooled warming (FCW), (ii) substantial divergence between zero-field cooling (ZFC) and FCW curves. The lower temperature magnetic state is much closer to a spin glass at smaller ionic radius and larger particle size. At smaller ionic radius and smaller particle size, it shows a better resemblance to a cluster glass state. The presence of a large thermal hysteresis in the insulator-metal transition (IMT) coupled with the one in FCC-FCW magnetization at particle sizes ~200 nm-160 nm, and ~460-

400 nm demonstrates that this particle size regime is the most conducive to the phase separation. IMT disappears at smaller ionic radii and larger particle sizes due to the enhancement of AFM and charge-ordering. The observed phenomena are explained in terms of the interplay between the ionic radii and particle size induced changes in the average apical bond angles and the average bond length.

Chromium Sulfide Bromide Down to Ferromagnetic Nanoribbons: The Study of Electrochemical Exfoliation Method and Magnetic Transitions in Bulk end Exfoliated CrSBr Kseniia Mosina, Vlastimil Mazanek and Jan Luxa; University of Chemistry and Technology, Prague, Czechia

Recent advancements in the field of 2D materials have opened up exciting possibilities for applications in emerging technologies; however, the research focuses on magnetic atomically thin crystals that offer intriguing prospects in the realm of magnetoelectricity and magneto-optics is still in its infancy. In this study, we delve into the magnetic properties of chromium sulfide bromide (CrSBr), a material with a complex magnetic behavior. Recent reports have labeled chromium sulfide bromide CrSBr as an ideal candidate for studies of magnetism due to its antiferromagnetic state in bulk with a Neel temperature around 132 K and ferromagnetism in the monolayer. For the first time, we introduce the electrochemical exfoliation of CrSBr down to ferromagnetic nanoribbons in a non-aqueous environment. The exfoliated material preserves its orthorhombic crystalline structure and exhibits strong optical anisotropy, with Raman signals displaying polarization dependencies. The unique cleavage behavior of CrSBr is facilitated by its structural anisotropy and weak interlayer hybridization, allowing for efficient exfoliation along the crystal's a-direction. Interestingly, electrochemically exfoliated CrSBr exhibits a broad but clear FM transition with a T Curie around 130 K, which opens up the possibility of utilizing CrSBr nanoribbons in innovative magneto-optical and spintronic devices. Moreover, we demonstrate the potential application of exfoliated material in high-performance electrochemical photodetectors and their use as anodes in lithium-ion batteries, where they exhibit promising self-improving capabilities.

Characterization of Alloyed $Fe_{3-x}Co_xSn_2$ Kagomé-Lattice Films Grown Using Molecular Beam Epitaxy Anna Li[1,2], Prajwal Laxmeesha[2], Tessa D. Tucker[2] and Steven May[2]; [1]University of California, Berkeley, United States; [2]Drexel University, United States

Materials in which transition metals form a kagomé lattice have generated interest in recent years due to their unique magnetic and electronic properties. Ferromagnetic Fe_3Sn_2 is one such example where the Fe kagomé sublattice results inleads to the presence of Weyl fermions and flat bands. Being able to tune Weyl nodes has been an area of immense study, and hole and electron-doping are a potential avenues for changing the position of Weyl nodes in energy and momentum-space, and as a result, as well as moving the Fermi level with respect to the Weyl pointsthem with respect to the Fermi level. We performed an experimental investigation on[PM1] the effect of electron-doping in epitaxially- grown thin films of Fe_3Sn_2 through substitution of Co for Fe. We have grown $Fe_{3-x}Co_xSn_2$ films using molecular beam epitaxy (MBE) at various concentrations of Co (x = 0, 0.1, 0.5, 0.75, 1.0) on Al_2O_3 (0001) substrates buffered with a thin Co (111[SM2]) wetting[PM3] buffer layer. The $Fe_{3-x}Co_xSn_2$ films are capped with CaF_2 to prevent oxidation. Structural characterization of the heterostructures by *in situ by* reflection high-energy electron diffraction *RHEED* confirms the growth of ordered films, and further surface characterization via X-ray reflectivity and atomic force microscopy identifies smooth surfaces. X-ray diffraction was used to confirm that the films have uniform *c*-axis orientation and that no secondary phases are present, while magnetometry was used to study the magnetic properties of the films . Further, it was observed that both the *c*-axis parameter and saturation magnetization decreases with increasing Co concentration, in agreement with previous density functional theory calculations (M. Adams *et al* 2023 J. *Phys.: Condens. Matter* **35** 265801). [PM4] Magnetometry measurements revealed a decrease in saturation magnetization as the Co content was increased. Our results provide the groundwork for further investigation on the changing magnetic properties and electronic band structure in doped alloyed epitaxial Fe_3Sn_2 heterostructures.

5:00 PM QT02.07.04
High-Frequency Electron Paramagnetic Resonance Properties of Kagome Crystal YMn6Sn6 Lovia Ofori[1], Johan van Tol[2], Nirmal J. Ghimire[3] and Srinivasa Rao Singamaneni[1]; [1]The University of Texas at El Paso, United States; [2]Florida State University, United States; [3]University of Notre Dame, United States

Kagome magnetic crystals received a great deal of research attention in the recent past for their intriguing magnetic properties. Recently, YMn6Sn6 has been shown to exhibit a number of nontrivial magnetic phases, and the origin remains elusive. We measured EPR/FMR at high fields and frequencies to investigate the local field at the magnetic Mn ions in YMn6Sn6. In particular, we studied the signals at 120 and 240 GHz (4 and 8 cm-1, resp.) We observe the phase transitions and the coexistence of different phases in the transition region, which are approximately in line with the B-T phase diagram for YMn6Sn6. This work underscores the importance of employing the high/multifrequency EPR technique in probing for the microscopic mechanisms to better understand the observed new magnetic phases/textures.

Pressure-Dependent Magnetic and Optical Properties of Fe2.7GeTe2 Rubyan Olmos[1], Gilberto Fabbris[2], Rahul Rao[3], Michael A. Susner[3] and Srinivasa Rao Singamaneni[1]; [1]The University of Texas at El Paso, United States; [2]Argonne National Laboratory, United States; [3]Air Force Research Laboratory, United States

van der Waals magnets offer a great opportunity for tunable magnetic properties as they are susceptible to external perturbations. Among all, pressure is a versatile tuning knob. In this work, we present our recent experimental findings collected on Fe2.7GeTe2 by employing SQUID magnetometry, Raman spectroscopy, and synchrotron-based XMCD measurements as a function of applied pressure. We observe that the saturation magnetization and the Curie temperature decreased as the external pressure increased. The Raman data showed the pressure-induced structural phase transition. This work signifies the application of pressure in tuning the magnetic properties of layered van der Waals magnets.

Epitaxial Growth and Magnetic Properties of Kagomé Metal FeSn/Elemental Ferromagnet Heterostructures Prajwal Laxmeesha[1], Tessa D. Tucker[1], Rajeev Kumar Rai[2], Shuchen Li[3], Myoung-Woo Yoo[3], Eric A. Stach[2], Axel Hoffmann[3] and Steven May[1]; [1]Drexel University, United States; [2]University of Pennsylvania, United States; [3]University of Illinois at Urbana-Champaign, United States

Binary kagomé compounds T_mX_n (*T*=Mn, Fe, Co; *X*=Sn, Ge; *m*:*n* = 3:1, 3:2, 1:1) have garnered significant interest due to the coexistence of topological band crossings and flat bands stemming from the geometry of the metal-site kagomé lattice. In order to harness these distinctive electronic band features for potential applications in spintronics, it is imperative to grow high-quality heterostructures. In this work, we detail the synthesis of Fe/FeSn and Co/FeSn bilayers on *c*-axis-oriented Al_2O_3 substrates, achieved *via* molecular beam epitaxy. The use of elemental buffer layers (Fe and Co) facilitates the growth of smooth and continuous FeSn films, while also enabling the formation of heterointerfaces between elemental ferromagnetic metals and antiferromagnetic

kagomé metal FeSn. Structural characterization using high-resolution X-ray diffraction, reflection high-energy electron diffraction, scanning electron microscopy and transmission electron microscopy revealed the FeSn films were flat and epitaxial with well defined interfaces. Rutherford backscattering spectrometry was used to confirm the stoichiometric window where single phase FeSn films are stabilized, while transport and magnetometry measurements were conducted to verify metallicity and magnetic ordering in the bilayers. We observe exchange bias in both bilayer systems, affirming the existence of antiferromagnetic order in FeSn, thus opening possibilities for further investigations into interfacial magnetism in kagomé heterostructures and the potential integration of these materials into spintronics devices.

5:00 PM QT02.07.07

Synthesis of Mn-Doped Bi_2Te_3 via Chemical Vapor Deposition Matthew E. Metcalf[1], Bamidele O. Onipede[1], Shaan Dias[2], Alexander Glasgo[1] and Hui Cai[1]; [1]University of California, Merced, United States; [2]Carleton College, United States

Doping a topological insulator with magnetic elements can produce magnetic ordering within the material, breaking the time-reversal symmetry of the surface electronic states. Without this symmetry, topological insulators can exhibit many exotic quantum phenomena that are of theoretical interest and not well studied, including the quantum anomalous Hall effect, chiral Majorana modes, and topological magnetoelectric effects. In this work, we synthesized Mn-doped Bi_2Te_3, a topological insulator doped with a magnetic element, using atmospheric pressure chemical vapor deposition (CVD) and characterized our samples with optical microscopy, Raman spectroscopy, and X-ray photoelectron spectroscopy. The optimal values and acceptable ranges of several CVD growth parameters were determined by systematically varying each parameter one at a time. By utilizing CVD to synthesize Mn-doped Bi_2Te_3, this work demonstrates a simple, scalable, and low-cost process that offers precise control over the stoichiometry of grown crystals and opens the door to the production of high-quality atomically thin crystals–features which make CVD a useful and promising technique for future studies of magnetic topological insulators.

5:00 PM QT02.07.08

Strong Above Room Temperature Intrinsic Magnetism of Freestanding Layered $CrTe_2$ Crystal Lihua Zhang[1], Kim Kisslinger[1], Suji Park[1], Seng Huat Lee[2], Yu Wang[2], Zhiqiang Mao[2], Neha Dhull[3,4], Weichang Lin[3,4], Zonghuan Lu[3,4], Toh-Ming Lu[3,4] and Gwo-Ching Wang[3,4]; [1]Center for Functional Nanomaterials, Brookhaven National Lab, United States; [2]2D Crystal Consortium, Materials Research Institute, The Pennsylvania State University,, United States; [3]Physics, Applied Physics and Astronomy Department, Rensselaer Polytechnic Institute,, United States; [4]The Center for Materials, Devices, and Integrated Systems, Rensselaer Polytechnic Institute,, United States

Abstract: Magnetism in van der Waals (vdW) layered materials has attracted worldwide attention in fundamental condensed matter material research. Magnetism in low dimension materials has many exciting emerging properties and great potential for applications in low power spintronics, quantum computing, data storage, etc. Most monolayer (ML) vdW materials have been demonstrated to have Curie temperatures (Tc) below 300 K [1] or near room temperature [2]. This is because thermal fluctuations destroy the long-range magnetic order in a ML material according to Mermin-Wagner theorem. Thus, demands for the growth of bulk vdW layered materials to increase its Tc to above room temperature remains challenging.
Only recently, bulk 1T-$CrTe_2$ crystal of mm size was synthesized from K deintercalation of $KCrTe_2$ and its room temperature Tc (310 K) was reported [3]. In this work, we present synthesized $CrTe_2$ crystals made from a similar method. We present their structure, chemical stoichiometry, vibrational, and magnetic properties of free standing $CrTe_2$ crystal measured by transmission electron microscopy (TEM), X-ray diffraction (XRD), electron backscatter diffraction (EBSD), energy dispersive X-ray spectroscopy (EDS), Raman scattering, superconducting quantum interference device **(**SQUID), and surface magneto-optical Kerr effect (SMOKE) techniques. TEM and XRD show $CrTe_2$ has crystalline layered structure with (0001) out-of-plane orientation with bulk lattice constants. EBSD shows a six-fold hexagonal crystal symmetry. EDS and Raman spectra show correct stoichiometry of 1 to 2 for Cr to Te ratio. All data support the synthesized crystals are of high quality. The temperatures dependent magnetization shows a phase transition at a Tc (317 K) above room temperature. The critical exponents extracted from the critical region are consistent with the classic 3D Ising model's prediction. SMOKE measurement of crystal at room temperature shows hysteresis loops with low coercivity (~20 Oe). Since the 632 nm laser wavelength's penetration depth depends on the laser incident angle, the probing depth is within sub-tens to tens of nm below surface, therefore the magnetic hysteresis loop measured by SMOKE is effectively from ultrathin layers of the $CrTe_2$ crystal.

Diffuse Scattering in The Chiral Magnet $BaCoSiO_4$ James W. Beare[1], Huibo Cao[1], Chenyang Jiang[1], Zachary Morgan[1], Feng Ye[1], Yongqiang Cheng[1], Erxi Feng[1], Xiaojian Bai[2], Xianghan Xu[3] and Sang-Wook Cheong[3]; [1]Oak Ridge National Lab, United States; [2]Louisiana State University, United States; [3]Rutgers, The State University of New Jersey, United States

In certain chiral magnets, a chiral arrangement of magnetic spins breaks both time reversal and spatial inversion symmetry, forming a toroidal moment. This symmetry breaking allows for the magnetoelectric effect, making these materials promising candidates for device applications. In $BaCoSiO_4$, Co ions form hexagonal layers in which magnetic interactions between the nearest five Co neighbors, as well as the antisymmetric DM interaction, are all important, leading to a complicated competition between interactions on this frustrated lattice. The ground state structure can be explained by a trimerization of Co ions into toroidal moments which form three interpenetrating sublattices, one of which has a toroidal moment opposite to the other two. Along with the frustration due to antiferromagnetic interactions within triangular trimers, there is structural short-range order which may contribute to additional frustration. In this talk, I will present diffuse scattering results which give insight into the short range magnetic and structural order within the material. Modeling both types of short-range order within the paramagnetic phase will improve our understanding of this exotic magnet.

Pillars of Discovery: Two Novel Divalent Transition Metal Germanates as Potential Multiferroics Megan Smart[1], Jie Xing[1], Colin McMillen[2], Joseph Kolis[2], Fankang Li[1] and Huibo Cao[1]; [1]Oak Ridge National Laboratory, United States; [2]Clemson University, United States

The pursuit of novel magnetic materials has driven inorganic crystal chemistry towards many exciting discoveries, from rare earth magnets to hexaferrites to elusive quantum materials such as spin liquids. One material class of interest are multiferroics, which combine the desirable properties of ferromagnetism and ferroelectricity, the latter of which requires crystallization in a polar space group. High-quality single crystals of inorganic oxides can be grown *via* hydrothermal synthetic methods using magnetic ions such as Co^{2+} and Cu^{2+}, with non-magnetic Ge^{4+} as a building block. Two such compounds were hydrothermally synthesized, $Ba_7Rb_2Co_6Ge_{18}O_{50}$ (**1**) and $Sr_7K_2Cu_6Ge_{17.3}O_{47.2}(OH)_{2.8}$ (**2**), which crystallize in the acentric, polar space group $P6_3cm$. The polar feature of the unit cell is the 'pillar' propagating along each vertex on the *c*-axis. These pillars contain alternating trimers of TM^{2+} (TM = Co, Cu) in tetrahedral and trigonal bipyramidal geometries, and are separated by a central germanate cluster. With the conditions for ferroelectricity met, initial magnetic studies were performed, and their results are presented here. The Co-germanate shows two magnetic transitions in the susceptibility measurements, both suggesting magnetic short-range orders. The compound does not have structural disorder, therefore the magnetic short-range order likely originates from magnetic frustration. Two successive transitions possibly represent dimensionality cross-over transitions. The neutron scattering studies are underway to uncover the nature of magnetic transitions and phases in $Ba_7Rb_2Co_6Ge_{18}O_{50}$.

5:00 PM QT02.07.11
Quantum Criticality in Spin Dimer System $BaNd_2ZnS_5$ Kyle Ma[1], Brianna Billingsley[2], Madalynn Marshall[1], Xiaojian Bai[3], Barry Winn[1], Cristian Batista[4], Tai Kong[2] and Huibo Cao[1]; [1]Oak Ridge National Laboratory, United States; [2]The University of Arizona, United States; [3]Louisiana State University, United States; [4]The University of Tennessee, Knoxville, United States

We investigated the partial-disordered state of the Shastry-Sutherland system BaNd2ZnS5 utilizing the time-of-flight inelastic neutron scattering spectrometer HYSPEC at the Spallation Neutron Source (SNS) of the Oak Ridge National Laboratory (ORNL). Through modeling the field evolution of low-energy spin excitations up to 4T, we uncovered that the disordered states result from a delicate balance between the external magnetic field and antiferromagnetic (AF) inter-dimer Ising interactions. The intra-dimer interaction is predominantly Ising along the ordered moment direction, with a slight mixing of J++ and J--.
Parametric measurements ranging from 0 to 4T of the order parameters of the ferromagnetic (FM) and antiferromagnetic (AFM) phases at 40mK were conducted using the DEMAND diffractometer at the High Flux Isotope Reactor of ORNL. The order parameter displays characteristics indicative of a quantum critical point and can be effectively modeled using semi-classical treatment based on SU(4) coherent states. Although the longitudinal mode can not be quantitatively characterized, its presence is essential to explain the observed data, suggesting that the puzzling metamagnetic transition originates from the ordered antiferromagnetic state transitioning to the disordered quantum paramagnetic state.

SESSION QT02.08: Ultrafast Imaging and Control of Magnetism

Room 421, Level 4, Summit

8:45 AM *QT02.08.01
Engineering Quantum Geometry at Oxide Interfaces Andrea Caviglia; Université de Genève, Switzerland

In oxide heterostructures, different materials are integrated into a single artificial crystal, resulting in a breaking of inversion symmetry across the heterointerfaces. A notable example is the interface between polar and nonpolar materials, where valence discontinuities lead to otherwise inaccessible charge and spin states. This approach paved the way for the discovery of numerous unconventional properties absent in the bulk constituents. However, control of the geometric structure of the electronic wave functions in correlated oxides remains an open challenge. Here, we create heterostructures consisting of ultrathin SrRuO3, an itinerant ferromagnet hosting momentum-space sources of Berry curvature, and LaAlO3, a polar wide-band-gap insulator. Transmission electron microscopy reveals an atomically sharp LaO/RuO2/SrO interface configuration, leading to excess charge being pinned near the LaAlO3/SrRuO3 interface. We demonstrate through magneto-optical characterization, theoretical calculations and transport measurements that the real-space charge reconstruction drives a reorganization of the topological charges in the band structure, thereby modifying the momentum-space Berry curvature in SrRuO3 [1]. We will also report the discovery of the first material system having both spin- and orbital-sourced Berry curvature: LaAlO3/SrTiO3 interfaces grown along the [111] direction. We independently detect these two sources and probe the Berry curvature associated to the spin quantum number through the measurements of an anomalous planar Hall effect. The observation of a nonlinear Hall effect with time-reversal symmetry signals large orbital-mediated Berry curvature dipoles. The coexistence of different forms of Berry curvature enables the combination of spintronic and optoelectronic functionalities in a single material [2,3].

9:15 AM QT02.08.02
Exciton Transport in Van der Waals Antiferromagnet CrSBr Florian Dirnberger[1], Sophia Terres[1], Kseniia Mosina[2], Zdenek Sofer[2], Akashdeep Kamra[3], Mikhail M. Glazov[4] and Alexey Chernikov[1]; [1]Institute of Applied Physics and Würzburg-Dresden Cluster of Excellence, Germany; [2]Department of Inorganic Chemistry, Czechia; [3]Departamento de Física Teórica de la Materia Condensada and Condensed Matter Physics Center (IFIMAC), Spain; [4]Ioffe Institute, Russian Federation

The recent discovery of *magnetic excitons* – a rare type of optical excitation that emerges from spin-polarized electronic states in magnets – raises important questions about elemental interactions between excitons, magnons, and light. The prototypical layered antiferromagnetic semiconductor CrSBr and its strongly bound excitons are an exceptional platform to address such questions. In this contribution, we present the results of a study of the spatial transport of this intriguing type of exciton with particular focus on the role of crystal anisotropy, magnons and the magnetic order. We demonstrate highly non-linear exciton transport with unusual temperature dependence that culminates in substantially enhanced exciton propagation at the antiferromagnet-to-paramagnet phase transition. Observations of anomalous and effectively negative transport further indicate the substantial coupling of excitonic, vibronic,

and magnetic degrees of freedom.

9:30 AM *QT02.08.03
Spin-Orbit Torque in Magnetic Heterostructures: Exchange Interactions and Ultrasensitive Sagnac Magneto-Optic Interferometry Thow Min Jerald Cham[1], Saba Karimeddiny[1], Orion Smedley[1], Reiley Dorrian[1], Xiyue S. Zhang[1], Avalon Dismukes[2], Daniel Chica[2], Andrew F. May[3], David A. Muller[1], Xavier Roy[2], Daniel C. Ralph[1] and Yunqiu Kelly Luo[4,1]; [1]Cornell University, United States; [2]Columbia University, United States; [3]Oak Ridge National Laboratory, United States; [4]University of Southern California, United States

In this two-part talk, we will first present our recent progress in advancing spin-orbit-torque metrology by adapting an ultrasensitive Sagnac magneto-optic interferometry originally developed for measuring time-reversal-symmetry breaking in exotic superconductors, and applying it for the first time to measuring spin-orbit torques. We will introduce the concept of Sagnac interferometry with an ultrahigh Kerr sensitivity of ~ 5μRad/√Hz and describe how such high sensitivity allows quantitative measurements of spin-orbit torque by sensing current-induced small-angle magnetization tilting. This method is especially advantageous for insulating magnets for which conventional transport spin-orbit torque metrology can be disrupted by magneto-thermal artifacts, but it can also be applied widely to broad classes of magnets regardless of conductivity and small net magnetization.
Secondly, we will present our recent work in identifying the gigahertz antiferromagnetic resonances within the easy-axis van der Waals (vdW) magnet CrSBr and understanding how their frequencies and intermode coupling can be controlled by the combination of external magnetic fields and magnetic anisotropy [3]. We will show that exchange bias from CrSBr acting on the van der Waals ferromagnet Fe3GeTe2 induces a spatially non-uniform spin configuration through the thickness of the Fe3GeTe2 that is not readily achievable with conventional magnetic materials, and can provide the symmetry breaking needed to enable field-free spin-orbit-torque switching in Pt/Fe3GeTe2/CrSBr heterostructures [4].

10:30 AM *QT02.08.04
Nonlinear Optics in Magnetic Quantum Materials and Axion Electrodynamics Prineha Narang and Emily Been; University of California, Los Angeles, United States

Parametric optical nonlinearities are critical to a wide spectrum of photonic technologies, from optical parametric oscillators to frequency combs to quantum information processing. Optical nonlinearities also serve as a powerful method for mapping material properties including the symmetries of electronic structure. Optical nonlinearities are generally very small in conventional materials as they depend on higher order effects. Parallel to these technical needs, the field of topological materials has seen the prediction and discovery of a large number of massless, three-dimensional linear dispersion systems known as Dirac and Weyl semimetals. It was soon realized that these materials may offer a rich new material phase space for extending the nonlinear effects of graphene including the role of topology and Berry connection. In this context, I will present our recent work on predicting the optoelectronic and nonlinear properties of Dirac and Weyl semimetals with an emphasis on figures of merit (FoMs) that we will evaluate for these new Weyl and Dirac semimetals that capture the confinement and nonlinearity to describe the second and third order susceptibilities and electro-optic coefficients of the materials. Next, I will discuss our recent results on the multiphoton spectroscopy of a dynamical axion insulator. Here, the axion receives contributions from the collective motion of electrons, leading to a nonlinear topological magnetoelectric effect. Identifying this collective axion response faces a number of major experimental difficulties, which necessitate a theory-predicted smoking gun signature. We demonstrate a two-step protocol for the unambiguous optical identification of the collective axion mode in such a system. First, we show how collective oscillations of the axion mode can be induced by two-photon absorption or stimulated Raman spectroscopy, with the magnetoelectric nature of the excitation manifesting in the polarization dependence of the excitation beams. Second, we show how the axion oscillations can be confirmed through their manifestations in the time-resolved Kerr-rotation, which again carries signature polarization dependence due to the magnetoelectric nature of the coupling. Looking ahead, I will discuss how collective responses in topological quantum materials can be unambiguously identified in nonlinear electrodynamical probes, as well as identify potential avenues for intersections with particle physics in axion electrodynamics.

11:00 AM QT02.08.05
Scalable One-Dimensional Excitons in a Van der Waals Magnet Yinming Shao[1], Florian Dirnberger[2], Siyuan Qiu[1], Swagata Acharya[3], Sophia Terres[2], Evan Telford[1], Dimitar Pashov[4], Frank Ruta[1], Daniel Chica[1], Yiping Wang[1], Youn Jue Bae[1], Andrew Millis[1], Mikhail Katsnelson[5], Mark van Schilfgaarde[3], Kseniia Mosina[6], Zdenek Sofer[6], Alexey Chernikov[2], Rupert Huber[7], Xiaoyang Zhu[1], Xavier Roy[1] and D. Basov[1]; [1]Columbia University, United States; [2]Technische Universität Dresden, Germany; [3]National Renewable Energy Laboratory, United States; [4]King's College London, United Kingdom; [5]Radboud University, Netherlands; [6]University of Chemistry and Technology Prague, Czechia; [7]University of Regensburg, Germany

The discovery of two-dimensional (2D) van der Waals magnets has greatly expanded our ability to create and control nanoscale phases. A unique capability appears when a 2D magnet is also a semiconductor, which features tightly bound excitons with large oscillator strengths and potential tunability with magnetic field. While crystalline and geometric anisotropy can lead to anisotropic 2D (black phosphorus) and even 1D excitons (carbon nanotube), the superior excitonic properties do not easily scale up with increasing layer number/system size. Here we report scalable 1D excitons in the 2D A-type antiferromagnetic semiconductor CrSBr from few-layer to the bulk limit. The 1D confinement originates from a combination of in-plane crystalline anisotropy and inter-plane magnetic anisotropy. Magnetic confinement of the 1D excitons is established through the layer dependence and temperature dependence of the exciton properties, and further corroborated with *ab initio* theory calculations. Our work establishes a novel avenue towards the large-scale application of emergent functionalities of low-dimensional materials.

11:15 AM *QT02.08.06
Fast Light-Driven Domain Walls in a Parent Cuprate Kyle Seyler; University of Arizona, United States

Quantum materials exhibit fascinating phenomena when perturbed on short time scales or viewed at small length scales. For example, ultrafast light pulses can induce nonequilibrium behaviors that are thermally inaccessible. In addition, rich mesoscopic heterogeneity often exists in equilibrium, including the

presence of domain walls that lie at the interface between different domains. Merging direct spatial imaging with ultrafast time resolution therefore has tremendous potential to reveal intriguing light-induced domain wall dynamics but is often experimentally challenging. In this talk, I will show how ultrafast optical pulses can be harnessed to both image and dynamically manipulate the antiferromagnetic domain walls in a variant of the parent cuprates. In particular, I will highlight our discovery that antiferromagnetic domain walls can be driven to fast speeds by intense circularly polarized laser pulses. These results provide an unprecedented view of domain wall dynamics in quantum materials.

11:45 AM QT02.08.07
Angle-Resolved Photoemission Spectroscopy Studies of Flat Bands in Rhombohedral Graphene Anil Rajapitamahuni, Turgut Yilmaz, Asish Kundu, Suji Park, Abdullah Al-Mahboob, Jerzy Sadowski and Elio Vescovo; Brookhaven National Laboratory, United States

The emergence of interaction driven phases in the twisted two-dimensional van der Waals heterostructures is due to the presence of van Hove singularities or flat bands where Coulomb repulsion energies dominate the kinetic energy of electrons. However, the correlated phenomena in twisted systems are extremely sensitive to angle disorder and strain, making them hard to achieve for experimental reproducibility. In this regard, graphene multilayers with rhombohedral or ABC stacking offers a different route to achieve flat bands. In this work, we have systematically studied the flat band electronic structure of ABC stacked multilayer graphene via high resolution angle resolved photoemission spectroscopy (ARPES). Few-layer (4 - 120) graphene flakes are directly exfoliated on to highly conducting Si (100) substrates using blue tape. We then identified ABC stacked flakes via Raman spectroscopy measurements. The thickness of the flakes is determined via atomic force microscopy (AFM). Synchrotron-based micro-ARPES experiments revealed intense flat bands around the *K* point, close to Fermi level (E_F). The presence of the flat bands over a large, measured photon energy range (44 -235 eV) confirms their surface origin. From the energy distribution curves (EDCs) stacks a curvature in the ΓK and KM direction exists, and this dispersion extends over 25 meV. The width of the dispersion shrinks to ~10 meV, when the layer number is reduced to 4-5 layers, suggesting an increase in the correlation strength with the decrease of layer number in ABC stacked graphene. We have also performed temperature (12 – 300 K) dependent and polarization ARPES studies of the flat bands, to determine the magnetic origin of the curvature. Since RG is thermally more stable than twisted bilayers and naturally available, avoiding the need for fabrication, our work provides critical insights in understanding the correlated phenomena in chemically simple systems devoid of disorder.

SESSION QT02.09: Imaging and Control of Magnetism

Room 421, Level 4, Summit

1:30 PM *QT02.09.01
Symmetry-Breaking Pathway towards The Unpinned Broken Helix Veronika Sunko[1,2], Elizabeth Donoway[1,2], Thais Trevisan[1,2], Alex Liebman - Pelaez[1,2], Ryan Day[1,2], Kohtaro Yamakawa[1,2], Yue Sun[1,2], Rafael M. Fernandes[3], Jian Rui Soh[4], Dharmalingam Prabhakaran[5], Andrew Boothroyd[5], James G. Analytis[1,2], Joel Moore[1,2] and Joe Orenstein[1,2]; [1]UC Berkeley, United States; [2]Lawrence Berkeley National Laboratory, United States; [3]University of Minnesota, United States; [4]Institute of Physics, École Polytechnique Fédérale de Lausanne, Switzerland; [5]University of Oxford, United Kingdom

The search for materials exhibiting novel emergent properties relies on identification of their characteristic symmetries. A prominent example are materials in which magnetic symmetries promote topological phases, and consequently quantized responses to external stimuli.

$EuIn_2As_2$ attracted attention when ab-initio calculations predicted that it hosts the elusive axion insulator state, based on the assumption of a simple collinear antiferromagnetic structure. Recently, scattering measurements revealed a much more intricate magnetic ground state, characterized by two coexisting magnetic wavevectors, reached by successive thermal phase transitions. The proposed magnetic phases were a spin helix and a state with interpenetrating helical and antiferromagnetic order, termed a `broken helix.' The symmetries of both deduced phases protected the axion state.

In this talk I will show results of magneto-optical experiments which are not compatible with the magnetic structures deduced by scattering. I will further demonstrate how combining the experimental information from scattering and symmetry-sensitive optics with an analysis based on group theory allowed us to uniquely identify the magnetic structure associated with each of the two phases. We find that the higher temperature phase hosts a ‘nodal amplitude-modulated’ structure rather than a helix, characterized by a variation of magnetic moment amplitude from layer to layer, with the moment vanishing entirely in every third Eu layer. The lower temperature structure is similar to the `broken helix,' with one important difference: the relative orientation of the magnetic structure and the lattice is not fixed, resulting in an ‘unpinned broken helix.’ As a result of the consequent breaking of rotational symmetry, the axion phase is not generically protected in $EuIn_2As_2$ but we show that it can be restored if the magnetic structure is tuned with externally applied uniaxial strain. Finally, I will present a spin Hamiltonian that identifies the interactions needed to account for the complex magnetic order in $EuIn_2As_2$, and how they arise from coupling to itinerant degrees of freedom.

Taken together, our results emphasize the power of a multimodal approach combining scattering and symmetry-sensitive optical probes in identifying complex magnetic structures, as well identifying $EuIn_2As_2$ as a remarkably tunable platform for exploration of magnetic symmetries.

2:00 PM QT02.09.02
Ferromagnetism in a Monolayer 2D Metal-Organic Framework Egzona Isufi Neziri[1,2], Karl-heinz Ernst[1,2,3] and Christian Wäckerlin[4,5]; [1]Universität Zürich, Switzerland; [2]Swiss Federal Laboratories for Materials Science and Technology, Switzerland; [3]The Czech Academy of Sciences, Czechia; [4]Swiss Federal Institute of Technology Lausanne, Switzerland; [5]Paul-Scherrer-Institut, Switzerland

Motivated by applications in information and energy technology, the search for new materials with stable long-range magnetic ordering continues. In this respect, metal-organic magnets, being built by coordination of metal-atoms with suitable ligands, have attracted significant attention in the recent years. Nanoscale magnetic materials with reduced dimensionality promise very interesting applications in information technology, e.g. information storage, information processing (spintronics) or quantum computing. The Mermin-Wagner theorem establishes that in systems with dimensions $D \leq 2$, governed by the isotropic Heisenberg exchange with short-range interactions, continuous symmetries cannot break spontaneously at finite temperatures. Only in presence of a significant magnetic anisotropy that counteracts random spin reorientations (or non-Heisenberg exchange interactions), ferromagnetism at low dimensions can occur. In this work, we show the existence of ferromagnetic coupling in a 2D metal-organic framework (MOF) consisting of Ni atom centers and tetracyanoethylene (TCNE) ligands on a Au(111) surface. Scanning tunneling microscopy (STM) shows a well-ordered MOF after co-deposition of Ni and TCNE. Analyses based on x-ray magnetic circular dichroism (XMCD) measurements reveal a strong out-of-plane magnetic

anisotropy and a square like hysteresis loop with a coercive field of 1 T. Origin of such 2D ferromagnetism will be discussed

2:15 PM QT02.09.03
Structural and Electronic Properties of Ti- and Ca-Doped Hexagonal $TbInO_3$ Kuntal Talit[1], Nabaraj Pokhrel[1], Yang Zhang[2], Johanna Nordlander[2], Ismail El Baggari[2], Julia Mundy[2] and Elizabeth Nowadnick[1]; [1]University of California, Merced, United States; [2]Harvard University, United States

Magnetic frustration combined with strong quantum fluctuations can create a quantum spin liquid ground state in that material. Doped spin liquids, which may host novel properties such as fractionalized charges and unconventional superconductivity are of fundamental interest and may hold promise for quantum computing applications. However, understanding what happens to added charge carriers in doped spin liquids remains a challenging problem. Recent research has demonstrated that hexagonal ferroelectric $TbInO_3$, characterized by anisotropic exchange interactions, substantial spin-orbit coupling, and f-electron magnetism, is a candidate spin liquid material. Low-dimensional frustrated magnetism in $TbInO_3$ arises from its layered crystal structure, consisting of nonmagnetic layers of corner-sharing InO_5 trigonal bipyramids alternating with layers of magnetic Tb^{3+} ions arranged in a distorted triangular lattice featuring two distinct Tb sites. In this work, we employ density functional theory (DFT) calculations together with scanning transmission electron microscopy (STEM) imaging to investigate the effects of doping hexagonal $TbInO_3$ thin films via chemical substitution. We explicitly introduce Ti^{4+} for electron doping and Ca^{2+} for hole doping, systematically exploring various dopant concentrations and configurations. We investigate the evolution of the structural and ferroelectric properties of electron- and hole-doped $TbInO_3$, finding good agreement between changes to lattice parameters and atomic displacement amplitudes from our DFT calculations and STEM measurements We also combine DFT calculations of the density of states with electron energy loss spectroscopy measurements to probe the evolution of the electronic structure of $TbInO_3$ upon Ti^{4+} and Ca^{2+} substitution. This research provides new insight into the structural and electronic properties of doped $TbInO_3$ and their implications for conductivity in low-dimensional frustrated magnetic states.

2:30 PM QT02.09.04
Inelastic Neutron Scattering of The Spin-Liquid Candidate $Ba_3ZnRu_2O_9$ and Diluted $Ba_3Zn(Ru_{0.1}Sb_{0.9})_2O_9$ Daniel M. Pajerowski[1], Daniel P. Phelan[2], Yu Li[2], Matthew Stone[1], David Dahlbom[1], Alexander Kolesnikov[1] and Duminda Sanjeewa[3]; [1]Oak Ridge National Lab, United States; [2]Argonne National Laboratory, United States; [3]University of Missouri–Columbia, United States

$Ba_3ZnRu_2O_9$ (BZRO) is a 6-H perovskite compound with layers of S=3/2 Ru^{5+} dimers arranged in a triangular lattice. There is no evidence of long-range magnetic order at temperatures as low as 37 mK, which suggests a potential spin-liquid ground-state.[1] Inelastic neutron scattering results are presented from from BZRO (powder, crystal arrays) and the diamagnetically doped $Ba_3Zn(Ru_{0.1}Sb_{0.9})2O_9$. The BZRO shows highly dispersive excitations with no magnetic Bragg peaks. So, contrary to prior suggestions that a similar compound, $Ba_3CaRu_2O_9$, consists of magnetic dimers with negligible inter-dimer interactions,[2] these data show that BZRO clearly deviates from a dimer model. Different analysis techniques of the correlations are illustrated, including coarse-graining the system so that dimers are local entangled units.

3:15 PM *QT02.10.01
Superlative Spin Transport in Two-Dimensional Black Phosphorus Luke Cording[1], Jiawei Liu[2], Jun You Tan[2], Kenji Watanabe[3], Takashi Taniguchi[3], Barbaros Ozyilmaz[2] and Ahmet Avsar[2]; [1]Newcastle University, United Kingdom; [2]National University of Singapore, Singapore; [3]National Institute for Materials Science, Japan

Exploitation of the intrinsic spin of an electron, spintronics, facilitates the development of multifunctional and novel devices which could play an important role in the Beyond-CMOS era. Two-dimensional (2D) crystals and their van der Waals heterostructures are particularly promising for spintronics device applications due to their unique properties, including strong responses to field effect gating and proximity interactions, which may enable new functionalities that are not possible with conventional bulk materials [1].

Two-dimensional black phosphorus is a promising material for semiconducting spintronics research due to its high charge mobilities, low atomic mass, and puckered crystalline structure, which are expected to lead to anisotropic spin transport with nanosecond spin-lifetimes. In this presentation, I will introduce ultra-thin BP as a unique platform for studying rich spin-dependent physics. Firstly, I will show that BP supports all electrical spin injection, transport, precession and detection up to room temperature [2]. Then, I will present our recent findings on the impact of the unique crystal structure of BP on its spin dynamics, revealing strong anisotropic spin transport along three orthogonal axes [3]. Finally, a van der Waals bonded spintronics device utilizing BP as channel material and 2D magnets for spin injection/detection will be introduced. The exceptional spin transport and strong spin-lifetime anisotropy we observe in BP add to the growing body of evidence for the potential of 2D materials in functional spin-based device applications.

Current-Driven Magnetic Resistance in Van der Waals Spin-Filter Antiferromagnetic Tunnel Junctions with $MnBi_2Te_4$ Lishu Zhang; Forschungszentrum Jülich GmbH, Germany

The field of 2D magnetic materials has paved the way for the development of spintronics and nanodevices with new functionalities. Utilizing antiferromagnetic materials, in addition to layered van der Waals (vdW) ferromagnetic materials, has garnered significant interest. In this work, we present a theoretical investigation of the behavior of MnBi2Te4 devices based on the non-equilibrium Green's function method. Our results show that the current-voltage (I-V) characteristics can be influenced significantly by controlling the length of the device and bias voltage and thus allow us to manipulate the tunneling magneto-resistance (TMR) with an external bias voltage. This can be further influenced by the presence of the boron nitride layer which shows significantly enhanced TMR by selectively suppressing specific spin channels for different magnetic configurations. By exploiting this mechanism, the observed TMR value reaches up to 3690%, which can be attributed to the spin-polarized transmission channel and the projected local density of states. Our findings on the influence of structural and magnetic configurations on the spin-polarized transport properties and TMR ratios give the potential implementation of antiferromagnetic vdW layered materials in ultrathin spintronics.

4:00 PM *QT02.10.03
Proximity Spin Interactions in 2D Materials and Correlated Phases Jaroslav Fabian; University of Regensburg, Germany

Graphene has weak spin-orbit coupling and no magnetic order. But when placed in contact with a strong spin-orbit coupling material, such as a TMDC, or a ferromagnet, such as Cr2Ge2Te6, Dirac electrons acquire strong spin-orbit or exchange coupling, respectively. Such proximity effects render graphene suitable for spintronic applications that require spin manipulation [1]. In addition, graphene with strong proximity spin interactions can host novel topological states [2]. Fascinating new phenomena appear when bilayer graphene gets encapsulated by a TMDC from one side, and a ferromagnet from another. The resulting, so called ex-so-tic structure [3], offers spin swap functionality: switching spin-orbit and exchange coupling on demand by the gate. In this talk, I will review the recent developments in the proximity phenomena in graphene, and present some recent theoretical results on the control of the proximity spin-orbit and exchange coupling by twisting the van der Waals layers. I will show that the signature proximity spin-orbit coupling in graphene---valley Zeeman coupling---can be efficiently tuned by the twist angle [4], and that proximity exchange coupling can be switched by the twist angle, and even morph from ferromagnetic to antiferromagnetic [5]. Finally, I will also discuss the emergence of new correlated phases in AB bilayer and ABC trilayer graphene [6] due to the presence of proximity spin-orbit and exchange couplings. Support from DFG SPP1244, SFB 1277, FLAGERA 2DSOTECH, and EU 2DSPINTECH is acknowledged.

The Fabrication and Characterization of Spintronic Terahertz Emitter Using Magnetic/Non-Magnetic Bilayer with Nanometer Thickness
Mikihiko Nishitani, Kohei Ejiri, Shinya Isosaki, Ruochen Dai, Shojiro Nishitani and Makoto Nakajima; Osaka University, Japan

The response time of electrons below the fermi energy in solids to electromagnetic waves is known to be on the order of femtoseconds. As a result, the energy transfer between electromagnetic waves and spins is ultrafast, at the terahertz frequency [1]. Similarly, spin currents generated by spin polarization are described according to the LLG equation, i.e., the time dynamics of magnetization, and spin currents are expected to have a response time equivalent to that of electrons in the solid to electromagnetic waves. Furthermore, the effect of those spin currents being converted into electric currents by spin-orbit interactions is known as the inverse spin Hall effect, and the response time of those phenomena is also on the order of sub-picoseconds.
In 2013, Kampfrath et al. reported the emission of terahertz waves by femtosecond laser (photon energy of 1.55eV) irradiation of magnetic/nonmagnetic bilayers composed of nanometer-thick films [2]. Subsequently, those devices were named STE (Spintronic Terahertz emitters (STEs), which have been actively studied in basic research as well as in application fields. We have been studying STE using ultrathin (several nanometer-thick) bilayers (Pt/Fe, W/Fe, etc.) of nonmagnetic/magnetic materials on inexpensive, large-aperture (large area) substrates such as glass substrates, and the intensity of terahertz radiation by femtosecond laser irradiation is comparable to that of conventionally used nonlinear optical crystal ZnTe, and further advances are being made [3,4]. Specifically, we have been studying 1) how to efficiently generate spin currents by femtosecond laser irradiation and 2) how to maximize the inverse spin Hall effect at the interface between magnetic and nonmagnetic materials.
In this report, we quantitatively evaluate the spin Hall angle, which is the figure of merit of the effect shown in 2) above mentioned, and investigate its relation to the experimental terahertz wave radiation intensity. The spin Hall angle was obtained by analyzing the magnetic field dependence of the spin Hall magnetoresistance [5], which is used to evaluate spintronic devices, and the terahertz radiation intensity was obtained using our TDS system. The obtained results show a good linear correspondence between the magnitude of the change in spin Hall magnetoresistance and the intensity of terahertz radiation. We plan to reflect these results in the fabrication conditions and in the progress of the technique to further improve the performance of this system.

8:30 AM *QT02.11.01
Synthesis and Ferroelectric Field Effect Studies of Few-Layer $CrCl_3$ Xia Hong; University of Nebraska-Lincoln, United States

The van der Waals magnets CrX_3 (X = I, Br, and Cl) exhibit highly tunable magnetic properties and are promising candidates for developing novel two-dimensional (2D) spintronic applications. The ability to synthesize atomically thin CrX_3 samples and achieve voltage control of their magnetic states is critical for their technological implementation. In this talk, I'll discuss our recent progress in the synthesis and ferroelectric field effect studies of large size few-layer $CrCl_3$ flakes. Using the physical vapor transport technique, we have deposited high-quality $CrCl_3$ flakes down to monolayer thickness on mica. Both isolated flakes with well-defined facets and long stripe samples exceeding 60 μm length have been obtained. High-resolution transmission electron microscopy and Raman studies confirm the high crystallinity of these samples. The tunneling magnetoresistance of graphite/$CrCl_3$/graphite tunnel junctions reveals in-plane magnetic anisotropy and Néel temperature of 17 K of $CrCl_3$. We encapsulate the tunnel junctions with free-standing ferroelectric $PbZr_{0.2}Ti_{0.8}O_3$ membranes and define the polarization state of the top-gate via conductive atomic force microscopy. Ferroelectric polarization reversal leads to nonvolatile modulation of the tunneling current, with an on/off ratio of 10^6 obtained at room temperature. Compared with the negative tunneling magnetoresistance observed in hBN encapsulated devices, the PZT-gated $CrCl_3$ tunnel junctions exhibit positive tunneling magnetoresistance at low temperatures, suggesting a change of magnetic state. Our study provides an effective strategy to design low power, scalable, flexible 2D nanoelectronics and spintronics.
This work was primarily supported by NSF through Grant No. DMR-2118828 and ERSCoR EQUATE Award No. OIA-2044049, and Nebraska Center for Energy Sciences Research.

9:00 AM *QT02.11.02
STEM Developments: Atomic-Resolution SE Imaging, Fast 4D STEM, Ultra-High Energy Resolution Tracy C. Lovejoy; Nion, United States

A new type of secondary electron (SE) detector designed by Nion for a modern STEM combines SE detection with an atom-sized probe in the operating range 20-200 kV, clean (metal-sealed and bakable) UHV vacuum conditions, and state-of-the-art electron energy loss spectroscopy (EELS) and 4D-STEM capabilities [1,2]. Running experience reveals that common S/TEM samples (e.g. MoS_2 or metal nanoparticles on a carbon film) that give atomic-resolution annual dark field (ADF) images initially show only surface contamination in the SE signal. We use multiple methods for UHV surface cleaning, including resistive heating of the whole sample in a side entry holder (e.g. Protochips) and direct laser illumination of a small spot (20 mm x 40 mm). Direct laser illumination is particularly interesting because the laser light modulates the SE signal in some samples by changing the local charge distribution on the surface [3].

After cleaning, atomic-resolution SE signals are readily visible. Expanding on previous work with atomic-resolution SE imaging [4], lower operation voltage in a modern STEM avoids knock-on damage and enables atomic-resolution SE studies of 2D materials. We will show two examples: (1) combining atomic resolution ADF, SE, and 4D-STEM to study MoS_2 with intentional Vanadium dopants at 60 keV primary energy, and (2) combining atomic resolution EELS and SE analysis to study the origins of the SE signal in a model system that can tolerate very high electron doses -- monolayer graphene with Nitrogen and Boron dopants.

4D-STEM and especially EELS experiments on 2D materials have traditionally been complicated by slow detectors and readout noise. The latest direct detectors avoid readout noise and achieve high DQE and dynamic range with speed approaching that of traditional single-channel detectors (>10,000 frames/second). Combining these detectors with powerful open-source software for smart acquisition/compression and live processing makes multi-frame (time series) 4D-STEM or EELS imaging possible, bringing significant advantages when changing the sample environment (e.g. heating, cooling, light-, or gas-injection) causes sample drift that makes longer exposures impractical.

Doing these experiments in an instrument capable of <5 meV energy resolution [5] makes possible synergistic experiments such as mapping the absolute temperature of the sample in and around the spot illuminated by a laser using electron energy gain spectroscopy [6] and measuring the presence and local bonding configuration of hydrogen in the sample by detecting the "infrared absorption" signal of the H bonds with vibrational EELS [7]. Phonon spectroscopy of surface dopants visible in the SE signal is also very promising.

Scanning NV Microscopy Mathieu Munsch and Peter Rickhaus; Qnami AG, Switzerland

We introduce Scanning NV Microscopy (SNVM) as a non-contact characterization technique to investigate magnetic materials and thin films. We show that SNVM can be used to evaluate MRAM performance at the individual bit level. Magnetic random-access memory (MRAM) is a leading emergent memory technology that is poised to replace current non-volatile memory technologies such as eFlash. However, controlling and improving distributions of device properties becomes a key enabler of new applications at this stage of technology development. Here, We demonstrate magnetic reversal characterization in individual, < 60 nm sized bits, to extract key magnetic properties, thermal stability, and switching statistics, and thereby gauge bit-to-bit uniformity. We showcase the performance of our method by benchmarking two distinct bit etching processes immediately after pattern formation. Finally, we will provide other examples of the applications of SNVM for the study of multiferroics, 2D materials, and magnonics.

Spin-Orbit Studies of Ferrimagnetic, Antiferromagnetic and Oxide Weyl Semimetals Eric Fullerton; University of California-San Diego, United States

Topology has emerged in many areas of magnetism that included both chiral spin structures and emergent electronic structures such as Weyl semimetals [1]. The further lowering of the symmetry of the crystal via strain or magnetic order can provide additional functionality. I will discuss recent studies of thin films of candidate Weyl semimetals and their potential use as sources of spin currents in spin-orbit torque devices. Materials studies include ferrimagnetically ordered $CrPt_3$ [2], antiferromagnetically ordered FeRh [3] and transition metal oxides such IrO_2 [4], $CaIrO_3$.and $NdNiO_3$. For each we have grown epitaxial chemically ordered films and studied the spin structure, magneto-transport properties, and spin-to-charge conversion that is a source for spin-orbit torques. For $CrPt_3$ we obtain large anomalous Hall conductivity of 2000 S/cm and large negative magneto-resistance consistent with Weyl semimetal properties. However, this, somewhat surprisingly, does not manifest itself in enhanced charge-to-spin efficiencies. For the antiferromagnetic FeRh phase we observe extremely large, strongly temperature-dependent exotic spin torques with a geometry that is tied to the magnetic ordering direction. Many 5d transition metal oxides such as IrO_2 and $CaIrO_3$ have unique electronic structures, where the density of states near the Fermi level is dominated by only 5d electrons with strong spin orbit coupling. IrO_2 is one of the simplest of these oxides is a Dirac nodal line semi-metal that exhibits a charge-to-spin conversion that is roughly 8 times larger than that of Pt. I will highlight the potential uses for complex materials that generate large, tunable spin-orbit torques. They may be used in conventional computing to non-volatile memory schemes, or for neuromorphic computing approaches exploiting spin dynamics in more complex magnetic systems. This work is supported by US Department of Energy under Grant No. DE-SC0019273

11:00 AM *QT02.12.02
Enabling Energy Efficient Logic through Magneto-Electric Spin Orbit (MESO) Device Punyashloka Debashis; Intel Corporation, United States

Energy efficient and high functionality logic devices are key to sustain the long-term progression of Moore's law. The Magneto-Electric Spin Orbit (MESO) device is one such beyond-CMOS device that has attracted research attention recently. The MESO device uses an input voltage across a multiferroic material to switch the state of a ferromagnet and uses spin-orbit effects to transduce the magnetization state to an output voltage. This talk will present some of the key experimental advances in reducing the switching voltage, increasing the switching speed as well as improving the output voltage from spin-orbit module. Finally, some important challenges and opportunities towards achieving the target device specification will be discussed.

11:30 AM *QT02.12.03
Magnetic Tunnel Junctions for Enabling Novel and Neuromorphic Computing Matthew W. Daniels[1], William A. Borders[1], Advait Madhavan[2,1], Liam Pocher[2], Sidra Gibeault[2], Temitayo Adeyeye[2], Brian Hoskins[1], Daniel Lathrop[2], Mark Stiles[1] and Jabez McClelland[1]; [1]National Institute of Standards and Technology, United States; [2]University of Maryland, United States

Magnetic tunnel junctions (MTJs) are versatile devices with multiple modes of operation. Commonly thought of as memory elements in MRAM applications, magnetic tunnel junctions can also be used as stochastic bitstream generators or nanoscale oscillators. Among modern nanodevices of interest, magnetic tunnel junctions are also technologically mature and are already available in the back-end-of-line setting. In this talk, I discuss our group's recent work on utilizing these devices for alternative computing concepts, using properties like randomness and signal timing to generate energy-efficient brain-inspired computational patterns. We briefly consider the challenges of scaling device research from single-device experiments to the large numbers of devices needed for realistic computing demonstrations; to that end, I discuss NIST's Nanotechnology Accelerator Program and our upcoming hardware AI testbed that researchers can use to quickly close the technology transfer gap in moving from single-devices measurements to computing demonstrations utilizing advanced materials.

SESSION QT02.13: Devices and Control of Magnetism

2:00 PM QT02.13.02
Low-Frequency Electronic Noise Characteristics of Vertical Quasi-Two-Dimensional Antiferromagnetic Semiconductor Devices Subhajit Ghosh[1,2], Zahra E. Nataj[1,2], Fariborz Kargar[1,2] and Alexander A. Balandin[1,2]; [1]University of California Riverside, United States; [2]University of California, Los Angeles, United States

A new frontier in the search for the next-generation electronic, photonic, and spintronic devices is quasi 2D films of transition-metal phospho-trichalcogenides (MPX_3) where "M" is a transition metal and "X" is a chalcogen [1]. Recent studies have reported that MPX_3 structures are one of rare few-layer van der Waals (vdW) materials with stable intrinsic antiferromagnetism (AFM) even at mono- and few-layer thicknesses. The diverse properties of layered MPX_3 materials, tunable by proper selection and combination of the "M" and "X" elements make them an interesting platform for investigating novel low-dimensional device functionalities. The existence of weak vdW bonds between the MPX_3 layers allows one to scale them conveniently to individual atomic planes. The "M" element determines the AFM spin ordering. While $FePS_3$ shows an Ising-type phase transition at the Néel temperature (T_N), $NiPS_3$ follows XY-phase transitions, respectively. MPX_3 structures are semiconductors in nature and variation in the metal element modifies their bandgap from ~1.3 eV to ~3.5 eV. The latter opens up unique opportunities to design novel electronic and magnonic nanodevices suitable for optoelectronic and spintronic applications. However, the data on the electron transport properties and their interaction with spin ordering in these structures is scarce and requires detailed investigations. MPX_3 materials are highly resistive making electron transport measurements a formidable challenge in conventional lateral device structures. To overcome this challenge, we fabricated vertical *h*-BN/MPX_3 heterostructure devices with different MPX_3 components hosting various AFM spin orderings. In this presentation, we report the results of our temperature-dependent cross-plane electrical transport and noise measurements. The low-frequency noise spectroscopy was used to detect the magnetic phase transitions [2]. In vertical *h*-BN/$FePS_3$ devices with the active layer characterized by the Ising-type spin order, we observed a combination of two Lorentzian bulges appearing in the overall *1/f* noise envelope at or close to T_N. These two features were attributed to the generation-recombination (G-R) and magnetic phase transition. The noise measurements of the

vertical devices with both $FePS_3$ and $NiPS_3$ active layers, characterized by the Ising and XY AFM spin orders respectively, revealed mulitple noise peaks near the magnetic phase transitions. The intensity of the noise peaks in $NiPS_3$ was significantly higher than that in the $FePS_3$ device. The comparison of noise characteristics for devices fabricated with two materials of different AFM spin ordering shows a strong dependence of noise on the particular magnetic spin direction and suggests a strong interplay of the magnetic and electrical properties in these AFM materials.

Probing and Manipulating Spin States in Low-Dimensional Fe_xNbSe_2 for Antiferromagnetic Spintronics Matthew Erodici and Kwabena Bediako; University of California, Berkeley, United States

Magnetically intercalated, two-dimensional (2D) transition metal dichalcogenides (TMDs) represent a promising class of low-dimensional, magnetic materials for ultralow-power device applications based on the manipulation of electron spin. The ability to tune the magnetic properties of these compounds based on the choice of host lattice, intercalant, and relative stoichiometry offers a versatile platform for designing 2D magnetic materials, which would otherwise be difficult to access via direct exfoliation of bulk (3D) analogues. Recent work has shown that iron-intercalated tantalum disulfide (Fe_xTaS_2) exhibits long-range ferromagnetic order down to the bilayer limit, due to strong out-of-plane, magnetocrystalline anisotropy, showcasing the tremendous potential of this methodology to engineer non-trivial, low-dimensional magnetic systems.[1] While this approach endows one with a highly modular system of possible configurations, the materials phase space remains largely unexplored—and corresponding experimental demonstration of low-dimensional magnetic order is lacking. Here, we leverage this soft chemical intercalation process to synthesize few-layer iron-intercalated niobium diselenide (Fe_xNbSe_2) and probe the resultant magnetotransport response, in the pursuit of electrically manipulable, antiferromagnetic ground states akin to this family of iron-intercalated niobium-based dichalcogenides.[2] We utilize a suite of confocal Raman spectroscopy methods and electron microscopy-based imaging techniques to detect intercalant superlattice formation and examine the local atomic structure, as the distribution of magnetic sites in these compounds underpins the robustness of long-range magnetic order. These findings will bolster the possibility for engineering more complex magnetic heterostructures within this auspicious family of designer materials.

Spin Dynamics and Exchange Interactions from a Van der Waals Antiferromagnet Yunqiu Kelly Luo; University of Southern California, United States

This talk will present our recent progress in identifying the gigahertz antiferromagnetic resonances within the easy-axis van der Waals (vdW) magnet CrSBr and understanding how their frequencies and intermode coupling can be controlled by the combination of external magnetic fields and magnetic anisotropy [1]. We have recently advanced beyond the published results [1] to achieve direct electrical detection of the resonance dynamics in few-layer CrSBr devices via their effect on tunnel magnetoresistance, and to explore the effects of externally-applied spin-orbit torque on the mode damping. We have also demonstrated that exchange bias from CrSBr acting on the van der Waals ferromagnet Fe3GeTe2 induces a spatially non-uniform spin configuration through the thickness of the Fe3GeTe2 that is not readily achievable with conventional magnetic materials, and can provide the symmetry breaking needed to enable field-free spin-orbit-torque switching in Pt/Fe3GeTe2/CrSBr heterostructures [2]. These results will be of broad interest to the magnetism and spintronics community, for researchers interested in the fundamental physics of spin order in van der Waals materials, and for those working toward making practical devices using van der Waals antiferromagnets and ferromagnets.

Enhanced Magnetoelectric Coupling in Van der Waals Heterostructures Li Yang[1], Yan Lu[2] and Xilong Xu[1]; [1]Washington University in St Louis, United States; [2]Nanchang University, China

Multiferroic materials exhibiting coupled ferroelectric (FE) and ferromagnetic (FM) properties are vital for multifunctional devices. However, achieving enhanced magnetoelectric coupling remains a notable challenge. The emergence of ultra-thin, two-dimensional (2D) van der Waals (vdW) FE and magnetic materials offers unique opportunities to create artificial multiferroics through heterostructures. In this presentation, I showcase enhanced magnetoelectric couplings in two vdW heterostructures: CrI3/Sc2Co2 and CrCl3/CuCrP2S6. Our first-principles simulations predict that reversing FE polarization can efficiently switch their interlayer FM and antiferromagnetic (AFM) orders. Further analysis reveals that these observed magnetoelectric couplings stem from rich proximity mechanisms. In the first heterostructure, the magnetoelectric coupling is achieved through substantial changes in band alignment and subsequent charge transfer (doping effect). In the second heterostructure, the system remains insulating throughout the process, and the

mechanism primarily arises from the unique spin local field effect on interlayer exchange interactions. These results underscore the promising prospects of coupling electric polarization with correlated magnetic orders through the unique proximity physics in vdW multiferroic heterostructures.

$Fe_{5-x}GeTe_2$ is a promising two-dimensional (2D) van der Waals (vdW) magnet for practical applications, given its remarkable magnetic properties. These include Curie temperatures above room temperature, and topological spin textures – TST (both merons and skyrmions), responsible for a pronounced anomalous Hall effect (AHE) and its topological counterpart (THE), which can be harvested for spintronics. Here, we show that both the AHE and THE can be amplified considerably by just adjusting the thickness of exfoliated $Fe_{5-x}GeTe_2$, with THE becoming observable even in zero magnetic field due to a field-induced unbalance in topological charges. Using a complementary suite of techniques, including electronic transport, Lorentz transmission electron microscopy, and micromagnetic simulations, we reveal the emergence of substantial coercive fields upon exfoliation, which are absent in the bulk, implying thickness-dependent magnetic interactions that affect the TST. We detected a 'magic' thickness t ~30 nm where the formation of TST is maximized, inducing large magnitudes for the topological charge density (~6.45 x 10^{20} cm^{-2}), and the concomitant anomalous ($\rho_{xy}^{A} \approx 22.6$ μΩ cm) and topological ($\rho_{xy}^{T} \approx 15$ μΩ cm) Hall resistivities at $T \sim 120$ K. These values are higher than those found in magnetic topological insulators and, so far, the largest reported for 2D magnets. The hitherto unobserved THE under zero magnetic field could provide a platform for the writing and electrical detection of TST aiming at energy-efficient devices based on vdW ferromagnets. are higher than those found in magnetic topological insulators and, so far, the largest reported for 2D magnets. The hitherto unobserved THE under zero magnetic field could provide a platform for the writing and electrical detection of TST aiming at energy-efficient devices based on vdW ferromagnets.

Ultra-High Q Nanobeam Cavities for 2D Heterostructures Jonathan J. Finley; Technical University of Munich, Germany

In this talk, I will describe our recent investigations of the heterogeneous integration of 2D materials onto novel Si_3N_4 nanobeam optical cavities [1-5]. These nanobeam optical resonators host ultra-high cavity modes and allow us to explore novel light-matter and multimodal *vibronic – phonon – photon* couplings mediated by electronic excitations. For hBN-encapsulated MoS_2monolayers, we observe a nonmonotonic temperature dependence of the cavity-trion interaction strength, consistent with the nonlocal light-matter interactions in which the extent of the centre-of-mass wave function is comparable to the cavity mode volume in space[1]. For $MoSe_2$ homo-bilayers [2], we study the twist-dependent moiré coupling. For small angles, we find a pronounced redshift of the K−K and Γ−K excitons, an effect that we trace to the underlying moiré pattern. Studies of thick hBN layers coupled to the high-Q nanocavity modes reveal intriguing dynamics: For example, we identify the zero-phonon line transition of charged boron vacancies () [3,4] and observe a novel tripartite coupling between the cavity photonic modes, lattice phonon and nanobeam vibrational modes. The fingerprint for this tripartite coupling is a pronounced asymmetry in the emission spectrum for cavities with a Q-factor above a threshold of ~10^4. Similar asymmetries are not observed for cavities without centers, or lower Q-cavities. To explain our findings, we model the system with phonon-induced light-matter coupling and compare it to the

Jaynes-Cummings model for usual emitters. Our results reveal that the multipartite interplay arises during the light-matter coupling of centers, illustrating that it is phonon-induced, rather than caused by the thermal population of phonon modes. Our results indicate how different photon (emission, cavity photonic) and phonon (phonon, cavity mechanical) modes provide a novel system to interface spin defects, photons, and phonons in condensed matter systems.

Nano and Sub-Micro Scale Optical Characterization of Transition Metal Dichalcogenide Nanoribbons by AFM-Optical Spectroscopy T. Kien Mac[1], T.T. Trinh Phan[1], Ashley P. Saunders[2], Fang Liu[2], Dmitri Voronine[3] and Tuan M. Trinh[1]; [1]Utah State University, United States; [2]Stanford University, United States; [3]University of South Florida, United States

Two-dimensional (2D) transition metal dichalcogenide (TMDC) nanoribbons have attracted significant interest recently due to their intriguing optical, magnetic, and electronic properties, all of which can be controlled by manipulating their edges and ribbon width via quantum confinement. The specific termination, structure, strain, or defects at the edges play crucial roles in shaping the characteristics of TMDC ribbons. For instance, MoS_2 exhibits distinct signals in second harmonic generation (SHG) for S-zigzag versus S-Mo Klain edges. However, understanding the correlation between optical properties and intricate ribbon edges is challenging largely due to the diffraction limits of conventional optical techniques. The integration of optical spectroscopy with an atomic force microscope (AFM) allows for nanoscale optical imaging by enhancing the optical signal through plasmonic confinement between the metallic AFM tip and the sample. The techniques could reveal more detail on the impact of the edge on the ribbons. In this study, we focus on optical nano-imaging of TMDC nanoribbons using tip-enhanced photoluminescence and second harmonic generation. Our observations reveal variations in emission energy across different locations on the ribbons, indicating the influence of defects and edges on photoexcited exciton and trion energies in TMDC ribbons. To delve deeper into the effects of ribbon edges, we conducted polarization-resolved SHG experiments both with and without the application of an external magnetic field. The results not only shed light on the influence of edges but also offer opportunities to tune and manipulate the optical and magnetic properties of these nanoribbons.

11:30 AM *QT03.01.04
Measuring and Controlling The Dimensions of Liquid-Exfoliated Nanosheets Claudia Backes; Kassel University, Germany

Liquid phase exfoliation (LPE) has become an important production technique for colloidal dispersions and solution-processeable inks of a range of materials due to its versatility and applicability to a broad range of material classes. While mass production is possible, samples are inherently polydisperse and aspect ratios of lateral size/thickness are limited due to scission and delamination occurring simultaneously.[1]
In this talk, I will first discuss our state-of-the-art in measuring nanosheet dimensions through atomic force microscopy, highlighting the challenges associated with this measurement. I will then present our recent in-depth analysis of nanosheet dimensions of WS_2 samples produced by tip sonication in both aqueous surfactant solution and the organic solvent N-methyl-2-pyrrolidone in conjunction with the effect of the liquid environment in centrifugation-based size selection. This data shows that the solvent not only has an impact on the outcome of the centrifugation, but also during sonication with aqueous surfactant based nanosheets having slightly higher length-thickness aspect ratios.
In the second part of the talk, I will demonstrate that it is possible to derive and validate an accurate equation of motion of nanosheets in the centrifugal field accounting for nanosheet dimensionality by implementing length/thickness and length/width aspect ratios that are widely constant for a given material produced in LPE. We show that this equation allows us to predict the nanosheet dimensions in sediment and supernatant after centrifugation.

Hot Exciton Dynamics in Two-Dimensional Organic-Inorganic Hybrid Perovskites Cherie R. Kagan; University of Pennsylvania, United States

Two-dimensional, organic-inorganic hybrid perovskites (2DHPs) are stoichiometric compounds composed of alternating sheets of corner-sharing, metal-halide octahedra and organoammonium cationic layers. We study 2DHPs containing single lead iodide layers separated by intervening substituted, phenethylammonium (PEA) cations with the chemical structure $(x\text{-}PEA)_2PbI_4$, where x=F, Cl, Br, or CH_3. These 2DHPs form type-I heterojunctions in which excitons and carriers are strongly confined to the lead halide layers with exciton binding energies > 150 meV. We use x-ray diffraction and variable-temperature steady-state and time-resolved absorption and photoluminescence (PL) measurements to uncover the correlation between their structure and photophysical properties. $(PEA)_2PbI_4$ excitonic absorption and PL spectra at 15 K show splittings into regularly spaced resonances every 40-46 meV.[1] Anti-Stokes hot exciton PL is observed at the same energy as the optical absorption resonances. Replacing a single atom in the *para* position of the PEA-cation phenyl group increases its length and therefore the interlayer spacing, but leaves the cross-sectional area unchanged and results in structurally similar metal halide frameworks.[2] As the cation length increases, the absorption spectra broaden and blueshift, but the PL spectra remain invariant. Substitution in the *ortho* position with progressively larger cations increasingly distorts and strains the inorganic framework.[3] Ortho substitutions change the number of and spacing between the discrete excitonic resonances and increase the hot exciton PL by >10X. By correlating the atomic substitutions on the cation with changes in the excitonic structure, we show that the origin of the discrete excitonic resonances is consistent with a vibronic progression caused by strong exciton-phonon coupling to a phonon on the organic cation. We also show evidence of the structure-dependent formation of exciton polarons.[4] The properties of 2DHPs can be tailored by the selection of the cation without directly modifying the inorganic framework.[5,6]

2:00 PM *QT03.02.02
Realizing and Imaging Ballistic Transport in Van der Waals Semiconductors Milan Delor; Columbia University, United States

Achieving long-range ballistic (coherent) electron flow in materials at room temperature is a long-standing goal that could unlock lossless energy harvesting and wave-based information technologies. The key challenge is to overcome short-range scattering between electrons and lattice vibrations (phonons). I will describe several avenues to achieve ballistic transport by harnessing strong interactions between coherent and incoherent excitations in solid-state lattices. The first is to leverage polaritons, part-light part-matter quasiparticles resulting from hybridization between photons and semiconductor excitations. The second is to leverage strong electronic and electron-phonon interactions, yielding either highly delocalized excitons or acoustic polarons that are intrinsically shielded from phonon scattering. In all cases, we develop ultrafast optical imaging capabilities enabling us to track the propagation of these quasiparticles with femtosecond resolution and few-nanometer sensitivity over a frequency range spanning the visible to the mid-IR, providing a precise measurement of quasiparticle velocity, scattering pathways, and transition from coherent to incoherent transport.

2:30 PM QT03.02.03
Probing the Hot Carrier Cooling Process in Low-Dimensional Halide Perovskites through Ultrafast Spectroscopy Ziyuan Ge[1], Ben Carwithen[1], Tom Hopper[1,2] and Artem Bakulin[1]; [1]Imperial College London, United Kingdom; [2]Stanford University, United States

Halide perovskite has shown promising applications in perovskite-based optoelectronic devices, e.g., solar cells, and light-emitting diodes, owing to its superior properties including defect tolerance, long carrier diffusion distance, and significant absorption coefficient. Perovskites in nanoscale dimension to lower dimensional networks have recently emerged as having high luminescence efficiency, color purity, and stability. Owing to the soft nature of the perovskite lattice, these electronic properties are primarily governed by the carrier/exciton-phonon coupling strength. Understanding the role of individual phonons in modulating photophysical properties of these class of materials is largely limited to three-dimensional perovskites, (like $MAPbI_3$), Here in our research, we employ femtosecond Pump – push – probe and transient absorption spectroscopy in low-dimensional perovskite systems to study the influence of electron-phonons interaction in hot-carrier cooling to the fate of band-edge excitons. Furthermore, our spectroscopic approach allows us to discern the role of carrier-carrier interactions from carrier-phonon, which is otherwise difficult in conventional measurements. Our finding reveals that suppression of hot phonon bottleneck effect for systems with increasing quantum confinement (i.e., larger exciton binding energy). We predicted that electron-hole coupling within an exciton (in those confined systems) plays a dominant role in hot-carrier cooling over phonons and carrier-phonon coupling. On the other hand, band-edge electronic dynamics in low-dimensional excitonic systems studied through impulsive excitation provide direct evidence of involvement/coupling of various low-frequency phonon modes.

2:45 PM QT03.02.04
Propagation of Excitons and Trions in Two-Dimensional Hybrid Perovskites Sophia Terres[1], Jonas Ziegler[1], Kai-Qiang Lin[2], Barbara Meisinger[2], Yeongsu Cho[3], Xiangzhou Zhu[4], Manuel Kober-Czerny[5,6], Pabitra K. Nayak[5,6], Cecilia Vona[7], Matan Menahem[8], Takashi Taniguchi[9], Kenji Watanabe[9], Henry J. Snaith[5], John Lupton[2], Claudia Draxl[7], Omer Yaffe[8], Timothy C. Berkelbach[3], David A. Egger[4] and Alexey Chernikov[1]; [1]Technische Universität Dresden, Germany; [2]Universität Regensburg, Germany; [3]Columbia University, United States; [4]Technische Universität München, Germany; [5]University of Oxford, United Kingdom; [6]Tata Institute of Fundamental Research, India; [7]Humboldt-Universität zu Berlin, Germany; [8]Weizmann Institute of Science, Israel; [9]National Institute for Materials Science, Japan

Two-dimensional hybrid perovskites are a highly intriguing class of materials. They are considered natural quantum well systems composed of alternating inorganic and organic molecular layers. Their reduced dimensionality combined with weak dielectric screening leads to the formation of tightly bound excitons that are shown to be both efficient light emitters as well as highly mobile. However, external control of their optical response has proven difficult due to challenges to introduce electrical doping into these systems. Moreover, a key feature of some of these materials is the occurrence of a structural phase transition that can alter the electronic band gap as well as their optical response. To what extent the phase transition can affect these fundamental properties has been barely explored so far.

Here, we study the temperature-dependent exciton binding energy and exciton diffusion across the phase transition using a combination of time-resolved microscopy and non-linear spectroscopy. We demonstrate that neither exciton binding energy nor exciton diffusion are affected by the phase transition in contrast to initial predictions. These findings are unexpected considering the substantial changes of the free carrier masses and contrast the semi-classical understanding of their transport, highlighting the unusual behavior of excitons in 2D hybrid perovskites. To better understand excitonic equilibration and relaxation, we investigate non-equilibrium dynamics at cryogenic temperatures at both off-resonant and near-resonant excitation conditions. Beyond that, we report realization of electrically doped, ultrathin 2D perovskite layers, studied in ambipolar field-effect transistor geometries. We demonstrate formation of three-particle exciton complexes, known as trions, by detecting photoluminescence spectra as a function of gate voltage and we reveal the influence of exciton-carrier interaction on the exciton mobility. The experimental realization of both tunable and mobile trions encourages potential applications involving electrically guided charged exciton currents.

3:30 PM *QT03.02.05

Phonon Bottleneck Slowing Down Exciton Dynamics in 2D Perovskites and Transition Metal Dichalcogenides Ermin Malic; Philipps University Marburg, Germany

Monolayer transition metal dichalcogenides (TMDs) and 2D perovskites exhibit a rich exciton physics. The combination of spin-orbit and exchange coupling leads to a complex excitonic landscape of bright and dark states in 2D perovskites, which dictates not only optical signatures but also exciton formation, relaxation and decay dynamics. Despite having a lowest energy dark state, a surprisingly large photoluminescence from the higher-energy bright states has been observed. Combining low temperature magneto-optical measurements with a sophisticated many-particle theory we reveal the microscopic origin of the unexpected enhanced emission of bright excitons in 2D perovskites. We attribute the emission to a pronounced phonon-bottleneck effect, which considerably slows down the relaxation of excitons towards to energetically lowest dark states at low temperatures. We show that this bottleneck can be controlled by changing the bright-dark splitting and the energy of optical phonons by considering different perovskite materials and dielectric surroundings.

We demonstrate that a similar phonon bottleneck can also occur for exciton polaritons created in $MoSe_2$ monolayers integrated into a Fabry-Perot cavity. Efficient scattering into the exciton polariton ground state is a key prerequisite for generating Bose-Einstein condensates and low-threshold polariton lasing. However, this can be challenging to achieve at low densities due to the appearanche of the polariton bottleneck effect that impedes phonon-assisted scattering into the lowest polariton states. However, the rich exciton landscape of TMDs provides potential intervalley scattering pathways to rapidly populate these polariton states. By exploiting phonon-assisted transitions between momentum-dark excitons and the lower polariton branch, we demonstrate that it is possible to bypass the bottleneck region and efficiently populate the low-momentum states in the lower polariton branch at room temperature.

Our work provides new insights on exciton dynamics in atomically thin semiconductors offering strategies for tuning the exciton emission in layered perovskites and populating the polariton groundstate in TMD monolayers that is crucial for many technological applications based on these materials.

4:00 PM QT03.02.06
Effect of Energy Bands Overlap in the Interlayer Energy Transfer Processes in 2D Heterostructures Arka Karmakar; University of Warsaw, Poland

Heterostructures (HSs) made by the monolayers (1Ls) of transition metal dichalcogenides (TMDs) have shown great promises in designing next-generation optoelectronic device applications. Interlayer charge (CT) and energy transfer (ET) processes are the main photocarrier relaxation pathways in the TMD HSs. In semiconductor HSs, usually the CT processes happen at a faster timescale (~100s fs) than the nonradiative ET processes (~few ps). CT processes mainly occur due to the energy level offset between the materials and can survive only up to a few nm. Several studies have already been done using different ultrafast spectroscopic techniques to understand the different aspects of the CT process. Whereas, the interlayer ET process mediated by the dipole-dipole coupling between the donor and acceptor materials, can survive up to several tens of nm. Also, due to the experimental challenges to observe the dipole-dipole coupling, many key factors related to the ET processes remain incomprehensible. In this talk, I would like to present our recent studies to understand the effect of energy bands overlap in the ET process in TMD HSs. First, we study the effect of resonant overlaps between the optical bandgaps of two materials [1]. In this work, we showed that in the type-II HSs formed using the 1Ls of molybdenum diselenide ($MoSe_2$) and rhenium disulfide (ReS_2), an ET process dominates over the fast CT process, resulting 360% photoluminescence (PL) enhancement in the HS area. After completely blocking the CT process, this enhancement increased further up to more than 1 order of magnitude higher. In the second part, we showed that HS formed between the 1Ls of molybdenum disulfide (MoS_2) and tungsten disulfide (WSe_2), an unusual ET process occur from the lower bandgap WSe_2 to higher bandgap MoS_2 due to the resonant overlaps between the high-lying excitonic states [2]. These works will help us to realize the complex ET processes in TMD HSs for better development of the TMD-based novel optoelectronic device applications.

Electronic Transport in 2D Chalcogenide Semiconductors Yuanyue Liu; The University of Texas at Austin, United States

Many commonly-used 2D chalcogenide semiconductors suffer from low carrier mobility at room temperature. There is a critical need to understand the transport bottleneck and improve. Here I will present our recent progress in developing and apply first-principles methods to accurately calculate and understand the electronic transport in 2D chalcogenides, including both phonon and defect scatterings. I will also present new materials with improved transport properties.

The family of hybrid organic-inorganic lead-halide perovskites are the subject of intense interest for optoelectronic applications. Due to the electronically inert nature of most organic molecules, the inorganic sublattice generally dominates the electronic structure and therefore optoelectronic properties of perovskites. However, over the past years interest in the incorporation of electronically active organic cations has been increasing.[1] We use optically and electronically active carbazole-based Cz-C_i molecules [2-3], where C_i indicates an alkylammonium chain and i indicates the number of CH_2 units in the chain, varying from 3−5, as cations in the 2D perovskite structure $(Cz\text{-}C_i)_2PbI_4$. We demonstrate a tunable electronic coupling between the inorganic lead-halide and organic layers. The strongest interlayer electronic coupling was found for $(Cz\text{-}C_3)_2PbI_4$. We measure ultrafast hole transfer from the photoexcited lead-halide layer to the Cz-C_i molecules, the efficiency of which increases by varying the chain length from i=5 to i=3. The charge transfer results in long-lived carriers (10 – 100 ns) and quenched emission. Electrical charge transport measurements using single-carrier devices show markedly

increased out-of-plane carrier mobilities compared to $(PEA)_2PbI_4$, with carrier mobility increasing from i=5 to i=3.[4]

Towards In-Plane Control of Neutral Exciton Flux in Semiconducting 2D Materials Hassan Lamsaadi[1], Dorian Beret[2], Ioannis Paradisanos[3], Pierre Renucci[2], Delphine Lagarde[2], Marie Xavier[2], Bernhard Urbaszek[4], Ziyang Gan[5], Antony George[6], Kenji Watanabe[7], Andrey Turchanin[5], Takashi Taniguchi[7], Laurent Lombez[2], Nicolas Combe[1], Aurelien Cuche[1], Vincent Paillard[1] and Jean-marie Poumirol[1]; [1]CEMES-CNRS, France; [2]INSA-CNRS-UPS, LPCNO, France; [3]Institute of Electronic Structure and Laser, Foundation for Research and Technology-Hellas, Greece; [4]Institute of Condensed Matter Physics, Technische Universität Darmstadt, Germany; [5]Friedrich Schiller University Jena, Institute of Physical Chemistry, Germany; [6]Abbe Centre of Photonics, Germany; [7]Research Center for Functional Materials, National Institute for Materials Science, 1-1 Namik, Japan

For a wide range of next-generation applications in excitonic circuits, quantum optics and optoelectronics, neutral excitons in semiconducting 2D materials need to be controlled. Until now, and in particular in transition metal dichalcogenides, such control has been achieved through the local strain gradient engineering. However, the charge-neutral nature of the dominant exciton types in such materials limits their interaction with external electric or magnetic fields, still making their manipulation a challenging task. Recently, we demonstrated efficient unidirectional transport of excitons from high-gap to low-gap material at room-temperature in high-quality lateral heteromonolayer [1]. Tip enhanced Raman and Photoluminescence spectroscopies (~30nm resolution) performed on high-quality heteromonolayers reveal that excitons generated inside the high-gap material are able to pass through the junction before recombining inside the low-gap material, while propagation in the opposite direction is forbidden. Going further, we have shown that the abrupt change in exciton energy and effective mass has resulted in a strong Kapitza resistance-like effect, allowing excitons to be accelerated locally at the junction as they move from high-gap to low-gap material while being blocked in the opposite direction [2]. This effect causes a strong discontinuity in the excitonic density profile at the junction. As a result, a quenching of high-gap material-related PL is observed while low-gap material-related PL is enhanced near the junction. Finally, by using µ-Photoluminescence(µ-PL) imaging combined with a simulation-based statistical approach of randomly moving excitons through specific geometries of a high-quality CVD-grown $MoSe_2$-WSe_2 lateral heteromonolayer, we demonstrated that the exciton Kapitza effect enhances the exciton diffusion length, and is able to focus and confine excitons down to sub-wavelength dimensions [3]. We believe that our work provides new tools for manipulating neutral excitons in flat semiconducting 2D materials and will enable the incorporation of lateral heteromonolayers in next-generation excitonic devices.

Structure-Property Engineering in The 2D Hybrid Perovskite Family David B. Mitzi; Duke University, United States

Two-dimensional hybrid organic-inorganic perovskite (2D HOIP) semiconductors based on metal halide frameworks offer unprecedented opportunity to tailor structural and materials properties using the full flexibility afforded by the realms of inorganic and organic chemistry,[1] and such tunability offers wide-ranging potential for applications including solar cells, light-emitting devices, detectors, transistors and advanced computing devices. This talk will focus on examining the role that the organic cation plays in tuning one or more of the following: 1) self-assembling quantum well structures with predictable energy band offsets and charge carrier response,[2,3] 2) chirality transfer and symmetry breaking within the inorganic framework,[4] and/or 3) melting and glass formation/crystallization kinetics.[5,6] Recent examples of such structure-property flexibility highlight the unique versatility and promise of using the organic component to control charge, light and spin within the wide-ranging 2D HOIP family.

Growth of Arbitrary 2D TMDs Nanopatterns via Thermal Scanning Probe Lithography Giorgio Zambito, Maria Caterina Giordano, Matteo Gardella and Francesco Buatier de Mongeot; University of Genoa, Italy

Two dimensional (2D) materials have emerged as promising platforms for creating new generation, atomically thin devices in various fields, from nanoelectronics and nanophotonic, to quantum technologies and energy conversion [1–3].
These materials are generally manufactured from mechanically exfoliated flakes, which suffer from stochastic positioning and micrometric sizes. The re-shaping of 2D materials is attractive, since it opens interesting possibilities for engineering optoelectronic and photonic responses, as well as it enables the fabrication of devices with optimized geometries. Nanopatterning of exfoliated flakes is generally obtained by subtractive chemical etching methods [4] which, although effective for creating single demonstrative configurations, are not suitable for fabricating scalable devices for real-life applications.
Here we propose a process that allows the direct fabrication of few-layer MoS_2 nano-circuits with arbitrary geometries. Our approach combines i) a custom-developed sputtering growth for creating few-layers MoS_2 extended films and ii) a high-resolution lithography technique which makes use of a nanoscopic (~10nm) hot silicon probe (thermal Scanning Probe Lithography – t-SPL, NanoFrazor). By the accurate manipulation of such hot nanoprobe, transiently heated by Joule effect, we write deterministic nanopaths onto a sacrificial polymer layer; these nanopatterns spread over a large-area substrate are homogeneously coated by few-layer MoS_2 by the Ion Beam Sputtering (IBS) of a MoS_2 target, leading to MoS_2 nano-circuits with complex geometries and in-series scalability. After a proper high-temperature recrystallization process in a controlled atmosphere, these arbitrary MoS_2 nano-interconnections are characterized by the means of micro-Raman spectroscopy and Kelvin Probe Force Microscopy (KPFM). The observed vibrational and electronic responses confirm the presence of the stable 2H semiconducting phase confined inside the nano-circuits.
After the fabrication of a proper nano-device configuration, the local electrical transport properties of these MoS_2 nano-paths are investigated via conductive - AFM (ResiScope c-AFM), demonstrating the possibility to employ these 2D semiconducting nanocircuits as building blocks of integrated electronics devices.
Finally, we show some preliminary results on alternative applications of t-SPL on 2D materials, such as multilevel patterning of polymer films by 3D grayscale lithography. Indeed, the creation of three-dimensional patterns with arbitrary submicrometric features can serve as a tool to induce and study on-demand strain engineering of 2D materials.

Layered Halide Perovskites: Rich Structural Chemistry and Untapped Potential in Optoelectronics Constantinos Stoumpos[1,2]; [1]University of Crete, Greece; [2]Saint Petersburg State University, Russian Federation

Halide perovskites have shown an immense potential as semiconductors in the past decade, exemplified by their remarkable prowess in photovoltaics, but also in other fields of optoelectronics with successful proof-of-principle demonstrations as radiation sensors, light-emitting devices and lasers. Halide perovskites hold great promise in the sense that they can match in performance the classical semiconductors, but in addition, they can exhibit unconventional behavior such as their unusual defect tolerance that derives from the dynamic nature of the crystal lattice. A specific branch of halide perovskite class of materials that have been drawn enormous attention in recent years, is the dimensionally reduced layered perovskites. Layered perovskites are produced by the incorporation of "molecular scissors" that disrupt the continuity of the inorganic lattice and produce nanoscale-sized two-dimensional sheets, periodically oriented in the form of macroscopic crystals. Layered perovskites possess all the privileges of the parent compounds, but in addition, they are subject to spatial and dielectric confinement effects, thus generating quantum phenomena within their multiple-quantum-well structure. In this talk, I will discuss the early developments in the field of layered halide perovskites and how this early work has led to the current state-of-the-art. I will outline the synthetic methods that have been utilized to obtain the materials in pure form and I will discuss the evolution of important homologous series that constitute the arch types of many related compounds. I will discuss how the optical properties of the materials vary in these systems, focusing of their ability to form stable excitonic states and the peculiar changes that occur in the spectra upon the numerous phase transitions observed in variable temperature experiments. I will conclude my talk by describing potential applications of layered perovskites that can benefit from the presence of stable excitons.

2D hybrid organic-inorganic perovskites (HOIPs) are exciting materials for optoelectronic device applications due to their high degree of chemical and structural tunability. The ability to electronically dope these materials via incorporation of extrinsic dopants is essential for control over carrier concentrations. Conversely, the presence of intrinsic defects can negatively impact electronic doping efficiencies. Here, we present a systematic study of intrinsic point defects and extrinsic dopants (eg. Bi, Sn [*PRX Energy*, **2, 023010** (2023)]), both in isolation and as combined defects, in phenylethylammonium lead iodide (PEA_2PbI_4). Using spin-orbit coupled hybrid density functional theory (DFT) and supercell models up to 3,383 atoms in size, we pinpoint the expected positions of dopant-derived electronic levels in the bandgap. Complementary experimental findings reinforce hypotheses of compensation mechanisms and limiting factors derived from DFT.

10:45 AM QT03.03.06
Interdigitation and Hydrogen Bonding in Benzotriazole-Based 2D Layered Perovskites: a Study of Organic Non-Covalent Interactions Arthur Maufort[1], Jesús Cerda Calatayud[2], Kristof Van Hecke[3], Davy Deduytsche[3], Arne Verding[1], Bart Ruttens[4], Christophe Detavernier[3], Laurence Lutsen[1,4], Claudio Quarti[2], Wouter Van Gompel[1], David Beljonne[2] and Dirk Vanderzande[1,4]; [1]Hasselt University, Belgium; [2]University of Mons, Belgium; [3]Ghent University, Belgium; [4]IMEC, Belgium

Extensive research in the past decade has shown that hybrid perovskites might become a cornerstone in the future global energy economy. Although three-dimensional 3D perovskites have been receiving a lot of research attention, their 2D layered counterparts have also been proven valuable to the field. In state-of-the-art 2D layered perovskites, alkylammonium and phenethylammonium cations are still mostly employed. Although these organic cations succeed in stabilizing the perovskite, they don't offer valuable properties of their own to complement the attractive optoelectronic properties of the perovskite layers. Synergy could be achieved by choosing larger organic cations with more suitable optoelectronic properties, [1,2] or by inserting organic charge-transfer complexes [3] or dipole stacks in the organic layers. However, the non-covalent interactions acting within these more advanced organic layers need to be fully understood in order to formulate design rules and structure-property relationships for this novel class of materials.

In this work, [4,5] benzotriazole-based organic cations are synthesized and subsequently successfully applied to 2D layered hybrid perovskites. The structural and thermal properties of thin films and single crystals of these perovskites are investigated. Single-crystal analysis reveals that benzotriazole-based organic layers in lead(II) iodide lattices show interdigitation, reducing the organic layer thickness and leading to an unusually dense aromatic stacking. Moreover, 2D layered benzotriazole perovskites contain hydrogen bridges – both inter- and intramolecular – within the organic layers. Through theoretical modelling using density-functional theory (DFT), we elucidate this interdigitation and hydrogen bonding and quantify the lattice stabilization. We relate the phenomenon of interdigitation to the available lattice space and to stabilizing non-covalent interactions. Finally, we show that these structural properties lead to enhanced thermal stability with respect to the state of the art.

Self Trapped Exciton Emission under Ambient Conditions in Two-Dimensional Halide Double Perovskites Triggered by Heterovalent Metal Substitution Chunyang Chi; National University of Singapore, Singapore

Layered double perovskites (LDPs) possess soft lattice and strong exciton-phonon interactions, which represent an emerging class of materials as promising self trapped exciton (STE) emitters. However, few LDPs have been discovered with observable photoluminescence (PL) under room conditions hindered by the intrinsic parity-forbidden band transition. Herein, manganese (Mn) is incorporated into $(PA)_4AgInBr_8$ ($PA=CH_3(CH_2)_2NH_{3+}$) to form $(PA)_4Ag_{1-0.5x}Mn_xIn_{1-0.5x}Br_8$ ($0\leq x\leq 1$) heterovalent-metal alloyed layered double perovskites. Halogen substitution is applied to characterize tunable optoelectronic properties of LDPs. Highly oriented thin films are fabricated and investigated via X-ray diffraction $2\theta/\omega$ and ψ scan. With this alloy-induced extrinsic exciton self-trapping strategy, broadband emission is obtained under room conditions via tuning STE states from dark to bright. Temperature-dependent PL gives insights to the emissive behavior and charge-carrier dynamics. The associated Huang-Rhys factors and exciton binding energies show the complexity of excitonic localization in this quantum-well-like structure. This study provides inspiration for designing novel lead-free PL-active perovskites and highlights the significance of understanding the intricate details of exciton-lattice coupling dynamics in LDPs.

SESSION QT03.04: 2D Halide and Chalcogenides Semiconductors IV – Devices

1:30 PM *QT03.04.01

Low Dimensional Metal Halides: Optical Ad Electronic Properties of An Emerging 2D Semiconductor Class Maria Antonietta Loi; University of Groningen, Netherlands

Low dimensional metal halides are currently under the spotlight for optoelectronic applications due to their remarkable photophysical properties. 3Dimensional compounds of similar chemical composition have been used to demonstrate highly efficient solar cells, light emitting diodes, and x-ray detectors. Very recently, 2D and quasi-2D Ruddlesden–Popper metal halide compounds, have also been explored for optoelectronic devices.
Low dimensional metal halide affords specific advantages over other inorganic 2D materials such as transition metal dichalcogenides. As they are easily grown by both solution methods and vapor transport methods at low temperature, and they display a tuneable direct bandgap. In my presentation I will discuss the excitonic properties, transport and stability of two 2D perovskites based on Pb and on Sn, respectively. Concluding on the prospective for these materials in new optoelectronic devices.

2:00 PM *QT03.04.02

Optoelectronics of Atomic Dopants in 2D Semiconductors Goki Eda; National University of Singapore, Singapore

Substitutional doping is a versatile approach for tailoring desired functionalities in 2D semiconductors. Unlike conventional semiconductors, dopants in 2D systems often possess a high activation energy due to reduced screening, leading to apparently minor effects on the host's electronic properties, even at relatively high concentrations. In this presentation, we will delve into the distinctive impact of atomic dopants on the optical, electrical, and optoelectrical characteristics of 2D semiconductors in contrast to traditional semiconductors. As an illustrative example, we will demonstrate that a single atomic impurity significantly enhances the local out-of-plane conductivity of 2D semiconductors by up to two orders of magnitude through resonant-assisted tunnelling. This breakthrough enables the rapid quantification of selected impurities in the dilute limit (<10^10 cm^(-2)) under ambient conditions, leveraging conductive atomic force microscopy [1]. Additionally, we will elucidate how atomic impurities create a narrow impurity band that facilitates in-plane conduction beyond a critical concentration. We conclude by showcasing the photovoltaic effect generated by individual atomic impurity dipoles within homobilayers of doped transition metal dichalcogenides, as observed using photoconductive atomic force microscopy.

Emerging Van der Waals Heterostructures for Ultrathin Solar Cells: Implication of Type-II Band Edge Alignment on Photo-Conversion Efficiency Ponnappa K. Prasanna and Sudip Chakraborty; Harish Chandra Research Institute (HRI), India

The emerging two-dimensional (2D) materials, $ZrSe_2$ and $HfSe_2$, have been envisaged to construct the possible van der Waals heterostructures (vdW), for enhancement of solar cell efficiency. We have performed systematic first principles electronic structure calculations to explore the electronic band structures and optical properties of the heterostructures in order to determine the photo-conversion efficiency (PCE). We have considered both H and T phases of $ZrSe_2$ and $HfSe_2$ while constructing four different possibilities of heterostructures. From the analysis of band edge alignment, it has been found that the heterostructures are having Type-II band alignment, which helps in boosting the effective separation of electron-hole pairs, paving the way towards its application in materials for ultra-thin excitonic heterojunction solar cells. The electrostatic potential shows a huge difference in the dip which signifies the inbuilt electric field that is generated between two different surfaces therefore enhancing the transfer of electrons and holes between different layers. The optical absorption spectra of the heterostructures cover the wider range of the incident solar energy therefore better utilization of the incident radiation. The results show that the heterostructure formed by the H phase of $ZrSe_2$/$HfSe_2$ has attained a maximum power conversion efficiency of over 21%.

3:45 PM QT03.04.04
Spin LEDs Based on a Chiral Halide Perovskite Spin Injector Matthew Hautzinger, Kirstin M. Alberi and Matthew C. Beard; National Renewable Energy Laboratory, United States

The chirality induced spin selectivity (CISS) effect is the selective transmission of electron spin dictated by the handedness of chiral molecules (or structures). Materials exhibiting the CISS effect have great potential in acting as spin injectors, yet there are limited demonstrations of incorporating CISS active materials into spintronic devices. Here, we successfully integrate semiconducting chiral halide perovskites with semiconducting LED emitters. Based on the optical selection rules and conservation of angular momentum, we observe circularly polarized light emission as a result of the spin polarized injection from the chiral perovskite into the semiconductor. The large degree of spin polarization is enabled by the semiconductor-semiconductor interface. To further understand what parameters dictate CISS based spin injection efficiency, we have incorporated chiral perovskites with a variety of emitter materials to probe the impact of band offsets, spin lifetimes, and composition. This demonstration opens numerous opportunities to incorporate CISS materials with semiconductors as opto-spintronic technologies and provide some ground rules for achieving high CISS based spin injection efficiency.

4:00 PM QT03.04.05
Ultrathin Chalcogenide Light Harvesters: Charge-Carrier Transport and Fast NIR Photodetectors Robert Hoye; University of Oxford, United Kingdom

Bismuth-based semiconductors have gained increasing attention as potential nontoxic alternatives to lead-halide perovskites.[1] Whilst most attention has been on bismuth-halide-based compounds, there is growing interest in broader families of materials, including chalcogenides, such as ABZ_2 materials (A = monovalent cation; B = Bi^{3+} or Sb^{3+}; Z = chalcogen).[2] However, the semiconductors explored thus far have gradually-increasing absorption onsets, and their charge-carrier transport is not yet well understood. The first half of this talk discusses our recent work on cation-disordered $NaBiS_2$ nanocrystals,[3] which have a steep absorption onset, with absorption coefficients reaching $>10^5$ cm^{-1} just above its pseudo-direct bandgap of 1.4 eV. Surprisingly, we also observe an ultrafast (picosecond-timescale) photoconductivity decay and long-lived charge-carrier population persisting for over one microsecond in $NaBiS_2$ nanocrystals. These unusual features arise because of the non-bonding S *p* character of the upper valence band, which leads to a high density of electronic states at the band edges, ultrafast localisation of spatially-separated electrons and holes, as well as the slow decay of trapped holes.

The second half of this talk covers our recent work on $AgBiS_2$, which also has high absorption strength, such that films only 50 nm thick are required to achieve adequate light absorption. Given the small bandgap of 1.2 eV, we demonstrate the utility of this material in near-infrared photodetectors. We achieve high cut-off frequencies reaching 0.5 MHz at 940 nm wavelength, along with >1 MHz cut-off frequencies in the visible wavelength range. Through detailed characterisation, we reveal the electronic-ionic transport properties of this material, and how these properties can be controlled to achieve fast NIR photodetectors. Finally, we demonstrate the practical application of these devices for heart beat monitoring.[4]

Overall, in this talk, the critical role of cation disorder in these ternary chalcogenide systems is revealed, especially how they influence optical absorption and charge-carrier kinetics.

Optoelectronic Interactions of WS_2-ZnO for Scalable LEDs Based on Two-Dimensional Materials Osamah Kharsah[1], Leon Daniel[1], Denys Vidish[2], Dedi Sutarma[1], Stephan Sleziona[1], Peter Kratzer[1], Kevin Musselman[2] and Marika Schleberger[1]; [1]Universität Duisburg-Essen, Germany; [2]University of Waterloo, Canada

Recent advances in scalable large-area light-emitting diodes (LEDs) utilizing two-dimensional materials have spurred the investigation of promising architectures. Among the forefront LED architectures under investigation is the n-i-p design, featuring distinct layers comprising an electron-transport material (n), an intrinsic active material (i), and a hole-transport material (p). This framework facilitates efficient electron-hole recombination and subsequent light emission. Tungsten disulfide (WS_2) has attracted significant attention as an active material in such LEDs, given its direct bandgap, high stability, and robust photoluminescence (PL). Meanwhile, zinc oxide (ZnO), an n-type semiconductor, is under examination as a candidate for the electron-transport layer. This study investigates the interactions between WS_2 and both single-crystalline ZnO and spatial atomic layer deposition (SALD)-grown ZnO, with a primary focus on evaluating the optoelectronic interaction of this heterostructure. A comprehensive set of characterization techniques, including PL and Raman spectroscopy to probe optoelectronic properties, atomic force microscopy for morphological insights, Kelvin probe force microscopy for surface potential variations, and X-ray photoelectron spectroscopy to delve into chemical composition and electronic states at the WS_2-ZnO interface, is employed. Ultimately, this research aims to determine whether SALD-grown ZnO is a suitable candidate for integration into the n-i-p LED architecture, paving the way for scalable and efficient optoelectronic devices based on 2D materials.

Controllable Photoluminescence Modification of Monolayer Molybdenum Disulfide via Superacid Treatment and Atomic Layer Deposition of High-κ Dielectric Materials Brendan F. Healy, Sophie Pain, Nicholas Grant and John D. Murphy; University of Warwick, United Kingdom

Transition metal dichalcogenides (TMDCs) are an exciting class of two-dimensional (2D) materials that exhibit exceptional physical and chemical behaviour at the monolayer limit. [1] Molybdenum disulfide (MoS_2) is a prototypical TMDC that has emerged as a leading candidate for inclusion in numerous optoelectronic technologies, owing to its novel optical properties. [2] With a direct bandgap in the visible spectral range, monolayer MoS_2 emits a relatively strong photoluminescence (PL) signal. [3] The ability to control the PL character of MoS_2 is important for full realisation of its optoelectronic application. The PL spectrum of MoS_2 has been shown to be sensitive to a range of external treatments, including oxygen plasma exposure, [4] annealing, [5] laser irradiation, [6] superacid treatment, [7] and dielectric encapsulation. [8] Each treatment will induce a change in response, potentially enabling tuneable modification of the PL behaviour of MoS_2 via the choice of treatment.

In this work, we present controllable variation of the PL signal from chemical vapour deposition (CVD)-grown MoS_2 monolayer films. We demonstrate selective alteration of the MoS_2 PL intensity, bidirectional energy shift and spectral reshaping via superacid treatment or atomic layer deposition (ALD) of a high dielectric constant (high-κ) material. By submerging monolayer MoS_2 in a solution containing the superacidic bis-(trifluoromethanesulfonyl)amide (TFSA), we achieve improvement of the PL character, in agreement with previous reports. [7, 9] We find that superacid treatment induces significant enhancement of the absolute MoS_2 PL intensity, as well as blueshift in the energy of the emission and narrowing of the dominant peak. Conversely, we reveal opposing changes to the MoS_2 PL signal result from deposition of a high-κ dielectric. Grown by ALD, an atop layer of hafnium oxide (HfO_2) or aluminium oxide (Al_2O_3) layer is shown to attenuate the strength of the PL emission from monolayer MoS_2, with an accompanying redshift and broadening of the PL spectrum also observed. Via PL mapping, we confirm the treatment-induced modifications of the PL intensity to be prevalent across the MoS_2 surface following both TFSA and ALD-dielectric treatments. We utilise Lorentzian deconvolution of the PL spectra, coupled with a correlative analysis of the characteristic Raman peaks, to attribute the varying PL changes to differing charge doping and strain effects.[10] This work demonstrates facile control of the PL behaviour of CVD-MoS_2 monolayer films via application of an external chemical or dielectric treatment.

5:00 PM QT03.05.02
Developing Bismuth Sulfoiodide Pellets for Low-Energy X-Ray Detection Maia Mombru[1], Kavya Reddy Dudipala[2], Hugh Lohan[2], Robert L. Hoye[2], Matthew C. Veale[3], Laura Fornaro[4] and Ivana Aguiar[1]; [1]Universidad de la Republica, Uruguay; [2]University of Oxford, United Kingdom; [3]Science and Technology Facilities Council, United Kingdom; [4]Universidad de la República, Uruguay

Bismuth based semiconductor materials are increasing in popularity due to their potential in optoelectronic applications such as solar cells and radiation detection. The latter application has uses spanning many fields, from medicine to homeland safety. Given the nature of soft and hard X-rays and gamma radiation, being able to correctly detect their presence and measure them is imperative. In particular, BiSI has been studied for solar cells, especially in film deposition, and for X-ray detection in pellets from nanostructures. In this work, we present the study of soft X-ray detection in BiSI pellets. BiSI nanorods were synthesized by either a solution or solvothermal method, using mono ethylene glycol as a reaction medium, and Bi_2S_3 and I_2 as reagents. The solution method yielded pure crystalline BiSI nanorods of 200 nm in average width, while the solvothermal method produced a composite of BiSI nanorods and amorphous carbon particles. Pellets were constructed with the powders by cold pressing in a uniaxial press. The orientation of the BiSI nanorods is parallel to the surface of the pellet, evidenced both by SEM and XRD characterization. In the case of the nanocomposite, this orientation is partly disrupted by the spherical nature of the carbon particles. Prototype devices were built by depositing Au contacts through evaporation in a sandwich configuration.
I-V curves were measured both in the dark and under X-ray irradiation. Dark current was measured up to 600 V and the resistivity was two orders of magnitude higher for the nanocomposite versus the pure compound, with values of 10^9 to 10^{11} Ω.cm, respectively. This is in accordance to the fact that the composite has amorphous structure that limits the conductivity. The response to X-rays of 9 keV in energy was measured up to 20 V, and a linear response was obtained in both cases. When the dose was up to 4.2 $\mu Gy_{air}\ s^{-1}$ at a fixed voltage of 20 V the current increased linearly. When comparing the two materials, the nanocomposite had a considerable better performance than the pure compound. The amorphous carbon particles lower the dark current, but do not contribute negatively to the photoconduction of the charge carriers generated by the X-rays. A notable advantage of this study is that the bias applied is considerably low with regards to usual operating voltages of direct semiconductor detectors, allowing for the possibility of using these devices in wearable technology, for instance in direct dosimeters. This work presents an easy, scalable and cheap way to produce low energy X-ray detectors with a suitable performance.

5:00 PM QT03.05.03
Observations and Maps of Second Harmonic Generation on 2D Chalcogenide MoS_2 Monolayers and Single Crystalline Thin Films Xiaojuan Fan[1,2], Lawrence Mubwika[2] and Lian Li[2]; [1]Marshall University, United States; [2]West Virginia University, United States

Non-linear optical responses in 2D transition metal dichalcogenides (TMD) have attracted increasing attention due to unique layered structures and the ability to generate a series of non-linear harmonic waves, such as second harmonic generation (SHG). As an exotic class of atomically thin semiconductors, TMDs have emerged as a new generation of electronic and optoelectronic devices. MoS_2 monolayers and single crystalline thin films were deposited on Si substrates by a high-temperature tube furnace-based physical transport CVD system. MoS_2 monolayers showed SHG signals conducted by a homebuilt

optical microscope system with filters to block the fundamental and higher frequency lasers. It was found that powerful SHG signals can be generated from single crystalline thin films compared to monolayers, indicating that the intensity of the non-linear optical responses is proportional to the number of layers. We have successfully mapped SHG profiles on monolayers and thin films through reflection mode by an optical detector, and the maps are analogous to their optical microscopic images. The mapping technique utilizes the intensity contrast of reflected lasers between the SHG area and the substrate region, which is different from the general method used by others. Powerful SHG signals are generated from thick single crystalline thin films, potentially enabling immediate applications in optoelectronic devices and SHG light generators.

5:00 PM QT03.05.06
Understanding The Role of Defects in WS_2 Layer in Contact with ZnO Substrate Dedi Sutarma and Peter Kratzer; University of Duisburg-Essen, Germany

The remarkable properties of two-dimensional (2D) materials have garnered significant attention in recent years, and understanding their fundamental behavior is critical for developing next-generation technologies. In this study, we investigate the microscopic behavior of a 2D material, WS_2, with ZnO (1 -1 0 0) taking the role as the substrate as well as charge injection layer in this van der Waals (vdW) heterostructures. Unique combination of tunable optical properties and high carrier mobility of WS_2, as well as ZnO wide band gap, large exciton binding energy and compatibility with existing fabrication technique, provides an attractive outlook for optoelectronic devices. Specifically, we aim to elucidate the role of native defects in WS_2/ZnO, such as sulphur and oxygen vacancies. Using Density Functional Theory (DFT) calculations, we examine the structural and optoelectronic properties of the WS_2/ZnO, including the impact of point defects.

Herein, band alignment of the heterojunction is found to be type I, with the larger band gap in ZnO, which is desirable for using ZnO as an electron injector for radiative recombination in monolayer WS_2 forming the active layer in a light-emitting device. Our results demonstrate that defects can significantly modulate the electronic properties of the interface, including band alignment and charge transfer. Furthermore, absorption and Raman spectra are calculated to understand the optical behavior of this system. These insights give crucial information for the design and optimization of devices based on 2D materials, and offer a pathway for enhancing their performance in a wide range of applications.

5:00 PM QT03.05.07
Bandgap Opening in Monolayer $MoSe_2$ Induced by Selenium Vacancies Zhuohang Yu, Natalya Sheremetyeva, Shreya Mathela, David Sanchez, Alexander J. Sredenschek, John Asbury, Vincent Meunier and Mauricio Terrones; The Pennsylvania State University, United States

Transition metal dichalcogenide (TMD) monolayers hold great promise for advancing next-generation electronics and optoelectronics. The synthesis of large-area TMD monolayers with a high degree of crystallinity is crucial for enabling mass production and real-world applications. However, the influence of structural defects on the optical properties of these two-dimensional (2D) materials remains unclear. In this study, we demonstrate a method for synthesizing $MoSe_2$ monolayers with high concentrations of selenium vacancies. Using liquid-assisted chemical vapor deposition and by controlling the duration of the selenium feedstock during synthesis, we were able to introduce selenium vacancies into $MoSe_2$ monolayer flakes. As the flakes grew, we observed that double-selenium vacancies became more frequent at the edges of the flakes when compared to the central regions, whereas the concentration of single-selenium vacancies remained relatively constant throughout the entire flake of $MoSe_2$. These observations were confirmed by atomic-resolution high-angle annular dark field scanning transmission electron microscopy (HAADF-STEM). Furthermore, femtosecond transient absorption spectroscopy revealed a notably accelerated decay rate at the edges of the flakes, implying a higher likelihood of nonradiative transitions related to defects (e.g. double-selenium vacancies). Interestingly, photoluminescence (PL) spectroscopy showed an increase of approximately 40 meV in the energy of emission for both excitons A and B at the flake's edges when compared to the central region. Laser power-dependent PL measurements performed at the edge of the samples indicated a linear power relationship with the emission on the edge, suggesting the nature of a free exciton. Through first-principles density functional theory calculations, we confirmed that the selenium vacancy concentration is correlated with an increased bulk bandgap, which confirmed our observations in the PL measurements. These findings not only unveil the growth mechanism of liquid-assisted chemical vapor deposition on $MoSe_2$, but also contribute to a better understanding of the role of double-selenium vacancies in tailoring the optical properties of $MoSe_2$ monolayers.

5:00 PM QT03.05.08
White-Light Emission and Diffusion of Self-Trapped Excitons in Antimony- and Bismuth-Based Hybrid Perovskites Philip Klement[1], Lukas Gümbel[1], Meng Yang[2], Johanna Heine[2] and Sangam Chatterjee[1]; [1]Justus Liebig University Giessen, Germany; [2]Philipps-Universität Marburg, Germany

Lead halide perovskites have set the stage for the emergence of main-group metal halide materials as promising candidates for next-generation optoelectronics, spanning applications like solar cells, light-emitting diodes, lasers, sensors, and photo-catalysis. Within these materials, efficient light-emission arises from self-trapped excitons, where excitations create transient defects in the crystal lattice that effectively capture excitons.

However, the complex interplay of factors, including ground- and excited-state lattice distortions, lattice softness, and electron-phonon coupling strength, presents a challenge in establishing the structure-property relationship. This complexity hinders the targeted design of optical properties and necessitates a deeper exploration of the influence of elemental composition and anion dimensionality.

In this study, we investigate two families of antimony and bismuth halide compounds that systematically vary in composition, anion dimensionality, connectivity, and the organic cation. These compounds possess crystal structures that facilitate self-trapped exciton formation, resulting in broad photoluminescence spectra with pronounced Stokes shifts. Our analysis identifies the relevant factors influencing bright white-light emission and quantifies the electron-phonon coupling strength, expressed by the Huang-Rhys factor (ranging from 5 to 22 in these materials). Furthermore, we investigate the diffusion of self-trapped excitons through temporally- and spatially resolved photoluminescence spectroscopy.

The insights gained from this research deepen our understanding of the emission mechanisms in hybrid halide perovskites, promising to guide the development of advanced optoelectronic materials.

5:00 PM QT03.05.09
Tunable White-Light Emission from Self-Trapped Excitons in Ultrathin Sheets of a Low-Dimensional Hybrid Perovskite Philip Klement[1], Natalie Dehnhardt[2], Chuan-Ding Dong[3], Florian Dobener[1], Julius Winkler[2], Samuel Bayliff[4], Detlev Hofmann[1], Peter Klar[1], Stefan Schumacher[3], Johanna Heine[2] and Sangam Chatterjee[1]; [1]Justus Liebig University Giessen, Germany; [2]Philipps-Universität Marburg, Germany; [3]Paderborn University, Germany; [4]The University of Oklahoma, United States

Low-dimensional organic-inorganic perovskites complement the advantages of two classes of materials for next-generation optoelectronics: They combine customized building blocks for atomically thin, layered materials with the enhanced light-harvesting and -emitting capabilities of perovskites. These materials promise a playground for exploring novel phenomena driven by the dynamic interplay of electronic, photonic, and vibrational excitations.

Traditionally, the prevailing belief has been that in-plane covalent interactions are an absolute prerequisite for forming atomically thin materials. This belief has, in turn, limited the range of candidates for 2D materials.

In this study, we challenge this prevailing paradigm and present single layers of the one-dimensional organic-inorganic perovskite $[C_7H_{10}N]_3[BiCl_5]Cl$.[1] Its unique crystal structure facilitates the exfoliation of single layers and the formation of self-trapped excitons, resulting in tunable white-light emission. Remarkably, the thickness-dependent behavior of exciton self-trapping leads to an unprecedented photoluminescence shift of 0.4 eV between bulk crystals and ultrathin sheets.

Our research demonstrates that even 1D covalent interactions suffice to create atomically thin materials, granting access to unique photophysics. These findings enable a versatile construction principle for identifying and creating two-dimensional materials, eliminating the prior constraint of covalently bonded 2D sheets.

5:00 PM QT03.05.10

Elucidating The Impact of Niobium Substitution in WSe_2 Nanosheets through Monochromated EELS, 4D-STEM and Deep Neural Networks

Tinsae Alem[1], Kevin Roccapriore[2], Eric R. Hoglund[2], Pulickel Ajayan[3], Jordan A. Hachtel[2], Kory D. Burns[1], Anand B. Puthirath[3] and Anchal Srivastava[3]; [1]University of Virginia, United States; [2]Oak Ridge National Laboratory, United States; [3]Rice University, United States

Adding an additional degree of freedom to two-dimensional layered materials through alloying emerges as a suitable technique to tailor its thermal and optoelectronic properties. [1] Unfortunately, the relative concentration of the film can change drastically at micron-length scales, [2] making it difficult to directly correlate the true stoichiometry of a material with its respective properties. In this contribution, we first use aberration-corrected scanning transmission electron microscopy (STEM) and 4D-STEM to map out atomic positions in $Nb_{1-x}W_xSe_2$ and the crystalline phase of the material. Next, we use monochromated electron energy loss spectroscopy (EELS) to measure lattice phonon modes over a range of the alloying content. Last, with the assistance of deep neural networks, we extract coordinates and type/class of the atoms to correlate localized atomic displacements of atoms in the WSe_2 nanosheet and statistical inference on the atomic distributions. This work aims to help understand the correlation between phase, stoichiometry, and lattice phonon modes in ternary alloys of layered materials.

Star-Shaped WS_2 Monolayers with Twin Grain Boundaries Promoted by Molybdenum Atoms

Na Zhang[1], David Sanchez[1], Nadire Nayir[2,1], Yanzhou Ji[3], Yueze Tan[1], Natalya Sheremetyeva[1], Swarit Dwivedi[1], Mengyi Wang[1], Nannan Mao[4], Tianyi Zhang[4], Da Zhou[1], Zhuohang Yu[1], Andres Fest Carreno[1], Adri Van Duin[1], Vincent Meunier[1] and Mauricio Terrones[1]; [1]The Pennsylvania State University, United States; [2]Istanbul Technical University, Turkey; [3]The Ohio State University, United States; [4]Massachusetts Institute of Technology, United States

Monolayers of transition-metal dichalcogenides (TMDs) exhibit fascinating properties that make them attractive in optics, electronics[a], spintronics, and valleytronics[b], and it is of vital importance to understand and control their morphology and tune their physical properties[c]. However, the origin of their morphology evolution is still highly elusive, which hinders the synthesis of desired morphologies for specific applications. Herein, we report the controlled synthesis and formation mechanism of star-shaped WS_2 monolayers by adding trace concentrations of molybdenum using a liquid-phase precursor-assisted approach. Fluorescence imaging and photoluminescence (PL) mapping of six-arm stars revealed bright lines between adjacent arms. To correlate the morphology and optical properties with the microstructure, second harmonic generation (SHG) microscopy and dark-field transmission electron microscopy (DF-TEM) were implemented to confirm the presence of polycrystal domains with a 60° lattice misorientation and a mirror twin grain boundary. Detailed analysis of the grain boundary and molybdenum atom distribution was assessed using high-resolution, high angle annular dark-field scanning transmission electron microscopy (HAADF-STEM). The relationship of the growth morphology of WS_2 stars and the molybdenum to tungsten ratio of the precursor was also carefully investigated. In corroboration with the experimental results, we further developed a multiscale model which combines density functional theory, ReaxFF based molecular dynamics simulations, a Wulff construction and a phase-field model, which demonstrated that the anisotropy of grain boundary (GB) energy due to molybdenum doping can lead to the star morphologies of WS_2. Our study provides further insights into controlling the morphology of crystalline TMD monolayers, with implications for the development of field-programmable semiconductor memristor devices.

Self-Powered Photodetectors Based on Ruddlesden-Popper 2D Hybrid Perovskites with Carbazole Derivatives

Anna N. Alphenaar, Xiaoyu Zhang and Qiuming Yu; Cornell University, United States

Recently, carbazole-based organic cations have attracted the interests of scientists in a variety of fields for their potential application in 2D layered hybrid perovskite solar cells. These materials have demonstrated enhanced stability compared to other 2D and 3D hybrid perovskites
which could allow them to achieve the level of self-sufficiency and environmental durability required of commercial solar cells. However, the potential incorporation of these highly efficient materials in photodetection has been largely unexplored. In this study, we synthesized CzEAP, a 2D layered organic-inorganic hybrid perovskite (OIHP) containing PbI_2 and a large organic ammonium 1-(9H-carbazol-9-yl) ethanaminium iodide (CzEAI) in a 1:2 molar ratio. We developed a series of thin films and devices in the configuration ITO/PEDOT:PSS/$(CzEA)_2PbI_4$/PCBM/BCP/Al using this novel OIHP. We conducted atomic force microscopy, UV Vis, photoluminescence, and external quantum efficiency measurements on these films and devices to assess their surface and optical properties. We also determined the hole mobility of CzEAP-based hole only devices in the configuration ITO/PEDOT:PSS/$(CzEA)_2PbI_4$/MOO_3/Ag. Through optimization of the deposition procedure for this perovskite, we constructed novel photodetector

devices with a specific detectivity of 6.95×10^{10} Jones at 485 nm illumination and the ability to operate in a self-powered condition at 0V. The development of highly efficient self-sustaining photodetectors is essential to the progression of a wide range of fields including optical communications, security, video imaging, biomedical imaging, motion detection, and gas sensing.

5:00 PM QT03.05.13
Triexciton Emission and Multiexcitonic Optical Gain in 2D Perovskites Vadim Trepalin, Yang Ding and Masaru Kuno; University of Notre Dame, United States

Over the last decade the interest in 2D and quasi-2D perovskites has been growing rapidly thanks to their superior stability and unique optoelectronic properties as compared to the more commonly studied 3D perovskites. Spatially separated layers of metal-halide octahedra in these materials naturally form quantum wells with strongly pronounced excitonic effects due to both quantum and dielectric confinements. Exciton binding energies of up to several hundred millielectronvolts facilitate formation of stable multiexcitonic complexes such as biexcitons and even triexcitons under relatively low excitation intensities at cryogenic temperatures. Multiexciton radiative recombination enables a highly efficient pathway for light amplification and thus, these materials show a great potential in cost-efficient laser applications as optical gain media. Moreover, existence of stable triexcitons makes 2D perovskites a unique platform to study the exotic world of many-body physics.
In the present work we investigate the formation and radiative recombination of single excitons and multiexcitonic complexes, including rarely observed triexcitons, in the single crystals of phase-pure quasi-2D Ruddlesden-Popper perovskites $(PEA)_2MAPb_2I_7$ and $(n\text{-}BuA)_2MAPb_2I_7$ (PEA = phenethylammonium, MA = methylammonium, n-BuA = n-butylammonium). By means of time-integrated and time-resolved photoluminescence spectroscopies we confirm the existence of stable triexcitons at cryogenic temperatures after high-energy femtosecond pulsed laser excitation. We also support our experimental findings with a developed kinetic model of a dynamic equilibrium between excitonic species that qualitatively explains different laser fluence-dependent behaviors of each excitonic transition. Additionally, we observe Amplified Spontaneous Emission on single crystals of $(PEA)_2MAPb_2I_7$ with threshold fluences as low as ~2 $\mu J\ cm^{-2}$ and estimate optical gain coefficient of ~1100 cm^{-1} using the Variable Stripe Length method. These promising lasing characteristics and strong excitonic effects together with low-cost solution-based synthetic methods, compositional tunability and enhanced stability make 2D perovskites a unique class of materials for future light-emitting applications and studies of higher order exciton physics.

5:00 PM QT03.05.14
Strain-Engineered Thermophysical Properties ranging from Band-Insulating to Topological Insulating Phases in β-Antimonene Sumit Kukreti; Indian Institute of Technology Jodhpur, India

Employing strain may lead to unusual modifications in the material's properties. Low-dimensional materials having large mechanical strength are well suited for strain engineering. In our work, we present the structural, electronic, thermal, and vibrational characteristics along with the phonon and carrier dynamics of β-Sb elemental monolayers for achieving the band-insulating phase at no strain and topological insulating phase at ~15% biaxial strain. The weakened π and σ bonds under strain, leading to anharmonicity in the system. It is further reflected by the drop in lattice thermal conductivity (κ_l) from 4.5 to 3.1 $W\ m^{-1}\ K^{-1}$ at ~15% strain, i.e., in the topological phase. Helical edge states at 15% strain and meeting the Z_2 invariant criterion confirm the non-trivial topological state. Here we noticed the significant contribution of the out-of-plane A_{1g} vibrational mode in the topological phase compared with the band-insulating phase. Importantly, the dominance of the out-of-plane optical modes contributes significantly to the topological phase along the band edges, which is primarily due to the reduced buckling height under strain. This work emphasizes the microscopic origin of the onset of the topological phase in strained β-Sb monolayers and provides strain-engineered structure–property correlations for better insights.

5:00 PM QT03.05.15
Charge and Energy Transfer Across the Organic-Inorganic Interfaces of Two Dimensional Lead Halide Perovskites Angana De and Libai Huang; Purdue University, United States

Creating heterojunctions enables the amalgamation of optimal properties from diverse materials, effectively bypassing individual bottlenecks. The essential photophysical phenomena in these materials are propelled by charge and energy transfer across these heterojunctions, making a comprehensive understanding of these processes imperative for optimizing such systems for energy conversion and harvesting applications. In our work on pyrene-based quasi-2D lead iodide perovskites, we explore how band engineering can instigate the formation of distinctive excited states and diverse optical phenomena. We conduct an in-depth analysis of their underlying mechanisms, also examining their competition with other parasitic processes. For the n =1 perovskite, efficient triplet energy transfer (TET) occurs from the inorganic sublattice to the organic layer, within the Marcus inverted domain. This transfer is driven by quantum tunneling, resulting in rarely witnessed temperature-invariant TET rates. On the other hand, the n =2 perovskite exhibits no TET. Instead, we observe the emergence of long-lived and mobile 'interlayer' excitons, originating from ultrafast charge transfer across the organic-inorganic interface.

Phonon-Induced Ultrafast Exciton Decomposition in Transition Metal Dichalcogenides: An *Ab Initio* Approach Tomer Amit and Sivan Refaely-Abramson; Weizmann Institute of Science, Israel

Underlying relaxation processes following light excitation in semiconductors are key in materials-based quantum information science. These processes are broadly studied in transition metal dichalcogenides (TMDs), where constructed atomistic design allows for tunable excited-state properties, lifetime, and stability. In this talk, I will describe our new ab initio theoretical approach to compute exciton decomposition in these systems, paving a route to explore microscopic processes occurring between optical absorption and emission. Our approach, based on a Lindblad density matrix formalism, captures quantum many-body effects by combining predictive assessment of the exciton states and a band-resolved analysis of their scattering with phonons. In particular, we explore the effect of mixed exciton states on both momentum and spin transitions, and study how these vary as a function of layer composition. Our findings supply an understanding of the underlying exciton relaxation mechanisms, offering new insights into the concept of excitons as stable quantum states in functional materials.

Layered and Low-Dimensional Halide Perovskites: Electronic Structure, Optical Properties and Charge Carrier Mobilities from First-Principles.
George Volonakis; Université de Rennes, France

Ab initio calculations are becoming more and more efficient and have emerged as an indispensable tool to characterize and understand these complex systems. In particular, for halide perovskites and perovskite-like compounds, over the last decade, such computational approaches have been extensively employed and successfully unveiled the underlying atomic-scale physical mechanisms of these exciting materials. In this talk, I will overview our most recent results on prototypical structure of layered halide perovskites, vacancy ordered double perovskites, and low dimensional halide perovskite-like materials. I will present the key details of their electronic structure for each type of system that define their experimentally observed optical properties and achieved performances [1,2,3]. In the last part of my talk, I will show our latest findings on the effects of structural dimensionality on the charge carrier transport properties when comparing three-dimensional ABX_3 and layered halide perovskites.

Mechanism of Circular Dichroism in Chiral 2D Halide Perovskites Peter C. Sercel[1], Ruyi Song[2], Matthew P. Hautzinger[3], Volker Blum[2] and Matthew C. Beard[3]; [1]Center for Hybrid Organic Inorganic Semiconductors for Energy, United States; [2]Duke University, United States; [3]National Renewable Energy Laboratory, United States

A key motivator for research in hybrid organic-inorganic metal halide perovskites (HOIPs) is the potential to combine distinct characteristics of the inorganic and organic constituents to elicit desirable functional properties. For example, incorporation of chiral organic cations lacking a center of inversion into layered 2D halide perovskites with large spin-obit coupling has been shown to result in structural chirality transfer, leading to Rashba/Dresselhaus-type spin-splitting while at the same time leading to the emergence of chiroptical effects such as circular dichroism (CD) [1,2]. Here we address the question: What is the connection, if any, between the spin textures that emerge by virtue of the structural chirality transfer and the emergence of chiroptical properties associated with the band edge exciton transitions? In this talk we explore the mechanism of excitonic CD in chiral 2D layered perovskites utilizing an analytical k.p/effective mass theory model, parameterized by hybrid density functional theory calculations. We develop analytical expressions for the electric and magnetic dipole transition matrix elements and show the direct connection between particular spin textures and the emergence of CD in these materials [3].

Atomistic Mechanisms of Temperature-Induced Phase Transitions of 2D Lead Halide Perovskite by Molecular Dynamics Simulation Reza Namakian, Maria Garzón Vargas, Qing Tu, Ali Erdemir and Wei Gao; Texas A&M University, United States

A series of phase transitions has been experimentally observed in 2D lead halide perovskites within the Ruddlesden-Popper category in response to temperature changes. With increasing temperature, their crystal symmetry transitions from a low-symmetry phase to a high-symmetry phase, evident from the transition from a triclinic to an orthorhombic crystal system. This phase transition has been primarily attributed to the melting of organic spacer molecules. Separate experimental observations have also suggested that the transition is prompted by the disruption of hydrogen bonds between the ammonium headgroup of the spacer molecules and the iodides of the octahedra in the inorganic layers. To the best of our knowledge, there is a notable absence of atomistic modeling in the literature to provide a clear understanding of the atomistic mechanisms underpinning this transition.

In this study, we utilize molecular dynamics (MD) simulations to gain an in-depth understanding of the phase transition mechanisms in $BA_2MAPb_2I_7$, a compound containing n-butylammonium (BA) as the organic spacer molecule. In agreement with prior experiments, our results indicate that both the melting of the BA ligands and the hydrogen bond breakage play pivotal roles in facilitating the phase transition. At the onset of phase transition as temperature rises, the BA ligands begin localized rattling motion and undergo partial melting at the tail C-C bond. As the temperature continues to increase, the melting extends through the entire ligand backbone, intensifying the rotational motion of the ligands and causing the top and bottom ligands to swipe against each other. In addition, our study offers solid evidence supporting earlier experimental hypothesis regarding the in-plane shear deformation between adjacent organic layers at the onset of phase transition during the contraction of BA ligands. Intriguingly, our analysis unveiled another synchronized in-plane shear deformation within the inorganic layer. Such dual shearing effect results in notable octahedral distortions, which are characterized by the bond length distortion and bond angle variation of the octahedron.

In summary, our study bridges the gap between experimental observations and atomistic modeling and offers some unique understanding of the complex mechanisms underlying phase transition of 2D lead halide perovskites. Our findings pave the way for future research aiming to optimize the thermal stability and performance of these materials in various applications.

10:45 AM QT03.06.05
Magnetic-Field-Induced Wigner Crystallization of Charged Interlayer Excitons in Transition Metal Dichalcogenide Bilayers Igor Bondarev[1] and Yurii E. Lozovik[2,3,4]; [1]North Carolina Central University, United States; [2]Institute of Spectroscopy, RAS, Russian Federation; [3]Tikhonov Moscow Institute of Electronics & Mathematics, Russian Federation; [4]Russian Quantum Center, Russian Federation

We develop the theory of the magnetic-field-induced Wigner crystallization effect for charged interlayer excitons (CIE) discovered recently in transition-metaldichalcogenide (TMD) heterobilayers [1]. The Wigner crystal phase has been one of the longest anticipated exotic correlated phases, a phase that is very closely related to excitonic insulator, and originally was thought of as a periodic array of electrons held in place when their Coulomb repulsion energy

exceeds the Fermi and thermal fluctuation energies. Here, we derive the ratio of the average potential interaction energy to the average kinetic energy for the many-particle CIE system subjected to the perpendicular magnetic field of an arbitrary strength, analyze the weak and strong field regimes, and discuss the 'cold' crystallization phase transition for the CIE system in the strong field regime [2]. We also generalize the effective g-factor concept previously formulated for interlayer excitons [3], to include the formation of CIEs in electrostatically doped TMD heterobilayers. We show that magnetic-field-induced Wigner crystallization and melting of CIEs, the two correlated phases that block or allow the CIE transport in the system, can be observed in strong-field magneto-photoluminescence experiments with TMD heterobilayes of systematically varied electron-hole doping concentrations. Our results advance the capabilities of the TMD bilayers as a new family of transdimensional quantum materials. – [1] L.A.Jauregui, et al., Science 366, 870 (2019); [2] I.V.Bondarev and Yu.E.Lozovik, Communications Physics (Nature) 5, 315 (2022); [3] P.Nagler, et al., Nature Communications 8, 1551 (2017).

Rational Design of Point Defects with Small Electron-Phonon Coupling in 2D Materials Fatimah F. Habis[1,2] and Yuanxi Wang[1]; [1]University of North Texas, United States; [2]Jazan University, Saudi Arabia

Point defects in semiconductors have emerged as an attractive candidate for applications in quantum information science. Due to their ability to create well-localized states within the band gap, point defects can serve as effectively isolated atoms that can be utilized as single photon emitters (SPEs) and qubits.

Small Electron-phonon coupling is a key factor in producing higher photon indistinguishability which determines the suitability of defect systems as SPEs. Huang-Rhys (HR) factors are commonly calculated to measure the degree of electron-phonon coupling in a system. However, not only is the computation of HR factors a complex task, but once determined, they are often used solely as a numerical value without any effort to establish a meaningful connection between HR factors and the physical defect system. Establishing such a correlation would enable the development of a rational design principle for defects, with the goal of minimizing HR factors.

We propose that small HR factors are linked to the preservation of bonding-character between the initial (occupied) and final (unoccupied) states involved in a specific transition. We demonstrate this principle for realistic SPEs candidates in hBN defect systems. HR factors are first calculated through first-principles employing the one-dimensional configuration coordinate diagram (1DCCD) approximation, then compared with full calculations involving phonon spectra, where we carefully extrapolate spectral functions towards the dilute defect limit. These extrapolations are carried out through an embedding method that depends on the limited range of interatomic force constants within covalent semiconductors. Calculated HR factors are then related to the degree of bonding-character similarity between the excited and ground states.

11:15 AM QT03.06.07
Electronic Structure and Conductivity of $Ge_2Sb_2Te_5$ Heterostructures with Different Layer Orderings from Density Functional Calculations Tomi Ketolainen and Janne Kalikka; Tampere University, Finland

Chalcogenide phase change materials (PCMs) have been studied extensively in the past decades due to promising applications comprising e.g. memory devices and optical systems. In these materials, an external electric voltage can be used to transition from an amorphous phase to a crystalline one, leading to a significant change in the electrical resistivity and optical reflectivity. One scientifically interesting and technologically relevant chalcogenide PCM is $Ge_2Sb_2Te_5$.

Previous experimental studies suggest that a large contrast in the electrical conductivity of $Ge_2Sb_2Te_5$ can be achieved also in heterostructures comprising specific sequences of single-atom layers without the amorphous-to-crystalline phase transition. In this work, we explore the effect of different layer orderings on the electrical conductivity and basic electronic properties of $Ge_2Sb_2Te_5$ heterostructures. We employ the VASP code package based on density functional theory (DFT) along with the DFT-D3 van der Waals correction and BolzTraP2 code to compute electrical conductivity for six previously investigated stacking configurations. Furthermore, the lattice parameters, electronic band gaps, and electronic band structures are calculated for our set of 18-atom unit cells by using the DFT method.

Our calculations show that the in-plane (along the atomic layers) electrical conductivity is clearly larger than the out-of-plane (perpendicular to the atomic layers) electrical conductivity. Some layer orderings result in larger out-of-plane electrical conductivities than the other structures. The PBE band gap calculations show that some structures are metallic whereas others are semiconducting with band gaps of 0.2-0.4 eV. The PBE band structure calculations confirm these results. According to the HSE06 calculations, all structures are semiconducting with band gaps between 0.2 and 0.7 eV. Our studies indicate that the layer ordering in $Ge_2Sb_2Te_5$ heterostructures affects the electrical conductivity remarkably although the differences between the selected six structures are not as large as those observed experimentally in $Ge_2Sb_2Te_5$ heterostructures.

SESSION QT03.07: 2D Halide and Chalcogenides Semiconductors VI – Physics

Optical Sensing of Strongly Correlated Electronic Phases in 2D Materials Tomasz T. Smolenski; ETH Zurich, Switzerland

When the Coulomb repulsion between itinerant electrons dominates over their kinetic energy, the electrons in solid state materials start to develop strong correlations. A paradigm state of matter that is expected to emerge in this regime is an electronic Wigner crystal, in which the electrons spontaneously break continuous translation symmetry and arrange themselves into a periodic lattice mimicking that of the real crystals. In this talk, I will review our recent experimental explorations of strongly correlated electronic phases in transition metal dichalcogenides (TMD) and their van der Waals heterostructures. In particular, I will present our novel spectroscopic technique allowing us to detect the Wigner crystal in a TMD monolayer through the periodic potential it generates for the excitons [1]. This potential allows the excitons to undergo a Bragg diffraction, which gives rise to a new, Bragg-umklapp transition in the optical excitation spectrum that heralds the presence of a crystalline electronic order.

In the second part of the talk, I will describe magnetic properties of the electrons forming a charge-ordered Mott insulating state in a MoSe2/WS2 bilayer that hosts strong moire potential. In particular, I will show that when such a Mott state is electron-doped, the system exhibits unusual ferromagnetism [2] that is driven not by Coulomb exchange interactions, but arises due to minimization of kinetic energy of itinerant electrons. This observation provides

direct evidence for the Nagaoka ferromagnetism in an extended two-dimensional system.

From Spin Dynamics of Charge Carriers to Fundamental Insights into The Band Structure of Lead Halide Perovskites Erik Kirstein[1], Dmitry R. Yakovlelv[1], Mikhail M. Glazov[2], Evgeny A. Zhukov[1], Dennis Kudlacik[1], Ina V. Kalitukha[1], Victor F. Sapega[2], Grigorii S. Dimitriev[2], Marina A. Semina[2], Mikhail O. Nestoklon[1], Evgeny L. Ivchenko[2], Natasha E. Kopteva[1], Dmitry N. Dirin[3], Olga Nazarenko[3], Maksym V. Kovalenko[3,4], Andreas Baumann[5], Julian Höcker[5], Vladimir Dyakonov[5] and Manfred Bayer[1]; [1]TU Dortmund, Germany; [2]Ioffe Institute, Russian Federation; [3]ETH Zürich, Switzerland; [4]Empa–Swiss Federal Laboratories for Materials Science and Technology, Switzerland; [5]Julius-Maximilians-Universität Würzburg, Germany

The emerging field of lead halide perovskite semiconductors offers a plethora of promising material compositions for applications. Experimentally exploring all of these combinations is challenging, especially in light of the increasing number of tandem devices. Theoretical models help predict suitable candidates, but require a fundamental understanding of the perovskite band structure. This is where our experimental methods come into play. Experimental spin physics helps improve, validate, and substantiate these models and provides insight into the underlying physics. The experimental method uses the optically oriented spin property of resident and photoexcited charge carriers as a probe. A strong and distinct charge carrier spin signal, typically the electron and hole spin simultaneously, can be observed and its spin precession resolved in time. The spin dynamics of the charge carriers is in the ns range and allows intense studies in different directions. The spin reveals the pronounced interactions between the charge carriers and their environment and is sensitive to band mixing, allowing, for example, the determination of the importance of distant bands as well as the study of the effective mass of the charge carriers. The methodological tools include time-resolved pump-probe Kerr spectroscopy, spin-flip Raman scattering, and optical orientation, which we have successfully applied to macroscopic perovskite crystals, nanocrystals, and 2D films.

Two-Dimensional Lead Organic Chalcogenide Materials with Strong Electron-Phonon Coupling Hanjun Yang, Sagarmoy Mandal, Yoonho Lee, Jee Yung Park, Libai Huang, Ming Chen and Letian Dou; Purdue University, United States

Two-dimensional (2D) metal organic chalcogenides (MOCs) such as silver phenylselenolate (AgSePh) have emerged as a new class of 2D materials due to their unique optical properties. However, these materials typically exhibit large band gaps, and their elemental and structural versatility remains significantly limited. In this work, we synthesize a new family of 2D lead organic chalcogenide (LOC) materials with excellent structural and dimensionality tunability by designing the bonding ability of the organic molecule and the stereochemical activity of the Pb lone pair. The introduction of electron-donating substituents on the benzenethiol ligands results in a series of LOCs that transition from 1D to 2D, featuring reduced band gaps (down to 1.7 eV), and broadband emission. Furthermore, strong electron-phonon coupling is characterized by the presence of coherent optical phonons with long dephasing time, suggesting the low phonon anharmonicity in the LOC materials

2:45 PM QT03.07.04
Direct Observation of Polaron Vibronic Progression in 2D Layered Perovskites Mateusz Dyksik; Wroclaw University of Science and Technology, Poland

Hybrid perovskites have emerged as a new class of materials with unique electronic properties, which are inherited from both their organic and inorganic constituents. The inorganic framework provides a basis for the semiconducting band structure, whilst the organic molecules stabilize the lattice, indirectly controlling the optical properties. These soft and ionic crystals possess many new and unexpected properties bridging the worlds of classic and organic semiconductors.

A direct consequence of the soft ionic lattice is the significant coupling of charge carriers to the ions of the lattice (i.e. the electron-phonon interaction). The microscopic description of the electron-phonon coupling is nontrivial, essentially due to the fact that it is mediated by a large anharmonicity and dynamic disorder, which requires the introduction of polarons – a quasiparticle representing charge carriers coupled to the lattice vibrations. Polarons are often regarded as a charge carrier “dressed” in a phonon cloud and are characteristic excitations for organic and ionic semiconductors. Polarons are widely invoked to understand the low mobilities of charge carriers, the long carrier lifetimes and diffusion lengths in metal halide perovskites.

Despite tremendous progress in understanding of the fundamental properties of 2D layered halide perovskite, unresolved questions of paramount importance remain to be elucidated. The most important is the origin of the complex optical response of these materials, which cannot be understood by considering only the band structure of these materials. Starting with the pioneering work of Noboru Miura, already 30 years ago, the peculiar line shape of both emission and absorption, composed of equidistant signals separated by tens of meV, is still under debate. Although multiple explanations were suggested in the intervening years, to date the understanding of linear optical response of 2D layered perovskites remains vague requiring further clarification, not only for fundamental understanding of these materials, but also for successful deployment in future opto-electronic devices.

In this work we provide, for the first time, a conclusive proof that the complex structure observed in the optical response of 2D layered perovskites is due to the formation of polarons. Using resonant Raman scattering to investigate various 2D layered perovskites, we observe a spectacular difference of the Raman response with respect to current literature data. Under resonant excitation conditions, the Raman scattering spectrum is dominated by a feature in the high-frequency region >200 cm^{-1} (>25 meV), in striking contrast to typical non-resonant Raman spectra, where the scattering is dominated by the expected low-frequency optical modes (<50 cm^{-1}). This newly observed Raman signal is exactly at the energy corresponding to the spacing observed in absorption/emission (i.e. 280 cm^{-1} (35 meV) for $(PEA)_2PbI_4$) and possess all the characteristics of polarons, allowing for the first time to comprehensively understand the emission and absorption spectra of 2D perovskites. This is the first direct correlation between absorption spectra and Raman studies in these materials.

An analysis of the polaronic response allows us to determine important physical parameters, such as the Huang-Rhys factor, and polaron binding energy. For all investigated samples, we find a consistently large Huang-Rhys factor S>6, indicating a charge carrier – lattice coupling approaching the strong coupling regime. Importantly, the parameters determined in this work are first of their kind for 2D layered perovskites, and could serve as a benchmark for future band structure theory of 2D layered perovskites, including carrier-lattice coupling.

3:30 PM *QT03.07.05
Anomalous Interlayer Exciton Diffusion in WS2/WSe2 Moiré Heterostructure Archana Raja; Lawrence Berkeley National Laboratory, United States

Stacking van der Waals crystals allows for on-demand creation of a periodic potential landscape to tailor the transport of quasiparticle excitations. We investigate the diffusion of photoexcited electron-hole pairs or excitons at the interface of WS2/WSe2 Van der Waals heterostructure over a wide range of temperatures. We observe the appearance of distinct interlayer excitons for parallel and anti-parallel stacking, and track their diffusion through spatially and temporally resolved photoluminescence spectroscopy from 30 K to 250 K. While the measured exciton diffusivity decreases with temperature, it surprisingly plateaus below 90 K. Our observations cannot be explained by classical models like hopping in the moiré potential. Using a combination of ab-initio theory and molecular dynamics simulations, we demonstrate that low energy moiré phonons, also known as phasons, may play a key role in describing and understanding this anomalous behavior of exciton diffusion. In particular, we show that the moiré potential landscape is dynamic down to very low temperatures. Our observations show that the phason modes arising from the mismatched lattices of a moiré heterostructures can enable surprisingly efficient transport of energy in the form of excitons, even at low temperatures.

4:00 PM QT03.07.06
Understanding and Engineering Excitonic Properties in 2d Metal Halide Perovskites John S. Colton[1], Kameron R. Hansen[2], Cindy Wong[3], C. Emma McClure[4], Blake Romrell[1], Michele Eggleston[1], Daniel J. King[5], Carter M. Shirley[1], Andre Schleife[3] and Luisa L. Whittaker-Brooks[2]; [1]Brigham Young University, United States; [2]The University of Utah, United States; [3]University of Illinois at Urbana-Champaign, United States; [4]University of Chicago, United States; [5]University of Wisconsin–Madison, United States

As the field of 2d metal halide perovskites (MHPs) matures, state-of-the-art techniques to measure fundamental properties such as the band gap (E_g) and exciton binding energy (E_b), continue to produce inconsistent values which defy a coherent interpretation. In this work we present the results of a recently published paper [Hansen et al., Matter 6, 3463-3482 (2023)] in which we have used electroabsorption spectroscopy to precisely and unambiguously measure E_g and E_b for 31 different MHP compositions which include variations in metal atoms, halide atoms, organic cation molecules, and "n-number". Among other things the results show a clear and direct correlation between E_g and E_b, and also a clear dependence of E_b on organic cation length which indicates that models of isolated quantum wells cannot in general be used to explain excitonic behavior in 2d MHPs. Instead, we have applied a known superlattice theory of repeating wells and barriers, which includes both quantum and dielectric confinement effects. This theory requires separate knowledge of dielectric constants for wells and barriers, which we were able to deduce in a self-consistent manner for many materials. Using the results of that theory we can tell that the most important parameters that affect E_b are well dielectric constant (metal halide layers), barrier length (organic molecules), and exciton reduced mass which we also relate to the MHP octahedral distortion; and we generate a parameter space map of realistically achievable (E_g, E_b) values. Finally, the dielectric constants required by the theory are between the microwave and optical-frequency dielectric values, indicating that the excitonic interaction is partially screened by phonons.

Magneto-Optical Studies of The Exciton Fine Structure in Two-Dimensional Perovskites Katarzyna Posmyk[1,2], Natalia Zawadzka[3], Lucja Kipczak[3], Mateusz Dyksik[1], Alessandro Surrente[1], Duncan K. Maude[2], Tomasz Kazimierczuk[3], Adam Babinski[3], Maciej R. Molas[3], Watcharaphol Paritmongkol[4,5], William Tisdale[4], Michal Baranowski[1] and Paulina Plochocka[2,1]; [1]Wroclaw University of Science and Technology, Poland; [2]Laboratoire National des Champs Magnétiques Intenses, France; [3]University of Warsaw, Poland; [4]Massachusetts Institute of Technology, United States; [5]Vidyasirimedhi Institute of Science and Technology, Thailand

Two-dimensional (2D) lead halide perovskites are a very interesting group of novel semiconducting materials, considered an alternative for applications in photovoltaics and optoelectronics. Their structure can be seen as the "natural" quantum wells, where slabs of metal-halide octahedral units are surrounded from both sides by large organic cations, acting as potential barriers. As a consequence of the quantum and dielectric confinement, the exciton binding energy can reach several hundreds of millielectronvolts, which results in significant splitting of states of the exciton fine structure. This makes them attractive objects for the investigation of exciton physics, since all excitonic effects are greatly enhanced in this system. Significant state spacing and whether or not the lowest excitonic state interacts with photons are also crucial aspects affecting the performance of a device based on 2D perovskites. Gaining a deeper understanding of the exciton fine structure is therefore very important from the point of view of potential applications.
We combine the optical spectroscopy techniques with the use of magnetic field to investigate the exciton fine structure of perovskite compounds with the general formula (PEA)2(MA)n-1PbnI3n+1, where n=1,2,3,4 denotes the number of octahedra layers within a slab. For the thinnest quantum wells (n=1) we reveal the full exciton fine structure, including the optically inactive dark state. We also observe the bright state oriented out-of-plane of the crystal, located above the in-plane states - contrary to the theoretical predictions. For the first time in 2D perovskites, we observe the lower lying, brightened dark exciton state in the Faraday configuration. Knowing the energies of all four states of the exciton fine structure, we were able to quantify the bright-dark state splitting and the dark exciton g-factor along the c-axis of the crystal, which allowed us to estimate the values of the electron and hole g-factors along this direction [1,2].
Further magnetooptical spectroscopy studies on the perovskite compounds with n=2, 3 and 4 provide valuable information about the evolution of the properties of 2D perovskites with the change of confinement strength, as well as a solid base for further studies of the band structure and excitons in lead halide perovskites.

4:30 PM QT03.07.08
The Phase Transition in HfS_2 Induced by The Pressure Non-Hydrostaticity Igor Antoniazzi[1], Amit Pawbake[2], Natalia Zawadzka[1], Magdalena Grzeszczyk[3], Tomasz Wozniak[1], Jordi Ibanez[4], Zahir Muhammad[5], Weisheng Zhao[5], Clement Faugeras[2], Maciej R. Molas[1] and Adam Babinski[1]; [1]University of Warsaw, Poland; [2]LNCMI, France; [3]National University of Singapore, Singapore; [4]Geosciences Barcelona, Spain; [5]Beihang University, China

Layered van der Waals crystals are an exciting class of materials of properties, which strongly depend on their thickness. Their structure makes them very sensitive to the interlayer spacing, which can be modulated by temperature or strain.This motivates the recent interest in the strain engineering as an effective way to modify their mechanical, optical, and electronic properties.
We have addressed the effect of pressure on hafnium disulphide (HfS2), material of promising electrical properties. We study Raman scattering (RS) in bulk HfS_2 using λ=632.8 nm (1.96 eV) and λ=561 nm (2.21 eV) at room temperature under pressure up to 10 GPa. A methanol-ethanol mixture or crystallographic oil were used in our diamond anvil cell (DAC) as the pressure transmitting medium (PTM).
HfS_2 under ambient conditions adopts the 1T octahedral structure with the RS spectrum dominated by the out-of-plane A_{1g} mode.
A systematic pressure-induced blue-shift of the RS features in the spectrum was observed when hydrostatic conditions of pressure were supported by a

methanol-ethanol mixture as PTM, confirming that no phase transition occurred in HfS_2 up to 10 GPa.
On the contrary, seven new modes appeared in the RS spectrum around P=7 GPa when crystallographic oil was used as PTM. The non-hydrostatic component of pressure in that case, which emerged around P=4 GPa was deduced from the characteristic splitting of ruby-related photoluminescence lines. Both ”low-pressure” and ”high pressure”-related peaks coexisted in the RS spectrum up to P=10 GPa with the former features systematically decreasing their intensity. The ”high-pressure” peaks were observed under decompression down to P=1.2 GPa pointing out to a metastability of the observed transition.
Polarization angle-resolved measurements were performed at 7.4 GPa to study properties of all the observed RS peaks. A strong anisotropy of the RS for both the mode, evolving from the A_{1g} symmetry vibrations and the ”high pressure” modes was observed. Moreover, the effect of excitation energy on the anisotropy was clearly appreciated. In particular for the A_{1g}-related mode, the two-fold (four-fold) polar symmetry of the RS intensity for co- and cross-polarization conditions was observed for l=561 nm (l=632.8 nm) excitation.
We conclude that the observed evolution of the RS spectra under pressure corresponds to the partial phase transition in HfS_2. The transition was triggered around P=7 GPa by the non-hydrostatic component of pressure. Both phases coexist up to P=10 GPa and upon decompression down to P=1.2 GPa. The anisotropy of the RS polar dependence at P=7.4 GaP points out to the distortion of crystal lattice in both co-existing phases. The effect of excitation energy on the A_{1g}-related mode was explained in terms of the non-resonant (λ=632.8 nm) and resonant λ=561 nm) excitation conditions. Our results confirm the critical effect of the PTM on the pressure-induced phase transition in HfS_2, as revealed by the RS spectroscopy.

Reduced screening contributes to the particularly strong Coulomb interaction characteristic of 2D materials[1], which is behind the emergence of exotic quantum many-body phases found therein. While the 2D nature of these material systems complicates the screening description, its understanding is, to date, considered well-established, mainly based on static approaches[2]. Here, we use exciton resonances as probes to study screening in monolayer WSe_2, which we embed in dielectric environments with dielectric constants ranging from 5 to more than 1000. At odds with previous reports[3], we find evidence for an optical bandgap *blueshift* for larger dielectric constants. We understand the experimental findings by developing a fully dynamical approach to the environment dielectric response. Starting from the 3χ model[4], we take the frequency dependence into account via the dynamical dielectric function, both in the bandgap renormalization and in the exciton binding energy calculations. While binding energy remains mainly controlled by low-frequency dielectric screening, we find that high-frequency dielectric response is predominant in bandgap renormalization. Our results show that a fundamental understanding of Coulomb interaction in atomically thin materials cannot ignore dynamical effects. The achieved tunability of the optical bandgap by more than 30 meV, together with the qualitatively different theoretical framework developed, offer new opportunities for tuning the optoelectronic properties of 2D semiconductors and advance the study of many-body interactions in layered materials and their heterostructures.

SESSION QT03.08: 2D Halide and Chalcogenides Semiconductors VII – Chirality
Session Chairs: Erik Kirstein and David Mitzi
Friday Morning, April 26, 2024
Room 444, Level 4, Summit

8:30 AM *QT03.08.01
Phase Purity in Chiral 2D Perovskites Yana Vaynzof[1,2]; [1]Technical University Dresden, Germany; [2]Leibniz Institute for Solid State and Materials Research Dresden, Germany

The introduction of chiral organic spacers in low-dimensional metal-halide perovskites triggers chiroptical activity, making these materials of great interest for spintronic applications. To enable such applications, it is necessary to develop a deep understanding of the structure formation of chiral two-dimensional (2D) perovskites and its impact on their optical properties. In the first part of the talk, I will discuss how changing the processing conditions impacts on the phase purity, microstructure, and chiroptical properties of chiral 2D perovskites. In the second part, I will focus on the optical properties of these materials, focusing in particular on the origin of the common observation of asymmetric shape of their photoluminescence.

9:00 AM *QT03.08.02
Novel Chiroptical Probes to Track Spin & Light in Space and Time in Semiconductors Sascha Feldmann; Harvard University, United States

Solution-processable semiconductors like halide perovskites and certain molecules are promising for next-generation spin-optoelectronic applications [1]. Yet, we still don’t fully understand what governs the excitation and spin dynamics in these materials, and how these are affected by chirality.
In this talk, I will give an overview of our recent efforts to understand the spin-optoelectronic performance of these materials by developing time-, space- and polarization-resolved absorption spectroscopy and microscopy. For halide perovskite films, we find here that locally varying degrees of symmetry-breaking drive spin domain formation within picoseconds [2].
I will then briefly explain the fundamentals and artifacts involved in measuring circularly polarized luminescence (CPL) reliably [3], and finally show our most recent development of full Stokes-vector polarimetry with unprecedented time- and polarization resolution to track the emergence of chiral light emission in these fascinating materials [to be submitted].

The Impact of Anisotropy and Anharmonicity on The Magneto-Optical Properties of Bulk 3D and 2D Lead Halide Perovskites Efrat Lifshitz; Technion-Israel Institute of Technology, Israel

The renaissance of interest in halide perovskites, triggered by their unprecedented performance in optoelectronic applications, elicited worldwide efforts to uncover various intriguing physical properties, with a particular interest in spin-orbit effects. The current work presents magneto-optical experimental evidence for anisotropic electron-hole interactions in the 3D orthorhombic $MAPbBr_3$ and the 2D $(PEA)_2PbI_4$ bulk single crystals. The evidence was seen in the magneto-photoluminescence spectra while monitoring several different crystallographic directions. The observations exposed a highly non-linear response to a magnetic field and asymmetry to the influence of the sign of the magnetic field. A theoretical model implementing anisotropy in the electron-hole interaction, Rashba effect, Landé *g*-factors, and a lesser contribution from an Overhauser effect corroborated the experimental results.

A continuation of the work involved the investigation of the anharmonic ground-state of the $(PEA)_2PbI_4$ compound, using complementary information from low-temperature x-ray diffraction (XRD) to the photoluminescence spectroscopy, which was also supported by density functional theory (DFT) calculations. The study extrapolated four crystallographic configurations from the low-temperature XRD. These configurations imply that the ground state has an intrinsic disorder stemming from two coexisting chiral sub-lattices, each with a bi-oriented organic spacer molecule (see scheme). We further show evidence that these chiral structures form unevenly populated ground states, portraying uneven anharmonicity, where surface effects may tune the state population. Our results uncover a disorder that may be associated with a dynamic Rashba effect. The current efforts include using a unique pump-probe experiment to follow a dynamic Rashba effect. Also, preliminary magneto-photoluminescence of $(F\text{-}PEA)_2PbI_4$ uncovered two opposing chiral structures alone through the entire temperature range under investigation. This result was already corroborated by XRD measurements, confirming the locking of the F-PEA degree of freedom. Further study is ongoing regarding the relation between anharmonicity, the Rashba effect, and the dependence on structure and composition.

Manipulating Chirality of 2D Lead Halide Perovskites via Mixed Chiral and Achiral Organic Ligands Xiaoyu Zhang, Adewale J. Babatunde and Qiuming Yu; Cornell University, United States

Hybrid organic-inorganic halide perovskites have emerged as an important family of materials for optoelectronics with broader applications in solar cells, photodetectors, light-emitting diodes (LEDs), and lasers. As ionic semiconductors, the flexible crystal structures and tunable compositions make it possible to rationally design hybrid halide perovskites with desired properties. Chiral halide perovskites demonstrate such possibility and the breakthrough with respect to the development of a new class of chiral semiconductors, which opens up new applications of hybrid perovskites to chiroptoelectronics, ferroelectrics, and spintronics. One type of chiral perovskites is based on two-dimensional (2D) hybrid organic-inorganic halide perovskites by incorporating chiral organic ligands between achiral inorganic single layers composed of corner-sharing metal-halide octahedra. As a new class of chiral semiconductors, the chirality of hybrid 2D perovskites is attributed to the symmetry-breaking in the inorganic framework induced by the enantiopure chiral organic cations via asymmetric hydrogen bonding interactions, which transfers the structural chirality across the organic-inorganic interface. In this work, we demonstrate that the chirality of 2D halide perovskites can be widely tuned via incorporation of mixed chiral and achiral organic ligands in the organic layer. A broad range of alkyl and aryl chiral and achiral cations are used in forming 2D chiral halide perovskites. Additionally, we also synthesized semiconducting organic cations and integrated into the 2D chiral halide perovskites. To reveal the origin of the chirality, we conducted density functional theory (DFT) calculations to gain the insights of hydrogen bonding and octahedral structure as well as their relationship to the electronic band structure and spin spilt. We also conducted time dependent DFT to calculate circular dichroism (CD) spectra and to understand the correlation of rotatory strength at the orbital symmetry level. We performed temperature dependent synchrotron powder X-ray diffraction (PXRD) and pair distribution function (PDF) measurements and analysis to reveal the structural properties. To understand the chiroptoelectronics embedded in these new chiral perovskites, we conducted temperature dependent circularly polarized photoluminescent (CPPL) and conventional and circularly polarized transient absorption spectroscopy (TAS) measurements. While many phenomena are unknown and needed further investigations, this work provides a new way to manipulate chirality of 2D perovskites, which could lead to broader applications.

10:45 AM QT03.08.05
Enhanced Circular Dichroism and Polarized Emission in an Achiral, Low Bandgap Bismuth Iodide Perovskite Derivative Philip Klement[1], Jakob Möbs[2], Gina Stuhrmann[3], Lukas Gümbel[1], Marius Müller[1], Johanna Heine[2] and Sangam Chatterjee[1]; [1]Justus Liebig University Giessen, Germany; [2]Philipps-Universität Marburg, Germany; [3]Karlsruhe Institute of Technology (KIT), Germany

Lead halide perovskites and related main-group halogenido metalates exhibit unique semiconductor properties, positioning them as promising candidates for next-generation optoelectronics. Their applications span solar cells, light-emitting diodes, lasers, sensors, and photo-catalysis. The approach of assembling customized building blocks into materials with tailored properties opens doors to explore novel phenomena. Recent advances in incorporating chiral organic cations have given rise to chiral metal-halide semiconductors. These materials exhibit intriguing properties such as chiroptical activity and chirality-induced spin selectivity, enabling the generation and detection of circularly polarized light and spin-polarized electrons for applications in spintronics and quantum information.

However, understanding the structural origin of chiroptical activity presents a challenge due to macroscopic factors and experimental constraints.

In our study, we present an achiral perovskite derivative $[Cu_2(pyz)_3(MeCN)_2][Bi_3I_{11}]$ (pyz = pyrazine; MeCN = acetonitrile), which displays remarkable circular dichroism (CD) arising from the material's noncentrosymmetric structure. CuBiI features a unique crystal structure as a poly-threaded iodido bismuthate, with $[Bi_3I_{11}]^{2-}$ chains are intertwined within a cationic two-dimensional coordination polymer. The material exhibits a low, direct optical band gap of 1.70 eV. Notably, single crystals exhibit both linear and circular optical activity with a substantial anisotropy factor of up to 0.16. Intriguingly, despite the absence of chiral building blocks, CuBiI exhibits a substantial degree of circularly polarized photoluminescence, reaching 4.9%. This value is comparable to the results achieved by incorporating chiral organic molecules into perovskites, typically ranging from 3% to 10% at zero magnetic field.

Our findings shed light on the macroscopic origin of CD and provide valuable insights for the design of materials with high chiroptical activity.

Photonic Ferromagnets: Leveraging Chemistry to Develop New Van der Waals Ferromagnets with Strongly Coupled Spin and Optical Functionalities Kelly M. Walsh, Kimo Pressler, Thom Snoeren, Rachel Smith and Daniel R. Gamelin; University of Washington, United States

Materials with strongly coupled electronic, magnetic, and optical properties are highly desirable for application in next-generation spin-based devices. Magnetic van der Waals materials have been demonstrated to be attractive candidates for archetypal spin-based electronics, but such ferromagnets are often non-emissive or show only broad, nondescript luminescence. Moreover, their chemical parameter space is often largely unexplored. This presentation will describe the use of composition to develop new van der Waals materials that both are ferromagnetically ordered *and* show unique optical properties, with strong coupling between the two. In one example, we show that deliberate doping with optical impurities can transform the broad luminescence of the prototypical 2D ferromagnet, CrI_3, into sharp *f-f* luminescence of the lanthanide impurity, sensitized by the CrI_3 host. We show that the impurity spin is pinned to the ferromagnetism of the CrI_3 lattice, reflecting strong dopant-host exchange coupling and providing sensitive magnetic control over lanthanide emission polarization at exceptionally low fields. In another example, we have developed solution routes to growth of ferromagnetic 2D perovskites with complex compositions. These materials show strongly temperature-dependent absorption whose intensity reflects coupling to thermally populated 2D magnons. We also show that the air stability of these compounds can be increased dramatically through composition tuning. These demonstrations illustrate the ability to leverage the chemical tunability of layered 2D materials to access new and unusual magneto-optical functionalities.

Iron-Based Superconductors as a New Majorana Playground Hong Ding; Shanghai Jiao Tong University, China

Majorana zero modes (MZMs) in solid materials and devices have attracted tremendous interest owing to their potential applications in robust quantum computation. Last ten years witness rapid progresses and serious setbacks in searching for MZMs. Recently iron-based superconductors (FeSCs) emerged as a new and promising Majorana platform due to relatively high temperature and high purity. In this talk I will report a series of our discoveries which help to establish this iron-Majorana platform. We have observed a superconducting topological surface state of Fe(Te, Se) by using ARPES, and a pristine MZM inside a vortex core of this material by using STM. We have also observed a half-integer level shift of vortex bound states and nearly quantized Majorana conductance in this material, which are hallmarks of MZMs. We have found that most of FeSCs have similar topological electronic structures. Finally, we found that uniaxial strain can be used as a good tuning method to control MZMs in FeSCs. The combination of intrinsic topological nature of vortex and large energy spacing among the discreet bound states, all of which can be tuned by pressure, offers compelling evidence for the Majorana nature of vortex zero-modes discovered in FeSCs, thus creating an exciting playground for realizing and manipulating Majorana modes.

The Structural Origin of Superconductivity in K-Intercalated FeSe System Maw-Kuen Wu[1,2], Guo-Tsung Huang[1], Chih-Han Wang[1], Ming-Jye Wang[1], Phillip M. Wu[3] and Kung-Yu Yeh[1]; [1]Academia Sinica, Taiwan; [2]National Tsing Hua University, Taiwan; [3]National Chung-Hsin University,

Taiwan

The discovery of relatively high Tc in potassium (K) intercalated FeSe, where the sample composition labeled as $K_{0.8}Fe_2Se_2$, has attracted extensive attentions in order to better understand the exact origin of superconductivity in this intriguing system. It has been known right after the observation of superconductivity in this system that there exists two distinguished crystal phases, one with full Fe-occupation of I4/mmm symmetry, the other with ordered Fe-vacancy of I4/m symmetry. Most of the reports designated the I4/mmm phase to be the one superconducting. However, this assignment could not provide proper answers to several phenomena observed: (A) Small fraction of superconducting phase is observed in the well Fe-vacancy ordered $K_2Fe_4Se_5$ sample when it is quenched from high temperature annealing; (B) Bulk superconductivity emerges in $K_2Fe_{4.2}Se5$, with extra Fe-content, and superconducting volume fraction varies with the quenching temperature; (C) Superconductivity in $K_2Fe_{4.2}Se_5$ sample disappears after being annealed at a temperature lower than 400°C; (D) Superconducting transition temperature reaches a maximum of ~48K under high pressure. In this report, based on the results of high resolution x-ray diffractions, we show unambiguously that the Fe-vacancy ordered I4/m phase is the parent phase, which became superconducting after additional Fe partially occupied the vacant sites. Furthermore, we also identify the presence of an intermediate phase embedded in a Fe-vacancy ordered phase and a fully-occupied phases within the I4/m symmetry to be the structural origin of superconductivity, which could satisfactorily explain those unanswered questions. Our results closely associate with the picture of the interface superconductivity, which can be at either a non-magnetic semiconducting-metallic interface or an antiferromagnetic insulating-metallic interface.

Superconducting and Possible Topological States in Fe (Te, Se) Thin Film on YSZ Substrate Using Pulsed Laser Deposition (PLD) Technique
Himanshu Chauhan, Shivam K. Miglani and Ghanshyam D. Varma; Indian Institute of Technology Roorkee, India

Since the initial discovery of superconductivity in iron-based superconductors (IBSs), thin films of Fe (Te, Se) superconductors are at the forefront of research in condensed matter physics and materials science. For the development of advanced superconducting devices, it is essential to fabricate the high-quality epitaxial thin films of IBSs. In recent years, several groups have been trying to understand the origin of topological states in thin films, but so far there is not much experimental agreement on these issues, and further studies are needed. In this approach, we have fabricated $FeTe_{0.55}Se_{0.45}$ thin film of different thicknesses on Yttria-stabilized zirconia (YSZ) single-crystalline substrates using pulsed laser deposition (PLD) technique. The effects of thickness on the structural, superconducting, and topological properties have been systematically investigated. The superconductivity in the grown thin film has been affirmed by the temperature-dependent resistivity measurements. It has been observed that superconducting transition temperature vary with the thickness of the films. Superconducting parameters such as upper critical field $H_{C2}(0)$ and corresponding coherence lengths (ξ) and activation energy (U_0) have been estimated using magnetotransport measurements. In addition, a non-saturating linear magnetoresistance (LMR) is also observed, suggesting the presence of a possible topological superconducting state in the grown thin films. Furthermore, current-voltage (I–V) measurements have been used to calculate transport critical current density, J_C of the grown thin films. In this paper a detail correlation between thickness and observed superconducting properties of the grown thin films will be presented and discussed. The study of the presence of possible topological phase in the grown film is relevant to the current focus of developing quantum devices.

11:45 AM QT04.01.04
Electronic Structure and Transport Properties of Partially Ni-Substituted Superconducting Iron Chalcogenide $FeSe_{0.45}Te_{0.55}$
Juntao Yao[1,2], Sarah Paone[1,2], Genda Gu[2] and Qiang Li[1,2]; [1]Stony Brook University, United States; [2]Brookhaven National Laboratory, United States

Iron chalcogenides bring together superconductivity, non-trivial electronic topology, and magnetism in a single material, making it a potential platform for hosting Majorana fermions which are the building blocks for topological quantum computing. We investigated the change of electronic structure and transport properties in a series of superconducting iron-nickel chalcogenides $(FeNi)Se_{0.45}Te_{0.55}$ by partial Ni substitution for Fe. Ni substitution increases the electron count. Ni 3d spin-orbit energy is ~ 50% higher than that of an Fe atom, leading to enhanced topological properties in this class of materials. From combined ARPES and transport measurements, we found that Ni substitution reduces superconducting transition temperature T_c and superconducting gap. Temperature dependent normal state resistivity changes from a weak metallic behavior to an insulating-like behavior with Ni-substitution level above 2% (nominal composition). A low level of Ni-substitution was found to enhance the critical current density in iron chalcogenide superconductors that peaks around 2% substitution level.

SESSION QT04.02: REBCO Films and Coated Conductors, HTS Applications
Session Chairs: Xavier Obradors Berenguer and Venkat Selvamanickam
Tuesday Afternoon, April 23, 2024
Room 445, Level 4, Summit

1:30 PM *QT04.02.01
Vortex Pinning in Complex Heterogeneous Microstructures in REBCO Thin Films Formed by High-Density Artificial Pinning Centers
Kaname Matsumoto[1,2,3], Tomoya Horide[2,1,3], Yutaka Yoshida[2,3] and Ataru Ichinose[4,3]; [1]Kyushu Institute of Technology, Japan; [2]Nagoya University, Japan; [3]JST-CREST, Japan; [4]CRIEPI, Japan

Development of REBCO coated conductors is in progress, and it is desired to improve the superconducting current-carrying capability for equipment applications at operating temperatures near 20 K and 65 K. For this purpose, appropriate introduction of artificial pinning centers (APCs) into REBCO thin films is effective, and higher concentrations of APCs are needed. For example, the main pinning center in NbTi metallic wires is the α-Ti normal-conducting precipitate, with an upper limit of about 25-30% in volume fraction. However, the upper limit for the volume fraction of APCs in REBCO thin films is much lower. If it is possible to introduce APC in REBCO thin films up to the same level as the volume fraction of α-Ti, higher Jc performance is expected to be achieved. At present, it is known experimentally that the upper limit of APC concentration in REBCO thin films is about 5-10%. The reason for this is thought to be the increase in epitaxial distortion, formation of various lattice defects, and oxygen deficiency at the interface due to the introduction of APC, as well as the reduction of the superconducting current path due to the complex structure. Under such a complex and inhomogeneous structure, it is very difficult to find the optimal APC distribution for high magnetic field applications by a conventional screening method. We first investigate the microstructure of REBCO thin films near the upper limit of APC concentration and the degradation of superconducting performance caused by epitaxial distortion, in order to obtain clues for solving the upper limit problem of APC volume fraction. In this study, GdBCO thin films with BHO nanorods were fabricated on IBAD-CeO2 substrates by PLD method. The PLD targets were 4.0, 4.5, 5.0, and 5.5 wt% BHO-doped GdBCO, and the PLD conditions were as follows: deposition temperature 760-840°C, oxygen partial pressure 300 mTorr, distance between substrates 60 mm, laser frequency 10 and 100 Hz, and laser energy 300 mJ/pulse. The sample was subjected to structural analysis by XRD, evaluation of superconducting properties such as Jc

and Tc by PPMS, and microstructural observation by TEM and STEM. Degradation of Jc properties was observed along with a decrease in Tc at higher BHO concentration. Interestingly, in the films fabricated at 10 Hz, the BHO nanorods collapsed and a BHO layered structure appeared. Elemental mapping by STEM confirmed that these were BHO additives. The collapse of the nanorod structure clearly causes degradation of the c-axis Jc property. This structural transition from nanorods to layers is considered to depend on the competition between the release of strain energy stored in the thin film and the kinetic process of thin film nucleation and growth. To quantitatively evaluate the origin of the above structural transition, epitaxial strain energy was analyzed based on micromechanics theory. Furthermore, vortex pinning simulation using TDGL (time-dependent GL) was performed to evaluate the elemental pinning forces at the complex APC interface, and the optimized APC structures to be considered in the future were discussed.

2:00 PM *QT04.02.02
Materials Research on REBCO Superconductors to meet Application Requirements Venkat Selvamanickam; University of Houston, United States

REBCO superconductors are in great demand now for many applications, particularly compact fusion. While these superconductors are being implemented in prototype devices, several issues remain before they can be widely used in commercial applications. Cost, capacity, uniformity, mechanical properties, and quench damage are the main issues of concern. High and uniform critical current to reduce cost, high growth rates to increase capacity and reduce cost, alternate conductor architectures for improved strength, flexibility, and defect tolerance are ongoing areas of research. Progress in these areas at the University of Houston will be discussed in this presentation.

2:30 PM *QT04.02.03
Development of Novel Methodologies for Better Understanding and Manufacturing of REBCO Coated Conductors by Integrating High Throughput Magnetic Microscopy and Machine Learning Takanobu Kiss[1,1], Zeyu Wu[1], Kohei Higashikawa[1,1], Shinya Sera[1], Yuto Tanaka[1], Natthawirot Somjaijaroen[1], Roman Valikov[2], Miyuki Nakamura[2], Valery Petrykin[2] and Sergey Lee[2]; [1]Kyushu University, Japan; [2]Faraday Factory Japan LLC, Japan

Recent advances in manufacturing techniques have made it possible to obtain commercial $RE_1Ba_2Cu_3O_{7-\delta}$ (REBCO, RE: Rare Earth) coated conductor (CC) tapes having a length of several 100 m. Along with this trend, research on the development of CC applied equipment is also being vigorously promoted in various countries of the world. However, in developing REBCO CC based large-size superconducting equipment, unexpected quenching and lowering of critical current (I_c) and yield at coil-forming are noticed as problem. Technology development for obtaining more stable performance with good reproducibility becomes an urgent issue. The author considers that, as the cause, 1) the behavior of the long CC tape under the practical operation condition is not sufficiently understood, and 2) the problem of the complexity of the manufacturing process. In this study, the local nonuniformity of critical current density (J_c) in the tape-plane of the long CC is measured nondestructive and noncontact manner at high spatial resolution using a reel-type high-speed magnetic microscope. Integrating with image analysis by machine-learning (ML), we succeeded in the automated analysis of several thousands of magnetizing current images and clarified the presence of domains of the local nonuniformity in the long tape, which is difficult to be detected by the conventional inspection by local I_c criterion, and obtained detailed information on the J_c lowering domain such as the size, position, and statistical distribution. To improve the process conditions, we also developed a ML regression model which can quantitatively estimate I_c obtained by the manufacturing condition through a coupled analysis by high-speed I_c measuring and ML regression using a combinatorial sample in which the manufacturing condition was systematically changed in the longitudinal direction of the tape. Furthermore, using the Genetic Algorithm on the basis of this ML regression model, we have also succeeded in deriving the combination of control variables, i.e., the production conditions, to maximize the I_c as output as the solution of the inverse problem. These new methodologies enable us to elucidate the reason for local non-uniformity of long CC tapes, to develop CC tapes with better spatial uniformity, to derive process parameters quickly on PC to maximize the tape performance and are expected to greatly contribute to drastic shortening of lead times for CC tape development and realizing stable tape performance.

Ultrafast transient liquid assisted growth of $YBa_2Cu_3O_7$ coated conductors: why is it a novel process? Xavier Obradors Berenguer[1], Teresa Puig[1], Lavinia Saltarelli[1], Diana G. Franco[1], Kapil Gupta[1], Elzbieta Pach[1], Roxana Vlad[1], Aiswarya Kethamkuzhi[1], Carla Torres[1], Adrià Pacheco[1], Silvia Rasi[1], Albert Queraltó[1], Jordi Aguilar[1], Daniel Sánchez[2], Emma Ghiara[1], Ona Mola[1], Victor Fuentes[1], Laia Soler[1], Julia Jareño[1], Juri Banchewski[1], Natalia Chamorro[1], Cornelia Pop[1], Joffre Gutierrez[1], Susana Ricart[1], Jordi Farjas[2], Cristian Mocuta[3], Ramon Yañez[4] and Eduardo Solano[5]; [1]Institute of Material Science of Barcelona (ICMAB-CSICJ), Spain; [2]Universitat de Girona, Spain; [3]Soleil Synchrotron, France; [4]Universitat Autònoma de Barcelona, Spain; [5]Alba Synchrotron, Spain

Coated conductors (CC) of $REBa_2Cu_3O_7$ (REBCO, RE= Rare Earth) are an exceptional achievement in materials science which encompassed many scientific and engineering challenges. These superconducting materials have emerged as the most attractive opportunity to reach unique performances at high and low temperatures, particularly at high magnetic fields, while reducing the cost/performance ratio continues to be a key objective for a large scale marketability.
To address the challenge of reducing the cost/performance ratio it is unavoidable to develop ultrafast growth rate processes which will lead to high throughput manufacturing of CCs with high performance. Liquid assisted growth of epitaxial REBCO films appears as a very promising approach to reach growth rates beyond 100 nm/s. We have recently created a novel concept, the Transient Liquid Assisted Growth (TLAG) [1-3], which differs from previous growth paths because it is a non-equilibrium process, i.e. the Ba-Cu-O transient liquid with different stoichiometries leading to the formation of REBCO is not an equilibrium one and its properties can be manipulated through kinetic parameters [4]. We will show that different REBCO (RE= Y, Gd, Yb) films can be grown through TLAG using either the temperature or the PO_2 routes and also with different liquid compositions. The TLAG process is fully compatible with the use of preformed $BaMO_3$ (M=Zr, Hf) nanoparticles to prepare nanocomposite CCs when propionate metalorganic solutions are used in a Chemical Solution Deposition (CSD) route. Finally, we show that the TLAG process can also be extended to other precursors such as amorphous phases deposited by Pulsed Laser Deposition (PLD) at low temperatures [5]. The growth process has been analyzed by in-situ synchrotron X-ray diffraction analysis which have confirmed that ultrafast growth rates (> 1.000 nm/s) can be achieved. We will show that high critical current densities have been achieved up of 3-5 MA/cm^2 at 77K in thin films and CCs and the process has been transferred to thicker films and metallic substrates. An overall overview of the features of the TLAG process, as compared to other growth approaches, will be presented [6], together with an outlook of the future potential and the pending challenges of this novel technique.

Ultra-fast Growth of REBCO Superconducting Thin Films by Transient Liquid Assisted Growth Elzbieta Pach[1], Diana G. Franco[1], Lavinia Saltarelli[1], Carla Torres[1], Daniel Sánchez[2], Jordi Farjas[2], Eduardo Solano[3], Cristian Mocuta[4], Xavier Obradors Berenguer[1] and Teresa Puig[1]; [1]Institut de Ciència de Materials de Barcelona, Spain; [2]GRMT, University of Girona, Spain; [3]ALBA Synchrotron, Spain; [4]SOLEIL Synchrotron, France

Cuprates, $REBa_2Cu_3O_{7-\delta}$ (REBCO, RE = Y or rare earth) are the most important class of High Temperature Superconducting (HTS) materials, due to their outstanding properties. They are the superconductors with the highest operational temperature and highest operational magnetic field, hence, nowadays the materials of choice for Coated Conductor (CC) technology in most of the high current applications. The synthesis of REBCO-type superconducting films is compatible with standard chemical solution deposition methods (CSD) and pulsed laser deposition growth (PLD). However, recently, the development of a novel synthesis approach promises the reduction of the cost/performance ratio in the CC field. The, so called "Transient Liquid Assisted Growth" (TLAG) method [1-3] is a high-throughput, ultra-fast, non-equilibrium, kinetic process of growth of REBCO type superconducting films and coated conductors compatible with industrial applications. The understanding of the TLAG process requires application of advanced tools and techniques for its characterization and optimization. Therefore, development of a specialized instrumentation for the characterization and optimization of TLAG process in real time and in real conditions by synchrotron radiation based in-situ X-Ray Diffraction, was achieved. This new instrumentation allows to follow the precursors reaction, the generation of intermediate phases and follow the dynamic growth of the superconducting phase while acquiring the resistance of the sample in real time and in-situ by XRD. Epitaxial REBCO TLAG growth at 1000 nm/s has been reached in superconducting films of 3 MA/cm^2 at 77 K. Furthermore, TLAG growth method was shown to be compatible with introduction of inorganic nanoparticles as vortex pinning centres to increase the performance of such films. In this presentation, I will mainly report on the present understanding of the TLAG process based on the results gathered from the in-situ instrumentation setup.

4:15 PM QT04.02.06
Monte Carlo Simulation of Nanostructure Formation in BMO-Doped REBCO Films Yusuke Ichino[1,2], Noriyuki Taoka[1], Yoshiyuki Seike[1], Tatsuo Mori[1], Tomonori Arita[3,2], Tomoya Horide[3,2] and Yutaka Yoshida[3,2]; [1]Aichi Institute of Technology, Japan; [2]Japan Science and Technology Agency, Japan; [3]Nagoya University, Japan

When BMO-doped REBCO superconducting thin films (BMO+REBCO films) are prepared by vapor-phase-epitaxy (VPE) such as PLD and MOCVD, BMO self-organizes into nanorods and/or nanoparticles in the REBCO matrix. On the other hand, only incoherent BMO nanoparticles are observed in the solid phase growth method such as MOD. These experimental results suggest that the kinetics of the raw material particles at the surface of the thin film crystal growth contribute significantly to the self-organization of BMO. In fact, it is known that BMO exhibits various nanostructures depending on the growth temperature (T_G), the volume fraction of BMO added (V_{BMO}), and the deposition rate (*DR*) in the VPE. Therefore, we have developed a BMO+REBCO thin film growth simulation considering the kinetics using the Monte Carlo (MC) method to investigate the effect of deposition conditions on the nanostructure and the formation mechanism of nanorods.
As a result, the following trends were obtained.
(1) When T_G is high and *DR* is low, nanorods are formed perpendicular and linear to the substrate surface. In addition, the diameter of the nanorods becomes thicker.
(2) At a lower T_G and higher *DR* than (1), the nanorods are inclined and their diameters are narrower and their number density is higher.
(3) When *DR* is high enough, nanoparticles consisting of short nanorods are observed.
(4) Even if *DR* is high enough, linear nanorods can be obtained if T_G and V_{BMO} are sufficiently high.
The above trends are qualitatively in good agreement with experimental results and reported cases.
The time evolution of nanostructure formation can also be observed in the MC simulations. This indicates that nanorods are formed in the following steps. First, crystal nuclei of REBCO and BMO are generated on the substrate surface, from which crystal growth proceeds. Since the volume fraction of BMO is small, the BMO islands are eventually surrounded by the REBCO layer, and BMO can only grow in the direction perpendicular to the substrate surface. This process is repeated, consequently, BMO nanorods are formed. On the other hand, at low T_{G} and high *DR*, more BMO crystal nuclei are generated, which slows down the growth rate of BMO islands in the vertical direction, resulting in tilted or shortened nanorods. In other words, the competition between REBCO and BMO growth rates results in the formation of various nanostructures.
The above are mainly MC simulations in the VPE. On the other hand, the VLS growth method, which is a thin film growth method via thin liquid layer on a films surface, has the advantage that high-quality crystals can be fabricated even at high *DR*. However, it is difficult to control the BMO nanostructure. This is because the kinetics of the raw material particles is different from that of the VPE due to the presence of the thin liquid layer. Therefore, MC simulations concerning to the VLS growth method were developed and compared with the VPE for the formation of BMO nanostructures. MC simulations were also performed by intentionally adding screw dislocations to obtain a more detailed picture of the crystal growth environment.
In this presentation, we will discuss the growth conditions, nanostructure formation, and thin film crystal growth environment.

A Novel Application of High Temperature Superconducting Cable for Seabed Coils in Ship Magnetic Deperming Megumi Hirota; Naval Ship M&UEP R.C., NPO, Japan

The zero electrical resistivity of superconducting materials makes them ideal for long-distance electric-current transmission. In particular, high-temperature superconducting (HTS) materials require only moderate cooling power, and a few trials have successfully demonstrated their capability for power transmission. Utilizing a long extended HTS cable to generate an external magnetic field is an emerging application with unique challenges. Our study introduces a conceptual design of a flat seabed coil, proportional to a ship's size, for the purpose of ship magnetic deperming. Magnetic deperming involves imposing a magnetic field on the ship's hull to saturate the magnetization of its steel components. The required field is estimated to be 2,400 A/m, achievable by the flat seabed coils in shallow water. The deperming process requires an alternating magnetic field with decreasing peak intensity. We have designed the coil for the largest destroyer and submarine ships of the Japanese Maritime Self-Defense Force. The parameters required for the coil design were obtained from publicly-available information. Our design features three racetrack-shaped coils, each carrying a maximum current of 200 kA,

spanning a total length of 1,200 m for a single coil, set flat at a depth of 12 m, and cooled by liquid hydrogen, using the currently available HTS materials and technologies.

Low-Temperature Fabrication of High-T_c $NdBa_2Cu_3O_y$ Films by Oxygen Partial Pressure Controlled KOH Flux Method Shuhei Funaki, Haruki Shigenobu, Eisuke Sasaki and Yasuji Yamada; Shimane University, Japan

To apply coated conductors operated at boiling temperature of liquid nitrogen (77.3 K) to various fields, an improvement of the superconducting properties is required. In the case of $REBa_2Cu_3O_y$ (RE123; RE: rare earth elements) coated conductors, a biaxial orientation of RE123 crystals on substrate and the improvement of a critical current density (J_c) have been greatly conducted. However, this RE123 coated conductor needs a high growth temperature during film fabrication that causes degradation of superconducting properties due to impurity diffusion from metallic tape substrate. Moreover, for the achievement of high critical current (I_c), a particular technique for the fabrication of thick RE123 film is needed. A single crystalline $REBa_2Cu_4O_8$ (RE124) has been fabricated by a low-temperature liquid-phase growth process using molten alkali hydroxide (KOH) in an ambient atmosphere [1–3]. By this approach, we synthesized biaxial oriented RE124 epitaxial films on $NdGaO_3$ (001) single crystalline substrate at low-temperature of ~650°C [4]. Furthermore, by controlling the oxygen partial pressure (pO_2), we fabricated biaxial oriented Y123 epitaxial films [5]. The critical temperature (T_c) of Y123 film fabricated at 650°C was ~90 K, comparable to that of conventional Y123 films. Recently, we have focused on light RE123 (*L*RE123), which has potentially high T_c, and prepared the Nd123 on $SrTiO_3$ (100) single crystalline substrate with high T_c by a low-temperature crystal growth process using KOH [6]. We succeeded in obtaining biaxially oriented Nd123 films even at a low temperature of 425°C. However, the T_c was dramatically reduced due to the increase of Nd/Ba substitution as the deposition temperature was lowered. In contrast, by increasing the Ba/Cu composition ratio of the flux to Ba-rich, the T_c of the Nd123 film was slightly improved, but was much lower than the conventional T_c [7]. In addition to Ba enrichment of the flux composition, a low pO_2 is also reported to be effective in suppressing Nd/Ba substitution in Nd123 [8]. In this investigation, to establish the fabrication method of high performance *L*RE123 films by feasible simple process, we endeavored to fabricate the *L*RE123 films on single crystalline substrate at low temperatures by liquid phase epitaxial growth using KOH flux with controlled pO_2.
Obtained films of *L*RE123 (*L*RE=Gd, Sm, Nd, La) fabricated at 700°C in various pO_2 of $2x10^{-1}$, $1x10^{-2}$, $1x10^{-3}$ atm showed biaxial orientation of 123 single phase completely, and *c*-axis length was elongated to the stoichiometric value with decreasing pO_2. Moreover, Nd123 films fabricated at 700°C in $pO_2 \leqq 1x10^{-2}$ atm showed high-T_c^{onset} of ~90 K. From these facts, we succeeded in the fabrication of high-T_c (> 90 K) Nd123 film using KOH flux method at low temperature by controlling of pO_2.

Magnetic ac Susceptibility of Superconducting Ta Films for Quantum Computing Juntao Yao[1,2], Chenyu Zhou[2], Sarah Paone[1,2], Mingzhao Liu[2] and Qiang Li[1,2]; [1]Stony Brook University, United States; [2]Brookhaven National Laboratory, United States

Recently, breakthroughs were reported in the long coherence time (> 0.5 ms) transmon qubit using tantalum films (Ta). Identifying the loss mechanism in Ta films will help further improve the performance of Ta-based superconducting qubits. Here, we report a study of superconducting properties in two sets of Ta films grown on c-cut and a-cut sapphires respectively using contact transport and noncontact magnetic ac susceptibility measurements. Although the resistive transition appears to be similar in both films, we found strikingly different responses in their complex magnetic susceptibilities $\chi'+i\chi''$. χ'' in the c-cut films exhibits a sharp peak at superconducting transition T_c and becomes featureless below T_c indicating a strongly coupled superconducting state. In contrast, χ'' in the a-cut films exhibits a broad peak near T_c and a second peak appears below T_c, indicating granular superconductivity behavior. This second peak in χ'' is associated with the hysteresis loss at weak-link-type grain boundaries, which is believed to be a leading source of decoherence in the a-cut Ta films. The derived magnetic loss tangent in the a-cut films is about one order of magnitude higher than in the c-cut films. This study demonstrates that ac susceptibility is an excellent probe for characterizing bulk superconducting properties of the constituent superconducting materials used in qubits.

Integrating Novel Nitride Barriers and Conventional Nitride Superconductors into Epitaxial Junctions: Early Steps toward New Materials Platforms for Quantum Computing Sage Bauers; National Renewable Energy Laboratory, United States

Although nitrogen is approximately four times more prevalent than oxygen in the Earth's atmosphere, the stability of dinitrogen leads to an order of magnitude fewer known nitrides than oxides. Despite this, many of the known nitrides are important technological materials. Transition metal nitrides (*TM*Ns) in the rocksalt crystal structure are one such example: these chemically stable, high-symmetry superconductors are well suited for epitaxial thin film integration with common substrates. To extend the functionality of *TM*Ns and create epitaxial superconductor–semiconductor heterojunctions, suitable rocksalt-structured semiconductors are required. Our team has discovered a series of new rocksalt-structured nitride semiconductors with band gaps ranging from E_G=0.9-2.4 eV, described as either Mg*TM*N_2 (*TM*=group 4 transition metal) or Mg_2*TM*N_3 (*TM*=group 5 transition metal). The lattice parameters of these new materials are compatible with *TM*Ns, suggesting the possibility for integration into epitaxial structures, such as Josephson junctions and other circuitry forming superconducting qubits. Here, we study the epitaxial integration of *TM*Ns on Al_2O_3 substrates and of Mg*TM*N_2 and Mg_2*TM*N_3 compounds onto *TM*Ns. We optimize *TM*N growth to repeatably achieve high T_C for epitaxial NbN (15K), TiN (5K), and $Nb_{0.5}Ti_{0.5}N$ (13K). Using electron and X-ray probes we show that heteroepitaxy can be readily achieved between *TM*Ns and the novel semiconductors. Epitaxial NbN-

Mg_2NbN_3-NbN trilayer heterojunctions grown on sapphire are demonstrated with barrier layers down to ~3 nm and crystal coherence across the entire heterojunction stack. However, we also find that the inherent polymorphism of NbN complicates it's use, motivating the eventual use of other *TM*Ns such as $Nb_{0.5}Ti_{0.5}N$ alloys.

Electronic Transport Studies of InAs Quantum Well Layla Smith[1], Kent Smith[2], Leroy Salary[1], Doyle Temple[1] and Wei Pan[2]; [1]Norfolk State University, United States; [2]Sandia National Laboratories, United States

Google researchers have recently demonstrated quantum advantage in a superconducting quantum computer by solving a specific problem that is beyond the most powerful classical computers. The next step is to construct a universal quantum computer to solve real world problems such as new-drug design and discovery. This formidable advance will require a much larger number of fully functional qubits. Unfortunately, a relatively low average qubit gate fidelity of ~ 99% in current transmon qubits has been detrimental in this pursuit.
A different approach, topological quantum computing, may overcome these difficulties, due to its enhanced tolerance to errors. In a topological quantum computer, a qubit would be constructed out of four Majorana quasiparticles (MQPs), with a gate performed by moving one MQP around another, or braiding MQPs. Because the braiding is topological and nonlocal, Majorana-based qubits would be intrinsically robust against local decoherence sources and thereby enable fault-tolerant quantum computing.
InAs has emerged as a promising material platform to realize topological superconducting states (TSSs) which can host MQPs: (1) It can form a highly transparent interface with aluminum (Al, a superconductor); (2) the strength of spin-orbit-coupling (SOC) is large and tunable, a key ingredient for realizing TSSs. Indeed, recent work by Microsoft Quantum shows exciting results in InAs-Al hybrid devices that are consistent with the observation of TSSs and MQPs.
In this work, we will present our recent low temperature electronic transport characterization in a high quality InAs quantum well (QW), grown by molecular-beam epitaxy. A specimen of a standard 5mm × 5mm geometry is cleaved from an as-grown wafer. Eight indium contacts are diffused symmetrically around the perimeter of the specimen to form ohmic contacts to the 2D electron gas (2DEG) realized in the InAs QW. The specimen is then cooled down to the liquid helium temperature, and the magneto-resistance Rxx and the Hall resistance Rxy are measured as a function of magnetic (B) fields. Rxx displays the typical Shubnikov-de Haas oscillations. For Rxy, it is linear with B in the low field range but displays quantized plateaus at high B fields.
Our low temperature measurements demonstrate high quality 2DEG in our InAs QW. In the future, we will examine the SOC strength in InAs by analyzing the weak-antilocalization effect. Results from this study will provide critical information for the realization of MQPs.

5:00 PM QT04.03.04
Investigating The Superconducting and Structural Properties of Trigonal $PtBi_2$ Single Crystals Ting-Wei Kuo[1,2], Liangzi Deng[1], Hung-Duen Yang[2] and Ching-Wu Chu[1]; [1]Texas Center for Superconductivity at the University of Houston, United States; [2]National Sun Yat-sen University, Taiwan

In our research, we report the intriguing structural and superconducting characteristics of trigonal $PtBi_2$ single crystals. Originating from the synthesis process using high-purity elemental powders of Pt and Bi, the mixture, sealed in a quartz tube, was heated to 850°C and cooled to 420°C. Excess flux from the resulting crystals was subsequently removed through centrifugation, ensuring the crystal's integrity and purity. Our primary focus revolves around understanding the intricate relationship between their unique structural attributes and their emergent physical properties. Significant potential in their superconducting capabilities, positioning trigonal $PtBi_2$ as a compelling subject in the realm of condensed matter physics.

5:00 PM QT04.03.05
Superconducting Materials Exploration for Quantum Devices Aidar Kemelbay, Arian Gashi, Ed Barnard, Shaul Aloni and Adam Schwartzberg; Lawrence Berkeley National Lab, United States

The performance of quantum devices strongly depends on the quality of materials and interfaces between them, controlling which at every fabrication step is crucial. The parameter space for superconductor synthesis is typically very large and scales up rapidly with more complex material systems, for example when going from binary to ternary or quaternary alloy superconductors. As a result, understanding the fundamental underpinnings of growth and fabrication processes needed to fine tune the application-specific superconductor performance becomes increasingly important. To address this problem a cluster deposition and characterization system was designed and recently launched at the Berkeley Lab's Molecular Foundry user facility, that includes multiple nanofabrication tools (deposition, oxidation, ion milling), a characterization suite (XPS, ellipsometry, FTIR, OES) and automated robotic system — all combined in an integrated vacuum system. This new capability enables synthesis and characterization of materials at every fabrication step, as well as their integration into quantum devices in a single vacuum cycle, preserving pristine interfaces between various device layers. By using the synthesis - characterization - machine learning loop we can efficiently tune material properties and accelerate new materials discovery. For example, we have optimized multiple superconducting systems towards their integration into all-nitride Josephson junctions, or to improve phonon management in superconducting sensors. In this presentation I will discuss this new user accessible capability and the wide range of ongoing and future applications of it.

5:00 PM QT04.03.07
Acid-Assisted Soft Chemical Route for Preparing High-Quality Superconducting 2M-WS_2 Brianna L. Hoff[1], Xiaoyu Song[1], Ratnadwip Singha[1], Joseph Stiles[1], Grigorii Skorupskii[1], Jason F. Khoury[1], Guangming Cheng[2], Franziska Kamm[3], Ayelet Uzan[1], Stephanie Dulovic[1], Sanfeng Wu[1], Florian Pielnhofer[3], Nan Yao[2] and Leslie Schoop[1]; [1]Princeton University, United States; [2]Princeton Materials Institute, United States; [3]University of Regensburg, Germany

2M-WS_2 is a metastable, superconducting polymorph of the transition metal dichalcogenide (TMD) WS_2, comprised of layers of face-sharing distorted WS_6 octahedra. It is predicted to host non-Abelian quantum states, promising for topological computing. Due to its thermodynamic instability, 2M-WS_2 cannot be synthesized using solid-state synthesis. Rather, it requires a top-down approach in which K^+ is deintercalated from K_xWS_2; so far, this process has been completed using a strong oxidizer, $K_2Cr_2O_7$ in dilute H_2SO_4. A disadvantage of such an indirect synthesis is that the harsh reaction condition may cause the crystal quality to suffer. To date, no studies have been performed to optimize the synthesis or understand the chemical nature of this reaction. In this study, we found that the K-deintercalation process from K_xWS_2 is spontaneous, and a non-oxidative acidic reaction environment is sufficient to facilitate the oxidation of K_xWS_2 to 2M-WS_2 while reducing H^+ to H_2. By analyzing the superconducting transition in the heat capacity, we found that 2M-WS_2 made using less aggressive methods has higher superconducting volume fractions. We describe how to access the thermodynamically unfavorable superconducting 2M phase of WS_2 as high-quality crystals.

5:00 PM QT04.03.08
Anisotropic Superconductivity in Atomically Thin $(Sn_{1-x}In_x)Bi_2Te_4$ Jack M. Barlow[1], David Graf[2], Jared Madsen[3], Salman Ahsanullah[3], Chaowei Hu[1], Jiaqi Cai[1], Jordan Fonseca[1], Zhaoyu Liu[1], Jiun-Haw Chu[1], David Cobden[1], Jiaqiang Yan[4], Michael McGuire[4], Xiaodong Xu[1,1] and Dmitry Ovchinnikov[3]; [1]University of Washington, Seattle, United States; [2]University of Florida, United States; [3]University of Kansas, United States; [4]Oak Ridge National

Laboratory, United States

Combining superconductivity with non-trivial band topology has been an emerging research area in recent years. It is especially appealing to identify material candidates in the van der Waals family of compounds where atomically thin films may allow the control of carrier density and disentanglement of bulk and topological states. In this talk, I will describe our progress in measuring and understanding the thickness-dependent electronic response of topological superconductor candidate $(Sn_{1-x}In_x)Bi_2Te_4$. By decreasing the thickness from bulk to several layers we observe an increase in anisotropy of the superconducting state with high in-plane critical fields. Furthermore, I will discuss non-linear transport measurements above the critical temperature and their implications for the nature of superconductivity in this material.

5:00 PM QT04.03.09
Selective Area Epitaxial Growth of Magnesium Diboride on SiC using Epitaxial Graphene Patrick A. Rondomanski, Chengye Dong, Joshua Robinson, Qi Li and Joan M. Redwing; The Pennsylvania State University, United States

Magnesium diboride (MgB_2) has a bulk transition temperature (T_c) of 39 K, the highest temperature BCS s-wave superconductor at ambient pressure, and it has been shown to achieve an upper critical field (H_{c2}) larger than 60 T. Furthermore, MgB_2 possesses two superconducting energy gaps, a small gap of ~2.3 meV due to the π band and a larger gap of ~7.1 meV due to the σ band which contributes to the high T_c. Access to the desirable σ band carriers for proximity coupled superconductivity are largely confined to the *ab*-axes and is not readily available in standard *C*-plane films. Selective area growth of *C*-plane films would allow not only direct growth of superconducting devices, but it also affords the opportunity to fabricate high quality thin film-based lateral devices. To selectively deposit MgB_2, a chemically inert masking material is preferred to isolate growth regions to the substrate. Graphene is a unique 2D material that is highly stable and is chemically inert due to its strong sp^2 bonding. Moreover, graphene possesses high mobility, Dirac bands, and has been observed to have a room temperature quantum Hall effect in relatively low magnetic fields. The Josephson effect across graphene has been a subject of intense research recently due to the predictions of exotic states due to its Dirac bands, gate tunability, and even in low Landau level quantum Hall states. However, current studies on this matter mostly utilize low T_c superconductors, such as Nb, and it is therefore desirable to employ higher T_c materials to increase the operational temperatures. The high T_c and H_{c2} of MgB_2 make it an ideal candidate to pair with the quantum Hall or fractional quantum Hall effect found in graphene to study the predicted chiral superconductivity.

In this work we present selective area epitaxial (SAE) growth of *C*-plane MgB_2 by hybrid physical-chemical vapor deposition (HPCVD) using patterned epitaxially grown graphene on semi-insulating 6H-SiC (EG). We find that EG patterned using positive resist photolithography and etched with a N_2 plasma restricts MgB_2 deposition predominantly to the exposed SiC and allows for fabrication of lateral MgB_2/graphene heterostructures. Low surface energy combined with minimal available oxygen bonds prevents Mg from sticking to the graphene and allows high surface mobility of adatoms to the exposed SiC. Thus, this makes graphene a suitable candidate to mask MgB_2 growth. The SAE technique also allows for simple and direct synthesis of MgB_2 devices, such as thin film nanoribbons for applications as single photon detectors or as other quantum sensors, on a semi-insulating substrate without the contamination and degradation of the superconductor from standard lithography processing after deposition. We have fabricated 5 μm wide by 1 mm long *C*-plane MgB_2 nanoribbons of 30 nm thickness that retain the bulk T_c of 39 K. Scanning electron microscopy shows that parasitic deposition on graphene is largely limited to photoresist contaminated areas or point and edge defects of the masking material that allow for Mg bonds to form. Furthermore, XPS analysis suggests the graphene is decoupled from the substrate during the MgB_2 deposition process, which allows for greater carrier mobility in the graphene. Lastly, the van der Waals bonding of graphene allows for easy physical exfoliation of the mask without damaging the MgB_2 device. Thus, this allows for isolation of superconducting devices on the semi-insulating SiC substrate if desired for the device application. Discussions in this talk will include synthesis considerations of developing these structures, such as chemical modification of the graphene during MgB_2 deposition, and the electrical properties of as-grown nanoribbons and other devices fabricated.

High Entropy Analogues to The Superconducting Face Centered Cubic W-Pt Binary Denver P. Strong and Robert J. Cava; Princeton University, United States

We report single phase superconducting face centered cubic (FCC) high entropy alloys (HEAs) synthesized via splat cooling. The single phase materials fall at electron counts in the HEA superconductor alloy family where structural stability and optimal superconducting electron counts clash. The materials' superconducting properties follow the general trends published for metallic alloys. Insights are provided as to why an FCC structure may be stable.

5:00 PM QT04.03.11
Capping Effects in Parent and Superconducting $Nd_{1-x}Sr_xNiO_2$ Shiyu Fan[1], Harrison LaBollita[2], Qiang Gao[3], Yanhong Gu[4], Taehun Kim[1], Jiemin Li[1], Vivek Bhartiya[1], Yueying Li[5], Jiangfeng Yang[5], Shengjun Yan[5], Xingjiang Zhou[3,6], Andres Cano[7], Fabio Bernardini[8], Yuefeng Nie[5], Zhihai Zhu[3,6], Valentina Bisogni[1], Antia Botana[2] and Jonathan Pelliciari[1]; [1]Brookhaven National Laboratory, United States; [2]Arizona State University, United States; [3]Chinese Academy of Sciences, China; [4]University of Tennessee, United States; [5]National Laboratory of Solid State Microstructures, Jiangsu Key Laboratory of Artificial Functional Materials, China; [6]Songshan Lake Materials Laboratory, China; [7]CNRS, Universite Grenoble Alpes, Institut Neel, France; [8]Dipartimento di Fisica, Universit`a di Cagliari, Italy

The discovery of superconductivity in infinite layer nickelates ($Nd_{1-x}Sr_xNiO_2$) has attracted a lot of attention. So far, superconductivity in $Nd_{1-x}Sr_xNiO_2$ is a prerogative of thin films making the role of substrates and interfaces crucial. On this end, capping has been shown to affect the interface structure highlighting its active role on the electronic and magnetic properties of nickelates. However, only few spectroscopic studies specifically address this topic. Here, we use Resonant Inelastic X-ray Scattering (RIXS) to investigate the influence of the $SrTiO_3$ capping layer on the excitations of $Nd_{1-x}Sr_xNiO_2$ (x = 0 and 0.2). Spin excitations are observed in $Nd_{1-x}Sr_xNiO_2$ regardless of capping. While doping softens the spin excitations, capping moderately hardens them in both parent and superconducting samples and increases their spectral weight. Additionally, the hybridization between Ni 3d and Nd 5d orbitals is reduced by capping, as evidenced by a weaker charge transfer peak at ∼ 0.6 eV. These observations can be rationalized phenomenologically in the context of the polar discontinuity at the $NdNiO_2$-$SrTiO_3$ interface leading to the atomic and electronic reconstruction, possibly extending to the whole film. Finally, our findings uncover the effects of $SrTiO_3$ capping on the spin and charge excitations in $Nd_{1-x}Sr_xNiO_2$ and pave the way for a general understanding of infinite layer nickelates thin films.

5:00 PM QT04.03.12
Memristively Programmable Josephson Junctions Julian Liedtke and Stefan Tappertzhofen; TU Dortmund University, Germany

Superconducting quantum interference devices (SQUIDs) can be used for realization of highly sensitive magnetic field sensors and qubits for quantum computers. SQUIDs rely on Josephson junctions and flux quantization. Achieving ultra-high sensitivity, low noise, and long coherence times demands precise tuning of the junction's critical current while simultaneously suppressing the sub-gap current. Nb/NbOx/Nb junctions are highly attractive due to the large gap-energy of Nb, which minimizes the sub-gap current. However, the inherent reactivity of Nb with its native oxide introduces considerable

variations of the critical current. Today, Al/AlOx/Al and Nb/Al/AlOx/Al/Nb junctions show the best and reliable performance. Nevertheless, even with the application of advanced fabrication techniques like laser annealing or high-voltage electron beam lithography, the critical current variation still extends up to 15% on the wafer level. Here, we introduce an innovative solution by utilizing a memristive Nb/NbOx/Nb heterostructure, serving as a programmable Josephson junction. By resistive switching at room temperature, a filamentary weak link (metallic quantum point contact) or tunneling junction between two electrodes formed, effectively operating as a Josephson junction at cryogenic temperatures. In this proof-of-concept, we analyzed in detail and modelled the electrical and physico-chemical properties of the Nb-based memristors. Particular attention is paid to the quantum charge transport at cryogenic temperatures and the statistical variations of the critical current. We demonstrate reproducible forming and erasing of the filamentary junction, which may transcend the limitations of conventional Nb-based junctions such as stress or degradation. The fundamental transport and switching studies are complemented by advanced spectroscopic and microscopies techniques. These memristively programmable Josephson junctions allow for precise tuning of the junction properties post-fabrication through simple programming steps. This may eliminate the need for sophisticated deposition or patterning techniques and unlock the full application potential of Nb-based superconducting electronics.

Tuning The Thermodynamic Stability of High Hydrogen-To-Metal Ratio Superconducting Hydrides Vitalie Stavila; Sandia National Laboratories, United States

Superconducting superhydrides are typically formed under high pressures by densely packing hydrogen atoms in unique clathrate structures with strong electron-phonon coupling. The hydrogen-metal interactions in these clathrate networks lead to diverse stoichiometries and exceptionally rich, hypervalent compounds (e.g. CaH_6, YH_8, LaH_{10}). Typically, such compounds are thermodynamically stabilized in bulk at ultra-high pressures, of the order of tens and hundreds of GPa. Here we show that reducing the particle size has a remarkable effect on phase diagram of and thermodynamic stability of such clathrate structures. Spacial confinement of Ca, Yb, and La in the presence of ammonia borane leads to significant changes in the thermodynamic stability, and in selected cases allows stabilization of metastable superhydride phases at lower pressures compared to bulk. Examples of successful interplay between theory and experiment to identify new promising sueprhydride materials and provide fundamental insights into their stability will be also presented.

5:00 PM QT04.03.14
A Study on Oxygen Post-Annealing of $GdBa_2Cu_3O_y$ Coated Conductors Irradiated with Low-Energy Ions Toshinori Ozaki[1], Hiroyuki Okazaki[2], Hiroshi Koshikawa[2], Shunya Yamamoto[2], Tetsuya Yamaki[2], Morihisa Saeki[2], Tetsuro Sueyoshi[3] and Hitoshi Sakane[4]; [1]Kwansei Gakuin University, Japan; [2]National Institutes for Quantum Science and Technology, Japan; [3]Kyushu Sangyo University, Japan; [4]SHI-ATEX Co., Ltd., Japan

High-temperature superconducting coated conductors (CCs) based on $REBa_2Cu_3O_y$ (REBCO, RE = rare earth) with high current carrying capacity are being developed for use in high magnetic field applications. For these applications, increasing critical current density J_c under magnetic fields is important considerations. The in-field J_c can be improved by the introduction of artificial pinning defects with nano-meter size, which can pin the vortices. The desired defect structures can be created by ion irradiation, which is a promising technique applicable to all superconducting materials. Depending on appropriate ion species and energy, ion irradiation enables the creation of a variety of defects, such as points, clusters and tracks in the materials. Recent studies show low-energy ion irradiation could be a viable option for creating uniform pinning defects in superconducting films[1-3]. We have reported the effect of low-energy Au-ion irradiation on superconducting properties in GdBCO CCs. The superconducting transition temperatures T_c's of the GdBCO films irradiated with 2 and 10 MeV Au-ions decrease gradually with increasing fluence up to around 8.0×10^{11} ions cm^{-2} and then significantly started to drop. The J_c in the GdBCO CCs irradiated with 10 MeV Au-ions shows over 70% enhancement at around 3 T and 30 K, indicative of effective pinning defects by the irradiation. In this talk, we will present a study on the oxygen post-annealing of GdBCO CCs irradiated with 2 and 10 MeV Au-ions. The oxygen post-annealing at 450 °C leads to a recovery of T_c, which is close to the pre-irradiation level up to 8×10^{11} ions cm^{-2} dose. We also observe an appreciable recovery of T_c above 8×10^{11} ions cm^{-2} dose, but these T_c values are much less than the one before the irradiation. These results indicate that the oxygen annealing is effective to restore the T_c of the GdBCO CCs irradiated 2 and 10 MeV Au-ions. We will present self-field and in-field J_c before and after the oxygen post-annealing in the irradiated GdBCO CCs. We will also report the effect of oxygen post-annealing temperature on superconducting properties of GdBCO CCs irradiated with 300 keV He-ions.

We would like to thank Sumitomo Electric Industries, Ltd. for providing the GdBCO CCs.
Ion beam irradiation was performed at the Takasaki Ion Accelerators for Advanced Radiation Application (TIARA) of Japan's National Institutes for Quantum Science and Technology (QST).

Imaging Defects in Epitaxial β-Nb_2N /AlN/ β-Nb_2N Josephson Junctions via Multislice Electron Ptychography Naomi Pieczulewski, John Wright, Debdeep Jena and David A. Muller; Cornell University, United States

Coupling of superconducting qubits to the external environment through dielectric traps, oxidized surfaces, defects, or inhomogeneous phases can introduce undesired energy levels in form of host two-level systems leading to quantum decoherence. Identifying and eliminating the defects responsible for the decoherence will lead to scalable quantum computers. Recent developments in epitaxial growth of single phase, atomically smooth β-Nb_2N has confirmed superconductivity with a critical temperature $0.35<T_c<0.6$K [1]. This opens the opportunity for large single-crystal layers to be used in Josephson junctions and enables easier identification of defects in comparison to amorphous and polycrystalline materials.
Here, we investigate an epitaxial transition metal nitride (TMN) Josephson junction with β-Nb_2N /AlN/ β-Nb_2N trilayer structure grown by molecular beam epitaxy (MBE) on c-plane sapphire. We measure non-linear I-V characteristics showing superconducting current across the junction. Hexagonal (non-polar) β-Nb_2N and wurtzite (polar) AlN are symmetry-matched and have only a 1.8% lattice mismatch. Here, we use multislice electron ptychography on four-dimensional scanning transmission electron microscopy (4D-STEM) to obtain a three-dimensional reconstruction of the junction and its interfaces with atomic-scale imaging and depth sectioning to show the presence of polarity-inversion boundaries of AlN at β-Nb_2N step edges.

Probing Buried Interface Properties in Ta/Sapphire Superconducting Resonators Aswin kumar Anbalagan[1], Rebecca Cummings[1], Chenyu Zhou[1], Junsik Mun[1,1], Jean-Jordan Sweet[2], Vesna Stanic[2], Kim Kisslinger[1], Conan Weiland[3], Steve Hulbert[1], Nathalie P. de Leon[4], Yimei Zhu[1], Mingzhao Liu[1], Peter V. Sushko[5], Andrew L. Walter[1] and Andi M. Barbour[1]; [1]Brookhaven National Laboratory, United States; [2]IBM T.J. Watson Research Center, United States; [3]National Institute of Standards and Technology, United States; [4]Princeton University, United States; [5]Pacific Northwest National Laboratory, United States

Dielectric loss significantly impacts the coherence time of superconducting qubits, suggesting that surfaces and interfaces are the primary limiting factors. Despite constituting a smaller fraction of the qubit's electromagnetic mode, they have the potential to exert significant influence as sources of high-loss tangents. This study investigates the structure and composition of the interfacial layer in Ta/sapphire-based superconducting qubits. Ta (222) films, comprising a pure α-phase, were sputtered onto a C-plane sapphire substrate at a growth temperature of 750 °C. Characterization of the film, including thickness, roughness, and electron density, was performed using synchrotron-based X-ray reflectivity (XRR) and Hard X-ray photoemission spectroscopy techniques. Notably, our analysis revealed an unexplored layer at the metal-substrate interface that is not possible to detect with the lab-based XRR. To establish the composition and the spatial extent of this interface layer, high-angle annular dark field–scanning transmission electron microscopy (HAADF-STEM) coupled with core-level electron energy loss spectroscopy (EELS) was employed. HAADF- STEM technique provided evidence of an interfacial layer approximately 0.7 nm thick between the metal-substrate layer, aligning well with the measurements from synchrotron XRR fitting. Further examination of the elemental composition of these interface layers using HAADF-STEM with EELS revealed an intermixing layer containing Al, O, and Ta atoms. Ab initio calculations suggest the substrate-metal interface structure's dependence on the sapphire termination before Ta deposition, offering the potential to modulate the Ta film structure through pre-treatment of the sapphire surfaces. These findings offer valuable insights into controlling the structure and composition of the substrate-metal interface that may be able to increase qubit coherence times.

Additively-Manufactured YBCO Superconductor Dingchang Zhang[1], Cristian Boffo[2] and David C. Dunand[1]; [1]Northwestern University, United States; [2]Fermi National Accelerator Laboratory, United States

Due to its brittleness, the high-temperature superconducting cuprate $YBa_2Cu_3O_{7-x}$ is currently manufactured in simple shapes (e.g., thin films or pellets) as complex 3D architectures are very difficult to achieve. Here, we show that 3D ink-printing (an additive manufacturing method) can fabricate cuprate superconductors with complex 3D architectures and high performance. An ink is first created with Y_2O_3, $BaCO_3$, and CuO submicron powders of various shapes. The ink is extruded layer by layer to form green parts, which are then sintered to achieve $YBa_2Cu_3O_{7-x}$ with high density. The isothermal sintering and subsequent slow cooling prevent the formation of cracks induced by thermal shock, which are always found in laser-beam-based additive methods. 3D ink-printing is demonstrated for various $YBa_2Cu_3O_{7-x}$ items: horizontal and toroidal coils, magnetic shielding tubes, and Origami folded objects.

5:00 PM QT04.03.19
Strain-Switchable Field-Induced Superconductivity Shua Sanchez[1], Philip J. Ryan[2] and Jiun-Haw Chu[3]; [1]Massachusetts Institute of Technology, United States; [2]Argonne National Laboratory, United States; [3]University of Washington, United States

Field-induced superconductivity is a rare phenomenon where an applied magnetic field enhances or induces superconductivity. Here, we use applied stress as a control switch between a field-tunable superconducting state and a robust non–field-tunable state. This marks the first demonstration of a strain-tunable superconducting spin valve with infinite magnetoresistance. We combine tunable uniaxial stress and applied magnetic field on the ferromagnetic superconductor $Eu(Fe_{0.88}Co_{0.12})_2As_2$ to shift the field-induced zero-resistance temperature between 4 K and a record-high value of 10 K. We use x-ray diffraction and spectroscopy measurements under stress and field to reveal that strain tuning of the nematic order and field tuning of the ferromagnetism act as independent control parameters of the superconductivity. Combining comprehensive measurements with DFT calculations, we propose that field-induced superconductivity arises from a novel mechanism, namely, the uniquely dominant effect of the Eu dipolar field when the exchange field splitting is nearly zero. Finally, we introduce a device architecture which uses combined strain and field to make a metal/superconductor toggle switch.

SESSION QT04.04: High Tc Materials I

9:00 AM *QT04.04.01
Pairing Symmetry and Electronic Origin of High-Tc in High Temperature Superconductors Xingjiang Zhou; Institute of Physics, Chinese Academy of Sciences, China

We will report our recent angle-resolved photoemission (ARPES) studies of the iron-based and cuprate superconductors:

1. Observation of high superconductivity pairing temperature up to 83K in single-layer $Fe/SrTiO_3$ films [1]. By preparing high-quality single-layer $Fe/SrTiO_3$ films, we observe strong superconductivity-induced Bogoliubov back-bending bands that extend to rather high binding energy ~100 meV by high-resolution ARPES measurements. They provide a new definitive benchmark of superconductivity pairing that is directly observed up to 83 K.

2. Nodal s+- pairing symmetry in an iron-based superconductor with only hole pockets [2]. We carried out ultra-high resolution ultra-low temperature (<1 K) laser ARPES measurements on KFe_2As_2 which is a prototypical iron-based superconductor with hole pockets both around the zone center and around the zone corners. We have determined the superconducting gap distribution and identified the locations of the gap nodes on all the Fermi surface. The pairing symmetry in KFe_2As_2 is found to be of the s+- type. These results unify the pairing symmetry in the hole-doped iron-based superconductors and point to the spin fluctuation as the pairing glue in generating superconductivity.

3. Ubiquitous coexisting electron-mode couplings in high-temperature cuprate superconductors [3]. We find that the electrons are coupled simultaneously with two sharp boson modes with energies of ~70meV and ~40meV in different superconductors with different doping levels, over the entire momentum space and at different temperatures above and below the superconducting transition temperature. These comprehensive results provide a unified picture of the two energy scales and key information to understand the role of the electron-mode couplings in cuprate superconductors.

4. Electronic origin of high-TC maximization and persistence in trilayer cuprate superconductors [4]. We observed for the first time the trilayer splitting in Bi2223 superconductor. The observed Fermi surface, band structures, superconducting gap and the selective Bogoliubov band hybridizations can be well described by a three-layer interaction model. The electronic origin of the maximum Tc in Bi2223 and the persistence of the high Tc in the overdoped region is revealed. They are consistent with the composite picture where high-Tc can be realized in an array of coupled planes with different doping levels. These results provide key insights in understanding high Tc superconductivity and pave a way to further enhance Tc in the cuprate superconductors.

Impact of Intrinsic Disorder on Superconductivity in Cuprates John M. Tranquada; Brookhaven National Laboratory, United States

Theoretical analyses of superconductivity typically assume a compositionally-uniform lattice. In cuprates, the dopant ions, such as Sr^{2+} for La^{3+} in $La_{2-x}Sr_xCuO_4$ (LSCO), are randomly distributed in the lattice and are poorly screened, resulting in an inhomogeneous charge landscape that is commonly ignored by theory [1]. As a consequence of the inhomogeneity, features such as spin and charge stripe correlations evolve with doping through a percolation transition, rather than a quantum critical point [2]. In underdoped cuprates, the presence of charge disorder can help to explain why the *d*-wave superconducting gap does not appear to be coherent at the gap maximum [1,3]. In overdoped LSCO, the charge inhomogeneity leads to multiple superconducting transitions [4] and appears to underlie the strange-metal behavior in the normal-state resistivity [2]. I will discuss the evidence behind these claims.

10:00 AM BREAK

10:30 AM *QT04.04.03
2G-HTS Wire Research at Faraday Factory Japan Valery Petrykin, I. Matviian, J. Renel, M. Okube, A. Molodyk, Miyuki Nakamura, Roman Valikov, H. Nanjo, S. Samoilenkov and Sergey Lee; Faraday Factory Japan LLC, Japan

Over the past few years, the world has experienced a steadily increasing demand for high-temperature superconducting wires of the second generation (2G-HTS wires). A significant proportion of wires require the exceptional performance under moderate to strong magnetic fields at reduced temperatures of 4-65K. These wires are primarily used in applications such as fusion magnets, rotating machines, and accelerators. Among these, fusion applications are a key driver for the development and manufacturing of 2G-HTS wires, having specific property requirements at 20K and in 15-20T magnetic fields.
In 2023, Faraday Factory Japan (FFJ) supplied over 2,000 kilometers of 4mm wide wires. The technology utilizes an electropolished Hastelloy substrate, alongside technologies involving the formation of an ion-beam assisted MgO (IBAD-MgO) textured buffer layer and pulsed laser deposition (PLD) of superconducting materials. Our research activities aim at improving the deposition process in all stages of the tape fabrication. This presentation will focus on our current research efforts to enhance the quality of the buffer substrate, improve the performance of superconducting materials in strong magnetic fields, and achieve higher uniformity in the Cu and solder layers. Our results have led to produce wires with an engineering critical current density (Je) at 20K and 20T of approximately 900-950 A/mm^2, with an average piece length of 350 meters. We will also discuss further practical improvements in our 2G-HTS fabrication process, which includes development of the new equipment, improvement of quality management, and addressing the challenges related to the scaling up of daily production.

11:00 AM *QT04.04.04
Unconventional Characteristics of REBCO Containing CuO Double Chain and Similar Defect Structures Jun-ichi Shimoyama, Takanori Motoki, Tetsuya Matsushita and Haruto Niitsu; Aoyama Gakuin University, Japan

Crystal structure of RE247 ($RE_2Ba_4Cu_7O_{15-\delta}$) can be regarded as alternate stacking of RE123 and RE124 along the *c*-axis direction. There are three copper sites in RE247, which are at CuO_2 plane, $CuO_{1-\delta}$ chain and CuO double chain. Among them, $CuO_{1-\delta}$ chain has large oxygen nonstoichiometry, δ = 0~1, as in the case of RE123. Superconductivity with T_c above 90 K can be observed for Y247 with $\delta \sim 0$, while it does not disappear even in largely oxygen deficient composition, δ ~1, because the mean valence of copper is always higher than 2. T_c of RE247 monotonically decreases with an increase in δ except for Pr247. Pr247 shows 20 K class bulk superconductivity at δ ~0.6 where CuO_2 plane is insulating state due to hole trapping by Pr^{3+}. Therefore, the superconductivity of Pr247 is considered to be originated in CuO double chain. In addition, reentrant superconductivity by changing oxygen composition from $\delta \sim 0$ to 0.7 was observed in partially Y doped Pr247, where superconductivity by CuO_2 plane is observed at $\delta \sim 0$ and that by CuO double chain appeared at $\delta > 0.4$. (Pr,Y)247 also shows bulk superconductivity at δ ~0.5, however, its flux pinning properties are very poor reflecting very long interlayer distance between superconducting layer more than 2 nm. On the other hand, stacking faults similar to CuO double chain can be introduced in RE123 crystals by three new methods. For RE123 thin films, CuO double chain-like stacking faults was found to be introduced and their density and distribution were controlled by post annealing conditions, such as temperature, holding time and partial pressure of vapor. The defect introduced Y123 films show largely improved J_c in low field region. Similarly, CuO double chain-like stacking faults was introduced in silver coated RE123 films by oxygen annealing. Although the mechanism of defect generation due to diffusion of silver into the RE123 films is still unclear, some defect introduced films show improved J_c-*B* characteristics. High energy electron irradiation is one of the effective method to improve critical current properties of RE123 crystals. TEM observation revealed that CuO double chain-like short stacking faults generated in the crystal. Role of CuO double chain and similar defects on superconductivity and enhanced critical current properties of RE123 crystal will be discussed.

From LTS through HTS to RTS Paul C. W. Chu; University of Houston, United States

Superconductivity has been an ever-self-reinvigorating discipline since its discovery in 1911. It continues to generate excitement in science, materials, and technologies. One of the obvious hurdles to its full fruition in technology is to bring its transition temperature T_c to room temperature. In this talk, I shall first briefly review the impressive advancements made in low-temperature superconductivity (LTS) and high-temperature superconductivity (HTS) before the arrival of room-temperature superconductivity (RTS). Accompanying the advancements made in superconductivity science and technology over the last century, a solid experimental framework concerning the search, development, and even authentication of new discoveries has been established. All these can serve as valuable references in the infancy of RTS research. In this spirit, we will comment on the current status of rare-earth hydride RTS and present our preliminary negative results on Lu-N-H and LK-99, the two most studied materials in the search for RTS in the last few months, although several reports of more negation than affirmation have appeared. However, I do believe that when old wishes are dashed, new hopes will arise.

Research is supported in part by the Enterprise Science Fund of Intellectual Ventures Management, LLC; the U.S. Air Force Office of Scientific Research Grants No. FA9550-15-1-0236 and No.FA9550-20-1-0068; the T. Evidence for Near Ambient Superconductivity in The Lu-N-H system Russell J. Hemley[1], Alexander C. Mark[1], Adam Denchfield[1], Nilesh Salke[1], Muhtar Ahart[1] and Hyowon C. Park[1,2]; [1]University of Illinois Chicago, United States; [2]Argonne National Laboratory, United States

Superconductivity in the vicinity of room temperature has the potential to revolutionize both numerous technologies and our understanding of condensed matter. Zero electrical resistance and expulsion of magnetic field below critical temperature T_c are crucial tests of superconductivity. Previous work from our group has established near-room temperature superconductivity but only at megabar pressures (e.g., Ref. 1). Recently reported evidence for superconductivity at ambient *P-T* conditions in nitrogen-doped lutetium hydride (Lu-N-H) is promising but controversial[2] Our group has conducted independent measurements on the material synthesized by the methods described in Ref. 2. Four-probe electrical measurements on selected samples in diamond anvil cells show abrupt and reproducible loss of resistance at well-defined critical temperatures and pressures. Magnetic susceptibility measurements show reproducible signatures of field expulsion at similar critical temperatures. The T_c values from electrical resistance and magnetic susceptibility for these samples agree and are consistent with the previously reported data.[2] On the other hand, other samples prepared with similar procedures exhibit no measureable T_c. but instead show evidence for anomalous metal-insulator transitions that have been well-studied in lanthanide hydrides at ambient pressure (e.g., Ref. 4). Our measurements thus provide direct evidence for near ambient superconductivity in one or more Lu-N-H phases while some phases in the material are not superconducting. We also conducted first-principles DFT and DFT+U calculations to further understand the remarkable properties of these materials. Supercell calculations starting with N-doped *Fm*-3*m* LuH_3 reveal configurations such as $Lu_8H_{23-x}N$ that exhibit novel electronic properties such as flat bands, sharply peaked densities of states (van Hove singularities, vHs), and intersecting Dirac cones near the Fermi energy (E_F).[5] These electronic properties are present when N substitutes H in the octahedral interstices of Fm3m LuH_3. These structures also exhibit an interconnected metallic hydrogen network, a common feature of high-T_c hydride superconductors. Electronic property systematics gives an estimate of T_c for one structure that is well above the critical temperatures predicted for structures considered previously. DFT+U has an especially strong effect on one of the structures considered, enhancing the vHs and flat bands near E_F. These results provide a basis for understanding the electronic properties observed for nitrogen-doped lutetium hydride. Additional work is needed to fully characterize the material, optimize its synthesis, stabilize it at ambient pressure, and accurately determine the range of critical temperatures possible.

2:30 PM BREAK

3:30 PM *QT04.05.03
Superconductivities in Twisted Interface of Atomically Thin Van der Waals Materials Philip Kim; Harvard University, United States

Engineering moire superlattices by twisting and stacking two layers of van der Waals materials has proven to be an effective way to promote interaction effects and induce exotic phases of matter. After the discovery of superconductivity and correlated insulators in magic-angle twisted bilayer graphene, several different two-dimensional materials have been used to create twisted two-layer systems and various novel phases. In this talk, we will discuss the emergent electronic states observed in various twisted vdW materials. In the first part, we will discuss superconducting multilayer graphene, including twisted bilayer graphene, twisted trilayer graphene, and twisted quadrilayer graphene with alternative twist angles. In these twisted multilayer graphene systems, we also demonstrate a flat electron band tunable by perpendicular electric fields over a range of twist angles. Several correlated behaviors have been observed, including superconductivity and spontaneously broken symmetry states. In the second part of the talk, we will discuss twisted interfaces between stacked van der Waals cuprate crystals that enable tunable Josephson coupling. Using a novel cryogenic assembly technique, we fabricate high-temperature Josephson junctions with an atomically sharp twisted interface between $Bi_2Sr_2CaCu_2O_{8+x}$ crystals. We find that near the 45° twist angle, we observe two-period Fraunhofer interference patterns and fractional Shapiro steps at half integer values, a signature of co-tunneling Cooper pairs necessary for high-temperature topological superconductivity.

4:00 PM *QT04.05.04
Spin-Orbit Coupling and Superconducting Stripes in an Oxide Heterostructure EuO/KTO(110) Xianhui Chen; University of Science and Technology of China, China

Unconventional quantum states have been realized at the interfaces of oxide heterostructures, where they can be effectively tuned by the gate voltage. Recent studies reveal that the conductive interfaces in the $SrTiO_3$ (STO)-based and $KTaO_3$ (KTO)-based heterojunctions host a surprisingly enriched cascade of intriguing physical phenomena, most notably the emergence of two-dimensional (2D) superconductivity. Such 2D superconductivity is characterized by a Berezinskii-Kosterlitz-Thouless (BKT) transition; its unusual behavior in external magnetic fields and large tunability under varying electric fields render the superconducting oxide interfaces a promising platform for exploring the mechanism of unconventional superconductivity.

In this talk I will introduce our recent progress on the study of the interface between high-quality EuO (111) thin film and KTO (110) substrate. Both

oxides are insulating, yet the interface is metallic and shows superconductivity with onset transition temperature *T*onset c = 0.6-1.4 K depending on the carrier density. The 2D nature of superconductivity is verified by the large anisotropy of the upper critical field and the characteristics of a BKT transition. By applying gate voltages, *T*onset c can be largely tuned with an enhancement of ~70%; such an enhancement can be possibly associated with a boosted spin-orbit coupling (SOC) energy. Further analysis based on the upper critical field (H_{c2}) and magnetoconductance reveals complex nature of SOC at the EuO/KTO (110) interface with different dominant scattering mechanisms in the superconducting and normal states. Our results demonstrate that the SOC should be considered an important factor in determining the 2D superconductivity at oxide interfaces.

More interestingly, we discovered a peculiar band-filling-controlled dimension reduction at the superconducting interface between EuO and (110)-oriented KTO. In devices with low carrier densities, electrical transport measurements reveal different T_c and H_{c2} with current applied along the two orthogonal in-plane directions. Theoretical analysis suggests that strong coupling between Ta 5*d* and Eu 4*f* electrons occurs in the low-carrier-density samples, whereas in the high-carrier-density samples (wherein T_c becomes isotropic) such coupling is weakened. Complemented by experiments of local magnetic susceptibility imaging, our observations imply an unprecedented emergence of unidirectional stripe-like superconducting texture, presumably induced by the ferromagnetic proximity effect; we suggest that the superconducting phase coherence is first established within these “stripes”, leading to the peculiar directional dependence of T_c. The realization of such exotic superconducting states provides impetus for the study of novel physics in heterostructures possessing both magnetism and superconductivity.

4:30 PM QT04.05.05
Enhancement of Superconductivity by Isoelectronic Defects in The Fermi-Hubbard Ladder Fabio Pablo Mendez-Cordoba[1,2], Paula Giraldo-Gallo[1] and Juan J. Mendoza-Arenas[3]; [1]Universidad de los Andes, Colombia; [2]Universit□ät Hamburg, Germany; [3]University of Pittsburgh, United States

In this work we show that superconductivity across a two-leg Fermi-Hubbard ladder can be enhanced by introducing changes of the hopping parameter at specific locations in each leg. Using density matrix renormalization group calculations, we obtain the ground state of the model with repulsive on-site interactions, open boundary conditions and below half filling. We find that modifying the hopping at the position of extremal values of the density Friedel oscillations can strongly increase the value of the superconducting correlations and Luttinger parameter, compared to the homogeneous case. We discuss the mechanism underlying this finding, and experimental platforms where it can be implemented. Our results provide a possible pathway to enhance the superconducting dome by disrupting the lattice structure without changing the number of charge carriers.

Superconductivity in Thin-film Nickelates: Materials Synthesis Danfeng Li; City University of Hong Kong, Hong Kong

Developing new techniques to design and discover novel superconductors, especially those with unusual symmetries of superconducting order parameters and/or exotic pairing mechanisms, opens new doors to future applications in quantum devices. The recent discovery of superconductivity in infinite-layer nickelates has engendered reviving interest in the study of a cuprate-analog system [1]. Notably, superconducting nickelates display signatures of intriguing similarities and distinctions to the cuprates in their phase diagrams, proximity to strongly correlated electronic phases [2], antiferromagnetic interactions [3], superconducting anisotropy [4], etc. Partially owing to the non-trivial challenges in materials synthesis and their thin-film nature [5], experimental demonstration of the intrinsic properties of this materials family has still been limited. In this talk, I will introduce this new family of superconductors synthesized by a soft-chemistry approach and highlight the key aspects of their electronic and magnetic structure. I will also present our latest developments in synthetic approaches to the nickelate materials system and probing of their distinct features, in a broader context of the unusual role that rare-earth elements and chemical environment play.

8:45 AM QT04.06.02
Disentangling Symmetry-Breaking Charge Order from Oxygen Order in Infinite-Layer Nickelates Lopa Bhatt[1], Christopher T. Parzyck[1], Kyle Shen[1,1], Berit Goodge[2], David A. Muller[1,1] and Lena Kourkoutis[1,1]; [1]Cornell University, United States; [2]Max Planck Institute for Chemical Physics of Solids, Germany

As a $3d^9$ analogue to the cuprates, the recent discovery of superconductivity in infinite-layer nickelates has provided a promising direction to understand high-temperature superconductivity and its competing orders [1,2]. Despite their similarities in crystal structure and valence electron configuration, the cuprates and nickelates are distinguished by significant differences in T_c and competing ground states [3]. In cuprates, charge density waves break symmetry and compete with superconductivity at low temperature, while in nickelates charge order has been relatively elusive. There have been reports of charge order in the infinite layer nickelates [4,5], but it remains unclear whether these signatures arise from an intrinsic correlation-driven density wave or extrinsic modulation of the nickel valence from excess oxygen [6,7]. Due to the rich interplay between superconductivity and charge order found in cuprates and other superconducting systems, it is essential to build an understanding of the nature of charge order in the nickelates to shed light on universality in high temperature superconductivity.

In this work, partially-reduced capped $NdNiO_{2+x}$ thin films with intentional excess oxygen are characterized using scanning transmission electron microscopy (STEM). Electron ptychography - a phase retrieval algorithm providing highest resolution and 3D information in STEM - directly probes the atomic structure of the thin films. Precise measurement of O, Ni and Nd sites reveals the presence of excess oxygen which order with $3a_0$ periodicity, a period similar to that of previously reported charge order. Associated oxygen octahedral rotations and accompanying periodic lattice distortions (PLDs) of Nd and Ni sites are present in regions with oxygen ordering. Superlattice peaks which arise from these structural distortions enable mesoscale visualization of the excess oxygen ordering using electron nano-diffraction. We find that the ordering is not uniform across the film but exists in dispersed domains. No

superlattice peaks are observed in areas outside of ordered excess oxygen domains, suggesting that the signatures of charge order in $NdNiO_2$ reflect the presence of excess oxygen rather than intrinsic correlation effects. This work exemplifies the unique capability of a highly localized and sensitive probe, such as electron ptychography, to directly differentiate and disentangle exotic phases arising in finely tuned systems such as nickelates.

9:00 AM QT04.06.03
Eu Self-Doping Induced Superconductivity in NENO Thin Films Using *In-Situ* Synthesis Wenzheng Wei[1], Dung Vu[1], Zhan Zhang[2], Fred Walker[1] and Charles H. Ahn[1]; [1]Yale University, United States; [2]Argonne National Laboratory, United States

First observed in 2019, the superconducting infinite-layer-nickelates represent a novel class of unconventional superconductors that are spurring intense research interest due to their electronic and structural similarities to cuprate superconductors. One well known challenge to studying these materials is the ability to synthesize these materials. The common approach is to synthesize alkaline-earth-doped high-valance perovskite nickelate and conduct a topotactical reduction, a testament to the remarkable achievements to date.
In this talk, we apply an all-*in-situ* synthesis thin film processing technique to induce superconductivity in a new nickelate composition. This technique relies on the unique properties of Eu and its 4*f* electrons as a dopant and uses metallic Al deposited on top of thin film $Nd_{1-x}Eu_xNiO_3$ to reduce the samples to the superconducting phase. The resulting $Nd_{1-x}Eu_xNiO_2$ has an onset superconducting temperature as high as 21K and an unusually large upper critical magnetic field.
Work at Yale University was supported by the US DOE, Office of Science, Office of Basic Energy Sciences under award no. DE-SC0019211.

9:15 AM QT04.06.04
Structural Basis for Topotactic Transformation toward Superconducting Infinite-Layer Nickelates Hua Zhou[1], Yan Li[1], Xi Yan[1], Zihua Zhu[2], Binod Paudel[2], Yingge Du[2], Chengjun Sun[1], Shelly Kelly[1], Hong Zheng[1] and Dillon D. Fong[1]; [1]Argonne National Laboratory, United States; [2]Pacific Northwest National Laboratory, United States

The meticulous experimental verification of the infinite-layer superconducting nickelates heralds a new chapter of superconductivity after a long time extensive pursuit in rare-earth nickelate compounds for achieving cuprate-like unconventional superconductors. Despite great attention to explore the new forefront, the thermodynamic fragility of the parent precursor phase and infinite-layer phase adopting an unfavorably low nickle valence has posed a formidable experimental challenge in the thin film synthesis and the subsequent chemical reduction to attain superconductivity in infinite-layer nickelate heterostructures. Therefore, significant effort to obtain the metastable nickelate precursor phase thin films (i.e. RE0.8Sr0.2NiO3, RE = La, Nd, Pr...) with minimized extended defects has been undertaken to circumvent the main obstacles due to the chemical instability of high Ni valence and the concomitant Ruddelsden-Popper or other competing phases, for instance optimizing the non-equilibrium deposition energetics and the selection of close-matched substrate for epitaxy. However, the succeeding chemical reduction process to attain the infinite-layer structure hosting superconductivity remains serendipitous in experimental practice, and the holistic prospect of individual key steps of the evolving non-equilibrium reduction process has not yet been clearly revealed. The decisive understanding of the intricate topotactic reduction remains elusive due to its non-equilibrium dynamics and the lacking of real-time structural insights during key transformation steps.

Here, in this talk, we will demonstrate our *in situ* synchrotron surface X-ray scattering study combined with element-specific spectroscopies to probe at individual key steps of the topotactic reduction of the prototypical epitaxial Nd0.8Sr0.2NiO3 thin films into Nd0.8Sr0.2NiO2. The reduction occurs through a low temperature reaction with CaH2. The relationships between lattice structure, reaction temperature, and time within the strongly reducing environment are discussed. Our experimental observations provide much needed structural and chemical insights into formation of the square-planar structure key to the development of superconductivity in nickelate heterostructures, including clarifying the actual transformation pathway apart from other possible scenario. In particular, we uncovered that the infinite-layer phase initiates at the heterointerface and propagates toward the film surface. Notably, a dynamic surface boundary layer is present introducing hydrogen to the infinite-layer phase while removing and transferring apical oxygen ions to the reducing environment. Moreover, the measurements sensitive to the hydrogen distribution elucidate its intervening role in the intermediate reduction step, and further discount any significant contribution of hydrogen to stabilize superconductivity in the completely converted infinite-layer phase with fully suppressed oxygen octahedral rotations. These results timely address the pressing question whether superconductivity can still be realized in these nickelate compounds without hydrogen. Our study unveils the structural basis underlying the transformation pathway and provides precise experimental guidance to improve the effective reduction for obtaining intrinsic superconductivity behaviors.

10:00 AM *QT04.07.01
Exploration of Superconductivity in Layered Perovskite Nickelate $La_4Ni_3O_{10}$ under High Pressure Yoshihiko Takano[1,2]; [1]National Institute for Materials Science, Japan; [2]University of Tsukuba, Japan

Recent discovery of superconductivity in layered perovskite nickelate $La_3Ni_2O_7$ (Tc~80K) attract much attention due to its high superconducting transition temperature (Tc) and similarity of crystal structure to high-Tc cuprate [1]. And its mechanism of superconductivity is expected to be unconventional [2]. $La_3Ni_2O_7$ corresponds to the n = 2 case of the Ruddlesden-Popper phase represented by the general formula of $La_{n+1}Ni_nO_{3n+1}$, and it has two layers of NiO_2 plane. In general, Ruddlesden-Popper phase has two-dimensional crystal and electric structure which is suitable for appearance of superconductivity for instance $KCa_2Nb_3O_{10}$ [3]. Particularly, $La_4Ni_3O_{10}$, is corresponding to n = 3 case of the Ruddlesden-Popper phase having three layers of NiO_2 plane. Due to the similarity between these materials, we expect the possibility of superconductivity in $La_4Ni_3O_{10}$ under high pressure [4].
We synthesized polycrystalline samples, $La_3Ni_2O_7$ and $La_4Ni_3O_{10}$, via solid-phase reaction and Hot Isostatic Pressing process from La_2O_3 and NiO [4]. Samples are characterized by powder X-ray diffraction and thermogravimetry. High pressure was generated with Diamond Anvil Cell with boron-doped diamond electrodes designed for four-terminal resistance measurement [5]. Cubic boron nitride powder was used as a pressure-transmitting medium. $La_4Ni_3O_{10}$ displays metallic behavior across all measured pressures, with a slight upturn observed at temperatures below approximately 100 K. At 32.8 GPa, a drop in resistance suddenly appears below 5 K. With increasing the pressure beyond 46.2 GPa, the drop of resistance becomes significant. And the temperature where the resistance begins to drop elevated up to 23K at 79.2 GPa. Magnetic field dependence of resistance was measured at 69.4 GPa. As the magnetic field increases, the drop of resistance becomes smaller. Therefore, the drop in resistance is most likely to be the result of a superconducting transition of $La_4Ni_3O_{10}$ [4].

Pressure-Induced Superconductivity and Phase Transitions in Thermoelectric Material (Bi, Sb)$_2$Te$_3$ Liangzi Deng[1], Clayton Halbert[2], Busheng Wang[3], Melissa Gooch[1], Daniel J. Schulze[1], Xin Shi[1], Trevor Bontke[1], Ting-Wei Kuo[1,4], Shaowei Song[1], Nilesh Salke[2], Russell J. Hemley[2], Eva Zurek[3], Hung-Duen Yang[4], Zhifeng Ren[1], Xiao-Jia Chen[1] and Ching-Wu Chu[1]; [1]University of Houston, United States; [2]University of Illinois Chicago, United States; [3]University at Buffalo, United States; [4]National Sun Yet-Sen University, Taiwan

$Bi_xSb_{2-x}Te_3$ is a thermoelectric material with a high room-temperature figure of merit, which can be further enhanced through the application of pressure. Recently, we discovered pressure-induced superconductivity up to ~9 K in this system, and the variation in its superconducting transition temperature with pressure indicates possible phase transitions. Systematic X-ray diffraction measurements conducted at room temperature and pressures up to ~50 GPa reveal two distinct structural phase transitions. Our experimental results also suggest possible topological electronic transitions induced by pressure. In addition, our theoretical calculations have helped us verify and shed light on the structural and electronic phase transitions driven by pressure, as well as the underlying mechanisms responsible for the emergence of superconductivity in this system.

Superconducting Properties of Transition-Metal Nitrides from First Principles: Prospects for Strain and Isotope Modification of Superconducting Critical Temperatures Betul Pamuk[1] and Guru Khalsa[2]; [1]Cornell University, United States; [2]University of North Texas, United States

Epitaxial integration of metallic and superconducting transition metal nitrides into the Group IIIA-nitride semiconductor family opens new avenues for low-temperature electronics and quantum information systems. A challenge for superconducting devices in the nitride platform arises due to the incompatibility between the hexagonal GaN crystal structure and the cubic NbN phase, the main focus of existing experimental work. This incompatibility leads to twin domains that may hamper device design and functionality. Furthermore, due to epitaxial lattice mismatch, the superconducting material may be strained by several percent. Here we use first-principles theory to explore the structural polytypes of NbxN to gather insights into the microscopic physics at play in their metallic and superconducting properties. We focus this work on the prospect of using strain and isotopes to modify electron-phonon interactions and superconducting properties. We discuss the limitations of the theoretical approximations and present our results within the framework of current experimental capabilities. We weigh the desired properties against the constraints imposed by structural symmetry-dictated domains, aiming for the development of domain- and defect-free epitaxial devices.

11:00 AM QT04.07.04
Effect of Metamaterial Engineering on The Superconductive Properties of Ultrathin Layers of NbTiN Michael S. Osofsky[1], Vera Smolyaninova[1], Grace Yong[1], Will Korzi[1], Anne-Marie Valente-Feliciano[2], David Beverstock[2,3], Joseph Prestigiacomo[4] and Igor Smolyaninov[5,6]; [1]Towson University, United States; [2]Thomas Jefferson National Accelerator Facility, United States; [3]College William & Mary, United States; [4]US Naval Research Laboratory, United States; [5]University of Maryland, United States; [6]Saltenna LLC, United States

The electronic transport and optical properties of high quality multilayers of NbTiN/AlN with ultrathin NbTiN layers were characterized. The anisotropy of the dielectric function of the multilayers confirmed their hyperbolic metamaterial properties. The superconductive transition temperature, T_c, of these engineered superconductors was enhanced up to 32% compared to the T_c of a single ultrathin NbTiN layer while the resistivity per NbTiN layer remained unchanged. We have demonstrated that this T_c increase can be attributed to enhanced electron-electron interaction in superconducting hyperbolic metamaterials. The measured critical fields are high and have anomalous temperature dependence in the perpendicular to the magnetic field direction. These results demonstrate that the metamaterial engineering approach can be used to enhance H_{c2}.

SESSION QT04.08: Novel Materials III—Topological Materials

1:30 PM *QT04.08.01
Experimental Signatures of Higher Order Topology Richard Deblock; Laboratoire de Physique des Solides, France

In second-order topological insulators (SOTIs), the bulk and surfaces are insulating, while the edges or hinges conduct current in a quasi-ideal (ballistic)

manner, insensitive to disorder. As in the case of quantum spin Hall edges of 2D topological insulators, the current should be transported without dissipation by counter-propagating ballistic helical states with spin orientation locked to momentum. These edge or hinge states open up many possibilities, ranging from dissipation-free charge and spin transport to new avenues for quantum computing. Bismuth, although a semi-metal, has been shown to belong to this class of materials. In our group, we have studied Josephson junctions based on crystalline Bi nanowires and found that they exhibit robust sawtooth current phase relations in a high magnetic field, which is the signature of one-dimensional ballistic edge states. We also demonstrated the topological nature of Andreev states through the dissipative microwave response in a phase-biased configuration. More recently, in a SQUID constructed from a bismuth ring, we have identified the parity relaxation rate by exploring the statistics of the switching current. In order to find different topological insulators with reduced contribution from bulk non-topological states, we are now exploring the quantum transport properties of WTe2, which has been shown to exhibit a quantum spin Hall effect in the few-layer limit, and Bi4Br4. The latter material is a SOTI with a high bulk band gap.

2:00 PM QT04.08.02
Observation of a Resonant Andreev Plateau from Topologically Protected Hinge Modes Wenyao Liu; Boston College, United States

A key challenge in topological systems is finding unique signatures of their boundary modes. This is especially true in topological superconductors where the bulk is gapped, but the superfluid can short-circuit transport signatures seen in quantum Hall states. A particularly promising candidate is Fe(Te,Se), which is predicted to host a 1D high-order topological superconducting (1D-HOTSC) state. This can emerge either from the bulk sign-changing order parameter or from the combination of intrinsic magnetism and topological superconductivity. Here, we present systematic tunneling experiments to test the existence of 1D-HOTSC mode. Initially, we observe an anomalous conductance plateau signal centered around zero bias when electrons tunnel along the hinges of our Fe(Te,Se) device in the topologically nontrivial phase. Remarkably, this anomalous conductance plateau disappears when the current source and ground are no longer connected by the same hinge, suggesting the nonlocal resonant Andreev processes originating from a propagating TSC hinge mode. To confirm this originates from nontrivial topology, we have tested devices with different Te/Se composition that possess similar superconducting transition temperatures without the bulk topological band inversion. As expected, such resonant conductance signal disappears in these samples. Additionally, the conductance plateau is robust to applied magnetic field and temperature, so long as the long-range magnetic order detected by Kerr rotation is maintained. Thus, our results are consistent with chiral TSC modes rather than trivial superconducting states.

2:15 PM QT04.08.03
Searching for Ideal Topological Superconductors in Pb-Sn-In-Te System Genda Gu, Ruidan Zhong, John A. Schneeloch, Yangmu Li, Qiang Li and John M. Tranquada; BNL, United States

The discovery of 3D topological insulator materials and topological superconductor open up a new research field in the condensed matter physics. In order to search for the topological superconductor, we have grown a large number of the single crystals of Pb-system (Pb-Sn-In-Te) topological superconductor . We have measured the physical properties on these single crystals by various techniques. We have studied the effect of crystal growth condition, impurity and composition on the bulk electrical conductivity of these single crystals. We try to find out which composition and crystal growth condition is the best for the ideal topological superconductor. We have got the bulk topological superconductor with T c =5K.

2:30 PM QT04.08.04
Absence of Nematic Instability in The Kagome Metal CsV_3Sb_5 Zhaoyu Liu[1], Yue Shi[1], Qianni Jiang[1], Elliott M. Rosenberg[1], Jonathan DeStefano[1], Jinjin Liu[2], Chaowei Hu[1], Yuzhou Zhao[1], Zhiwei Wang[2], Yugui Yao[2], David Graf[3], Pengcheng Dai[4], Jihui Yang[1], Xiaodong Xu[1] and Jiun-Haw Chu[1]; [1]University of Washington, United States; [2]Beijing Institute of Technology, China; [3]National High Magnetic Field Laboratory, United States; [4]Rice University, United States

Ever since the discovery of the charge density wave (CDW) transition in the kagome metal CsV_3Sb_5, the nature of its symmetry breaking is under intense debate. While evidence suggests that the rotational symmetry is already broken at the CDW transition temperature (T_{CDW}), an additional electronic nematic instability well below T_{CDW} was reported based on the diverging elastoresistivity coefficient in the anisotropic channel (m_{E2g}). Verifying the existence of a nematic transition below T_{CDW} is not only critical for establishing the correct description of the CDW order parameter, but also important for understanding the low-temperature superconductivity. Here, we report elastoresistivity measurements of CsV_3Sb_5 using three different techniques probing both isotropic and anisotropic symmetry channels. Contrary to previous reports, we find the anisotropic elastoresistivity coefficient m_{E2g} is temperature-independent except for a step jump at T_{CDW}. The absence of nematic fluctuations is further substantiated by measurements of the elastocaloric effect, which show no enhancement associated with nematic susceptibility. On the other hand, the symmetric elastoresistivity coefficient m_{A1g} increases below T_{CDW}, reaching a peak value of 90 at T^{*}=20 K. Our results strongly indicate that the phase transition at T^{*} is not nematic in nature and the previously reported diverging elastoresistivity is due to the contamination from the A_{1g} channel.

3:15 PM *QT04.09.01
New Material Platforms for Quantum Computing Nathalie P. de Leon; Princeton University, United States

Constructing fault-tolerant quantum processors based on transmon qubits will require significant improvements in qubit relaxation and coherence times, which are orders of magnitude shorter than limits imposed by bulk properties of the constituent materials. However, significant improvements in the lifetime of planar transmon qubits have remained elusive for several years. We have fabricated planar transmon qubits that have both lifetimes and coherence times exceeding 0.3 milliseconds by using tantalum as the capacitor material. Following this discovery, we have parametrized the remaining

sources of loss in state-of-the-art devices using systematic measurements of the dependence of loss on temperature, power, and geometry. This parametrization, complemented by direct materials characterization, allows for rational, directed improvement of superconducting qubits.

3:45 PM QT04.09.02
Josephson Junctions and NanoSQUIDs Grown by Focused Electron and Ion Beam Induced Deposition Jose M. De Teresa, Fabian Sigloch, Amaia Sáenz and Soraya Sangiao; CSIC, Spain

Focused Electron and Ion Beam Induced Deposition (FEBID and FIBID, respectively) are direct-write resist-free nanolithography techniques enabling the growth of high-resolution nano- and micro-structures. They rely on a gas precursor that is injected into the area of interest and decomposed by a focused electron or ion beam. Using the $W(CO)_6$ precursor and Ga^+ or He^+ FIBID [1], we grow superconducting in-plane nanowires with high lateral resolution [2], as well as three-dimensional superconducting nanostructures [3]. In this contribution, we will present recent results on the fabrication of Josephson junctions and nanoSQUIDs based on FIBID- and FEBID-grown W-C deposits. First, results of W-C nanoSQUIDs patterned as two large pads connected by two short nanowires will be shown. In these devices, the critical current oscillates as a function of the externally-applied magnetic field, which results in a large output voltage to magnetic flux change (1.3 mV per magnetic flux quantum) [4]. Interestingly, these nanoSQUIDs can be implemented on a cantilever for application in scanning-SQUID technology [5]. Other experiments in which Josephson Junctions (JJs) are created with alternative geometries and also with FEBID will be shown here. In summary, FEBID and FIBID represent techniques that can be exploited for the direct-write fabrication of superconducting devices for application in quantum technologies [6].

Josephson Diode Effect in Chiral Carbon Nanotubes Joseph J. Cuozzo[1], Michael Sizemore[2], Francois Leonard[1] and Enrico Rossi[2]; [1]Sandia National Laboratories, United States; [2]William & Mary, United States

Within superconducting electronics, the Josephson diode effect (JDE) has attracted interest in recent years. Josephson diodes are characterized by an asymmetry in positive and negative switching currents of a Josephson junction (JJ) and could potentially find utility in a growing number of applications at cryogenic temperatures in the Quantum Information Sciences. Despite extensive theoretical and experimental work investigating the JDE, little attention has been paid to nanotube devices where non-reciprocity can be introduced in chiral structures. In this talk, we will present analytic and numerical results on the JDE in chiral carbon nanotubes (CNT). We find that chiral nanotubes in JJs can exhibit diode efficiencies far exceeding those of superconducting chiral nanotubes when an external magnetic field is applied along the nanotube. Furthermore, our numerical simulations show the Josephson diode *polarity* can be tuned by electrostatically gating CNTs in a Josephson junction. We will discuss the microscopic details that give rise to large diode efficiencies and gate-tunability in chiral CNT JJs.

This work was supported by the U.S. Department of Energy (DOE), Office of Science, Basic Energy Sciences (BES), under Award DE-SC0022245. The work at Sandia is supported by a LDRD project. SNL is managed and operated by NTESS under DOE NNSA contract DE-NA0003525.

4:15 PM QT04.09.04
Fabrication of Superconducting Devices on Diamond Manjith Bose[1,2] and Christopher I. Pakes[2]; [1]The University of Melbourne, Australia; [2]La Trobe University, Australia

Recent advancements in Chemical Vapour Deposition (CVD) based synthetic diamond growth have opened new avenues for the development of electronic devices capitalising on diamond's exceptional properties, including its high critical field (H_C) and transition temperature (T_C). Achieving superconductivity in lab-grown diamond with high boron concentrations is well-documented in bulk diamond, but limited research focuses on superconducting devices in diamond. The focus of this study was on developing innovative methodologies to engineer micro and nano-scale superconducting diamond devices using thin films of boron-doped nanocrystalline diamond (BNCD) and single crystalline diamond (BSCD). We employ electron beam lithography (EBL) and reactive ion etching (RIE) to engineer highly overdamped and non-hysteretic sub-micron bridges with varying dimensions on superconducting diamond films and low temperature magnetotransport measurements were conducted. A novel fabrication methodology involving neon-ion milling was developed to further define Dayem bridge junctions that demonstrated Josephson effects. The first NCD diamond nano-SQUID was created using these nanobridges as weak links, with a 50 nm loop size.

The nano-SQUID showed a very low flux noise $\Phi_{noise} = 0.14\ \mu\Phi_0/\sqrt{\text{Hz}}$ at 1 kHz, and concurrent spin sensitivity of 11 spins/√Hz, comparable to that of the lowest noise nano-SQUIDs reported so far in established materials such as niobium. The successful fabrication methodologies on BNCD films were further translated to locally grown BSCD films and superconducting bridges were demonstrated for the first time. In this presentation, we will discuss our results on BNCD nano-SQUIDs and outline our current efforts in developing devices on BSCD films and their corresponding transport measurement results.

4:30 PM QT04.09.05
Towards Atomic Precision in Superconducting Qubits: Mechanisms of Ta Oxidation and Strategies for Oxidation Suppression Peter V. Sushko[1,2], Chenyu Zhou[3], Junsik Mun[3], Mohammad D. Hossain[1], Jeffrey Dhas[1], Ekta Bhatia[2], Satyavolu Papa Rao[2], Yingge Du[1], Yimei Zhu[3] and Mingzhao Liu[3]; [1]Pacific Northwest National Laboratory, United States; [2]NY Creates, United States; [3]Brookhaven National Laboratory, United States

Coherence times of transmon devices can be affected by oxidation of the components made of superconducting metals, such as Nb and Ta. Spontaneous oxidation results in the formation of suboxide phases and surface amorphization that contribute to dielectric losses that are primarily attributed to two-level systems within such native oxide layers. Mitigating undesirable effects of surface oxidation requires understanding the mechanisms of interfacial interactions at the atomic scale.

We review recent experimental studies that provide new insights into the atomic structure and composition of the native oxide layer and focus on ab initio simulations of the mechanisms of Ta interaction with oxygen. In particular, we consider energetics and pathways of the early stages of the Ta(110) surface oxidation, including propagation of the oxidation front into the Ta subsurface and corresponding electronic structure changes. We also explore strategies for suppressing Ta oxidation with the help of reactive metal coating and discuss atomic-scale models of candidate two-level systems.

Superconductivity in Nanowire Devices Formed by Al-Si Exchange Jeffrey C. McCallum[1], Brett Johnson[2], Manjith Bose[1], Michael Stuiber[3], Daniel Creedon[4], Sergey Rubanov[5], Vincent Mourik[6], Jared Cole[2] and Alex Hamilton[7]; [1]The University of Melbourne, Australia; [2]RMIT University, Australia; [3]Melbourne Centre for Nanofabrication, Australia; [4]CSIRO Manufacturing, Australia; [5]University of Melbourne, Australia; [6]Julich Research Institute, Germany; [7]University of New South Wales, Australia

Development of devices that contain both superconducting and semiconducting components on a single chip is an important area of investigation for emerging quantum technologies. We have investigated superconductivity in nanowire devices fabricated using the Al-Si exchange process in silicon-on-insulator wafers. Aluminum from deposited contact electrodes undergoes an Al-Si exchange process with prepatterned Si nanowire device structures along the entire length of the nanowire, over micrometer length scales and at temperatures well below the Al−Si eutectic. The phase-transformed material is conformal with the predefined device patterns. In magneto-transport measurements, nanoring structures formed by this fabrication process exhibit periodic features in the differential resistance and in the critical current that result from fluxoid quantization. The retrapping current also exhibits oscillations. The devices can be operated in temperature/magnetic-field regimes where some components of the device are in the superconducting state while others are in a resistive state. Under these conditions the magneto-transport data exhibit more complex features which may provide insight into how these mixed-state devices could be further developed for uses in magnetometry and other quantum technologies. The details of the Al-Si exchange process also suggest that it could allow a range of new nanoscale superconducting-semiconducting device structures to be formed. In this presentation, our exploration of these superconducting nanowire devices and their promise for quantum technologies development will be discussed.

Uniformity of Orientation Degrees in Dy123 Superconductor through Linear Drive-Type Modulating Rotating Magnetic Field Walid B. Ali, Shintaro Adachi, Fumiko Kimura and Shigeru Horii; Kyoto University of Advanced Science, Japan

The rare earth-based cuprate superconductor $REBa_2Cu_3O_y$ (RE123) has garnered significant attention due to its high critical temperature (T_c) of approximately 90 K, making it suitable for various applications like liquid nitrogen-operated superconducting bulk magnets and cables. This material features an anisotropic crystal structure, comprising alternating 2D superconducting CuO_2 layers and 1D Cu-O chains. This anisotropy results in varying critical current densities (J_c) in different directions, with J_c//*c* being lower than J_c//*ab* [1]. To enhance the practical use of RE123, it's crucial to achieve biaxial or triaxial orientation and densification of its grains. One non-epitaxial method for grain orientation enhancement is magnetic alignment. Magnetic alignment doesn't require a vacuum process and can be done at room temperature. It involves the generation of a modulated rotating magnetic field (MRF) with two or more axes. In this context, permanent magnets (PMs) have proven to be a cost-effective solution for creating a low-cost MRF and aligning RE123 grains.
A continuous production technique known as linear drive-type modulated rotating magnetic field (LDT-MRF) employs a PM array to achieve triaxial grain alignment [2]. This equipment can generate an MRF of ~ 0.8 T without physically moving the sample [3]. Using this approach, $DyBa_2Cu_3O_y$ (Dy123) grains were successfully biaxially aligned, as evidenced by a four-fold symmetric (103) pole figure at $\Psi \sim 45°$, similar to results achieved with a 10 T-MRF from a superconducting solenoidal magnet [4]. In prior work [3], we noticed location-dependent orientation degrees in the biaxially aligned sample. The center part displayed higher in-plane and *c*-axis orientation degrees of around 8.5° and 6.0°, respectively. The side portions also exhibited higher orientation degrees but with a shift of the four-fold symmetric spots toward the right and leftward of the (103) pole figures. To understand this shift in diffraction spots, 3D simulations using the Finite Element Method (FEM) software were conducted to analyze the behavior of flux lines in the air gap between the magnet arrays. The simulation revealed that the flux lines inclined toward the outside of the magnet array along the *Y*-axis (the width of the magnet array), causing a $\theta \sim 6°$ shift in diffraction spots from the center. This indicated non-uniformity in the MRF at the side parts of the magnet array, resulting in flux line leakage outside the array.
To address this non-uniformity, we designed a new magnet array with an increased width along the *Y*-axis, expanding it from 20 mm to 48 mm. The 3D simulation of this new design showed that the inclination angle remained under ~ 5° up to $Y = 16.5$ mm from the center, ensuring high orientation degrees. Biaxial alignment experiments with Dy123 powders in the newly designed magnet array consistently displayed four-fold diffraction spots at $\Psi \sim 45°$, extending from the center to $Y = 10.5$ mm, with a slight 3° shift at $Y = 14$ and 16.5 mm. Importantly, the experimental results quantitatively matched the simulation results, demonstrating a homogeneous MRF within the range of $0 \leq Y \leq 16.5$ mm in the newly designed magnet array, resulting in an in-plane orientation degree of ~ 8.4°. This research suggests that LDT equipment, in combination with improved magnet array designs, has the potential to advance RE123 superconducting tape production. However, challenges in material production and equipment limitations still need to be addressed. The presentation will feature 3D simulation results for the previous and newly designed magnet arrays, along with an explanation of how increasing the magnet array's width helped overcome location-dependent orientation degree issues.

'Seeing' Physical Properties of 2D Materials on Nanoscale Olga Kazakova[1,2]; [1]National Physical Laboratory, United Kingdom; [2]The University of Manchester, United Kingdom

We present a unique opportunity of 'seeing' physical (and chemical) properties of 2D materials and heterostructures on (sub)nanoscale. Using a combination of advances functional scanning probe microscopy (SPM) techniques, we perform a detailed local study of electrical, electronic, optoelectronic, and thermal properties. These studies are complemented by development of scanning gate microscopy techniques, where the gate can be a local source of electric/magnetic field, heat or near-field. We thus combine functional imaging with an active control and manipulation of the device properties. We demonstrate that advanced functional SPM techniques are a very powerful tool to obtain detailed information on the unique sample properties (such as the effect of non-uniformity, defects, degree of molecular absorption, etc.), which are not assessable by more traditional methods. We also demonstrate the accuracy of the measurements, which allows us to eliminate the common artefacts, which are not usually taken into account in many other approaches. The present work facilitates development of realistic 2D materials devices and their faster and reliable implementation.
We also aim to showcase the measurement capability associated with the quantum material nanoprobe facilities for the research and applications of materials for quantum technologies, at scales ranging from several micrometers down to individual atoms.

The Interplay of Topology and Symmetry in Non-Symmorphic Square-Net Tellurides Probed by Scanning Tunnelling Microscopy Sarah Burke; University of British Columbia, Canada

The non-symmorphic square-net materials have been of interest due to their symmetry enforced band crossings giving rise to Dirac nodal loops and both topologically trivial and non-trivial surface states. Crystals of the P4/nmm space group feature a plane of atoms in a square net (e.g. the Si plane in the ZrSiX family or Sn plane in RESnX family) with a 2-atom unit cell due to the surrounding lattice. This doubling of the square net unit cell, along with glide plane symmetry enforces a degeneracy at the edge of the Brillouin zone driving a crossing of different orbital symmetry that prevent hybridization. These features give rise to wide-bandwidth linear crossings which revolve around the Brillouin zone enclosing regions of distinct topology.

I will describe our recent work on two of these materials: ZrSiTe which exhibits a topologically non-trivial surface state, and LaSbTe which has a doping-dependent structural distortion that gaps portions of the nodal loop. Using Scanning Tunnelling Microscopy and Spectroscopy (STM/STS), we have investigated the surface structure and electronic states through quasiparticle interference (QPI) measurements. In ZrSiTe, the large area between two nodal loops hosts a topologically non-trivial "drumhead" surface state, previously observed up to Ef by ARPES[1]. However, the presence of spin-orbit coupling in this system gaps the nodal lines, raising the question of what happens to the drumhead state. Using QPI we observed strong signatures of the drumhead state below and above E_f confirming this topologically protected state persists, owing to the small energy scale of spin-orbit coupling relative to the large band width of the nodal lines[2]. We find that the drumhead state disperses over an energy range of ~600meV and is split, but not gapped by the presence of spin-orbit coupling.

Unlike the mild perturbation of spin-orbit coupling, changes in symmetry (perhaps obviously) break the symmetry-enforced protection of the nodal-lines giving the potential for much larger gap openings. While Si square net is held together by strong interaction with Zr, the square nets with rare-earths off plane are prone to distortion from the heavily nested Fermi surface. Indeed, stoichiometric LaSbTe forms in an orthorhombic phase featuring a buckled square-net with zig-zag chains, with a gap opening in the nodal-lines in Γ-S direction. Here we have investigated the surface structure and electronic states

of twinned *o*-LaSbTe. The zig-zag rows of the Sb lattice can be seen in STM images, and a soft-gap of ~300meV can be observed consistent with DFT calculations for the distorted structure. Twin-boundaries show the two perpendicular orientations with domain "walls" several unit cells wide that appear tetragonal. Highly directional QPI is seen around Sb-lattice defect sites and is consistent with scattering from the remaining pockets of the nodal loops appearing in the tetragonal phase. I will also discuss the potential for doping to traverse this phase diagram and topological implications of these structural changes.

3:00 PM *QT05.01.03
Multiscale Characterization of Quantum Materials Donald M. Evans; University of Warwick, United Kingdom

Quantum materials, defined by their unique electronic properties, are central to current scientific and technological research. Their distinct conductivity and complex phase behaviour present an intriguing puzzle with both opportunities and challenges. Central to this exploration is the interplay between microstructures, compositional changes, and the resulting electronic properties. Adopting a multiscale approach provides essential insights into the impacts of these atomic-scale changes on the material's functional properties. In this presentation, we utilize the topical superconductor Fe(Se,Te) to showcase the importance of applying advanced multiscale characterization techniques. Initial bulk characterization confirmed the quality of our material system, indicating high-quality homogeneous single crystals. However, local real-space mapping of the enhanced conductivity of the superconducting phase, via low temperature conductive atomic force microscopy (cAFM), revealed unexpected spatial inhomogeneities. Specifically, across five orders of real space imaging, we see that the majority of the crystal is relatively insulating, with only localized regions of heightened conductivity. To confirm and substantiate these observations, we use atom probe tomography (APT) and energy dispersive x-rays (EDX) to discern that the different regions have distinct chemical compositions. This highlights the vital role of multiscale characterization in quantum materials, illustrating their true complexities that may elude classical characterization techniques. Such approaches are essential for refining our methods and advancing quantum material research.

3:30 PM QT05.01.04
Revealing Emergent Magnetic Charge in an Antiferromagnet with Diamond Quantum Magnetometry Anthony Tan[1], Hariom Jani[2,3], Michael Hogen[1], Lucio Stefan[1], Claudio Castelnovo[1], Daniel Braund[1], Alexandra Geim[1], Annika Mechnich[1], Matthew Feuer[1], Helena Knowles[1], Ariando Ariando[3], Paolo Radaelli[2] and Mete Atature[1]; [1]University of Cambridge, United Kingdom; [2]University of Oxford, United Kingdom; [3]National University of Singapore, Singapore

Whirling topological textures play a key role in exotic phases of magnetic materials and offer promise for logic and memory applications. In antiferromagnets, these textures exhibit enhanced stability and faster dynamics with respect to ferromagnetic counterparts, but they are also difficult to study due to their vanishing net magnetic moment [1]. One technique that meets the demand of highly sensitive vectorial magnetic field sensing with negligible backaction is diamond quantum magnetometry. Here, we show that the archetypal antiferromagnet, hematite, hosts a rich tapestry of monopolar, dipolar and quadrupolar emergent magnetic charge distributions [2]. The direct readout of the previously inaccessible vorticity of an antiferromagnetic spin texture [1] provides the crucial connection to its magnetic charge through a duality relation. Our work defines a novel paradigmatic class of magnetic systems to explore two-dimensional monopolar physics, and highlights the transformative role that diamond quantum magnetometry could play in exploring emergent phenomena in quantum materials.

3:45 PM *QT05.01.05
Exploiting The Coherence of Synchrotron X-Rays to Study The Dynamics of Quantum Matter Sophie Morley; Lawrence Berkeley National Laboratory, United States

A challenging aspect of designing functional materials is to understand the impact of a wide range of characteristic spatial and temporal scales on stabilizing novel quantum phases. Commonly used mean field approaches often provide reasonable estimates for static properties at macroscopic length scales, however, it does not provide the requisite fundamental insight into the important processes governing deviations from these averages. Such fluctuations are critically important. Soft x-rays are a powerful element-specific probe to study such mesoscopic charge and spin textures. The coherence available at current and newly upgraded light sources will enhance our tools to give significantly more detailed information of otherwise difficult to probe quantum states. We select the coherent part of the x-ray beam to produce an interference pattern known as speckle. Here I will discuss how we use that speckle to look inside, and better understand, the transitions of orbital order, amorphous noncollinear magnets and metal-to-insulator materials.

4:15 PM QT05.01.06
Optimisation of CVD Diamond for Applications in Room-Temperature Masers Daan M Arroo, Wern Ng, Yongqiang Wen, Philip Diggle and Neil McN. Alford; Imperial College London, United Kingdom

Masers are the microwave analogue of lasers and can be operated as oscillators and amplifiers with quantum-limited noise performance. Despite their exceptionally low noise, conventional masers have historically been limited to niche applications in radio astronomy and deep-space communications due to their requirement for ultrahigh vacuums and cryogenic temperatures.

Recently masers capable of operating continuously at room temperature have been demonstrated using ensembles of nitrogen-vacancy (NV) centres in diamond, opening a route to the widespread use of masers across a range of new applications in telecommunications, medical imaging and quantum sensing.

In order to realise these broad applications it will be necessary to build miniaturised, portable diamond masers that can be readily integrated into existing standards but to date this has been limited by the highly homogeneous magnetic fields required for diamond masers to maintain coherence. Here we discuss strategies for relaxing the field-homogeneity requirement by optimising the material parameters of CVD-grown NV-diamond and present results benchmarking the performance of diamond masers using diamond gain media in which the concentrations of 13C nuclei and nitrogen-vacancy spins are varied. We conclude by discussing recent progress in the development of miniaturised diamond masers.

4:30 PM *QT05.01.07
A Quantum Coherent Spin in a Two-Dimensional Material at Room Temperature Hannah Stern[1], Carmem M. Gilardoni[2], Qiushi Gu[2], Simone E. Barker[2], Oliver F. Powell[2,3], Xiaoxi Deng[2], Stephanie A. Fraser[2], Louis Follet[2], Chi Li[4,4], Andrew Ramsay[3], Hark Hoe Tan[5], Igor Aharonovich[4] and Mete Atature[2]; [1]The University of Manchester, United Kingdom; [2]University of Cambridge, United Kingdom; [3]Hitachi Cambridge Laboratory, Hitachi Europe Ltd, United Kingdom; [4]University of Technology Sydney, Australia; [5]The Australian National University, Australia

Quantum networks and sensing require solid-state spin-photon interfaces that combine single photon generation and long-lived spin coherence with scalable device integration, ideally at ambient conditions. Despite rapid progress reported across several candidate systems, those possessing quantum coherent single spins at room temperature remain extremely rare. In this talk, I will show new results of quantum coherent control under ambient conditions of a single-photon emitting defect spin in a two-dimensional material, hexagonal boron nitride. I show that the carbon-related defect has a spin-triplet electronic ground-state manifold and that the spin coherence is governed predominantly by coupling to only a few proximal nuclei and is prolonged by decoupling protocols. These results allow for a room-temperature spin qubit coupled to a multi-qubit quantum register or quantum sensor with nanoscale sample proximity.

SESSION QT05.02 Advances in Detection Methods for Emergent Phases in Quantum Materials II
Session Chairs: Shelly Michele Conroy and Jessica Wade
Wednesday Morning, April 24, 2024
Room 446, Level 4, Summit

8:30 AM *QT05.02.01
Nanoscale Advanced Materials Engineering for Quantum Technologies Ravi Acharya[1,2], Maddison Coke[1], Mason Adshead[1], Kexue Li[1], Barat Achniuq[3], Rongsheng Cai[3], Baset Gholizadeh[1], Janet Jacobs[1], Jessica L. Boland[1], Sarah J. Haigh[3], Katie Moore[1], David Jamieson[2] and Richard J. Curry[1]; [1]Photon Science Institute, United Kingdom; [2]The University of Melbourne, Australia; [3]The University of Manchester, United Kingdom

The ability to engineer the electrical, optical and magnetic properties of advanced materials on the nanoscale is of increasing importance to the development of future quantum technologies. One approach to achieving this is through impurity doping, with increased control over the spatial resolution and isotopic purity enabled by the development of dedicated tools. To achieve this goal a new capability (the 'Platform for Nanoscale Advanced Materials Engineering, 'P-NAME', Facility) has been developed and applied specifically to the engineering of materials for quantum technology. We demonstrate how the combined utilisation of novel ion source and mass selection technology enables the direct-write creation of bespoke materials utilising ultra-high ion doses (>1E19 ions/cm^2) down to single-ion doping. The validation of such capability requires the utilisation of advanced detection and characterisation techniques. We draw upon the combined use of electrical, photonic, mass spectroscopy and electron microscopy methods in order to enable this. Together this allows us to demonstrate the delivery of ultra-enriched ^{28}Si as a platform for quantum technology device fabrication, and also for the doping of single-ion impurity centres within solid-state systems. Of particular interest is the development of methods to reliably detect single-ion doping events. This is a key enabling step to overcome the inherent limitation that is otherwise imposed by Possionian statistics. Progress within this area remains a key challenge if scaling to deliver qubit arrays of the order of 10^6 is to be achieved in order to deliver full error corrected quantum computation.

9:00 AM *QT05.02.02
Magnetotransport for Dirac Semimetal Phase of Topological Insulator Sb_2Te_3 Satoshi Sasaki and Joshua T. Gretton; University of Leeds, United Kingdom

Antimony Telluride (Sb_2Te_3) makes up the second generation of Topological Insulator (TI) materials with other layered chalcogenides Bi_2Se_3 and Bi_2Te_3. The TI phase in these materials arises from a spin-orbit induced band crossing of opposite parity orbitals at the Γ point of the Brillouin Zone, resulting in a single topologically protected Dirac cone projected to all surfaces.[1] Another set of surface states have been identified in Sb_2Te_3: intrinsic Rashba spin-orbit split surface bands extending from 300 to 750 meV below the valence band edge exist within a partial valence band gap.[2–5] Also, a strong linear character to the bulk valence band dispersion has been established in Angle Resolved Photo-Emission Spectroscopy (ARPES) experiments,[4] where accidental band crossing points[2,3,6,7] imply a Dirac energy spectrum and so Dirac semimetal phase.[8,9]
Sb_2Te_3 is usually heavily hole doped due to a combination of Te vacancies and Sb_{Te} anti-site defects,[10,11] with $p \sim 10^{20}$ cm^{-3} the typical carrier density for nominally stoichiometric samples.[12,13] The intrinsic doping effects in this material class are typically difficult to overcome, however they should also place the chemical potential close to the Dirac-like spectrum of bulk bands,[2,3,12] meaning these could contribute to the transport without significant tuning of the carrier density.
So far no studies of the electronic transport looking for indications of these states has been carried out. To better understand the material system and probe for these contributions, Sb_2Te_3 single crystals have been grown using a modified Bridgman method with excess Te in the melt, and the magnetotransport of (001) oriented single crystal Sb_2Te_3 with p-type carrier densities in the range $2.4 - 12 \times 10^{19}$ cm^{-3} is studied up to 8 T. It is found that the semiclassical magnetotransport is described by a two-carrier band model, finding contributions from majority hole and minority electron bands, and clear Shubnikov de Haas Oscillations (SdHO) are resolved at 1.5 K across the carrier density range. The convolution of different frequency SdHO cause novel beating envelopes for samples with reduced carrier densities and non-trivial Berry phases are extracted for carrier densities in the range $4.1 - 7.9 \times 10^{19}$ cm^{-3}. Detailed consideration of the SdHO points away from either the Rashba or Dirac surface bands causing these, and instead the region of multiple pockets of linearly dispersive Dirac-like bulk band crossing points in the upper valence band is found responsible. This work therefore confirms a bulk Dirac semimetal phase in the well-known TI Sb_2Te_3.

10:00 AM *QT05.02.03
Intrinsic Magnetism in Infinite-Layer Nickelate Superconductors Jennifer Fowlie; Stanford University, United States

Nickel and copper are nominally similar so the search for superconductivity in nickelates is a story as old as the quest to understand the high temperature superconductivity of the cuprates.
In this talk, I will introduce the recent discovery of superconductivity in infinite-layer nickelates [1] and the ever-growing family of nickelate superconductors. I will touch on some of the materials challenges involved before summarizing the key physics we have learned so far. In particular I will focus on results from low-energy muon spin rotation [2] that reveals local magnetism in these materials that 1) onsets at rather high temperature, 2) is independent of the rare earth 4f electrons, 3) appears to be robust to doping 4) is antiferromagnetic and possibly short-range-ordered in nature and 5) coexists with superconductivity at low temperatures.
Finally, I will come back to the comparison between nickelates and cuprates and discuss how the disparities in the magnetic properties may be understood.

[2] J. Fowlie et al, Nature Physics 18 (2022) 1043

10:30 AM *QT05.02.04
Microstructural Effects of Topotactic Reduction in Nickelate Single Crystals Y. Eren Suyolcu, Yu-Mi Wu, Pascal Puphal, Hangoo Lee, Masahiko Isobe, Bernhard Keimer, Matthias Hepting and Peter A. van Aken; Max Planck Institute for Solid State Research, Germany

Rare-earth nickel oxides, known for their intricate interplay between structure and properties, serve as a pivotal foundation for the exploration of novel quantum phases and advanced applications. Recent topotactic transformations of perovskite nickelates have enabled precise control over oxygen vacancies, thereby harnessing the consequential coupling effects in these materials. Gaining in-depth insights into the atomic-scale lattice and electrical structure during topotactic reduction is imperative for unraveling the potential of these phenomena. In this study, we employ atomic-resolution scanning transmission electron microscopy (STEM) imaging and electron energy-loss spectroscopy (EELS) to examine two distinct nickelate single crystals variants, namely $R_{1-x}Ca_xNiO_{3-\delta}$ (where *R* represents either La or Pr). These single crystals are synthesized through topotactic reduction of the perovskite phase, employing CaH_2 as a reducing agent. The presentation will provide a comprehensive analysis of the oxygen vacancies, hole doping into the material, and the influence of cation structure.

We primarily focus on $Pr_{1-x}Ca_xNiO_{3-\delta}$ single crystals, revealing an oxygen-deficient phase with $\delta \sim 0.25$ occurring during topotactic reduction. A novel arrangement of oxygen vacancies within the brownmillerite structure, diverging from previously observed in reduced rare-earth nickelates. Precise quantification of polyhedral tilting and bond angles shows that a significant amount of internal strain drives wave-like variations in polyhedral tilting and rotations to accommodate the local lattice structure [1]. Subsequently, we studied $La_{1-x}Ca_xNiO_{3-\delta}$ single crystals subjected to topotactic reduction, resulting in the formation of an infinite-layer phase with a composition of $\delta \sim 1$ [2]. Additionally, we unraveled the microstructural effects of topotactic reduction on the undoped $LaNiO_2$ single crystals [3]. Our attention is devoted to a precise examination of the detailed lattice and chemical structures of these crystals, where our measurements of Ni–O bonding conditions and electronic structures affirm the existence of the infinite-layer structure following the reduction process. The removal of apical oxygen atoms forming NiO_2 planes within the infinite-layer phase results in metallic behavior reminiscent of weakly doped thin films. These discoveries establish a critical connection between the observable characteristics of nickelates and their underlying microscopic origins, paving the way for further exploration of nickelates with distinct crystal structures achievable only through topotactic reduction. [4]

11:00 AM QT05.02.05
Visualizing Thermal Vibrations and Phonon Mode Softening in Real Space Harikrishnan K. P.[1], Yilin Li[1], Yu-Tsun Shao[2,1], Christo Guguschev[3], Sang-Wook Cheong[4], Darrell G. Schlom[1,3] and David Muller[1]; [1]Cornell University, United States; [2]University of Southern California, United States; [3]Leibniz-Institut für Kristallzüchtung, Germany; [4]Rutgers, The State University of New Jersey, United States

Lattice vibrations lie at the very heart of exotic phases in quantum materials, either directly as in the case of phonon mode softening that drives the polarization in ferroelectrics or indirectly as in the phonon mediated interaction that creates Cooper pairs in superconductors. Typical methods for characterizing phonons like infrared or Raman spectroscopy and neutron scattering provide only spatially averaged measurements. Although vibrational electron energy loss spectroscopy offers high spatial resolution, the measurements often require detailed theoretical models for interpretation. Here, we demonstrate the capability of electron ptychography[1,2] as a novel detection tool to directly visualize lattice vibrations in real space.

We illustrate the capability of the technique to directly visualize the thermal ellipsoid of metal atoms that are intercalated in the van-der Waals gap of layered materials. The in-plane vibrational modes of the intercalants have a larger amplitude in comparison to the quenched out-of-plane mode[3] and is reflected in the anisotropic thermal blur of the intercalant columns. We also show how ptychography enables us to study lattice distortions associated with a spatially localized phonon mode that is on the verge of softening in barium hexaferrite, a candidate material for quantum paraelectricity and room temperature multiferroicity[4]. By analysing the potential landscape associated with this near-soft phonon mode in three dimensions, we detect the presence of nanometer-scale polar regions[5] from short-range ordering in the material.

Characterizing Coupled Order Parameters Across Successive Phase Transitions at Atomic Resolution in $SmBaMn_2O_6$ Noah Schnitzer[1], Yorick Birkholzer[1], Anna S. Park[1], Evan Krysko[1], Jacob Steele[1], Shigeki Yamada[2], Taka-hisa Arima[3], Ismail El Baggari[4], Berit Goodge[5], Darrell G. Schlom[1,1,6], David Muller[1,1] and Lena Kourkoutis[1,1]; [1]Cornell University, United States; [2]Yokohama City University, Japan; [3]The University of Tokyo, Japan; [4]Rowland Institute at Harvard, United States; [5]Max-Planck Institute for Chemical Physics of Solids, Germany; [6]Leibniz-Institut für Kristallzüchtung, Germany

Rich phase diagrams and highly tunable ground states arising from strong coupling between electronic, magnetic, and lattice degrees of freedom make complex oxides an ideal playground for exploring connections between material structure and exotic strongly correlated properties. The A-site ordered double-perovskite manganite $SmBaMn_2O_6$ is a paradigmatic example: a complex set of structural distortions host a charge and orbital ordered (COO) polar antiferromagnetic ground state [1,2]. With increasing temperature, the material undergoes a series of structural, magnetic, and COO transitions governed by competing order parameters [3]. Coupling of these order parameters to the lattice generates intricate structural distortions and offers a tuning knob to control and stabilize new phases such as an anticipated ferromagnetic metallic phase under biaxial compressive strain [4].

To characterize these distortions, we measure $SmBaMn_2O_6$ in bulk and epitaxial thin films at atomic resolution with *in situ* scanning transmission electron microscopy (STEM) and electron energy loss spectroscopy (EELS). Studying the ground states and successive phase transitions in both the strain-free single crystal and epitaxial thin films under a series of strain states allows the role of the lattice in stabilizing electronic and magnetic order to be systematically investigated. Cryogenic STEM reveals the polar COO distortion defining the ground state structure as well as the low temperature phase transitions which reshape the COO and extinguish the polar and antiferromagnetic order. Characterization at higher temperatures can in turn clarify the structural mechanisms at play as the system undergoes an insulator-metal transition into a charge disordered phase.

Brownian Electric Bubble Quasiparticles Jorge Iniguez[1,2]; [1]Luxembourg Institute of Science and Technology, Luxembourg; [2]University of Luxembourg, Luxembourg

In this talk I will describe our theoretical predictions on the possibility to stabilize a new kind of quasiparticle in ferroelectric nanostructures, by suitably controling the elastic and electric boundary conditions. These novel particles are electric bubbles (e-bubbles) that present a non-trivial topology at low temperatures (skyrmion-like) and become spontaneously mobile upon moderate heating (Brownian diffusion). I will present the typical time scales for the e-bubble dynamics and discuss the basic inter-bubble interactions -- as predicted form our atomistic (second-principles) simulations. I will also show how the e-bubbles' diffusion speed and lifetime can be tuned by controlling the temperature and the defining features of the ferroelectric nanomaterials (thickness, epitaxial strain they are subject to). I will conclude by giving an outlook of the field; in particular, I will comment on the possible use of these objects in Unconventional Computing applications.

Work done in collaboration with Hugo Aramberri and Natalya Fedorova (Luxembourg Institute of Science and Technolgoy). Work funded by the Luxembourg National Research Fund through Grant C21/MS/15799044/FERRODYNAMICS.

Ultrafast Diffraction Microscopy for Revealing Emerging Phases and Their Dynamics Haidan Wen; Argonne National Laboratory, United States

Light-matter interaction has been an effective approach for producing emergent phases in quantum materials. However, these phases and associated dynamics often arise on nanometer scales and evolve on ultrafast time scales, making them challenging to capture. Combined with ultrafast laser excitation, x-ray and electron diffraction microscopes have become an essential tool for studying nanoscale structural evolution. In this talk, I will demonstrate the applications of laser-pumped x-ray and electron diffraction microscopy comparatively. In the first example, ultrafast x-ray diffraction imaging reveals ultrafast nanoscale phase transition in FeRh film and ferroelectric domain reconfiguration in $BiFeO_3$. In the second example, ultrafast electron microscopy reveals acoustic harmonic modes in $FePS_3$ mediated by defects. The strengths and limitations of x-ray and electron diffraction microscopy will be discussed. The exciting outlook of these techniques in the dawn of next-generation x-ray facilities will be presented.

These works are primarily supported by the US Department of Energy, Office of Science, Basic Energy Sciences, Materials Sciences and Engineering Division, under award no. DE-AC02-06CH11357 and DE-SC-0012509.

Characterizing Disorder in High Entropy Oxides at Every Length Scale Alannah Hallas; The University of British Columbia, Canada

The field of high entropy oxides (HEOs) flips traditional materials science paradigms on their head by seeking to understand what properties arise in the presence of profound configurational disorder. This disorder, which emerges as the result of multiple elements sharing a single crystalline lattice appears to imbue some HEOs with functional properties that far surpass their conventional analogs. However, there are significant questions surrounding the actual degree of configurational disorder, its role in stabilizing the HEO phase, and its effect on other physical properties. Grasping the true extent of the elemental disorder in HEOs requires advanced characterization across orders of magnitude in length scales - from the atomic scale to the average structure, preferably with elemental sensitivity.

In my talk, I will discuss my group's efforts towards addressing these questions using x-ray and neutron methods. Our measurements extend from the nanoscale (x-ray absorption and extended x-ray absorption fine structure, both of which are sensitive to the immediate environment at each metal site) to the microscopic (scanning electron microscopy and x-ray fluorescence microscopy) to the average (bulk diffraction). We find that the true configurational disorder is greatly influenced by synthesis method and that significant kinetic and thermodynamic control is needed to ensure the most random elemental distributions. The most profound differences between samples are, surprisingly, observed at intermediate length scales, in the mesoscopic regime. However, importantly, we find that these sample-to-sample variations do not strongly influence the functional magnetic properties. The most technologically important properties, including ordering temperature and saturated moment, are highly robust to preparation method, and therefore are highly suitable for real world applications.

Probing Topological Phase Transitions in Real-Space Polar Textures Yu-Tsun Shao[1], Sergei Prokhorenko[2], Lucas M. Caretta[3], Yousra Nahas[2], Sujit Das[4], Zijian Hong[5], Ruijuan Xu[6], Fernando Gómez-Ortiz[7], Pablo García-Fernández[7], Long-Qing Chen[8], Harold Y. Hwang[9], Javier Junquera[7], Lane W. Martin[10], Darrell G. Schlom[11], Ramamoorthy Ramesh[10] and David A. Muller[11]; [1]University of Southern California, United States; [2]University of Arkansas, Fayetteville, United States; [3]Brown University, United States; [4]Indian Institute of Science, India; [5]Zhejiang University, China; [6]North Carolina State University, United States; [7]Universidad de Cantabria, Spain; [8]The Pennsylvania State University, United States; [9]Stanford University, United States; [10]Rice University, United States; [11]Cornell University, United States

Real-space topological dipolar textures such as polar vortices, skyrmions and merons in ferroelectric heterostructures emerge resulting from the interplay of elastic, electrostatic and gradient energies. The emergence of these dipolar textures is often accompanied by functionalities such as emergent chirality and local negative capacitance for potential applications in next generation nanodevices. As these textures are intrinsically three-dimensional (3D), nm-sized objects, it poses a challenge for characterizing their detailed atomic structures as well as to understand and explore their potential topological phase transitions.

Here, we explore the topological phase transitions in epitaxial perovskite oxide heterostructures, for example in systems of $(PbTiO_3)/(SrTiO_3)$ and $(BiFeO_3)/(TbScO_3)$, using a combination of atomic resolution imaging, and four-dimensional scanning transmission electron microscopy (4D-STEM). Using 4D-STEM multislice ptychography, we found a new phase in multiferroic $BiFeO_3$, the 3D dipolar waves, which can be characterized by incommensurate periodicities and antiferrodistortive modes. Further, 4D-STEM-based approach enabled us to directly observe the transitions among polar skyrmions, merons and anti-merons, with some transitions accompanied by a change in their chirality.

4:30 PM *QT05.03.05
Recent Developments and Applications of Magnetic-Field-Free Atomic-Resolution Electron Microscope Naoya Shibata; The University of Tokyo, Japan

In recent years, new magnetic objective lens system that realizes a magnetic field free environment at the sample position has been developed for (scanning) transmission electron microscopy. Combining this objective lens system with higher-order aberration corrector, atomic-resolution imaging under magnetic field free condition has been finally achieved [1]. This magnetic-field-free atomic-resolution electron microscope will be a powerful tool for characterizing many interesting topological structures in quantum materials. In this talk, recent developments and applications of this electron microscope with related new techniques will be presented.

5:00 PM QT05.04.01
STEM-EELS/EDS Identification and Manipulation of Color Centers in Nanodiamond Bethany M. Hudak[1] and Rhonda Stroud[2]; [1]U.S. Naval Research Laboratory, United States; [2]Arizona State University, United States

Single-photon-emitting color centers in nanodiamonds are studied extensively for their application in quantum systems. In addition to strong single-photon photoluminescence from the color centers, diamond has many advantages such as chemical inertness, mechanical hardness, and zero nuclear spin. Nitrogen-vacancy (NV) centers in nanodiamonds are a potential architecture for single-atom quantum systems. However, unambiguous identification of a single NV center in a nanodiamond is challenging. Computational work has predicted that the NV center produces a peak at 282.4 eV near the carbon K-edge in electron energy loss spectroscopy (EELS). Here, we perform simultaneous EELS and energy dispersive x-ray spectroscopy (EDS) spectrum imaging in an aberration-corrected scanning transmission electron microscope (STEM) to identify single NV centers by identifying pixels that contain both the EELS 282.4 eV peak and the EDS nitrogen signal at 0.39 keV.
Atomic-scale identification of NV centers is an important first step toward single-atom quantum device fabrication. We further demonstrate that the

focused probe of the STEM can be used to reposition N and NV centers in the diamonds. By scanning the electron beam over a single nanodiamond for an extended period of time, we demonstrate the ability to: 1. corral N atoms into one region of the nanodiamond; and 2. redistribute the N throughout the nanodiamond. This is a significant step toward single-defect manipulation in nanodiamond, and density functional theory (DFT) calculations will help elucidate the exact mechanism of this atomic-scale manipulation.

5:00 PM QT05.04.02
Fabrication of a Micro/Nano-Structure-Based Sensing Platform using Two-Photon Polymerization for Detecting Cadmium Ions Akanksha Sharma, Rahul K. Das, Tejas Y. Suryawanshi, Sweta Rani, Arun Jaiswal, Sumit Saxena and Shobha Shukla; Indian Institute of Technology Bombay, India

The escalating global issue of heavy metal contamination, largely stemming from industrial activities, particularly those in mining, refineries, petrochemical plants, chemical synthesis, fertilizer, paint, and battery production, has significantly contributed to cadmium pollution in water and soil. The World Health Organization (WHO) has established a strict allowable threshold of 3 parts per billion (ppb) for cadmium in drinking water, underscoring the urgent necessity for a detection method that is both sensitive and specific. While conventional techniques like atomic absorption spectrometry and inductively coupled plasma mass spectrometry are highly precise, they are hindered by their high cost, bulkiness, and time-intensive nature. Modern methods, such as fluorescence, colorimetry, and chemical and electrochemical sensing, offer simpler and real-time solutions for monitoring cadmium levels. In this research, we present an innovative approach involving a polymerized 4D structure that incorporates nonmetal-doped carbon quantum dots (CQDs) to enable fluorescence-based detection of cadmium. Our investigation meticulously delves into the fabrication of this hybrid sensor using two-photon polymerization, demonstrating its potential for integration into the next generation of compact devices designed for cadmium detection.

5:00 PM QT05.04.03
Optoelectronic Properties of Cubic Phase of $CsPbBr_3$ Quantum Dots Prepared by Hot Injection for Perovskites-Based Photosensors Yen Shuo Chen[1], Pin Chia Tseng[1], Ching Chang Lin[2] and Fu-Hsiang Ko[1]; [1]National Yang Ming Chiao Tung University, Taiwan; [2]The University of Tokyo, Japan

In recent years, perovskite materials have been widely used in solar cells and photovoltaic devices, of which $CsPbI_3$ colloidal quantum dots (CQDs) have been reported to be able to reach 30% power conversion efficiency (PCE), due to their excellent optical properties and potential for large-scale applications. The photovoltaic properties of quantum dots are less frequently used in photoelectric sensors. In this study, we propose that the $CsPbBr_3$ QDs photosensor was structured with an ITO substrate as the bottom layer. A layer of silicon oxide (SiO_2) was deposited by chemical vapor deposition (CVD) as a dielectric layer. Finally, the $CsPbBr_3$ QDs were grown by hot injection method and spin coating process and deposited with Au electrodes of 100 nm. The objective of this study was to compare the photoelectric properties of cubic-phase $CsPbBr_3$ QDs under 395 nm UV light irradiation for photosensor applications.
For synthesis of the cubic phase $CsPbBr_3$ QDs we are using the hot-injection method, the first step is adding 0.752 mmol $PbBr_2$ (Lead (II) bromide) into 20 mL ODE (1-octadecene), add 2 mL OA (oleic acid) and 2 mL OAm (oleylamine) into the solution vial the three-neck bottle. The cubic phase of $CsPbBr_3$ quantum dots (QDs) was synthesized by a thermal injection method. The successful synthesis of $CsPbBr_3$ QDs was verified by ultraviolet-visible (UV-Vis), photoluminescence (PL), X-ray diffraction (XRD), Transmission electron microscope (TEM). To verify the accuracy of the encapsulated crystal structures, we performed a series of comprehensive analyses. The cubic phase CsPbBr3 QDs emit a bright green color at room temperature. In the UV-Vis absorption spectra, the cubic phase exhibited an absorption edge at 517 nm. For PL response spectra, the photoluminescence of the cubic phase CsPbBr3 quantum dots (QDs) are significantly high at an intensity of about 517 nm compared to that of $CsPbBr_3$ QDs, which suggests that cubic-phase $CsPbBr_3$ QDs have a high quantum yield. The average grain size of $CsPbBr_3$ QDs was calculated from TEM images to be 25.1 nm when the reaction temperature was 120°C. The CsPbBr3 QDs show strong diffraction peaks consistent with the literature (Li Q. et al., 2017).
In this analysis, we employed a 395 nm wavelength light source. The primary function of the photodetector is to discern specific wavelengths of light. This validation is based on the observed significant difference between light and dark currents, exceeding the photocurrent properties by an order of magnitude, highlighting the efficiency and precision of the $CsPbBr_3$ QDs photosensors. In addition to considering light and dark currents, there are several other factors that play a critical role in evaluating the performance of a photodetector. One such factor is responsivity, which quantifies the input-output gain of a detector system. Compared with no 395 nm UV light, the responsiveness of the cubic phase inclusion layer after illumination was significantly improved by two orders of magnitude. Responsivity indicates how efficiently the detector responds to an optical signal, while detectivity (D*) reflects the detection capability of a photoelectric detector, for a photodetector is a figure of merit used to characterize performance. For detectors, the higher the detection rate, the better the detector performance. We found that the increase in detection efficiency under 395 nm UV irradiation may be due to the rapid recombination of electron-hole pairs after separation for faster detection. The results are consistent with the External Quantum Efficiency (EQE) results. CsPbBr3 QDs-based sensor in a UV detector at a wavelength of 395nm provides good and fast detection. The most promising applications for photosensors.

SESSION QT05.05: Advances in Detection Methods for Emergent Phases in Quantum Materials IV

8:30 AM *QT05.05.01
Capturing Excitons and Phonons in Quantum Materials Sandhya Susarla; Arizona State University, United States

The interplay of spin, lattice, orbital and charge degrees of freedom controls most of the emergent properties in quantum materials. The detection of these parameters at the atomic scale can unravel novel structure-property relationship that could be used to create interesting device architectures. The recent developments of direct electron detectors in analytical scanning transmission electron microscopy (STEM) have made the detection of subtle electronic and structural features in quantum materials possible. In this talk, I will enlighten the contribution of our group towards measuring subtle features in quantum materials from 1) unravelling light-matter interactions in the twisted moiré materials, to 2) exploring vibrational properties across ferroelectric and multiferroic domain walls. I will end my talk with the current and future challenges that we need to address to unravel atomic scale structure-property relationship in quantum materials.

9:00 AM *QT05.05.02
Emergent Excitons in Two-Dimensional Organic-Inorganic Van der Waals Heterostructures Jeffrey B. Neaton[1,2,3]; [1]University of California, Berkeley, United States; [2]Lawrence Berkeley National Laboratory, United States; [3]Kavli Energy NanoScience Institute, United States

The ability to synthesize new classes of chemically-diverse two-dimensional materials attractive for optoelectronic applications has driven the development

of new theory, computational methods, and intuition for predicting the nature of their excitons and how they may be tuned. Here, we describe the recent synthesis and measurements of an emerging class of van der Waals heterostructures, namely a bilayer consisting of atomically-thin monolayers of non-covalently bonded molecular monomers interfaced with a transition metal dichalcogenide (TMD) monolayer. Specifically, we consider different recently-synthesized monolayers of perylene-derivative monomers, whose relative orientation can be tuned via choice of functional group, on $MoSe_2$ and WS_2 monolayers. We use state-of-the-art first-principles calculations – based on density functional theory and the ab initio GW-Bethe-Salpeter equation approach – to reveal the nature of the 2D molecular monolayer-TMD interface, their excitons, and their polarization-dependent optical response. We will describe how their excitonic properties are influenced by lattice structure, dielectric screening, and carrier concentration, and compare the predicted spectral response to photoluminescence and device measurements. General implications for similar systems are also discussed. This work is supported in part by ASOFR-MURI and DOE-BES. Computational resources provided by NERSC.

9:30 AM *QT05.05.03
Quantum Monochromated EELS: Accessing Emergent Phenomena in The Electron Microscope with High Spatial and Spectral Resolution Jordan A. Hachtel; Oak Ridge National Laboratory, United States

Monochromated electron energy loss spectroscopy (EELS) in a scanning transmission electron microscope (STEM) is a technique that has achieved the ability to combine ultrahigh energy and spatial resolution simultaneously. As a result, a new wave of experiments on ultralow energy excitations, such as phonons, phonon-polaritons, molecular vibrations, shallow electronic structure, and infrared optical excitations have achieved exciting results in the STEM.

Here, I will show recent work at ORNL on the monochromated EELS of quantum materials with an emphasis on the emergence electronic structure and quasiparticles generated from coupling between layers in quantum dot networks and oxide superlattices. I will also focus on recent efforts at ORNL to incorporate cryogenic cooling alongside monochromated EELS in the analysis of quantum materials and some of the challenges and progress that has been made on the spectroscopy of low-dimensional quantum materials at liquid nitrogen temperatures.

10:00 AM BREAK

10:30 AM *QT05.05.04
Design of Novel Low-Dimensional Heterostructures via *In Situ* Atomic-Scale Observation Kate Reidy; Massachusetts Institute of Technology, United States

Control of material processes at the level of atoms and electrons is a ‘grand challenge’ of materials design. With the rise of quantum materials and increasing security, resource scarcity, and sustainability considerations, the need for alternative methods of manufacturing at the atomic scale is paramount. Direct visualization of atomic-scale mechanisms allows precise tailoring of nanostructures from the bottom up. *In situ* transmission electron microscopy (TEM) is powerful in achieving this goal due to its high spatial and temporal resolution, obtaining atomic-scale movies while the sample undergoes functional changes, for example during nucleation, phase transformation, or current-biasing. Such direct observation of atomic motion can uncover kinetic models of nucleation and growth, as well as allow direct comparison with *ab-initio* or molecular dynamics simulations.
Here, I will explore the atomic-scale structure and *in situ* growth of an emerging class of van der Waals bonded materials termed ‘mixed dimensional’ heterostructures, which consist of two-dimensional (2D) + nD (where n is 0, 1 or 3) materials adhered primarily though non-covalent interactions.[1] The weak quasi-van der Waals bonding in certain 2D/3D heterostructures (exemplified by Au/MoS_2) results in reproducible moiré patterns that modify the electronic structure at the interface.[2] In contrast, more strongly bound heterostructures, such as Ti/Gr, exhibit ordered arrays of dislocation networks that are strongly modulated by the 2D material layer number and compliance. We introduce a criterion for dislocation formation in such suspended systems and tailor the thin non-dislocated structures towards ultra-thin heterostructure stacks, of application in quantum sensors.[3] We demonstrate the feasibility of forming epitaxial and single crystalline metal/2D/metal (3D/2D/3D) heterostructures using suspended 2D materials, with implications for next-generation Josephson junctions. Lastly, we explore the nucleation and growth of lower symmetry structures, such as 1D nanowires and nanoribbons, examining the influence of symmetry on nanostructure morphology. Such understanding of growth kinetics allows versatile design of heterostructures for next generation nanoscale devices and showcases the powerful role of *in situ* TEM in unraveling the intricacies of quantum materials at the atomic scale.

11:00 AM *QT05.05.05
High-Energy-Resolution Dark-Field EELS for Quantum Materials: From Mapping Localised Vibrational Modes to Magnonics in The STEM
Quentin Ramasse[1,2], Demie Kepaptsoglou[1,3], Khalil el Hajraoui[1,3], Vlado Lazarov[3], Paul Zeiger[4], Keenan Lyon[4], Jose Angel Castellanos-Reyes[4], Jan Rusz[4], Anders Bergman[4], Michele Lazzerri[5] and Guillaume Radtke[5]; [1]SuperSTEM Laboratory, United Kingdom; [2]University of Leeds, United Kingdom; [3]University of York, United Kingdom; [4]Uppsala University, Sweden; [5]Sorbonne Université, France

State-of-the-art monochromated electron energy loss spectroscopy (EELS) in the scanning transmission electron microscope (STEM) now offers angstrom size electron beam and an energy resolution for EELS under 5meV [1]. These capabilities enable studies of the interplay between fundamental properties of matter such as charge, spin and local chemistry, at the atomic scale. A striking example is presented by epitaxial graphene grown on SiC(0001) by thermal methods, which is known to present a so-called ‘buffer’ layer, whereby the last layer of carbon in contact with the SiC substrate possesses a strikingly different electronic structure from the free-standing epitaxial graphene, impacting possible applications in quantum devices [2]. The use of a dark-field EELS (DF-EELS) geometry to probe the vibrational response of the system [3], atomic plane by atomic plane, reveals the true nature of the chemical bonds formed at this interface, a characterisation that would not be possible with any other technique. Further growing Bi_2Se_3, a topological insulator (TI) with topologically-protected helical two-dimensional surface states and one-dimensional bulk states associated with crystal defects, on top of the graphene layers, takes advantage of strong spin-orbit interaction and proximity effects and results in subtle and controllable electronic band structure changes. The same experimental geometry allows the observation of the Dirac plasmons in the TI layers, and the study of their dispersion in momentum space. DF-EELS was also proposed to be a leading candidate technique to attempt the detection of magnons, even down to at the atomic scale, thanks to a recently developed theoretical calculation framework and preliminary experimental investigations [4,5]. Magnonics is an emergent field within spintronics research whereby a spin-wave (or magnon) is propagated controllably in nano-dimensional magnetic structures allowing to build a new generation of devices for data processing and storage. In addition, it was recently demonstrated that magnons can be utilised to convert spin to charge currents and vice versa, a critical step for integration of spin and charge devices. Despite recent progress, many challenges hinder practical applications due a lack of fundamental understanding of these processes at the nanoscale in the vicinity of interfaces. DF-EELS experiments can be used to study the spin-to-charge conversion in a system consisting of Yttrium Iron Garnet (YIG)/platinum (Pt) bilayer, a widely and intensively used materials combination and a prototypical system to demonstrate the detection of magnons and magnon-phonon polarons in the STEM.

11:30 AM *QT05.05.06
EELS Compton Scattering and The Electronic Structure of Materials Alina Talmantaite[1], Yaoshu Xie[2], Assael Cohen[3], Pranab Mohapatra[3], Ariel Ismach[3], Teruyasu Mizoguchi[2], Stewart Clark[1] and Buddhika Mendis[1]; [1]Durham University, United Kingdom; [2]University of Tokyo, Japan; [3]Tel Aviv University, Israel

Electronic structure is fundamental to a large class of materials phenomena, including mechanical, optical, magnetic and electronic transport properties. Momentum based spectroscopies such as angle resolved photoemission spectroscopy (ARPES), electron-positron annihilation and Compton scattering are traditionally used to measure the electronic structure. Compton scattering in the transmission electron microscope (TEM) was first explored in the 1980s using electron energy loss spectroscopy (EELS) [1]. Despite early success it did not achieve widespread use, largely due to the limitations in EELS spectrometer detector efficiencies, and artefacts arising from Bragg scattering within a crystalline specimen. However, with modern advances in EELS spectrometers as well as computational techniques for modelling dynamical scattering artefacts [2] many of the challenges facing EELS Compton scattering are arguably now resolved. EELS Compton scattering in the TEM provides several benefits over standard X-ray and gamma-ray Compton measurements, such as a higher spatial resolution and the ability to extract useful information from even poly-crystalline materials.

In EELS Compton scattering the incident electron beam undergoes an inelastic collision with individual electrons in the solid. The Compton signal appears as a broad peak in an EELS spectrum acquired at large scattering angles (i.e. high momentum transfer). The width of the Compton profile, which can be as large as several hundred eV, is due to the intrinsic momentum spread of the solid-state electrons. The Compton profile shape is therefore directly related to $J(p_z)$, i.e. the density of solid-state electrons with momentum component p_z along the scattering vector direction. $J(p_z)$ provides a 1D projection of the electronic band structure in reciprocal space. We have applied EELS Compton scattering to examine the electronic structure of bi-layer WS_2 [3], with a twist angle of 18° between the two layers. EELS Compton scattering is particularly suitable to this problem, since the low dimensional nature of the WS_2 flakes make it difficult or impossible to analyse using conventional methods. The $J(p_z)$ acquired along the 100 reciprocal direction indicates that the electrons are more delocalised in the bi-layer compared to monolayer WS_2. Comparison with density functional theory (DFT) simulations reveal that the delocalization is due to a small amount of electronic charge (i.e. 0.1%) accumulating in the inter-layer region. The inter-layer charge accumulates between overlapping W atoms, thereby screening the 'wrong' bonds generated by the twist angle. The charge accumulation is also accompanied by a local dilation of the inter-layer spacing. Time permitting I will also present other examples of EELS Compton scattering that are of interest.

SESSION QT05.06: Advances in Detection Methods for Emergent Phases in Quantum Materials V
Session Chairs: Jessica Boland, Shelly Michele Conroy, Juan Carlos Idrobo and Suk Hyun Sung
Thursday Afternoon, April 25, 2024
Room 446, Level 4, Summit

1:30 PM *QT05.06.01
Atomically Stable Cryogenic *In Situ* TEM Biasing Holder with Accurate Temperature Control Yevheniy Pivak; DENSsolutions, Netherlands

Cryo scanning transmission electron microscopy (STEM) becomes an indispensable tool to study phase transitions in various quantum materials [1-3] at the atomic scale. Detailed characterization of the structural and electronic properties of these samples across phase transitions necessitates the need of the double tilt capability of the sample holder, atomic image stability and a continuous temperature control of the specimen. The latter is achieved through using microelectromechanical systems (MEMS)-based heating and biasing chips [4] in combination with a cryo TEM sample holder.
To accurately control the temperature during in situ cooling and heating experiments, the chips need to be calibrated to correlate the resistance of the microheater with the temperature of the sample. Since not all heater materials possess a linear resistance-temperature response and the high temperature coefficient of temperature resistance might not be valid for negative temperatures, a dedicated calibration of chips on cooling is required. While the calibration above the room temperature is nowadays done routinely by different methods [5, 6], it's not so common in cryogenic conditions. In this talk we will present a novel method of subzero chip calibration based on Raman spectroscopy. The temperature calibration performed in a wide temperature range reveals the need for a correction factor for the R-T correlation at cryo conditions. The resulting calibration factor was used to continuously control the temperature of Au-Pd nanoparticles -175ºC to +800ºC while keeping the holder cooled. It was found that the atomically stable imaging at -175ºC is maintained till the highest temperature of +800ºC though the stabilization time increases as the difference between the holder and the sample temperature rises. Similar in situ cooling experiments with continuously varied temperature but in a smaller temperature range have been performed using ferroelectric FIB lamellas. With the help of electron diffraction and TEM imaging, we were able to follow all, known and unknown phase transitions, in these samples.

Spatially Structuring The Surface Energy of Monolayer Graphene through Selective Heterointerface Engineering Zakaria Al Balushi[1,2]; [1]University of California, Berkeley, United States; [2]Lawrence Berkeley National Laboratory, United States

Selective bottom-up chemical synthesis of low dimensional quantum materials with high spatial resolution has long been a goal of crystal growers. The challenge, however, lies in the spatial modification of the surface energy landscape of a substrate, a crucial factor that promotes the diffusion and

accumulation of adatoms and/or molecules along the surface energy gradient, consequently facilitating nucleation in regions of reduced surface energy. Herein, we demonstrate the achievement of a highly controllable surface energy landscape of monolayer graphene on diamond like carbon (DLC) substrate through a heterointerface containing trapped gallium in a uniquely designed spatial structure. The process involves three steps: (i) spatial-selectively Ga^+ ion implantation into DLC substrate to create "hill" features with a step height of 4 nm; (ii) polymer-free transfer of monolayer graphene on top of Ga^+-implanted DLC; (iii) *in-situ* high-vacuum annealing process above 300°C for gallium precipitation at the graphene-DLC heterointerface with low energy electron microscope (LEEM). During the annealing process, both gallium precipitation and gallium-catalyzed reconstruction of the DLC structure contribute to a shift in the local surface work function of graphene, resulting in a decrease in the surface energy of graphene compared to that of pristine graphene. At 300°C, the surface work function difference (between graphene residing on the "hill" features and unmodulated region is -142 meV, corresponding to a surface energy difference (between the modulated graphene region and unmodulated region of -0.23 mN/mm. However, at 500°C, is 240 meV with a of -14.5 mN/mm. Notably, this difference remains consistent even upon cooling down to 300°C due to the irreversibility of gallium precipitation. In summary, a surface energy landscape of graphene with a high level of complexity can be realized by carefully tuning annealing conditions and the spatial arrangement of "hill" features, facilitating the selective area growth of materials in various nanofabrication processes.

Emerging Properties of Chiral Functional Materials for Next-Generation Technologies Jessica Wade and Kim E. Jelfs; Imperial College London, United Kingdom

The use of organic semiconductors as low-cost, lightweight, easy-to-process active layers in optoelectronic devices has attracted considerable research and technological interest for over thirty years. The functional properties of chiral organic semiconductors, including the absorption and emission of circularly polarised light or the transport of spin-polarised electrons, are highly anisotropic. As a result, the orientation of chiral molecules impacts the functionality and efficiency of chiral devices. We have developed a strategy to control the orientation of helicenes, prototypical chiral small molecules. Our approach forces the helicenes to adopt a face-on orientation and self-assemble into upright supramolecular columns oriented with their helical axis perpendicular to the substrate, or an edge-on orientation with parallel-lying supramolecular columns, which can independently switch on and switch off low- and high-energy chiroptical responses. Our templating methodologies provide a simple way to engineer orientational control and, by association, anisotropic functional properties of chiral molecular systems for a range of emerging technologies. In this talk I will speak about our efforts to control and characterise the orientation, order and supramolecular assembly of chiral small molecules and polymers, and the impact that has on the functional properties of chiral thin films and devices.

Probing *In-Situ* Twistable Moiré Quantum Emitters with Near-Field Scanning Optical Microscopy Arnab Manna, Shiang-Bin Chiu, Laurel E. Anderson, Jiaqi Cai, Xiaodong Xu and Arthur Barnard; University of Washington, United States

Transition metal dichalcogenide (TMD) Moiré superlattices are formed when two layers of TMD materials are stacked with a slight twist angle. This creates a periodic potential that can trap electrons and holes to form an array of optically active single emitters and other exotic quantum states. Compared to other solid-state emitters, Moiré emitters exist in a planar crystal and do not rely on crystal defects, giving the advantage of scalability, electrical tunability, optimized photon extraction efficiency, and ease of integration with nano-photonic structures to realize single-photon nonlinear optical effects. The twist angle in TMD Moiré superlattices critically determines the properties of the superlattice potential and thereby the optical properties of the emitters. But twisted devices are generally fabricated with a fixed angle that cannot be modified once the device has been made. In addition, the Moiré unit cell is very small, making it difficult to address single emitters with free-space optics. In this work, we propose and develop a new platform for reliable creation and read-out of Moiré emitters. This platform combines two capabilities: 1) a "Twistronics" apparatus that can bring two vdW layers into direct contact and rotate them relative to each other which allows for precise in-situ control of the twist angle between the layers, and 2) a near-field scanning optical probe that can focus and collect light from a subwavelength scale spot, making it possible to address single photon emitters in moiré superlattices. We discuss the merits and challenges of the design and report our progress in using it to study the optical properties of TMD heterobilayers. We believe that our proposed platform will be a powerful tool for exploring the correlated physics of moiré superlattices and for developing new quantum technologies based on these materials.

3:45 PM QT05.06.05
Thermoelectric Probing of Flat Bands in Twisted Bilayer Tungsten Diselenide Chuting Cai, Yajie Huang, Devika Mehta and Li Shi; The University of Texas at Austin, United States

Due to the relatively strong electron coulombic interaction compared to the small kinetic energy of the flat bands, twisted bilayer graphene moiré system exhibits strongly correlated behaviors including superconducting, insulating, and topological states at different band fillings. Compared to twisted bilayer graphene, transition metal dichalcogenides (TMDs) moiré system with a large range of twisted angles can produce very flat bands and strong correlations based on tight-binding calculation. Transport measurements of twisted bilayer tungsten diselenide (WSe2) reveal insulating and superconducting state at half-filling of the first moiré valence band. With a twisted angle less than 3 degrees in this system, the topmost valence band appears at the Gamma-valley, with narrow bandwidths and strong correlation. Here, we employ thermoelectric measurement as a unique probe of the flat band structures and interactions in twisted bilayer WSe2 of different twisting angles. As a measure of the average entropy per charge, the Seebeck coefficient is highly sensitive to the asymmetry of the electron density of states near the chemical potential and is expected to switch sign when the chemical potential is moved across a flat band. For a sample with a twisted angle near 3 degrees, the measured Seebeck coefficient shows pronounced modulation as the hole concentration is varied by a gate voltage. The observed dependences of the measured Seebeck coefficient on the band filling and temperature provide detailed insight into both the flat band features such as the bandwidth, as well as electron-electron and electron-phonon interactions that cause a deviation of the Seebeck coefficient from the semiclassical Mott relation.

4:00 PM QT05.06.06
Electronic Viscous Flow in Hexagonal Boron Nitride Encapsulated Graphene FETs Wenhao Huang[1,2], Tathagata Paul[1], Mickael Perrin[1,3,3] and Michel Calame[1,2,2]; [1]Empa (Swiss Federal Laboratories for Materials Science and Technology), Switzerland; [2]University of Basel, Switzerland; [3]ETH Zürich, Switzerland

In most conductors, electron transport primarily involves diffusive scattering from defects and interactions with lattice vibrations (phonons), resulting in Ohmic behavior. Alternatively, transport can become ballistic when the dimensions of the conducting channel become the smallest length scale in the system. However, an intriguing and relatively unexplored transport regime emerges when electron-electron interactions attain a level of strength where they induce correlated and momentum-conserving flow, akin to the Hagen-Poiseuille flow observed in classical fluids.
Our research explores the fascinating realm of charge hydrodynamic transport effects, which unveil unique characteristics. These include width-dependent

channel conductivity and a significant reduction in resistivity at elevated electron temperatures. Furthermore, we observe the presence of charge vortices through non-local vicinity resistance measurements[1]. By combining various approaches, we validate the existence of viscous effects over a wide temperature range, extending even up to room temperature. This resilience of hydrodynamic transport in graphene, compared to other systems like two-dimensional electron gases (2DEGs) and WP_2, is a notable finding.
To underpin our experimental findings, we employ finite element calculations of the graphene channel. These calculations not only confirm our observations but also provide valuable insights into device geometries that can enhance viscous effects. The occurrence of viscous effects at room temperature opens up new possibilities for functional hydrodynamic devices, including geometric rectifiers like a Tesla valve and charge amplifiers based on the electronic Venturi effect. This research signifies a step forward in understanding and harnessing the potential of charge hydrodynamics in graphene-based systems.

Attosecond Quantum Technologies for Detecting Emergent Phases in Quantum Materials Margaret M. Murnane[1,2]; [1]University of Colorado, Boulder, United States; [2]KMLabs Inc., United States

The macroscopic properties of solids, such as the electrical conductivity, greatly depend on the electronic states and their low-energy excitations near the Fermi level. In strongly-correlated quantum materials, many-body interactions between charges, phonons and spins can lead to the formation of a lower-energy ground state characterized by a pseudogap, rather than a sharp energy gap. Pseudogaps and the absence of a clear Fermi edge are found in a broad class of materials including cuprates, colossal magnetoresistance manganites and quasi-one-dimensional (quasi-1D) materials, where it's origin has been a long standing and important puzzle.
Many-body interactions occur on extremely short timescales: electron-electron interactions occur on femtoseconds (10^{-15} seconds) or faster, while phonons respond more slowly, within hundreds of femtoseconds. Traditionally, these interactions are probed by changing a material's temperature, pressure, or chemical composition and then measure its electrical properties to learn about the interactions. However, materials that host different interactions can exhibit very similar properties, making it challenging to pinpoint the exact nature of these interactions.
In recent work we showed that by gently exciting a quantum material with an ultrafast laser pulse and probing it with extreme ultraviolet high harmonic pulses, we can measure not only the response times, but also see precisely how the electronic band structure changes. In combination, this makes it possible to identify the many body interactions underlying the ground state of a quantum material and thereby the nature of the pseudogap.[1]
Specifically, we compared how the electrons in two different 1D materials responded after they were gently perturbed by light: $(TaSe_4)_2I$ and $Rb_{0.3}MoO_3$, also known as rubidium blue bronze. Historically, both materials were thought to have a small insulating gap due to the coupling between electrons and phonons, called polarons. However, recent theory suggested that the insulating gap in such materials could be produced by polarons interacting to produce bipolarons. By tracking the energy and location of the excited electrons using time- and angle-resolved photoemission, we could see the signatures of bipolarons melting into single polarons in $(TaSe_4)_2I$.
In contrast, electrons in $Rb_{0.3}MoO_3$ respond and relax ten times faster (in ~60 femtoseconds) to light, clearly showing that interactions between electrons (Luttinger-liquid behavior) must be responsible for the insulating gap in that 1D material.
More generally, ultrafast high harmonic probes provide an exquisite source of short wavelength light, with unprecedented control over the spectral, temporal, polarization and orbital angular momentum of the emitted waveforms, from the UV to the keV photon energy region. They enable powerful new tools for near-perfect x-ray imaging, for coherently manipulating quantum materials using light, and for extracting the functional transport, electronic, magnetic and mechanical properties of ultrathin films and nanosystems.[2-6]

Non-Collinear Mn3NiN Antiferromagnets Lesley F. Cohen; Imperial College, United Kingdom

Antiferromagnets (AFM) hold interest because of their potential for application in high density, high speed spintronic devices, as an active layer and also as a component in superconducting S/AFM/S Josephson Junctions. Frustrated non-collinear antiferromagnets offer additional attractive functional properties due to their magnetic space group symmetry. Stimulated by these predictions we embarked on a growth program of non collinear antiferromagnetic antiperovskite Mn3NiN films on various perovskite substrates by pulsed laser deposition. We have used observation of the anomalous Hall effect [1] to piece together the experimental phase diagram of magnetic order with biaxial strain [2]. Theory predicts that compressively strained films should support a high temperature collinear ferrimagnetic phase [3]. We use polar MOKE spectroscopy which in combination with DFT calculations sheds light on the origin of the magneto-optical signal as the material evolves from antiferromagnetic to ferrimagnetic phase [4]. Employing a laser scanning technique to create an out-of-plane temperature gradient we can also use the anomalous Nernst effect to provide information about domain structure in our films [5]. Finally, I will review the evidence for piezomagnetism [6,7] predicted to exist in these materials and as time allows, our recent work on the role of piezomagnetism in films grown on highly mismatched substrates.

Imaging the Breakdown and Restoration of Topological Protection in Magnetic Topological Insulator $MnBi_2Te_4$ Mark T. Edmonds; Monash University, Australia

Quantum anomalous Hall (QAH) insulators transport charge without resistance along topologically protected chiral one-dimensional edge states. Yet, in magnetic topological insulators (MTI) to date, topological protection is far from robust, with the zero-magnetic field QAH effect only realised at temperatures an order of magnitude below the Néel temperature T_N, though small magnetic fields can stabilize QAH effect. Understanding why topological protection breaks down is therefore essential to realising QAH effect at higher temperatures. Here we use a scanning tunnelling microscope to directly map the size of the exchange gap ($E_{g,ex}$) and its spatial fluctuation in the QAH insulator 5-layer $MnBi_2Te_4$. We observe long-range fluctuations of $E_{g,ex}$ with values ranging between 0 (gapless) and 70 meV, uncorrelated to individual point defects. We directly image the breakdown of topological protection, showing that the chiral edge state, the hallmark signature of a QAH insulator, hybridizes with extended gapless metallic regions in the bulk. Finally, we unambiguously demonstrate that the gapless regions originate in magnetic disorder, by demonstrating that a small magnetic field restores $E_{g,ex}$ in these regions, explaining the recovery of topological protection in magnetic fields. Our results indicate that overcoming magnetic disorder is key to exploiting the unique properties of QAH insulators.

5:30 PM *QT05/QT07.04
Spiral Magnetism in a Weyl Semimetal Fazel Fallah Tafti[1], Xiaohan Yao[1], Jonathan Gaudet[2] and Predrag Nikolic[3]; [1]Boston College, United States; [2]National Institute of Standards and Technology, United States; [3]George Mason University, United States

We present evidence of spiral magnetic ordering in the Weyl semimetal SmAlSi from transport and neutron diffraction experiments. This material is a member of RAlSi family where R is the rare-earth. We show that a large magnetocrystalline anisotropy in PrAlSi, CeAlSi, and NdAlSi prevents the spiral order although chiral interactions may be present. However, SmAlSi shows a nearly isotropic crystal electric field which leads to its spiral order. We map the phase diagram of this material and reveal an A-phase at finite field and temperature. Within this phase, we observe a sizable topological Hall effect. We also find that the magnetic k-vector observed in SmAlSi matches the nesting between its Weyl nodes on the Fermi surface. As such, SmAlSi seems to be the first topological semimetal where spiral order is established from the direct engagement of Weyl electrons in magnetic interactions.

Engineering Boundary Conditions to Stabilize Improper Ferroelectricity in Hexagonal $LuFeO_3$ Films Down to the Monolayer Limit Darrell G. Schlom[1,2,3]; [1]Cornell University, United States; [2]Kavli Institute at Cornell for Nanoscale Science, United States; [3]Leibniz-Institut für Kristallzüchtung, Germany

Ultrathin ferroelectric films with out-of-plane polarization and high Curie temperatures are key to miniaturizing electronic devices, including low-power non-volatile memories. Most ferroelectrics employed in devices are proper ferroelectrics, where spontaneous polarization is the primary order parameter.

Unfortunately, the Curie temperature of proper ferroelectrics is drastically reduced as the ferroelectric becomes thin; nearly all proper ferroelectrics need to be thicker than several unit cells. The absence of an ultrathin limit has been predicted, but not verified for improper ferroelectrics. These are ferroelectrics where the polarization emerges secondary to the primary order parameter, such as a structural distortion. The prime issue in thin films of improper ferroelectrics has been that they clamp to substrates that lack a structural distortion; such clamping thwarts the needed structural distortion and thus ferroelectricity. In this talk I will describe the use of an insulating substrate covered by a conducting electrode and followed by a monolayer transition layer that are not improper ferroelectrics themselves, but that do possess a structural distortion akin to that of the improper ferroelectric deposited upon them by molecule-beam epitaxy. The result is ferroelectricity with an undiminished Curie temperature in a formula-unit-thick (0.5-unit-cell) improper ferroelectric hexagonal $LuFeO_3$ (*h*-$LuFeO_3$) film grown on a $SrCo_2Ru_4O_{11}$ bottom electrode with a carefully engineered monolayer transition layer. Our results* demonstrate the absence of a critical thickness for improper ferroelectricity and provide a methodology for creating ultrathin improper ferroelectrics by stabilizing its primary order parameter.

11:00 AM *QT06.01.02
Epitaxy enables emergent phenomena Ramamoorthy Ramesh; Rice University, United States

The past decade has witnessed dramatic progress related to various aspects of emergent topological polar textures in oxide nanostructures displaying vortices, skyrmions, merons, hopfions, dipolar waves, or labyrinthine domains, among others. For a long time, these nontrivial structures (the electric counterparts of the exotic spin textures) were not expected due to the high energy cost associated with the dipolar anisotropy: the smooth and continuous evolution of the local polarization to produce topologically protected structures would result in a large elastic energy penalty. However, it was discovered that the delicate balance and intricate interplay between the electric, elastic, and gradient energies can be altered in low-dimensional forms of ferroelectric oxide nanostructures. These can be tuned to create and manipulate order parameters in ways once considered impossible, thanks to a fruitful, positive feedback between theory and experiment: advances in materials synthesis and preparation (with a control at the atomic scale) and characterization have come together with great progress in theoretical modeling of ferroelectrics at larger length and timescales. The new emergent states of matter join together with exotic functional properties (such as chirality, negative capacitance, and coexistence of phases) that, along with their small size and ultrafast dynamical response, make them potential candidates in multifunctional devices. Finally, some open questions and challenges for the future are presented, underlining the interesting future that is anticipated in this field.

11:30 AM *QT06.01.03
The Emergence of Highly Defective Oxides in Material Development Nini Pryds; Technical University Denmark, Denmark

The array of intriguing characteristics found in complex oxides, including ferroelectricity, piezoelectricity, and pyroelectricity, consistently draws significant attention. Various approaches are utilized to disrupt lattice symmetry, thereby broadening the spectrum of functionalities. In this presentation, I will demonstrate that symmetry breaking provides exceptional opportunities. For instance, it can stabilize phases that are typically unstable by leveraging highly coherent interfaces. It can also amplify electromechanical effects at interfaces or generate piezoelectricity in systems that are usually centrosymmetric. This collection of opportunities opens the door to a diverse and rich realm of new functionalities in complex oxides and their interfaces, presenting unparalleled prospects.

SESSION QT06.02: Novel Synthesis for Complex Oxides

1:30 PM *QT06.02.01
Unlocking The Promise and Simplicity of Atomically Precise Synthesis for 4d- and 5d Metal Oxides through Hybrid MBE Bharat Jalan; University of Minnesota, United States

The ability to achieve atomically precise material synthesis has marked a profound advancement in the field of materials science. Yet, it is often the degree of ease and precision in the synthesis process that paves the way for groundbreaking application and discovery. Consider an element of periodic table that is hard to oxidize and also difficult to evaporate, how do we create an atomically precise thin films of such metals, metal oxides or their heterostructures? This has been a central question in the synthesis science for many decades. In this talk, I will present my group's effort to address this question. We have recently shown that both the low vapor pressure and difficulty in oxidizing a "stubborn" element can be addressed by using a solid metal-organic compound with significantly higher vapor pressure, and with the added benefits of being in a pre-oxidized oxidation state along with excellent thermal and air stability. Using this approach, we show, for the first time, the synthesis of Pt, RuO_2, $SrRuO_3$ and superconducting Sr_2RuO_4 films with the *same ease and control* as afforded by III-V MBE. Finally, I will present a detailed MBE growth study of $SrRuO_3$ films combined with structural and transport characterizations emphasizing the role of structural inhomogeneity on anomalous hump-like magnetotransport, which has long been interpreted as a signature of Skyrmions formation.

2:00 PM *QT06.02.02
Emergent Properties in $SrIrO_3$ Heterostructures Grown by Metalorganic MBE Ryan B. Comes; Auburn University, United States

Transition metal complex oxides exhibit a host of intriguing properties for new technologies that can be tuned by the choice of ions from the 3*d*, 4*d*, and 5*d* blocks of the periodic table. This combination of properties, including superconductivity, ferromagnetism, and ferroelectricity, in a single class of materials offers rich opportunities for engineering of unusual combinations of behavior through the design of multi-layer thin films. Such heterostructures can exhibit topological phenomena due to interfacial coupling between distinct phases. Our work employs hybrid metal-organic MBE and *in situ* X-ray photoelectron spectroscopy (XPS) to explore oxide films that exhibit strong spin-orbit coupling and interfacial charge transfer. We have demonstrated the growth of hard-to-grow materials including $SrNbO_3$, $SrIrO_3$, and $SrHfO_3$ using metal-organic precursors and examined how interfacial phenomena can be tuned via charge transfer.

In this talk, I will discuss our work on $SrIrO_3$ heterostructures grown using an $Ir(acac)_3$ solid-source metal-organic precursor. We have synthesized epitaxial films under different thickness and strain conditions and examined the role that these play on the electronic transport and carrier dynamics. We show that the metallicity can be tuned via increasing compressive strain and employ time-domain THz spectroscopy to examine the origins of this behavior. Additionally, we have examined ways to tune the Fermi level in $SrIrO_3$ using $SrNbO_3$ as an n-type interfacial donor and $SrCoO_3$ as a ferromagnetic p-type interfacial acceptor. I will discuss how these interfaces change the transport behavior in $SrIrO_3$ through charge transfer using *in situ* XPS and *ex situ* X-ray absorbtion spectroscopy and scanning transmission electron microscopy. These new synthesis capabilities open routes to tuning of electronic structure in iridate films, which have been predicted to exhibit superconductivity in low-dimensional systems.

2:30 PM *QT06.02.03
Thermal Laser Epitaxy for Ultraclean Heterostructures Hans Boschker[1], Felix Hensling[2], Lena Majer[2], Brendan D. Faeth[2], Jochen Mannhart[2] and Wolfgang Braun[1,2]; [1]Epiray GmbH, Germany; [2]Max Planck Institute for Solid State Research, Germany

We have developed a new thin-film deposition technique that is especially suited to the growth of an extremely wide range of heterostructures with atomic precision. Thermal laser epitaxy (TLE) uses chemical elements as sources, which are evaporated with continuous-wave lasers [1]. The lasers' virtually arbitrary power density allows for the evaporation of practically all elements of the periodic table in the same setup [2]. Furthermore, a wide range of elements has been grown in oxygen environments up to pressures as high as 10^{-2} mbar, yielding films of binary oxides [4,5]. In addition, extremely clean oxide surfaces can be prepared with the use of a CO_2 laser substrate heater that enables temperatures (T) up to 2000 °C [5]. Here, I will introduce the advantages of TLE for epitaxy and focus in detail on the epitaxy of ultraclean oxide heterostructures.

Novel Quantum Heterostructures enabled by Membrane Epitaxy Varun Harbola, Yu-Jung Wu, Felix Hensling, Hongguang Wang, Peter A. van Aken and Jochen Mannhart; Max Planck Institute for Solid State Research, Germany

Engineering of sharp interfaces and heterostructures with thin films of quantum materials is a cornerstone of thin films epitaxy. However, there is an inherent constraint of lattice compatibility, concerning not only the lattice symmetry but also lattice size, limiting the realizability of epitaxially grown heterostructures. To solve this problem and overcome that constraint, we introduce "vector substrates", for which the template layer for epitaxy can be chosen independently of the bulk of the substrate. The fabrication of vector substrates leverages thin-film membrane technology. The process begins by growing a template layer on a parent substrate. The template layer is then transferred onto a carrier substrate, thereby generating the vector substrate. Furthermore, these vector substrates can be handled and utilized for growth in the same way a traditional substrate is used. We show that this approach allows the deposition of heterostructures of quantum materials with clean and novel interfaces, opening up an unprecedented variety of possibilities in quantum materials research.

Unfolding The Challenges to Prepare Epitaxial Complex Oxide Freestanding Membranes Mariona Coll; ICMAB-CSIC, Spain

The possibility to prepare epitaxial complex oxide freestanding membranes has opened a whole new ground of research to investigate novel phenomena and device concepts envisaging new applications for complex oxides in next generation electronics. The use of the sacrificial layer approach emerged as one of the simplest and most versatile route to prepare complex oxide membranes. Yet, challenges remain on the synthesis level to accurately prepare and nanoengineer many complex oxide compositions, create new interfaces and exotic architectures.
Here it will be discussed the use of chemical methods to prepare high quality and ambient-stable Ca-doped $Sr_3Al_2O_6$ sacrificial layer [1] to deliver a series of freestanding complex oxide membranes including $CoFe_2O_4$, $La_{0.7}Sr_{0.3}MnO_3$ and $BiFeO_3$/ $La_{0.7}Sr_{0.3}MnO_3$ bilayers.
We identified that calcium doping in $Sr_3Al_2O_6$ has a key role on the stability of the sacrificial and define the subsequent epitaxial growth, strain and interface quality of the functional complex oxide. [2,3] Then it will also be presented a thorough study of the influence of both sacrificial and complex oxide thickness on the strain and mechanical properties of the freestanding membrane.
Finally, we demonstrate that the magnetic, electrical transport and piezoelectric properties of the $CoFe_2O_4$, $La_{0.7}Sr_{0.3}MnO_3$ and $BiFeO_3$/ $La_{0.7}Sr_{0.3}MnO_3$ membranes, respectively, are preserved when transferred on flat arbitrary substrates. [4]
Therefore, this study provides an innovative and versatile platform to synthesize transition metal oxide freestanding films and heterostructures that can be integrated in a wide variety of substrates and will empower the search for novel and enhanced properties with many technological benefits.

4:15 PM QT06.03.03
Self-Assembly of Nanocrystalline Structures from Freestanding Oxide Membranes Yu-Jung Wu[1], Varun Harbola[1], Hongguang Wang[1,2], Sander Smink[1], Sarah Parks[1], Peter A. van Aken[1,2] and Jochen Mannhart[1]; [1]Max Planck Institute for Solid State Research, Germany; [2]Stuttgart Center for Electron Microscopy, Germany

We present a novel route to fabricating nanocrystalline oxide structures of exceptional quality utilizing freestanding oxide membranes. The thermally induced self-assembly of nanocrystalline structures is driven by dewetting oxide membranes once they are lifted off and transferred onto sapphire substrates. Upon annealing at temperatures below the melting point of the membranes, they self-assemble systematically into a variety of nanostructures such as nanovoids, nanowires, and nanocrystals. The orientation of the nanostructures is exactly provided by the crystal lattice of the transferred membrane. The microstructure of the nanocrystals exhibits exceptional quality, characterized by a pristine crystal structure and uniform stoichiometry, and their alignment exceeds the capabilities of lithography and ion-milling techniques. These findings illustrate the nanofabrication opportunities created by dewetting complex oxides. Furthermore, the physics underlying the self-assembly process in the membranes can potentially enhance our understanding of interface diffusion, which is important to epitaxial thin film growth.

4:30 PM QT06.03.04
Spatially Reconfigurable Antiferromagnetic states in Topologically-Rich Freestanding Nanomembranes Hariom Jani[1,2], Jack Harrison[1], Sonu Devi[2], Saurav Prakash[2], Proloy Nandi[2], Junxiong Hu[2], Zhiyang Zeng[1], Jheng-Cyuan Lin[1], Charles Godfrey[1], Ganesh Ji Omar[2], Tim A Butcher[3], Jörg Raabe[3], Simone Finizio[3], Aaron Thean[2], Ariando Ariando[2] and Paolo Radaelli[1]; [1]University of Oxford, United Kingdom; [2]National University of Singapore, Singapore; [3]Paul Scherrer Institute, Switzerland

Antiferromagnets hosting real-space topological textures are promising platforms to model fundamental ultrafast phenomena and explore spintronics. However, to date, they have only been fabricated epitaxially on specific symmetry-matched substrates, to preserve their intrinsic magneto-crystalline order [1,2]. This curtails their integration with dissimilar supports, markedly restricting the scope of fundamental and applied investigations. Here, we circumvent this limitation by designing detachable crystalline antiferromagnetic nanomembranes of α-Fe_2O_3, that can be transferred onto other desirable supports after growth [3]. First, we show that flat nanomembranes host a spin reorientation transition and rich topological phenomenology via transmission-based antiferromagnetic vector-mapping. Second, we exploit the extreme flexibility of oxide membranes to demonstrate reconfiguration of antiferromagnetic states across three-dimensional membrane ‘folds’ resulting from flexure-induced strains. Finally, we combine these developments using an in-situ strain manipulator to realise the first demonstration of non-thermal Kibble-Zurek-like generation of topological textures at room temperature. Integration of such freestanding antiferromagnetic layers with flat/curved nanostructures could enable spin texture designs via magnetoelastic-/geometric-effects in the quasi-static and dynamical regimes, opening new explorations into curvilinear antiferromagnetism and unconventional computing.

Quantum Sensing with Rydberg Excitons Arya D. Keni, Nithin Abraham, Akshay Agrawal, Kinjol Barua, Yong Chen and Hadiseh Alaeian; Purdue University, United States

Rydberg excitons are promising quasi-particles for quantum sensing applications due to their extended wavefunctions and strong dipolar interaction strengths at higher quantum states. Electromagnetic excitations surrounding the excitons can be accurately quantified and measured when pump-probe processes are performed on them. The transitions between high-lying Rydberg states are in the microwave to terahertz frequency range, thus the excitons can absorb resonant or nearly resonant electromagnetic fields and eventually get excited into a higher state. This will lead to characteristic photon emission when the excited state spontaneously decays to the ground state. Exciton-based sensors are stable and immune to manufacturing variations, aging, and calibration issues since atoms of the same isotopic species are the same everywhere.

To enable Rydberg sensing, a suitable material platform capable of hosting highly excited Rydberg excitons is crucial. Until now, cuprous oxide (Cu2O) is the only known semiconductor in which Rydberg excitons having principal quantum numbers as high as n = 25 have been observed. This is because of its high binding energy and symmetric lattice structure, which allow it to support many Rydberg exciton states without succumbing to thermal ionization. However, reaching a defect-free condition in naturally occurring bulk cuprous oxide remains a challenge, necessitating a more controlled manufacturing technique to produce high-purity, customized synthetic cuprous oxide. Thin-film cuprous oxide samples with thicknesses less than the blockade radius are especially appealing because they make the Rydberg blockade utilizable for nonlinear behavior in semiconductors.

Here, we present photoluminescence and absorption measurements performed on Cu2O grown on a Strontium Titanate (STO) substrate. The dielectric permittivity of STO shows a large temperature dependence and we probe this using Rydberg excitons in Cu2O. The large temperature-dependent change in refractive index at terahertz frequencies sensitizes the transition between Rydberg states to the temperature, which can then be measured through the dynamics of the quasi-particle. The Cu2O/STO also provides us with a platform to study the effects of dielectric screening and dipolar interactions on the exciton dynamics. In this manner, a CMOS-compatible, integrable, and scalable solid-state semiconductor sensing platform can be realized which can pave the way for microwave sensing technologies.

Independence of Antiferrodistortive and Ferroelectric Transition in Strained $SrTiO_3$ Revealed by STEM Guomin Zhu, Alex Hallett, Nicholas Combs, Binghao Guo, Arda Genc, John Harter and Susanne Stemmer; University of California Santa Barbara, United States

Doped $SrTiO_3$ is a prominent example of an unconventional superconductor that cannot be described by the BCS-Eliashberg paradigm. One of the main open questions is how superconductivity is connected to two other order parameters in this material, namely an antiferrodistortive instability and a ferroelectric instability. Recently, we have revealed the presence of static polar distortions in the paraelectric phase of $SrTiO_3$, and have discussed their role in the superconducting transition.
Some studies have suggested that the antiferrodistortive distortion plays no role in the superconductivity, while others speculate that antiferrodistortive domain walls may enhance superconductivity. In this study, we use scanning transmission electron microscopy (STEM) to unveil the antiferrodistortive and ferroelectric distortion in the compressively strained, doped $SrTiO_3$ films. We identified the antiferrodistortive phase in real space by mapping out oxygen atoms using annular bright field (ABF) STEM. The dopant effects on the antiferrodistortive and ferroelectric phase are further elucidated by applying a free energy model with near density functional theory-level accuracy. The antiferrodistortive phase exhibits a single-domain structure, as expected due to the compressive in-plane strain. Using maps of the Ti column positions, we simultaneously measured the local polar domains. We find that unlike the local polar ferroelectric phase, which is suppressed by dopants, antiferrodistortive order persists in the presence of dopants. We show that the two transitions are largely independent of each other and the antiferrodistortive phase plays no role in the superconductivity.

8:30 AM *QT06.04.02
Cryogenic Electron Microscopy of Electronic Order in Oxides Ismail El Baggari; Harvard University, United States

In correlated oxides, quantum-mechanical effects and strong electron-electron interactions give rise to superb electronic properties and a vast potential for future technologies. In these materials, electrons may self-organize into new spatial patterns that break the symmetry of the underlying crystal. These electron ordered states display a rich interplay between distinct degrees of freedom and may induce novel functionalities through the breaking of additional crystal symmetries. I will show vivid atomic-scale visualizations of electronic order enabled by the development of cryogenic capabilities (near 100 K) for scanning transmission electron microscopy. These measurements are combined with advanced analysis tools to reveal picoscale atomic displacements governing electronic transitions, the nature and symmetry of electronic order at the local scale, and nanoscale fluctuations that underlie macroscopic properties. Despite these advances, a persistent challenge in the field of cryogenic transmission electron microscopy is the lack of stable liquid-helium-cooled sample conditions. I will discuss recent developments that provide access to ultra-low temperatures, as low as 20 Kelvin, while maintaining atomic-resolution imaging performance, paving the way for broader explorations of ultra-low temperature phenomena in oxide and beyond.

9:00 AM *QT06.04.03
Applications of High Spatial and Energy Resolution EELS in Functional Oxides for Thermoelectric Applications Demie Kepaptsoglou[1,2], Shihao Wang[1], Feridoon Azough[3], Robert Freer[3] and Quentin Ramasse[1]; [1]SuperSTEM, United Kingdom; [2]University of York, United Kingdom; [3]The University of Manchester, United Kingdom

Recent advances in instrumentation, such as the introduction of advanced, high-resolution monochromators have allowed for new exciting experiments in the electron microscope. Spectroscopic signatures of optical and acoustical phonons, excitons and defect gap states are now accessible with an atom size probe and in tandem with high precision imaging. Here, we present recent results on the phonon and electronic structure of thermoelectric (TE) materials systems for heat recovery applications, using advanced electron microscopy.

tobe expanded...

9:30 AM *QT06.04.04
Probing the Magnetic Cations in Multiferroic Magnetoelectric Thin Films Shelly Michele Conroy[1], Geri Topore[1], Demie Kepaptsoglou[2], Quentin Ramasse[2] and Sinead M. Griffin[3]; [1]Imperial College London, United Kingdom; [2]SuperSTEM, United Kingdom; [3]Lawrence Berkeley National Laboratory, United States

Magnetoelectric multiferroic materials show considerable potential for use in low-power computer memory and storage devices due to their coupled ferromagnetism and ferroelectricity, meaning that one could use an electric field to induce ferromagnetic domain switching. The opposite is also true, whereby a magnetic field can also cause ferroelectric domain switching. One such multiferroic material system is Aurivillius-phase $Bi_6Ti_xFe_yMn_zO_{18}$ (B6TFMO) thin films, where this coupling has been shown to exist in a single phase at room temperature. A large contribution to the room-temperature ferromagnetic ordering is the preferential partitioning of the magnetic cations (Mn and Fe) towards the center of the perovskite layers. Furthermore, even more complex polar topologies such as vortices around antiphase boundaries have been observed using atomic-scale scanning transmission electron microscopy (STEM) and polarization mapping. Understanding the mechanisms behind the cation segregation in the crystal structure and around crystallographic defects is of great importance if one aims to exploit the magnetoelectric ordering in these thin films for the manufacture of low-power, multi-state memory devices.
While atomic-scale STEM alongside techniques like Electron Energy Loss Spectroscopy (EELS) and Energy Dispersive X-Ray (EDX) spectroscopy have been invaluable characterization tools in analysing this material system, they only provide a 2D-projected view for what really are 3D features, especially in the case of complex topologies such as polar vortices. Hence, Atom Probe Tomography (APT) will be used due to its unique 3D chemical and structural analysis capabilities and a correlated workflow will be presented. For the same sample, structural information and specimen shape measurements from STEM will be correlated with APT analysis, as well as aid in the correct choice of atom probe reconstruction parameters. This combined dataset will provide invaluable insight about the mechanisms behind the fascinating room-temperature multiferroicity in these thin film material systems.
With the aim of better understanding the cation segregation mechanisms, we will show a controlled experimental method whereby magnetic Mn cations are implanted on $Bi_6Ti_3Fe_2O_{18}$ and their segregation will be observed before and after annealing, and compared to B6TFMO in which Mn was incorporated during growth from chemical solution deposition.

Machine-Guided Understanding of Functional Oxides in Extremes Steven R. Spurgeon[1,2]; [1]Pacific Northwest National Laboratory, United States; [2]University of Washington, United States

Directing the evolution of functional oxides in extreme environments is a longstanding challenge that requires new approaches to precision synthesis, characterization, and analytics. Our current inability to acquire, interpret, and act on multi-modal signatures greatly limits our control of materials for emerging applications, including quantum computing and energy storage. There is presently a transformative opportunity to harness artificial intelligence (AI) and domain-specific machine reasoning to guide the evolution of functional oxides more richly than ever before. Here I will describe our new framework for AI-guided experimentation, analytics, and modeling to explore oxides in extremes. This framework is transforming the study of fast-evolving phenomena, allowing us to discover latent defect signatures and determine key design parameters to control materials performance.

11:15 AM QT06.05.03
Irreducible Phonon Interactions and Phonon-Strain Couplings in $SrTiO_3$ Shenwei Wu[1], Mark A. Mathis[1], Enda Xiao[2] and Chris A. Marianetti[1]; [1]Columbia University, United States; [2]National Institute for Materials Science, Japan

While strontium titanate ($SrTiO_3$) has undergone extensive first-principles analysis, there remains a need for a systematic study of the irreducible phonon interactions to gain a comprehensive understanding of the vibrational Hamiltonian within a given first-principles method. Here we accurately compute cubic, quartic, and selected sextic irreducible phonon interactions, employing both the lone and bundled irreducible derivative approaches. Furthermore, the leading order irreducible strain phonon couplings are computed, yielding a detailed Taylor series of the Born-Oppenheimer potential in terms of displacements and strains. Particular focus is placed on the *R*-point antiferrodistortive (AFD) soft mode and the Γ-point T_{1u} manifolds. We demonstrate that the three-fold AFD manifold has a potential that is nearly spherical, while the linear strain coupling mildly favors the experimentally observed tetragonal distortion. The full anharmonic Hamiltonian is solved within the Hartree-Fock approximation for phonons, and the resulting observables are compared to previous similar calculations and experimental data.

11:30 AM *QT06.05.04
Precise Calculations of Strong Electronic Interactions and Transport in Oxides Marco Bernardi; California Institute of Technology, United States

Combining density functional theory with many-body techniques is enabling rapid advances in first-principles calculations of electron dynamics in materials. Yet, oxides remain challenging because of their intricate structure and electronic interactions.
I
n this talk, I will present new methods to model electronic interactions and transport from first principles, emphasizing their relevance to complex oxides. I will show calculations of electron interactions and transport in transition metal oxides with strong electron-lattice coupling, pronounced polaron effects, strong electron correlations, and their combinations. These results advance microscopic understanding of structure-property relationships in insulating and metallic oxides.

The talk will conclude with a discussion of PERTURBO, an open source code developed in my group providing quantitative tools to study electron interactions and dynamics in conventional and quantum materials. The recent addition of data-driven methods to compress electronic interactions and significantly speed-up their computation will be highlighted.

SESSION QT06.06: Advanced Metrology for Oxide Quantum Materials
Session Chairs: Lucas Caretta and Yu-Tsun Shao
Wednesday Afternoon, April 24, 2024
Room 447, Level 4, Summit

1:30 PM *QT06.06.01
Defect-Property Relations at Charged Interfaces in Ferroic Oxides Dennis Meier; Norwegian University of Science and Technology, Norway

Oxide materials exhibit a broad range of tunable phenomena, including magnetism, multiferroicity, and superconductivity. Oxide interfaces are particularly intriguing, giving a new dimension to property engineering of functional materials. The low local symmetry at the interfaces, combined with their sensitivity to electrostatics and strain, leads to unusual physical effects, offering amazing opportunities for fundamental and applied research.

In my talk, I will discuss the unique electronic properties that arise at natural and artificially designed charged interfaces in ferroelectric and multiferroic oxides. To give an overview and demonstrate how structural, electric, and compositional degrees of freedom at such interfaces control the material's behavior, I will present three examples: (i) ferroelectric domain walls in $BiFeO_3$, (ii) grain boundaries in ferroelectric $ErMnO_3$ polycrystals, and (iii) epitaxial heterointerfaces in multiferroic $(LuFeO_3)_9/(LuFe_2O_4)_1$ superlattices. To characterize the different types of interfaces, we perform correlated microscopy measurements, combining scanning probe microscopy, electron microscopy, and atom probe tomography. The imaging experiments provide new insight into the atomic-scale structure and chemical composition at charged oxide interfaces, clarifying the key role polar discontinuities and point defects play for their emergent physical properties.

2:00 PM *QT06.06.02
Spin Structures and Spin Transport in Oxidic Heterostructures Mathias Klaeui; University of Mainz, Germany

Magnetic oxidic insulators are exciting as they exhibit low damping and can thus be potentially used for low power GreenIT devices.
Recently topological spin structures have been observed in these systems [1] and and spin-orbit torques and in parrticular orbital torques can be used to efficiently manipulate these [2].
The low damping also lends itself to magnonic spin transport for instance in antiferromagnetic oxides. For the spin transport, spin currents are generated by heating as resulting from the spin Seebeck effect and by spin pumping measurements and we find in vertical transport short (few nm) spin diffusion lengths

[3,4].
For hematite, however, we find in a non-local geometry that spin transport of tens of micrometers is possible [5,6]. We detect a first harmonic signal, related to the spin conductance, that exhibits a maximum at the spin-flop reorientation, while the second harmonic signal, related to the Spin Seebeck conductance, is linear in the amplitude of the applied magnetic field [5]. The first signal is dependent on the direction of the Néel vector and the second one depends on the induced magnetic moment due to the field. We identify the domain structure as the limiting factor for the spin transport [6]. We also achieved transport in the easy plane phase [7], which allows us to obtain long distance spin transport in hematite even at room temperature [7]. Beyond hematite, we recently identified representatives of the broad class of orthoferrites, such as $YFeO_3$ and others to exhibit long distance spin transport, which additionally is highly anisotropic [8],

3:30 PM QT06.07.01
Boosting the Edelstein Effect of Two-Dimensional Electron Gases by Ferromagnetic Exchange Gabriel Lazrak[1], Annika Johansson[2], Börge Göbel[2,3], Ingrid Mertig[2,3], Agnès Barthelemy[1] and Manuel Bibes[1]; [1]Unité Mixte de Physique, CNRS / Thales, Université Paris Saclay, France; [2]Max Planck Institute of Microstructure Physics, Germany; [3]Martin Luther University Halle-Wittenberg, Germany

Strontium titanate ($SrTiO_3$) two-dimensional electron gases (2DEGs) have broken spatial inversion symmetry and possess a finite Rashba spin-orbit coupling [1], which endows the electronic bands with unique spin textures and couples the spin of mobile electrons to their momentum. This enables the interconversion of charge and spin currents through the direct and inverse Edelstein effects (EE/IEE), with record efficiencies at low temperature [2,3].
In this work, we show that making these 2DEGs ferromagnetic enhances the conversion efficiency by nearly one order of magnitude. Starting from the experimental band structure of non-magnetic $SrTiO_3$ 2DEGs [4], we mimic magnetic exchange coupling by introducing an out-of-plane Zeeman term in a tight-binding model. We then calculate the band structure and spin textures for increasing internal magnetic fields and compute the Edelstein effect using a semiclassical Boltzmann approach [5]. We find that the conversion efficiency first increases strongly with increasing magnetic field, then shows a maximum and finally decreases.
This field dependence is caused by the competition of the exchange coupling with the effective Rashba interaction. While enhancing the splitting of band pairs amplifies the Edelstein effect, weakening the in-plane Rashba-type spin texture reduces it.
Experimentally, we are studying the 2DEG at the interface between $SrTiO_3$ and the ferromagnetic oxide EuO, to imprint ferromagnetism in the gas.

3:45 PM *QT06.07.02
Multipolar Ordering in $CaIrO_3$ Thin Films Regina Dittmann[1], Marjana Lezaic[2], Alexandros Sarantopoulos[1] and David Gustin[2]; [1]PGI-7, Germany; [2]Forschungszentrum Jülich GmbH, Germany

5*d*-transition metal oxides, where correlations and spin-orbit coupling play at the same energy scale, create a great playground in search for high-T_C and unconventional superconductivity, spin liquids and novel magnetic ordering phenomena.
The metastable perovskite phase of $CaIrO_3$ was previously grown in thin-film form and characterized as semimetallic by *ab-initio* calculations (Yang et al., J. Phys. Condens. Matter (2010)), although the optical conductivity spectra were inconclusive in this respect, leaving open the possibility of a small-gap insulating state. We performed first-principles calculations which yield a small insulating gap, despite a large spatial extent of Ir 5*d* wavefunctions. Ordering of higher-order magnetic multipoles is shown to go hand-in-hand with the gap formation.
In order to verify our calculations we have grown $CaIrO_3$ thin films on $SrTiO_3$ by pulsed laser deposition. Due to the high volatility of IrO_3 significant off-stoichiometry is observed despite a high crystalline quality and the formation of a stable perovskite structure. In order to obtain stoichiometric $CaIrO_3$ thin films, we had to adjust the growth kinetics while reducing the oxygen partial pressure to prevent the formation of volatile IrO_3. We will discuss the electrical and magnetic properties of our films in the framework of the presence of multipolar ordering, gap formation and possible structural defects.

4:15 PM QT06.07.03
Epitaxial Synthesis of Oxide Dirac Semimetal $CaNbO_3$ Thin Films Yunkyu Park[1], Seoung-Hun Kang[1], Hua Zhou[2], Jong Mok Ok[3], Hwangsun Kim[1],

Shan Lin[1], Andrew R. Lupini[1], Mina Yoon[1], Satoshi Okamoto[1] and Ho Nyung Lee[1]; [1]Oak Ridge National Laboratory, United States; [2]Argonne National Laboratory, United States; [3]Pusan National University, Korea (the Republic of)

Dirac/Weyl semimetals exhibit massless behaviors, leading to high carrier mobility and exotic quantum transport phenomena. Until now, only a limited number of studies have been conducted to explore Dirac/Weyl semimetals in oxide system, because the observation of a topological band structure to enable quantum transport is rare in oxide materials. Here, we report epitaxial synthesis of high-quality $CaNbO_3$ thin films by pulsed laser deposition on various substrates and their structural and physical properties. While bulk $CaNbO_3$ is orthorhombic, thin films revealed a delicate change of the structure depending on the growth conditions, including the type of substrates, thickness, and strain. Both tetragonal and orthorhombic phases with different octahedral symmetries were observed through X-ray Bragg rod measurements. Epitaxial strain is found to effectively manipulate oxygen octahedral symmetry from $a^0a^0c^-$ to $a^-b^+c^-$ / $a^+b^-c^-$ along with structural phase transition from tetragonal phase to orthorhombic phase. Furthermore, high-mobility transport was achieved on $CaNbO_3$ films along with a large linear magnetoresistance (LMR), which is one of the representative signatures of a Dirac semimetal.

4:30 PM QT06.07.04
Directional Anomalous Skin Effect in ReO_3 Timothy Branch[1,1], Graham Baker[2], Mohamed Oudah[1,1], James Day[1,1], Alannah Hallas[1,1] and Douglas A. Bonn[1,1]; [1]The University of British Columbia, Canada; [2]Max Planck Institute for the Chemical Physics of Solids, Germany

Rhenium oxide (ReO_3) is the most highly conducting oxide material due to its extraordinarily low residual resistivity[1]. Due to this property it has a remarkably long low-temperature electronic mean free path, similar to that seen in the ultrapure delafossites. Recent observations from broadband microwave spectroscopy have revealed a new directional anomalous skin effect (ASE) in the quasi-2D delafossite material palladium cobaltate ($PdCoO_2$)[2]. This effect has also been found in ReO_3. The anisotropic ASE response in these materials is influenced by the alignment of surface currents, the electromagnetic wavevector, and the facets on their Fermi surfaces. For $PdCoO_2$, recent nonlocal Boltzmann transport models for anisotropic metals accurately describe its behaviour, which falls between the ballistic and hydrodynamic electronic transport regimes[3,4].

However, the directional ASE in ReO_3 has more complexity due to its three-dimensional electronic structure and multiple Fermi surface sheets. In this study, we provide microwave spectroscopy results for high-purity single-crystal samples of ReO_3 at low temperatures. These results demonstrate the unique anisotropy that arises for surface currents flowing in different directions with respect to the Fermi surface facets. Our findings confirm the directional ASE in ReO_3, and we interpret these results using nonlocal skin effect transport models.

Unusual Quantum Oscillations and Indications of Non-Trivial Electronic States in a Quassi Two-Dimentional Electron System at Intricate Oxide Interfaces Manish Dumen[1] and Km Rubi[2]; [1]INST Mohali, India; [2]Los Alamos National Laboratory, United States

Two-dimensional electron systems (2DES) built from perovskite transition metal oxides are potential prospects for the next generation of spintronics and quantum computing due to the simultaneous occurrence of electric-field driven superconductivity and spin-orbit interaction. To enhance technological applications, it is necessary to fully comprehend the electronic bands and confirm the anticipated electronic states in these 2DES by experimentation. Here, using thorough studies of Shubnikov-de Haas oscillations in two distinct systems, $EuO/KTaO_3$ (EuO/KTO) and $LaAlO_3/SrTiO_3$ (LAO/STO), we give new insights into the electronic states of the 2DES at oxide interfaces. We performed transport tests in high magnetic fields up to 60 T and low temperatures down to 100 mK in order to precisely resolve these oscillations. We saw a progressive increase in oscillations for 2D confined electrons at both contacts. We saw a progressive increase in oscillation frequency and cyclotron mass with the magnetic field for 2D confined electrons at both interfaces. We analyze these fascinating results by taking into account the possibility of non-trivial electronic bands, for which both linear and parabolic dispersion relations are included in the E−k dispersion. The unconventional oscillations presented in this study not only establish a new paradigm for quantum oscillations in 2DES based on perovskite transition metal oxides, where the oscillations frequency exhibits quadratic dependence on the magnetic field, but also provide experimental evidence for topological-like electronic states in KTO-2DES and STO-2DES.

Isotopic Purification of TiO_2 Obtained by Surface-Enhanced Interstitial Injection Heonjae Jeong, Ian I. Suni, Raylin Chen, Xiao Su and Edmund Seebauer; University of Illinois, United States

Use of isotopically pure semiconductors is important in the fabrication of devices for quantum computing, as spinning nuclei require isolation from environmental perturbation by isotopically pure layers having nuclear spins of zero. Raw materials of sufficiently high isotopic purity are expensive and difficult to obtain, so a post-synthesis method for removing isotopic impurities would be valuable. Through isotopic self-diffusion measurements of oxygen in rutile TiO_2 single crystals immersed in water near room temperature, we demonstrate fractionation of ^{18}O by a factor of three below natural abundance in a near-surface region up to 10 nm wide.[1] Application of electrochemical biases increases the width of this region by a factor up to five. The submerged surface injects O interstitials that displace lattice ^{18}O deeper into the solid due to the statistics of interstitialcy-mediated diffusion combined with steep chemical gradients of O interstitials. The steep gradients arise because lowered chemical coordination at clean metal oxide surfaces facilitates the creation of interstitial atoms from adsorbed atoms with energy barriers near or below roughly 1 eV.[2] The atomic configurations for interstitial injection resemble those for site hopping in the bulk, with barriers only slightly higher. The modest hopping barriers of many interstitial species in oxides, coupled with those for injection, make clean surfaces efficient pathways for populating the nearby bulk with O_i near room temperature. This physical picture is not restricted only to oxygen or TiO_2. Indeed we also show that, when metallic cations such as Mn are present in the aqueous phase, application of electrochemical bias enables the efficient injection of the corresponding metallic interstitials into TiO_2. Such an approach for the host cation (Ti in this case) should lead to

isotopic purification of the lattice cation.

Crystal Growth of Mixed Crystal Perovskites for Efficient Down Conversion Matthew Turner and Doyle Temple; Norfolk State University, United States

Materials with large nonlinear optical susceptibilities, that are highly transparent, and possess appropriately fast response times are essential for future DOD needs in telecommunications, as optical power limiters for eye/sensor protection systems, and quantum computing entangled state photon sources. The objective of this research is the discovery of new ultrafast nonlinear optical materials with an effort that focusses on single crystal growth of new mixed perovskite oxides based on the $BaTiO_3$ system. This talk will summarize the crystal growth of two compositions: $Ba_xCa_{1-x}TiO_3$ and $BaTi_xZr_{1-x}O_3$. Single crystals were grown using the optical float zone method with x= 0.01 and 0.05. XRD analysis shows that the crystals grown were tetragonal symmetry perovsite structure. Optical measurements of the second order nonlinear susceptibility are currently underway.

5:00 PM QT06.08.03
Single Crystal Growth and Properties of BaFeGaO4 using The Floating Zone Technique Orrin Clarke-Delgado[1], Kevin Allen[1], Leroy Salary[1], Sunil Karna[2] and Doyle Temple[1]; [1]Norfolk State University, United States; [2]Prairie View A&M University, United States

Materials with topological spin textures are in demand for applications like memory storage and quantum computing. The AB2O4 family of crystals has a spinel structure and has been extensively examined. However, there are cases where the typical spinel structure is replaced with a tetrahedral network. The cubic ferromagnetic CuOSeO3 has been previously shown to contain skyrmions. BaFeGaO4 (BFGO) is being grown to better characterize its magnetic and thermal properties.

We have successfully developed a polycrystalline sample of BFGO using the solid state method. Polycrystalline samples were prepared using stochiometric quantities of BaCO3, Fe2O3, and Ga2O3. Since BaCO3 decomposes at 1000 C, samples were annealed for 6 hours to convert it to BaO. The powder mixture was annealed twice at 1100 C, with intermediate grindings after each step. Growth rods were prepared by pressing the powder with a hydraulic press into rods approximately 6 mm in diameter and 5 cm in length.
BFGO crystallizes in the hexagonal crystal system with space group P63. Structural analysis revealed that the samples had the correct structure. Rietveld analysis of X-ray diffraction also indicated single phase samples. BFGO belongs to the hexagonal structure having space group P63. Lattice parameters at room temperature: a = 10.8137 (6) A and c = 8.6734 (5) A.

Magnetic measurements were conducted with a Quantum Design Dynacool PPMS. The BFGO sample shows an upturn in the magnetic susceptibility near 50 K, evidence of magnetic ordering. The M-H hysteresis curve was observed at a temperature of 2 K, indicating that the sample is ferromagnetic. To understand the underlying physics and intrinsic behavior of BFGO, a single crystal is needed. Therefore, single crystals of BaFeGaO4 are being grown using the floating zone technique to control the spinel structural phase and characterize its morphology, thermal, magnetic, and electronic properties. Results of single crystal growth will be presented.

5:00 PM QT06.08.04
A Thin-Film Study of Iron/MgO Using Scattering Geometry of ^{57}Fe Mössbauer Spectroscopy Olivia Checkley[1], Natarajan Ravi[1], Yilin Li[2] and Darrell G. Schlom[2]; [1]Spelman College, United States; [2]Cornell University, United States

An experimental technique known as Conversion Electron Mössbauer Spectroscopy (CEMS) is built in our laboratory to study the surface properties of thin films prepared by Molecular Beam Epitaxial method (MBE). Pure Fe (30% enriched with ^{57}Fe) deposited on MgO substrate of 100 nm thickness is used to calibrate the CEMS system. The Zeeman spectrum and its intensity ratios of the spectral lines are analyzed in relation to the single crystal orientation. X-ray data of the thin film is correlated with this single crystal orientation and the easy axis of magnetization is determined. Comparison to the conventional transmission geometry is made for a polycrystalline sample of natural Fe absorber. The theory behind the magnetic dipole transition and the origin of the intensity Mössbauer lines are explained. Lorentzian line functions are used to obtain the least-squares fit of the experimental data.

La -Doped Hafnia Thickfims for Cryogenic Cooling Jalaja M A and Pavan Nukala; Indian Institute of Science, India

Cryogenic operation of devices is one of the essential requirement in the field of quantum technologies. Electrocaloric (EC) materials are promising as silent solid-state alternates to conventional refrigeration technologies. EC materials are generally Pb based materials, and work at their maximum efficiency only in a limited temperature range near the room temperature. The Pb-based ferroelectrics and polymers are reported to have large pyroelectric coefficients and output power while working in the vicinity of the phase transition temperature, however, struggle to generate voltage threshold (with thin films of nanometer scale) suitable for power electronics where thousands of volts are required. Thin film geometries offer a potential solution to this issue, as they can provide large, continuous power output and fast thermal cycling.
Here we explore the efficacy of unconventionally ferroelectric Hafnia systems which are promising candidates for nanoelectronics due to their CMOS compatibility, robust ferroelectricity at nano scale thicknesses, low dielectric constant, large bandgap, simple chemical structure and less toxicity. The ferroelectricity in hafnia is originating from orthorhombic crystal structure which is stabilised by means of various parameters like dopants, temperature, electrodes, oxygen vacancies etc. Achieving ferroelectricity in Hafnia below 5nm and above 30 nm is quite challenging as the depolarization field effect becomes prominent while scaling down and the non -polar monoclinic phase accompanies the orthorhombic phase while scaling up.
Our study presents the effect of dopant and electrode on achieving robust ferroelectricity in hafnia thick films prepared by solution deposition method. Defect based systems like hafnia generally requires thousands of wake-up cycles to produce the ferroelectricity which is a practical issue while integrating in to nanoelectronics. The solution processed- La doped hafnia thick films shows ferroelectricity with out the wake-up effect and the polarization values are stable till 10^9 cycles. Surprisingly hafnia thick film shows a phase transition from ferroelectric to non- ferroelectric phase around 140K which is evident from the temperature dependent P-E loops and C-V loops. The pyroelectric properties and electrocaloric cooling effects in the system are well studied

correlating with the electrode induced phase transition in hafnia. The electrocaloric cooling effect in hafnia is significant with ΔT=-2.2 (K) and offers new avenue to built cryogenic coolers at low cost.

SESSION QT06.09: Unconventional Superconductivity in Nickelates

8:15 AM QT06.09.01
Absence of Hydrogen in Highly Crystalline Superconducting Infinite Layer Nickelates Martin Gonzalez[1,2], Kyuho Lee[3], Yijun Yu[3,2], Woojin Kim[3,2], Jennifer Fowlie[3,2], Anton Levlev[4] and Harold Y. Hwang[3,2]; [1]Stanford, United States; [2]SLAC National Accelerator Laboratory, United States; [3]Stanford University, United States; [4]Oak Ridge National Laboratory, United States

Infinite-layer nickelates are promising candidates for studying unconventional superconductivity because of their electronic and structural comparison with the cuprates [1]. Superconductivity in the nickelates was first realized in strontium-doped neodymium nickelate (Nd,Sr)NiO_2, which has since sparked a plethora of studies investigating Ni-based compounds [2,3]. The synthesis of infinite-layer nickelate thin films ($R$$NiO_2$, R = lanthanide), is a two-step process: first involving the growth of the perovskite precursor phase followed by the deintercalation of apical site oxygen atoms via topotactic reduction [4,5]. The topotactic structural transition is commonly achieved using calcium hydride (CaH_2) as a reducing agent [6,7]. It remains debated, however, whether the use of calcium hydride results in the insertion of hydrogen into the infinite layer structure [8–10]. To determine whether hydrogen is present in the infinite layer nickelates, we performed secondary ion mass spectroscopy (SIMS) measurements on optimally doped (Nd,Sr)NiO_2 thin films to quantify the hydrogen content resulting from calcium hydride reduction. We find that hydrogen does not play a critical role for superconductivity in nickelates, and that the presence of hydrogen is a result of poor crystallinity in non-optimally synthesized thin films.

Advances and Challenges in The Single-Crystal Synthesis of Infinite-Layer and Ruddlesden-Popper Phase Nickelates Matthias Hepting; Max Planck Institute for Solid State Research, Germany

Unconventional superconductivity remains a key focus in condensed matter research, traditionally centered on material classes such as cuprates, iron pnictides, and heavy fermion compounds. Recently, rare-earth nickel oxides have emerged as a new class with potential for unconventional superconducting behavior. Within this nickelate family, two types of structures have drawn particular interest. The first type comprises nickelates with the infinite-layer crystal structure, such as $Nd_{0.8}Sr_{0.2}NiO_2$, showing superconducting transition temperatures (T_c) up to 20 K. The second type encompasses Ruddlesden-Popper phase nickelates, such as $La_3Ni_2O_7$, which under hydrostatic pressure manifest a remarkably high T_c of 80 K. Despite these promising observations, the possibly distinct mechanisms driving the superconductivity in these two types of nickelates are not yet fully understood.

To address this, further investigations employing advanced spectroscopic methods are warranted, which are capable of probing the complex interplay between electronic, magnetic, and lattice degrees of freedom typically found in unconventional superconductors. Accordingly, a tailored sample synthesis is desirable to meet the specific requirements of each spectroscopic technique, such as large sample masses for neutron scattering and cleavable single crystals for surface sensitive techniques.

Yet, both nickelate families present unique challenges in material synthesis that have previously hindered the application of certain spectroscopic methods. For infinite-layer nickelates, synthesis can only be realized via a topotactic reduction of the parent perovskite phase. This process is invasive for the sample surface and has previously been executed primarily on thin films and polycrystalline powders. In this talk, I will discuss our advances in the topotactic reduction of single-crystalline samples [1,2]. Furthermore, we have performed resonant ineleastic x-ray scattering (RIXS) experiments on these crystals, providing unprecedented insights into spin excitations and charge ordering of the bulk phase [3]. The topotactic infinite-layer crystals are also suitable for future experiments using neutron or surfaces sensitive spectroscopies.

In the case of $La_3Ni_2O_7$, sizable single crystals can be readily grown using the optical floating zone method and do not necessitate topotactic treatment. However, we recently observed that these crystals exhibit multiple crystallographic phases and a pronounced sensitivity to oxygen stoichiometry, affecting their physical properties. I will delineate how a close feedback loop between advanced characterization methods and iterative adjustments of growth parameters facilitates control over the material's phases, thereby enabling the realization of single crystals optimized for subsequent spectroscopic studies.

Probing The Electronic Dispersion of Superconducting Nickelates Gael Grissonnanche[1,2], Grace A. Pan[3], Harrison LaBollita[4], Dan Ferenc Segedin[3], Qi Song[3], Hanjong Paik[2], Charles M. Brooks[3], Antia Botana[4], Julia Mundy[3] and Brad Ramshaw[2]; [1]École Polytechnique, France; [2]Cornell University, United States; [3]Harvard University, United States; [4]Arizona State University, United States

The origin of unconventional superconductivity in the cuprates remains a mystery partly due to the complex interplay of several competing states and relatively strong disorder. Superconducting nickelates are a new family of materials [1,2] that also combine strongly correlated magnetism with unconventional superconductivity. While comparisons with the superconducting cuprates are natural, very little is known about the metallic state of the nickelates, making these comparisons difficult.
To investigate the electronic structure of the nickelates, we measured the Seebeck coefficient *S* of a superconducting 5-layer nickelate $Nd_6Ni_5O_{12}$ (n = 5 nickelate), whose resistivity is predominantly linear—indicative of strange metal physics—as well as a more-overdoped, non-superconducting, 3-layer nickelate $Nd_4Ni_3O_8$ (n = 3 nickelate) for comparison. We find that both the n = 5 and n = 3 nickelate share a similar temperature-independent, negative *S*/*T*, but dramatically differs from the positive Seebeck effect measured on cuprates at similar doping [3].
To interpret our measurements, we used Boltzmann transport theory to show that the electronic dispersion obtained from first-principles calculations accounts for both the magnitude and sign of the temperature-independent Seebeck coefficient in the nickelates. This demonstrates that the electronic structure obtained from first-principles calculations is a good starting point for calculating the transport properties of superconducting nickelates, and suggests that, despite indications of strong electronic correlations, there are well-defined quasiparticles in the strange metallic state of this family of materials.
Finally, we explain the differences in the Seebeck coefficient between nickelates and cuprates as originating in strong dissimilarities in impurity concentrations. Beyond establishing a baseline understanding of how the electronic structure relates to transport coefficients in the superconducting nickelates, this work [4] demonstrates the power of the semi-classical approach to quantitatively describe transport measurements in strongly correlated electron systems, even in the strange-metallic state.

Topotactic Reduction: From Brownmillerite to Infinite-Layer Strontium Ferrite Aarushi Khandelwal[1,2], Woojin Kim[3] and Harold Y. Hwang[1,2]; [1]Stanford University, United States; [2]SLAC National Accelerator Laboratory, United States; [3]Pusan National University, Korea (the Republic of)

Isostructural to high-temperature superconducting cuprates, other infinite-layer materials like nickelates, cobaltates, and ferrites have attracted significant interest in recent years. A popular route to synthesizing these infinite layers in thin films is growing perovskite or brownmillerite films and removing oxygen through topotactic reduction [1].
In strontium ferrite, there has been substantial work dedicated to understanding both the as-grown brownmillerite phase, which is notable for high ionic conductivity and interesting magnetic structure [2,3], as well as the reduced infinite layer phase, which is an antiferromagnetic Mott insulator studied for its correlated electronic, magnetic, thermal, and optical properties [4-8]. However, relatively little is known about the mechanism of the reduction process, which can depend on the orientation of oxygen vacancy channels in the brownmillerite films [4,9].
In this work, we grow epitaxially-strained brownmillerite $SrFeO_{2.5}$ thin films on various substrates using pulsed laser deposition and reduce them to the infinite layer phase, $SrFeO_2$, through low-temperature topotactic reduction using CaH_2 reducing agent. During this reduction, we track the evolution of structure and topography, probing the spatial distribution of the brownmillerite and infinite-layer phases as a function of reduction time and strain. We also study the strain dependence of the final infinite layer phase. This work sheds light on the oxygen diffusion pathways relevant to the topotactic reduction process to enable further refinement and control of the transformation between the phases.

Emerging Phase Transitions in Lead-Free Antiferroelectric Thin Films Ruijuan Xu; North Carolina State University, United States

As one of the prominent lead-free antiferroelectric alternatives, $NaNbO_3$ has received considerable research attention owing to its significant potential in energy storage applications. It is also renowned for being one of the most structurally complicated perovskite materials, exhibiting a rich set of structural phases characterized by distinct symmetries, ferroic orders, and oxygen octahedral tilting patterns. This intricate energy landscape in $NaNbO_3$ also opens up possibilities for inducing novel phase transitions through various external stimuli. In this presentation, I will introduce our recent studies on the intrinsic size dependence of antiferroelectricity in freestanding $NaNbO_3$ membranes. Through a wide range of experimental and theoretical approaches, we probe an

intriguing antiferroelectric-to-ferroelectric transition that occurs as the membrane thickness decreases. Additionally, I will present our recent findings regarding an intriguing strain-induced phase transition in $NaNbO_3$ films, where we observed the presence labyrinthine domain patterns that self-organize into topological polar domains. Our work demonstrates enormous potential of using $NaNbO_3$ as a fertile ground for exploring emerging phase transitions and phenomena.

10:45 AM QT06.10.02
Many Body Localisation in $CeMnAsO_{1-x}F_x$? Abbie Mclaughlin, Gaynor Lawrence, Struan Simpson and Eve J. Wildman; University of Aberdeen, United Kingdom

Transition metal oxypnictides are known to exhibit a range of exotic phenomena. For example, high temperature superconductivity in $LnFeAsO_{1-x}F_x$ and colossal magnetoresistance in $LnMnAsO_{1-x}F_x$ (Ln = Nd, Pr), where the resistivity reduces by 95% at 4 K in a 7 T field. We have been investigating $CeMnAsO_{1-x}F_x$ (x = 0 – 0.075) and here we show how the electronic properties change with F^- doping. CeMnAsO is a Mott insulator. Upon electron doping, via substitution of O^{2-} with F^-, an unusual insulator – insulator transition is observed for $x \geq 0.035$. The resistivity increases by more than two orders of magnitude over a 2 K temperature range and a superinsulating state is achieved below the transition temperature T_{II}. The superinsulating trnasition temperature can be tuned by increasing x in $CeMnAsO_{1-x}F_x$. Variable temperature synchrotron and neutron diffraction studies confirm that there is no change in the crystal or magnetic structure at T_{II}. Results from AC transport and Hall measurements suggest this transition could be the first observation of many body localisation (MBL) in the solid state. The most significant characteristic of MBL systems is that below a transition temperature they become perfect insulators, exhibiting zero electronic conductivity. The MBL phase also acts as a quantum memory and can be used to protect quantum memory allowing the tantalising possibility of performing topological quantum computation at finite temperatures.

11:00 AM QT06.10.03
Spectro-Microscopic Investigation of 2DEGs in $KTaO_3$ Interfaces Aravind Raji[1,2], Srijani Mallik[3], Hugo Witt[3], Victor Porée[2], Alessandro Nicolaou[2], Manuel Bibes[3], Jean-Pascal Rueff[2,4] and Alexandre Gloter[1]; [1]Laboratoire de Physique des Solides Orsay, France; [2]Synchrotron Soleil, France; [3]Unité Mixte de Physique CNRS, Thales, Université Paris-Saclay, France; [4]LCPMR, Sorbonne Université, CNRS, France

Emerging thin-film technology, and its electronic applications rise in parallel with the advances in their atomic-scale synthesis and characterization. Oxide based heterostructures are one key player in it, and they possess remarkable functionalities. The two-dimensional electron gases (2DEGs) in the 5d perovskite $KTaO_3$ (KTO) based heterostructures exhibits intriguing properties such as superconductivity [1-3], spin-charge interconversion which can have direct applications in spin-orbitronics [4], etc. Depending on the orientation of the substrate KTO, the physical properties in these systems are varied. For instance, the EuO/KTO (111) systems exhibit superconductivity below 2.2 K [1](0.9 K for an AlOx/KTO (111) [5]), while an EuO/KTO (110) exhibited superconductivity below 1.35 K [6]. The KTO (100) based systems were found to be superconducting only with ionic liquid gating, and at a very low transition temperature of 40 mK [2].
In this path, here we study the Aluminium deposited- pristine KTO substrates in (111), (110), and (100) orientations and EuO/KTO (111) heterostructures with a focus on the emergence of 2DEG and how it influences the physical properties of interest in these. A microstructural and spectroscopic understanding of these interfaces is much appreciated in this direction. With this motivation, we conduct a study involving Scanning Transmission Electron Microscopy (STEM), Electron Energy Loss Spectroscopy (EELS) (Done at STEM Lab in LPS Orsay) and Standing Wave - Hard X-ray Photoemission Spectroscopy (SW-HAXPES) and Resonant Inelastic X-ray Scattering (RIXS) (Done at GALAXIES and SEXTANTS Beamlines in Synchrotron SOLEIL). STEM-EELS provides insights into the changes in the local chemistry and electronic structure together with an atomic scale resolution. On the other hand, SW-HAXPES is a depth selective and non-destructive technique, with a strong sensitivity to chemical differences in each layer. This combination enables us to extract the photoemission spectra from the interface separately. RIXS measurements with a linear polarized light sheds light on the orbital polarization, and also acts as a probe for the in-gap states. The objective is the characterization and determination of the spatial extension of 2DEG encompassing the possible Ferroelectric (FE) type distortion near the interface in these systems.
STEM-EELS element map analysis on a superconducting AlOx/KTO (111) 2DEG system already shown less cation intermixing and a cleaner Al-KTO interface [5]. Our following studies on the structural aspect using STEM, 4D-STEM, geometrical phase analysis (GPA) and SW-HAXPES unraveled the plane termination, and lattice reconstruction along with a substantial FE-type distortion near the last unit cell. These distortions are not the same between the samples. However, on a larger scale, a tetragonal out-of-plane compression up to 1% is observed on the three differently oriented AlOx/KTO systems, and they extend upto 10 nm into the substrate from the interface. On the spectroscopic part, monochromated EELS measurements shown clear fine structure variations at the Ta-$O_{2,3}$ edge near the interface, which constitutes the real space imaging of the spectroscopic charge, harboring the 2DEG. RIXS measurements shown possible in gap states, and differential charge localization between the samples. Such a combined study with microscopy and spectroscopy unfolds the more interesting physics occurring at the interface, which is not accessible by many bulk probing techniques.

Proton-Phonon Coupling, and Causality between Lattice Vibration and Proton Conductivity in Solid Electrolytes Artur Braun[1], Alexey Rulev[1], Qianli Chen[2] and Stephen P. Cramer[3]; [1]Empa, Switzerland; [2]Shanghai Jiao Tong University, China; [3]SETI Institute, United States

Ion conducting materials are key components in solid-state electrochemical devices including high-temperature fuel cells (SOFC) and electrolyzers. One of the shortcomings of SOFC – a high operating temperature – may be avoided by using another class of ion conductive ceramics: ceramic proton conductors. Proton conductivity is usually observed at lower temperature than oxygen conductivity due to higher proton mobility.
Ionic transport in solid state is a very important process in many areas; however, compared to, for example, electronic transport, ionic mobility is much less understood and not very well developed. Protonic mobility in particular is a specific peculiar case due to small mass of protons and its high mobility. The temperature dependence of proton conductivity in perovskites suggests that there might be a polaron-like mechanism of proton movement [1]. It implies that there is a significant interaction between the lattice vibrations and moving ions, and it is therefore of great interest to explore lattice dynamics of the perovskite materials.
Such problems are usually studied with conventional methods of lattice dynamics study such as Raman or infrared spectroscopy. These vibration spectroscopy methods provide convoluted information about lattice dynamics without element specificity. However, nuclear resonant vibration spectroscopy (NRVS) can provide element specific projected phonon density of states, which makes the method very attractive for combined studies of molecular and vibrational structure. NRVS, however, only works on Mössbauer-active isotopes, which narrows down its applicability.
For this study we chose barium stannate (BaSnO3), which is one of proton conductors of perovskite family and contains Mössbauer-active 119Sn isotope. We have performed NRVS on pure and yttrium-doped barium stannate in dry and water-loaded state; the data, backed up by precision neutron diffraction data of the dry and heavy water-loaded ceramic. Using these as of yet unpublished data and results of DFT calculations, we are able to pinpoint which ions play which role on lattice vibrations and then proton conductivity in perovskite-type solid electrolytes.

New Insights into Magnetization Dynamics in Multiferroics: Role of Two-Dimensional Correlations in Three-Dimensional $TbMnO_3$ and $DyMnO_3$
Narmada Hegde[1] and Subray Bhat[2]; [1]S N Bose Physics Learning Center, India; [2]Indian Institute of Science, India

In the multiferroic manganites such as $TbMnO_3$, $DyMnO_3$ and $GdMnO_3$, frustration, either geometric or that arising from competing microscopic interactions, is known to have a major effect in determining the phase diagram of the material [1,2]. Additionally, the complex incommensurate and cycloidal structures underlying the multiferroicity arise from freezing out of certain dynamical modes. The study of temperature dependence of Electron paramagnetic resonance (EPR) linewidth $\Delta H(T)$ provides valuable information about spin dynamics. For example, in $TbMnO_3$ [3] and $DyMnO_3$ [4] EPR studies showed the presence of frustrated magnetism and strong, short range antiferromagnetic fluctuations much above the antiferromagnetic transition temperature T_N. It turns out that the analysis of $\Delta H(T)$ requires fitting the data to an appropriate model. In the EPR studies on $TbMnO_3$ and $DyMnO_3$, following reference [5] , the 'spin freezing model', where $\Delta H(T) = A \exp[- (T-T_s)/T_0] + mT + \Delta H_0$, where A is a proportionality constant, T_S is the critical transition temperature, e.g., T_N, and T_0 is an empirical constant, was used to fit the experimental data. mT and ΔH_0 account for linear T-dependence and T-independent value of the line width. However, the fits reported in the papers do not appear to be very good. In a recent detailed study of EPR $\Delta H(T)$ in certain doped rare earth perovskite manganites we showed [6] that a more appropriate model to use is the Berezinskii-Kosterlitz-Thouless (BKT) model which takes in to account the possibility that the correlations could be two-dimensional, either due to the nature of the exchange interactions in the material or/and due to the effect of the applied magnetic field. According to this model, $\Delta H(T) = \Delta H_\infty \exp [3b/\sqrt{(T/T_{BKT} -1)}] + mT+ \Delta H_0$, where T_{BKT} is the BKT transition temperature, ΔH_∞ is a constant, b takes the value of $\pi/2$ for a square lattice but has been theoretically shown to take an arbitrary value. This result has been confirmed by a number of recent studies[7]. Following this work, we reanalyse the data on $TbMnO_3$ and $DyMnO_3$, the latter in both hexagonal and orthorhombic forms and find that indeed the BKT analysis leads to significantly better fits. We summarize the results below: for $TbMnO_3$, the spin-freezing model fits with the parameters $\Delta H_0 = 320.9$ (G), A = 7863.5 (G), $T_N = 50$ K, $T_0 = 49.5$ and the goodness of the fit factor $R^2 = 0.973$; whereas the BKT model fits better. According to this model $\Delta H_\infty = 7.92$ (G), m = -0.134, $T_{BKT} = 80.99$ K, $\Delta H_0 = 306.1$ (G) and a better fit with $R^2 = 0.996$. For hexagonal $DyMnO_3$ the spin freezing model values are $\Delta H_0 = 975.56$ (G). A = 9866.28 (G), $T_N = 79.37$ K, $T_0 = 24.02$ and the goodness of the fit factor $R^2 = 0.992$. The BKT model fits slightly better. The parameter values are $\Delta H_\infty = 30.32$ (G), m = -0.058, $T_{BKT} = 53.44$ K, $\Delta H_0 = 599.79$ (G) and a slightly better fit with $R^2 = 0.999$; however, we note that for orthorhombic $DyMnO_3$ the spin freezing model gives a better fit with parameters $\Delta H_0 = 1477.6$ (G). A = 3069.9 (G), $T_N = 70$ K, $T_0 = 189.69$ and the goodness of the fit factor $R^2 = 0.997$. The parameters for the BKT fit are $\Delta H_\infty = 185.26$ (G), m = -4.88, $T_{BKT} = 16$ K $\Delta H_0 = 3263.4$ (G) and a slightly poorer fit with $R^2 = 0.994$. We discuss the implications of the subtle differences in the spin dynamics as reflected in these numbers.

^ MRS Communications Early Career Distinguished Presenter

SESSION QT07.01: Fundamentals, Theory and Modeling I
Session Chairs: Stephan Lany and Stephanie Law
Tuesday Morning, April 23, 2024
Room 448, Level 4, Summit

10:30 AM *QT07.01.01
Fundamental Bound on Topological Gap Liang Fu; MIT, United States

I will present a fundamental bound on the energy gap of Chern insulators, derived from the consideration of optical absorption of circularly polarized light. The topological gap bound provides a guiding principle for finding integer and fractional quantum anomalous Hall states at higher temperature. I will also describe its deep connections to quantum geometry and optical response of solids. Applications of the topological gap bound to semiconductor moire materials and magnetic topological insulators will be described.

11:00 AM QT07.01.02
Redox-Coupled Structural Distortions in the Quasi-1-Dimensional Au2M1-xP2 System Scott B. Lee[1], Joseph Stiles[1], Fang Yuan[1], Fatmagül Katmer[1], Stephanie Dulovic[1], Tieyan Chang[2,3], Yu-sheng Chen[2,3] and Leslie Schoop[1]; [1]Princeton University, United States; [2]Advanced Photon Source, United States; [3]The University of Chicago, United States

Symmetry and Fermi-level filling are two variables that lie at the foundation in investigating topological materials. For example, in the $GdSb_xTe_{2-x-\delta}$ system, the Sb:Te ratio governs the electron-filling of the band structure, producing a tunable system of structural distortions in its square-net layer. At specific ratios, these distortions retain certain symmetry-protected bands, such as a Dirac node on the Fermi surface, and gap out topologically trivial bands at the Fermi surface. One interest now is to investigate tunable topological structural motifs beyond a square-net of atoms. A one-dimensional (1D) chain of atoms realizes analogous symmetry protected Dirac nodes as the square net. The first part of my presentation expands on previously reported Au_2MP_2 (M=Hg, Tl, Pb, and now Bi), which contains a 1D chain of M atoms. Surprisingly, this structure type stabilizes across a difference of four electrons per chain atom, while the Bi analogue also contains a monoclinic polymorph that retains the linear chain of Bi atoms. The second part of my presentation demonstrates the importance of chemical workup in solid state compounds. X-ray and electron diffraction characterizations indicate crystals of the Au_2MP_2 system undergoes a redox-mediated structural distortion whose resulting symmetry and size of supercell depends on the identity of M. Further characterization and computations suggest modulated coordination enviornments as a possible driving force for the distortions. Finally, electronic transport between the modulated and unmodulated compounds are compared. As a result of these insights, nearly isolated 1D chains can be further probed in differing chemical environments.

11:15 AM QT07.01.03
Theoretical Defect Model for Synthesis Control of The Fermi Level Position in Cd_3As_2 Chase Brooks[1], Mark van Schilfgaarde[2], Dimitar Pashov[3], Jocienne Nelson[2], Kirstin M. Alberi[2], Daniel Dessau[1] and Stephan Lany[2]; [1]University of Colorado Boulder, United States; [2]National Renewable Energy Laboratory, United States; [3]King's College London, United Kingdom

Cd_3As_2 is a three-dimensional Dirac semimetal with sustained scientific interest. Intrinsic point defects, however, induce excess electron carriers that elevate the Fermi level E_F away from the Dirac point and limit accessibility to its topological features. By combining density functional theory (DFT) calculations of defect formation energies and quasiparticle self-consistent GW (QSGW) electronic structure calculations, we demonstrate an innate concentration dependence of defect formation energies, and we find that Cd interstitials are the primary source of this self-doping. We extrapolate formation energies to arbitrary electron concentrations, and we utilize a thermodynamic defect equilibria model to study how extrinsic electron accepting dopants (e.g. Si, Ge, Sn) and particular growth conditions can tune E_F closer to the Dirac point. Separately, Zn_3As_2 is a trivial semiconductor with a direct band gap of 1.0 eV that typically forms with intrinsic *p*-type doping, so the $(Cd,Zn)_3As_2$ alloy system is expected to undergo both a topological phase transition and a net doping crossover. Using Monte Carlo simulations, we determined representative alloy structures, which can serve as the basis for predicting electronic structure and defect properties of the alloy.

11:30 AM *QT07.01.04
Chiral Topological Semimetals: Next-Generation Quantum Materials at The Intersection of Topology, Correlations and Magnetism Niels Schröter; Max Planck Institute of Microstructure Physics, Germany

The term chirality is derived from the Greek word for 'hand' χειρ (kheir) and generally describes objects that are distinct from their own mirror image. It is long known that chirality plays a crucial role in nature, providing powerful functionality to chiral molecules in living organisms. Our goal is now to extend this concept from the molecular to the solid state to discover new chirality-enabled functionalities in crystals that could form the basis for new technologies. One particular focus of our activities are chiral topological semimetals, a new class of quantum materials at the intersection of structural and electronic chirality. We discovered the first example of this material class a few years ago (*1*) and have since demonstrated that they host new fermionic quasiparticles without analogue in high-energy physics, which carry large and controllable topological charges (*2*).

In this talk, I will present new results that go beyond these initial works and demonstrate that these materials realize an isotropic parallel spin-momentum locking that can be considered the natural counterpart of Rashba spin-orbit coupling (*3*). Moreover, I will also present fingerprints of parallel locking of the linear momentum to the orbital angular momentum. Finally, I will discuss magnetic chiral topological semimetals and the effect of spin-dependent correlations on the quasiparticle lifetimes of bulk and chiral surface states.

SESSION QT07.02: Synthesis and Characterization I
Session Chairs: Kirstin Alberi and Stephanie Law
Tuesday Afternoon, April 23, 2024
Room 448, Level 4, Summit

1:30 PM *QT07.02.01
Two-Dimensional Topological States in Thin Films of Cadmium Arsenide Susanne Stemmer[1], Binghao Guo[1], Alexander Lygo[1], Wangqian Miao[1] and Xi Dai[2]; [1]University of California, Santa Barbara, United States; [2]The Hong Kong University of Science and Technology, China

In this talk, we will discuss two-dimensional topological states in high-quality thin films of cadmium arsenide (Cd_3As_2) grown by molecular beam epitaxy. Cd_3As_2 is known to belong to a class of topological materials known as three-dimensional Dirac semimetals, but, as we will discuss in this presentation, in thin films it can be tuned between a variety of topological phases. We will discuss the evolution of the electronic states of Cd_3As_2 films as their thickness is scaled. We also discuss a two-dimensional Weyl semimetal phase that is obtained under applied in-plane magnetic fields. We show that magnetotransport studies can distinguish between the different topological phases.

2:00 PM QT07.02.02
Extrinsic Doping Control in Cd_3As_2 Thin Films Grown via MBE Anthony Rice[1], Ian Leahy[1], Chase Brooks[2], Stephan Lany[1,2] and Kirstin M. Alberi[1]; [1]National Renewable Energy Lab, United States; [2]University of Colorado, Boulder, United States

Cd_3As_2 is a prototypical Dirac semi-metal, a class of materials with gapless topologically protected electronic states. In this system, these topological electronic states are close to the intrinsic Fermi level and are well isolated from non-trivial bands. Additionally, this system is air stable and compatible with molecular beam epitaxy, including lattice matching to III-Sb and II-Te layers, and similar elements to conventional semiconductors. With applications including low-energy computing, optoelectronics, and themoelectrics, these materials have the capability to impact a variety of areas. To achieve this, however, more capabilities for tuning their properties need to be developed. In particular, strategies for changing the intrinsic n-type carrier concentration beyond electrostatic gating must be explored.

Here, attempts to dope Cd_3As_2 further n-type, as well as p-type, are presented. First, Se and Te are introduced during growth, analogous to doping approaches in conventional semiconductors. This allows for films to be doped from 5e17 cm^{-3} up to slightly over 3e18 cm^{-3} for [112] oriented films before compensation occurs [1]. Prior to compensation, mobility vs n_{3d} follows an expected trend, and fundamental parameters pulled from oscillation fitting are consistent with shifting the Fermi level without major changes in the band structure. Recent results reveal more sensitive doping in [001] oriented films, with higher achievable n-type carrier concentrations. For lowering the Fermi level, $(Zn,Cd)_3As_2$ is pursued. Similar attempts in bulk crystals and films grown via pulsed laser deposition achieve p-type films at >20% Zn. Here, due to a lower starting n-type carrier concentration, multi carrier behavior is observed <10%, with reduced n-type concentrations also possible. Combined, these efforts allow for significant control in the Fermi level position of a Dirac semimetal.

2:15 PM QT07.02.03
Probing The Low-Resistivity in Sub-5 nm Thin Nanocrystalline NbP and TaP Semimetals Asir Intisar Khan[1,2], Emily Lindgren[1], Akash Ramdas[1], Byoungjun Won[3], Xiangjin Wu[1], Hyun-mi Kim[4], H.S. Philip Wong[1], Felipe H. da Jornada[1], Il-Kwon Oh[3], Yuri Suzuki[1] and Eric Pop[1]; [1]Stanford University, United States; [2]University of California, Berkeley, United States; [3]Ajou University, Korea (the Republic of); [4]Korea Electronics Technology Institute, Korea (the Republic of)

Ultrathin materials with low resistivity are important for energy-efficient nanoelectronics: from interconnects for dense logic and memory to spintronic devices and neuromorphic memristor arrays. However, the electrical resistivity of ultrathin metal films typically increases with decreasing film thickness due to electron-surface scattering, limiting the performance of metal-based interconnects and nanoelectronics [1]. To overcome this bottleneck, novel topological semimetals such as transition metal pnictides (NbP, NbAs, TaP, TaAs) have been suggested in the ultrathin film limit [2, 3]. These materials have been demonstrated to be topological Weyl semimetals in their single crystal forms [2], a class of materials wherein surface conduction is predicted to dominate thin-film transport even in the presence of disorder [3].

Here we uncover an unconventional (compared to metals) reduction of electrical resistivity with decreasing film thickness of thin nanocrystalline NbP and TaP semimetals. Our electrical measurements suggest surface-channel dominated transport with decreasing film thicknesses in these nanocrystalline semimetals.

NbP and TaP thin films are sputtered on both sapphire and MgO substrates at 400 °C, a process compatible with back-end-of-the-line semiconductor fabrication. High-angle annular dark-field (HAADF) scanning transmission electron microscope (STEM) imaging reveals nano-crystallinity of the ultrathin NbP films with short-range ordering at the NbP surface, irrespective of the film thickness. A thin seed layer of Nb (or Ta) is used to reduce lattice mismatch between the substrate and sputtered NbP (or TaP) thin films, which also helps promote the local short-range order within the NbP films. The compositional homogeneity of the NbP thin films is further confirmed by energy-dispersive X-ray analysis.

The electrical resistivity of NbP and TaP shows a decreasing trend with decreasing film thicknesses (from ~80 nm down to ~1-2 nm) measured across a temperature range from 5 K up to room temperature. The sub-5 nm thin TaP and NbP films show significantly lower resistivity (e.g., ~12 μΩ-cm for 1 nm thin TaP and ~34 μΩ-cm for ~1.5 nm NbP, at room temperature) compared to their bulk single-crystal counterparts, as well as topological insulators and most metals at similar thicknesses [1,2,5,6].

Temperature-dependent measurements of our thin NbP films show increased conductivity with decreasing temperature. In contrast, bulk thick NbP (~80 nm) shows an opposite trend indicating impurity- or disorder-limited transport [5]. Based on a two-channel (surface and bulk) model of the experimental transport data, we deduce that with decreasing film thicknesses, the surface-to-bulk conductance ratio increases. We simultaneously find that the surface conductance increases with decreasing temperature, consistent with metallic behavior [5, 6]. Hall measurements show a decreasing trend of carrier density with decreasing thickness, and thus the estimated mobility increases for thinner films (e.g., ~7.4 $cm^2/V/s$ for ~4.3 nm NbP vs. ~0.2 $cm^2/V/s$ for bulk NbP). This also allows us to estimate a high surface-area-normalized carrier density of ~10^{16} cm^{-2}, and a 2D surface mobility of ~12 $cm^2/V/s$. As film thickness decreases, the surface mobility contribution becomes more pronounced, leading to an increased conductivity in ultrathin NbP.

In summary, we uncovered surface-state-dominated conduction in ultrathin nanocrystalline NbP and TaP films. This leads to an exceptional decrease in the

resistivity with decreasing film thickness in such semimetals, promising for next-generation nanoelectronics. This work was supported in part by the Stanford SystemX Alliance.

Light-Field-Driven Non-Ohmic Current and Keldysh Crossover in a Weyl Semimetal Shin-ichi Kimura[1,2]; [1]Osaka University, Japan; [2]Institute for Molecular Science, Japan

In recent years, coherent electrons driven by light fields have attracted significant interest in exploring novel material phases and functionalities. However, observing coherent light-field-driven electron dynamics in solids is challenging because the electrons are scattered within several ten femtoseconds in ordinary materials, and the coherence between light and electrons is disturbed. However, when we use Weyl semimetals, the electron scattering becomes relatively long (several hundred femtoseconds - several picoseconds), owing to the suppression of the back-scattering process. This study presents the light-field-driven dynamics by the THz pulse to Weyl semimetal $Co_3Sn_2S_2$, where the intense THz pulse of a monocycle electric field nonlinearly generates direct current (DC) via coherent acceleration without scattering and non-adiabatic excitation (Landau-Zener Transition). In other words, the non-Ohmic current appears in the Weyl semimetal with a combination of the long relaxation time and an intense THz pulse. This nonlinear DC generation also demonstrates a Keldysh crossover from a photon picture to a light-field picture by increasing the electric field strength [1].

3:30 PM *QT07.03.01
Quantum transport and spintronics in topological semimetal heterostructures Nitin Samarth; The Pennsylvania State University, United States

We provide an overview of the synthesis and study of epitaxially grown topological semimetal heterostructures, focusing on Dirac semimetals (Cd_3As_2, $ZrTe_2$) and Weyl semimetals (TaAs, NbAs). Studies of the integer quantum Hall effect in high mobility films of Cd_3As_2 provide new insights into the effects of quantum confinement on the g-factor of Dirac states [1]. By interfacing Cd_3As_2 and TaAs with a ferromagnetic metal ($Ni_{0.8}Fe_{0.2}$), we probe efficient spin-charge conversion at room temperature, in agreement with first principles calculations of the spin hall conductivity [2,3]. We also observe suprising effects of an interfacial oxide on the magnitude and sign of the spin-charge conversion efficiency. Finally, we discuss the spin-charge conversion and spin orbit torque in $ZrTe_2/CrTe_2$ heterostructures wherein a Dirac semimetal is interfaced with a 2D ferromagnet [4].

This work is sponsored in part by SMART, a funded center of nCORE, a Semiconductor Research Corporation (SRC) program sponsored by NIST, the Institute for Quantum Matter under DOE EFRC grant DE-SC0019331, and the Penn State Two-Dimensional Crystal Consortium-Materials Innovation Platform (2DCC-MIP) under NSF Grant No. DMR- 2039351.

4:00 PM QT07.03.02
Magnetic Field-Effect Transistors based on The Topological Semimetal NbP Lorenzo Rocchino[1], Federico Balduini[1], Heinz Schmid[1], Mathieu Luisier[2], Vicky Süss[3], Claudia Felser[3], Bernd Gotsmann[1] and Cezar Zota[1]; [1]IBM Research-Zurich, Switzerland; [2]ETH Zürich, Switzerland; [3]Max Planck Institute for Solid State Research, Germany

In the ever-evolving landscape of electronics and semiconductor technology, the quest for faster and more efficient transistors has driven researchers to explore unconventional materials and device architectures. Topological semimetals, like Weyl semimetals (WSMs), are promising candidates for redefining transistor technology in this context[1]. Their unique transport properties, such as linear electronic bands, chiral fermions, and topologically protected surface states, can enable innovative device architectures, potentially outperforming standard complementary metal-oxide-semiconductor (CMOS) technology. Linear energy dispersion, in particular, yields low carrier mass and ultra-high mobility, which translates to the extreme magnetoresistance, up to 10^6 %, exhibited by these materials, such as Cd_3As_2, NbP, WP_2, and many others[2].
In this work, we demonstrate a new type of transistor that operates through a magnetoresistive coupling between a WSM and a superconductor. The active material is a topological WSM, NbP, whose resistivity is modulated via a magnetic field generated by the nearby superconductor. By using magnetic fields as a control quantity, the performance of the realized device is not reliant on ultra-thin channels, such as is the case for semiconductor electric-field devices. More importantly, this type of device allows to modulate the resistivity of a semi-metallic channel material with extremely low resistivity, ρ, and high carrier density (up to 10^{20} cm^{-3}), which is also not possible in a traditional semiconductor field-effect transistor.
A full characterization of the NbP crystallite, performed with an externally generated magnetic field (up to 9 T), reveals very high values of MR, consistent with the ones reported in the literature. The fit of quantum oscillation data according to the Lifshitz–Kosevich formula allows the extraction of the main transport-related quantities, such as electron mobility, carrier density, and effective mass. The superconductive gate is made of NbN, and it is implemented to eliminate the contribution of self-heating, caused by the power dissipated in the gate electrode, to the resistivity modulation. The SC transition of the NbN gate occurs in a temperature range of 13.1 to 13.4 K, above the operating point of the device (5 K).
The device characterization was done superposing the locally generated field with an external field offset which is able to shift the operating point of the

device towards a region where the MR coupling, dρ/dB, is maximized. Furthermore, we were able to accurately reproduce the resistivity variation of the external magnetic field with the local magnetic gate using point-wise measurements. Due to the exceptionally large electron mobility of this material, which reaches over 10^6 cm^2/Vs, and the strong magnetoresistive coupling, we show that the realized magnetic Weyl transistor operates with very high transconductance gain at nanowatt levels of power dissipation. Transconductance gain, together with overall low parasitic RC delay indicates the potential for improvements over standard cryogenic amplifier technologies.
We foresee qubit readout signal amplification as a highly attractive area of application for this device due to the increasing need for low-power cryogenic amplifiers, operating at power budgets that will continue to shrink as quantum computers advance. Moreover, our device presents a generalized scheme to control the transport properties of Weyl semimetals, many of which are sensitive to magnetic fields. Overall, the obtained results indicate a promising path forward for integrated Weyl semimetal electronics that can leverage the often extreme transport properties of such materials.

Quantum Metric Nonlinear Hall Effect in a Topological Antiferromagnetic Heterostructure Anyuan Gao[1], Ted Liu[1], Barun Ghosh[2], Thais Trevisan[3], Yugo Onishi[4], Chaowei Hu[5], Tiema Qian[5], Shaowen Chen[1], Mengqi Huang[6], Damien Berube[1], Hochen Li[1], Christian Tzschaschel[1], Thao Dinh[1,1], Zhe Sun[7], Sheng-Chin Ho[1], Shang-Wei Lien[8], Bahadur Singh[9], Kenji Watanabe[10], Takashi Taniguchi[10], David Bell[1], Hsin Lin[11], Tay-Rong Chang[8], Arun Bansil[2], Chunhui Du[6], Liang Fu[4], Ni Ni[5], Peter Orth[3], Qiong Ma[7] and Suyang Xu[1]; [1]Harvard University, United States; [2]Northeastern University, United States; [3]Iowa State University, United States; [4]Massachusetts Institute of Technology, United States; [5]University of California, Los Angeles, United States; [6]University of California, San Diego, United States; [7]Boston College, United States; [8]National Cheng Kung University, Taiwan; [9]Tata Institute of Fundamental Research, India; [10]National Institute for Materials Science, Japan; [11]Academia Sinica, Taiwan

Quantum geometry - the geometry of electron Bloch wavefunctions - is central to modern condensed matter physics. Due to the quantum nature, quantum geometry has two parts, the real part quantum metric and the imaginary part Berry curvature. Berry curvature has led to countless breakthroughs, ranging from the quantum Hall effect in 2DEGs to the anomalous Hall effect (AHE) in ferromagnets. In contrast, the quantum metric has rarely been explored. In this talk, I will report a new nonlinear Hall effect induced by quantum metric dipole by interfacing even-layered MnBi2Te4 with black phosphorus. This nonlinear Hall effect switches direction upon reversing the AFM spins. It exhibits distinct scaling demonstrating the non-dissipative nature. Like the AHE brought Berry curvature under the spotlight, our results open the door to discovering quantum metric responses. Moreover, our data suggests that the AFM can harvest wireless electromagnetic energy, enabling applications that bridges nonlinear electronics with AFM spintronics.

Theoretical Study of The Electronic Properties of a 3D Dirac Semimetal Ge_4Sn using First-principles Mahesh Balwade and Prabhakar Singh; Indian Institute of Technology Bombay, India

A recent theoretical study[1] has predicted the topological nature of two materials with tetragonal structures: Ge_5 and Sn_5. Building upon this research, we investigated the electronic properties of Ge_4Sn, which shares a similar crystal structure. Our study shows that Ge_4Sn is metallic and non-magnetic in nature. Notably, the lattice parameters of Ge_4Sn are somewhat larger than those of Ge_5, yet significantly smaller than Sn_5. This discrepancy can be attributed to the relatively smaller size of the Ge atom in comparison to Sn. The chemical bonds of Ge_4Sn have covalent characteristics confirmed by the charge density plot. Furthermore, we find a strong hybridization between Ge 4*p* and Sn 5*p* orbitals in the energy range −4 to 0 eV below the Fermi energy. The highly anisotropic Dirac cone appears near *the A* point in the band structure without spin-orbit interaction. However, the inclusion of spin-orbit interaction leads to a significant band-splitting around *A* point as well. Topological properties are studied by calculating topological invariant and surface states. These results collectively demonstrate that Ge_4Sn exhibits the characteristics of a 3D Dirac semimetal. Further study is needed to uncover novel properties of Ge_4Sn.

Chirality and Topology Claudia Felser; Max Planck Institute, Germany

Chirality is a very active field of research in organic chemistry, closely linked to the concept of symmetry. Topology, a well-established concept in mathematics, has nowadays become essential to describe condensed matter [1,2]. At its core are chiral electron states on the bulk, surfaces and edges of the condensed matter systems, in which spin and momentum of the electrons are locked parallel or anti-parallel to each other. Magnetic and non-magnetic Weyl semimetals, for example, exhibit chiral bulk states that have enabled the realization of predictions from high energy and astrophysics involving the chiral quantum number, such as the chiral anomaly, the mixed axial-gravitational anomaly and axions [3-5]. Chiral topological crystals exhibit excellent chiral surface states [6,7] and different orbital angular momentum for the enantiomers, which can be advantageous in catalysis. The potential for connecting chirality as a quantum number to other chiral phenomena across different areas of science, including the asymmetry of matter and antimatter and the homochirality of life, brings topological materials to the fore [8].

Electron Hydrodynamics and Signatures of Unconventional Transport in Topological Semimetals Prineha Narang; University of California, Los Angeles, United States

The re-invigorated field of electron hydrodynamics in quantum matter has recently garnered considerable scientific interest, both due to its technological promise of designing near dissipation-less nanoelectronics, as well as its fundamental importance as an experimental probe of strong electron-electron interactions. Investigating the capacity to which observations of electron hydrodynamic flows can inform the nature of electron-electron interactions is particularly important and timely with the advent of spatially-resolved transport measurements which, having demonstrated the hallmark spatial signature of electron hydrodynamic channel flow, must now turn their attention to studying more spatially-complex geometries, enabling the observation of intricate fluid phenomena such as vortices. Recently we have explored the effects of crystal symmetry on electron fluid behaviors starting from the most general viscosity tensors in two and three dimensions, constrained only by crystal symmetry and thermodynamics. In our work we demonstrate the anomalous landscape for electron hydrodynamics in systems beyond graphene, highlighting that previously-thought exotic fluid phenomena can exist in both two-dimensional and anisotropic three-dimensional materials with or without breaking time-reversal symmetry. In this context, the first part of my talk will discuss our recent predictions of hydrodynamics beyond graphene, especially the role of phonons in hydrodynamics in Weyl semimetals. We identify phonon-mediated electron-electron interactions, computed with techniques developed in the group that I will discuss in this talk, as critical in a microscopic understanding of hydrodynamics. In the context of these results in electron hydrodynamics, I will introduce a theoretical and computational transport framework from our group, the SpaRTaNS (Spatially Resolved Transport of Nonequilibrium Species) framework. I will discuss applications of this method in nonequilibrium electron and phonon transport in quantum matter. Time permitting, I will present recent work on unconventional mesoscopic transport regimes in kagome magnets. The kagome magnets TbMn6Sn6 (a Chern ferrimagnet) and Mn3Ge (a Weyl semimetal antiferromagnet) have interesting electronic and thermal conductivities, with the two showing large and opposing deviations from the Wiedemann-Franz law and Mott relation. Leveraging the aforementioned approach, we study whether such conductivities can be decoupled into independent diffusive modes and explore the possible emergence of hydrodynamics in finite channel geometries.

Insights into The Role of Disorder in Topological Semimetals Kirstin M. Alberi; National Renewable Energy Laboratory, United States

As a result of their bandstructures, three-dimensional topological semimetals (TSMs) exhibit phenomena that are of potential interest for device applications, including ultra-high electron mobility, broadband optical absorption, linear magnetoresistance and the chiral anomaly. These behaviors have largely been studied in bulk crystals, but thin films will be required for devices. Given that disorder, in the form of defects, impurities and interfaces, will inevitably be present in thin films, it is important to understand the role they play on the behavior of TSMs. In this talk, I will discuss our use of epitaxy to intentionally vary specific forms of disorder and thereby generate new insights into property-disorder relationships. Our studies, mostly performed in Cd_3As_2 grown by molecular beam epitaxy, suggest that point defects modestly affect electron mobility but can substantially influence magnetoresistance. Impurities also offer important control knobs for controlling the Fermi level, either as extrinsic dopants or through indirect influence on the balance of point defects. Finally, I will discuss challenges and outstanding questions that the TSM field must address to effectively implement these materials into device applications.

11:15 AM QT07.06.03
Properties of Topological Semimetal Cd_3As_2 Thin Films as a Function of Growth Optimization and Buffer Choice Thomas G. Farinha[1,2], Edwin Supple[3], Gregory M. Stephen[2], Nicholas A. Blumenschein[2], Adam L. Friedman[2], Brian Gorman[3] and Christopher J. Richardson[1,2]; [1]The University of Maryland, United States; [2]Laboratory for Physical Sciences, United States; [3]Colorado School of Mines, United States

The Dirac semimetal Cd_3As_2 is a high mobility, 3D topological semimetal with potential for exploration of quantum phenomena and future information science devices. However, the dependence of its topological properties on growth and heterostructure design is not well explored. Such parameters include growth temperature, dislocation density, and biaxial strain owing to lattice mismatch. The growth of Cd_3As_2 on different abrupt metamorphic buffer layers

is therefore completed via molecular beam epitaxy. The aforementioned growth variables are considered for their effect on the final electronic and physical quality and characteristics of the thin film Cd_3As_2.
Cd_3As_2 is grown on relaxed AlInSb, GaInSb, and InAsSb layers with engineered lattice constants at temperatures ranging from 50 to 130 °C. X-ray diffraction and transmission electron microscopy are used to evaluate the buffer layer quality and threading dislocation density. Van der Pauw measurements are conducted to determine carrier mobility and density according to the experimental variables. With the objective of maximizing electron mobility, films are grown over a range of variables including layer thickness and annealing times.

11:30 AM *QT07.06.04
Unique Electromagnetic Responses of Unconventional Topological Semimetals Junyeong Ahn[1] and Barun Ghosh[2]; [1]Harvard University, United States; [2]Northeastern University, United States

Elucidating the physical manifestations of nontrivial band topology in materials is of great interest in quantum materials science. Recent advances in the classification of topological band crossing have led to the discovery of various new kinds of low-energy excitations. Yet, the unique physical properties that qualitatively distinguish them from Weyl and Dirac fermions or conventional metals are rarely known. In this talk, we present our theoretical discovery of unique electromagnetic response properties in unconventional topological point-node semimetals [1,2]. First, we reveal the pattern of the divergent nonlinear responses as the chemical potential approaches the energy of an overtilted (i.e. the so-called type-II) nodal point, with the leading divergence determined by the dispersion and dimensionality [1]. Then, we show that chiral multifold nodal points feature the unique circular dichroism that is absent for Weyl or Dirac fermions [2]. Our finding demonstrates that new types of excitations indeed possess new responses, motivating further exploration of other unconventional fermions whose unique response properties are elusive.

This work was supported by the Center for Advancement of Topological Semimetals (CATS), an Energy Frontier Research Center funded by the U.S. Department of Energy Office of Science, Office of Basic Energy Sciences, through the Ames Laboratory under contract No. DE-AC02-07CH11358.

Lattice-Geometry Driven Hybrid Nodal Fermions in Topological Semimetals Bahadur Singh[1] and Sougata Mardanya[2]; [1]Tata Institute of Fundamental Research Mumbai, India; [2]Howard University, United States

Successful classification of topological electronic states based on the crystalline lattice symmetries led to the identification of many topological materials through high-throughput first-principles modeling. Such symmetry-to-topology characterizations, however, ignore the effects of various crystallographic or nanoscopic motifs and their associated wavefunction properties even though they are essential for describing the numbers, energy-momentum relations, and geometries of the nontrivial states. Here, we discuss how spatial arrangements of atoms dictate the nature of energy dispersions of topological states in materials [1]. Specifically, we focus on anisotropic lattice materials and demonstrate that the lattice geometry-driven effective mass anisotropies dictate the hybrid nodal-line states by considering transition metal tetraphosphides MP4 (M = Transition metal) as exemplary materials. We also discuss a general theory of incorporating orientation-dependent carrier effective masses as experimental fingerprints for determining energy dispersion in topological materials.

Structural Goldilocks Effect in The Ultra-Pure Topological Semimetal $PtSn_4$ Samikshya Sahu[1,1], Dong Chen[1,1], Niclas Heinsdorf[1,1,2], Mohamed Oudah[1], Douglas A. Bonn[1,1], Sarah Burke[1,3,1] and Alannah Hallas[1,1]; [1]University of British Columbia, Canada; [2]Max Planck Institute for Solid State Research, Germany; [3]The University of British Columbia, Canada

The Residual Resistivity Ratio (RRR) serves as a pivotal metric to gauge sample quality for metals, where RRR is the ratio of the resistivity at room temperature (~ 300 K) to the resistivity at base temperature (~ 0 K). For common metals like Au or Cu, transport behavior at 0 K primarily reflects the inherent defects and disorders within the material. Whereas at room temperature, the electronic transport is substantially influenced by other factors, such as phonons. Therefore, a sample with a high RRR can be valued as possessing fewer intrinsic defects and less disorder. However, such pristine materials are tough to come by and often require a lot of effort to optimize the crystal growth technique to make defect-free samples.

$PtSn_4$ is a rare exception, and shows ultra-low resistivity around 2 K and remarkable RRR values exceeding 1000. One of the other dominating electronic properties of this material is its ultrahigh magnetoresistance (XMR), which onsets at 30 K. Magnetoresistance (MR) is the resistance that develops in a material as a response to the application of the magnetic field. $PtSn_4$ is also classified as a novel topological semimetal and hosts Dirac arcs in its momentum space such that the conduction and valence band touch in loops and not at a point or line. Previous studies have linked this high mobility and XMR in $PtSn_4$ to its distinctive Fermi surface and the band dispersion of nodal arc surface states. Yet, despite numerous reports suggesting a connection between these surface states and electronic transport properties, a clear physical relationship remains elusive. Therefore, it is crucial to understand the origin of the high mobility and XMR in $PtSn_4$, which will also shed light on the underlying relation between the non-trivial band topology and experimentally observed electrical transport properties in $PtSn_4$.

Through this work on $PtSn_4$, we aim to resolve the question about the origin of the high carrier mobility by perturbing the system using defects and chemical substitution. This approach allows to disentangle whether the high mobility in $PtSn_4$ originates from forbidden backscattering, which results from topologically protected surface states, or whether it is related to an unusually low defect density. Using electrical transport measurements, scanning tunneling microscopy (STM) and density functional theory (DFT) calculation we confirm that $PtSn_4$ is remarkably robust against chemical substitution and resistant to defect introduction into its lattice. Comparing it with $AuSn_4$ and $IrSn_4$, which form locally similar structures to $PtSn_4$, we find significantly

lower RRR values in the latter two. This highlights the uniqueness of the $PtSn_4$ structure. The high electron mobilities in $PtSn_4$ can be attributed to the defect-intolerant Pt layers, which dominate electronic transport. Our STM mappings quantitatively assess the defect concentration in $PtSn_4$, revealing surprisingly low defects in the Pt layers compared to higher concentrations in the Sn layers. DFT calculations corroborate these findings, showing higher defect formation energies for Sn within the $PtSn_4$ lattice and the favorable energy associated with introducing defects into the $AuSn_4$ structure. Thus, we conclude that the crystal chemistry in $PtSn_4$ is a good example of a structural Goldilocks effect where the naturally defect-intolerant layers support the long electron-free paths.

2:15 PM QT07.07.03
Evidence for The Chiral Anomaly in The Cubic Type-II Dirac Metal Pd_3In_7 Aikaterini Flessa Savvidou[1,2], Andrzej Ptok[3], Gargee Sharma[3], Brian Casas[2], Judith Clark[4], Victoria Li[4], Michael Shatruk[1], Sumanta Tewari[5] and Luis Balicas[1,2]; [1]Florida State Univ, United States; [2]National High Magnetic Field Lab, United States; [3]Institute of Nuclear Physics, Poland; [4]Department of Chemistry and Biochemistry, United States; [5]Clemson University, United States

We report a transport study on Pd_3In_7 which displays multiple Dirac type-II nodes in its electronic dispersion. Pd_3In_7 is characterized by low residual resistivities and high mobilities, which are consistent with Dirac-like quasiparticles. For an applied magnetic field ($\mu_0 H$) having a non-zero component along the electrical current, we find a large, positive, and linear in $\mu_0 H$ longitudinal magnetoresistivity (LMR). The sign of the LMR and its linear dependence deviate from the behavior reported for the chiral-anomaly-driven LMR in Weyl semimetals. Interestingly, such anomalous LMR is consistent with predictions for the role of the anomaly in type-II Weyl semimetals. In contrast, the transverse or conventional magnetoresistivity (CMR for electric fields $E \perp \mu_0 H$) is large and positive, increasing by $10^3 - 10^4$ % as a function of $\mu_0 H$ while following an anomalous, angle-dependent power law $\rho_{xx} \propto (\mu_0 H)^n$ with $n(\theta) \leq 1$. The order of magnitude of the CMR, and its anomalous power-law, is explained in terms of uncompensated electron and hole-like Fermi surfaces characterized by anisotropic carrier scattering likely due to the lack of Lorentz invariance.

Wednesday Afternoon, April 24, 2024
Room 448, Level 4, Summit

3:30 PM QT07.08.01
Experimental Observation of Nonreciprocal Reflection in a Magnetic Weyl Semimetal at Zero Applied Field Arun Nagpal[1], Ioannis Petrides[2], Chandra Shekhar[3], Claudia Felser[3], Prineha Narang[2] and Harry A. Atwater[1]; [1]California Institute of Technology, United States; [2]University of California, Los Angeles, United States; [3]Max Planck Institute for Chemical Physics of Solids, Germany

The discovery of magnetic Weyl semimetals has inspired a flurry of investigation into the magneto-optical responses of such topological semimetals. In this work, we demonstrate modulation of the non-reciprocal p-polarized reflection coefficient by reversing the orientation remanent magnetization in a magnetic Weyl semimetal. Previously, measurements of nonreciprocity via the transverse magneto-optic Kerr effect, where the amplitude of the p-polarized reflection is modulated with respect to the polarity of a magnetization vector that is transverse to the optical plane, had remained elusive. We observe a net reflectance modulation of nearly 8% in the half-Heusler $Co_3Sn_2S_2$ at 80K without the concurrence of an external applied magnetic field, nearly an order of magnitude higher than previous measurements of the transverse magneto-optical Kerr effect in ferromagnets. Our results demonstrate the utility of magnetic Weyl semimetals for magneto-optical metasurfaces, applications in magnetic memory, and energy harvesting. Unlike traditional ferromagnets or magnetic semiconductors where the off-diagonal permittivity is a function of the cyclotronic resonance frequency, the nonreciprocal response of magnetic Weyl semimetals is believed to be governed by the nontrivial Berry curvature that exists between recombinant Weyl nodes. This unique topological effect paves the way for the realization of practical Berrytronic devices.

3:45 PM QT07.08.02
Pulsed Magnetic Field Studies of Topological Magnetic Kagome Compounds Joanna Blawat[1], Tyler Slade[2,3], John Singleton[1], Benjamin Ueland[2,3], Paul Canfield[2,3], Robert McQueeney[2,3] and Ross McDonald[1]; [1]Los Alamos National Laboratory, United States; [2]Ames Laboratory, United States; [3]Iowa State University of Science and Technology, United States

Magnetic Weyl semimetals provide an interesting opportunity to study the interplay between local spin texture, band topology and correlations. The rare earth 166 kagome materials are a prime example, which exhibit complex magnetic orders due to their geometrically frustrated 2D lattice, as well as an electronic structure that embodies both flat band and linear (Dirac) band crossings. Specifically, this includes $ErMn_6Sn_6$ which crystallizes in a hexagonal space group P6*/mmm* (No. 191). The recent neutron diffraction data shows that $ErMn_6Sn_6$ exhibits a first order transition from a planar-ferrimagnetic to distorted triple-spiral magnetic order at T = 92 K and the theoretical calculations using the mean-field theory predict a very rich magnetic phase diagram of $ErMn_6Sn_6$ [1]. We present the experimental measurements of magnetization in pulsed magnetic field with H//a, H//b and H//c. The rich variety of magnetic phases gives us opportunity to study the behavior of Dirac fermions with control of the spin orientations tuned by the magnetic field. High field magnetoresistivity and Hall effect measurement helped us to identify novel magnetic and topological phases and probe Fermi surface topology via quantum oscillations. This combination of experiments reveals the possibility of tuning topological properties in $ErMn_6Sn_6$ via the application of strong magnetic fields.

4:00 PM *QT07.08.03
Exotic Magnetotransport in Simple Magnetic Weyl Semimetal Films Masaki Uchida; Tokyo Institute of Technology, Japan

Magnetic Weyl semimetals host singularities called Weyl points in their band structures, and exotic magnetotransport phenomena involving the Weyl

points have been intensively studied. Magnetic Weyl semimetals discovered so far may be classified into two major groups. The first group includes Mn_3Sn, $Co_3Sn_2S_2$, and Co_2MnGa, which have 3*d* transition metal elements as magnetic elements and are characterized by high magnetic transition temperatures. On the other hand, these materials have high carrier density and complex band structures hosting Weyl points. The second group includes $EuCd_2Sb_2$ and GdPtBi, which have 4*f* rare earth elements as magnetic elements. Their magnetic transition temperatures are low, and it is necessary to apply a magnetic field for inducing the ferromagnetic Weyl phase. In these materials, their carrier density is low, and Weyl points occupy a large area compared to the Fermi surface. It is thus expected that exotic magnetotransport can be controlled and enhanced using thin-film techniques.
Based on our knowledge about film growth of II-V compounds such as Cd_3As_2 [1,2] and its combination to Eu magnetic elements [3-5], we have succeeded for the first time in fabricating single-crystalline $EuCd_2Sb_2$ thin films by molecular beam epitaxy [6]. While these films exhibit the same antiferromagnetic and field-induced ferromagnetic phases as $EuCd_2Sb_2$ bulks, they show a very large anomalous Hall effect compared to the bulks. We have systematically controlled the carrier density with electrostatic gating and have found that the anomalous Hall effect exhibits a sharp peak structure as function of carrier density. As also demonstrated by first-principles calculation, the intrinsic anomalous Hall conductivity is maximized reflecting the presence of Weyl points.
I will also present results about $EuCd_2As_2$, another Weyl semimetal candidate, and extensively discuss exotic magnetotransport phenomena appearing in simple magnetic Weyl semimetal films.

Rare-earth(*R*) based *R*SbTe materials, which are isostructural to the nodal-line semimetal ZrSiS, are gathering research attention because of the possible elements of electronic correlation and magnetism that the *R-4f* electrons may bring. Here, we study the electronic structure in PrSbTe by utilizing angle-resolved photoemission spectroscopy (ARPES) in conjunction with first-principles calculations and thermodynamic measurements. Thermodynamic measurements show that no discernible phase transitions occur down to 2 K. ARPES results and their comparison with first-principles calculations reveal the presence of multiple nodal-line crossings in this system. This study contributes to the understanding of the role of spin-orbit coupling in the topological electronic structure within the *R*SbTe family of materials.

The Josephson Diode Effect in Junctions formed from 2D Van der Waals Metals Stuart S. Parkin; Max Planck Institute of Microstructure Physics, Germany

Recently we have discovered a non-reciprocal Josephson diode effect in several Josephson junctions, both lateral and vertical, formed from conventional superconducting electrodes (Nb, $NbSe_2$) separated by several non-superconducting metals including the 2D van der Waals Dirac semi-metal, $NiTe_2$ [1]. We discuss a variety of other 2D metals that show a Josephson diode effect including WTe_2 [2], as well as those that do not show an effect such as $MoTe_2$. Each of these materials becoming superconducting by proximity to the conventional superconducting electrodes. The superconductivity can be sustained over long distances of, in some cases, up to ~1 micron. The critical supercurrent densities for current flowing in opposite directions within the junction are distinct and can vary by up to ~80%. The non-reciprocity is only observed in the presence of a small magnetic field oriented perpendicular to the supercurrent. For vertical Josephson junctions formed from WTe_2 we show that the non-reciprocity depends on the orientation of the magnetic field with respect to the crystal structure of the WTe_2, proving thereby the intrinsic origin of the Josephson diode effect. Such an effect could have important applications as a novel magnetic field detector at cryogenic temperatures, for example, to "read" magnetic domain walls in a cryogenic racetrack memory*.

Engineering Van der Waals Heterostructures of Layered Dirac Materials for meV-Scale Quantum Sensing Elizabeth Peterson and Jian-Xin Zhu; Los Alamos National Laboratory, United States

Quantum sensing of meV-scale scattering and absorption of impinging particles with electrons in solid state detectors has important applications not only of interest for fundamental physics, such as the detection of astronomical phenomena and light dark matter, but also for quantum information, such as single photon detectors for quantum key distribution. Current sensing and detection schemes often use single-phase detectors, such as superconductors or narrow band gap semiconductors. These detector targets face challenges in differentiating between signals that come from impinging particles of interest and those from inherent quasiparticles, such as phonons and magnons, requiring operation at extreme cryogenic temperatures.

Heterostructures of layered massive Dirac materials offer a novel pathway to selective detection of impinging particles that can operate at more realistic temperature scales for scalable quantum sensing technology. In our scheme, by engineering interfacial orbital hybridization in van der Waals heterostructures of Dirac materials, interlayer charge transfer is promoted only for pre-selected types of impinging particles based on their dispersion relations (i.e. specific quantum mechanically allowed combinations of energy and momentum transfer). Here we present first-principles density functional theory calculations on exemplar heterostructures of the layered Dirac materials $ZrTe_5$ and $HfTe_5$ as a proof-of-principle of this novel quantum sensing scheme. As massive Dirac materials with narrow band gaps and strain-sensitive band structures, $ZrTe_5$ and $HfTe_5$ are ideal testbeds for detection of meV-scale absorption and scattering events. We demonstrate that the electronic structure of these heterostructures exhibits a promising distribution of regions of single-layer and hybridized interlayer orbital character necessary for selective interlayer charge transfer. We examine the effects of strain and layer number for tuning hybridization in the electronic structure and the type of impinging particle that may be detected. We suggest that by exploiting hybridization in heterostructures of Dirac materials, it is possible to construct "dispersion filters" for next-generation quantum sensors.

Most materials are challenging to produce as uniform and thin crystals with large grain size. Varying the thickness of a material alters its electronic behaviors and enables new devices. We have developed a new synthesis technique to grow crystals in a nanoscale mold defined by atomically-flat van der Waals (vdW) materials. We heat and compress bismuth in a vdW-mold made of hexagonal boron nitride (hBN), resulting in controlled thickness such as ultraflat 10 nm to 100 nm thick bismuth. The vdW-molded bismuth at different thickness all shows exceptional electronic transport, enabling the observation of Shubnikov–de Haas quantum oscillations originating from the (111) surface state Landau levels, which have eluded previous studies. Our vdW-mold growth technique establishes a platform for electronic studies and control of bismuth's Rashba surface states and topological boundary modes. Other than molding bismuth, we have also successfully molded tin and gold. Beyond confining in thickness, we also molded bismuth into vdW-molds with predefined shapes. This vdW-molding approach provides a low-cost way to synthesize ultrathin crystals and directly integrate them into a vdW heterostructure.

Nonlinear Hall Effect in Dirac/Weyl Semimetals and Terahertz Detection Yang Zhang; The University of Tennessee, Knoxville, United States

We propose a method for broadband long-wavelength photodetection using the nonlinear Hall effect in Dirac/Weyl semimetals with/without magnetic field. With intrinsicly tiled spectrum or induced chirality imbalance, the net Berry curvature gives rise to a nonlinear current, with inherently quadratic relation between transverse current and input voltage. This effect is then used to rectify the incident terahertz or infrared electric field into a direct current, without invoking any diode. Our photodetector operates at zero external bias with fast response speed and has zero threshold voltage. Remarkably, the intrinsic current responsivity due to the Berry curvature mechanism is a material property independent of the incident frequency or the scattering rate, which can be evaluated from first-principles electronic structure calculations. We identify the Weyl semimetal NbP and ferroelectric semiconductor GeTe for terahertz/infrared photodetection with large current responsivity without external bias.

Zero-Field Josephson Diode Effect in Dirac Semimetal-Based Asymmetric SQUIDs Joseph J. Cuozzo[1], Wenlong Yu[1], Keshab Sapkota[1], Enrico Rossi[2], David Rademacher[1], Tina Nenoff[1] and Wei Pan[1]; [1]Sandia National Laboratories, United States; [2]William & Mary, United States

Conventional diodes are characterized by their non-reciprocal charge transport and are ubiquitous in electronic devices. Within superconducting electronics, the superconducting diode effect (SDE) has attracted interest in recent years. Superconducting diodes are characterized by an asymmetry in positive and negative switching currents and could potentially find utility in a growing number of applications at cryogenic temperatures in the Quantum Information Sciences. Currently, many superconducting diodes require an external magnetic field or ferromagnetic layers to break time-reversal symmetry and induce the SDE. In this talk, we will discuss the *zero-field* SDE in asymmetric superconducting quantum interference devices (SQUID) based on Dirac semimetals. In this case, the Josephson effects in the SQUID arms dictate the non-reciprocity (Josephson diode effect) and we theoretically explore the role of surface and bulk states in Dirac semimetals. We will discuss how coupling of surface and bulk states can give rise to a diode effect in the *absence* of external magnetic fields or ferromagnetic layers. We will then present experimental results showing a zero-field SDE in asymmetric SQUIDs based on Dirac semimetal Cd_3As_2.

Dark Matter Detection with Topological Materials Sinead M. Griffin; Lawrence Berkeley National Laboratory, United States

The last few decades have seen a huge surge of interest in matter that cannot be described by our standard theories. For instance, the nature of dark matter, which cannot be described by the Standard Model, remains one of the biggest mysteries in our current understanding of the matter in our universe. As ongoing experiments continue to rule out large regions of phase space for higher-mass dark matter (e.g. WIMPs), new ideas for the direct detection of low mass (sub-GeV) are needed. These lighter DM masses require us to rethink the fundamental requirements for dark matter detectors to be sensitive to these lower masses. In this talk I will discuss how low-energy excitations in condensed matter systems are apt for the detection of such low-mass DM. I will discuss some of our proposals for detecting such low-mass DM in topological materials. As examples, I discuss the coupling and detection of (i) particle-like DM in topological semimetals and (ii) wave-like axion dark matter in topological insulators and multiferroics. I will also discuss how topological materials provide a unique route for sensing these rare events. To finish, I will discuss current challenges and opportunities for the intersection of condensed matter approaches to dark matter detection.

Conduction via the surface states in topological semimetals yields unconventional scaling behavior such that resistivity decreases with reduced device dimensions down to ~nm. This may provide a solution for the interconnect bottleneck in highly scaled integrated circuits. In the first half of the talk, we will present first-principles-based electrical transport calculations of a Si-CMOS compatible topological semimetal CoSi and a prototypical Weyl semimetal NbAs. We will summarize the simulation results of pristine films and films with point defects, line defects, or grain-boundaries. We will also report the contact resistance scaling between a topological semimetal and a conventional liner material.

In the second half of the talk, we will report detailed experimental studies of CoSi. We first present resistivity scaling data of both polycrystalline and highly textured thin films down to ~5nm. Our magneto-transport measurements reveal coexisting high-mobility surface carriers with low-mobility bulk carriers and their temperature dependence. Most notably, we observe that the room-temperature resistivity in nanoscale CoSi thin films can drop below the ideal bulk single-crystal limit. Last, we present the resistance scaling of wafer-scale CoSi nanowires, both polycrystalline and highly textured. Our proof-of-principle studies demonstrate the potential of topological semimetals as post-Cu interconnect conductors and lay out the key challenges to tackle next.

Ion Diffusion and Morphology of PEDOT:PSS. Insight from Molecular Dynamics Simulations Igor Zozoulenko, Tahereh Sedghamiz, Mohsen Modarresi and Aleksandar Mehandzhiyski; Linkoping University, Sweden

Poly(3,4-ethylenedioxythiophene) polystyrene sulfonate (PEDOT:PSS) is one of the most important mixed electron-ion conducting polymers, where the efficiency of the ion transport is crucial for many of its applications. Despite of the impressive experimental progress in determination of the ionic mobilities in PEDOT:PSS, the fundamentals of ion transport in this material remain poorly understood and the theoretical insight of the ion diffusion on the microscopical level is completely missing.

In the present paper, Martini 3 coarse grained molecular dynamics (MD) model for PEDOT:PSS is developed and applied to calculate the ion diffusion coefficients and ion distribution in the film.[1] A prerequisite to study the ion diffusion in PEDOT:PSS is to build its adequate morphological model properly describing its two-phase morphology as well as water intake and ion exchange. Using the coarse-grained calculations we developed this model by mimicking experimental process of film formation by drying the emulsion of PEDOT:PSS particles.[2] We demonstrate that PEDOT:PSS film is an essentially three component system, consisting of positively charged PEDOT chains, PSS chains with mostly deprotonated sulfonate groups, and protonated PSS chains.[3] PEDOT-rich regions are predominantly composed of PEDOT and deprotonated PSS chains, whereas PSS-rich regions are composed of protonated PSS chains. Our calculations unravel how PEDOT-rich and PSS-rich regions are formed from the solution phase during drying process. We show that when the dry polymer film is immersed in water its swells by nearly 60%, and we demonstrate that the origin of swelling is related to deprotonation of the sulfonate groups in the PSS-rich regions. It is mostly PSS-rich regions that swell while the PEDOT-rich regions remain rather unchanged.

Using the obtained morphology we calculated the ion diffusion coefficients for Na^+ ions and we found that they are practically the same in the PEDOT-rich and PSS-rich regions and do not show sensitivity to the oxidation level. We compare the calculated diffusion coefficients with available experimental results. Based on this comparison, and based on the MD morphology simulation of PEDOT:PSS revealing the formation of pores inside the film, we revised a commonly accepted granular morphological model of PEDOT:PSS. Namely, we argue that PEDOT: PSS films, in addition to PEDOT-rich and PSS-rich regions, must contain a network of pores, where the ion diffusion takes place.

We believe that our results demonstrate the power of the MD simulations for organic mixed electron-ion conductors providing the essential insight into polymer morphology and ion diffusion that is difficult to obtain by other means.

11:00 AM *SB02.01.02
Organic Electrochemical Transistor Materials for Bio-Interfacing Electronics Ting Lei; Peking University, China

Organic electrochemical transistors (OECTs) are one of the most promising options for biointerfacing electronics, as they have high transconductance, low

operation voltage (<0.8 V), good biocompatibility, and intrinsic compatibility with ion-related biological events. Compared to the abundant high-performance p-type OECT materials, n-type and ambipolar OECT materials are rare, and more importantly, their performances lag far behind, which largely limits the development of OECT-based logic circuits and amplifiers for bio-interfacing electronics. To address this issue, we designed and synthesized a series of n-type and ambipolar materials and proposed a design strategy, namely "doped state engineering", which has greatly improved the performance and response speed of both n-type and ambipolar OECT materials. Based on these materials, we have realized high-performance logic circuits and amplifiers that exhibit high voltage gains, suitable for in vivo biosignal capture and amplification.

11:30 AM *SB02.01.03
Next-Generation Design Strategies for Organic Mixed Conductor Technologies Alexandra F. Paterson; The University of Kentucky, United States

Organic mixed ionic-electronic conductors (OMIECs) and organic electrochemical transistors (OECTs) have enormous potential to impact everyday life and society – from low-cost biotechnologies in a widespread healthcare internet of things, to versatile neuromorphic computing technologies operating at the bio-hybrid interface. While significant research progress has been made, poor stability remains a critical bottleneck for OECTs. Additionally, identifying, enhancing, and measuring figures of merit that inform the 'material-device-circuit-application' research stack is essential for the success of emergent OMIEC electronics. Here, materials and device design strategies that increase important figures of merit will be discussed, as well as how the figure of merit, the μC* product, can be overstated when extracted from OECTs.

Narrow Bandgap Conjugated Polymers with Strong Correlations and Open-Shell Electronic Structures: Towards New Phenomena and Emergent Technologies Jason D. Azoulay; Georgia Institute of Technology, United States

For over forty years, conjugated polymers (CPs) have been a source of enormous fundamental breakthroughs, enabling foundational insight into the nature of π-bonding and electron pairing, the creation of novel optoelectronic functionalities, and the development of commercially relevant technologies. Despite the achievement of significant technological milestones, the complex structural and energetic heterogeneities that define these materials preclude bandgap control at low energies, tailored interactions with infrared (IR) light, the study of fundamental physical phenomena, and the design and realization of new device functionalities. To address these modern challenges, we have developed precision synthetic methods that provide control of the frontier orbital energetics, coplanarity of the conjugated backbone, intermolecular interactions, and many chemical, electronic, and structural features that affect electronic coherence within these π-conjugated macromolecules, enabling unprecedented levels of bandgap control. The utility of these materials for understanding emergent light-matter interactions that enable the transduction of IR photons and the extension of CPs into high-performance IR optoelectronics will be discussed. We subsequently discovered that narrow bandgaps afforded through extended π-conjugation are intimately related to the coexistence of nearly degenerate electronic states. Through articulating novel mechanisms of spin alignment, topology control, and exchange, we have enabled the synthesis of neutral CPs with ground states that span the entire range from "conventional" closed-shell structures to biradicaloids with varying degrees of open-shell character, to diradicals in both singlet (S = 0) and triplet (S = 1) spin-states. These materials exhibit weaker intramolecular electron-electron pairing and stronger electronic correlations than their closed-shell counterparts, which imparts novel optical, transient, transport, thermal, spin, magnetic, quantum, and coherent phenomena not previously measured in soft-matter (polymer) systems. These novel attributes have enabled new optoelectronic and device functionalities that cannot be realized with current semiconductor technologies and provide a remarkable platform to study new phenomena at the interface of various fields such as chemistry, condensed matter physics, and quantum matter.

2:00 PM SB02.02.02
Effects of Processing-Induced Contamination on Organic Electronic Devices Ian Jacobs[1], Dimitrios Simatos[1], Ilya Dobryden[2], Malgorzata Nguyen[1], Achilleas Savva[1], Deepak Venkateshvaran[1], Mark Nikolka[1], Jerome Charmet[3], Leszek Spalek[1], Mindaugas Gicevičius[1], Youcheng Zhang[1], Guillaume Schweicher[4], Duncan Howe[1], Sarah Ursel[1], John Armitage[1], Ivan Dimov[1], Ulrike Kraft[5], Weimin Zhang[6], Maryam Alsufyani[7], Iain McCulloch[7], Róisín Owens[1], Per Claesson[8], Tuomas Knowles[1] and Henning Sirringhaus[1]; [1]University of Cambridge, United Kingdom; [2]RISE Research Institutes of Sweden, Sweden; [3]HES-SO University of Applied Sciences Western Switzerland, Switzerland; [4]Université Libre de Bruxelles, Belgium; [5]Max Planck Institute for Polymer Research, Germany; [6]King Abdullah University of Science and Technology, Saudi Arabia; [7]University of Oxford, United Kingdom; [8]KTH Royal Institute of Technology, Sweden

Organic semiconductors are often touted as 'defect tolerant', however to date there have been relatively few systematic studies of the role of impurities on device performance. In particular, little attention has been paid to processing-induced contaminants, originating from e.g. the glovebox atmosphere or solvents, even though anecdotal reports have long indicated that such factors may be important.
Here,[1] we present a systematic study of processing-induced contamination on the performance of indacenodithiophene-co-benzothiadiazole (IDTBT) organic field effect transistors (OFETs). We observe that glovebox vapor can result in film contamination, but that in gloveboxes with a typical carbon-based solvent trap, the dominant impurities are typically aliphatics such as vacuum pump oil, rather than aromatics typically used for spin coating. In clean gloveboxes, we observe that the solvent content in films is largely determined by the residual solvent vapor in the atmosphere, rather than annealing, due to the large surface to volume ratio of thin films.
In addition, we find that most common plastic laboratory consumables, such as pipette tips, syringes, and even metal needles, leach contaminants into organic semiconductor solutions. In some cases, such as poly(dimethylsiloxane) (PDMS) coatings on metal needles, contamination leads to improvements in film wetting and device performance. However, in other cases, such as leachates from micropipettes, we observe strongly degraded device performance. Using NMR, we identify two primary contaminants (oleamide and glycerol monostearate) leaching from micropipette tips. These chemicals are both ampiphilic, and therefore could plausibly lead to increased electrostatic disorder, or the formation of hydrophilic inverse micelles. Tellingly, quartz crystal microbalance measurements reveal that uncontaminated IDTBT films are entirely hydrophobic, while contaminated films swell by 20% upon exposure to water, suggesting that previous studies on the role of water uptake in IDTBT may have been dominated by impurities. Our results promisingly suggest that intrinsic OFET performance may actually be more stable than previously thought. However, they are also broadly relevant to a wide range of materials and devices fabricated from solution, and suggest important strategies to limit contamination and increase experimental reproducability,

High-Performance Organic Thermoelectric Materials by Shifting up The Fermi Level Jianyong Ouyang; National University of Singapore, Singapore

Organic thermoelectric materials are regarded as the next-generation thermoelectric materials because of their merits including low cost, high mechanical flexibility, and low intrinsic thermal conductivity. However, their Seebeck coefficient is usually quite low, which is lower than their inorganic counterpart by 1-2 orders in magnitude. Here, I will report a new strategy to greatly enhance the Seebeck coefficient of organic thermoelectric materials. This can shift up the Fermi level and thus increase the Seebeck coefficient, while it only slightly lowers the electrical conductivity. As a result, the orgnaic thermoelectric materials can exhibit high Seebeck coefficient and high electrical conductivity.

2:30 PM *SB02.02.04
Dopant-Induced Morphology Changes and Their Impact on Thermoelectricity in Polymers Oliver Fenwick; Queen Mary University of London, United Kingdom

Conducting polymers have attracted interest as thermoelectric materials because of their processability, light weight, flexibility, low toxicity and cost. In terms of performance, it is their intrinsically low lattice thermal conductivity (typically 0.2 – 0.5 $Wm^{-1}K^{-1}$) which is of particular interest to the thermoelectric community. However, can we assume that the thermal conductivity is always low in these systems? Doping these systems is required to obtain useful electrical conductivities, but causes significant morphological changes in order to incorporate the large molecular dopants and further structural adjustments occur to accommodate the polaronic charge carriers. How do these morphological changes impact the thermal conductivity of polymers? How does this impact zT?

This presentation aims to shed some light on these questions, by investigating the cases of four polymers, poly(3-hexyl thiophene) [P3HT], poly(3,4-ethylenedioxythiophene) [PEDOT], poly[6,9-dihydro-6,9-dioxobisbenzimidazo[2,1-b:1′,2′-j]benzo[1mn]phenan-throline-2,12-diyl] [BBB] and poly[17-oxo-7,10-benz[de]-imidazo[4′,5′:5,6]-benzimidazo[2,1-a]isoquinoline-3,4:10,11-tetrayl)-10-carbonyl]) [BBL]. We measure in-plane thermal conductivity of different P3HT morphologies produced by spin-coating, drop casting and aligned by mechanical rubbing. We also compare doped and undoped analogues of these films. We do find an effect of morphology on thermal conductivity in aligned polymer films that we can link to structural changes. However, by far the biggest effect on lattice thermal conductivity comes from electrical doping, which induces a subtle change to the morphology but a significant increase in thermal conductivity. We find thermal conductivity states in the range of 0.2 to > 1 $Wm^{-1}K^{-1}$.[1] In PEDOT, we de-dope the polymer to improve the Seebeck coefficient, but also aim to maintain or improve charge transport. We observe significant morphological changes in this process which we link to the macroscopic observables.

In the case of BBB and BBL we investigate the effect of ladderisation on polymers (BBL being a ladder-type polymer and BBB it's non-ladder type analogue). Ladder-type polymers should be more planar and more rigid than non-ladder types. Correspondingly, we find that the thermal conductivity in the ladder-type polymers can be >3 times that in the non-ladder-type analogue. When doped the lattice thermal conductivity increases to remarkably large values >2 $Wm^{-1}K^{-1}$.

Structure-Property Relationships in Thienoacenes for Improved Transport Properties Guillaume Schweicher; Université Libre de Bruxelles, Belgium

In spite of tremendous progress in molecular design, engineering and processing, only few small molecule organic semiconductors (OSCs) have reached charge carrier mobilities (μ) higher than 10 cm^2/Vs, typically with single-crystal devices. However, μ is a material property and not a molecular one. It is thus of paramount importance to take supramolecular order into consideration at all length scales. As recently evidenced, the best OSCs tend to self-organize into large plate-like single-crystals exhibiting a layer-by-layer herringbone packing motif.[1] Moreover, thermal lattice fluctuations cause temporal variations of transfer integrals (J) and impose a transient localization of charges leading to reduced macroscopic μ in these weakly bonded van der Waals solids.[2] We will present recent progress achieved in our group in terms of molecular design and understanding of the impact of thermal energetic disorder: design by theory, crystal engineering, quantum-chemical calculations and evaluation of transport properties in electronic devices.

Polymorphic Organic Crystals of P(NDI2O-T2): Impact of Microstructure on The Charge Transport Properties Chamikara D. Karunasena[1], Hong Li[1], Casey Davis[2], Megan R. Brown[3], Joel H. Bombile[3], Veaceslav Coropceanu[1], Chad Risko[3], Michael Toney[2] and Jean-Luc Bredas[1]; [1]The University of Arizona, United States; [2]University of Colorado Boulder, United States; [3]University of Kentucky, United States

The electronic charge transport characteristics of organic semiconductors (OSCs) are intricately linked to their solid-state morphology. Deciphering the complex interplay of these OSC polymer properties with the supramolecular organizations in their (semi)crystalline structure is of importance in the pursuit of high-performance materials for next-generation optoelectronic technologies. However, currently available *in-situ* experimental characterization

techniques offer limited nano-scale insight, making it challenging to comprehensively describe the microstructure of fabricated films in terms of crystallinity and polymer conformations and orientations, and thus to rationalize the relationship of structure with associated electronic properties. In this study, we present an in-depth characterization of the supramolecular crystal organization and its impact on the electronic charge transport properties of polymorphic crystalline forms of the n-type hairy-rod polymer P(NDI2O-T2); this material can have low energetic disorder and high electron mobility, making it well-suited for a wide range of electronic device applications. Based on available experimental data from X-ray scattering techniques and infra-red spectroscopy, we derive the crystal unit-cell structures of the three reported polymorphic forms at the atomistic scale, through a meticulously parameterized classical molecular dynamics force field in conjunction with periodic density functional theory (DFT) calculations. Furthermore, we extend our simulations to investigate the diverse morphological aspects of the semicrystalline structure following thermal treatment and account for the factors governing the polymorphic interconversion and selectivity. We sample the nano- to microstructure of the simulated thin films and quantify charge carrier transport through density functional theory calculations. These results serve as the foundation to establish critical and fundamental correlations between crystal transport properties and the nano- and microstructure of the polymer, as well as the associated disorder. This, in turn, allows the determination of the dominant transport microscopic parameters and provides insight into how these parameters can be tuned through precise processing techniques.

Synthesis and Functionalization of New Chromophores for Organic Electronics & Photonics John Anthony, Tanner Smith, Karl Thorley and Dean Windemuller; University of Kentucky, United States

High-performance organic electronic and photonic devices require optimization of both the core chromophore and the chromophores' interactions in the solid state. Recently, we have been exploring the synthesis and implementation of larger chromophores - either linked trimeric systems or very long (> 8) fused-ring aromatic compounds to enhance both photonic properties and improve intermolecular contacts. Along with these new chromophores, we have developed new functionalization strategies to allow solution processing and to impart some control over the solid-state order of the cores. By this process, we have made a series of remarkably stable large aromatic systems with absorption well into the near-infrared. By tuning electronic coupling within chromophores, we have developed new singlet fission chromophores that yield quintet states exclusively. By tuning the functional groups on other systems, we have found approaches using C-H-π interactions to dramatically reduce disorder, and are studying the impact on charge transport. Due to their increased rigidity, we expect these larger polycyclic systems to demonstrate significant improvements in mobility. Thorough studies of decomposition mechanisms for these higher fused aromatic compounds have elucidated new reaction pathways, along with approaches to minimize reactions with oxygen or dimerization, yielding materials with unprecedented stability.

Exploiting Charge Transfer States in Molecular and Organic Electronics Oana D. Jurchescu; Wake Forest University, United States

The growing demand for smaller, faster, and more versatile electronics has led to a surge of interest in new device concepts. One promising approach is to exploit the charge-transfer (CT) state that forms at the interface between charge donor and acceptor molecules. However, establishing reliable relationships between donor/acceptor molecular structures, the resulting CT, and physical properties is challenging. In this talk, the implications of the hybrid electronic states will be discussed by examining two model systems: a monolayer of co-assembled molecules with strong electron donor and acceptor termini, and a polymorphic system based on a donor/acceptor charge transfer salt in the form of single crystals with varying donor-acceptor overlap. In the molecular rectifiers based on self-assembled molecules, the charge transfer state is responsible for the observed increase in the rectification ratio, despite the reduction caused in the film degree of order. These high-performance molecular diodes have been employed in circuits to effectively rectify an AC signal. In the single crystals, we correlate the solid-state packing with the degree of charge transfer and the resulting electrical properties. We also probe the sub-gap, trap states, through the measurement of field-effect transistors, an analysis which has so far seen little application in ambipolar devices. Our results provide evidence that small differences in donor/acceptor overlap can induce significant changes in electronic coupling and electrical properties of organic devices and highlight the potential of charge transfer states as a disruptive approach to engineering organic electronics.

SESSION SB02.04: Poster Session: Charge Carrier Transport in Organic and Organic-Inorganic Hybrid Materials
Session Chairs: Xiaodan Gu, Alexandra Paterson and Bob Schroeder

A Highly Conductive n-Type Conjugated Polymer Polymerized in Water Qifan Li, Jun-Da Huang, Chi-Yuan Yang and Simone Fabiano; Linkoping University, Sweden

Poly(3,4-ethylenedioxythiophene):poly(styrene sulfonate) (PEDOT:PSS) is a benchmark hole-transporting (p-type) polymer that finds applications in diverse electronics devices. Most of its success is due to its facile synthesis in water, exceptional water processability, and outstanding electrical performance. Applications in fields like bioelectronics and thermoelectric devices often necessitate the complementary use of both p-type and n-type (electron-transporting) materials. However, the availability of n-type materials amenable to water-based polymerization and processing remains limited. Here, we present a novel synthesis method enabling direct polymerization in water, yielding a highly conductive, water-processable n-type conjugated polymer. By adjusting the synthetic procedure and use of surfactants, we achieve an impressive conductivity of up to 66 S/cm (with an average of 48 ±18 S/cm), ranking among the highest for n-type polymers processed using green solvents. The new n-type polymer also exhibits outstanding stability, maintaining 89% of its initial conductivity after 146 days of storage in air. Our synthesis approach, along with the novel polymer it yields, promises significant advancements in the field of printed electronics.

5:00 PM SB02.04.02
Spin Transport Modeling in The Small Tetraheme Cytochrome William Livernois and Anant Anantram; University of Washington, United States

Multi-heme cytochromes have attracted attention due to their conductive properties [1] and, more recently, their spin-selective properties [2]. The small tetraheme cytochrome (STC), a c-type cytochrome found in *S. oneidensis*, has been demonstrated experimentally to act as a spin filter [3], with the potential to be used in nano-scale spintronic devices. Building upon a spin-dependent transport model previously applied to related biomaterials and cytochromes [4], we investigated decoherent transport through the cytochrome and electron hopping between heme groups. This model incorporated spin-orbit coupling and a generalized spin model to explore non-collinear effects. Preliminary findings indicate that collinear effects, arising from electron exchange and spin state, predominantly influence the transport pathway while spin-orbit effects only cause minor shifts in orbital energies. Notably, the

peptide backbone functions primarily as a structural scaffold facilitating heme-to-heme electron transport, rather than directly contributing to electron conduction. We also examined the impact of solvation within our model and identified its role in modulating the coupling between heme sites and the overall conductivity of the cytochrome.

The research was supported by National Science Foundation NSF Grant Number 2317843, NSF Future of Manufacturing Grant No. 2229131, and the NDSEG fellowship.

Exploring DNA-Carbon Nanotube Interfacial Interactions and Transport Olaiyan M. Alolaiyan[1,2] and M. P. Anantram[1]; [1]University of Washington, United States; [2]King Abdulaziz City for Science and Technology, Saudi Arabia

In the rapidly changing world of combined scientific studies, two standout materials are drawing attention: DNA and carbon nanotubes (CNTs). DNA, known for its central role in carrying genetic information, is a wonder of nature's design. On the other hand, CNTs, recognized for their strength and electrical properties, represent the best of modern material advancements.
Studying the interaction between DNA and carbon nanotubes (CNTs) presents a series of tangible challenges. One of the main obstacles is that the inherent differences in their chemical properties make direct interactions between them non-trivial. In addressing the challenges of understanding the intricate interactions between DNA and CNTs, our approach leverages the power of Molecular Dynamics (MD) simulations. MD simulations offer a dynamic and detailed perspective, allowing us to scrutinize the behavior of our DNA-CNT system. To initiate our study, we began by modeling the direct interaction between DNA and CNTs without forming any covalent bonds. This step was pivotal, setting the groundwork before introducing the linker and further constructing the comprehensive DNA-Linker-CNT system. The introduction of a linker in the system, studied under MD, can provide insights into creating stable bonds that bridge DNA and CNTs, ensuring their effective interaction without compromising their individual properties.
In our comprehensive study on the DNA-Linker-CNT system, we utilize a systematic methodology to elucidate the behavior and stability of the structure complex. Each component of the system was carefully constructed: the DNA, in its B-form comprises a 12-basepair double-stranded sequence denoted as (3G3C3G3C). The linker, a 10-atom amino linker, served as the bridge in our system. The CNT has a chirality of (6,6) and is 10 primitive cells long. Crucially, to ensure accurate simulations, we employed specific force fields: the Amber force field bsc1 for DNA, and GAFF (General Amber Force Field) for the linker and CNT. By having the individual components, our next step was to bring them together into a cohesive environment. This involved forming bonds between the DNA, linker, and CNT, followed by the application of force fields – with specific force fields parameters calculated for the linker and CNT. To simulate a realistic biological environment, we introduced a water solvent using the TIP3P model, encapsulating our system in an octahedral geometry with a 15-angstrom buffer. Then we ionized the structure to ensure it was ready for the Molecular Dynamics (MD) simulations.
The MD simulations were significant in revealing the dynamics of our system. Across multiple runs, a consistent observation was the pronounced attraction between the DNA and CNT, with the DNA segment nearing the CNT's surface, adopting a stable configuration involving the interaction between pi-orbitals on the DNA and CNT. This proximity between the pi-orbitals of the two subsystems, sustained over a significant portion of the simulation, is indicative of potential electron transport opportunities, a phenomenon further corroborated by RMSD analyses which underscored the stability of each component. Our observations so far paints a promising picture for the DNA-Linker-CNT system, hinting at potential channels for electron transport. Complementing our MD studies, we are performing transport calculations which will be presented to further enhance our understanding. These calculations shed light on the electron transfer between the DNA and nanotube subsystems under a variety of CNT-Linker-DNA-Linker-CNT configurations. Together, MD simulations and transport calculations provide a comprehensive and promising approach to unravel the complexities of the DNA-Linker-CNT interactions, paving the way for a deeper understanding of these systems. [We acknowledge NSF FMRG 2328217 and NSF SemiSynBio 2027165 grants.]

5:00 PM SB02.04.04
Carbon Nanotube-Poly(3-Hexylthiophene) Hybrid Thin-Film Phototransistors with Ultra-High Responsively Zahra Bahrami[1], Kevin Schnittker[2] and Joseph Andrews[2,1]; [1]University of Wisconsin-Madison, United States; [2]University of Wisconsin–Madison, United States

Phototransistors (PTs) are photodetectors that combine light detection and signal amplification capabilities by modulating the charge-carrier density within the transistor's active channel upon exposure to light.[1–3] Solution-processable phototransistors (PTs) have gained prominence thanks to their outstanding attributes, notably their adaptability to various substrates, including flexible materials, facilitating large-area integration.[4–7] Among PTs, hybrid material phototransistors stand out, leveraging the strengths of inorganic materials' high carrier mobility and organic materials' efficient light absorption and tunable bandgap.[8] This synergy enhances light detection sensitivity and efficiency.[8,9] Conjugated Poly(3-hexylthiophene) (P3HT) and carbon nanotubes (CNTs) are frequently employed in optoelectronics due to P3HT's flexibility, absorption coefficient, and cost-effectiveness, and CNTs' exceptional electrical and optical properties driven by their unique one-dimensional structure.[10] In this study, we present a promising solution-processible technique to fabricate a phototransistor utilizing CNTs integrated with P3HT through heterogeneous crystallization as the channel of phototransistor, with the aim of investigating their capabilities in high-responsivity optical detection devices.
Our findings reveal that the devices demonstrate an exceptionally high photoresponsivity of 3.6×10^5 A/W at a wavelength of 470 nm. The exceptional photoresponsivity primarily stems from the high light-absorption characteristics of the conjugated polymer, complemented by the excellent mobility facilitated by the underlying CNT network. Additionally, we determined the device's detectivity by analyzing its noise profile at 10 Hz for various V_{GS} values. The device's maximum detectivity reaches approximately 0.9×10^{11}, a value that is approximately 5000 times higher than a control sample consisting solely of P3HT at the peak of responsivity. These results show the solution processed P3HT/semi-CNT hybrid platform is a promising approach for advanced photodetection applications.

Ordered Inorganic-Organic Hybrids can Crystallize with Differing Organic Cation Species Megan Cassingham[1], Yang Goh[1], Sujeewa Lamahewage[2], Aaron Rossini[2], Mark E. Thompson[1] and Brent Melot[1]; [1]University of Southern California, United States; [2]Iowa State University of Science and Technology, United States

Hybrid organic-inorganic materials have been employed in a variety of applications including photovoltaics, optoelectronics, and nonlinear optics. Despite their unique and diverse properties, there is still potential to employ the organic molecules as more active contributors to the optoelectronic properties of these materials. In this work, we explore the possibility of applying more than one organic cation specie to these systems to investigate possible charge transfer properties. We look at three materials, 1-methylquinolinium lead iodide (1-MQPbI_3), 1-naphthylammonium lead iodide (1-NAPbI_3), and the mixed hybrid of these two ((1-MQ)(1-NA)PbI_3). These systems were chosen for their similarity in structure. While there is precedent for other hybrid systems such as 3D systems like methylammonium lead iodide to incorporate more than one organic cation in the structure, this is the first system we are aware of to show clear order without distinct regions of one cation or the other. We corroborated the single crystal X-ray data of the structure using solid state NMR techniques to discover the distances between the organic cations. We also investigated the photophysical properties of all three systems including temperature dependent emission and lifetime data. Dielectric data was also collected to gain a better understanding of the relationship between possible structural changes and the unique photophysical properties we observed. Although these two organic cations do not display strong charge transfer characteristics, this work opens the door to further studies into the mixed hybrid space and shows promise for new ordered systems which can better utilize charge transfer properties.

5:00 PM SB02.04.06
Chain Length Dependent, Reversible Switching of Spiropyran-PMMA Blend Dielectrics for Light-Gated Organic Transistors Sten Gebel, Parham Derakhshanfar, Shoupeng Cao, Lucas Caire da Silva, Paul W. Blom and Ulrike Kraft; Max Planck Institute for Polymer Research, Germany

The increasing demand for mobile and flexible electronics and the rising interest in the “Internet of Things” promotes research on lightweight organic electronic devices and concepts where the integration of silicon chips is too expensive. One promising approach to introduce additional functionalities for sensing and memory applications into conventional organic electronic devices is the introduction of molecular switches. These small organic molecules undergo reversible isomerization between (at least) two isomers when irradiated with light of different wavelength and this induces drastic changes in physicochemical properties such as frontier orbital energy levels, dipole moment and/or molecular geometry. These reversible changes in molecular properties can be exploited to deliberately modify charge transport in organic field-effect transistors (OFETs) and therefore enable optical control over device characteristics.

Spiropyran is a photoswitch that can be used to fabricate light-switchable organic electronic devices. The system is particularly interesting, because the UV light-induced isomerization of the neutral spiropyran (SP) to the zwitterionic merocyanine (MC) can be exploited to reversibly tune OFET characteristics [1-3]. One possible approach to incorporate spiropyran-based photoswitches into organic transistors is to blend them with dielectric polymers to obtain light-responsive gate dielectrics. However, there is no consistent explanation in the literature for how isomerization of the photoswitch alters charge transport and performance of OFETs, and several mechanisms have been proposed. We address this issue by blending spiropyran molecular switches with alkyl side chains of different lengths (i.e. C_1, C_4, C_{10} and C_{16}) with poly(methyl methacrylate) (PMMA) and study the reversible switching of these functional blends using UV/Vis absorption spectroscopy, impedance spectroscopy and further electrical characterization in metal-insulator-metal capacitors and OFETs. The UV/Vis absorption data show that all four SP derivatives isomerize to their respective MC form upon UV irradiation. Thermal annealing induces the reverse reaction from MC to SP. In OFETs, the reversible switching between the SP and MC states translates into pronounced, reversible shifts of the threshold voltage.

Surprisingly, we find that the switching of both capacitor and transistor characteristics strongly depends on the length of the alkyl side chain of the photoswitch. This suggests that the change of the dipole moment (low versus high) and the charge (neutral versus zwitterionic) might not be the only cause for the altered device characteristics, but that the side chains must also be considered. This chain length dependent switching is further investigated by bias stress measurements using OFETs and a similar dependence on the chain length is found.

Such a chain length dependent reversal of the switching in light-gated devices has not been reported before. Hence, our results highlight the importance of the chemical design of photochromic molecules for well-controlled switchable devices.

5:00 PM SB02.04.07
Herringbone-Patterned Asymmetric Electron-Blocking Material for Stable Blue Phosphorescent Organic Light-Emitting Diodes Eunhye Hwang[1], Wonyoung Choe[1], Jun Yeob Lee[2] and Tae-Hyuk Kwon[1]; [1]Ulsan National Institute of Science and Technology, Korea (the Republic of); [2]Sungkyunkwan University, Korea (the Republic of)

Blue phosphorescent organic light-emitting diodes (PhOLEDs) have been suffered from severe triplet leakage issues between interfacial layers, resulted in rapid degradation of the device performance as well as considerable efficiency roll-off. So far, electron-blocking materials (EBMs) with high triplet energy levels (E_T) have been introduced to achieve triplet confinement in emissive layers, but the large energy bandgaps required by typical EBMs often increase turn-on voltages (V_{on}) of PhOLEDs and then rather accelerate their degradation. However, there is a lack of studies on the development of EBMs suitable

for blue PhOLEDs considering their charge carrier mobilities to act as efficient hole-transporting as well as electron-blocking channels, which is closely related to the consequent V_{on}.
Herein, we present a molecular design strategy of asymmetric EBMs for stable blue PhOLEDs with a focus on molecular packings and orientations to reduce their V_{on}. Adjusting photophysical properties and electrostatic interactions, four EBMs having high E_T are developed by fine-tuning of three-dimensionally twisted molecular structures. X-ray crystallographic analyses show that the compound containing a fully *ortho*-linked donor–donor–π–acceptor configuration achieves a herringbone-patterned crystal structure with a face-on-dominated orientation, advantageous for hole carrier transport. Resultingly, providing a decreased V_{on} and effective triplet confinement, power efficiency and operational lifetime of the corresponding blue PhOLEDs are successfully improved compared to a conventional symmetric EBM with a slow hole mobility. The structural modification of asymmetric EBMs considering their molecular arrangement will provide further insight into the design of interfacial layers, enhancing the device performance and stability in various optoelectronic applications.

Photoinduced Charge Transfer at Quantum Dot to Dye Inteface Svetlana V. Kilina; North Dakota State University, United States

Recent focus on assemblies of the QDs functionalized by various organic and metal-organic dyes is dictated by their promise to serve as a key element for both solar- to-electrical and solar-to-chemical energy conversion processes. Our simulations of QD/dye composites have led us to predictions of conditions that govern the direction and rates of the charge transfer from the QD to the dye and interpretation of transit-spectroscopy data.

Iteratively Synthesized, Atomically Precise Graphene Nanoribbons with Heteroatoms Steven Kolaczkowski, Nicholas Angello, Wesley Wang and Joseph Lyding; University of Illinois at Urbana-Champaign, United States

The semi-metallic electronic structure of graphene has been the major problem in the fabrication and integration of graphene electronic devices. While the thermal, optical, mechanical, and electronic transport properties of graphene vastly outperform silicon, the very low on-off current ratio prevents 2D planar graphene from being used as a controllable channel in field effect transistors (FETs). Graphene nanoribbons (GNRs), laterally confined, 1D structures of graphene exhibit a wide variety of bandgaps while maintaining similar physical properties. For example, GNRs are predicted to have electron mobilities and thermal conductivity over twenty-five times higher than that of Silicon. However, limitations in current GNR synthesis techniques prevent the use of heteroatoms from being incorporated into a length-controlled ribbon. Here, I discuss a solution-based iterative coupling technique capable of synthesizing GNR copolymers and GNRs with heteroatoms. This increase control over GNR synthesis arises from the use of tetramethyl *N*-methyliminodiacetic acid (TIDA) protected haloboronic acid difunctionalized GNR building blocks. By utilizing optimized catch-and-release purification methods and automated machinery, we've demonstrated the ability to create user-defined, atomically precise, length controlled GNR copolymers with no human intervention in as little as eight hours. Because TIDA-protected boronic acids can be deprotected under mild, basic conditions, these GNR building blocks can be synthesized with the inclusion of heteroatoms without degradation. GNR building blocks containing Oxygen, Sulfur, and Nitrogen have already been synthesized. The inclusion of these electron-rich species into the graphene lattice alters the electronic band structure and ribbon conductivity, effectively n-type doping the local environment. These synthesized GNRs and GNR copolymers are then exfoliated onto metallic and semi-conducting surfaces in situ in ultra-high vacuum (UHV) using dry-contact transfer. Finally, these on-surface GNRs probed using scanning tunneling microscopy (STM) to better understand their electronic structure, on-surface behavior, and stability. This procedure has the potential to open the floodgates to hundreds of novel GNRs and GNR heterostructures that can be used in post-silicon devices.

5:00 PM SB02.04.10
Active Learning Approaches to Predict Intermolecular Noncovalent Interactions in Organic Semiconductors Moses Ogbaje[1,2], Vijaykumar Karthikeyan[3], Kyle Eldridge[1], Vinayak Bhat[4], Baskar Ganapathysubramanian[5] and Chad Risko[1,2]; [1]University of Kentucky, United States; [2]Center for Applied Energy Research, United States; [3]Paul Laurence Dunbar High School, United States; [4]Columbia College, United States; [5]Iowa State University of Science and Technology, United States

The natures and strengths of intermolecular noncovalent interactions are critical to the formation of organic semiconductors (OSC) from their molecular or polymer-based building blocks. While there are several quantum-chemical approaches available to evaluate intermolecular noncovalent interactions, including symmetry-adapted perturbation theory (SAPT), these methods can be computationally expensive, especially for the types of large building blocks used in OSC. This computational cost limits the ability of machine-enabled searches of the OSC chemical and materials space. Machine learning (ML) models have emerged as powerful tools to provide fast predictions of a variety of molecular and material properties at a fraction of the computational cost when compared to quantum-chemical approaches, though they often require substantially large and labeled datasets, posing challenges when data is scarce or difficult to obtain. Here, we discuss an active learning approach that augments ML models trained to predict intermolecular noncovalent interactions by incorporating a prediction confidence. The active learning scheme is developed to enable the reduction of labeled data requirements by identifying regions in the chemical space where the model exhibits the most uncertainty. This combined approach demonstrates effective and fast determination of intermolecular noncovalent interactions in OSC.

Morphology Control Strategies for Efficient Charge Transport versus Injection in Solution-Processed Organic Electronic Devices Minsoo Kim, Woongsik Jang and Dong Hwan Wang; Chung-Ang University, Korea (the Republic of)

ABSTRACT BODY:
Organic electronic devices have attracted much attention owing to their advantages such as solution processable, low cost, superior absorption coefficient, flexibility, and so on. By developing of the non-fullerene acceptors (NFAs), organic photovoltaics (OPVs) achieved high power conversion efficiency (PCE) over 19% and organic photodetectors (OPDs) beyond the detectivity of 10^{14} Jones. These desirable results are thanks to the various morphology control strategies of organic semiconductor materials, and novel thin film formation process using their. In this study, we suggest the morphology control strategies in terms of materials engineering and thin film lamination process. Representative methods of controlling the morphology of photoactive materials include additive engineering (morphology regulator), and ternary strategies such as introducing the guest components, those enable efficient charge dynamics by controlling molecular orientation. The morphology of the photoactive material which composed of polymer donor PM6 and non-fused ring electron acceptors (NFREAs) TPDC-4F controlled by additive engineering which induce efficient vertical phase distributions of the donor and acceptor components through volatilization process of the high boiling point of additive. Accordingly, we successfully fabricated efficient OPDs (Detecitivty of 1.27×10^{13} Jones) with suppressed dark current (3.55×10^{-9} A cm^{-2}) [1]. Moreover, the ternary strategy introducing the high LUMO level guest acceptor (EH-IDTBR) with PM6:BTP-4F-12 binary blend, can block the injected charge from external efficiently and robust transfer the photo-genetrated charge carrier, is promising method for morpholgy regulation. The devices with ternary strategy based on optimal ratio of EH-IDTBR showed advanced OPV (PCE of 16.20%), and OPD (Detectivity of 1.33×10^{13} Jones) performances [2]. In addition, morphology also can be adjusted by thin film

lamination process. To achieve a desirable thin film surface morphology with a well-distributed donor (PM6) and acceptor (BTP-4F-12) phase in the vertical structure, we developed a vacuum-free (VF) lamination process, in which the blend films with various thicknesses using the adhesion-optimized PUA mediators are transferred onto the target substrates without the vacuum process. Consequently, the VF-laminated devices achieved improved OPV (PCE of 15.97%) and OPD (D* of 3.61×10^{13} Jones) performances. Additionally, the device prepared using the VF-lamination exhibited improved internal resistance, as well as photoresponse property, as observed by optical, electrical, and morphological analyses [3, 4].

Impact of Dielectric Environment and Counterion Size on Polaron Characteristics in Electrochemically Doped π-Conjugated Polymers Megan R. Brown[1], Joel Bombile[1], Jean-Luc Bredas[2], Zhiting Chen[2], Chamikara Karunasena[2], Hong Li[2], Erin L. Ratcliff[2] and Chad Risko[1]; [1]University of Kentucky, United States; [2]The University of Arizona, United States

Electrochemically doped π-conjugated polymers (CP) are central materials in several emerging applications such as semiconductors in optoelectronic devices, active materials in thermoelectric generators, and electrode or binder materials in batteries. In these systems, electronic transport is controlled by the formation of polarons, which act as charge carriers in the CP. As the CP interacts with counterions from an electrolyte source, the charge associated with the polaron is stabilized. While both the counterion and the solvent environment involved in this interaction can impact the optical and charge-carrier properties of CPs, a clear understanding of the governing mechanisms is still lacking. Here we focus on assessing how single-chain polaron properties are impacted by changes in the surrounding dielectric environment and counterion used. We use first-principles calculations based on density functional theory (DFT) and time-dependent density functional theory (TD-DFT) with a tuned range-corrected hybrid functional to determine various polaron characteristics in the model CP N2200 in assorted dielectric environments with and without counterions of varying sizes present. We find that the Coulomb interactions between the polaron and the counterion lead to smaller, more strongly bound polarons as reflected by changes in charge delocalization, bond distortion, and polaron features of the optical absorption spectra. These data provide valuable insight into how such variables impact the charge transport properties of electrochemically doped CP's.

5:00 PM SB02.04.13
Expanding The Compatibility of P3HT Hole Transport Layers for Stable NIP Perovskite Solar Cells David Hardy, Feng Wang and Feng Gao; Linköping University, Sweden

In order for perovskite solar cells to be commercially competitive, attaining robust environmental stability is of the upmost importance. In a standard nip device stack the material selection for the surface hole transport layer (HTL) is critical, as it will dictate the degree that air and moisture will penetrate into the sensitive perovskite layer. Present high performing devices rely upon the established small molecule: Spiro-OMeTAD due to its well aligned energy levels, high hole mobility and broad compatibility with differing perovskite chemistries and interfacial passivation layers.
Conductive organic polymers offer several advantages over small molecule materials like Spiro-OMeTAD, such as fast intramolecular transport, greater environmental stability, and reduced cost. Poly(3-hexylthiophene-2,5-diyl) (P3HT) is one such polymer, and has been successfully implemented as an HTL in numerous reported perovskite solar cells, attaining efficiencies up to 24.6% [1]. However, typically these high performances rely upon interfacial perovskite treatments to induce favourable P3HT orientation and packing, and thus introduce restrictions on choice of perovskite chemistry or passivation method, that are not present for Spiro-OMeTAD. While reports that rely on oxidative dopants such as F4TCNQ, to increase the conductivity of P3HT HTL, exhibit lower efficiencies [2]. Therefore, presently P3HT based devices lag behind their Spiro-OMeTAD counterparts, in terms of performance, and versatility.
Recently the novel "ion-modulated radical doping strategy" for Spiro-OMeTAD based HTLs has outlined a doping strategy that relies upon a stable radical ($Spiro^{2+}TFSI$) to increase conductivity, in conjunction with an ionic modulator (TMBP-TFSI) to improve hopping transport between molecules [3]. Drawing inspiration from the IM-Radical doping strategy, this work aims to develop an analogous co-doping approach, for P3HT (or other low-cost polymers). Oxidising dopants such as charge transfer materials, Lewis acids, photo-initiator salts, and electrophilic salts have been screened in order to maximise HTL conductivity, and thus short circuit current, while various ionic modulators have been employed to align material work-fucntions and maximise the open circuit voltage. Through this combined doping approach we aim to develop a low cost P3HT based HTL that can match the performance of established Spiro-OMeTAD based devices and offer imroved environmental stability, without imposing material restrictions upon the underlying device stack.

Measuring Carrier Lifetimes in Organic Solar Cells Ally Hurd[1,2], Awwad N. Alotaibi[2], Obaid Alqahtani[2], James R. Doyle[1] and Brian A. Collins[2]; [1]Macalester College, United States; [2]Washington State University, United States

Printable and flexible organic solar panels are promising sources of inexpensive, large-scale renewable energy, where panels can be manufactured by printing from polymer inks. There are some limitations to these types of solar cells, however. First, toxic halogenated solvents have historically been necessary to dissolve polymers to make the ink. In addition, organic solar cells typically have high rates of recombination, which limits their efficiency. Here, we use a transient photovoltage (TPV) technique to measure charge lifetimes in cells made from two different organic solvents. The first solvent is toxic, halogenated dichlorobenzene (DCB) which is typically used to make organic solar cells. The other is a less toxic, non-halogenated solvent, carbon disulfide (CS_2). By varying the processing methods in this way, we find that cells made from CS_2 have longer charge lifetimes and higher efficiencies than those made with DCB. Possible reasons for these differences are explored using semi-analytic and numerical modeling. This work demonstrates that we may be able to decrease the toxicity of organic solar cell manufacturing and simultaneously improve the efficiency of the devices, bringing this powerful method of capturing solar energy to the forefront of sustainable energy solutions.

Conductivity Control by Welding of Nanomembrane for Stretchable Electronics Jeeyoung Kim[1,2], Minjeong Kim[1,2] and Dae-Hyeong Kim[1,2]; [1]Seoul National University, Korea (the Republic of); [2]Institute for Basic Science (IBS), Korea (the Republic of)

Welding is a technology that enhances conductivity by forming junctions of metal nanomaterials within a nanocomposite. Conventional nanocomposites have difficulty forming percolation because conductive nanomaterials are mixed with insulating polymers. Conductivity can be improved only through welding with harsh conditions, making it a challenge to control conductivity through welding. Herein, we introduce welding control technology to enable control over the conductivity of nanomembranes on a wide scale under mild conditions. Welding control is a technique that regulates the interparticle junction diameter of the nanomembrane by controlling the reactivity of the reduction solution, which removes ligands attached to the surface of nanoparticles. Reduction solutions can directly act on the nanoparticles exposed in the form of a monolayer in the nanomembrane. The reactivity of the reduction solution is directly proportional to the degree to which ligands are removed, thus increasing the junction diameter. By adjusting the diameter of these junctions, resistance can be tuned from a few ohms to several thousand ohms. This technology is applicable to various metal nanoparticles, such as Au and Ag, and can simplify circuit design when used for patterning. Hence, it can be used as a universal strategy in stretchable devices.

Disorder-Tolerant Efficient Doping Strategy of Conjugated Polymers for High-Performance Organic Thermoelectrics Jimin Kim and Kilwon Cho; Pohang University of Science and Technology, Korea (the Republic of)

Molecular doping has been a paramount technique to modulate the electronic properties of conjugated polymers (CPs) used in various organic device applications. However, conventional redox doping requires a sufficient energy level offset between the host and dopant; otherwise, doping occurs through the formation of a charge transfer complex, which strongly reduces doping efficiency. Moreover, especially in organic thermoelectrics (TEs), excessive dopants introduced to form highly doped CPs generally cause structural distortion and broadening of the density of states (DOS) in CPs (i.e., dopant-induced disorder), thereby deteriorating their charge transport properties. Herein, we present an efficient doping strategy to attain highly doped CPs with dramatically suppressed structural and energetic disorder using a promising Lewis acid dopant, tris(pentafluorophenyl)borane (BCF), which has recently shown potential for doping CPs regardless of their ionization energy and enabling efficient integer charge transfer by forming a BCF–water complex. Using a non-polar aliphatic solvent, hexane, which can effectively swell the CP films due to its good affinity with the side chains of CPs, we successfully infiltrate BCF into the lamellar spacing of poly[2,5-bis(3-tetradecylthiophen-2-yl)thieno[3,2-*b*]thiophene] (PBTTT) films via sequential doping, producing a remarkable electrical conductivity of 230 S cm^{-1} and a TE power factor of 140 μW m^{-1} K^{-2}. Concomitantly, the resulting sequentially doped films show significantly high Hall carrier mobility and facilitated bipolaron formation within their high solid-state ordering compared to films doped by solution-mixing. In addition, the sequentially doped films exhibit highly delocalized transport characteristics through highly ordered domains with a narrow DOS, substantiated by charge transport modeling and quantitative investigation of crystalline ordering, charge carrier localization, and energetic disorder. This work would provide an approach for disorder-tolerant doping strategies with a comprehensive understanding of processing–structure–property relationships in highly doped CPs.

Ester Functionalized Di-Pyrrole Containing Chalcogenophene Based Semiconducting Small Molecules for Organic Field Effect Transistor Applications Ashutosh Shrivastava, Michael C. Biewer and Mihaela C. Stefan; The University of Texas at Dallas, United States

Pyrrole is the most electron-rich molecule among five-membered heterocyclic molecules like furan, thiophene, and selenophene. These five-membered chalcogenophenes are isoelectronic to each other and have the potential to be utilized for organic electronics. In this study, we have designed and synthesized three different organic compounds containing Di-pyrrole molecules fused with different chalcogenophenes: diethyl 1,7-dihydrofuro[3,2-b:4,5-b']dipyrrole-2,6-dicarboxylate (FDP), diethyl 1,7-dihydrothieno[3,2-b:4,5-b']dipyrrole-2,6-dicarboxylate (TDP), and diethyl 1,7-dihydroselenopheno[3,2-b:4,5-b']dipyrrole-2,6-dicarboxylate (SeDP). The molecular characterization of these compounds was done using ^{1}H, and ^{13}C Nuclear Magnetic Resonance (NMR) spectroscopy. The crystal structure determination and phase purity analysis of these compounds were performed using Single Crystal X-Ray Diffraction and Powder X-Ray Diffraction respectively. The XRD analysis reveals that fused rings of these compounds have a planar structure in which two compounds (TDP and SeDP) form dimers and are interacted by N-H●●●O hydrogen bonding. The optical and electrochemical properties were studied using UV-Vis Spectroscopy and Cyclic voltammetry respectively, that displays that these molecules are promising semiconducting candidates for electronic applications. The highest occupied molecular orbital (HOMO) and lowest unoccupied molecular orbital (LUMO) energy levels of these molecules were also calculated by density functional theory (DFT) calculations using Gaussian and are compared with experimental data. Thermogravimetric analysis and Differential Scanning Calorimetry studies show that these compounds are thermally stable (vary in the range of 150-200 °C) and do not have any phase transformation below decomposition temperature. These as-synthesized organic semiconducting molecules will be studied for organic field effect transistor applications.

5:00 PM SB02.04.18
Enhancing Stability and Thermoelectric Performances of Doped Oriented Regioregular Poly(3-Hexythiophene) Using Anion Exchange Doping Shubhradip Guchait[1], Aditya Dash[2], Antoine Lemaire[1], Laurent Herrmann[1], Martijn Kemerink[2] and Martin Brinkmann[1]; [1]Institute Charles Sadron, CNRS – Université de Strasbourg, France; [2]Institute for Molecular Systems Engineering and Advanced Materials, Heidelberg University, Germany

Doping polymer semiconductors is an elegant method to produce conducting polymer films for various electronic applications with effective structural control. In this contribution, we present an innovative method for preparing stable and efficient conducting polymer films by combining high-temperature rubbing with anion exchange doping using bis(trifluoromethylsulfonyl)imide (TFSI) as the dopant. We combine two doping methods i.e. anion exchange and incremental concentration doping to investigate the impact of progressive dopant introducting in the semi-crystalline structure of P3HT on the structural and thermoelectric properties of aligned thin films using a combination of Transmission electron microscopy, Polarized optical absorption spectroscopy and transport measurements. Our results demonstrate that anion exchange strongly depends on both the ratio of the dopants (F_4TCNQ and LiTFSI in n-butylacetate) but also on their concentration. Two regimes of doping are evidenced with different distributions of dopants in the semi-crystalline structure of P3HT: first crystalline domains are doped by exchange of F_4TCNQ^- with $TFSI^-$ followed by a progressive doping of amorphous regions of P3HT. The best thermoelectric performances are comparable to the ones observed for P3HT doped with tris(4-bromophenyl)ammoniumyl hexachloroantimonate (magic blue) with power factors of 150-160 μW/mK^2. In addition, we demonstrate a long-term stability of the doped films under inert atmosphere over > 50 days. The enhanced stability of TFSI-doped P3HT films is directly related to the specific distribution of dopants inside the semi-crystalline polymer structure. The enhanced stability is analysed in the frame of a modulation-doping mechanism considering the dopant distribution in the polymer structure and its impact on the accumulation layer that is created at the crystal/amorphous interface.

5:00 PM SB02.04.19
Solubilizing Benzodifuranone-Based Conjugated Copolymers with Single Oxygen Containing Branched Side Chains Diego Ropero Hinojosa[1], Nathan James Pataki[2], Pietro Rossi[2], Andreas Erhardt[3], Shubhradip Guchait[4], Francesca Pallini[5], Chris McNeill[3], Christian Müller[6], Mario Caironi[2] and Michael Sommer[1]; [1]TU Chemnitz, Germany; [2]IIT Milano, Italy; [3]Monash University, Australia; [4]CNRS Strasbourg, France; [5]University of Milano-

Bicocca, Italy; [6]Chalmers University, Sweden

Achieving simple methodologies to synthesize, scale up, and process organic polymeric materials from solution is paramount to simplify access to semiconductor devices. In this context, benzodifuranone-based copolymers have shown excellent performance in different electronic applications, such as organic field effect transistors or organic thermoelectric generators. Nevertheless, these materials commonly display limited solubility due to their highly coplanar structures, giving rise to significant aggregation. Large branched alkyl side chains are commonly used to circumvent this problem; however, these side chains suffer from long and cumbersome synthetic routes and high costs. In this work, single ether-containing branched side chains synthesized employing Williamson etherification were prepared to provide a straightforward strategy to attach long side chains to p-conjugated backbones. The starting materials used were costs-economic Guerbert alcohols and α,ω-dibromoalkyls. The robustness of the method allowed both spacers as well as side chain lengths to be varied. Molar masses of benzodifuranone-thiophene copolymers reached up to 50 kg/mol, and solubilities were as high as 90mg/mL. Furthermore, n-doping of the polymers with *N*-DMBI delivered conductivity values three times superior to similar copolymers reported in the literature. The synthetic approach is furthermore extended to different backbone structures.

Charge Carrier Transport in Individual Granules of Sepia Melanin Shahid Khaleel, Zhaojing Gao, Anthony Camus and Clara Santato; Polytechnique Montreal, Canada

Sepia melanin, a naturally occurring pigment found in the ink sac of cuttlefish, has garnered significant interest for its intriguing electrical properties and potential as an organic semiconductor material. Sepia melanin exhibits unique characteristics, such as its moisture-dependent electrical response [1] and broadband optical absorption [2], making it a promising material for applications in organic electronics, energy harvesting, and bioelectronics. Sepia melanin exhibits properties of disordered organic semiconductors whose charge transport behavior is attributable to a combination of band-like and hopping transport mechanisms [3]. The electrical conduction in Sepia melanin is influenced by its complex hierarchical structure, which eventually leads to melanin nanoparticles ~150-200 nm-sized self-assembled into granules. These nanoparticles result from variety of arrangements of pi-pi stacked molecules [4].
In this study, we explored the charge transport properties of Sepia melanin at the nanoscale, with the aim to fully harness Sepia melanin's potential for sustainable optoelectronic technologies.
We focus our investigations on a nanoscale, inter-digitated planar geometry of patterns (inter-electrodes distance ~200-700 nm) as our goal is to detect signals generated by individual granules of Sepia melanin. Patterns are fabricated by Electron Beam Lithography.
Findings from our ongoing study reveal the influence of structural disorder on charge carrier transport in Sepia melanin, including charge carrier localization and trapping effects as it is confirmed from current-voltage measurement. Also, Temperature-dependent electrical characterizations are helping us shed light on aspects related to hopping transport and de-trapping of charge carriers, such as calculating the activation energy.

Such effects represent opportunities for tailoring charge transport characteristics in Sepia melanin-based devices. We observed that Sepia melanin granules reveal their remarkable high electrical conductivity.
Work is in progress to study the Electrochemical Impedance Spectroscopy (EIS) response in dry and wet atmosphere complemented by current-time measurement to confirm the nature of the charge carriers (electrons or ions or both).

Bulk Doping of Conjugated Polymers and Interplay of Their Electrical and Mechanical Properties Christian Müller; Chalmers University of Technology, Sweden

Chemical doping is widely used to modulate the electrical properties of conjugated polymers. Doping of thin films facilitates fundamental spectroscopic studies and, ultimately, is important for the operation of devices from transistors to solar cells. However, some applications such as thermoelectrics and wearable electronics require bulk materials, which complicates doping processes. This talk will explore some of the fundamentals of doping of both thin films and bulk materials. The impact of doping on the electrical as well as mechanical properties will be discussed, and it is shown how doping can be used to tune both the conductivity and stiffness of conjugated polymers. Finally, strategies are explored that permit to decouple the effect of doping on the electrical and mechanical properties.

8:30 AM *SB02.05/SB04.04.02
Doping Glyocolated Polythiophenes with Lithium Salts Christine Luscombe; Okinawa Institute of Science and Technology, Japan

Polymer-based mixed ionic/electronic conductors (MIECs) are receiving increased attention, in part due to their utility across a wide-range of applications. MIECs show valuable properties, including volumetric capacitance changes, transduction of ionic and electronic signals, and biocompatibility. These properties result in a number of useful features, enabling their use in applications such as batteries and ultracapacitors, (bio)sensors, actuators, and organic electrochemical transistors (OECTs). Homopolymer MIECs originally showed limited ionic mobility due to their highly hydrophobic backbones. There has been a significant improvement in their ionic conductivity by introducing polar groups into the solubilizing side chains; the most popular chemistry for the polar side chains is oligoethylene glycol (oEG). This strategy of introducing oEG has driven significant improvements in MIEC performance in a number of conjugated polymer backbones.

Side chains are known to have a profound influence on the morphology, crystallinity, charge carrier concentration, charge thermal stability and ion/water uptake properties of conjugated polymers. By studying a range of polythiophenes across LiTFSI doping concentrations, we are able to elucidate how variations in the side chain architecture influence the evolution of morphology with increasing levels of LiTFSI doping, highlighting the importance of the architecture of oEG side chains in determining the blended material's morphology and resultant ionic and electronic conductivity. The presentation will focus on how small changes in the side chain structure can affect where the LiTFSI is located and thus the conductivity of the materials.

9:00 AM *SB02.05/SB04.04.03
Soft PhotoElectroChemical Systems for Solar Fuels Erin L. Ratcliff; University of Arizona, United States

Highly scalable, durable π-conjugated polymer materials provide control over local environments afforded through synthesis, long-lived charge carrier lifetimes, and flexible, low-cost, and scalable thin film formats which circumvent the shortcomings of inorganic materials (surface states, grain boundaries, challenges in processing, and mechanically unstable platforms). The Center for Soft PhotoElectroChemical Systems (SPECS) is an Energy Frontier Research Center focused on the basic science questions that underpin the development of low-cost, robust energy conversion and energy storage technologies based on new organic polymer (plastic) electronic materials. These materials are predicted to fill a critical position in the U.S. energy portfolio, providing for next-generation fuel-forming platforms (energy conversion) and batteries (energy storage) that cannot currently be achieved with conventional (hard) inorganic materials.

The realization of all-organic semiconductor systems that capture light energy and convert it into chemical energy requires a detailed understanding of structure-property relationships governing the interconnected dynamics of photo-generation, transport, and electron transfer across multiple interfaces. Dark electrochemical processes must be understood before increasing the complexity via light-matter interactions. This talk will focus on increasing complex, multiple interface platforms, towards the goal of photons-to-electrons-to-molecules energy conversion processes for all-polymer photocathodes. A number of emerging *in situ/operando* spectroelectrochemical and scanning electrochemical cell microscopy approaches will be discussed for this exciting new area of energy conversion.

9:30 AM *SB02.05/SB04.04.04
Organic Photodetectors for Shortwave Infrared Sensing Thuc-Quyen Nguyen and Hoang Mai Luong; University of California, Santa Barbara, United States

Shortwave infrared (SWIR) has various applications, including night vision, remote sensing, and medical imaging. SWIR organic photodetectors (OPDs) offer advantages such as flexibility, cost-effectiveness, and tunable properties, however, lower sensitivity and limited spectral coverage compared to inorganic counterparts are major drawbacks. We develop a simple yet effective and widely applicable strategy to extend the wavelength detection range of OPD to a longer wavelength, using resonant optical microcavity. We demonstrate a proof-of-concept in PTB7-Th:COTIC-4F blend system, achieving external quantum efficiency (EQE) > 50 % over a broad spectrum (450 – 1100 nm) with a peak specific detectivity (D*) of 1.1 x 10^{13} Jones at 1100 nm, while cut-off bandwidth, speed, and linearity are preserved. By employing a novel small-molecule acceptor IR6, a record high EQE = 35 % and D* = 4.1 x 10^{12} Jones are obtained at λ = 1150 nm. This work emphasizes the importance of optical design in optoelectronic devices, presenting a considerably simpler method to expand the photodetection range compared to a traditional approach that involves developing absorbers with narrow optical gaps.

Glassy Metallic Character in Amorphous Coordination Polymers of Tetrathiafulvalenetetrathiolate John S. Anderon[1], Jiaze Xie[2], Patrick Crossland[1] and Chen-Yu Lien[1]; [1]University of Chicago, United States; [2]Princeton, United States

New conducting coordination polymers featuring tetrathiafulvalenetetrathiolate (TTFtt) linkers will be presented. These materials possess no long-range order, but are still highly conductive and display signatures of glassy metallic charge transport. Deeper characterization of these charge transport properties including Hall effect measurements will be discussed, as well as new efforts in processing these materials and altering their electronic structures via doping or metal ion exchange.

11:00 AM SB02.06.02
Understanding Polymorphism-Driven Thermoelectric Properties in Molecularly Doped Poly(Dodecyl-Quarterthiophene) through Microstructure Gradients Shrayesh Patel; University of Chicago, United States

Our research delves into the intricate relationship between microstructure changes induced by thermal annealing and the resulting charge transport properties in poly(dodecyl-qaurterthiophene) (PQT). Employing targeted characterization techniques, including GIWAXS and ellipsometry, the study unveils the polymorphism and chain orientation within PQT and emphasizes the crucial role of interdigitation of side chains. Through vapor doping with F4TCNQ, the study demonstrates that polymorphs strongly control doping efficiency, thereby significantly influencing charge transport properties. Specifically, the research reveals that the 100 °C annealed sample, characterized by tightly packed side chains, displays low doping efficiency and corresponsing low electronic conductivity, whereas the 130 °C annealed sample exhibits markedly improved electronic conductivity from higher doping efficiency. Additionally, the study presents a novel method for fabricating continuously graded (CG) thin films of PQT using controlled thermal annealing, revealing diverse 1D in-plane microstructure gradient profiles modulating electronic conductivity and Seebeck coefficient across a 5 mm distance. Comparing these CG films to their equivalent uniform counterparts, the study showcases their enhanced cooling performance due to the effective redistribution of Joule heating and Peltier cooling effects. These findings underscore the significance of understanding the interplay between local order, polymorphism, and doping efficiency in molecularly doped conjugated polymers. In turn, this work provides valuable insights for the design of semiconducting polymers tailored for precise microstructure and doping levels for organic thermoelectric applications.

11:15 AM SB02.06.03
***Operando* X-Ray Fluorescence for Direct Ion Composition and Mobility Quantification in Organic Mixed Ionic/Electronic Conductors** Ruiheng Wu, Xudong Ji and Jonathan Rivnay; Northwestern University, United States

Organic mixed ionic-electronic conductors (OMIECs) represent a class of organic materials, mostly conjugated polymers, characterized by their ability to transport both electronic and ionic charges. Understanding the composition and mobility of ions within OMIECs is of paramount importance, as it directly influences the performance and fundamental mechanisms of OMIEC-based devices. Typically, such assessments have relied on indirect methods, often based on assumptions that may not always be accurate. Ex situ X-ray fluorescence (XRF) has been employed to quantify ion composition in OMIECs under different doping states, but potential errors could arise due to the need for sample washing to remove residual electrolyte.
Instead, operando XRF emerges as a powerful and direct tool for investigating dynamic ion composition and transport in OMIECs during electrochemical operations. Herein, operando XRF was harnessed to probe ion transport in a model OMIEC material, poly(3,4-ethylenedioxythiophene) polystyrene sulfonate (PEDOT:PSS). The findings from this investigation are highly enlightening: the initial electrochemical cycle showed a slow electrowetting and cation-proton exchange. Subsequent cycles demonstrated minimal cation fluctuation, around 5%, implying a rapid, stable response with small, consecutive steps of ion migration. The calculated effective ion mobility displayed thickness-dependent behavior, underscoring the significance of interfacial ion transport pathways with higher effective mobile ion density. This decoupling of bulk and interfacial effects on ion mobility enhances our comprehension of ion transport in both conventional and vertical organic electrochemical transistors (OECTs). Furthermore, the correlation between ion mobilities, domain boundaries, and mobile ion density suggests that ions within OMIECs migrate in a highly complex way. These findings promise to advance our understanding of ion transport in OMIECs and related devices, offering valuable insights that can guide molecular design, material processing, and charge/ion migration modeling. Ultimately, this research can contribute to enhanced device performance and faster response times. Importantly, this methodology is not limited to OMIECs; it can be effectively applied to investigate complex ion transport mechanisms in various mixed conductors, spanning diverse fields such as batteries and solar cells, holding the potential to revolutionize the design and optimization of a wide range of technologies.

SESSION SB02.07: Organic Semiconductor Design Through New Modeling Approaches

1:30 PM *SB02.07.01
Theoretical Description of Phonons Controlling Charge and Heat Transport in Organic Semiconductors Jerome N. Cornil; University of Mons, Belgium

The charge mobility in molecular crystals is governed by the extent of delocalization of the charge carriers, in turn dictated by the extent of fluctuations of the transfer integrals by lattice phonons. The latter also act as heat carriers in organic semiconductors. In order to maximize electrical conductivity and minimize thermal conductivity (for thermoelectric applications), there is a need for a detailed description of the phonons impacting the most charge and heat transport and for the establishment of structure-property relationships. In this contribution, I will describe our recent efforts aiming at assessing the role of individual phonons in the thermal fluctuations of the transfer integrals as well as the impact of phonon dispersion. I will also present some recent simulations of heat transport showing that the extent of delocalization of the phonons controls the thermal conductivity.

2:00 PM *SB02.07.02
High-Throughput Models of Conjugated Polymers Alessandro Troisi and Hesam Makki; University of Liverpool, United Kingdom

Structural models of semiconducting polymers are challenging to generate, validate against experiments and interrogate for novel properties and research hypotheses. Despite their importance, producing a model of reasonable quality requires weeks/months of human and computer time. This situation is totally unsuitable for designing polymers, deriving structure-property relations from large data sets or simply engage with a very dynamic community of synthetic chemists and characterization experts. This lecture explores the recent advances toward high-throughput modelling for polymeric materials and the workflow derived to be deployed over hundreds of different polymers. Methods to extract relevant properties of charge transport will be discussed alongside recent advances in the study of highly doped polymers. As common in our research group, these large scale calculations are used to derive practical generalizations and design rules.

Machine Learning Guided Prediction of Thermal Properties and Identification of Crystallizable Organic Semiconductors Holly Johnson[1], Filipp Gusev[2], Jordan T. Dull[1], Yejoon Seo[1], Rodney D. Priestley[1], Olexandr Isayev[2] and Barry P. Rand[1,1]; [1]Princeton University, United States; [2]Carnegie Mellon University, United States

Crystalline organic semiconductors feature improved exciton diffusion length and charge carrier mobility compared to their amorphous counterparts. Certain organic molecular thin films can be crystallized at large-scale via annealing of initially prepared amorphous layers. These films ideally crystallize as platelets with long-range order on the scale of tens to hundreds of microns, but have also been seen to crystallize as spherulites or to resist crystallization entirely. Molecules that can transform into a platelet morphology feature high melting point and crystallization driving force (ΔG_c). Here, we employ machine learning to identify candidate organic materials that were predicted to crystallize into large-area platelets by estimating the aforementioned thermal properties. Six materials identified by the machine learning algorithm were evaluated for their bulk thermal properties using differential scanning calorimetry, and their crystallization behavior via thin film crystallization. Of these six materials, three crystallized as platelets, one crystallized as a spherulite, and two resisted crystallization, displaying a successful application of machine learning in the scope of organic thin film crystallization and reinforcing the principles of melting point and ΔG_c as metrics that govern the crystallization behavior of organic thin films.

3:45 PM *SB02.07.04
Strategies to Improve the Performance of n-Type Conjugated Polymers Derya Baran; King Abdullah University of Science and Technology, Saudi Arabia

The development of organic semiconductors (OSCs) has gained significant attention in the realm of organic electronics (OEs). Organic thermoelectrics (OTEs) are of interest owing to their potential for harnessing power from residual waste heat and powering autonomous wearable devices. Although P-type OTEs showed robust thermoelectric performance from an early stage, the development of n-type OTEs has been slower in comparison, owed to limited doping efficiency and rapid degradation of electronic properties. Here, we present DPP-based n-type conjugated polymers (CPs) for OTEs with three different strategies to enhance their charge transport and TE performance. Our strategies are based on the Hansen solubility parameter (HSP) framework and provide insight to improve charge transport in doped OSCs from morphology control to solvent-host-dopant interaction. First, we utilize HSP to screen thousands of solvents to refine our selection and succeed in controlling the mesoscale morphology of DPP-based n-type CPs films transitioning from nanofibrils into nanofibers. We found that the nanofiber morphology can simultaneously maintain their electrical properties and enhance its mechanical robustness. Second, we address the limitations of the electrical conductivity (σ) of n-type CP by employing HSP to assess the suitable solvent that improves miscibility and charge transport. We found that solvent having higher solubility of dopant, and conjugated backbone of the CP can increase σ without sacrificing Seebeck coefficient (S). This work emphasizes the effectiveness of HSP-guided solvent selection in hindering σ-S trade-off and limitations from solution mixing doping. Last, we propose the idea of self-induced anisotropy in n-type OTEs which enhance the thermoelectric power factor (PF) by mitigating the trade-off between σ and the S. Utilizing HSP theory, we try to understand the solvent-host-dopant intermolecular interactions and elucidate the origin of self-induced anisotropy. We found that a preferential edge-on orientation would increase the in-plane delocalization length and thus improved the electrical conductivity without hindering the S.

SESSION SB02.08: Doping of Organic Semiconductors I
Session Chairs: Mariano Campoy-Quiles and Xiaodan Gu
Thursday Morning, April 25, 2024
Room 437, Level 4, Summit

8:15 AM *SB02.08.01
The Design, Synthesis and Application of Molecular Dopants for Electronics and Opto-Electronics Seth R. Marder[1,2]; [1]University of Colorado Boulder, United States; [2]National Renewable Energy Laboratory (NREL), United States

In this talk I shall describe issues related to the design and application of dopants for organic electronic and opto-electronics and highlight factors that influence how to select dopants to be paired with various materials. I will also discuss preliminary studies on doping materials with chiral dopants and doping chiral materials with an achiral dopant.

8:45 AM SB02.08.02
Ground-State Electron Transfer in All-Polymer Donor: Acceptor Blends enables The Aqueous Processing of Water-Insoluble Conjugated Polymers Tiefeng Liu, Johanna Heimonen, Qilun Zhang, Mats Fahlman, Renee Kroon and Simone Fabiano; Linkoping University, Sweden

Conjugated polymers offer a unique blend of solution processability, mechanical flexibility, and semiconducting properties, making them invaluable for diverse applications in industries ranging from displays and energy storage to healthcare. However, conventional processing methods often involve hazardous solvents, posing challenges for broad commercial and sustainable adoption. To address this, we introduce a novel approach based on mutual electrical doping in donor:acceptor polymer blends, which facilitates the dispersion of water-insoluble conjugated polymers in aqueous solutions. This approach leads to macromolecular charge-transfer salts with 10,000× higher electrical conductivities than the pristine polymers, low work function, and excellent thermal/solvent stability, providing a versatile platform for various electronic devices. The resulting conductive, water-processable inks demonstrate exceptional performance in non-fullerene organic solar cells, organic electrochemical transistors, inverters, and artificial neurons. This breakthrough offers a practical solution for achieving large-scale and sustainable implementation of organic electronics without the need for traditional chemical modifications.

9:00 AM SB02.08.03
Spontaneous Modulation Doping in Semi-Crystalline Conjugated Polymers Aditya Dash[1], Shubhradip Guchait[2], Dorothea Scheunemann[1], Vishnu Vijayakumar[2], Nicolas Leclerc[3], Martin Brinkmann[2] and Martijn Kemerink[1]; [1]University of Heidelberg, Germany; [2]Institute Charles Sadron, France; [3]Université de Strasbourg, France

The possibility to control the charge carrier density through doping is one of the defining properties of semiconductors. For organic semiconductors, the doping process is known to come with several problems associated with the dopant compromising the charge carrier mobility by deteriorating the host morphology and/or introducing Coulomb traps. While for inorganic semiconductors these factors can be mitigated through (top-down) modulation doping, this concept has not been employed in organics. Here, we show that properly chosen host/dopant combinations can give rise to spontaneous, bottom-up modulation doping, in which the dopants preferentially sit in an amorphous phase, while the actual charge transport occurs predominantly in a crystalline phase with an unaltered microstructure, spatially separating dopants and mobile charges. Combining experiments and numerical simulations, we show that this leads to exceptionally high conductivities at relatively low dopant concentrations.

9:15 AM SB02.08.04
Doping Effectiveness and Stability in Semiconducting Polymers Meghna Jha, Joaquin Mogollon Santiana, Aliyah A. Jacob, Kathleen Light, Megan L. Hong, Michael R. Lau, Leah R. Filardi, Sadi M. Gurses, Coleman X. Kronawitter and Adam J. Moule; University of California, Davis, United States

Molecular doping of semiconducting polymers has emerged as a prominent research topic in the field of organic electronics with new dopant molecules introduced regularly. $FeCl_3$ has gained attention as a p-type dopant due to its low-cost, availability, ability to dope high ionization energy co-polymers, and its use as a dopant that can be used with anion exchange. Here, we use a combination of UV-Vis-NIR spectroscopy, four-probe sheet resistance measurements, and X-ray absorption near-edge structure (XANES) spectroscopy to perform lifetime measurements to assess the stability of the doped polymers over time, which is crucial for evaluating the long-term performance and reliability of the doped films. $FeCl_3$ can cause radical side reactions that damage the conjugated polymer backbone, leading to degradation of the electronic properties. The rate of this degradation is orders of magnitude higher when the film is exposed to air. Anion exchange doping can reduce the $[FeCl_4]^-$ concentration, but does not necessarily improve the doping lifetime because anion exchange electrolytes can serve as co-reactants for the degradation reaction. By comparison, doping with (2,3,5,6-Tetrafluoro-2,5-cyclohexadiene-1,4-diylidene)dimalononitrile (F4TCNQ) as the reactive dopant results in lower initial conductivity, but the lifetime of the doped polymer is almost tripled as compared to $FeCl_3$ doped polymer films. These findings highlight that the use of $FeCl_3$ as a molecular dopant requires a cost/benefit analysis between higher initial doping levels and lower

film stability.

10:30 AM *SB02.09.01
Charge Transport Physics of Organic and Metal Halide Perovskite Semiconductors Henning Sirringhaus; Cambridge University, United Kingdom

Organic and metal halide perovskite semiconductors are soft functional materials that are emerging as a viable semiconductor technology in industries such as displays, electronics, renewable energy, sensing and healthcare. A key enabling factor has been significant scientific progress in improving the charge transport properties and carrier mobilities of these materials, which has been made possible by better understanding of the structure-property relationships and the underpinning charge transport physics. Here we aim to present a coherent review of how we understand the unique charge transport physics in these two classes of semiconductors and discuss similarities and differences. We are also interested in the use of these materials in thermoelectric devices and we will discuss approaches to their controlled doping and understanding of the relevant thermoelectric physics.

11:00 AM SB02.09.03
Effects of Nanoscale Morphology on Molecular Doping in Conjugated Polymers Sung-Joo Kwon[1], Rajiv Giridharagopal[1], Justin Neu[2], Wei You[2] and David S. Ginger[1]; [1]University of Washington, United States; [2]University of North Carolina at Chapel Hill, United States

Conjugated polymers are inherently nanostructured, with a mixture of crystalline and amorphous domains, investigating the underlying mechanism of doping benefits from nanoscale real-space imaging. Here, we studied the molecular doping on P($g_3$2T-TT) in solution-dripping doping with varying film-casting condition and dopants. Firstly, we perform spectroelectrochemistry to calibrate the optical bleaching to known polaron levels, and calculate the doping efficiency of molecular doping. We further perform functional atomic force microscopy (scanning Kelvin probe and conductive atomic force microscopy) methods to visualize the dopant aggregation and heterogeneity of local extent of doping on CPs. We show that the doping efficiency and dopant aggregation are both correlated with the ability of the dopant/solvent solution to swell the conjugated polymer, with combinations that swell resulting in more efficient doping and smoother films with less aggregation. We use these methods to provide a link between optical measurements of doping and local work function variations for films that have been molecularly and electrochemically doped. These techniques provide spatial mapping of topology with work function and time-resolved doping behavior of high resolution (sub-micron scale). Additionally, we investigated further dopant aggregations upon modifying the solvent of the dopant solution, side-chain and crystallinity of CPs; it reveals that swelling of dopant solution, and crystallinity both govern the aggregation of dopant on CPs, thereby limiting the doping efficiency of the CPs. This work will provide significant insight to understand molecular or electrochemical doping of conducting polymers at the microscopic level.

11:15 AM *SB02.09.04
Impact of Chain Conformation and Interchain Contacts on Charge Transport in Conjugated Polymers Jenny Nelson, Jack F. Coker, Jarvist M. Frost and Xingyuan Shi; Imperial College London, United Kingdom

Charge transport in organic semiconductors such as conjugated polymers proceeds through a combination of intrachain and interchain charge transfer events. Predicting transport properties for any new material requires an understanding of how the chemical structure and physical organisation of polymer chains influence these two processes. The polymer's conformational phase space influences intrachain charge dynamics through variations in the structure, and hence energy, of polaron states and also influences the type of interchain contacts that can be formed. We consider the case of the stiff, high-mobility indacenodithiophene-*co*-benzothiadiazole polymer (C16-IDTBT) and use a variety of electrical and structural measurements as well as molecular dynamics, electronic structure calculations and charge transport simulations to probe the nature of the intra and inter-chain charge transfer processes. We conclude that the polymer's unusually high connectivity, rather than high interchain coupling, is responsible for its hole mobility. We compare the behaviour with other conjugated polymers including polyfluorenes and polythiophenes, in terms of their chemical structure. We conclude by reviewing the factors that will ultimately limit charge transport in conjugated polymers.

SESSION SB02.10: Charge Transport in Organic Semiconductors II

1:45 PM *SB02.10.01
Charge Transport Properties of n-Type Conjugated Polymers and Photovoltaic Blends Samson A. Jenekhe, Sarah West and Duyen Tran; University of Washington, United States

Understanding of the charge transport properties of conjugated polymers is central to their applications in organic electronic devices, including organic light-emitting diodes, thin film transistors, electrochemical transistors, organic photovoltaics, thermoelectric devices, etc. Nevertheless, the underlying

mechanisms of how molecular and supramolecular factors influence the charge transport properties of semiconducting polymers remain to be fully elucidated. In this talk, I will highlight some examples of our recent work in addressing this knowledge gap for n-type and p-type conjugated polymer films as well as for photovoltaic polymer blend films. Our studies in one area have investigated how polymer molecular weight influences the charge transport properties in two topologically distinct classes of n-type conjugated polymers – those with rigid-rod chain topology and those with semi-flexible chain topology – and found that the chain length dependence of carrier mobility and mechanism of electron transport depend on the polymer chain topology. A detailed characterization of the thin film microstructures of the materials provided insights on the structural disorder and energetic disorder as a function of polymer chain length. How side chain engineering and tuning of the donor-acceptor character on the ladder polymer backbone influence their thin film microstructures and charge transport properties are investigated in a series of p-type conjugated ladder polymers. In another example, we have investigated the charge transport properties of binary blends of interest in all-polymer solar cells, including the roles of the molecular weights of the polymer components in achieving bipolar-symmetric blend charge transport and optimal morphology, photophysics, and device efficiency.

2:15 PM SB02.10.02
Multi-Band Filling and Non-Equilibrium Charge Transport in Conjugated Polymers at Charge Densities on The Order of 10^{21} cm^{-3} Xinglong Ren[1], Dionisius Hardjo Lukito Tjhe[1], Ian Jacobs[1], Gabriele D'Avino[2], Tarig Mustafa[1], Thomas Marsh[1], Lu Zhang[1], Yao Fu[1], Ahmed E. Mansour[3], Yuxuan Huang[1], Wenjin Zhu[1], Ahmet Hamdi Unal[1], Vincent Lemaur[4], Claudio Quarti[4], Jin-Kyun Lee[5], Iain McCulloch[6], Martin Heeney[7], Norbert Koch[3], Clare Grey[1], David Beljonne[4], Simone Fratini[2] and Henning Sirringhaus[1]; [1]University of Cambridge, United Kingdom; [2]Institut Néel, France; [3]Humboldt-Universität zu Berlin, Germany; [4]University of Mons, Belgium; [5]Inha University, Korea (the Republic of); [6]University of Oxford, United Kingdom; [7]Imperial College London, United Kingdom

Organic electrochemical transistors (OECTs) provide us a powerful tool for studying charge transport in conjugated polymers over a wide range of charge densities. It has been reported that in both n-type and p-type OECTs, charge densities on the order of one charge per monomer (~10^{21} cm^{-3}) can be achieved. At such high charge densities, Coulomb interactions among electrons and between electrons and counter-ions are expected to play a role in charge transport. However, charge transport in this regime, as well as the many-body correlated physics, is still not as well understood as charge transport in devices with much lower charge densities (e.g., organic field-effect transistors).

In this work, we show that in OECTs based on a class of p-type donor-acceptor polymers, it is possible to completely empty the HOMO and eventually access the HOMO-1 orbitals without any degradation, which is supported by a combination of electrical, thermoelectric, and photoemission spectroscopic measurements. More interestingly, under such extreme band filling conditions, by adding a second field-effect back-gate to the OECT, we observe unusual field-effect response when the ionic motions are frozen. Both the shape of the back-gate transfer curve (graphene-like) and the magnitude of drain current modulation (up to 300%) are substantially different from what one would expect from a conventional field-effect device based on an ultra-heavily doped polymer. Temperature-dependent measurements suggest that the unusual back-gate field-effect response is a non-equilibrium phenomenon, which provides unique insight into the formation of a frozen, soft gap in the density of states driven by Coulomb interactions.

2:30 PM *SB02.10.03
Chiral Assemblies of Conjugated Polymers for Controlling Charge and Spin Transport Ying Diao; University of Illinois at Urbana-Champaign, United States

Intimately connected to the rule of life, chirality remains a long-time fascination in biology, chemistry, physics and materials science. Chiral structures, e.g., nucleic acid and cholesteric phase developed from chiral molecules are common in nature and synthetic soft materials. Chiral semiconductors have been long leveraged by Nature to efficiently transduce energy and transfer electrons. However, it has been rarely used in synthetic semiconductors due to synthetic challenges. We recently discovered chiral emergence from high performance achiral conjugated polymers, in which hierarchical helical structures spanning nano- to micron scales emerge from a multistep assembly pathway in an evaporating meniscus during coating and printing. We further show that such hierarchical helical structures can be largely modulated by non-equilibrium processing during solution printing as well as by subtle changes in the polymer structure. With the ability to widely tune helical structures, we set out to demonstrate the ability of chiral helical structures in enhancing chemical doping efficiency and conductivity in redox polymers, and in efficiently converting spin to charge promising for spintronic applications.

3:30 PM *SB02.11.01
π-Conjugated Nickel Complexes as n-Type Organometallic Semiconductors for Thermoelectric Generators Michihisa Murata; Osaka Institute of Technology, Japan

Flexible thermoelectric generators, which convert waste heat into electricity, have received increasing attention as convenient and low-cost energy-harvesting devices. p-Type and n-type organic and organometallic semiconducting materials are particularly suitable for thermoelectric materials on account of their very low thermal conductivity, which affords significant advantages not only in realizing high efficiency, but also in generating a temperature gradient. However, the development of n-type organic materials has been hampered partially on account of their instability in air upon doping with an n-dopant.
One promising example of n-type organometallic semiconductors is π-conjugated nickel-ethenetetrathiolate (NiETT), which exhibits high air-stability and n-type thermoelectric behavior. We envisioned that the new design of π-conjugated ligands in nickel complexes should have a positive impact on the conductivity and the thermoelectric properties. In order to increase the accessible variety of this class of complexes, we have developed a versatile method for the synthesis of a variety of π-conjugated Ni complexes and examined their performance. Even though they are insoluble in virtually all common organic solvents, we found that the conductivity of the resulting films can be markedly improved by the choice of the π-conjugated core. For example, a nickel complex containing thieno[3,2-*b*]thiophene units was designed and synthesized. Composite films of the resulting nickel complex and polyvinylidene difluoride (PVDF), which can be fabricated via a simple solution process under atmospheric conditions, exhibit remarkably high n-type conductivity (>200 S/cm). Moreover, the thermoelectric power factor of the n-type composite film was proven to be air stable. A grazing-incidence wide-angle X-ray diffraction analysis (GIWAXD) indicated a significant impact of introducing the thieno[3,2-*b*]thiophene core into the backbone of the nickel complex on

the orientation within the composite films.
These results on the design and synthesis of air-stable n-type materials should contribute to the generation of advanced materials with potential applications in flexible thermoelectric generators.

4:00 PM SB02.11.02
Controlling Energetic and Structural Disorder of Doped Conjugated Polymers for High-Performance Organic Thermoelectrics Kilwon Cho; Pohang University of Science and Technology, Korea (the Republic of)

Molecular doping is a fascinating technology that can easily increase the electrical conductivity of conjugated polymers. It is actively being explored as a fundamental approach for developing thermoelectric materials and flexible bio-integrated electronics. A variety of dopants, from inorganic salts to molecular dopants and Lewis acids, along with innovative doping strategies, have successfully pushed the electrical conductivity of conjugated polymers to approximately ~1000 S/cm. Despite these noteworthy outcomes, inherent limitations hinder further progress in this field. Conjugated polymers lack a three-dimensional crystal structure and contain structural imperfections, leading to a substantial energetic disorder with a broad distribution of the density of states in their energy landscape. Moreover, the incorporation of dopants introduces structural disorder in crystalline ordering, localizing charge carriers to just a few monomer units. This energetic and structural disorder acts as a significant hurdle to advancing doped conjugated polymers. In this talk, I will present a chemically doped conjugated polymer, indacenodithiophene-co-benzothiadiazole (IDTBT), which is able to maintain low energetic disorder due to the highly planar backbone chain structure. I will thoroughly introduce the relationship between the exceptional charge transport properties revealed by the Kang-Snyder model and narrow-band model, and the polymer chain structure inspected through Raman spectroscopy and DFT calculations. Also, I will discuss a doping strategy aimed at reducing dopant-induced disorder in highly doped conjugated polymers, with a particular focus on a promising Lewis acid dopant, tris(pentafluorophenyl)borane (BCF). The improvements in charge transport properties that result from this strategy will be substantiated through an analysis of structural disorder, energetic disorder, and charge carrier localization, including quantitative investigation using coherence length, paracrystallinity, and paramagnetic susceptibility. Lastly, I will provide a brief overview of the high thermoelectric performance achieved in our research and present the potential of thermoelectric materials based on doped conjugated polymers.

4:15 PM SB02.11.03
Unlocking The Potential of Solution-Processed PEDOT:PSS Thin Films for Efficient Thermoelectric Energy Conversion Juhyung Park and Jeonghun Kwak; Seoul National University, Korea (the Republic of)

Thermoelectric (TE) generation using solution-processable conjugated polymers holds great promise for low-temperature energy harvesting due to their versatility in materials, processes and form-factors. Among these polymers, poly(3,4-ethylenedioxythiophene):poly(styrenesulfonate) (PEDOT:PSS) is considered a promising candidate owing to its high electrical conductivity, flexibility, and air stability. However, a lack of understanding on the relationship between microstructure and TE charge transport properties has been a significant obstacle, impeding further enhancements in performance of solution-processable PEDOT:PSS. Here, we present a solution-processed, high-performance TE device based on a PEDOT:PSS thin film and thoroughly investigate their microstructure–thermoelectric performance–charge transport property relationships. We first fabricated a highly conductive PEDOT:PSS films using a super acid, where the σ values increased up to ~3600 S cm^{-1} primarily due to the highly ordered microstructure with PSS removal. Through a successive reduction process, we achieved the highest power factor of 534.5 μW m^{-1} K^{-2} with delocalized charge transport properties. Additionally, high electronic tunability of the reducer allowed us to investigate the Seebeck–conductivity relation over a wide range of σ, suggesting that the maximum *PF* value may surpass the experimentally obtained values. To identify the origin of the discrepancy, we analyzed the macro- and micro-scale charge transport properties using the temperature-dependent σ, Hall effects, and magnetoconductance of the films, together with the morphology, and found out that the connectivity between crystalline domains and the resulting high degree of percolation for transport are important factors toward the theoretically ideal *PF*.

4:30 PM SB02.11.04
3D-Printed Bulk Organic Thermoelectrics with High Power Output for Stretchable Electronics Francisco Molina-Lopez; KU Leuven, Belgium

Distributed electronics are gaining traction for application in wearables and the Internet of Things (IoT). The increasing complexity of these systems comes with an acute need for energy that batteries struggle to satisfy, either because they are too stiff to be seamlessly integrated into soft wearable electronics, or because their replacement is unfeasible for the numerous and highly distributed nodes of the IoT. In those scenarios, thermoelectric (TE) materials, which can convert directly waste heat into electrical power, hold great potential. Conveniently, it has been suggested that TEs are more efficient than other thermal engines for low-power applications[1] like wearables and the IoT. However, the widespread of TE generators (TEG) is hampered by their expensive fabrication process; the use of critical elements such as Bi and Sb; and their limited form factor (rigid, flat, and small).[2] The ubiquity of the IoT nodes and the particular form factor of wearable devices (stretchable and large-area) call for a new technology that strongly relies on clean and abundant materials like polymers, and on scalable and versatile fabrication techniques, like printing. While the development of conducting polymers for organic thermoelectrics (OTEs) has recently witnessed tremendous progress, the reality is that the integration of such materials in actual devices has been seldom attempted, and when attempted, the high performance of the materials did not translate into performing devices. The reason for such lackluster outcome resides in the fact that most OTE materials are developed as thin films using technologies borrowed from organic FETs and photovoltaics. In sharp contrast, performing TEGs (such as commercial Peltier elements) are inherently bulk devices, presenting low internal resistance and capable of sustaining large temperature gradients in the through-plane direction, none of which is possible for thin films.

In my research group, we are working towards the development of high-performing 3D-printed bulk OTEs, which can be directly printed over large areas on flexible/stretchable substrates. In particular, we are developing direct ink writing (DIW) of conjugated polymers, which requires the careful formulation of pastes with very particular rheology, namely shear thinning and high yield strength. Moreover, specific strategies for drying and post-processing are necessary to ensure high shape fidelity. In return, DIW is not only potentially cheap and suitable for soft substrates, but offers also enough processing versatility to tune material morphology while enabling original device architectures that allow on-skin integration (to power wearables using the heat emitted by the human body) and conformability to hot curved surfaces, like hot pipes or engines (to power IoT nodes).

SESSION SB02.12: Doping of Organic Semiconductors II
Session Chairs: Jianguo Mei and Chad Risko
Friday Morning, April 26, 2024
Room 437, Level 4, Summit

8:30 AM *SB02.12.01
Dopant Complexes—A Highly Stable and Almost Universal Doping System for Organic Semiconductors Mariano Campoy-Quiles; ICMAB-CSIC, Spain

Chemical doping of organic semiconductors (OSCs) is mandatory in order to improve charge transport to the level required for applications such as thermoelectrics. However, the typical dopants used, such as F_4TCNQ or $FeCl_3$, invariably present limitations in terms of processability, thermal stability and/or generality. In this contribution, we will present Lewis-paired complexes as an alternative class of high-performance dopants that, remarkably, address all of the aforementioned drawbacks. Focus is given to solution-processable complexes formed by the Lewis acid BCF and F_4TCNQ bearing Lewis-basic -CN groups. Due to its exceptionally high electron affinity of ~6 eV, BCF:F_4TCNQ is shown to dope a broad range of OSCs (over 20 of which were studied) including non-fullerene acceptors and polyfluorenes. State of the art mobilities (up to 900 S cm^{-1}) can be obtained with this dopant system, which, moreover, exhibits a 3-fold higher dedoping activation energy compared to the neat constituent dopants making this a promising dopant system for thermoelectrics. Then, we will discuss the mechanism of complexation subsequent doping by looking at several Lewis acids, molecular dopants, and microstructures, as well as looking at DFT calculations. Finally, the capability of this system to be used for local doping will be demonstrated.

9:00 AM SB02.12.02
Mapping Ions and Polarons in Organic Mixed Conductors at The Nanoscale Connor G. Bischak; The University of Utah, United States

Organic mixed ionic-electronic conductors have emerged as promising materials for an array of devices that leverage mixed conductivity, including bioelectronics, biosensors, and neuromorphic computing. One challenge of understanding structure-function relationships in OMIECs is the heterogeneous nature of these materials at the nanoscale, which impacts both ionic and electronic transport processes. To uncover nanoscale structure-property relationships, our group has developed ways to image ion and polaron distributions with ~10 nm spatial resolution using photoinduced force microscopy (PiFM). We correlate these measurements with nanoscale stiffness mapping to directly relate local crystallinity to local ion and polaron concentrations. Our images show that ions and polarons preferentially reside in the crystalline regions of organic mixed conductors, consistent with previous bulk studies.

9:15 AM SB02.12.03
Pure Spin Current and Large Inverse Spin Hall Voltages in a Nonconjugated Radical Polymers Hamas U. Tahir, Carsten Flores-Hansen, Kangying Liu, Brett M. Savoie and Bryan Boudouris; Purdue University, United States

Spintronics is emerging as a potentially efficient alternative to traditional electronic devices that use spin rather than electric currents. Despite this, state-of-the-art non-magnetic metals and highly doped conjugated polymers that are critical for spin manipulation suffer from fundamental performance and stability issues when transforming spin currents to transverse electrical currents via Inverse Spin Hall Effect (ISHE). Nonconjugated radical polymers with unpaired electrons offer a unique solution to these challenges owing to their paramagnetic nature and ability to transport pure spin currents by rapid radical-radical exchange interactions with in the material and at device interfaces. Thus, there is a critical need to investigate these class of materials for their spin transport properties in practical device applications. Here, we investigate the spin-transport characteristics of two non-conjugated radical polymers named poly (4-glycidyloxy-2,2,6,6-tetramethylpiperidine-1- oxyl) (PTEO), and poly[3-(4-(1-(3-methoxy-2-methylpropyl)-1*H*-1,2,3-triazol-4-yl)phenyl)-1,5-dimethyl-1*H*-1,2λ^2,4,5-tetrazin-6(5*H*)-one], poly(verdazyl ethylene oxide) (PVEO). These polymers show excellent spin-filtering effect leading to giant magnetoresistance(GMR) effect of ~ 80 % in PTEO and ~ 35 % in PVEO at 4 K respectively. This relatively large GMR can be attributed to the radical-radical exchange interactions that promote spin-dependent charge transfer under the presence of external magnetic field. Large room temperature ISHE voltages of 0.10 mV in PTEO and 0.40 mV in PVEO demonstrate their exceptional capability in transporting pure spin currents. These values are comparable to many inorganic semiconductors and higher than many metal-free doped conjugated polymers. Our results demonstrate the first ever application of radical polymers in spintronic devices and thereby paves the way for further development of this field in spintronics community.

9:30 AM SB02.12.04
Electrically Programmed Doping Gradients Optimize the Thermoelectric Power Factor of a Conjugated Polymer Jian Liu[1], Mariavittoria Craighero[1], Vandna K. Gupta[1], Dorothea Scheunemann[2], Sri H. Paleti[1], Emmy Järsvall[1], Youngseok Kim[1], Kai Xu[3], Juan Sebastian Reparaz[3], Lambert Jan Anton Koster[4], Mariano Campoy-Quiles[3], Martijn Kemerink[2], Anna Martinelli[1] and Christian Müller[1]; [1]Chalmers University of Technology, Sweden; [2]Heidelberg University, Germany; [3]ICMAB-CSIC, Spain; [4]University of Groningen, Netherlands

Functionally graded materials (FGMs) have been widely explored in the context of inorganic thermoelectrics, but not yet in organic thermoelectrics. Here, the impact of doping gradients on the thermoelectric properties of a chemically doped conjugated polymer is explored. The in-plane drift of counterions in moderate electric fields is used to create lateral doping gradients in films composed of a polythiophene with oligoether side chains, doped with 2,3,5,6-tetrafluoro-tetracyanoquinodimethane (F_4TCNQ). Raman microscopy reveals that a bias voltage of as little as 5 V across a 50 µm wide channel is sufficient to trigger counterion drift, resulting in doping gradients. The effective electrical conductivity of the graded channel decreases with bias voltage, while an overall increase in Seebeck coefficient is observed, yielding an up to 8-fold enhancement in power factor. Kinetic Monte Carlo simulations of graded films explain the increase in power factor in terms of a roll-off of the Seebeck coefficient at high electrical conductivities in combination with a mobility decay due to increased Coulomb scattering at high dopant concentrations. Therefore, the FGM concept is found to be a way to improve the thermoelectric performance of not yet optimally doped organic semiconductors, which may ease the screening of new materials as well as the fabrication of devices.

9:45 AM SB02.12.05
Polaron Characteristics in Doped Conjugated Polymers Joel H. Bombile, Yusuf O. Augustine, Kyle N. Baustert, Kenneth R. Graham and Chad Risko; University of Kentucky, United States

Doping semiconducting polymers enables a variety of applications and is important for improving the performance of many devices. The process of doping involves injecting or transferring charges to a host material. The injected charges are stabilized by the reorganization of nuclei and electronic polarization to form polarons. Each polaron charge is balanced by a counterion, either an ionized dopant or a guest ion, to ensure electrical neutrality. The counterion interacts with the polaron, thereby influencing the polymer optical and electronic response and ultimately device performance. Elucidating how the counterion impacts the polaron characteristics in doped conjugated polymers (CP's) can provide an avenue for further optimizing performance. This work provides a detailed and comprehensive look at the characteristics of polarons in doped CP's and the different ways these characteristics can be impacted by the counterion. Focusing on a hole-transport (p-type) polymer, pDPP-4T, we use first-principles calculations based on density functional theory to

determine the ionization energy of single polymer chains for an excess charge sequentially stabilized by nuclei reorganization, electronic polarization and the counterion, relative to a non-stabilized charge. We also compute the associated polaron probability distributions. We observe that the resulting binding energies correlate with the polaron size and find that the counterion has the strongest stabilizing effect on the polaron. We also compute the optical response of the ionized chains and find that the position of the lowest energy polaron peak (P1) is increasingly blue shifted for more strongly bound polarons, with the polaron stabilized by the counterion exhibiting the highest energy P1 peak. The correlation between polaron binding and P1 peak position is explained using Koopman's theorem and the energy level of the polaron orbital within the electronic band gap. The different quantitative assessments of the counterion impact on the polaron point to an adverse effect on electronic transport. We examine the effects of counterion size and position relative to the polaron center of charge and conclude that the counterion impact on the polaron can be reduced with larger polaron-ion distances. The use of larger counterions, which sit at longer distances from the polymer backbone, is one way of achieving this.

SESSION SB03.01: Mixed Conductors In Neuromorphic Applications
Session Chairs: Francesca Santoro and Benjamin Tee
Tuesday Morning, April 23, 2024
Room 436, Level 4, Summit

10:30 AM *SB03.01.01
Stable Organic Electrochemical Neurons Simone Fabiano; Linkoping University, Sweden

Recent progress in the design and synthesis of both p-type and n-type organic mixed ionic-electronic conductors (OMIECs) has led to the creation of power-efficient devices for diverse applications, including sensors, nervetronics, neural interfaces, and artificial synapses. A cutting-edge addition to the bioelectronic toolkit is the organic electrochemical neuron (OECN) with ion-modulated spiking, facilitating the development of event-based sensors capable of local sensing, signal processing, and stimulation/actuation. However, the current technology encounters stability challenges, primarily stemming from the degradation of the p-type organic electrochemical transistor (OECT) characteristics. Therefore, achieving stable p-type OMIECs is deemed essential for unlocking the full potential of high-performance OECNs. Here, we leverage the inherent stability of rigid ladder polymers, which can sustain a high degree of electrochemical doping. This intrinsic property results in exceptional operational stability, high charge carrier mobility, and large volumetric capacitance. By integrating both n-type and p-type ladder polymers with an engineered backbone to ensure efficient charge transport, we present integrate-and-fire OECNs exhibiting biologically relevant firing frequencies and unparalleled stability. Our findings represent a significant leap forward in OECN technology, addressing previous stability limitations and promising novel opportunities for the advancement of in-sensor computing and the broader field of bioelectronics.

11:00 AM *SB03.01.02
Unlocking The Versatility of n-Type Mixed Conductors for Bioelectronic Applications Sahika Inal; King Abdullah University of Science and Technology, Saudi Arabia

Establishing close interactions between biological systems and synthetic materials is the key to forming biohybrid assemblies that find use in sensors, actuators, and robotics. In this talk, I will present n-type conjugated polymers as multifunctional bioelectronic interfaces. I will show how they can be tailored to form favorable interactions with catalytic enzymes.[1] When this biohybrid is used in an enhancement mode organic electrochemical transistor (OECT), the device detects glucose and lactate in blood serum or saliva with excellent sensitivity and selectivity over six orders of magnitude wide detection range. While showing the unique characteristics of these devices, I will discuss the possible pathways through which the polymer film generates charges as the enzyme reacts with its metabolites.[2] I will then show how these polymers respond to visible and NIR light by generating photocurrents in aqueous electrolytes. [3] This system is then integrated into adaptable circuits with output controlled by various stimuli, mimicking the function of a neuron.

A Novel Class of Soft Materials for Neuromorphic Electronics and Wearables: From Conducting Hydrogel to Semiconducting Hydrogel Shiming Zhang, Dingyao Liu and Yan Wang; The University of Hong Kong, Hong Kong

Thin-film semiconductor-based devices have revolutionized the field of microelectronics. In the realm of biomedical applications, conducting hydrogels have rapidly gained prominence due to their mechanical and biocompatible nature with biological systems. The realization of semiconducting hydrogel materials holds significant value within the field of bioelectronics [1]. Advancing towards flexible and stretchable semiconducting hydrogels can enable direct applications at the interface of soft biological systems [1].

However, the development of semiconducting hydrogels presents challenges, primarily due to the thin-film nature of semiconductors, which are generally less than 1 micrometer in thickness. In contrast, hydrogels tend to have thicker thicknesses and struggle to achieve good semiconductor properties.

The advent of organic electrochemical transistors (OECTs) has introduced a new paradigm that can be a powerful testbed to evaluate the performance of a semiconducting hydrogel. In this report, we present the development of the PEDOT:PSS semiconducting hydrogel and its application in the development of OECTs. Furthermore, we delve into the development of stretchable semiconducting hydrogels and explore how they can revolutionize applications in the field of biomedical research.

11:45 AM SB03.01.04
Neuromorphic Organic Electrochemical Transistors: High-Endurance Long-Term Potentiation induced by PEDOT:PSS Electrochemical Polymerization on the Gate Electrode Isacco Gualandi[1], Federica Mariani[1], Francesco Decataldo[2], Filippo Bonafè[2], Marta Tessarolo[2], Giada D'Altri[1], Tobias Cramer[2], Beatrice Fraboni[2] and Erika Scavetta[1]; [1]Dipartimento di Chimica Industriale 'Toso Montanari', Università di Bologna, Italy; [2]Dipartimento di Fisica e Astronomia, Università di Bologna, Italy

Organic electrochemical transistors (OECTs) are emerging devices in the field of artificial intelligence, as they are able to emulate several synapses functionalities. While short-term processes (short-term plasticity, spike-dependent plasticity, etc..) can be successfully simulated by exploiting peculiar features of OECTs ionic circuit, long-term potentiation (LTP) must be further investigated to increase the retention of the induced neuromorphic states [1]. A recent successful approach is based on electrodeposition occurring in the transistor channel [2].
This contribution describes the use of PEDOT:PSS electrodeposition on the gate electrode to obtain long-term potentiation [3]. The presynaptic signal (V_{pre}) is the potential applied to the gate electrode, which acts as a controller of the drain current, that represents the postsynaptic signal (I_{post}). The neuromorphic behavior does not stem from the channel employed as a memory element but from an enhancement of the gating efficiency and switching properties. The deposition of PEDOT:PSS film raises the gate capacitance and thus the ability of the gate electrode in modulating the current flowing in the channel. LTP depends on both the number of pulses used and the V_{pre}, which generates LTP when a threshold of +0.7 V is overcome. The synapse weight is evaluated by measuring the transconductance, which varies from 0.3 μS for the native device to 30 μS for the neuromorphic OECT with the highest LTP. In-operando atomic force microscopy shed light on operating principle by showing the modifications of the gate electrode induced by V_{pre}. The structural strengthening of the artificial synapse is stable for at least two months, and the behavior can be reset by inducing long term depression by applying V_{pre} pulses that leads to a PEDOT:PSS overoxidation and to the formation of a nonconductive layer on the gate electrode.
The artificial synapse also mimics short-term plasticity (STP), and in particular paired pulse depression, with two distinguishable exponential decay phases. The time constants associated with STP in our device, i.e., 0.4 and 2.0 ms, are considerably smaller than those characterizing the decay phases reported in some biological synapses. It is worth noting that PPD and LTP were induced using different shapes of V_{pre} waves with the same experimental setup. These results suggest that the proposed device could combine short-term plasticity and long-term plasticity in a hybrid process. The integration of these devices in neuromorphic circuits could open fascinating perspectives in the realization of advanced neuromorphic circuits based on OECTs.

SESSION SB03.02: Organic Electrochemical Transistors
Session Chairs: Dimitra Georgiadou and Sahika Inal
Tuesday Afternoon, April 23, 2024
Room 436, Level 4, Summit

1:30 PM *SB03.02.01
Organic-Based Synapses, Neurons and Dendrites Alberto Salleo; Stanford University, United States

Polymer-based artificial synapses have shown outstanding performance in terms of switching speed, switching energy and endurance. The working principle of these devices leverages the dynamics of ion diffusion in polymers. The same dynamics can be used to fabricate organic circuits that mimic spiking neurons that exhibit adaptive behavior. Furthermore, the same materials set is used to fabricate multi-gate devices that reproduce the features of dendrites, specifically spatial and temporal pulse sequences. Device and circuit design allows to tune the temporal response of organic synapses, neurons and dendrites. Semiconducting polymers are thus attractive to fabricate all components suitable for neuromorphic computing.

Unraveling The Bistability of Solid-State OECTs Lukas M. Bongartz[1,2], Garrett LeCroy[2], Tyler Quill[2], Adam Marks[2], Hans Kleemann[1], Alberto Salleo[2] and Karl Leo[1]; [1]Technische Universität Dresden, Germany; [2]Stanford University, United States

Organic electrochemical transistors (OECTs) are excellent building blocks for a new class of neuromorphic devices. Owing to a peculiar switching mechanism based on a redox reaction, the ions of an electrolyte couple with the electronic charge carriers of the active material and unique properties absent in other types of thin-film transistors emerge. Among these is often a pronounced switching hysteresis, an attractive feature widely applied as a non-

volatile memory. However, its physical origin has hardly been studied.

Using a specific electrolyte with the benchmark channel material PEDOT:PSS, we are able to report on OECTs of significantly enhanced hysteresis, as well as an off-state lowered to the regime of nA. Both of these properties, previously sought through complex material modifications, can be achieved here through the simple use of the commercially available ionic liquid [EMIM][$EtSO_4$], which does not require any further material processing. Based on a thermodynamic framework, we can describe this hysteretic behavior as a bistability and trace it back to the dominance of enthalpic effects over entropy. We substantiate this concept with experiments demonstrating the theoretically predicted scenario in which the subthreshold swing exhibits a non-monotonic dependence on temperature. This behavior is contrary to what is expected from classical transistor theory. Going further, we set out to investigate the microscopic origin of the bistability, that is, the interactions underlying the enthalpic effects. To this end, we have turned to spectroscopic methods, including *ex situ* XPS, GIWAXS, UV-Vis-NIR and Raman spectroscopy, which allow us to decipher the unique interplay between PEDOT:PSS and [EMIM][$EtSO_4$]. We find that the ionic liquid introduces significant changes to the channel material, as it removes excess dopant and induces an ion exchange, both of which contribute to the device's exceptional electrical performance. To further study this performance *in situ*, we employ spectroelectrochemistry, which reveals a unique de-/doping behavior compared to other electrolyte systems, and which we can quantify by fitting the spectral signals with a vibronic model. As such, we can draw a conclusive picture of the OECT performance, ranging from the broad ensemble-picture of thermodynamics to the narrow view on microscopic interactions underlying the bistability.

We are convinced that this work will not only expand the understanding of OECT physics, but also provide simple access to devices of remarkable performance based on the mechanisms revealed herein.

2:15 PM SB03.02.03
Top-Gate Organic Electrochemical Transistors: A New Paradigm for Fast and Energy Efficiency Operation Ali Solgi; Photonic Materials (IAPP) and Institute for Applied Physics, Technische Universität Dresden, Germany

Organic electrochemical transistors (OECTs) have garnered significant interest due to their ease of fabrication, flexibility, biocompatibility, and suitability for biosignal sensing, including applications in neuromorphic computing. However, power consumption is pivotal in neuromorphic computing and logic circuit applications. The central challenge in these applications lies in identifying the optimal balance between the operational speed of the device and the magnitude of current flowing through the channel, which is ultimately all defined by the transistor geometry. Consequently, much effort has been put into miniaturizing the OECTs, which unfortunately comes with the disadvantage of increasing integration complexity and cost.
Here, we propose a novel top-gate architecture for OECTs in pursuit of higher operational frequencies, power efficiency, and the ability to integrate using low-cost printing techniques seamlessly. We analyze the scaling of these printed, all-solid-state top-gate devices vs. side-gate structures, and we define a figure of merit describing how efficiently transconductance is utilized for device speed, which is most relevant for integrated circuits. Using this figure of merit, we should reduce the channel length and increase charge carrier mobility, or the mobility capacitance product does not make device operation more efficient. Instead, sub-millisecond device operation can be obtained even for devices with a channel length as long as 200µm, enabling, e.g., the design of fast and power-efficient spiking neurons using the top-gate architecture.

2:30 PM *SB03.02.04
Neuromorphic Sensing Data Transmissions and Soft Actuators Benjamin C. Tee; National University of Singapore, Singapore

Neuromorphic architectures can enable significant power efficiencies in machine learning tasks. The use of soft, organic materials can allow for integration of sensing, actuation and data transmission onto neuromorphic platforms. In this talk, I will share our work on developing asynchronous data transmission systems[1] for neuromorphic in combination with soft flexible electronic materials and devices[2]. Using such systems, we can generate unique datasets containing high speed sensory data, for e.g., a MNIST like tactile dataset[3] and apply them to use cases in robotics[4,5].

3:00 PM BREAK

SESSION SB03.03: Neuromorphic Devices
Session Chairs: Paschalis Gkoupidenis and Alberto Salleo
Tuesday Afternoon, April 23, 2024
Room 436, Level 4, Summit

3:30 PM *SB03.03.01
Modeling Organic Electrochemical Neuromorphic Devices Ugo Bruno[1], Henrique Frulani de Paula Barbosa[2], Francesca Santoro[3] and Bjorn Lussem[2]; [1]Istituto Italiano di Tecnologia, Italy; [2]Universität Bremen, Germany; [3]Forschungszentrum Jülich GmbH, Germany

Organic Electrochemical Transistors are seen as a key element for a fully flexible and wearable sensor technology. In addition, they can be functionalized to show short- or long-term depressive behavior, and long-term potentiation. These devices, often called electrochemical neuromorphic devices (ENODes) have attracted intense research interest in the last couple of years, which led to a continuous increase in device performance.
However, although the progress of the field has been impressive, their fundamental working mechanism is still under debate and an experimentally verified

model to discuss ENODe behavior has been elusive. Here, we discuss our progress towards such a model. A focus is put on a correct description of the steady-state and transient switching observed in OECTs, describing important dynamics of ions and holes. In addition, faradaic reactions are introduced in the model, enabling simulations of voltage-driven processes that are usually behind countless sensing applications. Lastly, an outlook is given towards the implementation of charge transfer and ion trapping in the device that form the basis for describing neuromorphic behavior.

4:00 PM SB03.03.02
Electrochemically Controlled Neurotransmitter Delivery for *In Vitro* Neuromodulation Craig Milroy[1,2], Eric Reed[2], Alena Veigl[2], Tyson Back[3], Nicholas Glavin[3], Rhonda Pitsch[2], Matthew Grogg[2], Tyler Nelson[2] and Steve Kim[2]; [1]NRC Postdoctoral Fellow, United States; [2]711th Human Performance Wing, Air Force Research Laboratory (AFRL), Wright-Patterson AFB, United States; [3]Materials and Manufacturing Directorate, Air Force Research Laboratory (AFRL), Wright-Patterson AFB, United States

The National Academies of Science and Engineering have issued a grand challenge to “reverse-engineer the brain”. Addressing this challenge requires a more complete understanding of how connections between individual neurons and groups of neurons are formed and maintained, as well as a more thorough elucidation of the signaling processes that drive neural network optimization. However, to achieve these goals, it is first necessary to develop the appropriate fundamental tools and protocols for adaptive biointerfacing, bottom-up neuroscience, and neuromodulation, which all involve a tightly coordinated synergy between sensors and specialized devices for neurotransmitter delivery. To date, extensive research efforts have been devoted to neurotransmitter sensing, but relatively little attention has been given to developing methods for electronically controlled *in vitro* neurotransmitter delivery.

To address this challenge, our research team has developed devices that can both sense and selectively dispense the biochemical cues that drive the formation, regulation, and modulation of *in vitro* cellular/neural networks. Here, we report electrochemically controlled dispensing of both excitatory and inhibitory neurotransmitters (*e.g.* glutamate, GABA, dopamine) from functionalized electrodes that operate at low voltage. The regulated uptake and release of neurotransmitters is mediated by electrochemically controlling the electrostatic affinity between the neurotransmitter and a polarized electrode that has been functionalized with an electroactive affinity molecule.

To optimize our devices, our team tested a variety of electrode functionalization approaches (*e.g.* alkane-thiol or silane chemistry, layer-by-layer or covalent modification) and a variety of electroactive affinity molecules (*e.g.* ferrocene, methylene blue, viologens). Our controlled dispensing devices function as a faradaic capacitor – when the functionalized electrode is anodically polarized, the redox affinity molecule becomes oxidized (*i.e.* positively charged), and the neurotransmitter loads on the functionalized electrode through electrostatic attraction to the oxidized redox affinity molecule. The neurotransmitter may be conveniently “stored” on the electrode by maintaining the applied electrode potential, and then released on demand by reversing the applied bias using controlled steps or pulses, which reduces the electroactive affinity molecule and releases the neurotransmitter. This controlled adjustment of applied electrode potential permits quantitative biochemical release. In addition, the electrochemical signature associated with the loading of different neurotransmitters permits sensing as well as delivery.

We confirm the operational principle through a variety of analytical and electroanalytical techniques, such as cyclic voltammetry, chronopotentiometry, open-circuit potentiometry, continuous enzymatic monitoring, electrochemical quartz crystal microbalance (EQCM), X-ray photoelectron spectroscopy, and triple quadrupole mass spectrometry. We then demonstrate that the functionalized electrodes may also be coupled with electrochemical transistors (ECT) for triggered neurotransmitter release in conjunction with changes in the concentration of important physiological ions (*i.e.* sodium, potassium, calcium) or biochemical messengers.

Finally, we will present the steps we have taken to implement these devices within organ-on-a-chip systems, and demonstrate the utility of our devices for studying the formation and longitudinal evolution of neural networks within *in vitro* neuronal colonies.

4:15 PM SB03.03.03
Organic Electrochemical Transistors based Decoding Hardware for Near-Sensor Brain Signal Processing Yuyang Yin and Paddy K. L. Chan; The University of Hong Kong, Hong Kong

As the thriving of brain-computer interface (BCI) technologies, signal decoding algorithm and hardware have been rapidly developing for information interpretation as a crucial part of the BCI system. Although state-of-the-art algorithms can be capable for successful brain wave decoding to realize tasks such as speaking intention prediction or robot arm manipulation, unconventional processing and computing hardware are indeed desired for low-cost and high-speed decoding. Neuromorphic hardware provides solutions in this regard, for which low-complexity protocol and true-hardware implementations have been pursued. Herein, reservoir computing (RC) hardware is constructed based on memristive organic electrochemical transistors (OECTs) for intention of decoding signals from brain. The OECT devices with PEDOT:TOS/PTHF channel layer can be electrically regulated to realize transition from short-term memory (STM) element to long-term memory (LTM) element, which benefits the one-batch fabrication of reconfigurable dual-modal memory device. Based on this merit, the reservoir unit of the RC system is constructed with STM elements and designed as an adjustable network to fit the feature of inputs, at the same time LTM elements are used as trainable weights of the neural network in the readout layer. It is beneficial that the reservoir maps temporal inputs into reduced-size vectors, allowing feasible hardware demonstration of the readout layer in a small network size and leading to desirable short-delay decoding. With this hardware system, simulated epileptic seizure signals can be detected online at decent accuracy, which further direct the generation of stimulus to form a close-loop BCI system for early depression of seizures. This function is transferable for varied types of brain signals at appropriate configuration, paving the way for further design of feasible decoding hardware for efficient online interpretation of brain disease or intentions.

4:30 PM SB03.03.04
Hemispherical Nanowire Array based Bionic Eye Devices with In-Sensor Neuromorphic Signal Processing Zhenghao Long and Zhiyong Fan; Hong Kong University of Science and Technology, Hong Kong

Vision plays a crucial role in artificial systems such as surveillance, manufacturing, and robotics. However, the capabilities of conventional cameras are constrained by their design. Planar image sensors often result in significant aberration issues. While complex multi-lens systems can mitigate aberrations, they also increase the size and weight of the camera and limit its field of view. Additionally, the separation of imaging, memory, and signal processing units can lead to excessive signal transmission, delays, and high energy consumption—all of which are detrimental to the rapid advancement of artificial intelligence applications.
Drawing inspiration from the natural vision of animals, we have developed bionic eye devices featuring a curved artificial retina equipped with onboard signal processing capabilities. These devices use high-density curved nanowire arrays that emulate a retinal neuron array, endowing the bionic eye with a compact design, superior imaging performance, and an ultra-wide field of view exceeding 120 degrees. We have embedded advanced neuromorphic signal processing functions at the pixel level, including capabilities for color distinction, contrast enhancement, noise reduction, and motion detection. Additionally, we have incorporated electrically switched working modes and adaptive optics to enhance the adaptability of our bionic eyes in a variety of application settings.

4:45 PM SB03.03.05
Dual-Function IGZO Phototransistor for Rate-Based Encoding and Photonic Synaptic Characteristics in Neural Networks Ya-Chi Huang, Yu-Chieh Chen, Li-Chung Shih and Jen-Sue Chen; National Cheng Kung University, Taiwan

Machine vision has emerged as a pivotal technology with applications ranging from autonomous driving to intelligent vision systems. However, contemporary machine vision systems typically rely on separate imaging sensors and von Neumann computing architectures for real-time information perception and processing, respectively. This approach generates significant redundant data, leading to increased data latency, a substantial computing load, and reduced energy efficiency. In contrast, the human visual system efficiently processes visual information. Photoreceptors perceive images and ganglion cells convert this information into electrical spikes using neural encoding algorithms. These encoded signals are then transmitted to the visual cortex in the brain for further processing.
Taking inspiration from the human visual system, we introduce an indium gallium zinc oxide (IGZO) phototransistor capable of simultaneously perceiving and encoding information within a single device. To ensure effective perception and encoding capabilities, the IGZO phototransistor was exposed to 405 nm light of varying intensities while simultaneously being subjected to gate voltage pulses of stochastic intensity. These gate voltage pulses were randomly sampled from a Gaussian distribution with a mean (μ) of − 0.4 V and a standard deviation (σ) of 0.2 V. Concurrently, the drain terminal generated spikes whenever it exceeded the threshold current (I_{TC}). As a result, as the light intensity increased, the spike rate also rose, demonstrating the IGZO phototransistor's ability to efficiently encode light intensities into spike rates.
Furthermore, to make the IGZO phototransistor suitable for integration into neural networks, we conducted tests to assess its photonic synaptic properties. Initially, we examined the temporal effects of light/voltage pulses by exposing the IGZO phototransistor to a 10 ms light pulse with a light density of 77 mW/cm^2 and a 10 ms voltage pulse of either 0.7 V or − 0.1 V, while adjusting the time intervals between them. As the time interval between the light and positive voltage pulse (0.7 V) increased, the drain current of the device decreased. On the other hand, as the time interval between the light and negative voltage pulse (− 0.1 V) increased, the current either decreased when the negative voltage pulse was supplied later or increased when the negative voltage pulse was supplied first. Subsequently, the IGZO phototransistor was exposed to 64 light pulses (for potentiation) and 64 negative voltage pulses (for depression), aimed at regulating the photonic synaptic weight of the device. As a result, the IGZO phototransistor exhibited the capacity to represent a total of 128 distinct conduction states. Finally, the IGZO was illuminated by 405 nm light for 10 ms at gate voltage of 0.1 V and 1 V, and the retention time after illumination was assessed. The result indicates that the retention time at V_G = 1 V is longer than at V_G = 0.1 V, suggesting that the photonic retention capability of the device can be adjusted by the gate voltage.
The results of the experiments discussed above reveal that the IGZO phototransistor exhibits both spike encoding and photonic synaptic functions, making it a promising candidate for neural networks applications. In our future work, we plan to utilize the IGZO phototransistor to encode the MNIST dataset into spike rates and subsequently train it using spiking neural networks (SNNs). With further development and exploration, our goal is to utilize a single device for perception and encoding, eliminating the need for separate light sensors and enhancing the efficiency of machine vision systems.

SESSION SB03.04: Wearable Neuromorphic Devices
Session Chairs: Dimitra Georgiadou and Ioulia Tzouvadaki
Wednesday Morning, April 24, 2024
Room 436, Level 4, Summit

9:00 AM *SB03.04.01
Materials for Neuromorphic Supercomputers Jeffrey Shainline, Bryce Primavera, Jeffrey Chiles and Saeed Khan; NIST, United States

Many efforts in neuromorphic computing seek extreme energy efficiency for edge devices by leveraging principles of neural information processing. Fewer efforts aim to capture the full complexity and scale of biological brains, potentially implementing neural principles in technological hardware at a scale that surpasses that of the human mind. For this second thrust, which we term “neuromorphic supercomputing”, the materials challenges are quite unique.

Utilizing existing silicon microelectronics is a natural choice for neuromorphic supercomputing. Yet when implementing neuro-inspired circuits, architectures, and algorithms with existing silicon microelectronic hardware, communication bottlenecks emerge as a major limitation. Biological neurons make thousands of connections to near and distant synapses, whereas silicon neurons cannot achieve this level of fan-out due to wiring parasitics. Address-event representation of spikes is employed with a shared communication infrastructure. As the number of neurons grows, that infrastructure becomes overwhelmed, and the rate at which each neuron can spike drops below the rate of biological neurons, rendering the technological approach inferior to the biological one, even for relatively small systems. This is a severe obstacle for neuromorphic supercomputers.

To overcome this barrier, we use light for communication. A neuron spike is represented by a pulse of photons distributed to synaptic connections via nanophotonic waveguides, circumventing wiring parasitics that prevent direct electrical communication. Superconducting single-photon detectors allow communication to occur at the lowest possible light level for extreme energy efficiency. For computation, the photonic components must be paired with electronic devices and circuits. Using superconducting single-photon detectors requires low temperature operation, so other superconducting elements such as Josephson junctions can be used as well. To realize the full spectrum of synaptic, dendritic, and neural functions, a combination of cryo-CMOS and Josephson circuits are uniquely powerful.

The full hardware stack for this neuromorphic supercomputing platform includes conventional CMOS working in conjunction with superconducting electronics, semiconducting light sources, multiple planes of passive dielectric waveguides, and single-photon detectors integrated with those waveguides. To realize this full stack, multiple challenges in materials science remain. First and foremost, we must integrate light sources with CMOS electronics. Such a feat has been a goal of the industry, yet this context provides one crucial advantage: low-temperature operation. Silicon itself is a reasonable light emitter at low temperature, provided the crystalline lattice is modified to contain emissive centers. The optimization of silicon for this unique optoelectronic purpose represents an important objective of this research. A second objective relates to the single-photon detectors. For scalability, we seek to operate at 4.2K. Polycrystalline materials such as NbTiN make excellent single-photon detectors with superconducting transition temperatures above 4.2K, but the yield and detection plateau are sub-optimal. Other amorphous materials such as MoSi and WSi have much higher yield and detection plateau, but they typically must be operated between 1K and 2K. Finding a material with the best of both worlds remains an important goal for the project as well. Finally, to achieve large systems with the number of neurons and synapses as the human brain will require many planes of waveguides and active superconducting devices. Numerous materials integration challenges must be solved to realize this sophisticated microelectronics process at the 300mm scale. If these problems can be solved, the world will have access to a new domain of advanced computational technology for neural information processing, achieving several important fundamental physical limits of cognition.

9:30 AM SB03.04.02
Volatile Memristive Devices with Analog Resistance Switching Based on Self-Assembled Squaraine Microtubes as Synaptic Emulators Gareth Redmond; University College Dublin, Ireland

In this work, the discovery of volatile memristive devices that exhibit analog resistive switching (RS) and synaptic emulation based on squaraine materials is presented. Specifically, organic microtubes (MTs) based on 2,4-bis[(4-(N,N-diisobutyl)-2-6-hydroxyphenyl]squaraine (SQ) are prepared by evaporation-induced self-assembly (EISA). The MTs are ca. 2 μm in diameter (aspect ratio: 10−130). While powder X-ray diffraction data for MTs identify monoclinic and orthorhombic polymorphs, optical data report the monoclinic phase with energetic disorder. By favorable energetic alignment of the Au work function with the SQ HOMO energy, unipolar (hole-only) symmetric metal−insulator−metal devices are formed by EISA of MT meshes on interdigitated electrodes. The DC I−V characteristics acquired exhibit pinched hysteretic I−V loops, indicative of memristive behavior. Analysis indicates Ohmic transport at low bias with carrier extraction by thermionic emission. At high bias, space-charge-limited conduction in the presence of traps distributed in energy, enhanced by a Poole-Frenkel effect and with carrier extraction by Fowler-Nordheim tunneling, is observed. These data indicate purely electronic conduction. I−V hysteresis attenuates at smaller voltage windows, suggesting that carrier trapping/detrapping underpins the hysteresis. By applying triangular voltage waveforms, device conductance gradually increases sweep-on-sweep, with wait-time-erase or voltage-erase options. Using square waveforms, repeated erase-write-read of multiple distinct conductance states is achieved. Such analog RS behavior is consistent with trap filling/emptying effects. By waveform design, volatile conductance states may also be written so that successive conductance states exhibit identical current levels, indicating forgetting of previously written states and mimicking the forgetting curve. Finally, advanced synaptic functions, i.e., excitatory postsynaptic current, paired-pulse facilitation, pulse-dependent plasticity, and a transition from short- to long-term memory driven by post-tetanic potentiation, are demonstrated. In conclusion, operating on the principle of purely electronic RS, these novel organic semiconductor MT mesh devices provide an attractive combination of large dynamic range, access to multiple conductance states, linear and symmetric conductance tuning, and biorealistic synaptic emulation.

9:45 AM SB03.04.03
Inkjet Printed Metal-Organic Framework Memristors for Non-Volatile Memory and Neuromorphic Applications Yan Liu[1], Franz Fischer[2], Hongrong Hu[1], Hartmut Gliemann[1], Carsten Natzeck[1], Christof Wöll[1], Ben Breitung[1] and Jasmin Aghassi-Hagmann[1]; [1]KIT, Germany; [2]RWTH Aachen University, Germany

Memristors, as fundamental electronic components, have the unique ability to retain a memory of its past electrical resistance state based on the charge that has flown through it. They have generated considerable interest in the field of electronics due to their potential to revolutionize memory and computing technology. Moreover, they offer a combination of non-volatile storage, high-speed operation, and the ability to perform analog computation, which can be advantageous in certain computing tasks and artificial intelligence applications.
Metal Organic Frameworks (MOFs) consist of metal ions connected by organic linkers, resulting in intricate structures with well-defined porosities, which leave spaces for ions, vacancies or guest molecules to immigration and provides an excellent environment for electrochemical metallization (ECM) memristors.
Integrating MOFs into additive manufacturing techniques like inkjet printing can revolutionize their applicability, opening doors to large-scale production of patterned MOF devices. In this talk, the first demonstration of inkjet printed HKUST-1 directly integrated into a printed electronic device, particularly a memristor, will be presented, marking a significant advancement in the field of printed electronics. Furthermore, the inkjet printed memristors can serve as both, non-volatile memories and artificial synapses, for neuromorphic computing. Additionally, the ability of inkjet-printed memristors to act as artificial synapses for neuromorphic applications under different forms of synaptic short-term plasticity was investigated. This study showcases the potential of inkjet printed MOF memristors and will pave the way for high performance memristors in the field of neuromorphic computing, thus, it will further advance the development of artificial intelligence.

10:30 AM SB03.05.02
Infrared Nanoimaging of Hydrogenated Perovskite Nickelate Memristive Devices Sampath Gamage[1], Sukriti Manna[2], Marc Zajac[2], Steven Hancock[1], Qi Wang[3], Sarabpreet Singh[1], Mahdi Ghafariasl[1], Kun Yao[1], Tom Tiwald[4], Tae Joon Park[3], David Landau[1], Haidan Wen[2], Subramanian Sankaranarayanan[2], Pierre T. Darancet[2], Shriram Ramanathan[5] and Yohannes Abate[1]; [1]University of Georgia, United States; [2]Argonne National Laboratory, United States; [3]Purdue University, United States; [4]J. A. Woollam Inc., United States; [5]Rutgers, The State University of New Jersey, United States

Solid-state devices from correlated oxides such as perovskite nickelates are promising for neuromorphic computing by mimicking biological synaptic function. However, comprehending dopant action at the nanoscale poses a formidable challenge to understanding the elementary mechanisms involved. Here, we perform operando infrared nanoimaging of hydrogen-doped correlated perovskite, neodymium nickel oxide ($H\text{-}NdNiO_3$) devices and reveal how an applied field perturbs dopant distribution at the nanoscale. This perturbation leads to stripe phases of varying conductivity perpendicular to the applied field, which defines the macroscale electrical characteristics of the devices. Hyperspectral nano-FTIR imaging with density functional theory calculations unveils a real-space map of multiple vibrational states of H-NNO associated with OH stretching modes and their dependence on the dopant concentration. Moreover, the localization of excess charges induces an out-of-plane lattice expansion in NNO which was confirmed by in-situ - x-ray diffraction and creates a strain that acts as a barrier against further diffusion. Our results and the techniques presented here hold great potential in the rapidly growing field of memristors and neuromorphic devices wherein nanoscale ion motion is fundamentally responsible for function.

Event Driven Optical Sensors based on Perovskites and Organic Semiconductors John Labram; University College London, United Kingdom

While great progress has been made in visual object recognition in recent years, almost all strategies occur in software, relying on conventional video input. This represents a major bottleneck that could limit the speed at which objects can be identified. Recently, we have demonstrated simple capacitive event-

driven sensors inspired by the way that animals perceive visual stimuli. [1] These so-called *retinomorphic sensors* provide a spiking voltage in response to changes in illumination, but no response under constant illumination. [2]

In this talk I will discuss our motivations for detecting light in this way, strategies to achieve this experimentally, and how we expect arrays of these sensors to interpret the visual field. We have demonstrated sensors which employ both metal halide perovskites and organic semiconductors as the absorber layer, with each system exhibiting vastly different behavior. Our latest devices can detect objects which spend less than 10 μs in the visual field, and generate an output voltage with zero input voltage. [3] I will end my talk by describing a framework to quantify behavior in these devices, evaluate performance limits, and discuss strategies to improve functionality in the future. [4]

Exploring the Potential of Combining Polyoxometalates (POMs) and 2D Materials with Nanogap Electrodes for Neuromorphic Computing.
Roshni S. Babu[1], Emilie Gerouville[1,2], Ioannis Zeimpekis[1,2] and Dimitra G. Georgiadou[1,2]; [1]University of South Hampton, United Kingdom; [2]Optoelectronics Research Centre, United Kingdom

Neuromorphic computing, inspired by the human brain's remarkable computational capabilities, has emerged as a promising paradigm for advancing artificial intelligence and cognitive computing systems. In contrast to the Von Neumann computing architecture, the human brain relies on neurons and synapses for both storage and computation. Consequently, there has been a growing interest in exploring nanodevices that mimic synapses to achieve highly efficient computing. Among these nanodevices, memristors have gained a lot of attention due to their advantages, such as low power consumption, high integration density and the capability to replicate synaptic plasticity, which align with the requirements of neuromorphic computing. In this work, we explore two nanomaterial classes, namely polyoxometalates (POMs) and two-dimensional (2D) transition metal dichalcogenide (TMD) materials, to facilitate the development of efficient neuromorphic hardware.POMs, a class of nanoclusters composed of metal and oxygen atoms, exhibit tunable multi-redox properties. Their excellent electron-accepting ability, high stability, and photo stimulable redox properties, render them suitable for mimicking synaptic plasticity and being employed in in-memory and neuromorphic computing devices. In this study, we have fabricated resistive switching memory devices based on Keggin-type POMs, bearing various counterions, and the role of these cations on memristive switching characteristics was investigated. The POMs are deposited by spin coating or drop casting on coplanar nanogap metal electrodes. The coplanar electrodes of Au and Al separated by a nanogap of 10 nm are prepared by adhesion lithography. This coplanar nanogap geometry is an ideal platform to accommodate such 1-nm sized molecular clusters. Preliminary results showed a resistive switching behaviour with a low operating bias voltage and high endurance and retention, while control over the reversible redox states can be used in neuromorphic and reservoir computing. Furthermore, our research involved an investigation into POMs, a class of nanoclusters composed of metal and oxygen atoms, exhibit tunable multi-redox properties. Their excellent electron-accepting ability, high stability, and photo stimulable redox properties, render them suitable for mimicking synaptic plasticity and being employed in in-memory and neuromorphic computing devices. In this study, we have fabricated resistive switching memory devices based on Keggin-type POMs, bearing various counterions, and the role of these cations on memristive switching characteristics was investigated. The POMs are deposited by spin coating or drop casting on coplanar nanogap metal electrodes. The coplanar electrodes of Au and Al separated by a nanogap of 10 nm are prepared by adhesion lithography. Preliminary results showed a resistive switching behaviour with a low operating bias voltage and high endurance and retention, while control over the reversible redox states can be used in neuromorphic and reservoir computing. Furthermore, our research involved an investigation into 2D memristors, employing coplanar nanogap electrodes with MoS_2 as the channel material. The MoS_2 is directly grown on to a Si/SiO_2 substrate using atomic layer deposition (ALD) process and transferred onto a coplanar nanogap electrode array. The utilization of MoS_2 in memristors fabricated with nanogap electrodes has demonstrated the potential to reduce switching voltages to a crucial minimum. In conclusion, as we delve into nanomaterials, such as POMs and 2D materials, and their incorporation into artificial neural networks, we can expect significant advancements in neuromorphic computing, bringing us closer to a future, where computational systems mimic the remarkable efficiency and adaptability of the human brain.

2:15 PM SB03.06.03
Integration of Sputtered Molybdenum Disulfide Layers into a Wafer Thin Film Technology for Memristive Devices
Anna Linkenheil[1,1], Theresa Scheler[1,1], Jonas Schneegaß[1,1], Ole Gronenberg[2], Hendrik Groß[2], Benjamin Spetzler[1], Peter Schaaf[1,1], Lorenz Kienle[2] and Martin Ziegler[1,1]; [1]TU Ilmenau, Germany; [2]Kiel University, Germany

In the last decade, various classes of memristive materials have demonstrated promising properties for emerging information processing technologies such as neuromorphic computing. Among the innovative materials for memristive devices, the class of transition metal dichalcogenides (TMDCs) has attracted much attention, due to their excellent physical properties and scaling capability, which allows scaling to atomically thin layers with defined electronic structure. However, many of the physically relevant properties have so far only been demonstrated on single devices made from TMDC flakes produced by exfoliation which commonly suffer low reproducibility with the fabricated flakes/sheets being rather sensitive against ambient influences like humidity and light. Thus, to exploit their full potential in applications, reliable thin-film processes at wafer-level are requested to tailor the materials precisely for the desired application and integrate them into functional devices and systems. It is therefore beneficial to introduce homogeneous layers on a large scale, enabling to encapsulate targeted areas from the ambience and build vertical devices of controllable size fingerprints.
This contribution therefore presents a technology platform that allows TMDC materials to be integrated into a thin-film process. In detail, a wafer-level 4-inch thin-film technology for fully encapsulated molybdenum disulfide (MoS_2) memristive devices is presented, allowing for a systematic statistical analysis of electrical properties. The developed method, paired with material analyses, further enables us to compare the different material configurations and draw conclusions about the physical switching mechanism and suitability for integration into circuits. MoS_2 layers of 10 nm thickness were deposited in a tri-layer process, sandwiching the material between two 30 nm electrodes using magnetron sputtering. Devices were structured using an optical

lithography lift-off process, comprising more than 32,000 devices in six different sizes, areas ranging from 10x10 to 50x50 square micrometers. The sputtered MoS_2 was found to have an amorphous structure. Devices were encapsulated using high quality chemical vapor deposited silicon dioxide (CVD-SiO_2). To understand and tailor the switching mechanism of the memristive devices, the electrode material (active and non-active) was varied and the influence of the encapsulation of the MoS_2 were investigated in detail.
Experimenting with different electrode materials, Cu and Ag showed a strong interaction between electrode and MoS_2, deploying transmission electron microscopy (TEM). Even though these combinations tend to exhibit switching behavior, they have an undesirably high variability due to the material interactions.
Furthermore, comparing the current-voltage characteristics measured on both encapsulated and non-encapsulated devices revealed that in the encapsulated devices, no resistive switching could be observed. In contrast, I-V hysteresis could be found in non-encapsulated devices. To realize the objective of encapsulated, reliable, and reproducible devices, technology was then adapted from tri-layer to bilayer sputtering, introducing a defined oxidation step for the MoS_2 layer before the deposition of top electrode and encapsulation.
The therewith resulting devices were systematically evaluated, studying their current-voltage characteristics, number of resistive states, retention time, on/off ratio, and switching energy. Finally, a model of the switching is proposed, explaining the cause of memristive characteristics in sputtered MoS_2 and their link to external influences.

Funding by the Deutsche Forschungsgemeinschaft (DFG, German Research Foundation) – Project-ID 434434223 – SFB 1461 and the Carl-Zeiss Foundation via the Project MemWerk as well as support by the Center of Micro- and Nanotechnology (ZMN), a DFG-funded core facility at TU Ilmenau, is gratefully acknowledged.

SESSION SB03.07: Phase Change Materials
Session Chairs: Simone Fabiano and Dimitra Georgiadou
Wednesday Afternoon, April 24, 2024
Room 436, Level 4, Summit

3:30 PM *SB03.07.01
Wearable Neuromorphic Device for Personalized Healthcare Wei Gao; California Institute of Technology, United States

The rising research interest in personalized medicine presents a tremendous opportunity for developing wearable devices toward predictive analytics and treatment. Emerging neuromorphic computing technologies that mimic the data processing properties of biological neural networks offer a promising solution for handling overflowing data related to personalized healthcare. In this talk, I will first introduce the implementation of a simplified, functionally flexible analog-type operator by physically defining short-term plasticity and long-term plasticity in a crossbar synapse array. The applicability of such neuromorphic processor consisting of short-term synapses and long-term synapses was evaluated by constructing a small-sized analog-type operator to conduct representative data-processing tasks for wearable applications. I will also introduce our latest works on the development of wearable, flexible, and multifunctional bioelectronic systems with multimodal physicochemical sensing and neuromorphic computing capabilities for personalized healthcare.

4:00 PM SB03.07.02
Reconfigurable Memristive Devices based on Phase Change Materials for Artificial Synapses and Neuromorphic Computing Sundar Kunwar, Nicholas Cucciniello, Di Zhang, Pinku Roy and Aiping Chen; Los Alamos National Laboratory, United States

Phase change materials such as vanadium oxide (VO_2) possess great potentials for artificial neuron application because of its inherent nonlinear characteristics such as metal-to-insulator (MIT) phase transition with an applied electric field and quick relaxation. Recent studies have demonstrated that the VO_2 based artificial neurons achieve superior biological neuronal activities at lower energy as compared to those based on the filamentary type devices. Our recent study on the VO_2 based memristive devices have suggested that a reconfigurable resistive switching (RS) i.e., both volatile (as neurons) and non-volatile (as synapse) can be achieved, enabling the creation of more energy and area efficient artificial neural networks for neuromorphic computing. In this talk, I will present the case of the VO_2/La0.7Sr0.3MnO3 (LSMO) heterostructure devices and their dual RS properties. The movement of oxygen vacancies and the MIT phase change are deemed to be the main driving forces for such dual RS modes. A dual mode RS in a single device holds great promise for the application in memristive neural networks and neuromorphic computing.

4:15 PM SB03.07.03
Investigating The Interplay of Piezoelectricity and Synaptic Plasticity in Se-Based Photodiodes for Optically Controlled Memristors on Flexible Substrates Taizo Kobayashi[1], Kunal Tiwari[2], Sergio Giraldo[2], Marcel Placidi[2], Axel Gon Medaille[2], Arindam Basak[3,2], Edgardo Saucedo[2] and Zacharie Jehl Li-Kao[2]; [1]Ritsumeikan University, Japan; [2]Polytechnic University of Catalonia, Spain; [3]Kalinga Institute of Industrial Technology, India

Neuromorphic computing, situated at the forefront of the AI revolution, offers the promise of overcoming the Von Neumann bottlenecks in terms of energy consumption while excelling in tasks such as unsupervised learning, analysis of probabilistic and fast changing data. In the era of increasing significance for computer vision, visual learning, and soft robotics, **the fabrication of devices on flexible substrates becomes extremely relevant.**
This work proposes a pioneering investigation of t**he synaptic plasticity in Selenium (Se)-based photodiodes** with a particular focus on the complex **interplay between piezoelectricity and memory**. These Se-based photodiodes are fabricated on flexible polyimide substrates, introducing a novel dimension to their functionality by exhibiting a substantial piezoelectric effect, leading to a remarkable variation of the open circuit voltage under different strains as previously reported.
Our research methodology involves using **both continuous and pulsed light to explore the relationship between piezoelectricity and memory within these Se-based devices.** Remarkably, we observe changes in the dark current-voltage (JV) characteristics both before and after a train of illumination pulses, indicative of the device's behavior being very similar to an o**ptically controlled memristor**. It should be noted that t**his change in resistivity is fully reversible** and can be induced even at relatively low illumination power densities, as low as 5 $mW.cm^{-2}$.
To further investigate the interplay between piezoelectricity and memory, we follow a classic approach of sequential light write pulses and read voltage pulses. This monitoring process involves tracking the current at specific voltage pulses, thus providing indirectly the persistent photoconductivity. This dynamic data is collected as a function of time under various bending angles of the devices. Our findings bring important insights on the role played by the interface **band alignment between the Se absorber and the ZnMgO window layer** in driving the piezoelectric effect and affecting the memory effect.
Our research makes use of different illumination wavelengths, ranging from 350nm to 1400nm, which shows that the system is also **wavelength selective**.

To assess the synaptic plasticity in these devices, we systematically characterize the device's short term and long-term plasticity in terms of the Recovery Time Constant. Additionally, we utilize paired pulse facilitation ratio and rate sensitivity as figures of merit to gauge the device's performance in neuromorphic computing applications.
This potentially seminal work is to our knowledge the first reported exploration of the **interplay between piezoelectricity and visual memory** within the context of Se-based photodiodes. Moreover, our research proposes a pioneering use of Selenium-based photodiodes in the frame of neuromorphic computing applications. These findings hold important promise for advancing flexible, optically controlled memristors and their diverse applications in the domains of visual AI, soft robotics, and beyond.

4:30 PM *SB03.07.04
Engineering Mixed Conductor Transport and Device Form Factor for Neuromorphic Applications Jonathan Rivnay; Northwestern University, United States

Materials processing and synthetic design serve as ideal avenues to control the transport properties of organic mixed ionic/electronic conductors (OMIECs). Small changes in chemistry can affect the materials electronic mobility, swelling, ion uptake and stability. Devices based on these materials have thus opened up new opportunities in bioelectronics, energy, and neuromorphic computing. Furthermore, volumetric/bulk transport and charging in organic mixed conductors opens up opportunities for less common device form factors that can result in scaled down and co-localized function in circuits. In this talk I will present on the engineering of OMIECs for artificial synapses, as well as recent efforts to improve artificial neurons by engineering highly non-linear responses. I will first present a non-volatile organic electrochemical transistor (OECT) based on a poly(3,4-ethylenedioxythiophene):tosylate (PEDOT:Tos)/ Polytetrahydrofuran (PTHF) composite. This device can continuously and reversibly change its conductance state at a write bias less than 0.8 V and the state retention time can be longer than 200 min without decoupling the write and read operation. By incorporating a pressure sensor and a photoresistor into the gate terminal of volatile and non-volatile OECTs, a neuromorphic circuit is demonstrated with the ability to associate two physical inputs (light and pressure), which may have implications for biomimetic devices like electronics-skin and neuroprosthetics. I will then discuss recent developments in simple co-localized OECTs for on-site amplification, as well as for fine tuning of gaussian (or anti-ambipolar) responses in vertical OECTs for simplified spiking circuits, which present an exciting pathway for fully integrated artificial neurons that can directly interface with biological systems.

SESSION SB03.08: Poster Session
Session Chairs: Dimitra Georgiadou and Paschalis Gkoupidenis
Wednesday Afternoon, April 24, 2024
Flex Hall C, Level 2, Summit

5:00 PM SB03.08.01
Graphene/SiO_2 Nanoflakes as Reliable Bio-Photonic Synapse Integrating with Dual-Functionalities of Sensing and Memory Effects for Energy-Efficient Artificial Neural Networks Kuan-Han Lin, Tsung-Yen Wu, Zhe-Hao Liu and Chia-Yun Chen; National Cheng Kung University, Taiwan

In recent years, the system of artificial intelligence is still suffocated by the traditional von Neumann computing architecture. This inherent limitation has led to the bottleneck of computing speed and the problem of high energy consumption that needs to be imperatively solved. To ameliorate von Neumann bottleneck in conventional computing, we began to adopt a neuromorphic computing model, which is inspired by the neural network in human brain and allows the system to actualize "Computing in Memory". Herin, the photonic synapse based on graphene/PMMA@silica nanoflakes is demonstrated to emulate fundamental synaptic behaviors endowed with sensing and memory functionalities. The bio-photonic synapse proposed in this work offers a series of fundamental synaptic functionalities, such as excitatory postsynaptic current (EPSC), paired-pulse facilitation (PPF), and short-term plasticity (STP) to long-term plasticity (LTP) conversion under weak light stimulation. It is found that the resulting PPF index of our graphene-based bio-photonic synapse stimulated by 365 nm light is 267.3% when the interval time is 0.1 s under the employment of -3 V in gate voltage. Additionally, after 24 pulses of light stimulation at a frequency of 0.40 Hz, the relaxation time constant still reaches up to 193.7 s, indicating the critical synaptic plasticity of our devices. The plasticity can be flexibly modulated by the gate voltage, which further contribute to a dynamic synapse with controllable weight. The learning ability of our bio-photonic synapse is confirmed by simulating the learning process with distinct moods via adjusting the gate voltages. Furthermore, due to the charge-trap rich center in silica nanosheets, the bio-photonic synapse can also act as non-volatile flash memory, well mimicking the long-term plasticity (LTP) and keeping long retention time. It should be pointed out that the implement of light-stimulated photonic synapses via the strategy of heterostructure engineering represent a potential avenue that allows the ultrafast processing speed, high bandwidth and low crosstalk than electrical-stimulated synapses. This bifunctional-photonic synapse is anticipated to bridge the gap between the neuromorphic computing and sensing data in our life and pave the way for "Computing in Memory", promoting the emerging artificial neural networks.

5:00 PM SB03.08.02
TaO_x-Based Memristor with Nanostructured Electrode towards Neuromorphic Computing Patrick Chuang[1], Fei Qin[1], Han Wook Song[2], Yuxuan Zhang[1], Lisa Bosman[1] and Sunghwan Lee[1]; [1]Purdue University, United States; [2]Korea Research Institute of Standards and Science, Korea (the Republic of)

In-memory computing technology has garnered significant attention in recent years due to its integration of memory and central processing within a single unit cell, along with its ability to efficiently process tasks in parallel like the human brain. This technology is anticipated to subvert conventional computer architectures. Memristors, a type of passive two-terminal electronic component that exhibits a unique resistance change in response to the time history of the applied voltage or current, play a crucial role in the development of in-memory computing technology due to their non-volatile characteristic, low power consumption, fast switching, and high-density integration. In this research, tantalum oxide (TaO_x) is applied as the switching layer of our memristors because of its controllable resistive switching characteristics. The challenge of the memristor we trying to overcome in this research is the random growth of filaments, which is the main cause of the large variations observed in different cycles or different devices. This performance variation is one of the major obstacles to hindering the advancement of memristor in practical applications. In this presentation, we report on two approaches to mitigate the variation issues. We first focus on the engineering of the oxygen vacancy defect density in the TaO_x switching layer by controlling the oxygen partial pressure in the reactive sputter gas. XPS was utilized to examine the oxygen vacancy concentration of TaO_x switching layers. Next, the electrode's structure was rationally modified to further reduce the performance variation. The TiN bottom electrode was well defined as nano pyramid pattern. We propose that these purposely introduced nanoscale features can induce periodic higher electric fields across the device, which in turn significantly reduce the randomness of filament growth. Finite element analysis was employed to theoretically validate the hypothesis about the nanostructure effect on the electric field and filament growth. Electrochemical impedance spectroscopy was also used to verify the filamentary switching mechanism of our TaO_x-based memristors. In addition, through pulse measurements, we demonstrate synapse behaviors, i. e. multi-conductance levels of our TaO_x-based memristors. Finally, a neural

network simulation was conducted utilizing the attributes of TaO_x-based memristors, demonstrating their capability of image recognition abilities when applied to the Fashion Modified National Institute of Standards and Technology database.

5:00 PM SB03.08.03
Scalable Microfabrication of Intrinsically Stretchable Organic Electrochemical Transistor Array for Neuromorphic Computing Songsong Li[1], Max Weires[1], Zixuan Zhao[1], Fangfang Xia[2] and Sihong Wang[1]; [1]The University of Chicago, United States; [2]Argonne National Laboratory, United States

Organic electrochemical transistors (OECTs) for on-body neuromorphic computing require mechanical stretchability and large-scale manufacturability. However, developing intrinsically stretchable OECTs using a standard cleanroom microfabrication process is challenging due to limitations in the integrated processing of multiple materials. In this work, we develop a standard cleanroom microfabrication process to fabricate intrinsically stretchable OECT arrays with patterned solid-state ion gel electrolytes. This fabrication process offers a higher resolution and density compared to existing printing techniques. Using this innovative technique, we fabricate a stretchable 10 x 10 neuromorphic array and further construct artificial synapse/neuron functions. Utilizing our neuromorphic array, various machine learning algorithms are implemented to detect acute disease and to control the movement of soft robotics. Overall, this work spotlights a promising strategy for fabricating intrinsically stretchable OECT arrays to realize on-body neuromorphic computing.

5:00 PM SB03.08.04
Modulation of Synaptic Functions via Charge Trap Layer in Oxide Semiconductor-Based Synaptic Transistor by Light Irradiation Seokgyu Hong, Won Kyung Min, Jusung Chung, Dong Hyun Choi, Hyung Tae Kim, Moon Ho Lee and Hyun Jae Kim; Yonsei University, Korea (the Republic of)

Due to advancements in artificial intelligence (AI) technologies, such as machine learning, deep learning, and computer vision, computing systems are increasingly required to manage vast amounts of data storage and fast computational processing. However, current computing systems face limitations such as the bottleneck phenomenon associated with von Neumann architecture. To address these limitations, artificial synaptic transistors have emerged, emulating the intricate neural systems of humans, enabling them to store vast amounts of data while maintaining high-speed operation with low power consumption in computing systems. Nonetheless, as computing systems progressively demand enhanced learning capabilities in various environments of data, a necessity arises to distinguish the simple and complicated tasks by adjusting the modification of their synaptic properties as desired. Among the diverse research of synaptic transistors, oxide semiconductor-based synaptic transistors have attained prominence due to their relatively low off current, which contributes to low power consumption.
In this study, we propose a synaptic weight modulation layer (SML) in oxide semiconductor-based synaptic transistors by adjusting the quantity of charge trapping depending on the light irradiation. SML is comprised of ultra-violet (UV)-treated hafnium oxide (HfO_x), which generates varying amounts of oxygen vacancy (V_o) sites, acting as charge trap sites, simply by modifying the UV lamp (wavelength of 184.9 nm & 253.7 nm) exposure time. The devices are based on indium-gallium-zinc oxide (IGZO) thin film transistor (TFT) with two types of SMLs: low-synaptic weight modulation layer (L-SML) with 10 min UV-treated HfO_x and high-synaptic weight modulation layer (H-SML) with 1-hour UV-treated HfO_x located between the channel of a-IGZO and thermally grown silicon dioxide (SiO_2) from a heavily boron-doped p-type silicon substrate (p+-Si).
The hysteresis characteristics are measured to confirm the charge trapping phenomenon by threshold voltage shift (ΔV_{th}). IGZO TFT w/ L-SML and IGZO TFT w/ H-SML showed the ΔV_{th} of 5.15 V, and 10.10 V respectively. This result implies that the increment of ΔV_{th} is clearly influenced by UV treatment time, which occurs by the difference in charge trap density. To verify the UV effect on the HfO_x dielectric film, the current density versus electric field (J-E) curve is obtained in metal-insulator-metal (MIM) capacitors. The HfO_x dielectric film shows a dielectric strength of 10.13 MV/cm, L-SML shows 8.88 MV/cm and H-SML shows 7.35 MV/cm. The breakdown electric field decreases while UV exposure time increases. This phenomenon is expected by bond dissociation and X-ray photoelectron spectroscopy (XPS) analysis is performed to investigate the difference of chemical bonds in the HfO_x between L-SML and H-SML.
In general, the inhibitory post-synaptic current (IPSC) was measured to verify the synaptic characteristics of IGZO w/L-SML and IGZO w/H-SML-based synaptic transistors. These devices showed different synaptic characteristics through the ratio of post-synaptic current/pre-synaptic current in different pulse amplitudes. At 5 V, 6 V, and 7 V, the IGZO TFT w/H-SML ratios are 43.7%, 58.0%, and 75.0%, respectively, compared to the IGZO TFT w/L-SML ratios of 19.7%, 32.6%, and 49.8%. Additionally, potentiation and depression characteristics of IGZO TFT w/L-SML and IGZO TFT w/H-SML according to 128 consecutive pulses are measured to verify the difference in learning capability. The post-synaptic current (PSC) change in IGZO TFT with L-SML and H-SML exhibits a remarkable difference, with an increase from approximately 140 nA to 323 nA (2.3-fold) and 18 nA to 117 nA (6.5-fold), respectively. As a result, it was confirmed that the different characteristics of synaptic transistors via simple light irradiation method might be a candidate for enhancing the learning capability and computational efficiency of neural computing.

5:00 PM SB03.08.05
Solution-Processed Photosynapses Based on Graphene and Organic Dyes for Neuromorphic Computing Jonathan D. Yuen, Jakub Kolacz, Paul A. Brown and Christopher M. Spillmann; Naval Research Laboratory, United States

Combining optical detection and neuromorphic computing to create a bionic optoelectronic nervous system offers great prospects towards mimicking one of the essential components of the human perception, the visual system. We demonstrate a novel and simple implementation of a photosynapse, the fundamental unit of the bionic optical nerve, using graphene and organic conjugated dyes as the materials basis. Through a facile and flexible fabrication process, large-scale devices were created that successfully mimic synaptic behaviors including short- and long-term memory, spiking rate-dependent plasticity, spiking number-dependent plasticity and paired-pulse facilitation. Our work presents a path toward large-scale fabrication of artificial photosynapses of varying length scales employing photoactive materials using a simple, low-cost process, easing the potential development of applications covering artificial visual perception and neuromorphic intelligent systems.

5:00 PM SB03.08.06
Exploring Electro-Thermal Localizations and Metal Insulator Transitions in Micron to Sub-Micron Thin Film Devices Yeonju Yu[1], Adelaide Bradicich[1,2], Timothy D. Brown[2], Fatme Jardali[1], Suhas Kumar[2], R. Stanley Williams[1] and Patrick Shamberger[1]; [1]Texas A&M University, United States; [2]Sandia National Laboratories, United States

Two separate mechanisms, namely electrically induced current density and temperature localization (electro-thermal localization) and temperature driven metal–insulator-transition (MIT), give rise to volatile electrical responses, such as negative differential resistance (NDR) and threshold switching. [1] Devices exhibiting such electrical responses have recently garnered significant interest due to their potential applications in hardware based neuromorphic computing. [2, 3] Within microscale devices, both phenomena are characterized by spatial inhomogeneity, leading to the formation of channels with high current density due to increased temperature or the emergence of a higher conductivity high temperature phase in the material.
In transition metal oxide materials like VO_2, the emergence of electro-thermal localizations and MIT has been observed to occur sequentially, [4, 5] with the current induced MIT believed to occur within the previously established steady state localized channel. Nevertheless, it remains unclear under what conditions localization behavior precedes MITs, and whether these spatial inhomogeneities disappear as device dimensions are reduced below a certain

critical size, along with the impact this may have on the device's electrical response. The objective of this study is to investigate the interactions between electro-thermal localizations and MIT with the goal of providing insight into how localization behaviors affect the onset and properties of the MIT and how these behaviors vary with variations in device dimensions.
Here, the interplay between spatially inhomogeneous electro-thermal localizations and phase transitions is studied in 3D finite element models of two terminal lateral thin film devices with varying lengths (0.7 to 6 µm) and widths (0.7 to 10 µm) using COMSOL Multiphysics. The Joule heating Multiphysics interface combining the electrical and heat transfer modules is used throughout the simulations. The device model contains four domains including a thin film domain, an underlying dielectric substrate domain, separated from the thin film domain by an interfacial thermal conductance, and two electrode domains that span the width of the device. Simulations were conducted by applying a constant electrical current to one electrode and then allowing the system to evolve over time to reach steady state thermal and electrical solutions.
We demonstrate that the dynamical localization of current density and temperature precedes the onset of the MIT, determining the location of the emerging high temperature phase (metallic phase) in micron scale devices. Furthermore, we observe that as device dimensions are reduced to sub micron scales, distinguishing the emergence of spatial phase and thermal inhomogeneities becomes challenging. These results highlight the significant role that electrothermal localizations play on the onset of MIT, offering insight into electrically induced behaviors and corresponding responses of thin films with variable dimensions. Understanding this behavior suggests a pathway for designing desired electrical responses in non linear oscillator type neuromorphic devices.

Lithium-Modulated 3-Terminal Artificial Synapse with Long-Term Memory Function Induced by Fluorinated Self-Assembled Monolayer Minho Jin, Haeyeon Lee, Jiyeon Kim and Youn Sang Kim; Seoul National Univeristy, Korea (the Republic of)

Neuromorphic computing has been introduced as a revolutionary computing architecture to overcome the limitations of von Neumann architecture. Neuromorphic computing is known for its low operational speed and high power consumption, especially when dealing with large volumes of data in areas such as artificial intelligence and big data. This new architecture conducts calculations and memory operations at the same time within a specific resistor, known as an 'artificial synapse'. These artificial synapses, which are structured in parallel circuits, can be distinguished by their adjustable analog electrical conductance. For use in neuromorphic accelerators, artificial synapses need to have the ability to adjust synaptic weights variably, linearly, and symmetrically with a high dynamic range, and they need to be able to maintain updated synaptic weights.
Electrolyte-gated transistors (EGTs) are seen as a potential option for their low switching voltage thanks to the high capacitance of the electrolyte, their simple production process, and the high flexibility in device configuration. The way EGTs work is by altering the channel conductance through physical or chemical interactions of cations or anions in the electrolyte with the channel, thereby representing changes in synaptic weight. However, due to the natural characteristic of electrolytes to balance charges, an EDL formed at the interface by an immediately applied electric field is likely to be transient. Therefore, considering charge interactions with ions at the interface becomes crucial for achieving adjustable conductance with high linearity and long-term retention. In this study, we present Heneicosafluorododecylphosphonic acid (F21-DDPA) as an interfacial monolayer in EGT, specifically highlighting its role in the physisorption of ions caused by large dipole moment at the channel/electrolyte interface. The device uses amorphous indium gallium zinc oxide (a-IGZO) as the channel material, which is notable for its low off-current and high field-effect mobility in n-type thin-film transistors, and water-in-bisalt lithium electrolyte as the polymer dielectric, which is remarkable for its high areal capacitance and large electrochemical window. With the introduction of F21-DDPA in EGT, a strong ion-dipole force is observed between the lithium ions and F21-DDPA, leading to the immobilization of lithium ions at the channel/electrolyte interface. As a result, the lithium EGT with F21-DDPA shows exceptional synaptic characteristics, such as switching conductance with near-linearity and high dynamic range (~10), and long-term retention (>30 min), even at a switching voltage below 3 V. Specifically, through chemical analysis and DFT calculations, we speculate that lithium ions become strongly trapped within the van der Waals gap of F21-DDPA. This finding suggests the potential of a specific capacity of lithium ions within F21-DDPA. We propose an EGT-based artificial synapse with multimodal behavior by suggesting a new method of integration for F21-DDPA, indicating its significant potential in neuromorphic accelerators performing both training and inference tasks.

Organic-Inorganic Hybrid Memristor for Neuromorphic Electronics. Abdulaziz Aldubayan, Antonio Facchetti and Natalie Stingelin; Georgia Institute of Technology, United States

In the era of big data, there is a growing demand for highly efficient technologies to facilitate the acquisition, storage, and analysis of vast volumes of information. The Resistive Switching Random Access Memory (ReRAM), having non-volatile memory attributes, synaptic-like behavior, and energy-efficient, high-density features, had emerged as a promising tool poised to transform and shape the development of neuromorphic computing and wearable electronics. In this work, an organic-inorganic hybrid poly (vinyl alcohol)/titanium oxide hydrate hybrid memristor device is developed. The device of the structure Au/PVA:TiOH/Au exhibits bipolar non-volatile resistive switching characteristics. We hypothesize that the operational mechanism of the PVA:TiOH layer is driven by the formation and rupture of local conductive Ti^{3+} filaments caused by Joule heating and electric field-assisted reduction of Ti^{4+}, producing dioxygen, that induces a Schottky-like barrier behavior at one interface and a quasi-ohmic contact behavior at the other. This biocompatible memristor presents a compelling case for sustainable memory solutions in the increasing field of neuromorphic electronics.

5:00 PM SB03.08.09
Additively Manufactured 3D Membranes for Wearable Renal Assist Device Natalie Hwee[1], Kun Wang[2], Sijia Huang[1], Donglin Li[2], Wade Degraff[2], Longsheng Feng[1], Sangil Kim[2], Jianchao Ye[1] and Juergen Biener[1]; [1]Lawrence Livermore National Laboratory, United States; [2]University of Illinois at Chicago, United States

More than 400,000+ Americans require renal assist devices in the form of hemodialysis machines. This industry costs more than $50 billion dollars a year. Two limitations of current hemodialysis membranes are that they are prone to biofouling and have low packing density of the membrane resulting in a large device. Developing a wearable device that has improved filtration and efficiency would change the lifestyle of thousands of Americans from relying on hemodialysis centers.

We have developed a formulation for a material that has 3 times better antibiofouling properties than commercial materials while maintaining mechanical robustness. We have used a combination of additive manufacturing (AM) and polymerization induced phase separation (PIPS) to design a 3D membrane with controlled micropore size and two-phase flow. Our membrane has achieved over 10 times higher flow rate compared to commercially available membranes at similar pressure drop. This membrane design enhances filtration capabilities through the membrane wall by creating turbulent flow in the channels. Coupling material formulation and additive manufacturing is a way to develop high packing density membrane for a wearable renal device.

This work was performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344.

Brain-Inspired Electronic Learning Metamaterials Douglas Durian, Sam Dillavou, Menachem Stern and Andrea Liu; University of Pennsylvania, United States

Neural networks in the brain and artificial neural networks (ANNs) in silico are both able to learn complex functionality. While each artificial neuron is updated based on global information, using a central processor (CPU) and memory, each real neuron in the brain updates itself without external CPU. In this talk I will describe the first laboratory realization of such self-learning without use of CPU or memory. Our systems consist of a network of identical variable-resistive elements that self-adjust using a local rule based on the voltage drops they experience under contrastive boundary conditions. As such, they have many brain-like advantages over ANNs and enable study of learning as a bottom-up emergent process.

8:45 AM SB03.09.02
2D Axisymmetric Continuum Model for RESET Kinetic Variations in Electrochemical Metallization Cells Milan Buttberg[1] and Stephan Menzel[2]; [1]RWTH Aachen IWE2, Germany; [2]Forschungszentrum Jülich GmbH, Germany

Electrochemical metallization (ECM) cells operate on the principle of growing and dissolving a conducting filament (CF) in an insulator separating two metal electrodes. Typically, the thickness of the insulator is a few nanometres. The growth (SET) of the CF occurs by applying a positive voltage to the electrochemical active electrode (AE), which leads to oxidation of the electrode and migration by ion hopping within the oxide – also called switching layer (SL) – of the resulting metal ions. Reduction occurs preferentially on a critical nucleus at the inert electrode (IE), leading to growth of the CF. Reversal of the voltage leads to reversal of the above processes and dissolution (RESET) of the CF. A previously published 2D axisymmetric model [1] contains Butler-Volmer equations to describe ionic currents, Simmons tunnel equation for electronic tunnel current between the conducting filament (CF) and the active electrode, Fuchs-Sondheimer model for resistivity of the CF, mechanical stress, to limit the lateral CF growth and a moving mesh approach for growth of the CF. This model was extended with tunnel junction heating, an additional energy dissipation when electronic tunnel currents occur, the dissolution of the anode and the previously current limiting resistor was exchanged by an ideal current limitation. The model was then modified to simulate not only SET but also RESET kinetics. In this work the dissolution of the AE and the combined influence of heating, mechanical stress variations, dissolution of the active electrode, the length of the SET voltage pulse (programming time) and the maximum SET current on the RESET time was investigated. It is shown, that mechanical stress – which crucially affects the lateral size of the CF – and the dissolution of the active electrode have the largest impact on the RESET time and that only tunnel junction heating allows significant heating of the CF even at low currents in the low microampere range. The integration of this findings into compact models should lead to better descriptions of measurement results and thus improving and boosting the design of memristive devices and neuromorphic circuits.

Behavior Guided Design of Materials, Mechanics and Electromagnetics for Biosymbiotic Electronics Philipp Gutruf; University of Arizona, United States

Philipp Gutruf

Departments of Biomedical Engineering and Electrical and Computer Engineering, Bio5 Institute, Neuroscience GIDP University of Arizona, Tucson, AZ 85721, USA.;

The concept of digital medicine, which relies on streams of continuous information from the body to gain insight into health status, manage disease and predict onset health problems, is currently relying on biosensors with limited chronic capabilities.[1][2] Key technological hurdles that slow the proliferation of this approach are means by which clinical grade biosingals are continuously obtained without frequent user interaction.[3] To overcome these hurdles, solutions in power supply and interface strategies that maintain high fidelity readouts and function chronically are critical. Current approaches for high fidelity recordings typically rely on adhesive interfaces that are subject to epidermal turnover, limiting sensor lifetime. Additionally, they rely on electrochemical power supplies which are subject to frequent recharge, add bulk and weight, require user interaction and introduce motion artefacts. Here we introduce a new class of devices that overcomes the limitations of current approaches by utilizing context aware mechanical and electromagnetic design facilitated through digital human behavior assessment to create unique personalized devices optimized to the wearer. Specifically, we introduce new methods to use behavioral analysis of a user group to shape design to enable indefinite device lifetimes.[4] These elastomeric, 3D printed and laser structured constructs, called biosymbiotic devices, enable adhesive-free interfaces and the inclusion of high performance, far field energy harvesting to facilitate continuous wireless and battery-free operation of multimodal and multi device, high-fidelity biosensing in an at-home setting without user interaction. We present devices that can operate over weeks at the time, enable new sensing paradigms such as circumferential muscle strain, high fidelity

absolute position sensing, mK resolution thermography and 3D printed optofluidics to capture an encompassing and evolving record of health. The impact of this approach is also showcased in wearable devices that are low profile, soft and can transmit high fidelity biosignal data over tens of miles of distance without cell connection uninterrupted over weeks without user interaction.

Neuromorphic Computing Using Long Short-Term Memory Models with Memtransistor-Enabled Short-Term Memory Manipulation Yu-Chieh Chen, Ya-Chi Huang and Jen-Sue Chen; National Cheng Kung University, Taiwan

The conventional von Neumann bottleneck, characterized by the separation of information processing and storage, presents architectural limitations in computational efficiency and energy consumption. As the growing demand for energy-efficient computing systems, neuromorphic systems, inspired by the parallel processing principles of the human brain, have gained significant attention. Within this domain, the memtransistor, integrating the functionalities of both a memristor and a transistor into a single device, exhibits distinctive memresistive switching characteristics controlled by an external gate terminal. To ensure compatibility with CMOS process technology, we fabricated a metal oxide-based memtransistor on SiO_2/p^+ Si substrate. The memtransistor structure involves the stacking of hafnium oxide (HfO_x) as the gate insulator and indium gallium zinc oxide (IGZO) as the active layer. The redistribution of oxygen vacancies within HfO_x plays a crucial role in controlling the memristive conductance. Introducing an adequate number of oxygen vacancies near the HfO_x/IGZO interface can effectively modulate the Schottky barrier height between the IGZO channel layer and the aluminum (Al) metal source/drain (S/D) electrodes. Unlike traditional two-terminal memristors, the single-pulse measurements reveal the ability to manipulate short-term memory decay time by adjusting gate voltage levels, while the drain pulse waveform remains fixed, allowing us to simulate various degrees of short-term memory effects effectively.
The Long Short-Term Memory (LSTM) model provides distinct advantages for image recognition through controlled degrees of short-term memory states within the LSTM that adapt to varying image dynamics, ultimately enhancing accuracy and efficiency. In time-series data processing, we divide 4x4-sized black-and-white English letter images into four rows, each containing four pixels. The design of electrical pulse waveforms, based on stroke order, serves as inputs to the LSTM mode, enabling it to capture temporal relationships within image sequences. Our research advances memory and recognition technologies, promising enhanced accuracy and efficiency across diverse fields of application.

Brain Inspired Floating Redox Wiring for Neural Networks Roshani Madurawala, Maik-Ivo Terasa, Anna Lina Wyschkon, Soeren Kaps and Rainer Adelung; University of Kiel, Germany, Germany

The human brain is a remarkably complex and adaptable organ and its capability to change and adapt, is due to a phenomenon known as "neuroplasticity." Neuroplasticity in synapses refers to the brain's outstanding ability to change the strength and structure of the connections between neurons, which is crucial for information transfer. This has inspired the design and training of artificial neural networks (ANN), allowing them to learn and improve their performance over time. In the trend of implementing ANN in hardware, one specific challenge is the implementation of plasticity in the artificial synapses. Here we show a concept and a mechanism to incorporate plasticity into a system by means of electrochemical metallization in a liquid matrix, Dimethyl sulfoxide (DMSO). A liquid matrix inspired by the brain has been employed to facilitate the mobility of the ions in addition to its cooling purposes in this ionotronic system. These bio-inspired, dynamic and reconfigurable electronic connections are robust in DMSO while still being prone to manipulation upon applied external stimuli, because they float in DMSO. These connections are wires that grow as dendrites due to the redox reaction taking place at the electrodes. The thickness and the growth conditions of these wires influence their electrical properties, which could be altered by varying the initial experimental conditions such as the applied voltage. The manipulation of these wires could be done during the growth of the wire (filament) between two nodes or more, simultaneously. Furthermore, after the growth of one filament, the filament could be manipulated in a way to induce filament breakage which resembles synaptic properties. This process of plasticity in artificial synaptic connection equivalents, serves as a fundamental step in the refinement of network connectivity. Its replication within artificial systems marks a significant milestone in the quest to emulate the brain's adaptability. Intriguingly, this filament can grow in a span of over 200 µm. What is even more remarkable is their ability to overcome the limitations of traditional 2D growth, as they readily extend their presence into the 3D realm. Growth and manipulation of single 2D and 3D filaments and in extension, a filament network, using external stimuli will be shown along with electrical characterization of these filaments and possible applications. In essence, the groundwork laid in the field of dynamic filament growth within a liquid matrix holds the potential to reshape the landscape of technological advancement. With its capacity for synaptic mimicry, flexible growth, and 3D expansion, this innovation ushers in an era of transformative possibilities, making inroads into fields as diverse as neuromorphic computing, cognitive sciences, and advanced artificial intelligence. 9:45 AM SB03.09.06

Wireless Implantable Microwave Neural Device for Neural Inhibition Carolyn Marar, Ji-Xin Cheng and Chen Yang; Boston University, United States

Neuromodulation using electromagnetic wave allows manipulation of brain circuits in a minimally invasive manner. To date, researchers have explored a broad spectrum of electromagnetic wave and developed wireless neuromodulation methods. Microwave (MW), with frequencies between 300 MHz and 300 GHz, fills the gap between optical wave and magnetic wave, yet has rarely been explored for neuromodulation. Microwave has much longer wavelength than photons, which have been known to provide >50 mm penetration depth into the human brain noninvasively, while maintaining more than 50% of its energy, Yet, its wavelength is much shorter than that of magnetic wave, promising higher spatial resolution to specifically modulate subcortical regions. Here we will discuss a miniaturized millimeter size microwave antenna as a wireless implantable neural interface to inhibit neural activities in vitro, ex vivo and in vivo. The developed split-ring resonator (SRR) generates a localized and enhanced microwave field at the gap site of the ring with submillimeter spatial precision. The SRR breaks the microwave diffraction limit and greatly enhances the efficiency of microwave inhibition. With the SRR, microwaves at dosages below the safe exposure limit are shown to inhibit neurons within 1 mm from the gap site. Importantly, we measured the temperature at the neurons under microwave modulation using mCherry as a temperature reporter and found the temperature increase to be less than 1 degree, confirming a non-thermal effect for microwave inhibition. The inhibition effect was also confirmed in a crayfish nerve model using electrophysiology recording. Application of the microwave SRR to suppress seizures in an in vivo model of epilepsy is demonstrated. These results suggested that the millimeter microwave resonator is a novel platform for wireless, battery-free neuromodulation in the deep brain with high spatial precision. The device operates within safety limits and occupies a volume < 2 mm^3. This approach opens up a broad potential of wireless deep neural

inhibition through miniaturized microwave implants treating neural disorders as well as managing pain.

Memristive Devices for Advanced and Ultrasensitive Bio/Chemical Sensing Systems. Ioulia Tzouvadaki; Ghent University, Belgium

Memristive devices and systems, much akin to biological synapses, possess the intrinsic ability to simultaneously carry out computational tasks and store information at significantly reduced volumes and power consumption by modifying their memory state as a function of the integral of the input stimulus. These emerging technologies coupled with biological processes, opened new perspectives in the role of bio-inspired sensors introducing a versatile paradigm for label-free and ultra-sensitive bio/chemical sensing, holding great promise as intelligent bio-interfaces and sensory systems in the biomedical domain. The recent advancements in the transduction and processing of chemical biomarkers of the neural and immune system functions will be discussed while also providing a critical outlook on the prospective role of memristive devices as fundamental building blocks in advanced biosensing systems.

11:00 AM SB03.10.02
Artificial Thermomechanical Receptor for In-Sensor Multimodal Fusion Junhyuk Bang[1], Kyun Kyu Kim[2] and Seung Hwan Ko[1]; [1]Seoul National University, Korea (the Republic of); [2]Stanford University, United States

As wearable devices evolve in complexity, there's a surging demand for advanced multimodal sensing technologies. Especially the acquisition of thermodynamic information is essential, which allows human-like perception, sensor calibration, and hazard detection. While previous studies have succeeded in selectively capturing temperature and mechanical signals, these methods typically required individual measuring units of target stimuli, leading to increased structural complexity, and necessitating extra computational processes for signal matching.
To address these limitations of traditional multimodal sensors, we introduce the neuromorphic sensor for in-sensor multimodal fusion. This innovative design is inspired by the sensory nerve system's efficient computing architecture, which represents multimodal information by interleaving signals across time. To replicate this neural-like computing architecture, we utilized a stretchable memristive nanowire network (the Ag@Cu_2O core-shell nanowires) as the sensing material. This random network, with numerous memristive junctions of a metal-metal oxide-metal configuration, experiences a binary phase transition related to material and network geometry during the memristive switching process. In the high-resistance state, the conductivity pathway primarily goes through a dense network of Cu_2O shells, while in the low-resistance state, it predominantly goes through a sparse network of conductive filaments. This unique feature empowers active alteration in sensing capability, allowing for the selective extraction of thermal and mechanical signals through a singular resistance measurement unit. Furthermore, by carefully manipulating the signal measurement voltage pulse scenario, thermomechanical information is integrated into a singular interleaving response profile. It enables the spatiotemporal synchronization of thermal and mechanical information itself without the necessity of an external computing unit.
Owing to its design simplicity, our neuromorphic multimodal sensor is much more miniaturized than previous work, achieving a sensing channel size of under 0.1mm^2 and a device thickness of less than 40 μm. This advancement not only improves its conformability on curved surfaces but also ensures rapid response to external stimuli. To demonstrate the practical application of realizing human-like perception, we integrated our sensor with the deep neural network and recognized random objects. In-sensor multimodal fusion, which captures complex physical characteristics, shows superior recognition accuracy compared to datasets acquired by measuring single information (thermal information or mechanical information). These findings open new opportunities for wearable electronics with wearability, and functionality and pave the way for intelligent multimodal sensor systems.

11:15 AM SB03.10.03
High-Speed Edge Computing Implemented Using Reconfigurable Carbon Nanotube Transistor Memories Jingfang Pei[1], Lekai Song[1], Pengyu Liu[1], Teng Ma[2] and Guohua Hu[1]; [1]The Chinese University of Hong Kong, China; [2]Hong Kong Polytechnic University, China

The constant data transportation from the edges to the centralized cloud computing infrastructure causes considerable constrains over the computational power and latency as well as the energy cost. Decentralization of the computation with the computational tasks distributed to the edges is an emergent solution to address the problem. Processing onsite data in local memories holds great promise to implement the edge computing. Here, we demonstrate edge computing using reconfigurable nonvolatile carbon nanotube transistor memory arrays, and prove high-speed, real-time video processing.

We fabricate the transistors from solution-sorted semiconducting single-walled carbon nanotubes. The transistors exhibit fast switching with the switching times and delays down to tens of nanoseconds, a large switching ratio of over 10^5, and, particularly, a significant memory window of ~12 V arising from charge trapping in the sorting polymer. The above characteristics endow the transistors with highly-stabilized reconfigurable nonvolatile memory states and a high data processing speed. Owning to solution processing, the fabrication is wafer-scalable, the transistors exhibit uniform characteristic memory metrics, e.g. with 1.8% variation in the memory window, suggesting an industrial-scale manufacturing capability of the fabrication. Using the transistor memories, we design and implement an edge computing device with a convolution unit connecting to a differentiator, and demonstrate the application of the edge computing device in edge detection and motion track tasks of video streams. Particularly, the edge computing device successfully performs local video processing at a speed of 10,000 fps, exceeding the conventional high-speed cameras. Given the efficacy of the edge computing device, and the scalability of the fabrication, we envisage a promising prospect of realizing large-scale edge computing devices in implementing practical edge computing in, for instance, autonomous driving, virtual and augmented reality, and robotics.

11:30 AM SB03.10.04
Interfacial Engineering of Metal Ion Injection in Threshold Switching Memristor for Neuronal Applications Calvin Lee, Putu Andhita Dananjaya, Eng Kang Koh, Funan Tan, Lingli Liu and Wen Siang Lew; Nanyang Technological University, Singapore

Neural networks composed of artificial neurons and synapses mimicking the biological nervous systems have governed much attention because of their promising potential in high-density memory storage and large-scale neuromorphic computing. In this context, various resistive switching phenomena in memristors such as ionic charge transfer, oxygen vacancy ordering, and electrochemical metallization (ECM) have been utilized to replicate neuronal

dynamics. Among them, ECM threshold switching (TS) devices are favorable for realizing complex neural networks due to their simple structure, large on/off ratio, and low operation voltages. However, ECM TS device uniformity is relatively poor, which may affect the accuracy of artificial neural networks, limiting the practical applications of ECM TS memristors. In this work, we experimentally demonstrate a highly-uniform Ta_2O_5 - based TS device with nanoporous Pt interfacial layer as the high-performance selector, which shows low leakage current (< 1 pA), high on/off ratio (> 10^8), and high endurance (> 10^8 cycles). Furthermore, the Ta_2O_5/Pt-nanoporous layer TS device exhibits self-oscillation behaviour at low voltage (<1 V), where the oscillation frequency increases with the applied voltage and decreases with the load resistance.
Based on the studies of the nanoporous Pt interfacial layer with Ta_2O_5 - based TS devices, the overall variability of the operating voltages of TS devices with nanoporous Pt interfacial layer were reduced to levels below that achieved in TS devices without nanoporous Pt interfacial layer. Furthermore, the nanoporous Pt interfacial layer enables the TS devices to operate at higher current compliance levels (< 100 uA). The insertion of the nanoporous Pt interfacial layer offers a simplistic technique of metal ions manipulation in ECM TS devices.

11:45 AM SB03.10.05
Revealing Oxygen Donor Level in Tungsten Oxide Films for Neuromorphic Applications with Parallel Dipole-Line Hall System Hyunjeong Kwak[1], Chaeyoun Kim[2], Byungha Shin[2], Oki Gunawan[3] and Seyoung Kim[1]; [1]Pohang University of Science and Technology, Korea (the Republic of); [2]Korea Advanced Institute of Science and Technology, Korea (the Republic of); [3]IBM T.J. Watson Research Center, United States

Electrochemical random-access memory (ECRAM) devices stand as key candidates for realizing analog cross-point array-based AI computation accelerators thanks to its excellent programmability driven by ion movement, high stability, low cycle-to-cycle and device-to-device variation*(1)*. However, there have been limited efforts to investigate fundamental physical parameters of the key channel material, WO_{3-x}, that control ECRAM switching characteristics. Tungsten oxide serves as a channel layer since its conductivity can be modulated depending on the ion concentration, rendering it a fitting choice to realize the analog switching*(2)*. In this work, we fabricate ECRAM devices in a multi-terminal Hall-bar structure and conduct Parallel Dipole Line (PDL) Hall measurements to investigate the essential electrical properties of tungsten oxide films, including resistivity, mobility, carrier density and activation energy. The AC Magnetic PDL Hall system, based on strong magnetic field generation and lock-in detection, offers high sensitivity, allowing for sensing even weak Hall signals from low mobility and high resistivity samples*(3)*. Furthermore, we measure the mobility and carrier density of tungsten oxide as a function of temperature using variable temperature PDL Hall measurements. The observed Hall mobility in WO_{3-x} films reaches to 4.66 cm^2/Vs at room temperature. At lower temperatures, a slight decrease in Hall mobility is observed due to impurity scattering from ionized centers. We extract the activation energy of the oxygen donor level in tungsten oxide thin films using Arrhenius plots. Our findings show the experimental access of the key variables that change during switching in ECRAM, which is not only crucial for enhancing ECRAM's performance but also essential for providing vital insights into neuromorphic applications.

Halide Perovskite based Memristive Systems Nripan Mathews; Nanyang Technological University, Singapore

Halide perovskites have been under the focus for photovoltaic applications where their power conversion efficiencies have soared to efficiencies exceeding 26%. They have also garnered tremendous research interest over recent years for the development of next-generation light-emitting diodes (PeLED) in optical displays and light sources. The spotlight on this class of semiconducting material stems from several of its enviable traits such as long carrier diffusion length, defect tolerance, high colour purity, and spectral bandgap tunability which spans across the visible and infrared spectrum.

This talk will focus on our efforts on utilising the ionic characteristics of halide perovskites to enable memristive devices that can be employed for neuromorphic applications. The influence of the ionic compositions, thicknesses and interfacial layers in the memristive properties would be described. Going beyond conventional 2 terminal memristors, other device configurations that exhibit memory and switching in light emission, photovoltages would also be described.

Niobium Oxide-Based Threshold Switching and Dynamic Memristors for Spiking Neural Network Shuai Ming Chen, Kuan-Ting Chen and Jen-Sue Chen; National Cheng Kung University, Taiwan

Inspired by the human nervous system, neuromorphic computing based on spiking neural networks (SNNs) can offer numerous advantages including parallel processing, adaptive learning, energy efficiency, high fault tolerance, and high plasticity. However, implementing neuromorphic computing on traditional CMOS requires a substantially complex and extensive assemblage of components. The presence of the volatile threshold switching (TS) memristors simplifies the hardware structure of neuromorphic computing system, making hardware implementation more straightforward.

Niobium oxide (NbO_x) is a typical Mott insulator characterizing by its temperature-triggered insulator-metal transition. NbO_x-based memristors exhibit S-type negative differential resistance (NDR) during current-controlled I-V sweep measurement and show the volatile threshold switching (TS) characteristics when conducted voltage-controlled sweeping. Connected in parallel with a capacitor, TS devices can follow a Pearson-Anson-like relaxation oscillator circuit model, serving as a prototype for the Leaky Integrate-and-Fire (LIF) model. Due to the MIM (Metal-Insulator-Metal) structure of the TS device, the parasitic capacitance inherent in these components also simplifies the hardware implementation of the LIF model. When pulse strain is being applying to the NbOx-based LIF circuit, it generates spiking signals of various frequencies when pulse voltage and input frequency exceed a certain value (spiking from 4kHz to 15kHz depending on the input conditions). However, when the voltage level or input frequency falls below a specific threshold, no

spike signals are generated, demonstrating an all-or-nothing characteristic.

With varying the thickness of the niobium oxide active layer, NbOx-based devices can exhibit dynamic resistive switching (DS) as well. DS devices possess short-term memory characteristics that depend on operational history and duration, leading to dynamic resistance changes. After electrical stimulation with a 5V amplitude, 3ms pulse width square pulse, the DS device current value measured with 2V square pulse increased around 20 times larger than value measured before stimulation (from 10μA to 209μA). Applied the gradual increasing electrical wave from 0V to 3V, current level at 1.5V is 1.6μA and 3V is 590μA. This nonlinear growth in current value imparts DS devices with filtering capabilities.

DS devices also exhibit diode-like characteristics, enhancing their functionality within circuits. The combination of TS devices with DS devices allows for the realization of more complex LIF models, enriching the computational capabilities of SNNs, whether for controllable leakage behavior, gradual potential rise buffering, noise filtering or spatial summation characteristic. Both DS and TS devices utilize niobium oxide as active layer's material offering advantages in manufacturing, make the hardware implementation of neural networks more streamlined.

2:15 PM SB03.11.03
Inverse Design of Neuronal Action Potentials in Ge Implanted VO_2 Thin Films Rebeca M. Gurrola[1], John M. Cain[2], Timothy D. Brown[2], Fatme Jardali[1], Suhas Kumar[2], Tzu-Ming Lu[2] and Patrick Shamberger[1]; [1]Texas A&M University, United States; [2]Sandia National Laboratories, United States

Vanadium dioxide (VO_2) is a strongly correlated electronic material that exhibits a metal insulator transition (MIT) at 68°C. The MIT can result in up to four orders of magnitude change in the electrical conductivity, which is coupled with a structural phase transition (SPT) where VO_2 transforms from insulating monoclinic to metallic rutile. Its nonlinear transformation enables non-linear dynamics that make it a desirable material for neuromorphic computing applications. Yet, the use of VO_2 to emulate neuronal behavior requires control of the on/off ratio and aspects of the transition, such as the hysteresis and sharpness of transition. All these factors play a crucial role in extending the lifetime of a VO_2 -based memristor. Previous research has focused on 1) chemical doping of VO_2, [1] 2) applying strain to the material via lattice mismatch [2] and/or 3) creation of defects in order to tune aspects of the transformation [3]. It is poorly understood how modification of intrinsic properties of the film or the MIT translate to desired neuromorphic behavior (e.g., the neuronal action potential of a computing primitive).
The goal of this research is to first establish the feasibility of chemically doping VO_2 thin films with Ge ion implantation at moderate ion energies and various doses. Second, to investigate the changes in the electronic transport behavior and the MIT caused by the addition of various types of defects introduced into the system. Previous work using He^+ ions at low fluences showed the feasibility of modifying the resistivity of the insulating and metallic phases (ρ_{low} and ρ_{high}, respectively) without greatly altering the T_{MIT} or the on/off ratio [4]. Ideally, by controlling the ρ_{low} and ρ_{high} and by decreasing the sharpness of the transition we can maximize the interval at which negative differential resistance (NDR) occurs. This would result in a larger time frame in which device oscillations can occur within the NDR region. Finally, we aim to harness ion implantation as a technique to induce desired current oscillations or action potential-like behavior in simple neuromorphic computational primitives.
Polycrystalline VO_2 thin films were grown on SiO_2(100 nm)/Si substrate. These films were implanted with Ge+ ions at 110 keV, and at fluences ranging from $1x10^{14}$ to $1x10^{16}$ ions/cm^2. Photolithography was used to make a variety of 2-terminal and 4-terminal devices on the films to study device switching performance. Implanted devices were then subjected to rapid thermal annealing (RTA) at temperatures ranging from 300°C to 900°C to restore the VO_2 crystallinity. This allowed us to identify the RTA temperatures and fluence values that best modified the MIT without amorphizing the film. The present study describes changes to the electrical transport upon Ge^+ implantation as well as explores different oscillating behaviors observed within the NDR regions for devices subjected to different implantation conditions. Further exploration on the limits of controlling different aspects of the electrical transport behavior will 1) enable a larger class of materials that can emulate the neuronal functions and diverse neuronal dynamics, and 2) introduce a strategy to engineer biomimetic functionality into computational primitives.

Coexistence of Both Digital and Analog Response in Ta_2O_5-Based RRAM Devices toward Neuromorphic Hardware Eng Kang Koh[1,2], Putu Andhita Dananjaya[1], Han Yin Poh[1,2], Lingli Liu[1], Calvin Lee[1,2], Young Seon You[2] and Wen Siang Lew[1]; [1]Nanyang Technological University Singapore, Singapore; [2]GlobalFoundries, Singapore

With the amount of digital data growth in recent years, although the von Neumann architecture-based processors can efficiently conduct logic computations on structured data, they do poorly in image recognition and natural language processing for unstructured data. This leads to a paradigm shift towards a Neuromorphic computing architecture. The Resistive Random Access Memory (RRAM), or in particular its integration with a transistor, 1T1R (1 Transistor - 1 RRAM) structure, is a popular solution to this problem. These devices emulate storing synaptic weights in terms of the conductance of the devices. However, an innate problem is that the RRAM's switching mechanism typically involves an abrupt switching current response. This means that its ability to be used as a neuromorphic computing memory device is hindered because the total number of states that can be stored within a single device is restricted. In this work, using different voltage schemes, the Ta_2N/Ta_2O_5/Pt RRAM device demonstrates both filamentary (digital) and interfacial (analog) resistive switching within a single device. A thorough evaluation of the underlying principles governing both switching modes revealed that the anomalous gradual switching is linked to the modulation of interfacial oxides that form between the active electrode and the oxide switching layer. The coexistence of the two switching mechanisms means it is possible to operate the filamentary switching RRAM as a storage device and the interfacial switching RRAM as a neuromorphic device element within a chip fabricated using the same fabrication process steps. The devices also demonstrate good scalability (<150 nm), low operational voltage (< |2.5 V|), endurance (>10^6 cycles), good retention (85^{o}C at 10^4s), and the possibility of reversibility of the mechanisms while having good multi-level cell properties. With the duality of these two switching modes, our device is poised for application in both memory storage and synaptic weight-storing applications.

2:45 PM SB03.11.05
Enhancing Synaptic Plasticity with Metal Oxide-Based IGTs for Neuromorphic Computing Ramin Karimi Azari[1], Luan Camargo[1,2], Patrick Dang[1] and Clara Santato[1]; [1]Polytechnique Montreal, Canada; [2]State University of Londrina (UEL), Brazil

Neuromorphic computing, which relies on analog neural networks, seeks to significantly reduce computational power by minimizing the necessity for data transfers between memory and logic components. Within neuromorphic computing, the artificial synapse serves a dual purpose as both a storage and computational unit, paving the way for resilient learning and power-efficient in-memory computing. Diverging from conventional computing paradigms,

neuromorphic systems replicate the structural and functional attributes of the human brain.
Metal Oxides (MOs)-based IGTs and the tailoring of their properties for synaptic behavior, achieved by leveraging their unique electronic structure, composition, crystallinity, morphology, intrinsic, and/or extrinsic defects, as well as doping, have gained significant attention.
In this study, we used tungsten trioxide (WO_3) as channel material. WO_3 is earth-abundant with non-toxicity, high stability under ambient conditions, and biocompatibility. WO_3 can exist in different crystal structures, including orthorhombic, monoclinic, and hexagonal phases. The current modulation in MO IGTs arises from both electrostatic and electrochemical processes. The crystal structure of the metal oxide is anticipated to have an impact on ion permeability, leading to variations in doping, channel conductivity, and redistribution time of the anions in the IGT channel.
In our WO_3 synaptic transistor, channel conductivity, analogous to excitatory postsynaptic current (EPSC), was modulated with amplitude, width, interval, and the number of applied input gate-source voltage (V_{gs}) pulses. The fluctuations in conductance correspond to the learning and forgetting processes of the artificial synaptic device, with an increase signifying learning and a decrease signifying forgetting.
Another fundamental aspect that we investigated in WO3-based IGTs is their plasticity, denoting the strengthen of synaptic weight or connection. Synaptic plasticity is typically divided into two categories, namely short-term (STP) and long-term (LTP), determined by the duration of their persistence.
The spontaneous decay time of conductance, which is referred to as the response time, plays a critical role in artificial synapses and can be likened to the forgetting process in biological synapses. The presence of both fast and short response times is the key factor determining the occurrence of STP and LTP in artificial synapses. WO_3-based IGTs display a more prominent transition between STP and LTP, indicating superior synaptic performance.
The current modulation in IGTs is investigated also by changing the gating medium (including solvent-in-salt media).
The addition of Li to the ionic medium ([EMIM][TFSI]) of metal oxide IGTs can play a crucial role in modulating the conductivity and synaptic behavior of the transistor.
When Li ions are incorporated into the channel material or adsorbed at the interface between the transistor channel and the ionic medium, they can influence the diffusion dynamics and mobility of ions within the channel. This leads to an increase in the conductivity of WO_3 channels by almost 100 percent after applying V_{gs} to the gate.
This affects the ion redistribution and de-doping processes, leading to changes in the synaptic behavior of the transistor. In particular, when Li ions are readily diffusible back into the ionic medium after the removal of the low amplitude gate bias (under 1 volt), STP was observed. On the other hand, if the Li ions are intercalated into the channel material and do not diffuse back spontaneously, LTP effects were exhibited and response time increased.
In this sense, understanding metal oxide materials in IGTs and effectively tuning the presence and dynamics of Li ions through pulse parameters offers opportunities for tailoring the synaptic properties and performance of these transistors in developing new integrated circuits and neuromorphic devices.

SESSION SB03.12: Memristive Circuits and Arrays
Session Chair: Douglas Durian
Thursday Afternoon, April 25, 2024
Room 436, Level 4, Summit

3:30 PM *SB03.12.01
Noise and Variation in Memristive Devices and Crossbar Arrays Qiangfei Xia; University of Massachusetts, United States

Memristors are resistance switches with reconfigurable multilevel resistance states modulated by an electric field. Crossbar arrays of such devices can perform analog computation at the site where data is stored (in-memory computing) by directly using physical laws, such as Ohm's law for multiplication and Kirchhoff's current law for summation. Analog in-memory computing reduces the time and energy needed to access system memory. The multiply-accumulate operations can be performed through a single current sensing operation, dramatically increasing the computing throughput. However, ionic-based devices have noises due to the random trapping/release of charge carriers at thin-film interfaces or defect sites (random telegraph noise) and the fluctuation of defect concentrations (1/f noise). Together with thermal and shot noises, they impose a fundamental limit on the capability of analog computing. Furthermore, the device-to-device variation remains a challenge for large-scale crossbar arrays. In this talk, we will showcase how we mitigate these issues through precise conductance tuning of the devices to achieve an unprecedentedly large number of conductance states. We will then discuss the algorithm-hardware co-design approach for edge computing with the memristive crossbar arrays. Finally, we will explore utilizing the variation in the crossbar arrays for embedded hardware security applications.

4:00 PM SB03.12.02
Photo-Enhanced Output in Memdiodes based on Organic/Inorganic Hybrid Materials for Neuromorphic Synapses Jacob Lee[1], Dhriti Nepal[2], John Ferguson[2], Ajit K. Roy[2] and Xiaojuan Fan[1,2]; [1]Marshall University, United States; [2]Air Force Research Laboratory, United States

We report that memdiodes (MDs) have been created based on metal halide-embedded polymeric hybrids in ambient conditions, presenting unusual photo-enhanced electronic transport behaviors. The hybrid materials show nonconventional optoelectronic properties, providing alternatives to traditional semiconductors such as silicon. The blending of inorganic metal halides and organic polymers combined with an insulating polymer membrane facilitates resistive memory and diode behaviors. Two-terminal memristive devices are made of a hybrid photoactive layer of $CuCl_2$ blended with poly(ethylene glycol) (PEG) and a layer of poly(methyl methacrylate) (PMMA) deposited on substrates to form a *pn*-junction memdiode. Thin films were characterized using ATR-FTIR, SEM, UV-Vis-NIR microspectrophotometer, and *IV* curves. Cyclic voltage sweepings present polarity-related current curves, which manifest the MD characteristics as the current stays near zero in negative voltages, but significantly increases in positive voltages. Cyclic *IV* curves also present a moderate hysteresis, featuring a memory device. Surprisingly, the current magnitude increases by 4 times when the light radiation turns on, implicating that the electronic output is significantly enhanced by photoexcitation. The resistive transport mechanism is hypothetically attributed to electron-ion couplings, where both electronic mobility and ionic-hopping contribute to carrier transport as electrons migrate in an ionic “train”, where dielectric dipoles induce *IV* hysteresis. All materials in the MD devices are bio-compatible, stable, and flexible, potentially applicable to bio-electronic circuits, artificial neuromorphic synapses, and brain-inspired quantum computing.

Probing The Microscopic Origins of Device Performance and Stability in Organic Semiconductors through Trap Density of States Spectroscopy
Oana D. Jurchescu; Wake Forest University, United States

Organic semiconductors (OSCs) are highly susceptible to defect formation, owing to their weak intermolecular interactions, leading to trap states in the band gap that can drastically alter their optoelectronic properties. Characterization techniques that can elucidate the mechanisms of defect formation and evolution are essential for guiding the processing and design of high-performance stable OSC devices. In this presentation I will discuss a highly efficient methodology to elucidate the microscopic processes occurring within the OSC when deliberately exposed to different external stimuli. The methodology relies on real-time access to the trap density of states (t-DOS) spectrum of the OSC using organic field-effect transistor (OFET) measurements. The t-DOS spectrum provides detailed information about the origin and energetic distribution of electronic traps in OSCs, as well as their time evolution. Several different trap states will be discussed as case studies, including those arising from impurities and isomer coexistence, microstrain at device interfaces, environmental and bias stress. Methods for minimizing the trap density to enhance performance and stability will be presented. Finally, the exploitation of trap formation for the development of radiation dosimeters for cancer treatment will be discussed.

11:00 AM *SB04.01.02
High-Frequency Flexible Organic Thin-Film Transistors Hagen Klauk; Max Planck Institute for Solid State Research, Germany

Organic thin-film transistors (TFTs) are potentially useful for flexible electronics applications, as they can typically be fabricated at temperatures no higher than approximately 100 °C and thus not only on glass, but also on polymeric substrates and even on paper. An important TFT performance parameter is the transit frequency, which is the highest frequency at which a transistor is able to switch or amplify electrical signals. The transit frequency of organic TFTs depends mostly on the contact resistance and on the lateral TFT dimensions (channel length, gate-to-contact overlaps). A better understanding of the factors that determine the contact resistance of organic TFTs has made it possible to fabricate organic TFTs that have a contact resistance within three orders of magnitude of the theoretical limit and an experimentally measured transit frequency of 21 MHz (at 3 V). Any significant further reduction of the contact resistance of organic TFTs to the levels commonly achieved in inorganic field-effect transistors now hinges mainly on the elimination of the Fermi-level pinning induced by metal-induced gap states at the metal-semiconductor interfaces. In terms of decreasing the lateral TFT dimensions, flexible organic TFTs with channel lengths and gate-to-contact overlaps below 1 µm were recently demonstrated that display reasonable static characteristics (turn-on voltage of 0 V, subthreshold swing below 100 mV/decade, on/off current ratio greater than 10^9), but suffer from a relatively large contact resistance that limits the transit frequency to 36 MHz (at 3 V). One of the challenges in pushing the transit frequency of flexible organic TFTs to 100 MHz and beyond will be to minimize all three parameters (contact resistance, channel length, gate-to-contact overlaps) simultaneously.

11:30 AM SB04.01.03
Fully Edible Transistor: Towards Next Generation Edible Electronics Elena Feltri[1,2], Pierluigi Mondelli[1], Fabrizio Mario Ferrarese[1,2], Alessandro Luzio[1] and Mario Caironi[1]; [1]Italian Institute of Technology, Italy; [2]Politecnico di Milano, Italy

With the increased burden on healthcare workers in recent years, point-of-care medical devices for the gastro-intestinal tract that do not need external supervision (neither during ingestion nor for their retrieval) could be crucial for safe and early diagnosis, monitoring and treatment of many diseases. Edible electronics can enable such a vision through devices that are not only ingestible but are indeed digestible just like food, as they are made up of food-grade materials, thus zeroing the risks and health hazards posed by device retention and therefore the need for supervised administration. To turn this vision into reality, research efforts are steering towards functional edible electronic devices that can enable active signal monitoring and control of drug release inside the human body[1].
In this work, we present a printed fully edible transistor operating at low voltage (<1V). Inert metallic source-drain and gate staggered electrodes were inkjet-printed on top of an ethyl-cellulose edible substrate, while the chitosan solid electrolyte and the edible semiconductor Copper Phthalocyanine (CuPc) were drop-casted and thermally evaporated, respectively. The devices were characterized in terms of transport characteristics, air stability and reproducibility, showing performances comparable to conventional transistors based on the same semiconductor, an air stability of at least 12 months and a

high degree of reproducibility. To realize a proof-of-principle logic gate, the transistor was connected with a commercial resistor to create an inverter. We believe that the results of this work can pave the way to the development of edible circuitry for a broad range of future applications in the medical, food and entertainment industry.

11:45 AM SB04.01.04
Development of Strain-Induced Organic Single-Crystalline Transistors Mizuki Abe[1], Taiki Sawada[1], Yu Yamashita[1,2,3], Naotaka Kasuya[1], Shun Watanabe[1] and Jun Takeya[1,2,3]; [1]The University of Tokyo, Japan; [2]National Institute for Materials Science, Japan; [3]JST CREST, Japan

Organic semiconductors (OSCs) are known as flexible, solution processable, light-weight, and potentially low-cost materials which are applied in many electronic devices. There is considerable interest in developments in organic thin-film transistors (OTFTs) for applications such as flexible displays, sensors, and IC tags. Rapid developments in synthetic chemistry and device engineering allow us to explore high performance devices. However, there is limited study to improve static (DC) and dynamic (AC) performances of organic devices without employing synthesis and complicated device integration. A strain is used to control the electronic structure. Particularly in the case of single-crystalline OSCs, it has been demonstrated that a slight compressive lattice strain can modify the electronic structure via uniformly modified crystal structure, and enhances career mobility[1][2]. However, the method to apply strain into OSCs has been limited; bending substrate has been only the way to systematically control the strain in OSCs. Therefore, a novel method to introduce a persistently strain into OSCs particularly on a planar substrate will be highly desired.
Here, we establish a general method to persistently induce uniaxial strain into single-crystalline OTFTs to enhance the performance of OTFTs. OTFTs with single-crystalline films of 3,11-dioctyldinaphtho[2,3-d:2,3-d]benzo[1,2-b:4,5b]dithiophene (C_8–DNBDT–NW) as the active layer were fabricated on 15 μm thick polyimide (PI) substrate. To induce uniaxial compressive strain into OTFTs semi-permanently in a planar substrate, we developed following new method. First, OTFTs fabricated on PI substrate were adhered onto a convexly bent thick mother substrate (polyethylene terephthalate) by using cyanoacrylate adhesive. The OTFTs adhered on the extended surface of the bent mother substrate were compressed semi-permanently when the mother substrate is recovered in a flat state. In this method, the surface strain ε of the bent film was calculated by the following equation : $|\varepsilon| = h / 2(R + h)$, where h is the thickness of mother substrate and R is the curvature radius of bent substrate.
By applying this method, the modulation of career mobility by the introduction of uniaxial compression is observed. By changing the curvature of mother substrate, the ratio of compressive strain into OTFT changes accordingly. In this measurement, the maximum compressive strain induced into OTFTs is evaluated to be 3.1% along *c*-axis. The intrinsic mobility increases monotonically by inducing compressive strain by a factor of 156% when compressive strain reaches 3.1%. This large enhancement of intrinsic mobility agrees quantitatively with our previous study[1], and originates from the suppression of molecular vibration, rather than from the effect of effective mass; a reduction of lattice constant of C_8–DNBDT–NW directly restricts the molecular vibration that contributes particular to electron-phonon interaction.
The enhancement of dynamic performances of OTFTs by the strain is also observed consistently in strain-induced OTFTs. Cutoff frequency (f_T), the parameter which determines operation speed of OTFTs, improves by a factor of 140% when 1.0% compressive strain is induced into OTFTs. Theoretically, cutoff frequency is proportional to the career mobility of OSCs. Therefore, this result indicates that enhancement of career mobility by the introduction of strain also improves dynamic properties of OTFTs. From these results, strain-induced OTFTs showed high career mobility and improved cutoff frequency. Inducing even larger strain is expected to further improve both static and dynamic performances of OTFTs. This simple , but versatile method will open opportunities for further developments in high frequency operation of OTFTs.

SESSION SB04.02: Charge Transport
Session Chairs: Paddy K. L. Chan and Hagen Klauk
Tuesday Afternoon, April 23, 2024
Room 435, Level 4, Summit

1:30 PM *SB04.02.01
Charge Transport and Thermoelectric Properties of High Mobility Doped Conjugated Polymers Henning Sirringhaus; Cambridge University, United Kingdom

Doped conjugated polymers are critical to emerging device applications, including field-effect transistors, thermoelectrics, bioelectronics, and neuromorphic computing devices. We will present recent advances in controlling doping processes and understanding the resulting charge transport properties of doped polymers. This will include discussion of the role of Coulomb interactions between carriers and with the counterions at high doping densities, new experimental methods to study the electronic structure and transport properties of these doped polymers as well as recent advances in improving the electrical stability of FETs and thermoelectric performance.

2:00 PM *SB04.02.02
Charge Carrier Transport in Crystalline Organic and Hybrid Perovskite Semiconductors Investigated with a High-Resolution *ac*-Hall Technique Vitaly Podzorov; Rutgers University, United States

The importance of Hall effect measurements in evaluating the charge carrier mobility of novel materials is being increasingly recognized in materials science, semiconductor physics, and electronics. Hall measurements are advantageous over other mobility measurement techniques in that they: (**a**) allow a direct access to the mobile carrier concentration and mobility in a steady-state charge transport regime; (**b**) provide an alternative for mobility evaluation in systems where other techniques are hard to implement; (**c**) provide means of distinguishing between different transport mechanisms (e.g., hopping, band-like, or their combination); and (**d**) help disentangling the contributions of various carrier types or trap states. However, in many intrinsically low-mobility materials and devices, conventional (*dc*) Hall measurements are extremely hard to carry out due to typically weak Hall signals (and, thus, low signal-to-noise ratio).
High-resolution *ac* Hall and photo-Hall measurements recently developed in our group have resulted in a significant progress in our understanding of the charge transport and photophysical properties of organic semiconductors and lead-halide perovskites.[1,2] In this talk, I will discuss a few examples of the

transport physics studies using Hall-effect measurements. For instance, Hall measurements have led to elucidation of the role of grain boundaries in high-performance polycrystalline organic field-effect transistors (OFETs), where capacitively charged grain boundaries lead to an "underdeveloped" Hall effect.[3] In another example, the *intrinsic* mobility-strain relationship has been experimentally revealed in organic semiconductors for the first time, achieved by simultaneous measurements of FETs and Hall effect under a calibrated uniaxial strain in ultra-thin, flexible, single-crystal rubrene OFETs.[4] These measurements revealed an anisotropic and reversible modulation of charge mobility with strain. A photo-Hall effect has also been recently measured in organic semiconductors for the first time, with the developed model capable of correctly disentangling the mobilities and densities of the photogenerated mobile electrons and holes.[2] These photo-Hall effect measurements performed in high-mobility rubrene single crystals confirmed the older findings that photoconductivity in this material is due to the interaction of long-lived mobile triplet excitons with surface states [5,6]. Finally, high-resolution *ac*-Hall measurements have also proven very useful in the investigation of the intrinsic (trap-free) charge transport in epitaxial lead-halide perovskite FETs recently developed in our group.[7]

2:30 PM *SB04.02.03
Effect of Structural Dynamically Induced Disorder on Charge in Molecular Materials Lisa A. Fredin; Lehigh University, United States

Describing charge carrier anisotropy in small molecule crystalline semiconductors with ab initio methods is challenging because of the weak intermolecular interactions which lead to both localized and delocalized charge interactions. Hopping models (localized) are generally used to describe materials with small charge carrier mobilities, while periodic band models (delocalized) are used to describe materials with high carrier mobilities. Noncovalent interactions between the molecular components mean that dynamic disorder in these materials can have a large impact on the electronic properties of these materials at room temperature. In particular, dynamically induced structural disorder can lead to non-linear changes of the electronic response. Here we build new real temperature computational methodologies based on either Marcus Theory (hopping) or the Boltzmann Transport Equation (band transport) that allow for direct prediction of electronic response of single crystal organics while capturing the weak electrostatic interactions between π-interacting organic molecules, the surrounding crystal environment through periodic symmetry, delocalization of charge in a single calculation, and zero-point energy corrections. In particular, very small atomic displacements can sometimes have a large effect on the localization of electronic density and thus charge transport.

Understanding The Device Stability Through The Lens of Semiconductive Polymer's Chain Dynamics Xiaodan Gu; University of Southern Mississippi, United States

Organic semiconducting polymers were widely studied due to their unique optoelectronic and mechanical property. They are the key component in various functional electronic devices, such as organic photovoltaic devices, flexible displays, wearable sensors, neuromorphic computing, and more recently bioelectronics. Despite tremendous progress being made in improving the charge carrier mobility and optimizing energy bandgap, the conjugated polymer's physical property was not widely studied, particularly the glass transition phenomenon. However, it is important for device stability, preventing wide adoption of polymer-based organic devices.

In my talk, I will outline past works on studying the polymer dynamics for semiconductive polymers and provide an overview of our effort in this area using a wide range of unique characterization tools, from thin film to bulk. I will discuss the challenge associated with accurately measuring the glass transition temperature for rigid conjugated polymers. I will also discuss our approach to address this challenge using thin-film calorimetry and ellipsometry tools, as well as using molecular dynamic simulation and cheminformatics to accurately predict the glass transition temperature. Lastly, I will cover how dynamics could impact thin film morphology and device performance at different operation temperatures and should be carefully considered when designing new polymers and devices.

4:00 PM *SB04.03.02
Nanomechanics of Materials used in Flexible Electronics Deepak Venkateshvaran and Leszek Spalek; University of Cambridge, United Kingdom

Organic semiconductors are multifunctional soft electronic materials that play an impactful role in the flexible electronics industry. Their use spans printed electronic circuits, large area displays, flexible solar energy harvesters, and implantable bioelectronics. For their competitive optical, electronic, thermoelectric, and spin-based properties, these soft electronic materials attract significant academic engagement, seeding new technologies for the future. [1, 2, 3]

Although macroscopic flexibility on the centimetre to metre scale is a unique selling point for organic semiconductor technology, not much is known about their mechanical properties on the nanoscale. Quantification of these nanomechanical properties, together with an understanding of nanoscale stiffness tunability and homogenisation, holds significant potential for fundamental and applied science. [4, 5]

During the last decade, the development of high precision atomic force microscopes has made it possible to quantify the mechanical properties of organic polymers on the scale of a few polymer chains. Techniques such as higher eigen mode imaging make it possible to visualise molecular ordering on the nanoscale under ambient conditions with ease. These techniques allow one to correlate molecular ordering with the stiffness that such ordering manifests.

In this talk, the science and technology of precision nanoscale measurement of mechanics will be spotlight. The interrelation between molecular organisation and nanomechanical properties in high-performance polymers used for organic electronics will be shown. [6, 7] A quantification of differences in strain within organic nanocrystal polymorphs will also be demonstrated. The measurement techniques demonstrated in this talk are extendable to a wide variety of multifunctional materials with a broad range of elastic properties and have significant use in both academia and industry.

Discovering New Molecules for Organic Electronics from The Chemical Supply Chain Alessandro Troisi and Omer Omar; University of Liverpool, United Kingdom

We present our methodology to discover novel active molecular compounds for organic electronics combining high-throughput virtual screening and knowledge of the chemical supply chain. The talk with provide new recent examples of the discovery of (i) dual emitters, (ii) molecules with inverted single-triplet gap and (iii) low energy emitters. In all cases the discovery take places in two steps, the exploration of a large chemical space of pre-computed properties followed by a refinement of the search through more computationally demaning screening steps. The approach is designed to allow facile experimental verification of the predictions and some verifications will be presented as part of the lecture. The web platform enabling similar workflows to be adapted to different properties is presented.

Manipulating Self-Healing Properties in Organic Semiconductors through Supramolecular Chemistry Megan M. Westwood, Peter Finn, Lewis M. Cowen and Bob C. Schroeder; University College London, United Kingdom

Material degradation poses a significant concern for both material scientists and engineers, leading to costly repair efforts and more extensive consequences than mere failure. As a result, there is a growing interest in developing self-healing materials to eliminate the need for maintenance. In contrast to their inorganic semiconductor counterparts, organic semiconducting materials possess notably low Young's moduli, making them exceptionally well-suited for integration into wearable electronic devices that can be directly applied to the human skin [1]. However, wearable electronics are exposed to a myriad of environmental stressors, including mechanical wear, chemical exposure, temperature fluctuations, and radiation. The relentless impact of these stressors can lead to the deterioration of the chemical structure, ultimately resulting in the degradation and eventual loss of the material's physical properties. Within this context, we will delve into our strategic approach to mitigating the loss of physical properties through the development of intrinsically self-healing polymers. This significant achievement was made possible by harnessing the principles of supramolecular chemistry, with a particular emphasis on the utilization of intramolecular hydrogen bonds [2-4]. To gain a comprehensive understanding of how hydrogen bonding affects the viscoelastic and electrical characteristics of organic semiconductors, we devised two distinct material sets. The first consists of a conjugated polymer with integrated hydrogen bonding functionality, while the second involves a composite material comprising a conjugated polymer embedded within a self-healing polysiloxane matrix.
Our discussion will comprehensively cover the effects of these distinct approaches on charge transport and self-healing capabilities. Furthermore, we will outline how we can leverage the observed disparities to not only customize the electronic properties but also fine-tune the self-healing and mechanical attributes of the material to align with the specific demands of diverse applications.

Room 435, Level 4, Summit

10:30 AM *SB04.05.01
High-Performance Organic Devices based on Crystalline Stacks Karl Leo; IAPP, Germany

The research on organic electronics is driven by new applications using properties like flexibility, easy manufacturing, biocompatibility, etc. While OLED

displays and organic solar cells are commercially successful, organic electronic circuits have not yet reached broad application, mainly since device performance is lacking. In this talk, I will discuss highly ordered organic multilayer structures which have the potential to increase device performance by orders of magnitude. For the highly ordered layers, rubrene crystals are created by heating of amorphous layers and can be electrically doped during the epitaxial growth process to achieve hole or electron conduction. Analysis of the space charge limited current in these films reveals record vertical mobilities of 10 cm2/Vs. Furthermore, these structures allow comparatively long minority carrier diffusion lengths, allowing to realize the first organic bipolar transistors. OLED from highly ordered layers show high current densities and excellent emission homogeneity. Furthermore, I will address highly ordered organic thin-film blends with a similar chemical structure and show the effect of band structure engineering by spectroscopic methods. In contrast to previous studies where the experimental results can be described by quadrupole effects, delocalization is a significant effect for the crystalline layers.

11:00 AM *SB04.05.02
Organic Semiconductor Thin Film Crystal Growth: Formation and Propagation Barry P. Rand; Princeton University, United States

Organic semiconductors are commercially validated regarding OLED displays, with considerable scope for future applications. Toward these future prospects, I will present recent work from our group that seeks to better understand how to form crystalline films of organic semiconductors, approaching single-crystal-devices, but in a thin film platform. Through proper control of processing, we are able to realize pinhole free organic semiconductor films with single crystal grains with millimeter dimensions. We have found that transport in these films is considerably improved compared to disordered films, and that organic solar cells incorporating these long-range-ordered films exhibit highly delocalized and band-like charge transfer (CT) states, contributing to noticeably lower energy losses. We will discuss these aspects and our understanding to-date of which molecules are amenable to the formation of such films, and how to propagate crystal growth both homoepitaxially and heteroepitaxially.

11:30 AM SB04.05.03
On The Importance of Chemical Precision in Organic Electronics – Fullerene Intercalation in Perfectly Alternating Conjugated Polymers and Implications on Device Performance Jochen Vanderspikken[1,2], Zhen Liu[3], Xiaocui Wu[4], Stefania Moro[5], Tyler Quill[6], Bart Goderis[7], Vincent Lemaur[8], David Beljonne[8], Alberto Salleo[6], Laurence Lutsen[1,2], Koen Vandewal[1,2], Bruno Van Mele[3], Giovanni Costantini[5], Niko Van den Brande[3] and Wouter Maes[1,2]; [1]Hasselt University, Belgium; [2]IMEC, Belgium; [3]Vrije Universiteit Brussel, Belgium; [4]University of Warwick, United Kingdom; [5]University of Birmingham, United Kingdom; [6]Stanford University, United States; [7]KU Leuven, Belgium; [8]University of Mons, Belgium

The true structure of alternating conjugated polymers – the state-of-the-art materials for a number of organic electronics technologies – often deviates from the idealized picture. The presence of structural defects is inherently linked to the applied cross-coupling polymerizations (notably Stille) and varies according to the experimental conditions. Nevertheless, many polymers still perform excellently in the envisaged applications, which raises the question if one should even care about these defects. Here, this question is addressed by comparing a traditionally prepared alkoxy-PBTTT polymer to a newly synthesized homocoupling-free variant, as verified by scanning tunneling microscopy (STM). We (for the first time) quantify the amount of homocoupling by STM and shed new light on the actual distribution of these defects in the polymer material. Additionally, we demonstrate that matrix-assisted laser desorption-ionization - time of flight (MALDI-ToF) mass spectrometry only shows a fraction of the homocoupled species and hence gives an incomplete picture. Further, it is shown through a combination of experimental techniques (and supported by calculations) that these defects hinder fullerene intercalation, whereas this returns for the homocoupling-free polymer and then affords stronger intermolecular charge-transfer interactions. This demonstrates that molecular defects may (strongly) impact material and blend properties and calls for increased attention for defect-free materials.

11:45 AM SB04.05.04
Understanding of The Nanosprouts Structure Inhomogeneity of Organic Semiconductor and The Corresponding Optical Memory Property Lizhi Yan[1] and Paddy K. L. Chan[1,2]; [1]The University of Hong Kong, Hong Kong; [2]Advanced Biomedical Instrumentation Centre, Hong Kong Science Park, Hong Kong

The structure inhomogeneity of organic semiconductors had been widely observed in organic polycrystal or amorphous films. Detailed understanding of the crystal packing modes and orientations of these structure inhomogeneities has the potential to guide the design of advanced organic electrical, optical, mechanical, or magnetic devices for the corresponding properties difference of lattice planes. The identification of the crystal packing modes and orientations of organic inhomogeneity structures is a challenging part to research community for the limitations of commonly used characterization methods. For instance, X-ray diffraction can only identify the presence of these inhomogeneity structures but cannot be used to detect the specific packing mode and orientation of each structure; STEM, the commonly used method in inorganic materials show limited performance in organic materials for the severe damage of high-energy electrons to organic materials. Here in, we report a characterization approach which provides local structure information of organic thin films over a large area.
In this talk, a low damage, organic materials compatible characterization method-lateral force microscope test will be introduced. Detailed characterization results of the crystal packing mode and orientation of a commonly used evaporation-based 2,9-Diphenyl-dinaphtho[2,3-b:2',3'-f]thieno[3,2-b]thiophene (2,9-Dph-DNTT) organic film will be showed; the two inhomogeneity structures in the film-nanosprouts structure and terrace structure are corresponding to the molecular “face on” packing mode and “face up” packing mode, respectively. The electrical performance difference of the two nanostructures will be studied by conductive atomic force microscope test. The temperature dependent formation mechanism of the two structures will also be discussed in detailed.
Apart from the properties difference, the structure inhomogeneities in organic materials also have the potential to generate other interesting phenomenon, for instance, optical memory phenomenon for the charge trapping centers induced by the lattice mismatch in the interface of the inhomogeneity structures. Non-volatile optical memory transistor (OMT) based on the nanosprouts structure of 2,9-Dph-DNTT film is developed, combining with Al_2O_3 high-k dielectric, the OMT showed low operating voltage (less than 4V) and decent field effect mobility up to $3cm^2V^{-1}s^{-1}$ and promising data retention performance of binary states current ratio higher than 10^4 for more than 12hours, the mechanism of the optical-electrical memory phenomenon will be discussed in detailed. At last, a demonstration of a 16×16 flexible low operating voltage active matrix OMT array of 45ppi with image processing capability will be showed.

Charge Carrier Trapping in Organic Semiconductors Paul W. Blom, Oskar Sachnik, Xiao Tan, Yungui Li and Gert-Jan Wetzelaer; Max-Planck-Institute for Polymer Research, Germany

The efficiency and stability of single-layer polymer light-emitting diodes is compromised by unbalanced charge transport, absence of triplet-exciton harvesting and low photoluminescence quantum efficiencies. Especially charge traps have a triple negative effect: they give rise to non-radiative trap-assisted recombination, they dissociate singlet excitons leading to a reduced photoluminescence quantum yield and due to confinement of the emission zone at an electrode they lower the optical outcoupling efficiency. A strategy is developed that precludes trapping in large band gap organic semiconductors. We demonstrate that using thermally activated delayed fluorescence emitters in combination with trap-free transport high external quantum efficiencies for single-layer blue OLEDs can be obtained. Our results show that OLEDs with a simplified single-layer structure can rival the efficiencies of complex multilayer stacks.

2:00 PM SB04.06.02
Using Molecular Design to Engineer Solid-State Spin Qubits in Organic Semiconductors Robert M. Jacobberger; University of Wisconsin--Madison, United States

Molecular spin qubits promise to enable breakthroughs in quantum information science due to the ability of chemistry to (1) create atomically precise structures using synthetic methodologies; (2) tailor the magnetic, optical, and electronic properties of the molecular qubits; and (3) construct large-scale ordered arrays of qubits via crystal growth and self-assembly. Here, we present our work on engineering atomically precise hierarchical systems with tunable quantum states to serve as spin qubit arrays.

First, we engineer spin qubits based on high-spin multiexcitons photogenerated in organic semiconductors using singlet fission.[1] We engineer the packing of tetracene molecules within single crystals by using tailored linking groups to demonstrate multiexcitons that exhibit promising spin qubit properties, including a coherence time, T_m, of 3 μs at 10 K, a population lifetime, T_{pop}, of 130 μs at 5 K, and stability even at room temperature. The single-crystal platform also enables global alignment of the spins and, consequently, individual addressability of the spin-sublevel transitions. Decoherence mechanisms, including exciton diffusion, electronic dipolar coupling, and nuclear hyperfine interactions, are elucidated, providing design principles for increasing the spin coherence lifetime and operational temperature of the multiexciton spin qubits. By dynamically decoupling the qubits from the surrounding spin bath, T_m of 10 μs is achieved. This material system provides an exciting path to realize dense arrays of optically addressable qubits that are generated on demand at specific locations.

Second, we harness a new class of organic framework materials, known as ion-paired frameworks, to develop atomically precise arrays of molecular spin qubits.[2] We learn how to control the density of the paramagnetic Cu(II) porphyrin spins by engineering the linker groups and crystal growth conditions. Pulse-electron paramagnetic resonance (EPR) spectroscopy is used to probe the spin coherence of these single crystals at temperatures up to 140 K. The crystals with the longest Cu−Cu distances exhibit a spin coherence time, T_m, of 207 ns and a spin−lattice relaxation time, T_1, of 1.8 ms at 5 K, which are records for qubits in an atomically precise molecular system. The mechanisms of spin decoherence and spin-lattice relaxation will also be discussed. Incorporating molecular electronic spin qubits in ion-paired frameworks enables control of composition, spacing, and interqubit interactions, providing a rational means to extend spin relaxation times for next-generation quantum technologies.

2:15 PM SB04.06.03
The Photo-Hall Effect in High-Mobility Organic Semiconductors Vladimir V. Bruevich and Vitaly Podzorov; Rutgers University Physics Department, United States

High-mobility single crystal organic semiconductors are important for applications in advanced organic electronics and photonics. Photogeneration and transport of mobile photocarriers in these materials, although very important, remain underexplored. For sustained progress in the field, understanding the intrinsic (i.e., not limited by static disorder) charge transport properties of crystalline organic semiconductors is important. The Hall effect represents one of the most efficient experimental tools for assessing intrinsic charge transport, as Hall effect in single crystal materials probes band-like (i.e., delocalized) mobile charges. The photoconductivity-based *photo-Hall effect* can be used to address the fundamental charge transport properties of these functional molecular materials. Photocarrier generation by light allows circumventing the challenging problem of carrier injection from contacts (especially when measurements of both electrons and holes are pursued), avoiding carrier trapping and scattering associated with the interfacial charge transport as in OFETs, and preventing added disorder associated with chemical doping. Therefore, photo-Hall effect opens new opportunities in probing the intrinsic charge transport in organic semiconductors.
The photo-Hall measurements in pristine, ungated organic semiconductors pose an even greater challenge than the Hall measurements in OFETs or chemically doped samples, because a much lower carrier density (and, thus, much higher sample's resistances) is typically generated by light. By taking advantage of a sensitive ac-Hall methodology previously developed in our group, we have performed reliable photo-Hall effect measurements in a benchmark organic semiconductor rubrene.
We present the first clear demonstration of a photo-Hall effect in organic semiconductors, using a benchmark molecular crystal rubrene as an experimental platform. The concept of a photo-Hall effect allows probing the intrinsic transport properties of pristine semiconducting materials in stand-alone crystals, free from the problems associated with charge injection from contacts, interfacial transport, or additional disorder typically encountered in the conventional approaches based on FETs or chemically doped materials. In photo-Hall measurements, the steady-state carrier density and mobility are measured independently, with no assumptions regarding the photocarrier generation efficiency or lifetime, thus providing a direct experimental access to these important parameters. We find that under a *cw* illumination in the visible range, only mobile holes are generated in pristine rubrene crystals, leading to a substantial p-type surface photoconductivity with the hole mobility $\mu_{photo-Hall} = 11 \pm 1$ cm^{2}V^{-1}s^{-1} and the density that follows a power law $n_{photo-Hall} \propto P^{\alpha}$, with the power exponent $\alpha = 1/4–1/3$. In addition, by intentionally inhibiting the surface transport via the gauge effect, we observed a small residual bulk photocarrier density governed by a bimolecular electron-hole recombination ($\alpha = 1/2$) with a higher true-bulk hole mobility of $\mu_{photo-Hall} = 16 \pm 1$ cm^{2}V^{-1}s^{-1}. These experiments significantly advance our fundamental understanding of charge transport and photoconductivity in rubrene, based on triplet exciton diffusion and surface dissociation, in which the latter process is shown to be governed by electron trapping with a release of mobile hole. Overall, our work demonstrates that the photo-Hall effect is a powerful tool for addressing the intrinsic charge transport in organic semiconductors and potentially other emergent semiconducting materials.

3:30 PM *SB04.07.01
Advanced Functionalities in Organic Permeable Base Transistors Hans Kleemann, Amric Bonil and Juan Wang; Technische Universität Dresden iAPP, Germany

Vertical transistor architectures offer sub-micrometer channel dimensions and hence, high-frequency operation, without the need for advanced patterning techniques. However, while the fabrication procedures for lateral thin-film transistors matured, fabrication techniques for vertical organic transistors are less developed and as a consequence, yield, uniformity, and reliability of such devices remain poor. Furthermore, reports with vertical organic transistors addressing circuits and advanced device functionalities are rare.
For more than one decade, we have been developing organic permeable base transistors (OPBTs) – a vertical transistor structure that resembles a solid-state triode where nano-scale pinholes allow the current to pass from the emitter to the collector electrode through a control base. Starting with investigations on the fundamental device physics, we advanced the performance of these devices towards the ultra-high-frequencies region, and recently, we demonstrated the integration of complementary inverters with adjustable tripping point. In this contribution, I will discuss recent significant progress concerning device integration using large-area electrochemical anodization. In particular, using this technique, the yield of fabrication is close to 100%, allowing us to integrate circuits. Furthermore, the anodization gives us control over leakage currents, and device capacitance, and increases the tolerances against thickness variation, resulting in an excellent current gain of $>10^7$. Moreover, the anodization technique is vital for the realization of devices with advanced functionalities such as vertical memory or reconfigurable devices, opening up the perspective for the design of ultra-high-frequency application-specific circuits based on organic semiconductors.

4:00 PM *SB04.07.02
High-Speed Organic Integrated Circuits and Applications Jun Takeya[1,2]; [1]The University of Tokyo, Japan; [2]Pi-Crystal Inc., Japan

Electronic devices in the future sustainable societies require maximum function with minimum amount of constituent materials and energy cost for production. Electronic functions are often originated from two-dimensional material properties so that device components of large area and small thickness saves material consumption. The fundamental electronic functions of both analogue and digital circuits mostly rely on only a nanometer-scale thin layer at the very surface of the semiconductor material due to the very short penetration length of electric field. The presentation focuses on material bases, methods of circuit fabrication, dynamic operation of the devices, and several applications for commercialization.
Recently developed ultrathin organic semiconductor single crystalline films is suitable for large-area production with low energy consumption; the films are easily formed to large area from solution at relatively low temperature at 80 degrees centigrade [1]. Extremely thin crystal films are controllably grown to a-few molecular layers with the thickness of only 10 nm, so that material cost can be highly limited. Due to a careful material design for restricting harmful molecular vibration, very high carrier mobility more than 10 cm2/Vs is achieved. Furthermore, development of technologies for printed integrated circuits provides a manufacturable process for low-cost platforms for RFID tags and sensing circuitries. Finally, a technology for large-area light-weight display sheets will be demonstrated.
A dynamic transistor model is developed using device parameters such as channel length and overlap length of gate and source electrodes, so that high-frequency transistors are physically designed appropriately including charge-injection resistance [2]. A high cut-off frequency above 45 MHz is actually achieved which are composing elements of organic integrated circuits. Typical integrated circuits of approximately 500 transistors are formed. Moreover, a wireless power-supply is demonstrated using newly developed high-frequency organic rectifiers to operate an RFID tag with the NFC frequency [3].
Such prospect bears increasing reality because of recent research innovations in the field of material chemistry, charge transport physics, and solution processes of printable organic semiconductors. With excellent chemical and thermal stability in recently developed new materials, we are developing simple integrated devices based on CMOS using organic p-type and inorganic n-type FETs. Particularly important are new processing technologies for continuous growth of the organic single-crystalline semiconductor “wafers” from solution and for lithographical patterning of semiconductors and metal electrodes. Successful rectification and identification are demonstrated at 13.56 MHz with printed organic CMOS circuits. Future ten-meter scale large-area display also needs to be more “two-dimensional” to save materials and save energies to carry and equip on billboards.

4:30 PM SB04.07.03
Reversible Switching in Capacitors and Organic Transistors Employing Dihydroazulene/Vinylheptafulvene Photochromic Switches Sten Gebel[1], Oumaima Aiboudi[2], Franziska Lissel[2], Paul W. Blom[1] and Ulrike Kraft[1]; [1]Max Planck Institute for Polymer Research, Germany; [2]Leibniz Institute for Polymer Research, Germany

Organic field-effect transistors (OFETs) have been shown to rival or even outperform benchmark amorphous silicon-based devices. This has stimulated research efforts to further exploit organic transistors for more complex, multifunctional devices such as photodetectors or optical memories. One possibility to introduce additional functionality into OFETs is to employ molecular switches that undergo reversible isomerization under applied stimuli, such as irradiation with specific wavelengths in the UV-Vis regime. Both photoisomers exhibit different properties, such as frontier orbital energies, dipole moment or spatial extension resulting in a reversibly switchable electronic system once incorporated into an OFET device.

Here, we present that blends of semiconducting polymers and dihydroazulene (DHA)/vinylheptafulvene (VHF) photo/thermoswitches can be employed to fabricate OFETs with light/thermo-responsive device characteristics. Irradiation with UV light results in significant alteration of the transfer characteristics, especially of the subthreshold region of the gate voltage sweep. In contrast to previous work on spiropyrans or diarylethenes, the backreaction is induced thermally and not via visible light irradiation and reproducibly yields the characteristics of the pristine devices. Applying UV light of different doses shows that the magnitude of switching directly depends on the respective UV dose, hence enabling a multi-level electronic system.

We further demonstrate that DHA/VHF molecular switches can also be used to introduce stimuli-responsiveness into organic transistors by incorporating them into the gate dielectric of the device. To systematically explore this approach, we firstly focus on the evaluation of the dielectric properties of DHA/VHF blends with the dielectric polymer poly(methyl methacrylate) (PMMA) in metal-insulator-metal capacitors using impedance spectroscopy. Afterwards, these switchable dielectric blends are used as gate dielectrics in OFETs, allowing optical control of device characteristics and figures of merit such as field-effect mobility and threshold voltage.

Additionally, our results show that DHA/VHF molecular switches (unlike the established spiropyran (SP)/merocyanine (MC) photoswitch) exhibit excellent resistance to cycling fatigue when incorporated into both the semiconductor and the PMMA gate dielectric.

Bias stress experiments on transistors with DHA/VHF-PMMA and SP/MC-PMMA blend dielectrics reveal that the mechanism by which transistor performance is affected is fundamentally different for these two families of molecular switches.

4:45 PM SB04.07.04
Advanced Organic Field-Effect Transistors with pn-Heterojunction beyond Von Neumann Device Architecture Yutaka Wakayama, Debdatta Panigrahi, Junko Aimi and Ryoma Hayakawa; NIMS, Japan

In this presentation, we will introduce an antiambipolar transistor (AAT) as a key element for novel electronic device to overcome the limitation of conventional von Neumann architecture. The uniqueness of AATs is ascribed to their distinctive electrical properties; sharp increase and decrease in the drain current can be observed by monotonical increase in gate bias voltage. This characteristic Λ-shaped transfer curve is realized due to a pn-heterojunction formed around the center of a transistor channel. Particularly, negative differential transconductance (NDT), where the drain current decreases against increase in gate bias voltage, is the key property to yield various functionalities. By taking advantage of this character, we have been developing a variety of novel organic electronic applications.
These kinds of innovative electronic device are particularly required in the field of organic electronics. Despite their various advantages, such as mechanical flexibility, light weight, solution processability, and cost-effectiveness, organic electronics have been recognized to have weak points in terms of integration density and data processing capability because of their incompatibility with conventional lithographic processes. Meanwhile, organic AATs appear to offer means to overcome such weaknesses, and thereby open a new frontier in the field of organic electronics.
First, the fundamental mechanism of the carrier transport is discussed in terms of the characteristic device configuration. The essential part of the AATs is the pn-heterojunction at the transistor channels; thin films of a p-type and n-type organic semiconductors are partially overlapped. These films are contacted with respective metal electrodes (source and drain electrodes) to form a pn-heterojunction transistor. The carrier transport mechanism was analyzed by original measurement techniques: operando photoemission electron microscopy (operando-PEEM) and operando Kelvin probe force microscopy (operando-KPFM). These techniques allowed us to characterize carrier transport properties in the device operation status under bias voltage.
Second, the ATT applications are introduced those are multi-valued (ternary and quaternary) logic circuits and reconfigurable logic circuits. Both are advantageous to increase integration density with less device elements. Other applications are logic-in-memory and artificial synaptic device. These were realized by combining AATs and non-volatile memory effects. These novel devices have a potential to overcome the weak point of the organic electronics and limitation of conventional von Neuman type devices. Therefore, we categorize these devices as beyond von Neumann type electronic devices.

A Persistent Challenge in Organic Electronics: How Does Structure Affect Electronic Transport? Alberto Salleo; Stanford University, United States

Linking microstructure to transport remains the grand challenge preventing the rational design of new organic semiconductors. Indeed overcoming this hurdle might unleash the full power of organic synthesis to make materials with “designer” properties, be they electronic, excitonic or ionic transport. We have spent years developing complementary techniques that allow us to analyze the microstructure at different length-scales and from complementary points of view. In particular, the use of XRD, TEM and IR/UV-Vis spectroscopy allows to understand order from the molecular to the device level. We use these techniques coupled with transport measurements to understand the role of intra vs. interchain order as well as mesoscale order. These techniques can be extended to mixed conductors where the electrolyte controls order and provides one more knob to study the relationship between order and transport.

9:00 AM *SB04.08.02
Electrochemical Transistors: A Platform for Exploring Carrier Transport and Ion-Carrier Correlations at High Charge Densities in Organic Semiconductors Daniel Frisbie; University of Minnesota, United States

Electrochemical transistors are a powerful platform for fundamental investigations of hole and electron transport in organic semiconductors as a function of continuously tunable charge up to very large densities of order 0.1-1 carrier per molecule. There is increasing evidence that ion-charge carrier interactions are profoundly important in these devices. This talk will describe ongoing experiments to examine transport in electrochemical transistors based on single crystals and thin films of organic semiconductors. In one study, electron transport on the surface of electrolyte-gated C60 single crystals is measured as a function of cation radius in the gate electrolyte. For small cations, surface conductivity versus electron density exhibits a peak near 0.5 electron/C60. Conductivity is completely shut down at 1 electron/C60. As cation size increases, this peaked conductance behavior becomes less prominent and average electron mobility increases, indicating that cation-electron interactions at the surface of the C60 crystal play an important role. For devices gated with the largest cations, temperature dependent transport shows the gate-induced electrons are significantly delocalized. In a second experiment, transport is examined in a series of polythiophenes as a function of side-chain length. Again, a strong peak in conductance versus carrier density is observed, with the peak occurring near 0.15 hole/monomer for all of the polymers. Further, there is a marked dependence of the conductance maximum on side-chain length, with longer side chains giving higher conductances. The results are interpreted in terms of ion-carrier Coulomb interactions and the implications will be discussed.

9:30 AM SB04.08.03
In-*Operando* Spectroscopic Characterization of Non-Equilibrium States in a Highly Doped Polymer Ian Jacobs[1], Dionisius Hardjo Lukito Tjhe[1],

Xinglong Ren[1], Gabriele D'Avino[2], Tarig Mustafa[1], Thomas Marsh[1], Lu Zhang[1], Yao Fu[1], Ahmed E. Mansour[3], Yuxuan Huang[1], `Wenjin Zhu[1], Ahmet Hamdi Unal[1], Vincent Lemaur[4], Claudio Quarti[4], Jin-Kyun Lee[5], Iain McCulloch[6], Martin Heeney[7], Norbert Koch[3], Clare Grey[1], David Beljonne[4], Simone Fratini[2] and Henning Sirringhaus[1]; [1]University of Cambridge, United Kingdom; [2]Centre National de la Recherche Scientifique, France; [3]Humboldt-Universität zu Berlin, Germany; [4]University of Mons, Belgium; [5]Inha University, Korea (the Republic of); [6]University of Oxford, United Kingdom; [7]Imperial College London, United Kingdom

Heavily doped organic semiconductors are critical to a variety of applications, including thermoelectrics, bioelectronics, and neuromorphic computing devices. Recent advances have enabled the routine doping of polymer films to extremely high carrier densities on the order of one charge per polymer repeat unit. In this regime charge transport is comparatively poorly understood due to the non-negligible effects of electron-electron and electron-ion interactions, in addition to the ever-present role of static and transient disorder.
Here, we report on dual-gated indacenodithiophene-co-benzothiadiazole (IDTBT) organic electrochemical transistors (OECTs) and corresponding ion-exchange doped films, in which a second field-effect gate enables us to modulate the carrier density independently from the ion density. These devices show unusual behavior; at low temperatures, field effect transfer curves are highly non-linear and in many cases even ambipolar, while at high temperatures a purely linear curve is obtained. Using solid-state NMR and infrared charge modulation spectroscopy, we demonstrate that this non-linearity at low temperatures is a signature of a non-equilibrium state resulting from freeze-out of ionic motion. Under these conditions, we see an enhancement in charge delocalization, electrical conductivity, and Seebeck coefficient, pointing to a new pathway to enhanced thermoelectric performance.

9:45 AM SB04.08.04
Electrochemical Doping Induced Crystallinity in Organic Mixed Ionic/Electronic Conductors Lucas Flagg and Lee Richter; National Institute of Standards and Technology, United States

Organic mixed ionic-electronic conductors (OMIECs) are an exciting class of new materials with a range of potential applications including biosensors, electrochromics, and neuromorphic computing. These applications all require ionic transport from an electrolyte into the organic active layer during operation. Characterization of this electrolyte and ion swollen state is essential to understanding device operation on a fundamental level. However, this swollen state is particularly difficult to study because it requires development of *in-situ* techniques. Here, we utilize *in-situ* Grazing Incidence Wide Angle X-ray Scattering (GIWAXS) to study the crystallinity of the swollen state of OMIECS as a function of applied potential. We study a variety of conjugated polymer active layers and find consistent doping induced crystallinity across a variety of different polymer backbones. Interestingly, we find a maximum in the crystallinity as a function of doping level for some polymers. At moderate doping levels the crystallinity is enhanced relative to the undoped state, but then at the highest doping levels achieved the crystallinity decreases. Finally, we use organic electrochemical transistors (OECTs) to correlate the electronic conductivity with these doping induced morphological changes. These results demonstrate the importance of *in-situ* characterization to develop a better understanding organic electronic devices.

10:30 AM *SB04.08.05
Tuning Mixed Ionic-Electronic Transport in PEDOT:PSS Laure V. Kayser; University of Delaware, United States

Organic mixed ionic-electronic conductors (OMIECs)—conjugated polymers that can transport and capacitively store both ionic and electronic charges—are fundamental to the development of bioelectronics, energy storage, and neuromorphic computing. In organic electrochemical transistors (OECTs) in particular, OMIECs are used in the channel of the transistor to generate large currents under small voltage bias, making them attractive amplifiers for biosensing applications. While new OMIECs are regularly reported, the most commonly used material is the polyelectrolyte complex PEDOT:PSS. This material is commercially available as a dispersion in water and provides excellent performance in OECT after a variety of post-treatments. In this talk, I will share how our laboratory uses controlled radical polymerizations to precisely synthesize PSS and its derivatives towards a better understanding of structure-property relationships in PEDOT:PSS. I will also present a novel strategy to ensure that the films remain stable in water under repeated cycling operations by using an adhesion monolayer between the substrate and the PEDOT:PSS films.

11:00 AM SB04.08.06
Morphological and Structural Engineering of Conjugated Polymers for Near-Infrared Electrochromic Devices Robert M. Pankow[1,2], Antonio Facchetti[3] and Tobin Marks[2]; [1]The University of Texas at El Paso, United States; [2]Northwestern University, United States; [3]Georgia Institute of Technology, United States

The recent device engineering and material optimization of electrochromic devices (ECDs) has enabled new frontiers beyond the original focus of smart-window applications and display devices, including: NIR-IR optical filters, energy storage, active camouflage, and broadband communication. For conjugated polymer ECDs, the highly tunable polymer structures provide numerous handles for modifying the optoelectronic and physicochemical properties facilitating efficient optical switching across the visible wavelength range (400-700 nm) and into the NIR (>750 nm). Here, we first disclose the optimization of a porous nanostructured conjugated polymer morphology enabling vertically stacked redox-active p-type and n-type polymer multilayer ECDs. Specifically, efficient oxidative electrochromic switching at lower potentials (+0.4 V versus +1.2 V with a dense top layer) or dynamic oxidative-reductive electrochromic switching is found with a multilayered ECD architecture. Next, we disclose the synergistic optimization of the CP sidechain (either branched alkyl or EG_n) and the electrolyte cation identity for a series of diketopyrrolopyrrole (DPP) and 3,4-ethylenedioxythiophene (EDOT) or glycolated bithiophene (g2T) copolymers. It was found that by fine-tuning the extent of EG_n sidechain incorporation and the identity of the electrolyte cation a 2x increase in optical contrast (from 12 to 24%) and >60x reduction in switching time (from 20 to 0.3 s) could be realized in NIR-ECDs. To elucidate the influence of the polymer morphology/microstructure on these performance metrics, atomic force microscopy (AFM) and grazing incidence wide-angle X-ray scattering (GIWAXS) were performed. These findings provide material design guidelines for the development of next-generation CPs and mixed ionic-electronic conductors.

11:15 AM SB04.08.07
Stretchable, Enhancement-Mode PEDOT:PSS Organic Electrochemical Transistors Yan Wang and Shiming Zhang; The University of Hong Kong, Hong Kong

Stretchable organic electrochemical transistors (OECTs), based on the conducting polymer poly(3,4-ethylenedioxythiophene) doped with poly(styrene sulfonate) (PEDOT: PSS), have shown significant potential in bridging the gap between microelectronic devices and the soft biological environment [1,2]. However, there has been a lack of corresponding stretchable devices that can operate in enhancement mode, which has limited the development of low-power soft integrated circuits and systems.

In our research, we present the first stretchable PEDOT: PSS OECTs that operate in enhancement mode. This achievement is made possible by the

development of two key elements: A straightforward solution-based method that efficiently removes dopants from stretchable PEDOT: PSS thin films; A two-step soft annealing process that immobilizes the de-doping agents on the transistor's channel without affecting its functionality.

Experimental results have demonstrated that the combination of these two approaches allows for the creation of robust and stretchable enhancement-mode OECTs. These devices can be stretched between 0% and 50% strain and remain functional even after repeated stretching tests. These stretchable enhancement-mode PEDOT: PSS OECTs are expected to serve as new building blocks for the development of low-power organic biosensing and bioelectronics systems.

11:30 AM SB04.08.08
N-Type Semiconducting Hydrogel Peiyun Li, Wenxi Sun and Ting Lei; Peking University, China

Hydrogels are an attractive category of biointerfacing materials with adjustable mechanical properties, diverse biochemical functions, and good ionic conductivity. Despite these advantages, their application in electronics has been restricted due to their lack of semiconducting properties, as they have traditionally only served as insulators or conductors. We develop single and multiple network hydrogels based on a water-soluble n-type semiconducting polymer, thereby endowing conventional hydrogels with semiconducting capabilities. These hydrogels show good electron mobilities and high on/off ratios, enabling the fabrication of complementary logic circuits and signal amplifiers with low power consumption and high gains. We demonstrate that hydrogel electronics can sense and amplify electrophysiological signals with enhanced signal-to-noise ratios. Our work could enable more optoelectronic properties and greatly expand the applications of hydrogels in bioelectronics.

SESSION SB04.09: Materials II

1:30 PM *SB04.09.01
Semiconducting Polymers for Organic Electrochemical Transistors Iain McCulloch; University of Oxford, United Kingdom

Organic electrochemical transistors (OECTs) have been shown to be promising devices for amplification of electrical signals and selective sensing of ions and biologically important molecules in an aqueous environment, and thus have potential to be utilised in bioelectronic applications. The sensitivity, selectivity and intensity of the response of this device is determined by the organic semiconducting polymer employed as the active layer. This work presents the design of new organic semiconducting materials which demonstrate good OECT performance, through operation in accumulation mode, with high transconductance and low operating voltage.
We discuss here the design, synthesis and performance of novel intrinsic semiconducting polymers for efficient accumulation mode OECT devices. Key aspects such as ion and charge transport in the bulk semiconductor and operational voltage and stability of the devices are addressed in order to elucidate important structure-property relationships. A range of new semiconducting polymers, designed to exhibit facile electrochemical doping of either holes or electrons, facilitate ion penetration and migration, as well as have aqueous compatibility are reported. Optimisation of a series of polymer parameters including electrochemical doping, charge carrier mobility and capacitance are discussed.

2:00 PM *SB04.09.02
Chiral Organic Semiconductors Yves H. Geerts[1,2]; [1]University Libre de Bruxelles, Belgium; [2]International Solvay Institutes of Physics and Chemistry, Belgium

I will report on our latest results on the design, the synthesis, and the characterization of crystalline organic semiconductors with achiral and chiral pi-systems. Chiral induced spin selectivity (CISS) effect and electrical magnetochiral anisotropy e(MChA) have been investigated in organic field effect transistors (OFETs) with these materials. [Adv. Sci. 2023, 10, 2301914]

2:30 PM *SB04.09.03
Deciphering The Difference between Flexible Chain and Hairy-Rod Polymer Semiconductors Natalie Stingelin; Georgia Institute of Technology, United States

Organic electronic materials possess unique opto-electronic and processing properties that provide broad opportunities for use in light-emitting diodes, solar-energy harvesting systems, to next-generation sensors and neuromophic computing components. These technologies have been continually improving over the past decades, aided by advancements in materials chemistry and processing innovation. State-of-the-art polymer semiconductors typically have an electron donor-acceptor (D-A) backbone structure with a number of fused ring moieties, and complex aliphatic or, e.g., ethylene-oxide side chains that decorate the backbone to provide solubility. It is important to recognize that the physical properties of the side chains are substantially different from the backbone, constituting an amphiphilic-like characteristics transverse to the backbone reminiscent of phospholipid and surfactant molecular analogs, and simple classical descriptions of amorphous vs. semicrystalline structure no longer apply. Here, we discuss how the FSC technique can be used for the identification of thermodynamic transitions of next generation D-A polymers commonly used in the organic solar cell area to obtain important structural information of this new class of materials and, in turn, establish processing guidelines towards materials of specific optical or electrical characteristics, and improved materials design for organic optoelectronic devices.

3:30 PM *SB04.10.01
Novel Extended Chromophores as Organic Transistor Materials John Anthony; University of Kentucky, United States

The field of organic electronics benefits from the synthetic diversity of conjugated chromophores, which can be further functionalized to tune everything from optical gap to crystal packing. The ability to vary structure allows an impressive variety of related compounds to be compared, enhancing our understanding of design rules for the development of new semiconductor materials. For example, we know that two-dimensional electronic coupling is critical to high-mobility devices, as is a layered / lamellar motif for the 2D interacting layers. Design guidelines beyond that are only now emerging - such as a desire for isotropic electronic coupling within the 2D interacting layers, and functionalization that minimizes core vibration in the solid state. With these emerging notions in mind, I will present an array of new and exotic aromatic backbones and functionalization schemes designed to further explore these newer potential design guidelines, to attempt to determine their impact on performance in organic transistors. In particular, the impact of chromophore twisting / curvature on charge transport studies will be discussed.

4:00 PM *SB04.10.02
Harnessing Exciton Transitions for Sensing Devices: OLED and Transistor-Based Magnetic Field Sensors Emily G. Bittle; NIST, United States

The study of excitons has advanced optoelectronic device control and efficiency. Now, there is a growing interest in harnessing the unique exciton transitions of long-lived high-binding energy excitons (HBEE) for developing new device functionality. Our research has demonstrated the feasibility of using exciton dynamics in organic light-emitting diodes (OLEDs) as magnetic field sensors in fully electronic devices[1]. Additionally, wide-field optical detection of OLED output in a graded magnetic field has been demonstrated that shows the promise of sub-micron sensing using excitons[2]. By integrating exciton properties and functionality into LEDs and other electronic devices, we envision the potential for developing screens and lighting with built-in sensing capabilities. We are actively exploring the use of transistor-based sensors to refine exciton-based measurements within electronic devices[3,4]. The flexibility of controlling parameters in transistors, such as traps, interfaces, field, structure, etc, offers a versatile approach to enhancing exciton properties for optimal field sensing. Our ongoing work investigates material and device properties to enhance signal sensitivity, extending beyond the conventional focus on optoelectronic efficiency studies.

4:30 PM SB04.10.03
Characterization of Relaxation and Transport Properties of OLEDs with The Cross-Correlation Noise Spectroscopy Andrey Rogachev; University of Utah, United States

The state-of-the-art cross-correlation noise spectroscopy developed in our group significantly expands the sensitivity and bandwidth of the method. This in turn has allowed to characterize electrical noise of several systems beyond the 1/f term and access various contributions related to generation-relaxation and transport processes in both phosphorescent and fluorescent OLEDs. The unique feature of the method is that the relative noise contribution of the most resistive element of the system gets strongly enhanced. We found that it can be related to the bottle-neck step in the percolative propagation across a device or to a particular interface that impedes the transport. Application the method to solar cells and its expansion to the optical domain will be also discussed in the presentation.

4:45 PM SB04.10.04
Highly Efficient Intrinsically Stretchable OLEDs from Thermally Activated Delayed Fluorescence Cheng Zhang, Wei Liu and Sihong Wang; Pritzker School of Molecular Engineering, United States

Light-emitting devices are crucial for human-machine interfaces, which would function as read out displaying platform, health sensors, therapy unit, or optical neurostimulator in optogenetics. Considering the operation scenario of these devices, mechanical stretchability and electroluminance (EL) performance are two of the key aspects of device design. To achieve stretchability, we have reported a feasible method that is copolymerizing soft chain with conjugated functional unit. To achieve decent EL performance, among current light-emitting technologies, organic light-emitting diodes (OLEDs) stand out for their high efficiency, brightness, and low working voltage. To the best of our knowledge, most of the reported stretchable OLED are based on fluorescence emitters, 1st generation of OLED emitter. This kind of emitter has relatively simple requirements since it only harvest its singlet excitons, which leads to a theoretical internal quantum efficiency (IQE) as 25%. In contrast, thermally activated delayed fluorescence (TADF) emitters, the 3rd generation of OLED emitters, are more preferred due to its organic constituents as well as a near-unit IQE. However, its complicated device structure and requirement of energy alignment make the realizing of highly efficient fully stretchable TADF devices very challenging. Here, we want to bring up with a fully stretchable OLED devices based on TADF mechanism reaching an external quantum efficiency (EQE) around 20% and crack-onset strain exceeding 120%.

SESSION SB04.11: Poster Session
Session Chairs: Paddy K. L. Chan, Katelyn Goetz, Ulrike Kraft and Simon Rondeau-Gagne
Thursday Afternoon, April 25, 2024
Flex Hall C, Level 2, Summit

5:00 PM SB04.11.01
Low-Temperature Cross-Linkable Hole Transport Materials for High-Performance Solution-Processed Quantum Dot and Organic Light-Emitting Diodes Youngjun Hwang, Athithan Maheshwaran, Hyejeong Bae, Jaehyoung Park and Youngu Lee; Daegu Gyeongbuk Institute of Science and Technology (DGIST), Korea (the Republic of)

Solution-Processed Quantum Dot Diodes (QLED) and Organic Light-Emitting Diodes (OLED) have seen significant progress in recent years, offering numerous advantages in the display technologies such as enhanced color purity, brightness, and and suitability for large-scale manufacturing. However, it is difficult to fabricate efficient solution-processed QLEDs and OLEDs in conventional device architectures (anode/hole injection layer (HIL)/hole transport layer (HTL)/emitting layer (EML)/electron transport layer (ETL)/cathode). The main obstacle to the fabrication of solution-processed QLEDs and OLEDs is the interface mixing/interfacial erosion of solution-based emitting materials in a small molecular HTL, degrading the performance of QLEDs and OLEDs.
Recently, various studies were conducted to develop thermal/photo cross-linkable organic molecular hole transport materials (HTMs) for efficient and stable solution-processed QLEDs and OLEDs. In particular, thermal cross-linking of organic molecular HTMs is the most promising technique for achieving efficient solution-processed QLEDs and OLEDs because it does not require the use of the photoinitiator. However, previously developed thermal cross-linkable HTMs possessed poor hole transport properties, high cross-linking temperatures, and long curing times.
To achieve efficient cross-linkable HTMs with high mobility, low cross-linking temperature, and short curing time, we designed and synthesized a series of low-temperature cross-linkable HTMs comprising dibenzofuran (DBF) and 4-divinyltriphenylamine (TPA) segments for highly efficient solution-processed QLEDs and OLEDs. The introduction of divinyl-functionalized TPA in various positions of the DBF core remarkably affected their chemical, physical, and electrochemical properties. Interestingly, cross-linked 4-(dibenzo[*b*,*d*]furan-3-yl)-*N*,*N*-bis(4-vinylphenyl)aniline (3-CDTPA) showed a deep highest occupied molecular orbital energy level (5.50 eV), excellent thermal stability (T_d, 427 °C), high hole mobility (2.44×10^{-4} cm^2 V^{-1} s^{-1}), uniform surface morphology (RMS, 0.95 nm), low cross-linking temperature (150 °C), and short curing time (30 min). Furthermore, a green QLED with 3-CDTPA as the HTL exhibited an impressively high maximum external quantum efficiency (EQE_{max}) of 18.59% with a high maximum current efficiency (CE_{max}) of 78.48 cd A^{-1}. In addition, solution-processed green OLEDs with 3-CDTPA showed excellent device performance with an EQE_{max} of 15.61%, a CE_{max} of 52.51 cd A^{-1}. To the best of our knowledge, this is the first report on green solution-processed QLEDs and phosphorescent OLEDs showing high EQE, luminescence using DBF as the core and divinyl-functionalized TPA as the cross-linked HTL. These results reveal that TPA-functionalized divinyl moieties at suitable positions in the DBF core provide a new strategy to achieve high hole mobility, low cross-linking temperature, and short curing time in solution-processed QLEDs and phosphorescent OLEDs.

5:00 PM SB04.11.02
On-Site Amplification of Neural Signals by Organic Field-Effect Transistors Yifan Guo[1] and Paddy K. L. Chan[1,2]; [1]The University of Hong Kong, Hong Kong; [2]Advanced Biomedical Instrumentation Centre, Hong Kong

In the field of brain-computer interface, the transducing elements play a pivotal role in monitoring and recording neural signals. Compared to noise-sensitive microelectrodes, the high transconductance of organic electrochemical transistors enables on-site signal amplification, leading to an enhanced signal-to-noise ratio (SNR). However, the ion exchange process restricts its capability to record high-frequency (> 1 kHz) neural signals. Although lack of direct communication with the ions in the body, organic field-effect transistors (OFETs) exhibit not only high transconductance (up to 1 mS), low sensitivity to noise (down to 1 nA), and remarkable mechanical flexibility but also high operating speed (> 10 kHz). These combined merits may broaden the potential for full-frequency brain signals recording using active electrodes.
In this study, we developed an ultra-conformal OFETs (5 μm channel length) featuring a top-gate bottom-contact structure, achieving a transconductance of 100 μS and a cut-off frequency of 10 kHz. In comparison to microelectrodes (SNR = 10 dB), the electrocorticogram signals amplified by OFETs exhibit a superior SNR (over 50 % improvement) and an enhanced temporal resolution. The pre-ictal brain signals (500 μV) associated with epilepsy are effectively monitored by our OFETs array. With proper encapsulation, the devices demonstrate excellent stability and biocompatibility. We believe that the flexible organic active electrode paves a promising path for disease prediction and high-frequency neural signals recording.

5:00 PM SB04.11.03
Allrounder Strategy of Using a Photocrosslinker for Photopatterning Transparent Silver Nanowire/PEDOT:PSS Electrodes Wanho Cho[1], BongSoo Kim[1], JeongHo Cho[2], InCheol Kwak[2], Moon Sung Kang[3] and TaeHyun Kwon[3]; [1]Ulsan National Institute of Science and Technology, Korea (the Republic of); [2]Yonsei University, Korea (the Republic of); [3]Sogang University, Korea (the Republic of)

This work aims to develop transparent conductive materials for various applications such as next-generation displays, sunlight harvesting, lighting, and smart windows. These materials need to have high optical transparency, electrical conductivity, and mechanical flexibility. Additionally, they must exhibit environmental stability and be suitable for practical manufacturing processes. Silver nanowires (AgNWs) are considered promising candidates that meet these demanding requirements. AgNWs form a percolated network that offers high optical transparency and electrical conductivity. This network structure is also tolerant to mechanical deformation. Furthermore, Ag NWs can be dispersed in various solvents and applied to flexible substrates using solution-based methods.
Despite these advantages, the widespread use of AgNWs in commercial applications has been limited. One key challenge is the need for scalable processing methods to create precise and high-throughput AgNW networks that meet industrial standards. One common approach is the surface-energy-controlled transfer printing of AgNW networks onto target substrates, but this method faces challenges related to uniformity and fidelity. Photolithography, a prominent microfabrication technology, is also considered a reliable and scalable patterning technique for AgNWs. However, traditional photolithography methods, involving pre-patterned photoresist and subsequent etching or lift-off processes, are not fully compatible with AgNW networks due to their porous nature and poor adhesion to substrates.
To address these issues, we developed a direct photopatterning method for AgNW networks. This method requires only a small amount of photocrosslinking agent (<3 wt%). A crosslinker, (oxybis(ethane-2,1-diyl))bis(oxy))bis(ethane-2,1-diyl)bis(4-azido-2,3,5,6-tetrafluorobenzoate (2Bx-4EO), was designed and synthesized to induce crosslinking between AgNWs upon ultraviolet (UV) irradiation. This crosslinking approach allows for the precise patterning of AgNWs. To further enhance the electrode characteristics of the AgNW network, poly(3,4-ethylenedioxythiophene) polystyrene sulfonate (PEDOT:PSS) was selectively coated onto the AgNW patterns. The unique roughness-assisted wetting phenomenon facilitated the deposition of PEDOT:PSS, resulting in hybrid bilayer electrodes with low roughness, high oxidation resistance, and high mechanical stability. These AgNW/PEDOT:PSS hybrid transparent electrodes were used to create various electrochemical devices. Organic electrochemical transistors (OECTs) were employed as driver transistors, and they exhibited improved performance when using the hybrid electrodes compared to pristine AgNW network electrodes. This improvement was attributed to the low contact resistance and smooth surface of the hybrid electrodes.
Furthermore, the AgNW/PEDOT:PSS hybrid electrodes were integrated into electrochromic (EC) devices, demonstrating their stability and suitability for applications involving charge transfer reactions. The devices exhibited reversible color changes and maintained their performance over numerous voltage cycles.
Finally, a seven-segment active-matrix EC display was developed by integrating seven EC cells with their own driving OECTs. This display showcased the potential of the Ag NW/PEDOT:PSS hybrid electrodes for use in more complex optoelectronic devices.

5:00 PM SB04.11.04
Mitigation of Dark Current in Organic NIR Photodetector Achieved by Controlling Trap States in The Active Layer Using The Ternary Approach Alvin Joseph, Anitha B, Akhil Alexander, Muhammed Raees A and Manoj A. Namboothiry; Indian Institute of Science Education and Research, Thiruvananthapuram, India

Effective suppression of trap states or controlling the energetic disorder in the photoactive layer is of utmost importance to mitigate the dark current in near infrared organic photodetectors (NIR OPDs).[1, 2] Energetic disorder in the density of states distribution of the devices is determined by the nanomorphology of the active layer. A ternary approach by introducing a third component to the bulk heterojunction of a binary device is a strategic technique to control the trap density in the active layer.[3] In the present study, a recently developed non-fullerene acceptor (NFA), BTP-FTh is introduced as the guest component in the host system of donor polymer PCE-10 and a narrow bandgap NFA, COTIC-4F. The performance of the ternary organic photodiodes is systematically investigated by varying the weight ratio of the NFAs and studied its effect to control the trap density and energetic disorder in the active layer. The judicious selection of the guest component simultaneously regulated the nanomorphology, which further resulted in a significant reduction in the dark current density of the optimized devices to about 3.94 nAcm-2 at -1V. The Mott–Schottky analysis and capacitance-frequency spectroscopy studies also revealed that the dark current density suppressed due to the reduction in the trap density of state and energetic disorder in the photoactive layer of the OPDs. Moreover, the introduction of the third component in the host system synergistically improved the charge collection efficiency of the host system. Furthermore, the optimised devices exhibit fast photoresponse and good storage stability even after one month.

Engineering The Solid-State Aggregates in Brickwork Stacks of n-Type Semiconductors by Structural Alteration: A Way to Achieve High Electron Mobility Indrajit Giri and Ratheesh K. Vijayaraghavan; IISER Kolkata, India

Recent developments in the area of solution processed ambient stable organic semiconductors (OSCs) becoming promising towards lightweight, low cost and mechanically flexible aspects towards the next-generation electronic devices. It has got immense potential for industrial applications in organic field effect transistors (OFETs), solar cells, light-emitting diodes (LED), sensors etc. Specifically, the OFETs are diversely utilized in displays, logic circuits, amplifiers etc., and therefore OSCs with high carrier mobility and good ambient stability have been robustly demanded. Since the performance of electron-transporting *n*-type OSC materials are lagging behind *p*-type OSCs, and for the industrial advancement of OFETs, *p*-*n* heterojunction and integrated circuits assembled by both types of materials, the improvement of *n*-type OSCs including good environment stability and high electron mobility (μ_e) is in research hotspot.
In our work, the foremost importance was given to synthetic easiness to ensure the scalability and economic utility of active layer *n*-type materials. Need of strong intermolecular interactions to minimize the longitudinal slip between π-stacked molecules and to reduce the lattice vibrations, special care is devoted to the molecular design strategy. Additionally, the substitution should favor effective solid-state aggregation which is crucial in achieving high carrier mobility and device stability. Substitution of planar aromatics with electronegative atoms or groups to achieve n-type materials is a known concept. But, a deep insight on the required groups and the resultant molecular packing to enable efficient charge hoping is not well addressed. There are some random design concepts and examples known with the same strategy, but a lucid approach to investigate the structural features is limited. Such additional groups should not only endorse deep LUMO to ensure efficient electron injection at low operational bias, but also potentially lead to substantial electrostatic interactions in their aggregating solids states, particularly in the brickwork stack of molecular assemblies. Here, we were able to achieve an n-type OSC with excellent dopant-free field-effect electron mobility (μ_e) as high as 1.0 $cm^2 V^{-1} s^{-1}$, and a very high on-off current ratio (I_{on}/I_{off} ~10^9) by solution process deposition (spin coating). μ_e retained up to ~60 % upon ambient exposure for 100 h under 75 % humidity storage, indicating good ambient stability.

5:00 PM SB04.11.06
Intrinsically Stretchable Full-Color Light-Emitting Films via Elastomer Blend for Polymer Light-Emitting Diodes MinWoo Jeong[1], Jin Hyun Ma[1], Jae Seung Shin[1], Jun Su Kim[1], Guorong Ma[2], Tae Uk Nam[1], Phuong N. Vo[1], Kyu Ho Jung[1], Xiaodan Gu[2], Seong Jun Kang[1] and Jin Young Oh[1]; [1]Kyung Hee University, Korea (the Republic of); [2]The University of Southern Mississippi, United States

For skin-like display, intrinsically stretchable light-emitting materials are key components. However, the previously reported materials have been still restricted super yellow series materials, which could be emitting just green-like yellow lights. Therefore, three primary light-emitting materials such as red, green and blue (RGB) are necessary to develop skin-like full-color displays. Herein, we report highly stretchable three primary light-emitting films enabled by polymer blend between conventional RGB light-emitting polymer semiconductors and a non-polar elastomer (SEBS). Through nano-phase separation, these films are composed of multi-dimensional nanodomains that are interconnected in an elastomer matrix for efficient charge transport and light-emitting performance under strain. The polymer light-emitting diode (PLED) exhibited over 1,000 cd/m^2 luminance with low turn-on voltage (< 5 V_{on}) and the stretched blend films on rigid substrate preserved their light-emitting performance up to 100% strain even after 10,000 multiple stretching cycles.

Silicone-Induced Microlithography of Small-Molecule Phosphorescent Emitters for High-Resolution Micro-OLEDs Soyeon Lee[1], Hyukmin Kweon[1], Borina Ha[1], Ryungyu Lee[2], Seonkwon Kim[3], Seunghan Lee[4], Hyobin Ham[5], Hayoung Lim[1], Moon-Ki Jeong[6], Gyurim Park[3], Joon Hak Oh[6], Moon Sung Kang[4], Youngmin You[3], Jeong Ho Cho[3], BongSoo Kim[5], Hojin Lee[2] and Do Hwan Kim[1]; [1]Hanyang University, Korea (the Republic of); [2]Soongsil University, Korea (the Republic of); [3]Yonsei University, Korea (the Republic of); [4]Sogang University, Korea (the Republic of); [5]Ulsan National Institute of Science and Technology, Korea (the Republic of); [6]Seoul National University, Korea (the Republic of)

Organic light-emitting diodes (OLEDs) have emerged as a leading display technology, known for their exceptional color purity, rapid response time, slim design, and expanded color gamut. In the group of OLED materials, small-molecule based phosphorescent OLEDs, referred to as host-dopant systems, are favored for their superior luminous efficiency. These materials efficiently capture both singlet and triplet excitons, resulting in enhanced quantum efficiency and prolonged operational lifespans. This heightened efficiency makes phosphorescent OLEDs a preferred choice for a wide range of applications, including microdisplays for augmented reality, virtual reality, and mainstream commercial displays.
Patterning small-molecule-based phosphorescent materials conventionally rely on fine metal masks (FMM) for deposition-based techniques. Recent demonstrations have achieved resolutions up to 3,000 pixels per inch (ppi) for small-molecule OLED microdisplays using FMM. However, FMM-based approaches have inherent limitations, including shadow effects caused by factors such as vapor path, deposition angles, and mask thickness. Alternative methods like template-directed growth and inkjet printing have been explored, but they often exhibit issues related to resolution, pattern fidelity, and fabrication yield which necessitates the exploration of novel approaches to achieve high-resolution patterning.
To address these challenges, there is growing interest in utilizing reactive ion etching (RIE)-based photolithography for high-resolution patterning. RIE-based photolithography shows promise in achieving precise patterning. Nevertheless, the intrinsic limitations of small-molecule phosphorescent materials, characterized by their poor physico-chemical durability, have hindered their compatibility with RIE-based photolithography. This incompatibility leads to pattern degradation and compromises luminous properties, impeding the realization of high-resolution OLED microdisplays.

Herein, we designed a novel paradigm by incorporating silicone into phosphorescent small-molecule networks. This silicone-integrated phosphorescent organic light-emitting network (SI-phOLEN), in which silicone molecules are homogeneously crosslinked with small-molecule light-emitting materials, can effortlessly achieve ultrahigh-resolution patterns via the photolithography process without degradation of their exceptional phosphorescent emission efficiency. On the basis of the unique features of SI-phOLEN, we firstly demonstrate ultra-fine patterns of the SI-phOLEN (down to 1 um) and high-resolution full-color RGB OLEDs corresponding to 3,000 ppi (4 um x 5 um anisotropic pattern). Our SI-phOLEN represents a transformative step in the pursuit of high-resolution OLED microdisplays and promises both fine patterning and improved luminescence properties. It marks a significant advance in the field of display technology, offering the potential to maximize performance and resolution to unprecedented levels.

5:00 PM SB04.11.08
Coherent Arrangement of Interfacial Surface Assembly via a Functionalized Polymer for Organic Optoelectronics Jihyun Lim, Woongsik Jang and Dong Hwan Wang; Chung-Ang University, Korea (the Republic of)

Organic semiconductors are promising next-generation materials for various electronic applications such as light-emitting diodes, thin-film transistors, thermoelectric devices, energy harvesting, and light sensing due to their light weight and versatility. Recently, non-fullerene acceptor materials, especially Y6, have attracted much attention in organic photovoltaics due to their excellent optoelectronic properties that lead to high reproducibility performance.[1] In the related research, we successfully achieved a favorable molecular orientation for charge transport by using a functionalized polymer process instead of the spin-coating process, which had been a barrier to the fabrication and modularization of large-area devices based on the PM6:Y6 active layer.[2,3] This was demonstrated through simulations based on the wetting coefficient of the surface, validating a high reproducibility range. Furthermore, by adjusting the alkyl groups of Y6, we developed an environmentally friendly organic photodetector (OPD) with excellent detectivity based on Y6-BO material, which enhances eco-compatible solvent solubility.[4] Additionally, through facile surface treatment of the electron transport layer (ETL), we confirmed the effective suppression of deep hole injection barriers and trap density, resulting in effective dark current suppression in the photodetector.[5] Also, we verified the enhancement of performance in optoelectronic devices through interfacial control of the ETL even in a conventional device structure. In particular, n-type perylene diimide (NPDI) has been widely utilized as an interlayer between the active layer and the cathode in optoelectronic devices due to its work-function tunability and excellent charge mobility. However, because it is a two-dimensional planar small molecule, NPDI exhibits strong self-assembly leading to undesirable molecular aggregation, thus raising the risk of an insufficient coverage of the entire surface of the active layer, resulting in a higher leakage current. To improve the performance and stability of organic electronics, this aggregation of NPDI can be solved through effective interfacial engineering. In this research, well uniformed dry-printing nanotechnology was developed for the first time to produce a coherent arrangement of NPDI layer. We successfully controlled the film formation rate by employing the alcohol-based solvent 2,2,2-trifluoroethanol. Our proposed printing process used a functionalized polymer delamination substrate for the facile fabrication of a coherent arrangement of NPDI layer.[6] The use of a coherent arrangement of NPDI in organic optoelectronic devices enabled the flat and uniform coverage of the active layer, thus suppressing the leakage current when the generated charge carriers migrated towards the cathode. The coherent arrangement of NPDI layer significantly increased the charge mobility and effectively suppressed the trap density at the interface, effectively suppressed the dark current of the modified NPDI-based OPD and significantly enhanced the detectivity. Therefore, the coherent arrangement of NPDI is a process that facilitates the formation of high-quality thin films at the interface, leading to the enhanced stability of the optoelectronic devices.

Identity of T* Matters! Improved k_{rISC} by Modulating Locally Excited Triplet State in TADF Emitters Madalasa Mondal and Ratheesh K. Vijayaraghavan; IISER Kolkata, India

Abstract:
Effective triplet exciton utilization efficiency is an essential factor for constructing low-power operational OLED devices with high luminescence efficiency and durability. Thermally activated delayed fluorescence assists this 100% triplet harvesting by converting dark triplet excitons into radiative singlet excitons via a reverse intersystem crossing process. The enhancement of this rISC rate (k_{rISC}) is primarily realized by the low energy offset between lowest S & T states; to pursue an extremely large $k_{rISC,}$ the involvement of high energy locally excited triplet states has become a hot topic in TADF-OLED research in present days. However, the regulation of the ^{3}LE states to match precisely with the ^{1}CT energy level by suitable molecular design is still under progress.
Here, we demonstrated an effective electronic coupling between ^{1}CT & ^{3}LE or hybridized triplet state in a series of newly designed and synthesized TADF emitters with strongly twisted D-A structure. The detailed theoretical and experimental investigation reveals that the addition of peripheral donor units to the core D-A backbone incorporates multiple triplet excited states of locally excited or hybridized nature between S_1 and T_1 states, and the close alignment of ^{1}CT & ^{3}LE states accelerates the spin-flip process and the sizeable radiative rate results in suppressed efficiency roll off with short (ns) delayed lifetime. On the contrary, the isoenergetic alignment of ^{1}CT and ^{3}CT states realized due to the near orthogonal structure promotes the rISC mechanism. Our work highlights the pivotal role of the electronic nature of the intermediate triplet states in controlling the $k_{rISC;}$ a thorough photophysical investigation was also performed by manipulating ^{3}LE states by introducing variable donor units to the D-A backbone.

Investigating The Mechanisms of Nucleation and Growth of [1]Benzothieno[3,2-*b*] Benzothiophene (BTBT) and its Derivatives Using Molecular Dynamics Simulations Sashen Ruhunage, Chamikara D. Karunasena and Chad Risko; University of Kentucky, United States

[1]benzothieno[3,2-*b*] benzothiophene (BTBT) and its derivatives are of interest as the building blocks of organic semiconductors (OSC) for thin-film transistors. OSC charge-carrier mobility is influenced by the crystallinity and the molecular arrangements of molecules in their crystal lattice. To understand relationships between molecular structure and solvents used to process OSC, we investigate the nucleation and growth mechanisms of BTBT and its derivatives using constant chemical potential molecular dynamics (CμMD) simulations. We explore how concentration, solvent choice, and temperature affect the nucleation and growth of crystals along different crystallographic (template) planes, then quantify and analyze atomistic-scale thermodynamic and kinetic properties of crystallization. Our goal is to provide atomic-scale insights that can be used as guides for OSC design and processing.

Enhancing Integrated Circuit Properties through Engineering Backbone Alignment of Conjugated Polymers Jinseok Yoon, Nakhee Kang, Chae

Won Kim, Keon Joo Park, Sam Nyung Yi, Hyung Soo Ahn, Kyoung Hwa Kim and Young Tea Chun; Korea Maritime and Ocean University, Korea (the Republic of)

In recent years, there has been a growing fascination with polymer materials due to their lightweight and flexible properties. Furthermore, their highly cost-effective manufacturing processes, which employ simple solution methods, have significantly contributed to their surging popularity. Specifically, conjugated polymers of this nature have been widely utilized in various fields like transistors, logic circuits, and sensors, mainly owing to their scalability and affordability. However, it is widely recognized that polymer materials face numerous challenges in terms of their inferior performance compared to inorganic materials.[1] Consequently, extensive research is currently underway to bridge this gap and improve their overall properties. One of the key challenges in manufacturing a logic circuit with polymer is to achieve selectivity in coating a specific conjugated polymer on the target area. Different properties of various conjugated polymer semiconductor materials result in imbalanced operating characteristics of the integrated circuit, and this discrepancy is hard to eliminate. This is an issue that needs to be addressed in CMOS circuits based on conjugated polymers.[2]
This study presents a simple method to align polymer chains in a desired direction, resulting in controlled orientation of polymers, confirmed by UV-Vis spectroscopy and polarized optical microscopy. In contrast, conventional spin-coating techniques show random carbon backbones tangled in various directions. Comparative analysis between transistors fabricated using the proposed method and those made using spin-coating shows higher mobility and on/off ratios in the former. Furthermore, the use of n-type and p-type conjugated polymer semiconductor materials in logic circuitry fabrication achieved superior region selectivity, high mobility, and on/off ratios, leaded to enhanced gain values and noise margins. These findings highlight the potential of conjugated polymer backbone engineering in overcoming semiconductor performance imbalances without changing the geometric structure of components, thus enabling the design of simple symmetric logic circuits. This research provides a promising approch for applying organic semiconductors in various electronic devices.

Skin-Conformable Electrophysiological Sensor Devices with Tailored Negative Poisson's Ratio Hyun Seok Kang[1], Yung Lee[1], Sumin Kim[2], Jang-ung Park[2] and Byeong-Soo Bae[1]; [1]Korea Advanced Institute of Science and Technology, Korea (the Republic of); [2]Yonsei University, Korea (the Republic of)

Electrophysiological sensing is a crucial functionality that provides valuable information in clinical diagnosis and treatment. Recent advances in wearable electronics enabled tracking electrophysiological information such as electrocardiogram (ECG) in a daily basis.[1] However, conventional elastomer substrate-based devices suffer from the lack of long-term adhesion and conformability to human skin due to Poisson's ratio mismatch. To address these limitations, the Poisson's ratio (PR) of the devices should match with human skin, especially in the vicinity of joint areas which have negative Poisson's ratio. One approach to achieve negative PR is to utilize auxetic mechanical metamaterials with negative PR as device substrates.
In this study, we demonstrate electrophysiology devices with enhanced skin conformability, consisting of seamless auxetic substrates and printed liquid metal electrodes. To achieve a highly conformal contact, we analyze the PR of the human wrist skin directly, using 3D digital image correlation (DIC) method. Through this information, the devices are tailored to match the PR of the human skin. The negative PR of the device is achieved by the auxetic structured glass-fabric reinforced substrate with optimized geometric parameters. Also, a soft elastomer with extreme modulus difference with the glass-fabric reinforced film fills the perforations of the auxetic structure to form a continuous surface. [2] Utilizing the advantage of the seamless surface, we employ high precision 3D printing technique to fabricate liquid metal-based electrocardiogram (ECG) sensors and electrotactile stimulators with simple configurations.
The liquid metal electrodes maintain their conductivity during up to 30% of stretching and 100 times of repeated stretching. The resulting devices exhibit increased sensitivity and stability even under dynamic motion of the wrist thanks to their enhanced adhesion and conformability compared to pristine elastomer substrates. Precisely, the ECG sensors maintain signal to noise ratio of over 20 dB after 30 times of wrist bending, while pristine PDMS-based sensors showed degradation to 13 dB. Moreover, the electrotactile stimulators showed high consistency of perceived sensation for 6 stimulated perception levels, even stable under bending.

The Host-Guest Interaction Effect in all Organic Room Temperature Phosphorescence Light-Emitting Electrochemical Cells Hee Jung Kim and Eunkyoung Kim; Yonsei University, Korea (the Republic of)

A series of metal-free dyes, rooted in bromofluorene (BrFX) were synthesized to harness phosphorescence at room temperature within amorphous films and light-emitting devices (LECs). By incorporating aliphatic and aromatic side groups onto the bromofluorene structure, we achieved substantial control over the resulting color and fine-tuned the intensity of the room temperature phosphorescence (RTP). Our selection of host materials, including 3,3'-di(9H-carbazol-9-yl)-1,1'-biphenyl and poly(9-vinyl carbazole) was guided by their energy bandgap and their ability to facilitate energy transfer to BrFX, with the aim of achieving high electrophosphorescence in BrFX, with the aim of achieving high electrophosphorescence in BrFX based LECs. The intensity of the electrophosphorescence was strongly reliant on the chosen host. In-depth investigations employing theoretical computations based on density functional theory, infrared studies, and single crystal X-ray diffraction unveiled the crucial nature of the interaction between the host's ring structure and the guest material in influencing electrophosphorescence. This study sheds light on the impact of host-guest interactions and the role of energy transfer within the host material in endabling room temperature phosphorescence in a device.

Metal Nanoclusters as an Interfacial Modifier in Organic Solar Cells Yousuf Alishan[1,2], Alvin Joseph[1], Anitha B[1], Aparna R.K[1], Ranjini Sarkar[2], Sudip Chakraborty[3], Sukhendu Mandal[1] and Manoj A. Namboothiry[1]; [1]Indian Institute of Science Education and Research Thiruvananthapuram, India; [2]Indian Institute of Technology-Madras (IIT Madras), India; [3]Harish-Chandra Research Institute (HRI) Allahabad, India

Novel and diverse strategies are constantly under development to boost the efficiency and stability of organic solar cells (OSCs). Interface engineering involving various functional materials is currently a research focus because of its promising potential to enhance the device performance of OSCs.[1-3] Atomically precise metal nanoclusters, with tunable properties and notable dipole moments resulting from surface ligand interactions that provide stability to the nanoclusters, can be a promising candidate as an interfacial modifier.[4, 5] Copper nanoclusters (Cu NCs), synthesized by a one-pot synthesis method, are shown to exhibit dipole moment and can cause work function modification on a surface. The novel approach of introducing Cu NCs as an interfacial modifier between the electron transporting layer and the active layer has yielded improved photovoltaic performance in both fullerene and non-fullerene based OSCs (PTB7-Th:$PC_{71}BM$ and PM6:Y6 based OSCs). On insertion of Cu NCs, the best power conversion efficiency (PCE) obtained for the non-fullerene based system is 15.83% compared to that of 14.22% for the control device while the PCE enhanced from 7.79% to 8.62% for the fullerene based system. The interface modification has resulted in reduced recombination losses and charge accumulation at the interfaces. Impedance and transient measurements have also revealed efficient extraction of photogenerated charge carriers in Cu NC incorporated devices. The improved performance in Cu NC interfaced devices is attributed to work function modification, enabling reduced energy barrier and enhanced charge collection. Moreover, The Cu incorporated devices exhibit better operational stability under MPP tracking than the control device. This work demonstrates the potential of a new class of materials for interface modification and enhancing the performance of OSCs.

Thienoacene-Based Host Material for Near-Infrared OLED with High Efficiency Yasuharu Ujiie, Yuki Maeda, Chiaki Takahashi, Mari Ichimura and Yoshio Goto; Sony Semiconductor Solutions Corporation, Japan

A wide variety of organic thin-film devices have been investigated, including light-emitting diodes, photodiodes, transistors, memories and so on. One of the advantages of organic thin-film devices is that elements with various functions can be freely and finely arranged on a single substrate by using vapor deposition and/or coating methods. This capacity in device design will contribute to the evolution of electronic devices, lower costs of products and reduce environmental loads in manufacturing. Our particular interest is in the devices with OLEDs and organic photodiode elements on the same substrate, which can be applied to biometric identification, vital sensing, touchless sensors and so on. While OLEDs and organic solar cells for visible light have been well investigated, there still remain potentials in improvement of the near-infrared OLEDs[1][2][3].
We focused on the intermolecular interactions between organic semiconductors to achieve high luminous efficiency at low voltage drive for near-infrared OLED. In this study, we developed a new naphthodithiophene derivative (NDT) which is expected to show moderate intermolecular interactions in the film. NDT was introduced in near-infrared OLEDs as the host material in its emission layer with the near-infrared dopant 1 vol% of Pt(TPBP)[4] that has an emission peak at 770 nm . Compared to the reference of the DMFL-CBP[5] that is reported to form fine amorphous thin films, the near-infrared OLED with NDT showed 1.5 times higher EQE and 1.1 V lower driving voltage at 10 mA/cm2. As a result, the luminous power efficiency became 1.8 times higher, which is very important in terms of the power consumption of electronic devices. In this contribution, we present the synthesis and characterization of NDT, followed by the fabrication and evaluation results of near-infrared OLED elements.

Doping and Interlayer Engineering for High-Performance Filterless Blue Organic Photodetectors Tianyi Zhang, Louis C. Winkler, Jakob Wolansky, Jonas Schröder, Karl Leo and Johannes Benduhn; Dresden Integrated Center for Applied Physics and Photonic Materials (IAPP) and Institute of Applied Physics, Technische Universität Dresden, Germany

Red, green, and blue (RGB) sensing units form the foundation of image applications. To obtain color discrimination, commercial RGB sensors usually incorporate expensive optical filters, which also compromise the incident light intensity. Here, we elegantly demonstrate a fully thermal-evaporated filterless blue organic photodetector (OPD) based on exploring the dual role of the hole-transporting layer (HTL). Adopting Rubrene and C_{60} as the photoactive components, HTLs of our choice effectively quench short wavelength absorption to yield narrowband features. They also serve as charge-blocking layers to suppress dark current injection. By introducing a MoO_3-doped underlayer, the OPD achieves high external quantum efficiency (EQE) up to 50 % at 0 V while maintaining narrowband features in thin-film devices. This strategy boosts the EQE by 53% compared to the undoped sample. Such enhancement results from higher charge dissociation and extraction enabled by doping. However, the device with an intrinsic underlayer in planar junction configuration, sandwiched between efficient hole and electron blocking layers, achieves an ultralow dark current density (2.46×10^{-12} A/cm^2 at -0.1 V). It has a calculated specific detectivity (D^*) reaching a record-high value of 6.35×10^{14} Jones at zero bias, outperforming commercial silicon photodetectors, and an ultrahigh linear dynamic range of 205 dB. Our work highlights the versatility of doping and interlayer in realizing high-sensitivity narrowband organic photodetectors in the visible spectral region.

Wearable Respirometer for Pulmonary Disease Prediction Anand Babu[1], Isabelle Dufour[2] and Damien Thuau[3]; [1]Institute of Nano Science and Technology, India; [2]Université de Bordeaux, France; [3]Bordeaux INP, France

Breathing is a multifaceted indicator of health and performance, with pivotal parameters including tidal volume, inspiratory capacity, and forced expiratory volume crucial for healthcare assessment and disease detection. However, real-time, accurate, and continuous monitoring of these parameters is hindered by the limitations of cumbersome instruments. In response, this research introduces an innovative approach to estimate these critical parameters and predict associated diseases. Our method leverages descriptors extracted from breathing signals captured non-invasively via a wearable organic piezoelectric electronic patch, eliminating the need for invasive procedures. The wearable respirometer boasts impressive features, such as high sensitivity, with an

exceptional signal-to-noise ratio, and a low limit of detection.
To achieve precise and robust disease predictions, we conducted an extensive examination of various machine learning algorithms. Among these, gradient boosting regression emerged as the most suitable choice for predicting Chronic Obstructive Pulmonary Disease (COPD). Notably, our method achieved an accuracy of over 94% in predicting different COPD diseases. This research opens new avenues for continuous, real-time monitoring and early disease detection, addressing a critical need in healthcare and paving the way for improved patient outcomes.

5:00 PM SB04.11.18
Effects of Coffee Grounds in Modified Natural Rubber Thin Film on Resistive Switching Memory Characteristics Muhammad Awais[1], Nadras Othman[1], Mohamad Danial Shafiq[1], Feng Zhao[2] and Kuan Yew Cheong[1]; [1]University Sains Malaysia, Malaysia; [2]Washington State University, United States

Modified natural rubber thin film as a sustainable and green material for next generation resistive-switching memory application has been investigated. The natural rubber latex (poly 1,4-cis-isoprene) was formulated, modified, and processed with the additional of coffee grounds to form into a thin film with the objective of enhancing the resistive switching memory characteristics. With an optimum weight percentage of coffee grounds incorporated in the natural rubber, ON/OFF ratio and stability/endurance of the memory test structure have been improvement. Reason of the improvement is correlated to the chemical functional groups established between the coffee grounds and natural rubber as well as the intrinsic chemical property of the coffee grounds. With this evidence, a possible resistive switching mechanism based on this material system has been proposed.

Metal-Dielectric Photonic Crystal Organic Light Emitting Diodes Matthew S. White[1], David Allemeier[1,2], Khadga Thakuri[1] and Thomas Cleary[1]; [1]University of Vermont, United States; [2]Boston University, United States

A periodic array of stacked microcavity organic light emitting diodes (OLEDs) creates a photonic crystal comprising alternating metal and dielectric layers, a metal-dielectric photonic crystal (MDPC). In these MDPC-OLEDs, the semitransparent metals layers serve dual function as both mirrors and either the anode or cathode in the OLED device enabling simultaneous electroluminescence from each unit cell. The angle-resolved electroluminescence spectra of the MDPC-OLED reflects the photonic dispersion of the crystal with rich, energy, momentum, and polarization dependent behavior depending on the physical geometry of the crystal and the optical properties of the constituent materials. The number of states in the band, the bandwidth, and mid-band Peierls distortion can be controlled by varying the physical dimensions of the crystal through additive manufacturing. Linewidths of the photonic states are reduced by improving the optical symmetry of the unit cell. Crystal defects can be included to introduce mid-gap photonic states. These properties are modeled using a computational transfer matrix simulation and experimentally verified. Lastly, we develop an analytical model based on coupled mode theory and quasi-normal mode theory to determine the relationship between optical constants (index of refraction and extinction coefficient) of the metal and organic layers to the resulting photonic band structure.

pH-Dependent Electrochemical Doping of an n-Type Conjugated Ladder Polymer Duyen Tran, Sarah West and Samson A. Jenekhe; University of Washington, United States

The rise of electrochemistry-enabled applications of conducting polymers, including organic electrochemical transistors, batteries/supercapacitors, and electrocatalysis, has prompted the needs for new n-type π-conjugated polymers with rugged stability, robust redox reversibility, and high charge storage capacity. However, insights regarding the structure-property relationships, the nature of charge carriers, and how they are formed in n-doped conducting polymers remain scarce. In this talk, I will discuss how we leverage pH-dependent electrochemical doping of a model n-type π-conjugated ladder polymer to systematically map out the formation of different types of polaronic species. We found that the model conjugated polymer could exhibit one to three acid-based coupled redox reactions depending on the pH. By means of *in-operando* optical, electrical, and structural characterization techniques, we show that singlet polarons are the dominant species in lightly to moderately doped polymer films, whereas other charge carriers are found in heavily doped polymer films. Our findings provide new fundamental insights on the nature of charge carriers and their formation dynamics in n-doped conducting polymers that could be broadly applicable to various electrochemistry-driven device applications.

UV-Activated Cyclisation of Luminescent Organic Molecules: Correlating and Tuning Structural and Optical Properties Arya Karappilly Rajan, Pravien Rajaram, Ryan D. Baxter and Sayantani Ghosh; University of California, Merced, United States

Luminescent organic molecules (LOMs) combine the photo-induced charge carrier generation and recombination of inorganic semiconductors with the lightweight and easy fabrication techniques common to organic materials. Hence, they offer the potential to be used in various applications, including the development of inexpensive, flexible, and tunable organic electronic and optoelectronic devices, such as organic light emitting diodes (LEDs), solar cells, chemical and biochemical sensors, field-effect transistors, and nonlinear optical media for lasing applications, as cost-effective alternatives to inorganic semiconductors.
This project focuses on correlating the structural and functional properties of a novel class of benzoyl pyrazinium molecules, which undergo ultraviolet (UV) light induced cyclization reaction. Spectroscopic and NMR characterization of these molecules indicate changes to both electronic and structural properties before and after cyclization. The optical properties of these molecules can be controlled by tuning the chemical structure, their concentration and their interaction with surrounding materials. As the molecules were exposed to UV light, the corresponding cyclized products were seen to exhibit strong emission in the visible, with higher emission intensity observed at lower concentrations. Strong emission in solid state was also observed in drop-casted thin films of the molecules dispersed in PVA. The high emissivity at lower concentrations implies that these molecules can have great potential for applications in solar concentrators where the molecules can serve as fluorophores and help in minimizing losses due to self-absorption.

Magneto-Electroluminescence Responses mediated by Magneto-Conductance in Polymer and Thermally Activated Delayed Fluorescence Emitter-Based Light Emitting Diodes Tzung-Fang Guo[1], Anas Mujahid[1], Yi-Ting Lee[2], Yulin Lin[1], Chih-Ting Li[1] and Wei-Cheng Liu[1]; [1]National Cheng Kung University, Taiwan; [2]Soochow University, Taiwan

We characterize the magneto-electroluminescence (MEL) responses of polymer and thermally activated delayed fluorescence emitter-based light-emitting diodes (PLEDs and TADF LEDs) under constant voltage and current regimes to elucidate that the current as regulated by magneto-conductance (MC) mediate MEL of devices. Through the analytical fitting of MC and MEL curves, we discloses that MC (as interpreted by the polar pairs model) partially

involves the changes in the curve features, magnitudes, shapes, etc. of MEL responses. We observe a sharp W-shape curve feature in the MEL response of the TADF LED under the electric bias at the low magnetic field regime in our study. This result should be attributed to the mediation of the MEL by the negative MC response due to the unbalanced charrier dynamics of the device. While the carrier dynamics were balanced, the specific feature of the sharp W-shape curve disappeared. Our work clearly depicts an accurate analysis of MEL with MC response based on the polaron pairs model for studying the insight dynamics of the light-emitting LEDs and that the assessment of MEL is reliable if conduct the measurement at the constant current regime.

5:00 PM SB04.11.24
Thermal Conductivity Switch due to Topochemical Polymerization of Organic Material Sara Makarem[1], Amalie Attassi[2], Shannon Yee[2], James Ponder[2], Brian M. Foley[3] and Patrick E. Hopkins[1]; [1]The University of Virginia, United States; [2]Georgia Institute of Technology, United States; [3]Laser Thermal, United States

A material that exhibits significant change in thermal conductivity due to external stimuli can be used as a thermal switch and can allow the active control of heat flow. These materials are of high importance in various thermal management applications such as refrigeration and waste heat recovery. Due to their sensitivity to external stimuli, organic materials are considered as a promising class of materials in this regard. This study shows a potential thermal switching mechanism due to topochemical polymerization of [2,2′-bi-1H-indene]-1,1′-dione-3,3′-diheptylcarboxylate (BIT-Hep_2). The forward polymerization reaction of BIT-Hep_2monomer to polymer, P(BIT-Hep_2), occurs when exposed to light. Since polymerization alters the interchain interactions, breaking and reforming of bonds between repeat units can affect the thermal conductivity, . This study examines how changes in bond order affects the microscopic thermal conductivity. The thermal conductivities of these samples are measured using time domain thermoreflectance (TDTR). TDTR is a transient, non-contact, optical thermometry technique that utilizes a pump-probe experimental configuration. In addition, steady-state thermoreflectance (SSTR) technique was used to compose a map of thermal conductivity as a function of spatial coordinate for individual monomer and polymer crystallites. The complementary characterizations of these samples confirms that the topochemical polymerization of BIT-$Hep_2$to P(BIT-Hep_2) changes the bond order which affects the planarity of the repeat unit. Thus, the decrease in thermal conductivity due to this topochemical polymerization is likely due to a greater extent of disorder present in P(BIT-Hep_2). This study finds that the thermal conductivity within the crystallites differs significantly and reports the average values of 0.478±0.065 W/m/K and 0.110 ±0.060 W/m/K for the monomer and polymer, respectively.

5:00 PM SB04.11.25
Enabling Polymer Single Crystal to be High Performance Dielectric Min Chen[1], Wee-Liat Ong[1], Boyu Peng[1], Xuyun Guo[2], Jie Ren[1], Ye Zhu[2] and Hanying Li[1]; [1]Zhejiang University, China; [2]The Hong Kong Polytechnic University, Hong Kong

Polymer dielectrics hold great potential for electrical power applications and advanced microelectronics. Unfortunately, they exist commonly in semicrystalline form with disordered aggregating microstructures, such as amorphous regions, that limit their dielectric performances, including breakdown strength, dielectric loss, and temperature stability. Efforts to improve their performances are often hindered by the lack of understanding of the diverse dielectric properties in the complex structures of these semicrystalline polymer dielectrics (SPDs). Circumventing these gaps in knowledge by crystallizing homogeneously-ordered SPDs to remove these disorders has yielded little success to date. Here, taking a typical and widely used dielectric, polyethylene (PE) as a model, big homogeneously-ordered SPDs as lamellar single crystals are successfully crystallized and studied for their dielectric properties. We obtain high-quality PE single crystals by controlling the crystallization kinetics in a self-seeding method. Nanoscale MIM capacitors built on these crystals using a non-destructive strategy exhibit a high dielectric breakdown strength and low dielectric constant, with the measured values among the best-known for PE. By exemplifying a crystallization strategy for the ordered SPDs and elucidating the origins of their outstanding dielectric properties, this work illuminates a path for deepening the fundamental understanding and enhancing the electrical performance of SPDs.

5:00 PM SB04.11.26
Spatiotemporally Controllable Electrical Stimulator via Independent Photobending and Upconversion Photoluminescence Using Two Different Wavelengths of Near-Infrared/Visible Light as Dual Stimuli Jiyeon Lee, Dongjun Kim, Jaehyeok Ryu and Jiwon Kim; Yonsei University, Korea (the Republic of)

Multistimuli responsive materials are advantageous in that they can enhance the desired response or bypass unwanted reactions. Light is one of the most attractive stimuli since it allows remote spatiotemporal control and multiplexing of properties (e.g., wavelength, intensity, irradiation time, pulsed/continuous wave) for application on multiphotoresponsive materials. However, the operating wavelength for such photoresponsive systems often includes an ultraviolet (UV) range that limits its use in the biomedical field. Herein, we investigate near-infrared (NIR)/visible (Vis) light-responsive nanocomposite films composed of rare earth element (i.e., Yb, Er)-doped $NaYF_4$ nanoparticles (NPs) embedded in azobenzene-incorporated poly(dimethylsiloxane) (AzoPDMS), silk fibroin, and silver nanowire (AgNW) layers. Photobending (PB) of the nanocomposite film is induced by a Vis light of 400−700 nm, while upconversion photoluminescence (UCPL) of embedded NPs is activated by an NIR light of 980 nm. The excitation wavelength of photoluminescence (PL) is shifted to the NIR (λ = 980 nm) range via photon upconversion in rare earth element-doped NPs. Independent operation of PB and UCPL enables both on-demand electrical switching and real-time location monitoring for spatiotemporally controlled electrical pulse stimulation. As a result, the dual-photoresponsive nanocomposite film can be utilized as a remotely controllable electrical stimulator and location indicator via different wavelengths of light.

5:00 PM SB04.11.27
Defect-Engineering to Control The Photonic Band Structure of Organic Semiconductor based Metal Dielectric Photonic Crystals Khadga Thakuri[1], Thomas Cleary[1], David Allemeier[2,1], Naoya Aizawa[3], Ken-Ichi Nakayama[3] and Matthew S. White[1,1]; [1]The University of Vermont, United States; [2]Boston University, United States; [3]Osaka University, Japan

Alternating layers of metal and organic semiconductor (dielectric) thin films have been shown to form one-dimensional photonic crystals with application in organic optoelectronic devices like OLEDs. In this work, we introduce crystal defect engineering as a method to tune the photonic band structure of such metal-dielectric photonic crystals (MDPCs). The physical properties of each unit cell are determined by the index of refraction, extinction coefficient, and physical thickness of the layers. Varying the thickness of a single organic layer within the crystal introduces a substitutional point defect resulting in a mid-gap photonic state with varying impact on the photonic band dependent on the location of the defect within the crystal. The number of defect layers in the crystal can be increased until the defects constitute half of the layers. If done so with periodic distribution, this results in a binary unit cell and a Peierls distortion splitting the photic band. We explore this regime by controlling the thickness of even-numbered metal layers in the MDPC from 0% to 200% that of the odd-numbered mirrors, revealing photonic edge states within the Peierls bandgap.

5:00 PM SB04.11.28
Controlling Rigidity of The Conjugated Backbone Using Plasticizing Molecular Additives to Enhance Deformability in Organic Semiconductors Sein Chung and Kilwon Cho; Pohang University of Science and Technology, Korea (the Republic of)

Plastic electronics, featuring deformable polymer layers, have emerged as a promising technology in recent decades. Researchers have been focused on enhancing the deformability of conjugated polymers by fine-tuning both the intrinsic molecular structure, such as the conjugation length of the polymer backbone, and the characteristics of functional side chains, including their length, branching points, and hydrogen bonding capabilities. However, it has become evident that chemical tuning alone has its limitations in overcoming the inherent trade-off relationship between electrical performance retention and mechanical deformability. To address this trade-off phenomenon, recent studies have introduced extrinsic aids into conjugated polymers, which encompass elastomeric polymers, crosslinkers, dopants, and various molecular additives. This research explores the impact of the chemical structures of plasticizing molecular additives (PMAs) on the mechanical, thermal, morphological, and electrical properties of films containing PMAs under deformation. For the purpose of a comprehensive comparison, our study employs a solution-based rheology and small-angle neutron scattering (SANS) technique to elucidate the adjusted persistence length of conjugated polymer, Poly[2,5-(2-octyldodecyl)-3,6-diketopyrrolopyrrole-alt-5,5-(2,5-di(thien-2-yl)thieno [3,2-b]thiophene)] (PDPP2T-TT-OD) interacting with various species of PMAs. Our findings reveal a significant influence of the modified persistence length of PDPP2T-TT-OD on the thin films' mechanical deformability, as determined through pseudo-free standing tensile testing. Based on our systematic analyses, we propose that the uniform distribution of PMAs within a conjugated polymer substantially enhances the deformability of thin films. These results are anticipated to offer valuable insights into the establishment of design principles for plasticizing molecular additives in the realm of plastic electronics.

Improving The Performance of Organic Photodetectors with Removable Ultrathin Top Electrodes Kosei Sasaki, Takao Someya and Tomoyuki Yokota; The University of Tokyo, Japan

Recently, Organic photodetectors (OPD) with removable top electrode have attracted much attention for systematic analysis of the degradation of the device. This new structure of OPD consist of a bottom and top electrode sheets. The bottom electrode sheet was fabricated by forming a transparent electrode, electron transport layer (ETL) and active layer on a glass or flexible substrate. The top electrode sheet contains an electrode and hole transport layer (HTL) on another substrate. The top electrode sheet can be attached to the bottom electrode sheet by intermolecular forces. The top electrode sheet can be easily removed from the bottom electrode sheet without damaging the organic semiconductor layer. Using this structure, our group has succeeded in directly and continuously evaluating the electrical properties of the OPD and the crystallinity and chemical analysis of the interface between active layer and HTL before and after operating the device by removing the top electrode sheet.[1] In previous report, the thickness of the top electrode sheet is 1 mm. This thicker substrate shows the weak adhesion between the active layer and the HTL. So, the device cannot be operated as an OPD without applying pressure. However, continuous pressure distorts the active layer and accelerate the degradation and possibly change the crystallinity.[2] Therefore, it is important to develop OPD with removable top electrode that can be operated without applying pressure.
In this study, we developed OPD with removable top electrode that can be operated without pressure by using an ultrathin rubber sheet as a substrate of top electrode. The ultrathin rubber sheet is an extremely tough, self-adhesive and gas-permeable polydimethylsiloxane (PDMS) nanofilm with a thickness of approximately 700 nm, fabricated by dip coating a thin polyurethane nanofiber sheet with PDMS. [3] The fabricated OPD shows 67% EQE at 550 nm and -5 V (light intensity is 6.7×10^{-3} mW/cm^2) without applying pressure. The specific detectability of OPD is as high as 2.9×10^{12} Jones. The photocurrent and dark current at -2 V were changed 42.9 % and 117%, respectively after 100 cycles of lamination and delamination the top electrode sheet.

Efficient Electron Injection and Transport in Fully Stretchable OLEDs Wei Liu and Sihong Wang; The University of Chicago, United States

Fully stretchable electroluminescent devices have garnered significant attention due to their transformative potential in applications ranging from wearable displays to implantable light sources. Among the various approaches, OLEDs based on the thermally activated delayed fluorescence (TADF) mechanism hold much allure because of their unity internal quantum efficiency and environmental-/bio- -compatibility. However, the performance, based on the identical emitter, in stretchable OLEDs falls significantly short of that achieved in traditional rigid devices due to fewer n-type materials available for efferent electron injection and transport. Here we propose innovative solutions to bridge this efficiency gap. First, we develop a stretchable electron transport polymer that simultaneously achieves decent electron mobility, suitable HOMO/LUMO levels, high triplet state, good solution processability, and high stretchability. Secondly, we propose a stretchable cathode design with an extremely low work function that is on par with the conventional rigid cathode, which is unprecedented with previously stretchable cathode based on silver nanowires, carbon nanotubes, conducting polymers, and others. Based on those innovations, we remarkably narrow the efficiency gap and eliminate the turn-on voltage differential between the fully stretchable TADF-OLEDs and their rigid counterparts.

Accessing New Optoelectronic Devices and Architectures through The Solid-Phase Processing of Conjugated Polymers Guillermo Esparza, Darren J. Lipomi and David Fenning; University of California, San Diego, United States

Optoelectronic materials and devices are ubiquitous in the modern world. Thin-film processing of these materials is essential in a tremendous range of applications such as consumer electronics, healthcare, defense, scientific instrumentation, and renewable power generation and storage, to name a few. Among optoelectronic materials, conjugated polymers are of significant technological interest and are typically processed from either the vapor, liquid, or solution phases. Unfortunately, all of these techniques come with various downsides and limitations. Processing restrictions (such as solvent orthogonality) or device architectures (such as tectured surfaces) impose potential processing incompatabilities and therefore limits on the devices which may be realized. For this reason, exploring novel processing routes is pivotal to unlocking the full potential any material.

Processing and application of thin films directly from the solid phase (that is, the creation of standalone thin films which are subsequently transferred onto a substrate or undergo other processing) has not been well expored, but has the potential of addressing various pitfalls that arise in conventional processing methods. This talk will be focus several techniques in this category, which have utilized pre-formed thin-films to form coatings on non-planar surfaces, coat sensitive substrates without exposure to heat or liquid solvents, as well as serve as a sacrificial vehicle in order to premptively deposit materials which would otherwise damage the rest of a device stack. Special emphasis will be given to how these approaches can outperform conventional processing methods as well as how they can be leveraged to enable devices which may have been previously impossible to realize.

5:00 PM SB04.11.32

Continuous Production of Ultratough Semiconducting Polymer Fibers with High Electronic Performance Zhi Zhang and Ting Lei; Peking University, China

Conjugated polymers have demonstrated promising optoelectronic properties, but their brittleness and poor mechanical characteristics have hindered their fabrication into durable fibers and textiles. Here, we report a universal approach to continuously producing highly strong, ultratough conjugated polymer fibers utilizing a flow-enhanced crystallization (FLEX) method. These fibers exhibit one order of magnitude higher tensile strength (>200 MPa) and toughness (>80 MJ m^{-3}) than traditional semiconducting polymer fibers and films, outperforming many synthetic fibers, ready for scalable production. These fibers also exhibit unique strain-enhanced electronic properties and exceptional performance when employed as stretchable conductors, thermoelectrics, transistors, and sensors. This work not only highlights the influence of fluid mechanical effects on the crystallization and mechanical properties of conjugated polymers but also opens up exciting possibilities for integrating these functional fibers into wearable electronics.

5:00 PM SB04.11.33
Highly Conductive and Stretchable Metal Film Cathode for Intrinsically Stretchable Organic Light-Emitting Diodes Kun-Hoo Jeon and Jin-Woo Park; Yonsei University, Korea (the Republic of)

Stretchable electronics have received significant attention due to the increasing demand for skin-like biomedical devices in wearable healthcare and soft robotics applications. Intrinsically stretchable organic light-emitting diodes (is-OLEDs), which are essential components of stretchable electronics, have been actively studied in recent years. However, their performance, including luminance and operational stability (both before and after stretching), lags behind that of rigid, conventional OLEDs by several orders of magnitude. Among several drawbacks, the absence of suitable stretchable electrodes has been known as a major bottleneck in achieving further performance improvements. Electrodes for is-OLEDs must possess high conductivity and a smooth surface, along with superior charge injection properties. However, materials used for stretchable electrodes thus far have failed to meet these requirements. Conducting polymers, such as PEDOT:PSS, exhibit intrinsically low carrier density and mobility. Metal nanowires have rough surfaces that result in severe short circuits within the devices. Low-dimensional carbon materials, such as graphene, inherently lack stretchability. Therefore, new electrode materials must be developed to overcome the current performance limitations. Metal films are the most conductive materials due to their large free carrier density, but they are rarely used for stretchable electrodes because their conducting paths can be easily disrupted even under small strains. Several studies aim to enhance the mechanical flexibility of metal films by utilizing ultrathin structures, grain or crack engineering, or promoting strong adhesion between the substrate and metal films. Nevertheless, metal films have never been applied as electrodes for is-OLEDs, except for the cases involving geometrically engineered structures. In this study, we first demonstrated the use of stretchable silver films as the cathodes for is-OLEDs. We fabricated highly conductive and highly stretchable silver films by controlling their microstructures. The growth of the silver film was controlled by deposition conditions (evaporation rate and thickness) and the addition of seed layers, resulting in different grain morphologies. We studied the relationship between thin-film structure and electrical and mechanical properties to develop the optimal stretchable cathode. Slow evaporation and an ultrathin film structure could enhance the strain resilience of metal films. Introducing cesium carbonate seed layers could further improve conductivity and stretchability by suppressing silver aggregates due to their strong adhesion to silver. Although micro-cracks developed throughout the films under deformation, our cathodes were able to maintain their conductivity under repeated cyclic stretching of 40% strain, demonstrating superior elastic behavior compared to other reported stretchable electrodes. At the same time, the electron injection properties of silver films could be improved by composite electron transport layer (ETL) structures. Our stretchable silver film was sandwiched between a cesium carbonate seed layer, which possesses a desirable energy level for electron injection, and cesium carbonate-doped PEIE (d-PEIE) layers, which reduce injection barriers of the cathode. Our thin silver cathode has partially continuous film structures, thus providing numerous channels throughout the films that allow the participation of the upper-coated d-PEIE only in the electron injection process, excluding its insulating properties and effects on silver film growth. In conclusion, is-OLEDs with stretchable metal film cathodes showed improved luminance and operational stability compared to conventional AgNW-based cathodes. They also demonstrated stable operation under static stretching of 60% strain and cyclic stretching of 40% strain. We expect that our stretchable metal cathodes could become a new alternative to current stretchable electrodes.

5:00 PM SB04.11.34
Ultraflexible Organic Active Matrix Sensor for Tactile and Biosignal Monitoring Andreas Petritz[1,2], Esther Karner-Petritz[1,2], Takafumi Uemura[2,3], Naoko Namba[2,3], Christine Prietl[1], Matthias Hammer[1], Elisabeth Schreck[1], Manfred Adler[1], Andreas Tschepp[1], Herbert Gold[1], Teppei Araki[2,3], Tsuyoshi Sekitani[2,3] and Barbara Stadlober[1]; [1]Joanneum Research Forschungsgesellschaft mbH, Materials – Institute for Sensors, Photonics and Manufacturing Technologies, Austria; [2]The Institute of Scientific and Industrial Research (SANKEN) – Osaka University, Japan; [3]Advanced Photonics and Biosensing Open Innovation Laboratory AIST – Osaka University, Japan

Flexible sensors are currently the subject of intensive research, as they allow cost-effective and environmentally friendly production of large-area, flexible and, when fabricated on ultrathin substrates, highly conformable devices [1]. Among many intriguing applications, we focus here on tactile and biosignals monitoring, where light weight multi-parameter sensors with high wearing comfort are of particular interest.
The required spatiotemporal resolution of the signals is achieved by integrating the sensors in an active matrix configuration. We combine organic ferroelectric transducers of high uniformity, characterized by a sensitivity spread of only 1.5%, with similarly uniform ultralow noise level organic thin film transistors operating below 5 V, showing a threshold voltage variation of just 0.13 V in a 12x12 sensor array. The transistor's transition frequency of >10 kHz (linear range) allows for a high spatiotemporal resolution of ~ 3 mm at a frame rate of >1 kfps. The thickness of only 2.8 µm renders our organic active matrix sensor sheet sufficiently ultraflexible to make it virtually imperceptible on the human skin. We demonstrate real time monitoring of the pulse wave with simultaneous measurements of heart rate, augmentation index and blood pressure [2] and spatially resolved tactile modes [3].
All presented devices are manufactured by processes scalable to industrial throughputs, mainly screen-printing and shadowmask evaporation, with life cycle analysis already starting at the design and materials selection stage, maintaining the prospect of a smooth transition to production in the future.

Improved Thermally Activated Delayed Fluorescence based Electroluminescent Devices using Vacuum Processed Carbazole based Self-Assembled Monolayer Nrita Gaur, Manas Misra, Kashimul Hossain and Dinesh Kabra; Indian Institute of Technology Bombay, India

Engineering of the interface between organic emissive layer thin films and charge transport layers has fuelled the development of Organic light emitting diodes (OLEDs) over the past decade. This paper shows a comparative study between conventional poly(3,4-ethylenedioxythiophene): poly(styrene sulfonate) (PEDOT: PSS) vs carbazole functional groups based self-assembled monolayer (SAM) as hole-injection layer (HIL). SAM enables an improved interface to achieve the charge carrier balance and reduced interfacial recombination to enhance the external quantum efficiency in the *p-i-n* OLEDs. An industry compatible vacuum processed SAM-HILs ((4-(3,6-Dimethyl-9H-carbazol-9-yl) butyl) phosphonic acid (Me-4PACz)) as a hole transport layer in

thermally activated delayed fluorescence (TADF) based OLEDS is reported for first time, which facilitate to overcome the issues of poor device stability. Deeper highest occupied molecular orbital (HOMO @ -5.3 eV) of Me-4PACz enables the efficient hole injection with reduction in leakage current by 1 to 2 orders of magnitude compared to PEDOT: PSS (HOMO @ -5.00 eV) HIL based OLEDs. Also, built in potential is 1.3 times reduced to 2.45 V for Me-4PACz based OLEDs. With the further optimized thickness of Me-4PACz (d= 6 nm), OLED maximum external quantum efficiency (EQE) gets enhanced from 18.30 % to 20.79 % with luminous efficiency 62.79 cd/A. Further, the Me-4PACz is also investigated on the basis of its deposition method. Vacuum processed SAM based OLEDs showed a reduced operating voltages and enhanced brightness levels, which correlated with an improved electronic coupling between SAM/α-NPD interfaces. We note that, evaporated SAM-HTLs to complete OLED demonstrates comparable efficiency to their solution-processed counterparts. Furthermore, vacuum deposition SAM as HIL based OLEDs is found to provide a five- fold enhancement in the operational stability 60% (LT_{60}) of the initial luminance L_0 of the OLED in comparison to PEDOT: PSS as HIL based OLED. This study is further extended to a blue TADF OLED, with almost similar finding.

5:00 PM SB04.11.36
Development of Next-Generation OPLS Force Field for Accurate Modeling of Phosphorescent OLED Materials Steven Dajnowicz, Owen Madin, Hadi Abroshan, Shaun Kwak, Mathew D. Halls and Edward Harder; Schrodinger, United States

To address the inherent challenges of modeling organometallic complexes, which are commonly used as phosphorescent emitters in OLEDs, the OPLS4 force field is extended in order to have a more suitable functional form. These new developments include a fluctuating charge model to describe charge transfer, a Morse potential to describe the metal-ligand bonding, and an angular overlap model to describe d-orbital effects. The initial force field coverage is centered around common chemistries found in Pt(II) and Ir(III)-based emitters. Our model accurately represents geometries when comparing against DFT and crystal structure references. In addition, the model was validated on a series of organometallic emitters doped into an organic host layer, generating configurations from molecular dynamics simulations that are used to predict photoelectronic properties. Future developments include the extension of chemical coverage in the effort to more broadly aid in material design.

5:00 PM SB04.11.37
All Printed Vertical Organic Electrochemical Transistor with Fast Speed and Good Flexibility for High Frequency Inverter Yingjun Chen; Nanyang Technological University NTU, Singapore

Printing technologies have revolutionized the field of organic electronics through large-scale fabrication and low cost, but limitations in printing resolution and printable material selection have restricted the performance of printed devices. This work presents the first successful all screen printed vertical organic electrochemical transistors (V-OECTs) on a flexible substrate, exhibiting fast switching times of 0.8ms and 1.6ms from off to on and on to off, respectively. The vertical structure offers advantages over traditional planar structures such as higher transconductance, fast transient response, and symmetric switching performance. In this work, bending testing and various substrate printing confirm the flexibility and printability of the devices, while the application of the printed OECT in a unipolar inverter with high frequency (~100 Hz) demonstrates their potential in printed flexible circuit. The printed V-OECT can also be utilized as amplifier to detect the electrocardiogram (ECG) signal. These results suggest a potential method for producing high-performance printed OECTs, paving the way for the development of all-printed flexible electronics with fast response for various applications.

5:00 PM SB04.11.38
Interactions in GO/P3HT Layered Nanostructures: Spectroscopic Investigation for Organic Solar Cells Fokotsa V. Molefe[1], Bakang M. Mothudi[2], Mokhotjwa S. Dhlamini[2] and Mmantsae M. Diale[1]; [1]University of Pretoria, South Africa; [2]University of South Africa, South Africa

Herein, a simple and effective approach has been followed to deposit poly (3-hexylthiophene) (P3HT) and GO/P3HT layered nanostructures and fabricate their devices. Different structural, morphological, spectroscopic and electrical techniques were used to probe P3HT and GO/P3HT layered nanostructures properties. The X-ray diffraction (XRD) spectrum of GO/P3HT revealed a highly crystalline reflection of GO which is slightly shifted to higher diffraction angles as evidence of interaction with P3HT. As a proof of concept of interactions, the smooth surface morphology of P3HT translated to wrinkled structure for GO/P3HT presenting the existence of GO sheets in scanning electron microscopy (SEM). Fourier Transform Infrared spectroscopy (FTIR) confirmed the alteration of P3HT structure upon interaction with GO where the average conjugation length decreased from ~ 1.20 to ~ 1.12. The UV/VIS/NIR spectrum of GO/P3HT has an observable decrease in percentage reflectance leading to enhancement of the light absorption ability of P3HT with the inclusion of GO nanostructures. Furthermore, the bandgap energy decreased and resulted in a decrease in energetic driving force. The fluorescent decay curves revealed a decline in exciton lifetime depicting quicker charge transfer from P3HT to GO which resulted in a decrease in exciton diffusion length. Our findings suggest that the energetic driving force induced the mechanism involved during chemical interaction at the GO/P3HT interface. However, the calculated energetic driving force suggests that the interface between GO/P3HT be tuned, which agrees with J-V results where the GO/P3HT device revealed a low power conversion efficiency (PCE) of 3.07 %.

Pentacene Two-Dimensional Crystals with Layer-Dependent Morphologies and Mobilities Grown via Confined Molecular Flow Deposition Zhichao Cheng and Xiaomin Xu; Tsinghua University, China

Pentacene has gained significant attention as a channel material in organic field-effect transistors (OFETs). In most cases, the mobility, a key performance metric of the device, is evaluated for the entire film. However, there is limited understanding of its layer-dependent electric transport properties in the two-dimensional (2D) limit, particularly when compared to inorganic 2D materials that have been more thoroughly investigated. Furthermore, in OFETs, the growth of molecules is especially crucial at the initial stage, as the electrical conduction predominantly occurs in the few molecular layers adjacent to the dielectric surface. Herein, we successfully grew pentacene 2D crystals with 1, 2, and 3 molecular layers on thermally oxidized wafer surfaces using the confined molecular flow deposition method, under conditions of both high deposition rates and elevated substrate temperatures. The electric transport properties of these crystals were measured, and the results aligned well with the theoretical calculations. In addition, the growth mode of these pentacene 2D crystals differs from the classical models: layer-by-layer, layer-plus-island, and island growth modes. This deviation arises because the nucleation of pentacene under these conditions does not follow the classical nucleation process. Instead, it develops through two distinct steps. Initially, pentacene molecules nucleate as liquid clusters with the molecules adopting a lying-down orientation. Subsequently, these liquid nuclei transition to a solid crystalline state, where the molecules flip upright. The final number of molecular layers in the pentacene 2D crystals corresponds to the layer number in their solid nucleus, with each layer within the crystal growing synchronously. Additionally, the crystals with different numbers of layers exhibit distinct shapes: ellipses, rounded hexagons, and hexagons for one, two, and three layers, respectively. This phenomenon can be explained by phase field modeling. We believe our work not only verifies the electric transport properties of 2D pentacene crystals with different molecular layers, but also may pave the way for exploring new physics using small molecules.

Record-High Surface Potential by Spontaneous Orientation Polarization in Organic Semiconductors Albin Cakaj, Alexander Hofmann and

Wolfgang Bruetting; University of Augsburg, Germany

Molecular orientation in organic semiconductors has many different facets, such as optical anisotropy leading to birefringence, alignment of their optical transition dipole moments (TDMs) and/or their permanent electrical dipole moments (PDMs) [1]. While TDM alignment is well established and readily exploited to improve light outcoupling in organic light-emitting diodes (OLEDs) [2], PDM alignment and the resultant spontaneous orientation polarization (SOP) is by far less investigated, and it is not fully clear yet if it is beneficial or detrimental for device application [3].
SOP is observed in evaporated films of polar organic molecules and leads to a so-called giant surface potential (GSP), which can be measured by Kelvin probe, impedance spectroscopy or the displacement current method [4]. In general, the GSP slope is roughly proportional to the magnitude of the molecule's PDM. However, despite their very high PDM, many molecules exhibit only small SOP because they tend to aggregate in pairs with antiparallel alignment. Thus, the order parameter (i.e., the degree of net PDM alignment) is typically less than 10%.
Here we report a new class of materials with drastically enhanced PDM alignment, exceeding 30% for films grown at room temperature [5]. These phosphine oxides exhibit a highly polar phosphor-oxygen bond, which leads to large SOP despite the presence of different structural conformers. By evaporating them on a cooled substrate in combination with dilution of the polar species in a non-polar host, record-high GSP slope of almost 300 mV/nm (with an equivalent electric field of $3x10^8$ V/m) can be achieved. This opens new perspectives for application of organic semiconductors in energy harvesting devices.

5:00 PM SB04.11.41
Color Tunable Stacked QD-OLED Hybrid Devices Sung-Cheon Kang, Eun-young Choi and Jang-Kun Song; Sungkyunkwan University, Korea (the Republic of)

Organic light-emitting diodes (OLEDs) and quantum dot light-emitting diodes (QLEDs) stand out as highly promising display technologies due to their notable advantages, including high efficiency, rapid response speed, and a high contrast ratio. Typically, flat panel displays incorporate distinct red, green, and blue subpixels placed side-by-side to replicate a full spectrum of colors. However, this design exhibits drawbacks such as a low geometric fill factor, reduced efficiency, and challenges in fabricating high-resolution displays. A potential solution to address these limitations lies in a multicolor-emitting pixel structure, enabling the selective emission of more than two colors from a single pixel. AC-driven color-tunable devices present a promising avenue to achieve this goal. In an AC tandem device, the emitted light's color is determined by the applied signal's polarity, resulting in different colors emitted under forward and reverse bias voltages. In this presentation, we introduce AC-driven multi-color OLED-QDLED hybrid pixel structures. The foundational unit comprises two-pixel QDLEDs, fabricated using an inkjet process, with an OLED layer deposited atop these QDLEDs. Through the combination of these three pixels, a full-color display is achieved. Efficiency optimization is achieved by fine-tuning the materials and structures within the charge transport and charge generation layers. This device configuration features two horizontally arranged pixels and another vertically stacked pixel, enhancing the fill factor by 1.5 times. As a result, this approach holds promise for future display applications, offering high efficiency and resolution.

5:00 PM SB04.11.42
Micropatterned Elastomeric Composites for Encapsulation of Transient Electronics Choi So jeong; Korea University, Korea (the Republic of)

While transient electronic devices are biodegradable and intended to dissolve or decompose through environmental factors, the necessity of an effective waterproofing or encapsulation system remains critical for ensuring reliable and durable operation over a specified timeframe. Current protection methods rely on multiple layers of electrically inactive organic/inorganic elements combined with polymers. Nevertheless, their elevated mechanical stiffness poses challenges when applied to soft, time-dynamic biological tissues, skins, or organs. In this context, we present an innovative solution: a stretchable, bioresorbable nanoparticle-incorporated elastomeric composites, accompanied by surface morphology modifications. The introduction of nature-inspired micro-patterns reduces the diffusion area for water molecules, while embedded nanoparticles act to impede water permeation. This synergistic combination significantly enhances the water-barrier performance. The encapsulation mechanisms are empirically and theoretically validated under strains. A demonstration involving a soft, degradable shield with an optical component submerged in a biological solution underscores the potential applicability of the proposed encapsulation strategy.

5:00 PM SB04.11.43
Photoluminescence and Electroluminescence Confocal Imaging of an OLED Angela Flack, Paulina Carmona-Monroy and Matthew Berry; Edinburgh Instruments, United Kingdom

In recent years organic light-emitting diodes (OLEDs) have become one of the leading technologies for full-colour display panels in high-end smartphones and televisions. This rapid growth in use has occurred because OLEDs offer an all-around superior performance to liquid crystal displays (LCDs). For example, they are thinner, lighter, more flexible, less power consumptive, and brighter.
When new OLEDs are developed, the optoelectronic properties of individual components and the complete device can be characterised using photoluminescence (PL) and electroluminescence (EL) spectroscopy. In this poster presentation, we use a confocal Raman microscope to characterise and spatially resolve the optoelectronic properties of a fabricated OLED device with four imaging modalities: PL, EL, time-resolved PL (TRPL), and time-resolved EL (TREL). Using a confocal microscope to characterise an OLED's spectral and time-resolved properties provides much greater detail than bulk measurements.

SESSION SB04.12: Bioelectronics
Session Chairs: Lucas Flagg, Katelyn Goetz, Ulrike Kraft and Simon Rondeau-Gagne
Friday Morning, April 26, 2024
Room 435, Level 4, Summit

8:30 AM *SB04.12.01
***In Situ* Characterization of Electrochemical Transistors for High-Performance Biosensing** Sahika Inal; King Abdullah University of Science and Technology, Saudi Arabia

Solid-liquid interfaces have garnered significant attention for applications in bioelectronics, electrochromics, energy storage/generation, neuromorphic computing, and thermoelectrics. These devices operate in electrolytes that render ions mobile in the film, making the coupling between electronic and ionic charges crucial. An example of such a device is the organic electrochemical transistor (OECT), a high-gain transducer commonly used to monitor bio-ionic signals. In this talk, I will demonstrate OECT-based protein sensors based on organic mixed conductors and discuss the importance of the semiconductor type used in the channel and device dimensions for high-performance biosensing, based on the results acquired through a combination of operando techniques. I will also introduce polymer design and processing approaches that endow organic bioelectronic devices with longer shelf life and operational stability.

9:00 AM *SB04.12.02
Stable and High Performing *n*-Type and Ambipolar Organic Electrochemical Transistor for Next-Generation Bioelectronics Wei Lin Leong; Nanyang Technological University, Singapore

Organic mixed ionic-electronic conductors (OMIEC), which are capable of efficiently transporting and coupling ionic and electronic charge, have gained significant attention in recent years as emerging organic materials for bioelectronic, neuromorphic computing, circuits and energy storage systems. One emerging device that uses these OMIECs is the organic electrochemical transistors (OECTs), which offer the advantages of low operation voltage (< 1V), high sensitivity and excellent aqueous operating capability. To date, OMIECs for OECTs have predominantly been *p*-type materials, while their *n*-type counterparts lag far behind in performance and stability, hampering their adoption in complementary circuit designs, electrochemical energy storage, and sophisticated biosignal sensing that rely on electron transfer. In this talk, I will present our recent progress on developing new conjugated ladder-type polymers which exhibit good mixed ionic-electronic conduction properties, enabling stable and fast *n*-type organic electrochemical transistors. This is due to the polymer's predominant edge-on packing and enhanced backbone coplanarity which promote efficient charge transport, as well as its porous structure which facilitates efficient ion penetration and transport. These unique advantages make this polymer especially suitable for bioelectronics, such as being used as a pull-down channel in a complementary inverter for long-term stable detection of electrophysiological signals. Moreover, the developed device shows a reversible anti-ambipolar behavior, enabling reconfigurable electronics to be realized using a single material. In addition, my talk will present our studies on various conjugated polymer blends with ambipolar properties, providing a facile strategy to simplify the fabrication process and reduce the manufacturing cost while simultaneously obtain high performing logic circuits.

9:30 AM SB04.12.03
Electrolyte-Gated Organic Field Effect Transistor Integrated in Neurosignal Recording System for Monitoring Brain Activity Deng Zou[1,2] and Paddy K. L. Chan[1,2]; [1]University of Hong Kong, Hong Kong; [2]Advanced Biomedical Centre Limited, Hong Kong

Electrolyte-gated organic field-effect transistors (EGOFETs) have emerged as promising candidates for neurosignal detection, due to their high operating speed, effective transduction of biological inputs into amplified transistor signals and ability to operate stably in aqueous environments. Key limitations in these current microelectrode neuroprobes stemming from high electrode impedance and voltage drift, have necessitated innovative neurosignal recording solutions. In this study, we present a neural recording system that utilizes EGOFETs for on-site signal amplification. We demonstrate the capability of EGOFETs, when integrated into our recording circuit, to record neurosignals with an exceptional signal-to-noise ratio (SNR) at 16 dB and high fidelity. These EGOFETs are based on top liquid gate and top contact configuration, which can operate under low source-drain voltage (V_{DS} = -1.2 V) and gate voltage (V_G = 0 V) conditions, achieving a remarkable maximum transconductance of up to 500 μS. This achievement underscores the potential for broad applications of EGOFET technology in monitoring brain activity, encompassing both research and clinical domains.

9:45 AM SB04.12.04
On-Device Calibration of Organic Electrochemical Transistor Biosensors for Advancing Alzheimer's Diagnostics Stefany J. Kissovsky, Scott T. Keene, Gabriele S. Kaminski Schierle and George G. Malliaras; University of Cambridge, United Kingdom

Alzheimer's disease is a progressive form of dementia, which affects more than 50 million people worldwide and is expected to impact three times more by 2050. Although its cause and progression mechanisms are still not fully understood, Alzheimer's disease has been associated with the misregulation of certain biomarkers.[1] The quantification of these biomarkers requires expensive elaborate equipment, substantial experience, and time-consuming analysis due to their sub-nanomolar concentrations in blood. A much faster, cost-effective, and more convenient *in-vitro* method with very high sensitivity and good specificity is needed to advance Alzheimer's research and diagnostics.

Organic electrochemical transistors (OECTs) have emerged as a promising point-of-care testing platform for enzymatic biosensing due to their exceptional signal amplification properties, stability in aqueous environments, and biocompatibility.[2] However, due to their high sensitivity, OECTs are susceptible to signal drifts caused by changes in the surrounding environment, such as variations in pH levels, temperature fluctuations, and the presence of interfering species in the sample of interest. In this work we present a new OECT configuration design to achieve real-time on-device calibration. This configuration is designed to effectively compensate for signal drifts and faulty analyte detection, thereby ensuring stability and reliable results.

Three-terminal OECTs have been designed and microfabricated with a poly(3,4-ethylenedioxythiophene) polystyrene sulfonate (PEDOT: PSS) channel. This ion permeable channel is extremely sensitive to biochemical reactions occurring in the electrolyte placed directly on top of the device for testing.[2] The design of the device incorporates two gates, and it has been optimised to create highly sensitive enzymatic sensors.[3] An enzyme is immobilised via bioconjugation on the first gate electrode, while the second gate electrode acts as a reference. The system is tested in real-time by addition of varying concentrations of the target compound in the electrolyte, while the changes in current are recorded. This test allowed the on-device calibration of our OECTs, enabling the reliable measurement of the compound with high sensitivity and specificity. This is a new promising platform for achieving stability against signal drifts in the OECTs and robustness against interfering analytes in enzymatic sensors, outlining the pathway to very high sensitivity and low limit of detection of brain biomarkers.

Retinomorphic Motion Sensors and Integrated Energy Storage Systems Based on Donor-Acceptor Polymers Tse Nga Ng; University of California, San Diego, United States

Organic retinomorphic sensors offer the advantage of in-sensor processing to filter out redundant static background and are well suited for motion detection. To improve this promising photodetector, here we studied the key role of interfacial energetics in promoting charge accumulation to raise the inherent photoresponse of the light-sensitive capacitor. Specifically, incorporating appropriate interfacial layers around the photoactive layer was crucial to extend the carrier lifetime, as confirmed by intensity-modulated photovoltage spectroscopy. Compared to its photodiode counterpart, the retinomorphic sensor showed better detectivity and response speed due to the additional insulating layer, which reduced the dark current and the RC time constant. Lastly, three retinomorphic sensors were integrated into a line array to demonstrate the detection of movement speed and direction, showing the potential of retinomorphic designs for efficient motion tracking.

In addition to enabling motion detector, the class of donor-acceptor polymers showed highly delocalized redox states and operated as stable n-type anodes in energy storage devices. The redox polymer was used in supercapacitors and achieved a high areal power density of 227 mW/cm^2, allowing rapid charging and high power delivery. The capacitance retention was 84% after 11,000 full redox cycles, offering the critical benefit of long cycle life. This work demonstrated the application of a new class of stable redox-active materials suitable to meet the energy storage needs for short-range wireless electronics.

11:00 AM SB04.12.06
Organic Electronic Platform for Enhancing Plant Growth Eleni Stavrinidou; Linköping University, Sweden

To cover the food demands of the growing population in the changing climate we need to increase crop yield in a sustainable manner. Hydroponics cultivation minimizes water and fertilizers use while it can be integrated in the urban environment. However so far, the substrates used in hydroponics mainly offer support to the root system. Here we developed an active, organic electronic platform that stimulates the growth of plants in hydroponics culture. We demonstrate that Barley, one of the most important crops, grows well within the bioelectronic platform. When stimulated, the biomass of the Barley increases by 40%, and the effect is evident in both root and leaf development during the growth period after the stimulation treatment. Results also show that stimulated plants reduce and assimilate $NO3^-$ more efficiently than controls, a finding that can have implications on minimizing fertilizers use. Our work opens the pathway for enhancing plant growth in hydroponics settings using organic electronics that may result in more sustainable food production.

11:15 AM SB04.12.07
Spontaneous Recording of Cardiomyocytes' Action Potential by Electrolyte-Gated Field Effect Transistors: A Simple, Planar, Printed *In-Vitro* Platform for Cardiovascular Drugs Screening Giulia Z. Zemignani[1,2], Adrica Kyndiah[1], Luca Sala[3], Aleksandr Khudiakov[3], Carlotta Ronchi[1], Gabriele Tullii[1], Giuseppina Iachetta[4], Rosalia Moreddu[4], Stefano Chiodini[1], Francesco De Angelis[4], Maria Rosa Antognazza[1] and Mario Caironi[1]; [1]Center for Nano Science and Technology, Istituto Italiano di Tecnologia, Italy; [2]Politecnico di Milano, Italy; [3]Center for Cardiac Arrhythmias of Genetic Origin, Laboratory of Cardiovascular Genetics, IRCCS Istituto Auxologico Italiano, Italy; [4]Istituto Italiano di Tecnologia, Italy

In the context of cell-based biosensors, extensive endeavours have been dedicated to find accurate, in-vitro bioelectronic platforms capable of directly recording the electrical activity of electrogenic cells, namely neurons and cardiac cells, in a non-invasive way.
The amplitude, shape and duration of the Action Potentials (APs) contain significant information on the viability of cells. These attributes, in turn, facilitate the exploration of cardiac pathologies and the impact of novel pharmaceutical products.
To date, the available methodologies used to assess APs predominantly involve patch clamp techniques or complex 3D nanostructured electrodes, frequently combined with electro-/opto-poration, thereby rendering them very invasive in nature.
To this end, the principal objective of this study is to propose a simple and cost-effective device able to record the electrical activity of *in-vitro* cell cultures in a non-detrimental manner.
Within this research, we have accomplished for the first time the spontaneous recording of intracellular action potentials of human induced pluripotent stem cells-derived cardiomyocytes (hiPSC-CMs) by direct plating or seeding of cells on top of the channel of our printed, planar Electrolyte-Gated Field Effect Transistor (EGFET).
The EGFETs were fabricated employing carbon-based semiconductors via a simple and cost-efficient printing technique, aiming to facilitate large-scale production.
The cardiac cells APs were obtained by simply recording the transistor current at a fixed gate voltage V_{GS} corresponding to the maximum transconductance. The natural APs of cardiomyocytes are able to change the effective gate voltage applied, which is transduced in a modulation of the source-to-drain current I_{SD} in our device. Remarkably, this modulation occurs without the need of any external stimuli.
Our planar architecture was able to record signals with shape and duration comparable with patch clamp performed on the same batch of cells, confirming the fact that we recorded a major fraction of the intracellular action potentials (estimation in the range of 40-60 mV).
The exceptional sensitivity of our device made it possible to detect the APs perturbations induced by the addition of different drugs targeting specific ion channels. The Action Potential Durations (APDs) recorded in our device exhibit close congruence with those attained with patch clamp techniques, thus positioning our platform as an ideal candidate for long-term monitoring of cardiac arrhythmias, chronic disease and the screening of cardiovascular drugs.
The optimal EGFET-cell coupling enabled by our planar, printed, carbon-based semiconductors, reveals high stability and quality of the signal transduced, achieving excellent reproducibility over more than a hundred tested transistors.
Such an high-throughput device is opening the path to deeper comprehension of fundamental transduction mechanisms at the bio-electronic interface and possesses the potential to be further developed into a future cost-effective diagnostic tool.

11:30 AM SB04.12.08
Design of Injectable, Self-Adhesive and Highly-Stable Conductive Polymer Electrode for Sleep Recording Huiliang Wang; The University of Texas at Austin, United States

High-quality and continuous EEG monitoring is desirable for sleep research, sleep monitoring and the evaluation and treatment of sleep disorders. Existing continuous EEG monitoring technologies suffer from fragile connections, long-term stability, and complex preparation for electrodes in real-life conditions. Here, we report an injectable and spontaneously-crosslinked, conductive polymer hydrogel electrode for long-term EEG applications. Specifically, our electrodes have a long-term low impedance on hairy scalp regions of 17.53 kΩ for > 8 hours of recording, high adhesiveness on the skin of 0.92 N cm^{-1} with repeated attaching capability, and long-term wearability during daily activities and overnight sleep. In addition, our electrodes demonstrate a superior signal-to-noise-ratio of 23.97 dB in comparison to commercial wet electrodes of 17.98 dB and share a high agreement in sleep stage classification with commercial wet electrodes during multi-channel recording. These results exhibit the potential of our on-site formed electrodes for high-quality, prolonged EEG monitoring in various scenarios.

11:45 AM SB04.12.09
Selective Response of Organic Electrochemical Transistor by a Potentiodynamic Approach Isacco Gualandi[1], Federica Mariani[1], Luca Salvigni[2], Francesca Ceccardi[1], Danilo Arcangeli[1], Francesco Decataldo[3], Marta Tessarolo[3], Domenica Tonelli[1], Beatrice Fraboni[3] and Erika Scavetta[1]; [1]Dipartimento di Chimica Industriale 'Toso Montanari', Università di Bologna, Italy; [2]Organic Bioelectronics Laboratory, Biological and Environmental Science and Engineering Division (BESE), King Abdullah University of Science and Technology (KAUST), Saudi Arabia; [3]Dipartimento di Fisica e Astronomia, Università di Bologna, Italy

Organic electrochemical transistors (OECTs) are finding growing interest in the field of biological and chemical sensing. Although the OECT transduction is based on electrochemical reactions, the transistor architecture offers several advantages as compared to amperometric sensors such as signal amplification, use of easy and cheap readout electronics, low supply voltage (usually < 1 V), low power operation (< 100 μW), bio-compatibility. Moreover, OECTs can be easily miniaturized and adapted to non-flat, flexible and even textile devices [1]. Since electrochemical transduction usually detects all redox-active compounds in a sample, selectivity remains an open issue that should be addressed to achieve a reliable measure. Our group has developed a potentiodynamic approach for the selective detection of dopamine (DA) in the presence of interfering compounds (ascorbic acid, AA, and uric acid, UA) [2]. The trans-conductance curves allow linear calibration plots for AA, UA and DA and to separate the redox waves associated witheach compound with performances comparable or even better than those obtained by differential pulse voltammetry.
This contribution describes the recent achievements of OECT sensors, based on the potentiodynamic approach, to the design of robust and selective devices able to perform real-time analyses that do not strictly rely on laboratory facilities. The detection of the fat-soluble Vitamin A has been carried out in organic environment [3]. The OECT behaviour was thoroughly characterized, its structure was optimised and both potentiostatic and potentiodynamic detections were investigated. The potentiostatic determination exhibited a gain of 100 with respect to the electrochemical signal represented by Vitamin A oxidation current and the limit of detection was as low as 115 nM, but it did not address selectivity issues. On the other hand, the potentiodynamic approach showed a higher detection limit, but the sensor displayed selectivity in the presence of α-Tocopherol.
Excellent performances were found when analyzing commercial food fortifiers and a multivitamin premix powder, encouraging results to these bioelectronic devices beyond the watery part of life and biology, where they have already proved to provide uniquely performing electrochemical interfaces. Finally, ongoing research deals with potentiodynamic determination of uric acid in saliva with the aim to estimate oxidative stress.

3:00 PM *SB05.01.01
Fiber-Based Tools to Probe Brain-Body Physiology Polina Anikeeva; Massachusetts Institute of Technology, United States

Complex interplay between the brain and the other body system governs our behavior, immunity, and disease progression. Yet, probing of the brain-body circuits is challenging, as peripheral nerves and organs are in continuous motion and are subject to stringent immunosurveillance. Our group applies fiber-

fabrication methods in combination with traditional solid-state electronics to create multifunctional wireless interfaces with peripheral organs such as the gastrointestinal tract to probe physiological functions with cell-type and regional specificity. Concomitantly, we create fibers to interface with multiple brain regions, and develop materials-based approaches to enable straightforward surgical placement of multi-regional neural interfaces spanning multiple organs.

3:30 PM SB05.01.02
Magnetic Guidewires Driven Deployable Electronics for Minimal Invasive Epidural Electrocorticographic Brain-Computer Interface Tao Zou[1,2], Na Xiao[1,2] and Paddy K. L. Chan[1,2]; [1]University of Hong Kong, Hong Kong; [2]Advanced Biomedical Instrumentation Centre Limited, Hong Kong

Electrocorticographic Brain-Computer Interface (ECoG-BCI) has significantly contributed to both fundamental neuroscience research and clinical applications, including brain function recovery, speech neuroprostheses, epilepsy detection, and traumatic brain injury prognosis. Improving the recording coverage and density of ECoG-BCI are particularly valuable for analysing the activities correlations among the multiple brain regions and identifying the actual neural disease foci accurately. Traditionally, the deployment of large-area coverage devices commonly necessitates an equally substantial cranial opening, which expose significant brain tissue and could potentially cause brain tissue swelling, inflammation, heighten risk of cortical damage, and infection. As a result, diminishing the acceptance of these implants among BCI users.

Here we present a deployable ECoG-BCI platform operated via magnetically controlled guidewires in minimally invasive appraoch. The ECoG-BCI platform comprises a high-density array of flexible PEDOT:PSS/pHEMA electrodes (28.4 electrodes cm^{-2}) covering a large surface area (9 cm^2), sub-millimeter soft magnetic polymer guidewires, a robotic arm equipped with a permanent magnet for guiding the magnetic guidewire, and an automatic control system. The folded flexible electrode array can traverse the craniotomy and be unfurled by tracking the guidewires. The thin, 10 μm thick parylence based electrode array, featuring perfusion holes, ensures excellent conformability and close contact with the curved brain surface. We deploy the proposed ECoG-BCI platform within area V1 of the visual cortex in a macaca fascicularis, demonstrating chronic neural signal recording and cortical electrical stimulation capabilities. The monkey has responses to the phosphenes induced by the visual cortex stimulation. This deployable ECoG-BCI platform has the potential to restore effective vision for the blind with minimal invasive implantation injury.

3:45 PM *SB05.01.03
Miniature Battery-Free Implants for Distributed Bioelectronic Networks Jacob T. Robinson; Rice University, United States

Direct neural and cardiac stimulation is a powerful method to treat disorders when drug therapies are ineffective, or their side effects are intolerable. Unfortunately, traditional implantable stimulation technologies are based on wires that connect the stimulator to the target, which can lead to challenges for writing the wires, lead fractions, migration, and infection. This is particularly true when attempting to interact with a network of devices.

Here, we describe how magnetoelectric materials enable construction of distributed network interfaces with each node the size of a pea or smaller and capable of digitally programmable stimulation. With robust wireless data and power transfer it is possible to make miniature implants less than 1 cm across with the ability to deliver biphasic stimulation powerful enough to drive neural activity from above the dura.As an example, we show applications in brain and cardiac stimulation neuromodulation where minimally invasive devices can form a network of precisely timed stimulators. Our data from large animal and human studies show the kind of good misalignment tolerance and high-power bioelectronics capabilities that would enable networks of wireless, battery-free, neuromodulation technologies.

4:15 PM *SB05.01.04
Soft and Flexible Bioelectronics for Brain-Machine Interfaces Jia Liu; Harvard University, United States

Large-scale brain mapping through brain-machine interfaces is important for deciphering neuron dynamics, addressing neurological disorders, and developing advanced neuroprosthetics. Ultimately, brain mapping aims to simultaneously record activities from millions, if not billions, of neurons with single-cell resolution, millisecond temporal resolution and cell-type specificity, across three-dimensional (3D) brain tissues over the course of brain development, learning, and aging. In this talk, I will first introduce flexible and soft bioelectronics with tissue-like properties that can track electrical activity from the same neurons in the brain of behaving animals over their entire adult life. Specifically, I will discuss the fundamental limitations of the electrochemical stability of soft electronic materials in bioelectronics and present our strategies to overcome these limitations, enabling a scalable platform for large-scale, long-term, stable brain mapping. Then, I will discuss the creation of “cyborg organisms”, achieved by embedding stretchable mesh-like electrode arrays in 2D sheets of stem/progenitor cells and reconfiguring them through 2D-to-3D organogenesis, which enables continuous 3D electrophysiology during the development of human stem cell-derived brain organoids and animal embryonic brains. Next, I will highlight our current efforts that merge 3D single-cell spatial transcriptomics, machine learning, and electrical recording, enabling cell-type-specific brain activity mapping. In conclusion, I will envision the fusion of soft and flexible electronics, spatial transcriptomics, and AI for a comprehensive brain cell functional atlas to enhance future brain-machine interface applications.

4:45 PM *SB05.01.05
Soft Implantable Bioelectronics for Heart Disease Dae-Hyeong Kim[1,2]; [1]Institute for Basic Science, Korea (the Republic of); [2]Seoul National University, Korea (the Republic of)

Recent advances in soft electronics have attracted great attention due in large to its potential applications in personalized bio-integrated healthcare devices. The mechanical mismatch between conventional electronic devices and soft human tissues/organs oftentimes causes various challenges, such as the low signal-to-noise ratio of the biosensors, inflammations and/or excessive immune responses near the implanted devices, and unsatisfactory electrical/chemical stimulations in feedback therapies. Therefore, the ultra-flexible, stretchable, and bioresorbable electronic devices have been developed and applied, since their mechanical and material properties are compatible with the in-vivo environment and thus they have a high potential to solve the aforementioned issues. To develop such bioelectronic devices, nanomaterials, their composites, and biodegradable materials have been researched. In this talk, the unconventional electronic material and device strategies and their applications to the treatment of heart diseases are presented. The integration of wireless technologies with the unconventional bioelectronics could provide additional opportunities, and the related results of the wireless bioelectronics are also briefly introduced. These efforts in the development of various unconventional materials and bioelectronic devices are expected to contribute to addressing many unsolved issues in clinical medicine.

Tuesday Morning, April 23, 2024
Room 434, Level 4, Summit

10:30 AM SB05.02.01
Rubbery Bioelectronic Patch for The Heart Cunjiang Yu; The Pennsylvania State University, United States

Electronics that can seamlessly integrate with human body could have significant impact in medical diagnostic, therapeutics. However, seamless integration is a grand challenge because of the distinct nature between electronics and human body. Conventional electronics are rigid and planar, made out of rigid materials. Human body are soft, deformable and curvilinear, comprised of biological materials, organs and tissues. This talk will introduce our solution to address the challenge through the recent development of a new class of electronics, namely rubbery electronics. Rubbery electronics is constructed all based on elastic rubber electronic materials of semiconductors, conductors and dielectrics, which possesses tissue-like softness and mechanical stretchability to allow seamless integration with soft deformable tissues and organs. Rubbery electronic materials (semiconductors, conductors, dielectrics) and device innovations set the foundation. This presentation will describe the development the recent advances of rubbery electronics and rubbery bioelectronics. As a platform technology, rubbery electronics could address many challenges in biomedical research and clinical studies.

Effects of Leaflet Design on Structural Integrity and Pump Efficiency of Heart Valves Yu-En Yu[1], Lilian Lin[1], Ching-Chang Huang[2] and Hao-Ming Hsiao[1]; [1]National Taiwan University, Taiwan; [2]National Taiwan University Hospital, Taiwan

Heart valve disease results in inadequate blood supply from the heart to the body and could cause many complications, including heart attack, stroke, blood clots, heart arrhythmia, or even sudden death. Conventional heart valve treatments often involve risky and lengthy procedure that requires thoracotomy (open chest). In recent years, interventional transcatheter heart valve products have been launched on the market and becomes popular. The procedure includes deploying a transcatheter heart valve to the lesion site through a micro-catheter to restore normal blood flow.

This study proposed a novel design methodology for transcatheter heart valve leaflets. Unlike most transcatheter heart valves today, our heart valve designs deviated from conventional 3-D molding techniques and used 2-D quadrics sketches instead to save manufacturing cost. Polytetrafluoroethylene (e-PTFE) and e-PTFE with the addition of Polyethylene Terephthalate (e-PTFE + PET) were employed as the leaflet materials due to their high blood biocompatibility. The heart valve has to maintain appropriate valve orifice area during opening and ensure secured seal when closed. In addition, it is essential to withstand large dimensional changes and significant deformations during crimping (inside catheter) and deployment (to heart chamber). An interventional transcatheter heart valve was integrated by combining a nitinol scaffold with an expanded e-PTFE leaflet.

A series of tasks including design, computer simulation, laser cutting and its associated heat treatment, and bench testing were conducted. Ten leaflet designs were sketched using 2-D quadrics and cut from e-PTFE fabrics. Finite Element models were developed to facilitate the design iterations and evaluate the heart valve structural integrity from the crimping into a catheter to the deployment inside the heart chamber for both leaflet and nitinol scaffold. Computational Fluid Dynamics were also analyzed to evaluate the pump efficiency of the heart valve pre vs. post replacement. Laser cutting, heat treatment, electro-polishing, and bench testing were implemented to manufacture and test the prototypes for the proof of concept. Results showed that the leaflet design affected the pump efficiency of the heart valve and the 2-D quadrics leaflet designs were able to provide good performance with reduced cost.

11:00 AM SB05.02.03
Materials Considerations Enabling Chronic Validation of a Wirelessly-Powered, Implantable Drug Delivery System Joanna L. Ciatti[1,1], Abraham Vazquez-Guardado[1,2] and John A. Rogers[1,1,1]; [1]Northwestern University, United States; [2]North Carolina State University, United States

Chronically implanted drug delivery devices face significant challenges that affect tolerance and effective dosage upon implantation in living organisms. Foreign body reaction, for instance, is a well-known adverse response to implants and various materials strategies have been proposed to circumvent it, including surface coatings, topography, and morphology, but often they are limited to non-functional implants. Herein, we present a wireless and battery-free, fully-implantable drug delivery system capable of on-demand drug release enabled by rational materials selection. The system relies on electrolytic pumps for drug delivery, which necessitate optimization of surface degradation mechanisms to allow for long-term stability *in-vivo*. Materials choice, design, and fabrication techniques will be discussed, as they pertain to facilitating the chronic implantation and tolerance of devices. Carefully engineered devices have demonstrated excellent biocompatibility in studies as long as 4 months post-implantation, and successful drug delivery to the bloodstream from the subcutaneous implant after many weeks implanted.

2:00 PM SB05.03.01
Conducting Polymer-Based Bioelectrodes with Enhanced Wet Adhesion and Stretchability Jiwan Jeon and Jin-Woo Park; Yonsei University, Korea (the Republic of)

Bioelectronic devices are mounted on human skin and tissue to get physiological information, enable electrical stimulation, and treat diseases. To fulfill these challenging roles, bioelectronic devices must possess the same mechanical properties as tissues that are soft, stretchable, and conform to the tissue surface. Also, it requires high conductivity and tough adhesion for high-quality electrical communication with devices and organizations. However, traditional bioelectronic devices are typically constructed using rigid metals, carbon nanotubes (CNT), or graphene, which offer excellent electrical conductivity but suffer a significant mechanical mismatch when interfacing with biological tissues. This disadvantage leads to non-conforming electrode-tissue interfaces and can trigger pronounced inflammation. To address these issues, recently, soft bioelectronics have been developed that aim at improving compatibility between the devices and tissues and reducing inflammations by replacing rigid components with soft materials that closely mimic the characteristics of natural tissues. Therefore, bioelectronic devices composed of conducting polymers within a soft matrix have been thoughtas one of the ideal choices of materials. This combination offers excellent biocompatibility, mechanical properties resembling natural tissues, and desirable electrical

characteristics. Poly(3,4- ethylenedioxythiophene): poly(styrene sulfonate)(PEDOT: PSS) has been studied extensively in soft bioelectronics. However, pure PEDOT:PSS is brittle because PEDOT:PSS network cannot effectively dissipate strain energy. The methods for preparing stretchable electrodes using PEDOT:PSS can be broadly categorized into two main approaches: one involves the design of geometric structures, while the other entails blending with plasticizers, ionic liquids (IL), or polymers. Forming a second network within the existing PEDOT:PSS network to create an interpenetrating polymer network, can enhance the stretchability of the composite electrode. Polyurethane is a hydrophilic polymer that can be easily mixed with PEDOT:PSS. Blending with polyurethane can make low modulus and high stretchability, but it reduces electrical conductivity with increasing amounts of insulating polymer. A higher proportion of PEDOT: PSS is required to achieve higher electrical conductivity while blending with PEDOT: PSS. However, this may result in a more rigid and less stretchable blend due to the inherent properties of PEDOT:PSS. Here, we report a double-network conducting polymer electrode consisting of PEDOT: PSS and polyurethane with high electrical conductivity and large stretchability by using an additive method that effectively reduces the modulus of the matrix and increases conductivity. We use triton-x as an additive material. Triton-X effectively infiltrates the space between PEDOT:PSS chains and the polymer matrix, thereby increasing the free volume within both PEDOT:PSS and the polymer. This augmentation in free volume contributes to enhanced stretchability. Additionally, serving as a secondary dopant, Triton-X plays a crucial role in elevating the conductivity of PEDOT:PSS. When compared to DMSO, it has shown a more substantial improvement in conductivity. However, excessive Triton-X content can weaken the property of reverting to its original length, making it essential to incorporate an appropriate amount to maintain elastic characteristics. Subsequently, for effective attachment to tissues, wet adhesive properties are essential for signal measurement and stimulation. Polyacrylic acid (PAA) and N-hydroxy succinimide (NHS) have been employed in this regard. PAA-NHS forms covalent bonds on the tissue surface, resulting in robust adhesion. Using this approach, we demonstrate the electrodes that exhibit a low modulus, excellent stretchability, and effective wet adhesion properties, which can be used for implantable bio electrodes for nerve stimulation and implantable sensor for ECG.

2:15 PM SB05.03.02
Materials Science of a Multifunctional/Low Cost / Optimun Bcomptible Ultranano-Crystalline Diamond (UNCD^{TM}) Coating and Applications to New Generation Implantable Medical Devices/Prosthese and Biological Treatments Orlando Auciello[1,2]; [1]The University of Texas at Dallas, United States; [2]Original Biomedical Implants, United States

The presentation will focus on discussing materials science / technological applications of a unique material named ultrananocrystalline diamond (UNCD^{TM}) in film form integrated into new generations of medical devices/prostheses, as described below: UNCD^{TM} coatings, developed/patented by Auciello and colleagues, are grown on many substrates by low-cost Microwave Plasma Chemical Vapor Deposition (MPCVD) and Hot Filament Chemical Vapor Deposition (HFCVD) techniques, using a patented Ar/CH_4 gas flow into high vacuum chambers, coupling microwave power, or current-induced heating (~ 2200 C) of tungsten filaments. Both processes produce C^+, C^0, CHx^+, CHx^0 (x= 1, 2, 3) species, which establish chemical bonds on substrates' surfaces, inducing nucleation/grow of polycrystalline diamond films with the smallest (2-5 nm) grains of polycrystalline diamond film available today, thus, the name UNCD^{TM} (TM means trademark). UNCD^{TM} coatings exhibit lowest friction coefficient (0.02-0.04) compared with metals ($\geq$ 0.5) currently used in friction-prostheses like hips, knees. UNCD^{TM} exhibits unique biocompatibility, because it is made of C atoms (element of life in human DNA, cells, and molecules). Original Biomedical Implants (OBI-USA and OBI-México) companies are developing new medical devices/prostheses based on the UNCD^{TM} coating, namely: 1) UNCD^{TM}-coated silicon-microchip implantable inside the eye as key component of the future artificial retina (The Argus II device, implanted outside the eye, connected to the human retina from outside has been marketed in USA /EU, since 2011, returning partial vision to people blind by genetically-induced degeneration of photoreceptors); 2) New generation implantable prostheses (e.g., dental implants, hips, knees) coated with UNCD^{TM} eliminates failure of current metal-implants due to mechanical wear / chemical corrosion by body fluids (Clinical trials, since 2018, implanting UNCD^{TM}-coated dental implants (DI) in 51 patients in clinic in Querétaro-México, demonstrated transformational UNCD^{TM}-coated DI performance; 3) UNCD^{TM}-coated masks may trap COVID-19 virus better, due to $\leq$ 20 nm pores vs micron size pores in current masks, and surface C atoms trapping COVID virus more efficiently; 4) Unique electrically conductive/water corrosion resistant Boron-doped UNCD-coated metal electrodes passing electrical current through water, generate ozone (O_3) on the surface of the UNCD coating, enabling O_3 killing all virus, bacteria, and pathogen in water; also, ozonated water jets enable disinfection in 5-10 minutes of surgical instruments without heating them to high temperature for extensive time as currently done.

2:30 PM *SB05.03.03
Stand-Alone Conformable Implantable Bioelectronics Based on Internal Ion-Gated Organic Electrochemical Transistors Dion Khodagholy; Columbia University, United States

It is increasingly appreciated that individual variability can strongly affect response to clinical treatments, motivating approaches that enable long-term monitoring of physiologic signals and delivery of responsive therapeutics. Implanted bioelectronic devices are often critical components of such approaches. The incompatibility of traditional electronic components with physiologic media, risk of device-related tissue disruption, and limited means by which to interface and power implanted devices are key hurdles. Organic electronics can be biocompatible and conformable, enhancing the ability to interface with tissue. However, limitations of speed and integration have thus far necessitated reliance on silicon- based technologies for advanced processing, data transmission, and device powering. Here, we create a stand-alone, conformable, fully organic bioelectronic device capable of realizing these functions. This device is based on a novel transistor architecture that incorporates a vertical channel and miniaturized hydration access conduit to enable MHz signal range operation within densely packed integrated arrays in the absence of crosstalk (vertical internal ion-gated organic electrochemical transistor, vIGT). vIGTs demonstrated long-term stability in physiologic media, and were used to generate high performance multi-stage amplifiers, oscillators, multiplexers, and rectifiers. We leveraged the high speed and low voltage operation of vIGTs to link them with an ion-based powering and data transmission approach that provides power to the transistor in the form of MHz range alternating current and permits signal extraction via modulation of this applied current. The resultant stand-alone device was implanted in freely moving rodents to acquire, process, and transmit neurophysiologic brain signals. Such fully organic devices have the potential to expand the utility and accessibility of bioelectronics to a wide range of clinical and societal applications.

3:30 PM *SB05.04/SB08.04.01

Transient Bioelectronic Implants John A. Rogers; Northwestern University, United States

Recently developed classes of electronic materials create an opportunity to engineer 'transient' electronic devices that dissolve, disintegrate, degrade or otherwise physically disappear at triggered times or with controlled rates. This talk describes the latest work in bioresorbable classes of transient devices, designed as temporary implants with therapeutic function. Presented examples range from ultraminiaturized, self-powered cardiac pacemakers, to electrical stimulators of the diaphragm, phrenic nerve and spinal cord - each with well-defined envisioned uses in clinical care.

4:00 PM *SB05.04/SB08.04.02
Technology for Bioelectronic Medicine George G. Malliaras; University of Cambridge, United Kingdom

Neurological conditions affect nearly one in six people in the world, imposing significant health, economic and societal burden. Bioelectronic medicine aims to restore or replace neurological function with the help of implantable electronic devices. Unfortunately, significant technological limitations prohibit these devices from reaching patients at scale, as implants are bulky, require invasive implantation procedures, elicit a pronounced foreign body response, and show poor treatment specificity and off-target effects. Over the past decade, new devices made using methods from microelectronics industry have been shown to overcome these limitations. Recent literature provides powerful demonstrations of thin film implants that are miniaturised, ultra-conformal, stretchable, multiplexed, integrated with different sensors and actuators, bioresorbable, and minimally invasive. I will discuss the state-of-the-art of these new technologies and the barriers than need to be overcome to reach patients at scale.

4:30 PM SB05.04/SB08.04.03
Minimally Invasive Neuroelectronics Anqi Zhang; Stanford University, United States

Neuroelectronic interfaces have enabled significant advances in both fundamental neuroscience research and the treatment of neurological disorders. However, current neuroelectronic devices have a clear trade-off between invasiveness and spatial resolution, and are unable to achieve seamless integration into the nervous system with cell-type specificity. In this talk, I will first introduce an ultra-small and flexible endovascular neural probe that can be implanted into sub-100-micron scale blood vessels in the brains of rodents without damaging the brain or vasculature. Second, I will describe a biochemically functionalized electronic probe that enables cell type- and neuron subtype-specific targeting and recording in the brain. Third, I will present a bottom-up approach for constructing neural interfaces from the cell surface, where neurons are genetically programmed to express membrane-localized enzymes that catalyze in situ assembly of functional materials. Finally, I will discuss future advances toward clinical translation of minimally invasive neuroelectronic interfaces capable of long-term monitoring and treatment of neurological disorders.

Advancing Bi-Directional Electrophysiological Studies on The Intact Retina with Soft Multi-Electrode Arrays Yael Hanein, Ieva Vebraite-Adereth and Chen Bar-Haim; Tel Aviv University, Israel

The intricate nature of neural tissues presents formidable challenges in the realm of electrophysiological investigations, particularly when examining intact neural circuits. This challenge is amplified when studying the intact retina, where achieving bi-directional electrophysiological interfacing remains a significant hurdle, and currently available methods fall short of addressing this issue. In this presentation, a novel approach is introduced, leveraging cutting-edge soft multi-electrode arrays to enable comprehensive bi-directional electrophysiological studies on the intact retina. This endeavor involved the development and testing of soft electrode arrays meticulously designed to establish stable electrical connections with the retina. These soft probes were crafted to seamlessly conform to the curvature of the retinal structure within the eye, providing an unprecedented opportunity to study the retina in its unaltered state. Notably, this presentation demonstrates, for the first time, the concurrent capabilities of electrical recording and stimulation directly from the intact retina. Of particular significance is our achievement in mapping retina responses to electrical stimulation. This revelation of the retina's responses under electrical stimuli unveils a striking stability, both in direct and indirect responses, in stark contrast to ex-vivo conditions. Our findings propose an intriguing scenario in which intact retinas exhibit superior stability and resilience compared to their ex-vivo counterparts, positioning them as a more suitable substrate for effectively mapping responses to electrical stimulation. These results not only enhance our comprehension of intact neural circuits but also inaugurate fresh avenues for pioneering research in the field.

8:30 AM *SB05.05.02
NeuroEdge: Graphene Nanoedge Electronics for Monolithic and Chronic Recording at Neuronal Density Yuxin Liu, Yunxia Jin and John S. Ho; National University of Singapore, Singapore

Recording electrophysiological signals from every closely spaced individual neuron over long durations is crucial for understanding the brain micro-circuit and functionalities at the cellular level. However, existing probe technologies are limited by sparse sampling of neurons in the intralaminar plane due to large interelectrode spacing and the need for surface modification materials, which are susceptible to instability over time, in order to have small dimensions and low impedance. Here, we report a monolithic graphene-edge probe array (NeuroEdge) that achieves a density of >2000 electrodes/mm^2, approaching cortical neuronal density. NeuroEdge is composed of self-aligned reduced graphene oxide nanoflakes with well-exposed nanoedges and electrolyte-filling nanochannels at the end, achieving impedance < 0.2 MΩ at neuronal size. Owing to its monolithic material composition and exceptionally low impedance, NeuroEdge provides stable electrophysiological recording with a high signal-to-noise ratio > 20 dB over 6 months. We demonstrate the utility of NeuroEdge for interrogating closely packed neurons by revealing the heterogeneity of acoustic-triggered activity in mouse auditory cortex. NeuroEdge provides a tool for accurately discriminating spikes from neighboring neurons in microcircuits *in vivo*.

9:00 AM SB05.05.03
Scaling Effects on The Electrochemical Performance of $Ti_3C_2T_x$ MXene Thin-Film Bioelectronics for Neural Recording and Stimulation Spencer R. Averbeck[1], Raghav Garg[1], Michael S. Beauchamp[1], Yury Gogotsi[2] and Flavia Vitale[1]; [1]University of Pennsylvania, United States; [2]Drexel University, United States

In the last few decades there has been a growing interest in the development of technologies for neural recordings and therapeutic electrical brain stimulation. In these applications, microelectrode arrays offer the advantage of high-selectivity and sensitivity approaching the spatiotemporal scales of individual neurons. Recently, 2D $Ti_3C_2T_x$ MXene has emerged as a promising candidate for microscale recording and stimulation, due to its high electrical conductivity and volumetric capacitance. Here, we investigate the scaling effects on the electrochemical performance of thin-film 2D $Ti_3C_2T_x$ MXene microelectrodes with diameters ranging from 500 µm to 25 µm and film thicknesses varying from 100 nm to 700 nm. Prior to all electrochemical characterization measurements, we measured contact diameters, surface roughness, and thicknesses with confocal microscopy, atomic force microscopy (AFM), and 2D profilometry, respectively, in order to accurately assess geometric surface areas and available volumes. We then tested the electrodes with electrochemical impedance spectroscopy (EIS), cyclic voltammetry (CV), voltage transients (VT), as well as 10,000 continuous cycles of biphasic stimulation pulses. Through these experiments, we calculated impedance modulus at 10 Hz and 1 kHz, charge storage capacity (CSC), and charge injection capacity (CIC) across the various electrode contact sizes and thicknesses. We also investigated the effects of pulse-width and waveform asymmetry on the calculated CIC values to determine the optimal stimulation parameters for the safe and effective delivery of electrical stimulation in thin-film $Ti_3C_2T_x$ MXene microelectrodes. We found there was an expected increase in the magnitude of impedances at 1 kHz as the contact diameters decreased from 500 µm to 25 µm with an average thickness of 100 nm, increasing from 9.1 ± 1.9 kΩ in the 500 µm contacts to 506 ± 220 kΩ in the 25 µm contacts. Similarly, CIC values also increased as the contact size decreased, increasing from 40 ± 10 µC cm^{-2} to 400 ± 50 µC cm^{-2} in the 500 µm and 25 µm contacts, respectively. Ultimately, our findings indicate that $Ti_3C_2T_x$ MXene microelectrodes are able to safely deliver electrical microstimulation, opening the door to further diagnostic and therapeutic research as well as improve our biological understanding of neural activity through electrophysiological recording and electrical stimulation.

9:15 AM SB05.05.04
Orbit Symmetry Breaking in MXene Implements Enhanced Soft Bioelectronic Systems Wubin Bai; University of North Carolina, Chapel Hill, United States

Bioelectronic systems with soft mechanics, stable biocompatibility, and high-performance electronic recording and stimulation interfaces to internal organs offer paradigm-shifting potentials for advancing biomedical implants such as those for cardiovascular disease. Yet, challenges remain in the development of biocompatible materials with practical scalability for constructing bioelectronic systems that leverage performance and interfacial attributes to not only functionally approach those of conventional wafer-based technologies but also biologically compatible for long-term in-body operation. Here, we present the orbit symmetry breaking in MXene (a low-cost scalable, flexible, and conductive 2D layered material), implementing the improved electrode-tissue interface impedance, which stems from the out-of-plane charge transfer, and coupling with in-plane high conductivity comparable to precious metals. Besides, we compare MXene bioelectronics with commercial biotraces (gold, graphene oxide, and poly(3,4-ethylenedioxythiophene) polystyrene sulfonate), emphasizing its enhanced biocompatibility, durability, and imaging visibility in bioelectronic systems. Accordingly, we introduce an epicardial patch based on orbit-symmetry-broken MXene that integrates the matrix mapping of electrophysiological activity and therapeutic capabilities across large areas at high-fidelity spatiotemporal resolution. Last, a wireless and battery-free MXene module, combined with real-time recording and closed-loop stimulation, demonstrates high signal-to-noise ratio data transmission, and wireless power transfer within bioelectronic systems.

9:30 AM +SB05.05.05
Bioengineering Strategies towards Multielectrode Arrays for Chronic *In Vivo* Neural Recording and Chemical Sensing Xinyan T. Cui; University of Pittsburgh, United States

Microelectrode array (MEA) devices, placed in the nervous system to record and modulate neuroactivity have demonstrated success in neuroscience research and neural prosthesis applications. Functionalizing the microelectrode sites on MEAs to enable electrochemical sensing adds additional dimensions of information, and such multimodal MEAs present tremendous potential for understanding neural circuits and treating neurological diseases. In this talk, I will introduce the methods by which we enable chemical sensing from MEAs. By incorporating nanocarbon into the conducting polymer electrode coating, we achieved direct detection of electroactive species such as dopamine, melatonin, and serotonin. By immobilizing enzymes or aptamers on nanostructured electrodes, we achieved multisite detection of glutamate, GABA, and cocaine. Multisite and multiple analyte detection along with neural recording have been demonstrated with these MEAs. Currently, the chronic recording and sensing performance of implantable MEAs is sub-optimum due to material limitations and undesired host tissue responses. Quantitative histology, explant analysis, and 2-photon imaging revealed biofouling, neuronal damage, inflammation, and oxidative stress at the site of implants. Meanwhile, material degradation also contributes to device failure. We use several bioengineering strategies to minimize these failure modes. First, materials and devices that mimic the mechanical properties of the neural tissue have been developed and shown to significantly improve device-tissue integration. Secondly, biomimetic coatings and drug delivery have been applied to reduce biofouling and inflammatory responses. These approaches may be combined to achieve long-term and high-fidelity neural recording and chemical sensing.

A Thin-Film Optogenetic Visual Prosthesis Jonathan Reeder; Science Corporation, United States

Retinitis pigmentosa and macular degeneration lead to photoreceptor death and loss of visual perception. Despite recent progress, restorative technologies for photoreceptor degeneration remain largely unavailable. Here, we describe a novel optogenetic visual prosthesis (FlexLED) based on a combination of a thin-film retinal display and optogenetic activation of retinal ganglion cells (RGCs). The FlexLED implant is a 30 µm thin, flexible, wireless µLED display with 8,192 pixels, each with an emission area of 66 $µm^2$. The display is affixed to the retinal surface, and the electronics package is mounted under the conjunctiva in the form factor of a conventional glaucoma drainage implant. In a rabbit model of photoreceptor degeneration, optical stimulation of the retina using the FlexLED elicits activity in visual cortex. This technology is readily scalable to hundreds of thousands of pixels, providing a route towards an implantable optogenetic visual prosthesis capable of generating vision by stimulating RGCs at near-cellular resolution.

11:00 AM SB05.06.02
Implantable Bioelectronic Systems for Early Detection of Kidney Transplant Rejection Surabhi Madhvapathy[1], Jiao-Jing Wang[1], Heling Wang[2],

Manish Patel[3], Anthony Chang[4], Xin Zheng[1], Yonggang Huang[1], Zheng Jenny Zhang[1], Lorenzo Gallon[1] and John A. Rogers[1]; [1]Northwestern University, United States; [2]Tsinghua University, China; [3]University of Illinois at Chicago, United States; [4]The University of Chicago, United States

Early-stage organ transplant rejection can be difficult to detect. Percutaneous biopsies occur infrequently and are risky, and measuring biomarker levels in blood can lead to false-negative and -positive outcomes. We developed an implantable bioelectronic system capable of continuous, real-time, long-term monitoring of the local temperature and thermal conductivity of a kidney for detecting inflammatory processes associated with graft rejection, as demonstrated in rat models. The system detects ultradian rhythms, disruption of the circadian cycle, and/or a rise in kidney temperature. These provide warning signs of acute kidney transplant rejection that precede changes in blood serum creatinine/urea nitrogen by 2 to 3 weeks and approximately 3 days for cases of discontinued and absent administration of immunosuppressive therapy, respectively.

11:15 AM ^SB05.06.03
Wireless, Battery-Free Bioelectronics for Fully Implantable, Living Medical Devices Siddharth Krishnan, Matthew Bochenek, Suman Bose, Claudia Liu, Amanda Facklam, Nima Khatib, Ben Walters, Derin Gumustop, Laura O'Keeffe, Robert Langer and Daniel Anderson; MIT, United States

Living cells are a novel class of therapeutics that offer possibilities in long-term protein replacement. Primary cells such as pancreatic islets can offer functional cures for Type I Diabetes via responsive insulin secretion, as can stem-cell derived products[1]. Immortalized cell lines can be engineered or transfected to secrete nearly any protein of choice, to address a broad range of conditions from blood-borne disorders to degenerative neural disease and cancer[2,3]. Two core challenges limit the clinical translation of these types of cell therapies: first, the potential for recognition and attack by the host immune system necessitates the use of chronic immunosuppressants to maintain graft viability, with mixed success. Second, the formation of fibrotic capsules around transplanted cells isolates them from native vasculature, resulting in hypoxia[1].

In this work, we demonstrate a wireless battery-free device system capable of housing and supporting therapeutic cells in vivo by providing both immune-isolation and oxygen supply[4]. Transplanted cells are separated from host tissue by nanoporous membranes that prevent infiltration and attack by immune cells, obviating the need for immune suppression. A multilayer materials system comprising a proton-exchange membrane electrolyzer and an elastomeric encapsulation allows for direct splitting of molecular water into oxygen and hydrogen. Oxygen is stored in an elastomeric chamber that diffuses directly into regions containing transplanted cells. The entire reaction is sustained by a wireless power harvesting circuit based on resonant inductive coupling, at a frequency (13.56 MHz) chosen for its low specific absorption rate in biological tissue and compatibility with existing commercial infrastructure for two-way data and power transfer.
Systematic numerical modeling, benchtop testing, and in vitro experimentation highlight key aspects of device and materials performance.

In vivo studies demonstrate high levels of performance. HEK293T cells engineered to secrete a model protein system (erythropoietin, EPO), demonstrate sustained, significantly elevated levels of protein production when transplanted in O_2-Macrodevices relative to cells encapsulated in non-oxygenated control devices over several weeks. Xenogeneic rat islets transplanted into immune competent, diabetic C57BL/6J mice resulted in complete diabetic reversal for several weeks, with explantation studies revealing viable, glucose response islets. Notably, all of these studies involved transplantation into minimally invasive subcutaneous sites, that are clinically attractive owing to their easy accessibility for implantation and explantation procedures.

Taken together, these results combine advances in materials, electrochemistry, wireless power transfer and bioengineering to support xenogeneic and allogeneic therapeutic cells in vivo without the need for immune suppression, in minimally invasive sites. These hybrid “living” medical devices, combining cellular and inorganic device materials, could provide pathways for functional cures for a broad range of organ-specific diseases.

SESSION SB05.07: Engineered Materials for Biointerfaces
Session Chairs: Philipp Gutruf and Flavia Vitale
Wednesday Afternoon, April 24, 2024
Room 434, Level 4, Summit

1:45 PM SB05.07.01
Advanced Thermogel Biomaterials for Ophthalmic Applications and Drug Delivery Jason Y. Lim[1], Qianyu Lin[1], Xian Jun Loh[1] and Xinyi Su[2]; [1]Institute of Materials Research and Engineering (IMRE), Singapore; [2]Institute of Molecular and Cell Biology, Singapore

Retinal detachment is amongst the leading causes of blindness globally. After vitrectomy surgery, vitreous endotamponades are implanted into the vitreous cavity to facilitate retinal reattachment and recovery. Existing endotamponade materials are suboptimal: silicone oil can lead to inflammation and require follow-up surgery for removal, while expansile gases such as sulfur hexafluoride results in raised intra-ocular pressure and require the patient to adopt prolonged face-down positioning due to their buoyancy. Recently, temperature-responsive hydrogels, also known as thermogels, have emerged as a new highly-promising class of vitreous endotamponades. Our self-assembled thermogels offer easy injectability, transparency, possess the same density and refractive indices as native vitreous humor, show low in-vivo cytotoxicity and have the ability to provide sufficient swelling counter-force to facilitate retina re-attachment. In this presentation, our team’s efforts in developing new generations of biocompatible thermogel-based vitreous endo-tamponades will be discussed. We show that our thermogels can be naturally cleared from the vitreous cavity post-surgery, whilst allowing the regeneration of a vitreous-like body with high proteomic similarity as native vitreous – the first biomaterial known to do so. In addition, we show the profound influences of polymer branching on the in-vivo performance of thermogel endotamponades, and also demonstrate the importance of this often-overlooked parameter on applications such as sustained drug release. Our findings demonstrate the vast potential of self-assembled thermogels as a viable biomaterial that can

revolutionise ophthalmic treatment.

2:00 PM SB05.07.02
Enhancing The Properties of a Novel Mg-Ca-Mn-Sr Alloy using Phosphorus Ion Implantation for Potential Orthopedic Use Saqlain A. Shah and Mazhar Hussain Asdi; Forman Christian College, Pakistan

This research delves into the impact of phosphorus (P) ion implantation on the morphological, microstructural, mechanical, and electrochemical attributes of an innovative biodegradable Mg–2Ca–1Mn–1 Sr (XMJ211) alloy when exposed to simulated body fluid (SBF) for potential orthopedic implant applications. The distinctiveness of this study arises from the innovative alloy blend and the methodical enhancement of its features through P ion implantation at different levels. Through XRD assessments, we observed a rise in the proportions of secondary binary phases, notably Mg3P2, and a reduction in grain size, decreasing from about 71 µm to 39 µm as P implantation was escalated. The alloy's mechanical hardness saw an enhancement, moving from around 60 HV to 75 HV, owing to grain size reduction and an uptick in secondary binary particles. Electrochemical evaluations highlight the alloy's augmented bio-corrosion resistance, moving from 48 kΩ to 87 kΩ as we increased the P concentration, albeit with lesser impact at heightened levels. Our findings underscore the ability to strike a balance between the mechanical and electrochemical characteristics of the alloy using moderate phosphorus levels. This not only emphasizes its potential as a viable biodegradable material for orthopedic implantation but also underscores the elimination of a secondary surgical procedure post-recovery. The insights from this research fill an existing void in current scientific discourse, offering a fresh perspective on augmenting the efficacy of Mg-centric alloys in the realm of biomedicine.

2:15 PM SB05.07.03
Mechanical Properties of Hydroxyapatite Coatings via Plasma Spray Deposition Craig Rosenblum[1,2]; [1]Hitemco Medical Applications LLC, United States; [2]The Johns Hopkins University, United States

Hydroxyapatite (HA) coatings deposited via plasma spray deposition have gained significant attention in the field of biomaterials due to their excellent biocompatibility and bioactivity. Understanding the mechanical properties of HA coatings produced through this deposition technique is crucial for their successful application in various biomedical and dental fields. This review aims to provide a comprehensive overview of the mechanical properties of HA coatings produced via plasma spray deposition, including their adhesion strength, hardness, porosity, and fracture behavior.

Adhesion strength is a critical mechanical property of HA coatings, as it ensures their long-term stability and performance. The review highlights the factors influencing the adhesion strength, such as surface preparation, coating parameters, and substrate properties. Use of a resorbable blast media such as apatitic abrasive to roughen the substrate of medical implants prior to the application of HA coating will provide a residue-free, textured surface for effective coating adhesion. Various characterization techniques, including tensile testing, pull-off tests, and scratch tests, have been effectively used to evaluate the adhesion strength of HA coatings produced via plasma spray deposition.

The hardness of HA coatings is another crucial mechanical property, which determines their resistance against wear and deformation. The review discusses the influence of plasma spray parameters, such as feedstock particle size and distribution, spray distance, feed rate, and temperature, on the hardness of HA coatings. Hardness characterization techniques, including indentation testing, have been utilized to assess the mechanical hardness of these coatings.

Porosity is an inherent characteristic of plasma-sprayed HA coatings and significantly affects their mechanical properties. The review examines the impact of spray parameters, such as spray distance, gas flow rate, and powder feedstock, on the porosity of HA coatings. Various imaging and characterization techniques, including scanning electron microscopy (SEM), have been utilized to quantify the porosity of these coatings.

In conclusion, understanding the mechanical properties of hydroxyapatite coatings produced via plasma spray deposition is crucial for their successful application in biomedical and dental fields. By optimizing the deposition parameters and post-processing techniques, it is possible to tailor the mechanical properties of these coatings to meet specific application requirements of the subjet implantable device. Further research is needed to explore advanced characterization techniques and develop innovative strategies to enhance the mechanical performance of plasma-sprayed HA coatings.

3:30 PM *SB05.07.04
Towards Implantable Biohybrid and Regulated Cell Therapies Jonathan Rivnay; Northwestern University, United States

The union of bioelectronics with engineered mammalian cells is a transformative opportunity in regulated, personalized therapeutics. This approach involves combining the strengths of synthetic biology – namely biological specificity that leverages the natural machinery of cells – with bioelectronic systems, which offer precision timing, dose control, and communication with established sensing technologies and clinical feedback. To this end, we show how implanted biohybrid devices rely on bioelectronics to initiate the production of native peptides, control therapeutic dose, and support the health and productivity of these “cell factories”. We demonstrate optogenetic induction of drug production, fluorescence feedback via photometry to probe cell factory viability, and on-site electrocatalytic oxygenation for maintenance of implanted cell health at high cell density. Current efforts focus on regulation of circadian rhythms; however, the biohybrid cell therapy concept can be broadly applied to chronic diseases including Type I diabetes, obesity, and cancer immunotherapies.

SESSION SB05.08: Central Nervous System Interfaces II

Wednesday Afternoon, April 24, 2024
Room 434, Level 4, Summit

4:00 PM SB05.08.01
Electrochemically Mutable Soft Metasurfaces for Light Manipulation Siddharth Doshi[1], Anqi Ji[1], Ali Mahdi[1], Scott Keene[2], Skyler P. Selvin[1], Philippe Lalanne[3], Eric Appel[1], Nicholas Melosh[1] and Mark Brongersma[1]; [1]Stanford University, United States; [2]University of Cambridge, United Kingdom; [3]CNRS, France

Active optical metasurfaces, capable of dynamically manipulating light in ultra-thin form factors, enable novel interfaces between humans and technology.

Miniaturized implantable devices for light delivery open new applications in biophotonics, including minimally invasive sensing, endoscopic imaging, and optogenetic stimulation. The next generation of human-photonic interfaces will require mechanically adaptive, minimally invasive devices that can dynamically manipulate the shape of optical wavefronts and their spectral properties. In such interfaces, soft materials bring many advantages based on their flexibility, compliance, and large stimuli-driven responses.

Here, we realise electrochemically-mutable, soft (EMuS) metasurfaces that capitalise on the swelling of soft conducting polymers to alter the shape and associated resonant response of metasurface elements. Previous approaches to dynamic metasurfaces that rely on index-tuning of materials are fundamentally constrained by Kramers-Kronig relations, which prescribe that significant tuning (i.e. index changes) naturally comes with notable absorptive losses. By leveraging the deformability of soft materials to modulate geometry we circumvent these limitations, allowing for effective, low-loss phase tuning. Using the commercial polymer, PEDOT:PSS, we demonstrate dynamic, high-resolution color-tuning and high-diffraction-efficiency (>19%) beamsteering devices that operate at CMOS compatible voltages (~1.5V). Our devices can be realised as ultra-thin, sub-micron coatings, and provide a building block for a new generation of active opto-electronic devices amenable for integration with the human body, potentially enabling new applications in implantable light guiding and bio-imaging.

4:15 PM SB05.08.02
Implantable Microfluidics for Membrane-Free Neurochemical Sampling in Freely Moving Animals Yi Zhang and Guangfu Wu; University of Connecticut, United States

Extensive studies in both animals and humans have demonstrated that high molecular weight neurochemicals, such as neuropeptides and other polypeptide neurochemicals, play critical roles in various neurological disorders. Despite many attempts, existing methods are constrained by detecting neuropeptide release in small animal models during behavior tasks, which leaves the molecular mechanisms underlying many neurological and psychological disorders unresolved. Here, we report a wireless, implantable microfluidic system for membrane-free neurochemical sampling with cellular spatial resolution in freely moving animals. In vitro studies demonstrate the sampling of various neurochemicals with high recovery (>80%). Open-field tests reveal that the device implantation does not affect the natural behavior of mice. The probe successfully captures the pharmacologically evoked release of neuropeptide Y in freely moving mice. This wireless push-pull microsystem creates opportunities for neuroscientists to understand where, when, and how the release of neuropeptides modulates diverse behavioral outputs of the brain.

4:30 PM *SB05.08.03
Multimodality Sense and Actuate Bioelectrical Interfaces Tzahi Cohen-Karni; Carnegie Mellon University, United States

My team's efforts are focused on the development and engineering of nanomaterials-based flexible platforms to interrogate and affect the properties of tissue and cells. A few of the major questions we strive to answer are: Can we make materials and platforms tailored to allow seamless and stable integration with cells and tissue as well as enable sensing and actuation? Can hybrid-nanomaterials allow new insights into biological processes such as tissue development and disease progression? Highly flexible bottom-up nanomaterials synthesis capabilities allow us to form unique hybrid-nanomaterials that can be used in various input/output bioelectrical interfaces, i.e., bioelectrical platforms for chemical and physical sensing and actuation. The outstanding electrochemical properties of the synthesized hybrid-nanomaterials allow us to develop highly efficient catalysts, and electrical sensors and actuators. We demonstrated sensors capable of exploring brain chemistry and sensors/actuators that are deployed in a large volumetric muscle loss animal model. Finally, using the unique optical properties of nanocarbons in the form of graphene-based hybrid-nanomaterials and 2D nanocarbides (MXene), we have formed remote, non-genetic bioelectrical interfaces with excitable cells and modulated cellular and network activity with low needed energy and high precision. In summary, the exceptional synthetic control and flexible assembly of nanomaterials provide powerful tools for fundamental studies and applications in life science and potentially seamlessly merge nanomaterials-based platforms with cells, fusing nonliving and living systems together.

SESSION SB05.09: Poster Session: Materials and Systems for Fully Implantable Organ Interfaces
Session Chairs: Philipp Gutruf and Flavia Vitale
Wednesday Afternoon, April 24, 2024
Flex Hall C, Level 2, Summit

5:00 PM SB05.09.01
High Molecular Weight Branched Polyurethane Thermogels as Vitreous Endotamponades Qianyu Lin[1], Zengping Liu[2,3,4], Jason Y. Lim[1,3], Xinyi Su[2,3,4] and Xian Jun Loh[1,3,5]; [1]Institute of Materials Research and Engineering, Singapore; [2]Institute of Molecular and Cell Biology, Singapore; [3]National University of Singapore, Singapore; [4]Singapore Eye Research Institute, Singapore; [5]Nanyang Technological University, Singapore

Vitreous endotamponades are essential medical materials employed to seal retina tears and promote retinal reapposition after vitrectomy. Current clinical endotamponades in use include silicone oil and expansile gases but they require patients to assume prolonged faced down position and offer poor immediate visual acuity due to their buoyancy and low refractive indices respectively. Additionally, they are frequently associated with complications such as cataracts, glaucoma, and retinopathy due to emulsification of the silicone oil. As such, there has been great interest to develop biocompatible hydrogel-based vitreous endotamponades that offer much enhanced optical clarity and comfort to patients with reduced risk of complications. Among hydrogel-based endotamponades, thermogels are particularly advantageous. Thermogels are supramolecular hydrogels capable of self-assembly gelation in response to applied temperature. It undergoes spontaneous sol-gel phase transition when warmed above its gelation temperature without additional chemical crosslinkers. This allows thermogels to be facilely employed as vitreous endotamponades as clinicians can easily inject it as a sol and its gel phase will form spontaneously to fully fill the vitreous cavity and provide the required tamponading effect.

For hydrogel-based vitreous endotamponades, it is desirable to have low polymeric content to ensure low osmotic pressure; high osmotic pressure in the vitreous cavity is associated with mechanical damage to the retina. For a thermogelling copolymer, a high molecular weight would provide gelation at low polymeric concentrations (~ 5 wt%). However, our previous study had shown that a transparent thermogel of high molecular weight tend turned opaque after implantation in the vitreous cavity. We believe that the thermogel turned opaque in the eye due to protein adhesion and aggregation to the hydrogel matrix due to the high hydrophobicity of the high molecular weight linear copolymer used to formulate the thermogel. To address the current limitation, we propose to change the architecture of the thermogelling copolymer from linear to branched to allow the copolymer to possess brush-like capability to reduce protein adhesion and thus maintain optical transparency in the vitreous cavity. Herein, we demonstrate that a branched high molecular weight thermogelling copolymer is able to perform as a vitreous endotamponade and maintain optical transparency in the vitreous cavities of rabbit models.

We further demonstrated that there is an optimal amount of polymer branching to ensure biocompatibility of the thermogel in the eye. Molecular weight analyses showed that the copolymers become more globular with more branches. Subsequent critical micelle concentration (CMC) and thermodynamics analyses showed that the increasingly globular copolymers had reduced ability to form micelles. Further small angle X-ray scattering (SAXS) analysis of the sol-gel phase transition of the branched thermogels showed that higher degree of branching lowered the propensity of micelles to aggregate into a stable hydrogel matrix. This is later reflected as higher gelation temperatures, lower gel stiffness, and higher rate of thermogel erosion. Subsequent implantation into the vitreous cavities of rabbits showed that thermogels from highly branched polymers rapidly disintegrated into large floating gel blocks and debris, which significantly lowered the biocompatibility by causing retina atrophy. Overall, we identified a new family of branched thermogels that can function effectively as vitreous endotamponades and delineated the effects of polymer branching on the performance of thermogelling vitreous endotamponades.

5:00 PM SB05.09.02
Biodegradable Gel Electrolyte for Self-Electrified Implantable Biomedical Devices Giheon Kim[1,2]; [1]Korea University, Korea (the Republic of); [2]BK21 Four Institute of Precision Public Health, Korea (the Republic of)

Gel electrolyte have attracted increasing attention as one of compartment of battery system due to their mechanical strength and high capacitance-to-volume ratio. However, the non-biodegradable gel electrolyte is still challenging to apply to various applications because of the harmfulness to environment and the toxicity to human. Here, we developed the biodegradable gel electrolyte by blending the polyvinyl alcohol (PVA) with polyethylene glycol (PEG) to enhance their mechanical, electrical, and electrochemical stability for implantable bioelectronic devices. We synthesized the different ratio of blended hydrogel (PEG:PVA = 1, 2, 5, 10, 20 %) by freezing-thawing method. The biodegradable gel electrolyte is achieved by immersing the blended hydrogel into ion-rich solution (*i.e.*, Phosphate Buffered Saline (PBS) and ionic liquid etc.). The prepared gel electrolyte exhibits better mechanical strengths (tensile strength of ~30 kPa under 120 % of strain) and high ionic conductivity (~ 50 mS/cm) compared to pure PVA hydrogel and PEO hydrogel. Although the liquid electrolyte induces the corrosion of biodegradable electrode (Mg, W, Mo etc.) surface leading to poor electrochemical performance, the prepared gel electrolyte can increase the anodic reaction up to 3.7 V, which reduce the corrosion and hydrogen evolution reaction (HER) of biodegradable anode and cathode. In addition, the PEG:PVA blended hydrogel is degraded by 14 days at 37 °C, which can be applied to biodegradable bioelectric devices. We anticipated that the biodegradable gel electrolyte can be applied for the biodegradable self-powered electroceuticals and biodegradable supercapacitor for implantable biomedical applications.

5:00 PM SB05.09.03
Design, Simulation and Fabrication of Novel Flat-Wire Braided Flow Diverter for Cerebral Aneurysm Yao-An Zhuang[1], Lilian Lin[1], Chen-Hsin Lin[1], Ching-Chang Huang[2] and Hao-Ming Hsiao[1]; [1]National Taiwan University, Taiwan; [2]National Taiwan University Hospital, Taiwan

Cerebral aneurysm is a weakened cerebral artery which causes localized ballooning of the blood vessel. As an aneurysm grows, it puts pressure on adjacent tissues and may eventually rupture, leading to severe events or even sudden death. Today the flow diverter, a stent-like mesh device, has gained increasing popularity for the endovascular treatment of cerebral aneurysms. The mechanism is to stop the blood flow into an aneurysm via the fine-mesh structure of the flow diverter to reduce the risk of rupture. It also serves as a scaffold for endothelialization, effectively sealing off an aneurysm from the body circulation. The paradigm shift in the treatment preference from traditional craniotomy reflects the growing confidence in the effectiveness of the flow diverter for managing cerebral aneurysms.

Braided flow diverter is currently used to treat cerebral aneurysms, with the braiding technology adopted to build stent-like mesh devices. Braiding is considered to be more cost-effective when compared to other stent fabrication techniques such as laser-cutting. When braiding, round wires extending from bobbins can be secured to the end of a mandrel under tension to form a braided device around it. In this paper, instead of using round wires, a novel flat-wire design with the wire dimension of 25 μm in thickness and 127 μm in width was investigated. This unique wire geometry possesses a higher aspect ratio that results in thinner struts and greater metal coverage (less opening). It is believed that thinner struts reduce the low wall shear stress zones and thus the risk of in-stent stenosis, a significant complication of narrowed arteries. Therefore, using flat wires could reduce the occurrence of in-stent stenosis, while increasing the metal coverage to cut down the blood supply to the aneurysm simultaneously.

A flat-wire braided flow diverter was investigated in this paper. Finite element analysis (FEA, ABAQUS) and computational fluid dynamics (CFD, ANSYS) were conducted to evaluate the mechanical integrity and hemodynamic behavior under various conditions consistent with the current practice. CFD models were analyzed based on an ideal aneurysm assembly with a flat-wire braided flow diverter implanted to evaluate its therapeutic effects. Prototypes were fabricated in-house using a braiding machine with the capacity of up to 64 bobbins, followed by the validation of bench tests for proof of concept. FEA simulation results showed no material damage occurred during the manufacturing and deployment processes as the strains were within the safety range. CFD simulation results showed the flat-wire braided flow diverter stopped a significant portion of the blood flow into an aneurysm. The velocity streamlines helped visualize the effectiveness of the increased metal coverage. These conclusions suggest that the flat-wire braided flow diverter has a great potential to achieve the best possible clinical outcomes.

5:00 PM SB05.09.04
Porous, Antibacterial and Biocompatible GO/n-HAp/bacterial cellulose/*β*-glucan Biocomposite Scaffold for Bone Tissue Engineering Saqlain A. Shah[1] and Mua Khan[2]; [1]Forman Christian College, Pakistan; [2]University of Punjab, Pakistan

We developed a nanocomposite scaffold for bone tissue engineering (using bacterial cellulose (BC) and *β*-glucan (*β*-G)) *via* free radical polymerization and freeze-drying technique. Hydroxyapatite nanoparticles (n-HAp) and graphene oxide (GO) were added as reinforcement materials. The structural changes, surface morphology, porosity, and mechanical properties were investigated through spectroscopic and analytical techniques like Fourier transformation infrared (FT-IR), scanning electron microscope (SEM), Brunauer–Emmett-Teller (BET), and universal testing machine Instron. The scaffolds showed remarkable stability, aqueous degradation, spongy morphology, porosity, and mechanical properties. Antibacterial activities were performed against gram - ive and gram + ive bacterial strains. The BgC-1.4 scaffold was found more antibacterial compared to BgC-1.3, BgC-1.2, and BgC-1.1. The cell culture and cytotoxicity were evaluated using the *MC3T3*-E1 cell line. More cell growth was observed onto BgC-1.4 due to its uniform interrelated pores distribution, surface roughness, better mechanical properties, considerable biochemical affinity towards cell adhesion, proliferation, and biocompatibility. These nanocomposite scaffolds can be potential biomaterials for fractured bones in orthopedic tissue engineering.

5:00 PM SB05.09.05
Comparison of Tensile Properties of Amniotic Membranes Sterilized with Different Techniques Abbigail Poland, Molly Post, Olivia Logan, Isabella Sledge, Babak Safavieh and Mora Melican; Tides Medical, United States

The amniotic membrane has gained recognition as a promising biomaterial in the field of regenerative medicine. The market offers a diverse range of placental membrane products designed for various applications. When evaluating and characterizing the numerous amniotic products available, it becomes crucial to ensure that each product aligns with the specific user requirements, particularly concerning the mechanical characteristics for wound care

applications. One effective method for testing this characteristic involves tensile testing. In this study, the Instron 5544 was used to test tensile strength of two different amniotic products. A standardized and optimized procedure for conducting tensile tests on amniotic products has not been previously well-established. This study addresses this gap by introducing a standardized test method for the tensile testing of dehydrated amniotic membrane. Through this study, we compare the handling capabilities of Artacent Wound®, a dual layer amniotic scaffold, sterilized with electron beam (e-beam) sterilization, to Artacent Wound® sterilized using an alternative sterilization technique.

Multiple sterilization techniques, such as gamma irradiation, ethylene oxide (ETO) gas sterilization, e-beam, and several other approaches have been utilized to remove potential pathogens for products derived from human placentas. However, the sterilization method can lead to diverse impacts on the material's mechanical characteristics. To ensure that the mechanical properties are maintained with the alternative sterilization technique, the Artacent Wound® product is compared to the e-beam sterilized Artacent Wound® product.

Tensile tests were performed on two different Artacent Wound® products (one with e-beam sterilization and one with an alternative sterilization technique), and the products were tested for Failure Stress (MPa), Failure Strain (%), and Young's Modulus (MPa). The tests were used to characterize and better understand the product's mechanical properties and how the sterilization techniques impact these properties. By developing a method to test tensile strength for amniotic products, new products and new processing steps can be easily tested to determine the mechanical impacts to the product.

5:00 PM SB05.09.06
An Open-Source Platform for Clinical Autonomic Neuromodulation Therapies Mona A. Mohamed[1], Ali Soleimani[1], Farbod Amirghasemi[1], Ellis F. Meng[1], Victor Pikov[2], Raja Hitti[3], Hangbo Zhao[1] and Maral Mousavi[1]; [1]University of Southern California, United States; [2]Medipace Inc., United States; [3]Med-Ally LLC, United States

The field of bioelectronic medicine is rapidly progressing, with emerging therapeutic approaches necessitating precise closed-loop control of neural activity in peripheral nerves like the vagus nerve, sacral nerve, pudendal nerve, enteric nervous system, and others. However, transitioning neuromodulation therapies for human clinical application poses significant challenges due to the high costs and lengthy development timelines required for implantable devices suitable for human use. Presently, many clinical research teams rely on off-the-shelf commercial devices for testing on both large animals and humans. These commercial devices are often tailored to specific applications and may not align with the requirements of novel therapies. Collaborations with large corporations can be complicated by potential conflicts of interest that hinder successful partnerships. Furthermore, existing devices often lack the capacity to record biomarkers from multiple sites, limiting their therapeutic potential. As a result, access to customizable neuromodulation technology stands as a substantial obstacle to scientific breakthroughs and the advancement of new treatments.

The CARSS Center, a collaborative venture involving the University of Southern California, Medipace Inc., and Med-Ally LLC, aims to address this challenge. They are creating an open-source system for closed-loop autonomic neuromodulation specifically designed for human clinical investigations. The CARSS system consists of an implantable pulse generator (IPG) equipped with Bluetooth capabilities and native support for running machine learning algorithms. Additionally, it includes a variety of leads for both stimulation and sensing purposes. The initial set of leads comprises a vagus nerve cuff and a sacral nerve linear array with combined stimulation and neural sensing capabilities, as well as electrocardiography, electromyography, and motion sensing leads for physiological monitoring. Further leads in development encompass sensing leads for neurotransmitters such as acetylcholine and catecholamines, as well as physical sensing leads for strain and end-organ temperature. CARSS is actively seeking collaborators interested in utilizing the system to conduct comprehensive studies on large animals, with the goal of eventually advancing these therapies to initial use in human patients.

5:00 PM SB05.09.07
A Cellulose Aerogel-Based Drug Delivery System using Punica Granatum Extracts - Invention to Innovation Subharina Mahapatra[1], Jyotiraman De[2] and Manjula Hebbale[1]; [1]Bharati Vidyapeeth Dental College and Hospital, India; [2]Indian Institute of Technology Bombay, India

Oral lichen planus is a widespread chronic mucocutaneous, autoimmune inflammatory disorder affecting the oral cavity. Oral lichen planus is usually associated with pain, burning sensation and irritation of the oral mucosa. Multiple therapeutic approaches including both topical and systemic corticosteroids have been used in the management. As a consequence of the reported adverse effects of corticosteroids, different natural plant extracts have been suggested.
Pomegranates (punica granatum) have been identified for hundreds of years as natural treatment modality for their numerous benefits for health. Topical punica granatum extracts gel in management of oral lichen planus has been tried as a topical medication and according to research it has anti-inflammatory property, which help to subsite the symptoms of oral lichen planus but the disadvantage is that punica granatum extracts gel dissolve quickly inside the oral cavity by saliva, thus providing less application time. Prolonged application time of the medication is required for faster recovery.
As a result, drug (punica granatum extracts gel) -loaded cellulose aerogel have been introduced as a promising drug delivery carrier to deliver medications to the affected area by controlled release. They prolong the time of application as the medication slowly dissolves in saliva and is released to the particular applied area of irritation caused by oral lichen planus. Cellulose is used in this process, as cellulose is the perfect raw material for cellulose aerogel due to its easy availability, biodegradability, biocompatibility, and nontoxicity. It also offers a high surface area, a highly porous, interconnected fibre network, and the availability of various functional groups required for drug encapsulation.
Hence, a cellulose aerogel-based drug delivery system is developed from the punica granatum extracts gel in the management of oral lichen planus as an alternative treatment plan to prolong the application time and control release of the medication.
After development of the product, it has been applied in the oral lichen planus patients. Total thirty patients were divided into two groups, group a patient with topical corticosteroids and group b patients with drug (punica granatum extracts gel) -loaded cellulose aerogel. The results were better in group b patient, who were using drug (punica granatum extracts gel) -loaded cellulose aerogel.

5:00 PM SB05.09.08
Comparative Analysis of Sterilization Methods for Placenta-Based Products using an Animal Model Molly Post, Olivia Logan, Denae Landry, Isabella Sledge and Mora Melican; Tides Medical, United States

Placenta-based products, known for their regenerative potential in various clinical applications, are either aseptically processed or require effective terminal sterilization methods to ensure safety and maintain their therapeutic properties. Providing an overview of a comparative analysis of healing rate in a full thickness animal model has been used to show the importance of evaluating the impact of sterilization on these materials in a biologically relevant context. The Sprague Dawley full thickness model is used to assess the in vivo response to sterilized placenta-based products, and to provide critical insights into immunogenicity, tissue integration, and the overall regenerative potential of these materials.
Several sterilization methods, including gamma irradiation, ethylene oxide (ETO) gas sterilization, electron beam (e-beam), and various other methods have been employed to eliminate potential pathogens from placenta-based products. However, the choice of sterilization method can have varying effects on the biological activity and safety. In this study, we discuss the utilization of an animal model to assess the effects of different sterilization techniques on

the safety and efficacy of placenta-based products. The placenta-based product tested is Artacent Wound®, a dehydrated dual layer amniotic graft, terminally sterilized with two different techniques. Furthermore, it addresses the importance of selecting appropriate animal models that closely mimic human physiology, ensuring that the findings are translatable to clinical applications. The animals are monitored for wound healing progress and adverse effects.
In conclusion, employing relevant animal models allows for a more comprehensive evaluation of the impact of sterilization on these materials, bridging the gap between in vitro assessments and clinical applications.

5:00 PM SB05.09.09
Soft, Bioresorbable, Transparent Microelectrode Array Platform for Heart Disease Diagnosis and Treatment Zhiyuan Chen; The George Washington University, United States

Heart disease kills nearly 700,000 people in the United States each year, with an estimated annual cost of $219 billion. A key factor contributing to these alarming statistics is the lack of tools that can unravel complex pathophysiology, facilitate intraoperative or postsurgical monitoring, and provide effective and timely clinical treatments.

Noble metal–based microelectrode arrays (MEAs) have been widely used to probe the patterns of cardiac excitation waves and identify the regions causing arrhythmias, while electrical pacemakers and defibrillators are the cornerstone of therapy in clinical medicine to correct abnormal heart rhythm. However, they are **problematic in detecting critical cardiac parameters** such as intracellular calcium dynamics, metabolic activity, or target-specific cell types.

Optical mapping using voltage/calcium-sensitive dyes or intrinsic fluorescence can complement these electrical approaches by uncovering the roles of above-mentioned cellular parameters in both health and disease conditions. However, conventional opaque MEAs are not compatible with this as they block the passage of excitation illumination and fluorescence signals, and obscure the bio-signals by artifacts due to the photovoltaic effect. Furthermore, given the mechanical dynamic nature of hearts, higher requirements are placed on the flexibility of the interface devices. Therefore, developing such technology that can **bridge electrophysiology and opto-physiology at cardiac interface is of significance but very challenging**.

Soft transparent MEAs show great promise in tackling this challenge, as they allow light to transmit in both directions for simultaneous artifact-free optical and electrical investigation of cell/tissue from the same field of view and visualize the spatiotemporal distribution of cardiac activities with multiple parameters. Additionally, optically transparent MEAs are highly desired during clinical procedures to allow direct observation of areas of interest under the microelectrodes for concurrent optical diagnostics/therapies (such as endoscopy) and guiding other procedures (such as catheters) on the hearts. However, **all exsiting transparent MEAs are designed for chronic biointerfacing** and require surgical removal when they malfunction or are no longer needed.

In comparison, bioresorbable electronics provide unique opportunities to investigate, monitor, and treat short-lived cardiac complications, including postoperative arrhythmias and heart failure on the order of a few days to weeks following ischemic events or surgery, which account for at least one-third of postoperative deaths. Those devices can subsequently dissolve into benign products via natural metabolic mechanisms to avoid the complications, infection risks, and additional costs associated with surgical retrieval. However, **soft transparent MEAs that exhibit bioresorbable functionality remain unexplored**.

Here, we report materialas, device design, fabrication, characterization, and validation of **the first fully bioresorbable and transparent MEA platform**. The developed fabrication strategy achieves **nanoscale transient patterns for the first time**. The device enables multiparametric electrical and optical mapping of cardiac dynamics and on-demand site-specific stimulation to investigate and modulate cardiac physiology in rat and human heart models. In addition, the device can be used as a heart implant to perform the **continuous process of arrhythmia detection, monitoring, and bipolar-pacing treatment** *in vivo* over a clinically relevant period. The bioresorption dynamics and biocompatibility of the device are systematically investigated by histology and serology. The concept and design of this work lay the foundation for bioresorbable cardiac technologies that advance postoperative monitoring and treatment of temporary patient pathological conditions in certain clinical scenarios, such as myocardial infarction, ischemia, and transcatheter aortic valve replacement.

5:00 PM SB05.09.10
Structural and Biological Characteristics of a Novel Hydroxyapatite–Sodium Alginate-Based Biocomposite Material for Dental Implants Hussein S. Alrobei; Prince Sattam bin Abdulaziz University, Saudi Arabia

Materials intended for bone and dental implants must possess biocompatibility and good mechanical strength. To enhance these qualities, a novel hydroxyapatite–sodium alginate-based biocomposite was created by using wet precipitation technique. The XRD of the original and modified specimen closely matched the hydroxyapatite (HAp), and the presence of distinct HAp peaks in FTIR spectra endorsed the successful synthesis of both HAp and modified hydroxyapatite–sodium alginate. The SEM images vividly exhibited porosity in the modified specimen, with a recorded density of 3.1 g/cm. The peak microhardness value, 26.4 GPa, was attained in the optimized composition. As the dopant concentration increased, the antibacterial activity of the hydroxyapatite–sodium alginate-based composite also increased. The absence of dopant ion leakage under physiological circumstances was confirmed by a 35-day examination of ion release in simulated body fluids. The results indicate that the developed composite holds substantial potential as a material suitable for teeth and bone implants, owing to its mechanical and biological characteristics.

5:00 PM SB05.09.11
Zwitterionic Conducting Hydrogel for Suppressing The Foreign Body Response against Implantable Biosensors Shinya Wai, Nan Li, Seounghun Kang, Yahao Dai, Lavoie Tera, Wei Liu, Matthew V. Tirrell and Sihong Wang; The University of Chicago, United States

Implantable medical devices (IMDs) are playing an increasingly important role due to an aging population and the associated increasing prevalence of chronic diseases. However, an inflammatory and fibrotic process known as the foreign body response (FBR) has limited IMDs from realizing their full potential. The FBR leads to the production of degradative chemicals and enzymes that can damage the implant. Fibrotic encapsulation is particularly detrimental for biosensors and electrophysiological devices because it would impede the diffusion of analytes and ions. A class of materials with promising FBR suppressing properties are zwitterionic polymers which have been shown to nearly eliminate the FBR for at least a year in mice. As electronic materials for IMDs, poly(3,4-ethylenedioxythiophene):poly(styrene sulfonate) (PEDOT:PSS) is of interest because it is chemically stable, highly processable, non-cytotoxic, and has good mixed ion-electron conducting properties. Nonetheless, previous work addressing the FBR against PEDOT:PSS did not place their focus on long-term solutions or characterize FBR-related immune and tissue responses. We hypothesize that by combining PEDOT:PSS and a zwitterionic polymer into a double-network hydrogel and carefully tuning its phase separation morphology, the conductivity can be increased and the FBR can be suppressed indefinitely. In this work, we demonstrate a process for inducing PEDOT:PSS network formation in a pre-formed zwitterionic hydrogel matrix, which significantly improves its conductivity and reduces FBR-associated fibrosis. Our work demonstrates that controlling the phase separation morphology of composite materials can be an effective strategy for suppressing the FBR.

5:00 PM SB05.09.12
Advanced Multilayered Biodegradable Wireless Sensors: Combining Reference, Shielding and Extended Communication for Precise, Portable and High-Sensitivity Intracranial Pressure Monitoring Minki Hong, Seunghun Han, Kyung Su Kim, Sehwan Park, Sumin Kim, Daeun Sung and Jahyun Koo; Korea University, Korea (the Republic of)

Brain diseases have long posed significant health and economic challenges, with stroke being a prime example. In 2021, one in six cardiovascular deaths in the U.S. resulted from stroke, accounting for about 162,000 fatalities[1]. With a recurrent stroke rate of 25% and an economic burden of $55.6 billion between 2018-2019, there is an urgent need for advanced diagnostic and treatment modalities[2]. One promising development is the wireless brain pressure sensor[3]. However, long-term implantation raises concerns, particularly regarding Healthcare-Associated Infections (HAIs), with surgical site infections posing a notable threat[4]. Addressing these challenges, recent innovations present biodegradable devices, specifically wireless biodegradable Intracranial Pressure (ICP) sensors, that decompose and assimilate post-operation, minimizing complications[5,6]. Key criteria for these sensors include accurate pressure readings by eliminating physiological noises like blood flow and micro-vibrations and ensuring small sensor size, high sensitivity (within the adult brain pressure range of 500-5000 Pa), and effective wireless portability for continuous monitoring. In our study, we validated the efficacy of these biodegradable ICP sensors, emphasizing material choice, device architecture, noise mitigation, wireless communication, and in-vivo testing on rabbits. The sensors, crafted using biodegradable polymers and metals, utilized shielding and reference electrodes for noise reduction. A layered design enhanced sensitivity without compromising size, and Bluetooth technology enabled continuous and long-distance monitoring. Post-insertion into a rabbit's parenchyma and subsequent pressure modulation tests, the sensors exhibited comparable or superior performance relative to conventional pressure sensors. This research signifies a progressive stride toward the realization and clinical deployment of biodegradable diagnostic tools.

Highly Conductive and Ultra-Thin Elastic Silver-Nanosheet Membrane for Neural Recording Sonwoo Jung[1,2], Minjeong Kim[1,2], Seungyeon Kim[3], Tae-Wook Kim[3,3] and Dae-Hyeong Kim[1,2,2]; [1]Institute for Basic Science (IBS), Korea (the Republic of); [2]Seoul National University, Korea (the Republic of); [3]Jeonbuk National University, Korea (the Republic of)

Nanocomposites are gaining prominence as suitable materials for skin wearable and implantable electronics due to their tissue-like mechanical properties and adequate electrical properties. However, achieving both conformal adhesion and excellent electrical and mechanical properties is challenging, as thickness and conductivity are often in a trade-off relationship for most of the materials. To overcome the challenge, highly elastic and conductive nanomembranes have been developed by leveraging 1-dimensional nanowires to form a nanocomposite with enhanced percolation networks between conducting nanofillers. However, owing to the geometrical anisotropy of the nanowire, nanomembrane exhibited different properties depending on the directions. Here, we present a stretchable and laser-patternable nanomembrane using 2-dimensional(2D) silver nanosheets with isotropic and high electromechanical properties. The single layer of nanomembrane is ultrathin (~ 250 nm) and highly conductive (> 80,000 S/cm) yet remains stretchable since the elastomer layer separated from the nanosheets dissipates the stress induced to the membrane. Furthermore, 2-dimensional nanosheets endow the membrane with isotropic mechanical and electrical performances in every direction. Based on float assembly fabrication, silver nanosheets were tightly gathered and partially embedded into the elastomer on the larger surface area of the silver nanosheet and constructed partial face-to-face contact. This face-to-face junction decreases the contact resistance of the nanomaterials, contributing to the high conductivity of the membrane. In addition, the silver nanosheet membrane was able to be manufactured with different dimensions and thicknesses by controlling fabrication variables, displaying distinct characteristics in electrical conductivity, stretchability, impedance, and modulus in each variable-controlled membrane. Moreover, through the bilayer stacking process, the contacts between silver nanosheets created extra percolation networks, resulting in a significant enhancement of conductivity, reaching up to 125,000 S/cm. By patterning the encapsulated nanomembrane with laser, we fabricated a stretchable electrode array making a conformal adhesion to the skin and nerves, demonstrating the future potential of the membrane for broad application both in wearable and implantable approaches.

5:00 PM SB05.09.14
Etching of Failed Polymeric Heart Valve Leaflets Reveals Cross-Tie Craze Microstructure Nipa Khair[1], Katie Vinterella[2], Ethan Harrell[1], Julianne Kindsfater[1], Lakshmi P. Dasi[2] and Susan James[1,1,1]; [1]Colorado State University, United States; [2]Georgia Institute of Technology, United States

Rheumatic and calcified aortic heart valve disease presents a global health concern, impacting millions of individuals across various age groups. The gold standard medical treatments recommend replacing the sick heart valves with xenograft-based bioprosthetic valves that are chemically fixed using glutaraldehyde, commonly sourced from bovine or porcine. Clinical investigations over more than two decades have revealed fixed tissues are prone to premature calcification and tearing, thereby limiting their durability. Moreover, challenges related to supply chains, inconsistent mechanical characteristics, and high costs have been constant issues for tissue valves.

An innovative alternative approach involves enhancing polyethylene-based materials with hyaluronic acid (HA), a glycosaminoglycan naturally occurring in native heart valve leaflets. By incorporating small amounts of HA into a low-density linear polyethylene (LLDPE) thin film at the molecular level, a robust and hydrophilic biomaterial of *in vivo* anti-calcific and anti-thrombotic properties is achieved. The LLDPE thin film has high tear strength and excellent flexibility, making it an appealing choice for developing heart valves. Nonetheless, during durability testing according to ISO 5840-2005 standards, these valves exhibited premature failure. To uncover the fundamental mechanisms behind these failures, this study conducted a failure analysis of semicrystalline blown LLDPE thin film-based heart valves.
The valves consistently tear and wear around highly stressed (from finite element analysis) commissure posts. Six of these worn posts were retrieved from failed valves and chemically etched. Low-voltage scanning electron microscopy (SEM) imaging was taken before and after chemical etching. The semicrystalline LLDPE polymer, with a crystallinity of 36% as determined by DSC, underwent chemical etching using a standard 2% w/v permanganate etching solution, followed by multistep washing. The SEM analysis of pristine LLDPE unveiled distinctive spherulitic structures consisting of well-organized lamellae with diameters of approximately 3 µm and lamellae thickness of 40-80 nm. The etching process effectively eliminated low-energy amorphous regions, revealing the spherulites. A similar study was carried out on the worn and torn LLDPE valves.

The SEM images of the worn surfaces displayed signs of surface wear and aligned fibrils oriented perpendicular to the principal stress direction, akin to a phenomenon known as crazing. Following etching, some fibrils remained partially intact, while others exposed the crystals beneath them. These crystals within the fibrils lost their spherulitic superstructure, exhibiting thickened and fractured lamellae. The presence of these fibrils after etching suggested a state of hyper-crystallinity, a characteristic often observed in polyethylene-drawn filaments. In contrast, the worn surfaces that had tears displayed multiple irregularities at the torn surface. These included bumps, holes, a visually rough texture, and a lack of exposed crystals. Crystal disruptions were notably concentrated within 200-300 µm areas near the tear and wear, while the rest of the samples retained spherulitic morphology.

Remarkably, one of the worn samples unveiled the Kramer craze microstructure "cross-tie," composed of aligned and interlinked lamellae. The spacing between cross-tie lamella ranges between 100-200 nm, and the thickness remained 40-80 nm. To the best of the author’s knowledge, the cross-tie structure has been only theorized with indirect evidence collected from lab-grown crazes. Direct evidence of cross-tie structure indicates crazing initiates the tears.

Stress disentangles polymer strands, causing lamella fibrillation, but some do not disentangle. Instead, they pile up to bridge between fibrils. This study holds the potential to shed light on preventing polymer disentanglement, thereby mitigating crazing and improving heart valve durability.

5:00 PM SB05.09.15
Effects of Temperature on the Mechanical Properties of PEGDA and PDMS Copolymer Scaffold for Tissue Engineering Sam Lloyd-Harry[1], Samaher Shaheen[2], Ozgul Yasar-Inceoglu[1] and Ozlem Yasar[3]; [1]California State University Chico, United States; [2]California State University, Chico, United States; [3]The City University of New York, United States

Tissue engineering is a growing field of materials research concerned with finding new materials and methods for the replacement or improvement of natural tissue structures. Previous studies have shown poly (ethylene glycol) diacrylate (PEGDA) to be a promising engineering tissue structure, or scaffold material. However, PEGDA scaffolds have been shown to lack sufficient mechanical properties that would be required for implantation in the human body. More research must be done to tune the mechanical properties of the scaffold. Many research institutions do not have access to all testing equipment needed to fully study the limitations of scaffold samples. Thus, the need for collaboration between institutions is often necessary. Numerous common testing methods require consistent environmental conditions to maintain the structure of scaffold to accurately collect data. The study of the limitations of environmental conditions is significant to avoid degradation of the structure and therefore keep the mechanical properties of scaffold samples. Experiements have shown PEGDA scaffolds to experience a decrease in strength and elasticity after refrigeration for 24 and 48 hours, but a restoration of mechanical properties was found after 72 hours. No studies have looked at mechanical properties beyond 72 hours of refrigeration. This study investigates the effects of temperature on the mechanical properties of UV cross-linked PEGDA and polydimethylsiloxane (PDMS) copolymer scaffolds. Utilizing Fourier Transmission Infrared Spectroscopy, Scanning Electron Microscopy, X-ray Diffraction, and Raman Spectroscopy, the characterization of the copolymer scaffolds was performed. Compression testing was then performed on a QT 50 Universal Testing Machine at a rate of .75 *mm*/*min*. These results were compared with that of refrigerated copolymer samples and plain PEGDA scaffold samples. Samples were refrigerated at 0 degrees Centigrade for 24, 48, 72, and 96 hours.

5:00 PM SB05.09.16
Alginate Microgels Synthesized using Click Chemistry: A Benign Approach for Delivering Beta Lactamase to Gut Microbiota. Hema Choudhary and Niren Murthy; University of California Berkeley, United States

Microgels are crosslinked networks of polymer swollen in water with a size of 1-100 µm. Microgels have been extensively studied in the biomedical field due to the ease of engineering structural and mechanical properties. These microgels are typically made from biocompatible polymers such as alginate, agarose, gelatin, etc. which can be easily crosslinked by non-covalent interactions of ionic/hydrogen bonding. However, due to physical crosslinking, these microgels are susceptible to dissolution and degradation. To overcome this issue, generally methacrylate groups are introduced for covalent crosslinking. It requires the generation of free radicals which is unsuitable for biological applications, especially if microgels are used for encapsulating proteins or cells. Herein, we developed a new system for making mechanically robust microgels using alginate. These microgels are covalently crosslinked using click chemistry, a benign approach. For this, first alkyne/azide functional moieties are introduced on alginate polymer. Then microgels are created with modified alginate using a T-junction microfluidic device. These microgels are robust and remain stable in the buffer for 7 days as opposed to non-covalently crosslinked alginate which dissolves away within hours.
We expect this technology to have many applications, one of which is protein delivery. In this regard, we successfully encapsulated beta-lactamase protein in these alginate microgels without compromising on activity. Beta-lactamase is an interesting protein that can neutralize antibiotics. Antibiotics affect gut microbiome health which increases the risk of secondary infections and antimicrobial resistance. If beta-lactamase is delivered successfully in the gut, it could neutralize the remaining antibiotics post-treatment. Data from the oral delivery of beta-lactamase and other proteins encapsulated in our alginate click microgels will be presented in this talk.

5:00 PM SB05.09.17
Degradation Effects on Mechanical Properties of Polyethylene Glycol Diacrylate (PEGDA) and Polydimethylsiloxane (PDMS) Copolymer Scaffolds for Tissue Engineering. Ozgul Yasar-Inceoglu[1], Andre A. Fatehi[1], Sam Lloyd-Harry[1], Samaher Shaheen[1] and Ozlem Yasar[2]; [1]California State University Chico, United States; [2]The City University of New York, United States

The merging studies of innovative engineering and cell biology offers promising results for the repair and replacement of human tissues. The field of tissue engineering aims to address critical challenges in the medical field and to further advance research in the biomedical industry. Previous studies have shown engineered tissue scaffolds to degrade over time. Therefore, more research must be conducted on scaffold reliability and breakdown over time, to further understand the limitations of engineered materials inside of the human body. This study examines the degradation effects on the mechanical properties of polyethylene glycol diacrylate (PEGDA) and polydimethylsiloxane (PDMS) copolymer scaffolds submerged in a Phosphate-Buffered Saline (PBS) solution. PBS has been shown to mimic the environment of the human body in previously published studies. The characterization of the copolymer scaffolds was executed by performing Raman Spectroscopy, X-ray Diffraction (XRD), Scanning Electron Microscopy (SEM), and Fourier Transmission Infrared Spectroscopy (FTIR). Equilibrium Swelling testing was conducted by submerging samples in water over 15 minutes. Compression testing was conducted utilizing a QT 50 Universal Testing Machine at a rate of .75 *mm*/*min*. The tests performed on the degraded copolymer samples were also conducted on non-degraded copolymer, degraded PEGDA, and non-degraded PEGDA samples. The results of all samples were compared to understand the effects of degradation on the mechanical properties of copolymer scaffolds.

SESSION SB05.10: Engineered Materials for Organ Interfaces

10:00 AM *SB05.10.01
Engineering Conducting Polymer Hydrogels for Additive Manufacturing and Biointerfaces Alexandra Rutz; Washington University in St. Louis, United States

Hydrogels are insoluble polymer networks swollen with water (>90% water by mass) and are used widely in biomedical applications for their similarities to native extracellular matrix. For bioelectronics, there are many efforts to build devices based on these materials to achieve tissue-matching stiffness and other tissue-inspired properties in order to improve the biointerface. For making electrodes and other device components based on semiconducting

materials, conjugated polymers can be gelled into electronically conducting hydrogels. Such methods include simple mix-and-cast techniques, similar to other methods used widely in traditional (non-conducting) hydrogel processing. We have investigated conducting hydrogels based on the conjugated polymer poly(3,4-ethylenedioxythiophene) polystyrene sulfonate (PEDOT:PSS) fabricated by mixing in a gelling agent, ionic liquid. We have studied how the hydrogel precursor formulation and other fabrication variables of this method affect gel properties, such as swelling, conductivity, and elastic modulus. Further, we have evaluated the potential of these PEDOT:PSS hydrogels for biointerfacing applications and have found that these gels when processed appropriately are stable in vitro and support mammalian cell culture. Finally, we are developing these conducting polymer hydrogels for compatibility with additive manufacturing to grant structural control of these soft bioelectronic interfaces. Such techniques provide manipulation of dimensions and microporosity, important for assembling these hydrogels into functional devices and optimizing tissue integration.

Seeing the Sound: An Ultrasound-Mediated Intravascular Light Source enabled by Colloidal Mechanoluminescent Materials Guosong Hong; Stanford University, United States

Light is used in a wide range of methods in biology and medicine, such as fluorescence imaging, optogenetics, photoactivatable gene editing, photothermal and photodynamic therapies to treat cancers, and photochemotherapy to inactivate viruses *in vivo*. A critical challenge of applying light *in vivo*, such as deep-brain optogenetic neuromodulation and photochemotherapy in deep organs, arises from the poor penetration of photons in biological tissue due to scattering and absorption. Therefore, delivering light deep into the body requires invasive procedures, such as the insertion of optical fibers and endoscopes, as well as surgical removal of overlying tissues. The very invasiveness of these procedures also precludes easy repositioning and volume adjustment of the illuminated region in the same subject. To address these challenges, our lab has developed an ultrasound-mediated intravascular light source, leveraging the deep-tissue penetration of focused ultrasound. We capitalized on mechanoluminescent nanotransducers (MLNTs), which are colloidal nanoparticles of mechanoluminescent materials synthesized via a biomineral-inspired suppressed dissolution approach. These MLNTs can be delivered intravenously into blood circulation and emit light locally at the ultrasound focus. Owing to the deep penetration and fast temporal kinetics of ultrasound, we have demonstrated that this method can produce on-demand and dynamically programmable light emission patterns at elevated depths in different organs of live mice with millisecond precision. This ultrasound-mediated intravascular light source has allowed us to perform noninvasive “sono-optogenetic” neuromodulation in live mice, as well as brain-wide “scanning optogenetics” that activate different brain regions of the same mouse brain. Our development of the ultrasound-mediated intravascular light source has been published in *PNAS* (2019), *Science* (2020), *Science Advances* (2022), *JACS* (2022), *JACS* (2023), and *Nature Protocols* (2023).

Neural Interfaces to Human Organoids Designed for *In Vitro* and *In Vivo* Studies Duygu Kuzum and Madison Wilson; University of California, San Diego, United States

Human cortical organoids, three-dimensional neuronal cultures, are emerging as powerful tools to study brain development and dysfunction. However, chronic monitoring of structural and functional maturation of organoids is challenging due to limitations of existing technologies. Here, we will present the state of the art in neural interfaces for human brain organoids. We will discuss electrical and optical methods of interrogating organoids in in vitro and in vivo configurations. We will present multimodal data analysis for longitudinal monitoring of neuronal activity in the organoids and the surrounding neuronal circuits. We will highlight future applications of in vivo transplantation of human organoids for comprehensive evaluation of the development, maturation, and functional integration of neuronal networks.

11:30 AM *SB05.11.03
Flexible, Scalable, High Channel Count Stereo-Electrode for Recording in The Human Brain Shadi A. Dayeh; Integrated Electronics and Biointerfaces Laboratory, United States

Over the past decade, stereotactically placed electrodes have become the gold standard for deep brain recording and stimulation for a wide variety of neurological and psychiatric diseases. Current deep brain electrodes commonly known as the stereoencephalography (SEEG) electrodes, are limited in their spatial resolution and ability to record from small populations of neurons, let alone individual neurons. Here, we will discuss a novel, customizable, thin-film (polyimide) human-grade flexible depth electrode with platinum nanorod contacts that is capable of recording and stimulation at a depth of 10 cm in brain tissue, an electrode referred to as the UCSD microSEEG electrode. This 15µm thin, stylet-guided depth electrode is capable of recording local field potentials and single unit neuronal activity (action potentials), validated across species including humans. This device represents an advance in manufacturing and design approaches which extends the capabilities of a mainstay technology in clinical neurology.

SESSION SB05.12: On-Demand Presentation

10:30 AM SB05.12.01
Electromechanical Analysis of Silicon Nanomembrane Based Bendable MOS Capacitors with Ultrathin Nanolaminated Encapsulation Chen Liu, Zhuofan Wang, Hongliang Lü, Yuming Zhang, Haonan Zhang, Shiyuan Cheng and Yi-Men Zhang; Xidian University, China

Flexible silicon nanomembrane (Si NM) based active implants as advanced biomedical electronics are essential for futuristic applications in sensing, healthcare, and human-machine interfaces. The development of thin-film encapsulation with excellent mechanical robustness and conformability is indispensable for ensuring the long-lived operation of Si NM based functional devices in a biological environment. Here, the electrical properties have been investigated on Si NM based metal-oxide-semiconductor capacitors (MOSCAPs) encapsulated with ultrathin Al_2O_3/alucone nanolaminates under

mechanical strain conditions. As illustrated in the capacitance-voltage curves under mechanical-bending stress, the variation of the accumulation capacitance (C_{acc}) is observed to be lower than 1 % at both inward and outward bending radii of 85 mm and 38.5 mm compared with the planar condition for the encapsulated MOSCAP with a gate area of 0.02 mm^2, respectively. However, the corresponding reductions of C_{acc} are approximately 2 % and 4 % for the bare device with the same gate area. Up to 4 % and 26 % reduction in the accumulation capacitance have been measured for the encapsulated MOSCAP with a gate area of 0.08 mm^2 at a bending radius of 85 mm under tensile stress and 38.5 mm under compressive stress, respectively. Furthermore, the relevant reductions of C_{acc} are promoted to 9 % and 36 % for the bare device with the same gate dimension. Suppression of the gate leakage current has also been observed clearly for the encapsulated Si NM based MOSCAPs with an active area of 0.08 mm^2 compared with bare devices during bending, while the phenomenon could not be found for the devices with smaller gate areas. These findings demonstrate the great potential of nanolaminated films of Al_2O_3/alucone as the excellent encapsulation. It is also noted that a comprehensive study of the impact of the device gate area on the electromechanical properties will be beneficial to optimizing the scalable layout for achieving high mechanical reliable and high-performance flexible Si NM based MOSFETs to create the next-generation bioelectronic implants.

Functional neurological restoration of amputated peripheral nerve using biohybrid regenerative bioelectronics Damiano Giuseppe Barone; University of Cambridge, United Kingdom

The development of neural interfaces with superior biocompatibility and improved tissue integration is vital for treating and restoring neurological functions in the nervous system. A critical factor is to increase the resolution for mapping neuronal inputs onto implants. For this purpose, we have developed a new category of neural interface comprising induced pluripotent stem cell (iPSC)–derived myocytes as biological targets for peripheral nerve inputs that are grafted onto a flexible electrode arrays. We show long-term survival and functional integration of a biohybrid device carrying human iPSC-derived cells with the forearm nerve bundle of freely moving rats, following 4 weeks of implantation. By improving the tissue-electronics interface with an intermediate cell layer, we have demonstrated enhanced resolution and electrical recording in vivo as a first step toward restorative therapies using regenerative bioelectronics.

11:00 AM SB06.01.02
Skin-Preparation-Free, Stretchable Microneedle Adhesive Patches for High-Fidelity Electrophysiological Sensing and Exoskeleton Robot Control
Heesoo Kim[1], Juhyun Lee[1], Ung Heo[1], Dhileep K. Jayashankar[2], Karen-Christian C. Agno[1], Yeji Kim[1], Choong Yeon Kim[1], Youngjun Oh[1], Sang-Hyuk Byun[1], Bohyung Choi[1], Hwayeong Jeong[1], Woon-Hong Yeo[3], Zhuo Li[4], Seongjun Park[1], Jianliang Xiao[2], Jung Kim[1] and Jae-Woong Jeong[1]; [1]Korea Advanced Institute of Science and Technology, Korea (the Republic of); [2]University of Colorado Boulder, United States; [3]Georgia Institute of Technology, United States; [4]Fudan University, China

Ensuring highly reliable and comfortable recording of electrophysiological (EP) signals is vital in various applications, from medical care to human-machine interaction. Recent research has tried to address this issue by developing soft epidermal electrodes that offer time-dynamic accommodation to skin deformation. Although these sensors are suitable for long-term use and are conformable, the signals acquired using these approaches highly rely on skin conditions, thus requiring a cumbersome skin preparation setup. Microneedle electrodes can overcome the limitation by eliminating the need for skin pretreatment by providing direct access to the epidermis. Nevertheless, existing rigid or flexible microneedle electrodes face challenges related to mechanical elasticity and electrical reliability, particularly during dynamic body movement, hindering their suitability for accurate EP sensing over a

prolonged time.
To address these issues, we have developed a stretchable microneedle adhesive patch (SNAP) for skin-preparation-free, reliable EP monitoring. SNAP comprises gold-coated silicon microneedle arrays, stretchable serpentine gold interconnects, and electrically conductive adhesives. The microneedle array, with a height of less than 200 μm, ensures virtually pain-free penetration of stratum corneum and maintains consistently low and stable skin contact impedance regardless of skin conditions. The elastic, adhesive and conductive platform, featuring a serpentine mesh, enables dynamic adaptation to tissue deformations while also enhancing the electrical skin interface through the provision of an additional conductive pathway. Through this design, SNAP offers remarkable skin penetrability and establishes a robust electromechanical skin interface, ensuring prolonged and precise EP signal monitoring across diverse skin conditions. Analytical and experimental outcomes validate that SNAP enhances wearer comfort during intensive exercise and significantly decreases contact impedance under uncleaned skin, outperforming clinical gel electrodes and flexible microneedle electrodes. Demonstration using the wireless SNAP system in a human-machine interface (HMI) to control a back-support exoskeleton robot underlines its potential for high-fidelity HMIs, even in challenging scenarios involving time-varying skin conditions. We foresee that this SNAP system can be applied to various EP sensing, suggesting new strategies for enhancing comfort, reliability, and utility in applications ranging from healthcare and medical diagnostics to cutting-edge human-robot interactions.

11:15 AM *SB06.01.03
Hydrogel interfaces for merging humans and machines Xuanhe Zhao; Massachusetts Institute of Technology, United States

The last few decades have witnessed unprecedented convergence between humans and machines that closely operate around the human body. Despite these advances, traditional machines made of hard, dry and abiotic materials are substantially dissimilar to soft, wet and living biological tissues. This dissimilarity results in severe limitations for long- term, reliable and highly efficient interfacing between humans and machines. To bridge this gap, hydrogels have emerged as an ideal material candidate for interfacing between humans and machines owing to their mechanical and chemical similarities to biological tissues and the versatility and flexibility in designing their properties. In this talk, I will provide a comprehensive summary of functional modes, design principles, and current and future applications for hydrogel interfaces towards merging humans and machines.

11:45 AM SB06.01.04
An electroadhesive hydrogel interface for prolonged gastrointestinal theranostics Binbin Ying[1,2,1], Kewang Nan[1,2,3], Qing Zhu[4], Tom Khuu[2], Hana Ro[1], Sophia Qin[1], Shubing Wang[2], Karen Jiang[1], Yonglin Chen[2], Guangyu Bao[5], Joshua Jenkins[1,1], Andrew Pettinari[1,1], Johannes Kuosmanen[1], Keiko Ishida[2,1], Niora Fabian[1], Aaron Lopes[1,2], Jason Li[1,2,1], Alison Hayward[1], Robert Langer[1,1] and Giovanni Traverso[1,2,1]; [1]Massachusetts Institute of Technology, United States; [2]Brigham and Women's Hospital, United States; [3]Zhejiang University, China; [4]Zhejiang Pharmaceutical University, China; [5]McGill University, Canada

Establishing a robust and intimate mucosal interface that allows medical devices to remain for extended periods is valuable for theranostic purposes. However, achieving this goal has proven extremely challenging, particularly within the gastrointestinal (GI) tract. Here, we report the development of **e-GLUE**, an **e**lectroadhesive hydro**gel** interface for robust and prolonged m**u**cosal r**e**tention following electrical activation. Notably, this novel mechanism can amplify the adhesion performance on the mucosa by up to 30-fold and extend in vivo GI retention of e-GLUE devices for up to 30 days. Strong mucosal adhesion occurs within one minute of electrical activation, despite the presence of luminal fluid, mucus exposure, and organ motility, thereby ensuring compatibility with complex in vivo environments. In swine studies, we demonstrate the utility of e-GLUE for instantaneous mucosal hemostasis, sustained local delivery of therapeutics, and intimate biosensing in the GI tract. This system can enable improved treatments for various GI conditions, including recurrent gastric bleeding, inflammatory bowel disease, and potentially early monitoring of GI cancers.

SESSION SB06.02: Bioelectronics II
Session Chairs: Eleni Stavrinidou and Bozhi Tian
Tuesday Afternoon, April 23, 2024
Room 427, Level 4, Summit

1:30 PM *SB06.02.01
Bioadhesive and immune-compatible polymer bioelectronics Sihong Wang; University of Chicago, United States

The use of bioelectronic devices for acquiring biological information and delivering therapeutic interventions relies on direct contact with soft bio-tissues. To ensure high-quality signal transductions, the interfaces between bioelectronic devices and bio-tissues must combine signal amplification with stable and conformable contact. Semiconductor-based transistors (e.g., organic electrochemical transistors) have been developed as one of the most advanced technologies for high-performance bio-sensing. However, the rigid mechanical properties and the lack of tissue/skin adhesion from transistors largely prevent the formation of such intimate and long-term stable bio-interfaces. Also, immune-mediated foreign-body response (FBR) stands as the most widely existing challenge, which can lead to the growth of fibrotic tissue at the tissue-device interface. In this talk, I will first introduce our material and device designs for introducing tissue-adhesive properties onto transistor-based biosensors. Then, to combat FBR, I will introduce a set of molecular design strategies for enhancing the immune compatibility of semiconducting polymers. I will also introduce the strategies and advantages of using these new biomimetic properties in bioelectrical and biochemical sensing.

2:00 PM SB06.02.02
Electroadhesion as a Surgical Tool: Successful Repair of an Intestinal Injury in Mice by Electroadhering a Gel-Patch Leah K. Borden[1,2], Michele Saruwatari[3,4], Morine Nader[1], David J. Boegner[1], Paula M. Atienza[1], Ian White[1], Anthony Sandler[3] and Srinivasa R. Raghavan[1,1]; [1]University of Maryland, United States; [2]Massachusetts Institute of Technology, United States; [3]Children's National Hospital, United States; [4]MedStar Georgetown University Hospital, United States

We have demonstrated that cationic hydrogels can be permanently adhered to animal tissues by applying a low DC voltage (< 10 V) for a short time (< 60 s) [1]. This phenomenon is termed electroadhesion (EA). It works with tissues of many mammals (human, cow, pig, chicken, and mouse), and is especially strong in the case of the aorta, cornea, lung, and cartilage. Applying the DC field with reversed polarity reverses this adhesion and allows the materials to detach. Only cationic gels can be electroadhered to tissues, which suggests that the tissues have anionic character.

We then set out to study if EA could be used to repair an intestinal injury in mice without the use of sutures. A cut was made in the mouse intestine, and a cationic gel-patch was adhered over the cut by EA (9 V for 30 s). For comparison, the injury was repaired with sutures (positive control) or by weak

contact adhesion of the same gel-patch (negative control). After the surgeries, the mice were returned to their normal routine and were then assessed after six days. Mice in the EA group showed no complications due to the EA-based surgery and all of them were healthy at the time of assessment. When these mice had a laparotomy, their injuries were found to have healed, with the healing outcomes being equivalent to or better than the mice treated with sutures. These results suggest that EA can be a viable alternative to sutures, with advantages including the ability to achieve a fast and strong adhesion on-command, and moreover the ability to reverse the adhesion as needed.

2:15 PM *SB06.02.03
Organic Bioelectronic Point-of-care Devices as Drivers of Precision Medicine Anna-Maria Pappa; Khalifa University, United Arab Emirates

The development of micro-electronic devices that bridge the gap between traditional electronics with biological systems is highly desirable. The emergence of highly conjugated polymers has opened up exciting directions in biomedical research including point-of-care diagnostics. With the ultimate goal of fully integrated wearable sensors combined with IoT, and that of autonomous at-home diagnostic tests, organic bioelectronic technologies have been heavily explored the past decade resulting in novel device configurations. Multiplexing capability, ability to adopt to complex performance requirements in biological fluids, sensitivity, stability, literal flexibility and compatibility with large-area processes are only some of the merits of conjugated polymers for point of care diagnostics. This talk will summarize our recent efforts on developing biosensors for health monitoring, on rigid and flexible substrates showcasing the potential of conjugated polymers towards next generation point of care sensors.

Printable, Soft and Stretchable Conductor-Based Sensors for Human Body Interface Tao Zhou; The Pennsylvania State University, United States

Soft and stretchable electronics have garnered significant attention owing to its wide range of applicability. The versatility of this technology has resulted in its utilization across multiple fields, such as soft robotics, skin-integrated electronics, biomedical devices, flexible displays, and human-machine interfaces. Here we present a hybrid material based on hydrogel and metal particles that simultaneously possesses high conductivity, stretchability, tissue-level modulus (<10 kPa), as well as 3D printability. This novel material was further applied to develop devices that can interact with the human body for motion sensor and EMG signal acquisition device, demonstrating huge potential for sensors and biomedical devices.

Organic semiconductors for regenerative medicine: optical modulation of the cell fate Maria Rosa Antognazza; Istituto Italiano di Tecnologia, Italy

Use of light for selective and spatio-temporally resolved control of cell functions (photoceutics) is emerging as a valuable alternative to standard electrical and chemical methods. Here, we propose the use of smart materials, and in particular of organic semiconductors, as efficient and biocompatible optical transducers in the field of regenerative medicine.
Devices able to selectively and precisely modulate the fate of living cells, from adhesion to proliferation, from differentiation up to specific function, upon visible light will be presented. Examples of practical applications, recently reported by our group, include optical modulation of the activity of both excitable and non-excitable cells, the control of essential cellular switches like transient receptor potential channels and mechanosensitive channels, as well as effective modulation of intracellular calcium signaling for precise control of cell metabolic processes.
In more detail, we critically discuss the reliability and efficacy of our approach by focusing on a few, representative examples of possible applications:
i. Non-toxic modulation of the cell redox balance, by functional interaction with intracellular proteins;
ii. Optical modulation of cell differentiation, migration and wound healing processes, by hybrid interfaces with mesenchymal stem cells and epithelial cells;
iii. Optical modulation of cardiovascular cells, namely endothelial cells and human induced pluripotent stem cells-derived cardiomyocytes (hPSC-CM).
Novel materials to optically modulate angiogenesis and to optically induce an anti-arrhythmogenic effect will be presented. Interestingly, these results may represent a breakthrough, noninvasive approach to face the cardiovascular risk, in particular post-ischemic disease and arrhythmias.

The above-mentioned study-cases represent, to the best of our knowledge, first reports on use of organic semiconductors for optical modulation of the cell fate, with disruptive perspectives in cell-based therapies and regenerative medicine.

4:00 PM SB06.02.06
A Pixeless, Leadless Photoelectrochemical System for High Spatiotemporal Biosensing Pengju Li and Bozhi Tian; University of Chicago, United States

Microelectrodes and transistor-based biochemical sensors have paved the way for high-sensitivity electrical and electrochemical sensing of entities like reactive oxygen species (ROS), inflammatory cytokines, and metabolites. Yet, achieving leadless high spatiotemporal sensing remains a challenge due to the technical intricacies and spatial restrictions associated with micropatterned arrays. In this work, we introduce a leadless approach for photoelectrochemical sensing leveraging the plasmonic nanostructured Au-TiO2 systems. These systems are characterized by their efficient light-to-current conversion capabilities, offering precise high spatiotemporal photocurrent mapping. Notably, our method facilitates the quantification of chemical concentrations in randomly defined regions-of-interest and provides a detailed profile of biochemical distributions via photoelectrochemical mapping. Additionally, we showcase the potential of bionic imaging on the pixelless device with micrometer resolution, reconstructing light-generated patterns with multimodal information including position, intensity, and color. The monolithic system can also be made on flexible substrates to enable tissue-level photoelectrochemical sensing in vivo.

4:15 PM SB06.02.07
Electrocatalytic on-site oxygenation for transplanted cell-based therapies Inkyu Lee[1], Abhijith Surendran[2], Samantha Fleury[3], Ian Gimino[1], Cody Fell[3], Alexander Curtiss[2], Daniel J. Shiwarski[1], Omar Refy[1], Blaine Rothrock[2], Seonghan Jo[1], Tim Schwartzkopff[1], Abijeet S. Mehta[2], Yingqiao Wang[1], Adam Sipe[4], Sharon John[1], Xudong Ji[2], Georgios Nikiforidis[2], Adam Feinberg[1], Josiah Hester[5], Douglas J. Weber[1], Omid Veiseh[3], Jonathan Rivnay[2] and Tzahi Cohen-Karni[1]; [1]Carnegie Mellon University, United States; [2]Northwestern University, United States; [3]Rice University, United States; [4]The Pennsylvania State University, United States; [5]Georgia Institute of Technology, United States

Implantable cell therapies have been investigated as a promising approach for diseases requiring persistent treatment. However, oxygen insufficiency from a delay or lack of vascularization has been a key challenge. To address oxygen deficiency and support cells and tissues, exogenous oxygen delivery has

been studied. While targeted gas circulation and decomposition of peroxides were employed for pancreatic islets and engineered therapeutic cells, however, they require bulky implants and transcutaneous supply lines, and are limited in oxygen production and its regulation.
Here, we report an electrocatalytic on-site oxygenation (ecO2) platform that enables controlled bioelectronic oxygen production in physiological environments to maintain cell viability and therapeutic functionality of high-density engineered cells under hypoxic stress. Nanostructured sputtered iridium oxide serves as an electrocatalyst for oxygen evolution reaction in neutral pH. It enables a low oxygen evolution onset and presents selective oxygen generation without deleterious by-products over a 300 mV window of operation. ecO2 is capable of maintaining high cell loading (>60k cell/mm^3) in hypoxia in vitro and in vivo. We demonstrate that the exogenous oxygen-generating device can be readily integrated into bioelectronics and accomplish high cell loadings in miniaturized form factor. Our ecO2 platform can be deployed in broad bioengineering applications in cell therapies for chronic disease management.

4:30 PM *SB06.02.08
AI-driven cyborg tissue platform for functional maturation of human stem cell-derived organoids Jia Liu; Harvard University, United States

The ability to control and monitor the functional specialization and maturation of human-induced pluripotent stem cell-derived tissues is critical for tissue engineering, regenerative medicine, pharmacology, and synthetic biology. This talk will introduce an AI-driven cyborg tissue platform that integrates tissue-like flexible electronic sensors and actuators with developing tissues to offer multimodal recording and control. First, I will discuss seamless implantation, integration, and distribution of stretchable mesh nanoelectronics with miniaturized multifunctional sensors and electrical stimulators across the entire 3D organoids through organogenesis for continuous, multiplexed sensing and actuation. Then, I will discuss the integration of single-cell spatial transcriptomics with bioelectronics as an in situ electro-sequencing platform, capable of combining spatially resolved single-cell gene expression with the functional readouts from the electronics for multimodal characterizations. Next, I will discuss the utilization of different machine learning algorithms to analyze, integrate, and interpret multimodal electrical activities, gene regulatory, and signaling networks to determine the functional maturation and specialization of the organoids. Finally, I will discuss the implementation of reinforcement learning algorithms for real-time feedback control, electrical stimulation optimization, and model refinement to improve the functional maturation of organoids. Collectively, the potential applications of this platform as a cyber-physical biological system for various human organoid systems in both in vitro and in vivo settings will be highlighted.

SESSION SB06.03: Poster Session I

5:00 PM SB06.03.01
Photosynthetic vs Photovoltaic Efficiency of Limnospira Indica, Perspective Cyanobacteria Strain for Space Mission Live Support Systems.
Nikolay Ryzhkov[1], Nora Colson[2], Essraa Ahmed[2], Paulius Pobedinskas[2], Ken Haenen[2], Paul Janssen[3] and Artur Braun[1]; [1]Empa, Switzerland; [2]Hasselt University, Belgium; [3]SCK CEN, Belgium

Due to their excellent photosynthetic capability, which can be directly and efficiently applied in O_2 generation, CO_2 utilization, food and chemical production, as well as the photoelectrochemical production of fuels, cyanobacteria are being utilized by space agencies to establish life support systems in future space stations, planetary stations, and long-haul space missions [1].
In the harsh conditions of space, the use of live cyanobacteria is preferred over cellular components because cyanobacteria can adapt to and cope with stress, including ionizing radiation, enabling long-term autonomous operation.
Protein-pigment complexes located in intracellular structures (the thylakoid membranes) capture and transform photonic energies (in the wavelength range of 400-700 nm), leading to the liberation of electrons from water into an intricate electron flow that can be utilized for photosynthesis or driven into an external circuit of a photovoltaic or photoelectrochemical cell. Excess energy is also dissipated as heat. The productivity of photosynthesis can be estimated through a combination of electrochemical and spectroscopic methods. In an attempt to achieve the highest current output, electrical polarization of bio photovoltaic devices is required, either through external polarization bias or by implementing living cells into a self-biased device. Since photosynthesis, in a nutshell, is a process of electron transport involving a series of Redox reactions, it can be influenced by polarization, and electrical bias must be considered an environmental stress for cyanobacteria.
Pulse-Amplitude-Modulation (PAM) fluorometry, in conjunction with the saturation pulse method, has been successfully employed for studying the induction and quenching of chlorophyll fluorescence in plant physiological studies [2]. Here, we have employed PAM to investigate cyanobacterial photosynthetic performance under various polarization conditions and conducted in-situ spectroelectrochemistry to analyze the dependence of cyanobacterial pigment absorbance on electrical polarization.
We have found that negatively polarized bioelectrodes based on intact Limnospira, cyanobacteria reported to be resistant to Gamma irradiation and perspective for space applications [3, 4], demonstrate higher absorbance. Relative increase of absorbance in red region of visible light spectrum is higher compared to blue. As a result, biophotoelectrodes exhibit higher cathodic photocurrents under monochromatic red light than what can be expected from absorbance spectrum analysis. Furthermore, embedding cyanobacteria in either a conductive polymer matrix or a non-conductive matrix with a charge carrier facilitates higher photosynthetic efficiency, as measured by PAM, resulting in higher photocurrent output and improved efficiency in light-limited conditions.
This work was supported by the Research Foundation Flanders (FWO-Flanders) and the Swiss National Scientific Foundation under the Senior Lead Agency Project G0D4920N/189455.

5:00 PM SB06.03.02
Stable hemoglobin-based biosensor based on coordination-assisted microfluidic technology for hydrogen peroxide determination Rongwei Gao; KU Leuven, Belgium

Hemoglobin (Hb), a special redox protein, has received widespread attention because of its good selectivity to hydrogen peroxide, thus, has been employed in numerous sensing technologies. However, because Hb is easily inactivated after being separated from the biological environment, tremendous efforts have been devoted to enhance its stability and application potential. In recent years, a large number of bioconjugation strategies have been developed to

immobilize Hb, such as using (bio-) polymers, metal organic framework materials to encapsulate hemoglobin, sol-gel methods, porous materials to adsorb Hb, etc. Nevertheless, the factors affecting Hb activity are not only related to the strength of the interaction force between the immobilized carrier and hemoglobin, but are also affected by the immobilized microenvironment. Generally, the bio-friendly microenvironment for preparing an enzyme-based biosensor should: (i) maintain high intrinsic activity; (ii) limit exposure time to environmental stress; and (iii) not hinder the conformational dynamic mobility of the enzyme. While most traditional methods can improve the stability of Hb and enhance catalytic activity, only a few can maintain the conformational dynamic mobility of immobilized Hb.
In addition, hemoglobin is generally "inactive" and exhibits a closed form in aqueous media due to its active sites covered by hydrophobic amino acid chains. And the electroactive centers of Hb are deeply buried in its hydrophobic cavity, delaying electron transfer and subsequently limiting the practical application of hemoglobin sensors. HIL is composed entirely of anions and cations and takes on liquid form at or near room temperature, also showing good solubility, absorption, and stability. Interestingly, HIL can act as a "two-handed weapon." On one hand, the imidazole cation of HIL coordinates with the ferrous ion of Hb, realizing the effective immobilization of Hb. The combination of HIL and hemoglobin driven by hydrophobic and electrostatic interaction, which helps the expansion of the temporal polypeptide of Hb and ensures the dynamic migration of its conformation. On the other hand, the hydrophobic surface of HIL helps to "open" Hb, thereby exposing its active center – a process called "interfacial activation" and enhancing its biocatalytic activity. However, because of the strong trapping power of HIL, Hb can easily aggregate in HIL, which greatly decreases its biocatalytic activity.
The mussel foot protein is secreted by the shellfish, the concentrated protein solution and the metal were stored respectively. The two types of secretion capsules of ions are mixed in the microfluidic channel-like duct network and form protein-metal bonds in the newly formed bypass. Metal coordination provides strong adhesion and enhances the mechanical stability of silk protein. Herein, we used a microfluidic channel as a microreactor to immobilize Hb in HIL and construct an active layer of HIL@Hb, which can effectively prevent the aggregation of Hb. More wrinkles formed on the surface of the electrode surface synthesized using the microfluidic channel, subsequently enhancing the effective sensing area for more target molecules. Moreover, to obtain a sensitive biosensor, the effective collection and rapid transfer of electrons between Hb and the electrode is also highly important. Thus, ultra-thin MXene-Ti_3C_2 nanosheets were introduced to modify the electrode surface. The rough 2D structure of MXene-Ti_3C_2 is conducive to adhere HIL@Hb on the electrode surface; while the excellent conductivity of MXene-Ti_3C_2 can effectively reduce contact resistance and support fast electron transfer. Interestingly, the good selective sensing of MXene-Ti_3C_2 to H_2O_2 can improve the sensitivity of the sensor by synergistic catalysis. Overall, this work proposes an effective strategy to construct a stable and sensitive enzyme sensing platform, which is promising for enhancing the sensor's stability and sensitivity.

5:00 PM SB06.03.03
Real-time monitoring and Swarm-intelligence Nanorobots Enhancing Drug Delivery Precision Fan Wang[1,2]; [1]Max Planck Institute for Intelligent Systems, Germany; [2]ETH Zürich, Switzerland

In the evolving landscape of targeted drug delivery systems, the integration of advanced materials and nanotechnology is paving the way for next-generation medical treatments. This study explores the innovative conjunction of Zeolitic Imidazolate Framework-8 (ZIF-8) and iron-platinum (FePt) nanoparticles in the form of ZIF-8@FePt nanorobots, proposing a groundbreaking approach for precision drug delivery activated by radiofrequency (RF) stimulation.
ZIF-8, a renowned metal-organic framework (MOF), exhibits exceptional characteristics conducive to drug delivery, primarily due to its stable, porous structure capable of high drug loading and controlled release. Concurrently, FePt nanoparticles stand out with superior magnetic properties, including high magnetic anisotropy and responsiveness to external magnetic fields, marking their significance in biomedical applications.
This research underscores the synthesis of ZIF-8@FePt nanorobots, leveraging the symbiotic benefits of ZIF-8's drug encapsulation efficiency and FePt's magnetic navigability. The nanorobots are engineered for responsiveness to RF stimulation, a feature that sets them apart in controlled drug delivery scenarios. Upon RF exposure, the induced heat disrupts the MOF structure, triggering the release of the encapsulated therapeutic agents precisely at targeted sites. This mechanism not only promises enhanced drug delivery efficacy but also minimizes systemic side effects, presenting a favorable profile for cancer therapy, among other chronic conditions.
Furthermore, the study delves into the real-time monitoring aspect, facilitated by the inherent magnetic properties of FePt, allowing for tracking the nanorobots' journey within the biological system. The concept of swarm intelligence is also introduced, highlighting the potential for coordinated, intelligent behavior of nanorobots, significantly optimizing the therapeutic outcome.
However, the application of RF in such advanced drug delivery systems is not without challenges. The research emphasizes the need for meticulous optimization of RF parameters to prevent potential thermal damage and ensure patient safety. Additionally, extensive in-vivo studies are necessitated to ascertain the biocompatibility, efficacy, and safety of these ZIF-8@FePt nanorobots.
In conclusion, the ZIF-8@FePt nanorobots under RF stimulation herald a new era in drug delivery, merging materials science, nanotechnology, and medicine. While preliminary results are promising, comprehensive clinical trials are imperative for their transition from a theoretical model to a medical mainstay. This exploration marks a significant stride toward personalized, precision medicine, potentially revolutionizing healthcare paradigms.

5:00 PM SB06.03.04
Assessing Cellular Viability, Cytotoxicity, and Antimicrobial Susceptibility of Magnesium-Doped Hydroxyapatite Nanofibers in Primary Fibroblast Cultures: A Biological Characterization. Fabiola Hernández Rosas, José R. Alanis Gómez and Alana L. Villareal Campos; Anahuac Queretaro University, Mexico

Hydroxyapatite (HAp) is a bioceramic material of great interest in the field of tissue engineering and bone regeneration, given its high biocompatibility and bioactivity in the human body. HAp has been doped with different elements, including magnesium, strontium, silver, and others. Particularly, magnesium-doped HAp (Mg-HAp) appears to have high potential in biomedical applications. Therefore, it is relevant to characterize their biocompatibility. In this study, an in vitro model of fibroblasts obtained from chicken embryos was used to evaluate the effect of HAp-Mg on cell viability. HAp doped with 5% and 10% magnesium was synthesized by the Microwave hydrothermal-assisted method in a Monowave 300 [Anton Paar]. Subsequently, X-ray diffraction analysis was performed to characterize the HAp-Mg samples. The morphological and microstructural characterization of HAp-Mg was carried out using scanning electron microscopy (SEM). Additionally, chemical analysis was conducted using energy-dispersive X-ray spectroscopy (EDS) and FTIR-ATR spectroscopy. To evaluate the effect of HAp-Mg on cell viability, primary fibroblast cultures were obtained from 10-day-old chicken embryos. Cultures were maintained in DMEM medium supplemented with 10% FBS and incubated for 3 days in 5% CO_2 at 37°C. For the treatments, 5% and 10% HAp-Mg were diluted in DMSO at different concentrations (0.1-100 µg/ml) and added to the fibroblast cultures for 24 hours. Subsequently, cell viability was assessed using the MTT and AlamarBlue assays. Antimicrobial susceptibility tests were performed using the disk diffusion method to determine the antimicrobial activity against *Escherichia coli*, *Staphylococcus aureus*, *Enterococcus faecalis*, and *Candida albicans*. This helped determine its ability to inhibit microbial growth and prevent the formation of biofilms. In conclusion, this study explored the biocompatibility of HAp-Mg, an important material in biomedical applications. Using a fibroblast model, it characterized HAp-Mg samples and assessed their impact on cell viability. Additionally, the antimicrobial activity of HAp-Mg was evaluated against various pathogens. These findings have significant implications for tissue engineering and bone regeneration applications.

5:00 PM SB06.03.05

"Hydrogel Variability in Drug Delivery: Balancing Mechanical Strength and Stimuli-Responsiveness" Ji Ha Lee; Hiroshima University, Japan

Hydrogels have garnered significant attention as eco-friendly, renewable soft materials in the context of achieving Sustainable Development Goals (SDGs). These hydrogels can be broadly categorized into two types based on the formation of the crosslinked gel network that holds water molecules: those held together by covalent bonds and those formed through non-covalent processes. Covalently bonded hydrogels exhibit robust mechanical properties, including tensile strength, viscosity, and elasticity, while non-covalent bond-based hydrogels offer the advantage of responsiveness to external stimuli. Specifically, hydrogels assembled through non-covalent molecular aggregates can be precisely tailored to achieve ordered structures and diverse functionalities, making them promising candidates for advanced intelligent drug delivery systems (DDS).
When hydrogels are employed in DDS applications, the preservation of their shape until they reach the target site, serving as carriers for model drugs, necessitates substantial mechanical strength.
Within our research group, we have successfully developed a range of hydrogels using both covalent and non-covalent bonds as binding mechanisms. These hydrogels have been fabricated from materials such as natural polysaccharides, proteins, and supramolecular compounds. We have rigorously assessed the mechanical properties of these gels and conducted investigations into the correlation between their mechanical attributes and drug encapsulation and release behaviors.

5:00 PM SB06.03.06
Development of NmeGA, a Dual Scavenger for NO and ROS in Inflammation Treatment Yunyoung Nah and Won Jong Kim; Pohang University of Science and Technology, Korea (the Republic of)

Inflammation, an immune response to external stimuli, can be developed into severe inflammatory diseases if left uncontrolled. This study introduces NmeGA, a novel dual scavenger designed to target both nitric oxide (NO) and reactive oxygen species (ROS), two pivotal factors exacerbating inflammation. NmeGA combines *N*-methyl-1,2,-phenylenediamine (Nme), a NO scavenger, and gallic acid (GA), a ROS scavenger, through an amide bond. The unique structure of NmeGA yields superior NO and ROS scavenging abilities compared to single scavengers; the amide bond and Nme's methyl group function as electron donating groups (EDG), enhancing NO reactivity. Meanwhile, GA's catechol group and the amide bond serve as EDG and electron withdrawing group (EWG), respectively, effectively scavenging ROS. NmeGA's reduced toxicity and enhanced bioapplication suitability due to increased lipophilicity, indicate its potential for inflammation management. *In vitro* studies on lipopolysaccharide (LPS)-stimulated RAW 264.7 cells demonstrate NmeGA's enhanced NO and ROS scavenging abilities and remarkable anti-inflammatory effects. Moreover, in an LPS-induced peritonitis model, NmeGA significantly reduced mortality rates, NO levels, and inflammatory cytokine levels. This research highlights NmeGA's promising potential for targeting various inflammatory diseases with minimal toxicity.

5:00 PM SB06.03.07
Development of Supramolecular Gels using Calix[4]arene and its Mechanical Property Tomoyuki Tachibana and Ji Ha Lee; Hiroshima University, Japan

The development of soft materials, particularly viscoelastic systems like organogels and hydrogels, has found diverse applications in controlled release, soft tissue reconstruction, energy capture, storage, and sensing. These systems create stable networks through physical or chemical interactions, with physical gels offering reversible networks and self-healing properties. Recent efforts have improved the mechanical properties of polymeric hydrogels through various methods, but conventional supramolecular hydrogel systems still lack high tensile strength. Supramolecular gels, such as cyclodextrin-based hydrogels, exhibit relatively weak mechanical properties due to the non-covalent interactions forming their network structures. Attempts to strengthen them with multivalent interactions have had some success but still fall short of achieving high mechanical strength. Additionally, low-molecular-weight gelators face solubility challenges in water, particularly macrocyclic gelators, which are often hydrophobic. While some reports show functionalized calixarene-based hydrogels can be effective, there is a scarcity of studies on the mechanical properties of organogels and hydrogels made from self-assembled low-molecular-weight gelators, mainly because these materials are inherently weak.
In this research, we developed the supramolecular gels using calix[4]arene and analyze its mechanical property.

5:00 PM SB06.03.08
Stimuli-Responsive Soft Microactuators For Dynamic Microfluidics Chantal Barwig[1], Sadaf Pashapour[1,2], Tobias Spratte[1], Annabelle Sonn[1] and Christine Selhuber-Unkel[1,2]; [1]Institute for Molecular Systems Engineering and Advanced Materials (IMSEAM), Germany; [2]Microfluidic Core Facility Institute for Molecular Systems Engineering (IMSE), Germany

Microfluidic tools spark interest as drug delivery systems, miniaturized cell cultures and lab-on-a-chip devices. The main advantages of microfluidic systems arises from the ability to reduce the sample size and decrease the reagents volume by miniaturizing large scale systems, facilitating the development of rapid diagnostic devices. Still, there is a limit in the flexibility of microfluidics and the devices that are commonly adapted to a single static application. By combining responsive hydrogels with microfluidic systems we provide a compelling option to improve functionality. Stimuli responsive hydrogels are gaining traction for applications in soft microactuators. One of the most prominent thermoresponsive hydrogels is poly(*N*-isopropylacrylamide) (pNIPAM). The actuation of pNIPAM is based on a globule-to-coil transition at the lower critical solution temperature (LCST). Additionally, pNIPAM offers a LCST of around T~32°C close to physiological conditions. At this temperature pNIPAM undergoes a reversible volumetric change due to a transformation in its hydrophilicity. We observed a significantly higher volume change when using pNIPAM hydrogels engineered with 3D microchannels compared to the bulk pNIPAM hydrogel. Besides using such microengineering approaches, the modification of pNIPAM hydrogels with light-, pH-, or magneto-responsive molecules and particles led to multi-stimuli responsive soft actuators with new characteristics. Further, a variety of pNIPAM-based soft actuators have been developed. Recently, we fabricated a dynamic microfluidic system based on pNIPAM microactuators with a broad range of applications in analytical chemistry as lab-on-a-chip devices, biosciences, and diagnostic devices. Ultimately, the combination of microfluidic devices with stimuli-responsive hydrogels simplifies the fabrication of complex microfluidic systems, and additive manufacturing opens doors towards dynamic microfluidics.

5:00 PM SB06.03.09
Electrochemically Co-Deposited Au-Pt Bimetallic Nano-Clusters for Highly Catalytic Glucose Detection Rashid M. Khan[1,1,2], Namyun Kim[1] and Yi J. Lee[1,1]; [1]Korea Institute of Science and Technology, Korea (the Republic of); [2]University of Science and Technology, Korea (the Republic of)

Bimetallic nanoparticles (NPs) have been attention as attractive electrode materials owing to their unique and synergetic properties in many fields, especially in healthcare sensing platforms. Among them, Au-Pt bimetallic nano-clusters (NCs) are considered to be superior for their marked catalytic activity. We have confirmed this by comparing these bimetallic nanoclusters with dendritic Au (DenAu) NPs in glucose sensing applications.
Since high standards like a broad range and a low limit of detection with utmost selectivity are primary concerns, the demand for materials with exceptional catalytic activity has been raised. Herein, we have fabricated the sensor by co-depositing the Au-Pt NCs onto the patterned seed Au layer at optimal

agitation rates and applied potential, it was characterized by its properties (interfacial impedance, cyclic voltammogram, and response to the various glucose concentrations) compared to DenAu. During electrochemical deposition, the optimal growth conditions for Au-Pt NCs and DenAu were -0.1 V for 1000 sec (stirring rate of 1000 rpm) and -0.07 V for 400 sec, respectively, which were relatively low potential as well as fast deposition time.
As a result, the sensor with Au-Pt NCs and DenAu showed remarkably high charge density yields of 309.21 μA/cm^2 and 73.74 μA/cm^2, respectively, while the sensor with plane Au electrode exhibited a charge density yield of 2.37 μA/cm^2. Moreover, they showed extremely enhanced interfacial impedance values of 1.3 kΩ (Au-Pt NCs), and 5.6 kΩ (DenAu) at 0.1Hz compared to that of 92.5 kΩ (plane Au) Consequently, Au-Pt NCs are considered to be an optimal candidate for the highly catalytic glucose detection.
By virtue of the heightened catalytic activity of bimetallic NCs, our sensor with Au-Pt (NCs) could detect various concentrations of glucose at a wide range from 1 to 10000 μM without any use of a mediator. While considering the sensitivity and limit of detection (LOD), Au-Pt nano-clusters (NCs) exhibit exceptional sensitivity of 1715.46 μA m M^{-1}cm^{-2} and a very low limit of detection of 1.5 μM, comparably, DenAu shows 678μA m M^{-1}cm^2 sensitivity and 6 μM limit of detection.
In the near future, the Au-Pt bimetallic nano-clusters (NCs) will be integrated into various sensing platforms (e.g., immuno-sensing, fuel-cell application, and electro-chromic system application, etc.), and their practical feasibility will be investigated.

5:00 PM SB06.03.10
Platinum Metallized Focus Rotary Jet Spun Anisotropic Fiber Flexible Electrodes Felita W. Zhang[1], Honor C. Pimentel[2], Paul D. Trackey[1], Garret A. Longstaff[1], Kennedy V. Munz[1], Rosemary L. Calabro[1,3], Enoch A. Nagelli[1], Stephen F. Bartolucci[3], Joshua A. Maurer[3], Kevin K. Parker[2] and John Burpo[1]; [1]United States Military Academy, United States; [2]Harvard University, United States; [3]U.S. Army Combat Capabilities Development Command, United States

Flexible electrodes enable the development of wearable electronics, biosensors, and portable energy storage devices. Current flexible electrodes are often ink or silicon based with limited mechanical strength and flexibility.[1] To address challenges of mechanical strength and rigidity, we demonstrate a fiber and solution-based synthesis approach for flexible platinum electrodes. Platinum was chosen due to its resistance to oxidation, high catalytic ability, and biocompatibility. Focused rotary jet spinning (FRJS) was used to fabricate the fibers. FRJS is a method that uses focused air streams to direct flow of a fiber solution toward a rotating mandrel to produce aligned fiber scaffolds, which enable directional metallization.[2] Fiber scaffolds are composed of polycaprolactone and gelatin to possess both mechanical strength and charged amino acid side chains that facilitate binding to charged metal salt ions. Palladium salt solution was used to sensitize the fiber scaffolds for electroless deposition. Cu metal was deposited as continuous concentric shells around the fibers using an electroless deposition solution.[3,4] Controlling electroless deposition time allows tunable shell thickness in the Cu phase. The Cu metal phase was galvanically displaced with Pt salt solution to achieve surface Pt metallization of the Cu shell. The metallized fibers were characterized using scanning electron microscopy, energy dispersive x-ray spectroscopy, x-ray diffractometry, x-ray photoelectron spectroscopy, thermogravimetric analysis, Fourier transform infrared spectroscopy, orientation order parameter analysis, and force extension modulus testing. Electrochemical performance of the platinum fiber flexible electrodes was determined with electrochemical impedance spectroscopy and cyclic voltammetry. The rapidly synthesized, aligned, metallized fiber sheets have tunable metal thickness, porous structures, high mechanical strength, and high specific surface area. The fiber metallization synthesis technique is envisioned as an approach for a wide range of noble metal porous flexible electrodes to address energy storage, sensing, and catalysis applications.

Synthetic Route of Au-Fe_3O_4 Janus Nanoparticles for Continuous Separation and Purification of Selected Biomaterials Yunji Eom, Jaejong Lee, Soongeun Kwon, Hak-Jong Choi, Junhyoung Ahn, Hyungjun Lim, Kee-Bong Choi and Geehong Kim; Korea Institute of Machinery and Materials, Korea (the Republic of)

Magnetic nanoparticles(MNPs) have been received a great deal of attention in bio-applications such as hyperthermia, drug delivery, and biosensor. Recently, MNPs were one of the most promising candidates for separation and purification of biomaterials such as proteins, DNA, and exosome for disease diagnosis and treatment[1,2]. Magnetic separation is very useful technology to obtain specific biomaterial from whole blood or urine because it is simple process, high yield and non-toxic to biomaterials[3]. However, agglomeration by multiple binding sites on MNPs surface and biomaterials makes a little problem, such as insertion of undesired biomaterials and hindrance by precipitation, for separation and purification. The problems might be improved to apply MNPs based separation and purification to industrial level.
In this work, synthetic route of Au-Fe_3O_4 Janus nanoparticles(JNPs) has been developed for continuous separation and purification of specific biomaterials. First of all, Au nanocrystals have been synthesized by reduction of $HAuCl_4$. Then, Fe_3O_4 NPs have been attached on Au surface using thermal decomposition of $Fe(CO)_5$ as following literature to synthesize Au-Fe_3O_4 JNPs capped with oleic acid[4]. Each ligand on the surface of Fe_3O_4 and Au has been continuously exchanged with hydrophilic chain(PEG, COOH, etc.) functionalized phosphonic acid group and target binding head(antibody, biotin) functionalized thiol group, which makes stronger bind between ligand and surface. Target binding head on Au surface has been attached on the surface of specific biomaterials. Then, hydrophilic chain of opposite site of JNPs can provide high dispersibility in water and buffer solution and self-passivation to prevent undesired agglomeration between biomaterials and JNPs. In this study, biotin functionalized thiol, PEG functionalized phosphonic acid, and streptavidin functionalized polystyrene(PS) bead are employed as target bind head ligand, hydrophilic ligand, and artificial biomaterials to prove JNPs system works well, respectively.
To analyze the structural and morphological properties, as-synthesized and ligand-exchanged JNP were investigated using transmission electron microscopy(TEM). Then, magnetic properties of JNPs were observed using vibrating sample magnetometer(VSM). Finally, dispersibility of JNPs before and after binding with PS bead was measured using home-made dispersion analysis system and scanning electron microscopy(SEM). In this results, JNPs system is well operated with high dispersibility enables easy movement and continuous process for separation by magnetic force.

5:00 PM SB06.03.12
Self-Assembly Sugar Derivative-Linked Nucleic Acid Nanoparticle for Nucleic Acid Medicine Delivery Noriko Miyamoto and Yukio Kitade; Aichi Institute of Technology, Japan

DNA- or RNA-based nucleic acid structures (NASs) have garnered significant interest as potential carriers for nucleic acid medicine delivery due to their ability to create unique sequence-based structures. However, for the biological application of NASs, it is still challenging to create a nanostructure that is stable and avoidance of recognition as an immunogenicity under physiological conditions.
We have developed a novel type of NAS called RION (reversibly ionic oligonucleotide-based nanoparticles including microRNAs) through a self-assembly process involving RNA-RNA hybridization and electrostatic interactions facilitated by chemically modified oppositely charged ion oligo nucleic acids[Miyamoto N., et al., *Advanced therapeutics* 2023, 6, 2200265]. In this research, to demonstrate the versatility of the chemical modification of RION, we designed a sugar derivative linked to RIONs. The sugar derivative-linked RION nanoparticles exhibit a spherical shape with a diameter of less than 100 nm, as observed in transmission electron microscopy images. Moreover, we found that sugar derivative-linked RION, when loaded with tumor suppressor microRNA, effectively inhibits the growth of human colorectal cancer cells (DLD-1 cells) in a dose-dependent manner. On the other hand, the sugar derivative-linked RION demonstrated transfection efficiency in a floating cancer cell line, a well-known difficult transfection with commercialized Lipofection regents. This report introduces RION technology as an innovative platform for delivering nucleic acid-based medicines, offering promising potential for applications in the field of cancer therapy and beyond.

5:00 PM SB06.03.13
Nanocrystalline Gadolinium-Doped Hydroxyapatite: Synthesis, Characterization and Cytotoxicity Assessment for Enhanced Drug Delivery Applications Fabiola Hernández Rosas[1], José R. Alanis Gómez[1], Rodrigo Velazquez Castillo[2] and Emilio Carnaya Bustamante[1]; [1]Universidad Anahuac Querétaro, Mexico; [2]Universidad Autónoma de Querétaro, Mexico

Hydroxyapatite (HAp) is a ceramic material predominantly composed of calcium phosphate, possessing a crystalline structure similar to natural human bone. It holds a wide range of applications in the medical field, such as dental implants, and serving as a bone filler in orthopedic surgery. Moreover, HAp can be enriched with rare earth elements to bestow its luminescent properties. This makes HAp-based nanocarriers ideal candidates for incorporation into polymeric nanoparticles, which can be designed as nanospheres or nanocapsules, functioning as channels for precise drug delivery within biological systems.
In this study, we synthesized gadolinium-doped HAp nanofibers (HAp-Gd) using the Microwave-Assisted Hydrothermal Method to evaluate their suitability as drug carriers. After this, the HAp-Gd samples were characterized through X-ray diffraction. HAp-Gd was identified by comparing the results with the ICDD PDF files provided by Bruker. Morphological analysis and the determination of the elemental chemical composition of HAp-Gd nanofibers were performed through scanning electron microscopy (SEM) and energy-dispersive X-ray spectroscopy. Subsequently, luminescence analyses were executed to examine the interaction between the drug intended for transportation and the HAp-Gd nanostructures. This assessment was performed by analyzing the samples using photoluminescence spectroscopy. Then, we conducted an AlamarBlue Assay to assess the biosecurity and cytotoxicity of HAp-Gd in a culture model of chicken embryo fibroblasts. Results obtained from X-ray diffraction, scanning electron microscopy, and energy-dispersive X-ray spectroscopy collectively demonstrated the exceptional characteristics of the synthesized HAp nanofibers. These characteristics include a high level of crystallinity, purity, a hexagonal morphology, and a preferential crystalline orientation.
Furthermore, the chemical composition was uniform, indicating excellent integration of gadolinium into the HAp structure. Additionally, the biomaterial exhibited notable photoluminescent properties, suggesting its potential as a facilitator for drug transport within biological systems. Also, the results of the AlamarBlue assay indicate that the HAp-Gd does not exert a cytotoxic effect on fibroblasts.
In conclusion, the microwave-assisted Hydrothermal Method proved highly effective in synthesizing gadolinium-doped hydroxyapatite nanofibers with unique morphological and structural characteristics. We also demonstrate that this material is safe at the cellular level. These findings reinforce its potential application as a secure drug carrier in biological systems.

5:00 PM SB06.03.15
Modifying Bio-Ingredients within an Integrated Food Printer using an In-Situ Corona Discharge Non-Thermal-Plasma Approach: A Step Toward Creating Innovative Methods for Characterizing Engineered Food Materials and Biomedicine Kaiyu Vang[1], Derek Xiong[1], David Ryman[1], Edbertho Leal-Quiros[2], Saquib Ahmed[3,3] and Sankha Banerjee[1,4]; [1]California State University, Fresno, United States; [2]University of California, Merced, United States; [3]Buffalo State College, United States; [4]University of California, Davis, United States

The present research is focused on pioneering new in-situ non-thermal plasma treatment techniques for 3D printed bio-ingredients based on starch. Thanks to its natural abundance and cost-effectiveness, starch emerges as a highly pertinent raw material for substituting synthetic polymers in various applications. It enjoys a reputation for being non-toxic, biocompatible, and biodegradable, making it a secure choice for applications in the biomedical, food, and packaging sectors. Utilization of starch as a foundation for stabilizing, integrating, or releasing bioactive substances with applications as bioactive compounds incorporated within starch matrices in the pharmaceutical industry, with a particular emphasis on their use in orally disintegrating films. These methods aim to customize the attributes of the starch granule-surface proteins (SGSP). The study also involves assessing continuous and discontinuous gluten networks formed due to the interaction of SGSPs with quasi-static corona discharge plasma conditions. Additionally, the research investigates the bonding characteristics of starch-based bio-ingredients based on plasma current-voltage behavior. The surface of the cured starch-based samples will undergo profiling for characterization. The binding properties, gluten network formation, and porosity characteristics will be examined through electron microscopy for microstructural evaluation. Furthermore, advanced hybrid machine learning models will be developed in conjunction with analytical techniques and empirical datasets to create strategies for modifying both the surface and bulk properties of these materials.

5:00 PM SB06.03.16
An Open-Source Droplet Digital PCR (ddPCR) System for the Rapid and Accurate Detection of Bacteria from Environmental Water Samples Mason Brady, Ian M. Van Horn, Donald Ledvina, Albert Burkle, Paula Sanchez, Yiyan Li, Jerry Crawford, Micheal Grubb and Christie Chatterly; Fort Lewis College, United States

Droplet Digital PCR (ddPCR) is a method of rapid bacterial quantification in a liquid culture or solution. The development of an open source ddPCR system will allow this technology to become more affordable. The development of this open-source system utilized reused optical components, including a Photomultiplier Tube (PMT) from a flow cytometer, aligned using optical fittings. The signals received from the PMT were passed through a circuit containing passive bandpass filters and amplifier stages. FITC fluorescent microspheres were used to test the potential limits of the system's ability to quantify different concentrations of positive bacterial droplets in a sample. The system provided a large cluster of counts at 100% accuracy when particles were passed at a rate slower than 50 particles per minute. The functionality of the system was assessed by utilizing microfluidic droplets containing cultured E. coli samples. Different concentrations were used to test the system's accuracy through comparison. For each concentration the bacterial counts were within 10% of the expected values. To automate the quantification of signals from the system, a convolutional neural network is in development.

5:00 PM SB06.03.17
Potassium Hydroxide Etched Silicon Biomembrane Optimization and Characterization for Lung-on-a-Chip Applications Sahra G. Genc[1], Leif Gislason[1], Sally Thompson[1], Sarah M. Schreiner[2,3], Adrian Gestos[4], Virginia Ferguson[4] and Jeff Jessing[1]; [1]Fort Lewis College, United States; [2]STROBE

NSF, United States; [3]JILA, University of Colorado Boulder, United States; [4]University of Colorado Boulder, United States

Organ-on-a-chip technology is heavily studied as an alternative to animal and cell culture models. Most of these studies are primarily focusing on the biological aspects. There is a need to understand the mechanical and morphological properties and functionality of critical components of such devices. Our group is developing a Lung-on-a-Chip device based on a novel biomembrane formed from porous silicon (PSi) that mimics the interstitial space between the epithelial and endothelial cells in vivo, with a thickness of approximately 1 µm. The membranes are fabricated through a process of chemical thinning p-type silicon wafers and electrochemical anodization to create the porous structure. Previously published results from our group on membranes that did not undergo the chemical thinning characterized with nanoindentation and scanning election microscopy show a correlation between the porosity of the PSi samples with their reduced modulus and thickness. This current work focuses on the development and refinement of the technique used to etch ultrathin (less than ~5µm) silicon membranes using a potassium hydroxide (KOH) etchant. Further, we show the results of a small parametric study by varying the formation conditions during the KOH etch. The specific formation conditions that affect the resultant membrane surface quality are etchant temperature, inclusion of a surfactant, and post-etch quench “rinse”. The membranes mechanical and morphological traits are characterized using scanning electron microscopy, atomic force microscopy, and nanoindentation to discern the surface quality of the silicon biomembrane, considering parameters like roughness, defect density, and uniformity. These aspects are correlated to the different KOH process parameters to find the optimal approach, as well as its potential relationship with the membrane's morphological features. In general, the surface quality and membrane thickness uniformity improves with decreasing etch temperature, inclusion of propanol as a surfactant, and employing a multiple stage hot rinse following the KOH.

5:00 PM SB06.03.18
Bioprinting of photothermal responsive engineered biohybrid material for biomedical applications Prakriti Dhungana, Natalie Dando, Kyle Duke, Jonathan Caguiat and Byung-Wook Park; Youngstown State University, United States

Bioprinting has been shown to be an effective method for biomanufacturing biohybrid materials with designed structures and dimensions. Engineered biohybrid materials from micro- to macroscales can be constructed using a bioprinter for various biomedical applications. Stimuli-responsive biohybrid materials that respond to environmental conditions have attracted the attention to create material system that mimic the functions of living systems. Herein, we present a new biohybrid material system and method capable of bioprinting hydrogel bioinks with genetically engineered probiotic *Escherichia coli* Nissle 1917 (EcN) as photothermal responsive component. The engineered bacteria heat shock response (HSR) is triggered by the localized heating nanocomposite. We first discuss the design and optimization of the biotic and abiotic components encapsulated in a hydrogel bioprinted as engineered biohybrid material. We then demonstrate an expression of green fluorescent protein (GFP) upon near-infrared photo stimulus. Finally, the bioprinted engineered biohybrid material can survive for a period of at least 3 days in the M9 minimal medium. We anticipate the developed engineered biohybrid material system is further enabled by bioprinting of the photothermal responsive bacteria for biosensing and biomedical applications.

5:00 PM SB06.03.19
Detection of Bacteria Using Near-Infrared Raman Spectroscopy and Deep Learning Donald G. Ledvina, Sienna Mullin, Ian M. Van Horn, Mason Brady, Micheal Grubb, Jerry Crawford, Jeff Jessing and Yiyan Li; Fort Lewis College, United States

The process of identifying bacteria can often be challenging and time-consuming. Employing machine learning, Convolutional Neural Networks (CNNs), and Raman Spectroscopy, we strive to develop a rapid and effective solution to this problem. As a preliminary trial, we have designed a 4-layer CNN using TensorFlow, trained and evaluated on a recently published dataset comprising 30 different classes of bacteria isolates. Our CNN demonstrates enhanced accuracy in identification and reduced intricacy in comparison to other networks. Moving forward, we intend to utilize our in-house near-infrared Raman (785 nm) microscope spectrometer to gather our own bacterial spectra dataset. Bacteria samples will be cultured on agar plates and preserved until required. Subsequently, a small portion of the bacterial colonies will be spread onto a gold-coated slide for the spectrometer to analyze. This dataset will be employed for training the CNN, facilitating the development of a cost-effective, high-speed bacteria identification system.

5:00 PM SB06.03.20
Development of Artificial Joints Printed by 2-Photon-Laser-Printing and Actuated with pNIPAM Annabelle Sonn, Barbara Schamberger, Gaurav Dave, Chantal Barwig and Christine Selhuber-Unkel; Heidelberg University, Germany

Soft actuators are flexible components that can adapt to dynamic environments based on responsive materials like polymers, fluids, or hydrogels, to name a few. Hydrogels made of e.g., thermoresponsive poly-*N*-isopropylacrylamid (pNIPAM) are excellent candidates for soft robotic applications due to their ability to change in volume depending on the surrounding temperature. Below the lower critical solution temperature (LCST), which is 32 °C, pNIPAM is in its swollen, hydrated state, while it shrinks to the dehydrated state above the LCST. With 2-photon-laser-printing (2PP), which is making use of the absorption of two near-infrared (NIR) photons, it is possible to initiate highly precise polymerization of the hydrogel ink, in our case pNIPAM. This enables the generation of complex 3D structures on the microscale. Here, we show the design and printing of artificial joints with pNIPAM components in the micrometer range by two approaches: First, the structures are printed in two-steps consisting of a solid polymer base, surrounded by pNIPAM, which is mimicking muscle tissues. Second, a structure is printed entirely out of hydrogel resulting in a fully soft joint. After printing and mechanically analyzing the joints by nanoindentation measurements, the thermoresponsive actuation was evaluated by switching the ambient temperature between temperatures below and above the LCST of pNIPAM. In the future, the design of the soft joints may be improved to give more complex structures with sophisticated functionalities on the microscale.

5:00 PM SB06.03.21
3D Printing Conductive Hydrogels with Tunable Properties for Soft Robotics and Biosensing Trevor Kalkus, Tamara Unterreiner, Laura Wächter, Christina Schmitt and Christine Selhuber-Unkel; Heidelberg University, Germany

Soft electronics can serve a central role in the development of biosensors, wearable devices, and soft electronics. For these applications, flexible circuits with complex and organic geometries will be necessary. The 3D printing of conductive hydrogels offers a simple manufacturing method for creating such structures and provides opportunities for rapid iteration and modification. Because different applications may call for various hydrogel properties, we demonstrate the ability to tune ink viscosity, hydrogel stiffness, and hydrogel conductivity. These functional hydrogels are based on acrylamide, due its stability and ubiquity, and PEDOT:PSS, a commonly used conductive organic polymer, is embedded to provide conductivity. With thorough characterization, we highlight the advantages of designing conductive hydrogels in this way. Ultimately, we demonstrate the ability to print the components suitable for soft electronics. While this work provides a preliminary demonstration, future steps will focus on applying this method to create biosensors and soft robotics.

5:00 PM SB06.03.22
Electrochemical sensing of cytokines utilizing carbon nanotube fiber-based electrodes Megan N. Baker[1,2], Allison Yorita[2], Anna Ivanovskaya[2], Razi haque[2] and Samantha Santacruz[1]; [1]The University of Texas at Austin, United States; [2]Lawrence Livermore National Laboratory, United States

Aptamer based biosensors are a promising tool for further understanding mechanisms underlying various systems in the body at a molecular level. Aptamers allow for indirect electrochemical sensing of chemicals and biomolecules. As a specific target molecule binds to the aptamer, there is a conformation change. Scientists have taken advantage of this conformation change and designed aptamers that bring the charged free end closer to the surface of an electrode, sensing an electrochemical change in response to the chemical concentration. However, the binding of aptamers to the surface of metal electrodes has shown to be very fragile, making the lifespan of such biosensors limited. For *in vivo* and even future clinical applications, the devices need to be stable both in and out of solution for long periods of time. We propose using carbon nanotube fibers (CNTf) to improve the adhesion of aptamers to the surface of electrodes. CNTfs have great chemical stability, electrical properties, and high effective surface area making them ideal candidates for the substrate of the devices. The chemical bond between carbon and the aptamers is more stable than that with gold, a conventional biocompatible electrode material, allowing for a more stable device. To test this device design, we use aptamers that selectively bind to IL-6. The IL-6 aptamers are immobilized and attached to the CNTf using electrochemical conjugations. After successful attachment has been validated, the sensitivity of the device and limit of detection are evaluated and optimized. After optimization, the response time, lifetime, and biofouling response are analyzed. This is initially done in phosphate buffered saline (PBS) solution, but further testing in animal models is planned. The functionalized device can be used to decode immune status in blood using pro- and anti-inflammatory cytokines at physiologically relevant concentrations. This opens the door to being able to both monitor and intervene in the immune system using bioelectronic interfaces, with the CNTf sensor recording real-time immune system status and a future electrical interface with the nervous system modulating the immune system based on data from the sensor, a systems-level approach which has not been done before.

5:00 PM SB06.03.23
Continuous Whole Blood Dialysis Based on Regenerated Dialysate Utilizing TiO2 Nanowire Photo-Electrochemical Oxidation and Protective Forward Osmotic Membrane Guozheng Shao, Mingyuan Zhang, Hao Tang and Bruce Hinds; University of Washington, United States

While a traditional 4-hour dialysis treatment uses up to 120L of fresh dialysate per session, a full-scale bench-top system was developed to remove clinically relevant amounts of uremic toxins in whole blood using only 0.5L of commercial dialysate solution over a 24-hour continuous dialysis process. Urea was removed by photoelectrochemical method through a UV/TiO2 nanowires array device connected to a Forward Osmosis (FO) membrane in a protected close loop, while other non-urea toxins were removed by Activated Carbon (AC) in the dialysate loop. Here we demonstrate a daily urea removal rate of 14.2g using 0.4m^2 of hemodialyzer membrane and 2.3m^2 FO membrane with 0.18m^2 TiO2 nanowires array in Photoelectrochemical Oxidative Urea Removal (POUR) unit. Other non-urea toxins represented by creatinine and phenylacetic acid with a daily removal rate of nearly 7g were achieved by 70g of AC absorbent in the dialysate loop. Urea, creatinine and phenylacetic acid were constantly infused to the saline solution with the speed of 15g/24h, 5.6g/24h and 1.4g/24h to simulate actual human toxins level. Urea is continuously removed in a 0.15M NaCl saline solution by the photo-oxidation reaction occurring on TiO2 nanowire surface with the presence of UV source and applied bias to enhance the electron-hole pair separation within the single crystal TiO2 nanowire. The POUR loop was also protected from the potential oxidative species generated from the photooxidation of urea by inline AC absorbent with real-time ORP and pH sensors, showing non-cytotoxicity to the blood loop. The FO membrane is also a key component to prevent small solute molecules from dialysate entering the POUR loop to lower its efficiency as well as forming harmful oxidative byproducts. Our results also showed a wide variety of treatment modes (ie. 4, 8, 12 hr daily times) by coupling different membrane components. More importantly, by eliminating the need for the external water source, our system offers possibilities of a variety of portable kidney dialysis treatment options for home, work and travel.

5:00 PM SB06.03.24
Characterization of Single and Dual-Consortium Microbial Systems in 3D-printed Multi-Material Hydrogels LeAnn Le, Alshakim Nelson and Naroa Sadaba; University of Washington, United States

Engineered Living Materials (ELMs) capture the efficiency of cellular systems within polymeric matrices to provide bioreactor designs for production of commodities such as biofuels, vaccines, and the classic Seattle IPA. With extrusion-based 3D printing, we can print multi-material ELMs that afford controlled spatial organization of cell populations. With F127-bisurethane methacrylate (F127-BUM), an easily accessible triblock copolymer, we can synthesize bioinks with proper yield strain for extrusion-based printing while also gaining robust biocompatibility and free diffusion of metabolites across the material. We maintain a basic understanding of F127-BUM structure but have limited knowledge of how the network interacts with cells. While these hydrogel constructs display robust metabolic function, prior studies have shown cells escaping into the surrounding media despite complete encapsulation, suggesting random migration through the material. However, in studies that culture two microbial species in adjacent F127 gels, higher-order spatial organization is observed as cell populations consisting of one species do not migrate into gel areas occupied by another cell species. In our studies, we propose an alternative 3D-printed core-shell cube structure that consists of a cell-laden inner core surrounded by a cell-free outer shell. This construct affords a model to study cell behavior of single and dual-cell consortiums in F127-BUM hydrogels as we seek to improve cell containment and preserve metabolic function in 3D printed hydrogel designs for bioproduction.

Using the core-shell cube structure, we demonstrated robust multi-kingdom functionality with Green Fluorescence Protein (GFP)-secreting *E. coli* and betaxanthin-producing *S. cerevisiae*. After six days, the multi-material constructs showed continuous GFP and betaxanthin production and diffusion into the media**.** Optical fluorescence microscopy showed GFP E. coli distribution focused on the core-shell interface while S. cerevisiae distribution is uniform throughout the core. While visual spatial separation between the core and the shell elements was maintained, cell escape after 48 h was observed using SEM as a result of microscopic inconsistencies in the printing process and cross-contamination of the extrusion nozzles during printing. By altering flow speed and the print design g-code, we improved cell containment.

To investigate impact of form factor on microbial behavior, we proposed a rectangular prism design with improved surface area-to-volume ratio to investigate the impact of geometric parameters on bioproduction and diffusion. We saw improvement in the GFP-system but observed little difference in our betaxanthin system. Additionally, we tested the performance of both core-shell constructs in co-culture systems by placing gels containing one cell population into free media containing a different microbial species. With the gel system, viability was maintained in both cell species for 6 d.

Following the single consortia models, we expanded the core-shell design to contain a dual-microbial consortium. Inspired by symbiosis, this multi-kingdom hydrogel design contained a metabolically constitutive relationship consisting of engineered *E. coli* and *S. cerevisiae strains. S. cerevisiae* only produces betaxanthin in presence of L-DOPA.

During a six-day period, final betaxanthin production remained low as a result of the inner core consortia having limited access to oxygen as the outer shell consortia blocks nutrient access during overgrowth. As a result, we will adopt designs such as coaxial fibers or thinner dual-material biofilms to avoid limitations in oxygen and nutrient diffusion.

Overall, our investigation of multi-material F127-BUM hydrogels and their ability to afford a wide range of microbial systems and design possibilities establishes a necessary model to study the intricate relationship between hydrogel structure and cell behavior for bioproduction applications.

5:00 PM SB06.03.25
Spectrally-Resolved Ratiometric Multiphoton Fluorescence and Second Harmonic Imaging of Noninvasive Vascular Scaffolds Tolulope Ajuwon, Tochukwu Emeakaroha and Steve Smith; South Dakota School of Mines and Technology, United States

We present spectrally-resolved multi-photon induced fluorescence (MPIF) and second harmonic generation (SHG) imaging of porcine arterial wall tissue sections, both native tissues and damaged tissues subject to a proprietary therapy based on photo-activated crosslinking of collagen and other structural proteins in the arterial wall, a proposed treatment for peripheral artery disease termed non-invasive vascular scaffolding (NVS). We employ a spectrally-resolved multi-photon imaging system, based on a closed loop piezoelectric stage, a transmission grating and an EMCCD. From the spectrally-resolved multiphoton emission, we form ratiometric images of select spectral bands associated primarily with collagen (SHG) and elastin (MPIF). The ratiometric images aid in identifying representative regions for comparing the native and treated tissue sections, as well as reducing sensitivity to variations in intensity caused by scattering or attenuation of the excitation beam. Our aim is to use these ratios as a metric of the tissue structure and composition, indicating the relative contribution of collagen and elastin to the observed nonlinear signals. We note the photo-chemical modification results in a recovery of SHG intensity similar to the native artery, with the hypothesis that cross-linking of the compressed collagen fibrils in the arterial wall during the light activation step results in the formation of the NVS. We analyze the polarization anisotropy of the SHG from these tissues and evaluate the spectral dependence of control samples designed to calibrate the relative contributions elastin (MPIF) and collagen (SHG) to the observed spectra.

5:00 PM SB06.03.26
Tough, Non-Drying, and Tissue-Adhesive Glycerogel Dressing with Ferrocene Nanoparticles for Improved Wound Healing Ji Won Kang[1], Jin Han Cho[2] and Byoung Soo Kim[1]; [1]Korea Institute of Ceramic Engineering and Technology, Korea (the Republic of); [2]Korea University, Korea (the Republic of)

The benefits of employing moist wound dressings were firmly established in the late 1900s, driving notable progress in the evolution of modern wound care products, such as hydrogels and hydrocolloids. Notably, hydrogel-based dressings have demonstrated the ability to provide a soothing, cooling effect on the skin, making them a promising option for treating burns and painful wounds. Furthermore, studies have indicated that hydrogel-based dressings effectively minimize eschar formation, preserving tissue integrity and expediting the migration of epithelial cells. However, current hydrogel dressings lack adequate moisture balance and oxygen exchange that potentially leads to skin maceration, infections, and tissue damage by the constant changing of the material. Many hydrogel dressings available in the commercial market exhibit brittleness, necessitating the incorporation of a supplementary support layer, such as adhesive silicone, to reduce the water-vapor transmission rate. In this study, we designed tough, non-drying, and self-adhesive hydrogel dressing, synergistically integrated with stimulus-responsive drug nanoparticles for enhanced wound healing. First, we synthesize a tough hydrogel by optimizing the balance between physical and chemical cross-links by entanglements and covalent bonds. The achievement of non-drying and self-adhesive features can be attained by incorporating glycerol into the tough hydrogel matrix, leading to solvent exchange and partial contraction of the hydrogel matrix. The resulting tough hydrogel containing hygroscopic glycerol maintained its hydration state for 6 months in air. Additionally, they exhibited a substantial adhesion strength (183.73 kPa), attributed to the increased local concentration of hydroxyl groups. For enhance wound healing efficacy, we integrate the hydrogel matrix with stimulus-responsive ferrocene nanoparticles. We will discuss about clinical impact upon wound healing and antioxidation effect in moist wound care environment based on the resulting tough hydrogel dressing, infused with ferrocene nanoparticles.

5:00 PM SB06.03.27
Micro-vibrator integrated wet adhesive glycerogel patch for enhanced transdermal drug delivery system Seo Yoon Kim; Korea Institute of Ceramic Engineering and Technology, Korea (the Republic of)

Transdermal drug delivery system (TDDS) is a painless method of delivering drugs by applying patches directly onto skin. Among the evolving variations of TDDS, hydrogel patchis gaining prominence for its capacity to facilitate skin hydration and efficiently deliver pharmaceutical agents across the skin barrier. However, in order to facilitate commercialization, hydrogel-based patches need to effectively tackle three key challenges: (1) minimizing moisture evaporation, (2) enhancing adhesion in wet environments, and (3) precisely controlling the release dosage of the contained medicine. Here, we introduce a novel glycerogel matrix that exhibits wet-adhesive properties, does not dry out, and possesses high toughness. This matrix is first designed to facilitate prolonged skin contact and enhance the absorption of drugs. Next, the glycerogel matrix was combined with a micro-vibrator film in order to enhance medication penetration through the stimulation of skin microcirculation. The glycerogel matrix exhibits rapid adherence to various surfaces in a wet condition, with a time frame of less than 10 seconds. The strength of adhesion is influenced by the size and composition of the silica nanoparticles used for surface coating. We alsoconfirmed the vibrator-assisted drug release create a synergistic effect within the hydrogel, promoting efficient drug dispersion and enhancing skin penetration. This accelerates drug absorption and improves drug efficacy, resulting in faster drug release and shorter time to achieve therapeutic goals. We believe this synergistic integration of these components presents a novel paradigm in controlled drug release, allowing for precise modulation of therapeutic dosages.
Keywords? : Tough hydrogels, bioadhesives, transdermal drug delivery, micro-vibration film,active drug delivery

5:00 PM SB06.03.28
Biocompatible WSe_2 Nanosheet Antibiotics for The Therapy of Pathogenic Bacterial Infections Yoonhee So, Jun-Hyeong Lee, Jaewoo Lee, Sin Lee, Yejoo Yu, Yujin Choi and Jong-Ho Kim; Hanyang University, Korea (the Republic of)

Abuse of broad-spectrum antibiotics not only causes intestinal microbial imbalance but also emerges bacteria resistant to drugs. Therefore, it is an urgent task to develop narrow-spectrum antibiotics and new bactericidal mechanisms to overcome the limitations of broad-spectrum antibiotics. Herein, we present ultrathin WSe_2 and $MoSe_2$ nanosheets exfoliated and functionalized with poly(acrylic acid) (PAA-WSe_2 and PAA-$MoSe_2$) in an aqueous solution as a narrow-spectrum antibiotic or a species-specific agent, respectively, for treatment of bacterial infection diseases. PAA-WSe_2 nanosheets exhibited bactericidal activity only against gram-positive bacteria including multidrug-resistant *S. aureus*, whereas PAA-$MoSe_2$ showed selective bactericidal activity against *S. aureus* only. Moreover, PAA-WSe_2 accelerated the oxidation-reduction reaction mediated by lipoteichoic acid, a component of the cell membrane of gram-positive bacteria, producing Se^{4+} for antibacterial activity. Subsequently, the PAA-WSe_2 nanosheets induced depolarization and disruption of the bacteria-cytoplasmic membrane for the complete eradication of gram-positive bacteria. PAA-TMD nanosheets, including PAA-WSe_2 and PAA-$MoSe_2$, also exhibited outstanding biocompatibility against normal cells and hemocompatibility with red blood cells. Finally, PAA-WSe_2 nanosheets effectively eradicated *S. aureus* infecting the wounds of mice, showing excellent therapeutic effects *in vivo*. These results suggest that PAA-WSe_2 has been developed as a narrow-spectrum antibiotic used for various bacterial infections.

SESSION SB06.04: Living Materials I

8:00 AM SB06.04.01
Microbial encapsulation with polyethylene-glycol based hydrogel materials for protection against environmental stress factors Ryan Hansen, Niloufar Fattahi, Jeffrey Reed, Evan Heronemus, Priyasha Fernando and Prathap Parameswaran; Kansas State University, United States

Many emerging applications in microbial biotechnology require that microorganisms function under harsh or unfavorable environments. These environments may contain chemical toxins, reactive oxygen species, limited nutrients, extremes in pH and temperature, or exogenous microorganisms, among other stress factors. Microbial electrochemical cells (MxCs), which use electroactive biofilms of anode respiring bacteria (ARB) for current production, are often limited by loss of ARB electrochemical activity due to these stress factors. This inhibits the use of novel MxC systems in applications related to water treatment, sub-surface remediation, remote sensing, and self-powered bio-batteries. In this work, we report the use of polyethylene-glycol (PEG) based hydrogel materials for encapsulation, stabilization, and toxin protection of ARB biofilms in a MxC system.

Hydrogels were formed using PEG divinyl sulfone and PEG tetrathiol precursor molecules. These molecules couple together through based-catalyzed Michael addition reactions between thiol and vinyl sulfone end groups, generating highly crosslinked hydrogel networks with well-controlled, tunable mesh sizes. Precursor molecules were mixed together over anodic biofilms using an established dip coating procedure. The resulting hydrogels were resistant to acid or base hydrolysis over a range of pH values (pH = 3 to 10), appeared stable over ARB biofilms, and did not compromise biofilm viability over a 30-day trial period. The electrochemical activity of hydrogel-coated ARB biofilms was compared to uncoated ARB biofilms in a side-by-side manner, and it was found that the hydrogel coated anodes displayed higher current density under oligotrophic environments, higher current densities during exposure to high concentrations of ammonium toxin, and faster recovery after an ammonium shock. Hindered diffusion of ammonium ions through the hydrogel was identified as the cause for improved ARB performance during and after the ammonium shock.

These findings demonstrate the novel use of hydrogel materials to protect EAB from sharp chemical gradients that commonly occur during a chemical shock. Because hydrogel pore size can be modulated by controlling the molecular weights of the PEG precursor molecules, and catalytic functionality can be added to the hydrogel, these coatings can be further engineered to provide selective control of mass transport to functional microbes for their protection in a variety of applications. On-going work investigates enzymatic modification of these hydrogels to protect encapsulated bacterial cells from other chemical toxins for bioproduction and biomedicine applications.

8:15 AM *SB06.04.02
Living fabrications by the engineered bacteria Zhuojun Dai; Shenzhen Institute of Advanced Technology, Chinese Academy of Sciences, China

A key focus of synthetic biology is to utilize modular biological building blocks to assemble the cell-based circuits. Scientists have programmed the living organisms using these circuits to attain multiple delicate and well-defined functions. With the integration of tools or technologies from other disciplines, these rewired cells can achieve even more complex tasks. In this talk, we will present our recent work in versatile biomanufacturing of biologics and functional material fabrication by integrating the engineered cells and polymer physics and chemistry. By exploiting cell-material feedback, we are able to design a concise platform to achieve versatile production, analysis, and purification of diverse proteins and protein complexes, and also assembly of functional living materials. Our work demonstrates the use of the feedback between living cells and materials to engineer a modular and flexible platform with sophisticated yet well-defined programmed functions.

8:45 AM SB06.04.03
A deep insight into the mechanism of production of living conducting materials Marika Iencharelli[1], Giuseppina Tommasini[2], Vittorio De Felice[1], Natalia Dell'Aversano[1], Maria Antonietta Ferrara[1], Giuseppe Coppola[1], Francesca Di Maria[3], Mattia Zangoli[3], Maria Moros[2], Angela Tino[1] and Claudia Tortiglione[1]; [1]Istituto di Scienze Applicate e Sistemi Intelligenti "E. Caianiello", Consiglio Nazionale delle Ricerche, Italy; [2]Instituto de Nanociencia y Materiales de Aragón (INMA), Spain; [3]Istituto per la Sintesi Organica e Fotoreattività, Consiglio Nazionale delle Ricerche, Italy

Living cells are able fabricate complex structure starting from simple building blocks, offering new paradigms to create new hybrid materials by combing synthetic and living features. We have previously shown the capability of the living tissue-like organism, the freshwater polyp *Hydra vulgaris*, to produce fluorescent and conductive interface embedded into the animal tissues, starting from thiophene-based compounds, demonstrating the feasibility to use these organisms as biofactories of novel biocompatible and conformable bioelectronic interfaces [1-2]. Here we show that the potential of biofiber production is broadly valid in other biological systems, and showed that it can be promoted by several human and murine cell lines and by other invertebrate *in vivo* models (such as the sea anemone *Nematostella vectensis*). The cell type and organism developmental stage influences the fiber shape, amount and optical properties. In order to understand the mechanism underlaying the fiber biogenesis, on one side we performed a systematic chemical engineering approach to identify the structure/groups involved in the spontaneous fiber assembling. On the other, we performed several physical and chemical treatments to identify the cell machinery components involved in the biosynthetic process. Finally, by mean of advanced characterization methods and holographic imaging we shed light on the mechanism of biofiber production and the fine structure, paving the way to new bioengineering concepts to fabricate novel living conductive materials.

Selective Hydrogel Membranes For Modular SynBio Processing Units Claire Benstead, Maria Politi, David S. Bergsman and Lilo D. Pozzo; University of Washington, United States

Industrial microbiology has great potential in modernizing chemical manufacturing, particularly in the synthesis of high value products (HVPs) and precursors. To further mitigate issues within manufacturing regarding high energy consumption, environmental pollution, and slow response times to demand fluctuations, we can look to decentralized production and modular processing units. Hydrogels are 3D networks of crosslinked hydrophilic polymers that can retain large amounts of water without dissolution. Their rheological properties, cytocompatibility, and structural capabilities allow them a wide range of applications, including cell encapsulation, drug delivery, and membrane technologies. By encapsulating engineered microbes in hydrogel

membranes, we can create engineered living materials (ELMs) capable of on-demand activation, continuous bioproduction using simple raw materials like glucose, and membrane-based separations of the biomanufactured HVPs. We first investigate the application of poly(ethylene glycol) diacrylate/glycerol (PEGDA-Gly) hydrogels as semi-permeable membranes, including morphological characterization with high-throughput screening of Small Angle X-RAY Scattering (SAXS) and automated permeability testing. We further investigate the performance of these PEGDA-Gly membranes as ELMs by encapsulating betaxanthin-producing *S. cerevisiae* and assessing cell viability and productivity.

9:15 AM *SB06.04.05
Cellular Proliferation Driven Function in Engineered Living Materials Taylor H. Ware; Texas A&M University, United States

Engineered living materials derive functionality from the characteristics of living and non-living components. We will describe two unique functions, growth and cell delivery, driven by the proliferation of embedded microorganisms within covalently crosslinked hydrogels. Living yeast–hydrogel and bacteria-hydrogel composites are capable of undergoing programmed shape change, where volume can increase by >5x. As the cells have higher modulus (~100×) than the gel, cell proliferation results in a macroscopic shape change of the composite. This growth can be used to create stimuli-responsive materials or to manufacture components with >95% biomass. When the proliferating cells reach a boundary of the material, these cells are released to the surrounding environment. We will describe systematic relationships that govern cell release. For example, the elastic modulus of the hydrogel can be used to tune the rate of cell release over a range of four orders of magnitude. The use of these composites to deliver probiotic bacteria in a controlled fashion will be described.

Polymer-Coated Yeast Cells for Enhanced Biosynthesis of Medicine Rong Yang; Cornell University, United States

Metabolic engineering has made significant progress in producing complex and valuable medicinal products in microorganisms by reconstructing heterologous biosynthetic pathways. Such synthetic pathways often comprise a dozen or more sequential reactions. While the metabolic flux of the reaction intermediates could be optimized for improved productivity and/or efficiency, which holds enormous potential, there have been a limited number of reports on such efforts. That is partially due to a dearth of information on the trans-membrane transport mechanisms of the reaction intermediates. This talk will highlight the recent progress in the development of a new paradigm for the facile optimizing metabolic flux, thereby advancing the biosynthesis of medicines while reducing the optimizing cost. The paradigm is termed MetaLock, which involves creating a conformal ultrathin coating at the single-cell level to achieve perm-selectivity of nutrients and metabolites. We demonstrate that the coating does not inhibit the permeability of nutrients such as sugars and amino acids but creates a diffusion barrier for reaction intermediates to achieve high reaction rates and boost productivity. Through rational material design characterization and computational modeling, we systematically verify the effectiveness of this concept in regulating metabolic fluxes, first in a 6-step reconstructed reaction and then in an 11-step one, respectively. As such, MetaLock is a generalizable strategy that is applicable to improving the productivity of a variety of synthetic pathways. We seek to underscore the importance of understanding detailed microbe-material interactions and to provide an outlook on leveraging MetaLock to accelerate the development of engineered living materials.

10:30 AM SB06.04.07
Generation of Extracellular matrix protein-based Microcapsules by using Droplet-based Microfluidics Sadaf Pashapour[1,2], Christine Selhuber-Unkel[1,3,2], Joachim Spatz[1,3,4], Kerstin Göpfrich[4,2,5] and Michael Platten[6,2]; [1]Institute for Molecular Systems Engineering and Advanced Materials, Germany; [2]Microfluidic Core Facility, Germany; [3]Max Planck School Matter to Life, Germany; [4]Max Planck Institute for Medical Research, Germany; [5]Zentrum für molekulare Biologie Heidelberg, Germany; [6]University Medical Centre Mannheim, Medical Faculty Mannheim, Germany

Interactions of cells with the extracellular matrix (ECM) are involved in many cellular responses *in vivo*, and consequently activate multiple signaling pathways that initiate, drive and regulate nearly all motions of a cell. Therefore, cell-ECM interactions also underscore their central physiological roles, as well as their involvement in a wide variety of infectious diseases. Consequently, engineering 3D ECM niche systems for controlled observation and manipulation of bacteria *in vitro* has become an important strategy, particularly in medical applications. In this research, we have established a novel droplet-based microfluidic approach for the controlled assembly of ECM-based protein microcapsules loaded with *Escherichia coli (E.coli)*. Towards this end, water-in-oil emulsion droplets consisting of negatively charged block-copolymer surfactants are used as a template for the charge-mediated formation of a laminin- or laminin/collagen-based continuous layer on the inner droplet periphery. A double-inlet microfluidic flow-focusing device is implemented to encapsulate *E. coli*, proteins and divalent ions. The positively charged ions are attracted to the negatively charged block-copolymer surfactant layer at the inner periphery of the droplet wall. This in turn attracts the negatively charged proteins. After incubating the droplets at 37°C for at least 1h, the polymerized protein microcapsules are sequentially released into a physiological environment. Here, the droplets are covered with a layer of the release medium of choice and perfluoro-octanol is added dropwise from above. Perfluoro-octanol acts as a destablizing surfactant, which allows the fusion of the inside aqueous phase to the outer release medium, placed above the droplets. Incubating this solution for approximately 20min at room temperature releases the established protein microcapsules into the layer of release medium. Collecting the medium layer containing the microcapsules and seeding them on a glass coverslip allows for the analysis of bacterial behavior inside the capsules over longer time periods. We discovered two distinct behaviors of the same bacterial strain, depending on the type of protein used for generating the microcapsules. In the case of laminin-111 based microcapsules, bacteria colonies grow inside the microcapsules and simultaneously expand the microcapsule walls. The microcapsules can only withstand this growth up to a certain point, after that, the capsules break and release a great number of bacteria at once. This system can be taken to hand to e.g., conduct infection studies *in vivo*. By injecting the protein microcapsules at a point of interest, the encapsulated bacteria grow in confinement until the microcapsules burst and hence generate a local source of infection. In contrast to the outburst, E.coli incubated inside laminin-111/collagenIV-mixed microcapsules undergo filamentation. Here, the E.coli turn into long filamentous bacteria and start shedding small bacteria from the end of the filaments. This behavior is widely distributed in uropathogenic infections. This model can be used to conduct antibiotic studies on filamentous bacteria.
These are just two examples to show the purpose of this system. With our new method it is possible to generate different kind of protein microcapsules and further the content is also not limited. Exchanging the aqueous phase allows a wide variety of proteins, organisms and/or molecules being encapsulated inside water-in-oil droplets. Using microfluidics also allows us to tune the size of the microcapsules, which further increases the applicability of this system.

10:45 AM SB06.04.08
Active biointegrated living electronics for multi-dimensional inflammation management Jiuyun Shi and Bozhi Tian; The University of Chicago, United States

Life-like and seamless interfaces between electronic devices and biological tissues stand to revolutionize disease diagnosis and treatment. However, biological and biomechanical disparities between synthetic materials and living tissues present challenges at bioelectrical signal transduction interfaces. Here, we introduce the active biointegrated living electronics (ABLE) platform, encompassing capabilities across the biogenic, biomechanical, and

bioelectrical dimensions simultaneously. The living biointerface, comprising a bioelectronics layout and a *Staphylococcus epidermidis*-laden hydrogel composite, enables multi-modal signal transduction at the microbial-mammalian nexus. The extracellular components of the living hydrogels, prepared through thermal release of naturally occurring amylose polymer chains, are viscoelastic, capable of sustaining the bacteria with high viability, and facilitate freeze-storage of the ABLE device. Through electrophysiological recordings, and wireless probing of skin electrical impedance, body temperature, and humidity, ABLE monitors microbial-driven intervention in psoriasis (an intricate autoimmune skin disease) through the innate microbial activities. Comprehensive mechanistic studies show that *Staphylococcus epidermidis* from the living bioelectronics impedes activation of initiating dendritic cells and subsequent inflammatory phases of psoriasis pathogenesis. The ABLE platform offers a multifunctional and life-like biointerface solution for addressing intricate biomedical challenges, including autoimmune diseases and rehabilitation needs.

11:00 AM *SB06.04.09
3D Templating Biohybrids for Highly Efficient Growth of Decarbonizing Biocements Shu Yang; University of Pennsylvania, United States

Concrete is the second most consumed material in the world for the construction of various infrastructures. It also contributes 7-8% of total global carbon emissions due to the production of cement. Microbially induced carbonate precipitation (MICP) of calcium carbonate ($CaCO_3$), the main ingredient of concrete or biocement, catalyzed by urease offers a carbon neutral or carbon negative route to create environmentally friendly and CO2 capturing biocement. To enhance the efficiency of biological processes in MICP, while reducing material cost and operational cost, and increasing carbon capturing for biocement production, we exploit the use of 3D printed minimal surfaces coated with biocompatible gels as templates to immobilize *non-pathogenic* ureolytic bacteria genus *S. pasteurii*. We show that the amount of $CaCO_3$ crystals deposited on the 3D templates are an order of magnitude more than those deposited on an agar gel in a petri dish.

11:30 AM SB06.04.10
Biological nanofibres from electroactive microorganisms towards e-Biologics Jean V. Manca[1], Koen Wouters[1], Robin Bonné[1,2], Roland Valcke[1] and Bart Cleuren[1]; [1]University of Hasselt, Belgium; [2]Aarhus University, Denmark

In nature, biological 'nanofibers/nanowires' in electroactive microorganisms such as *Geobacter sulfurreducens*, *Shewenalla oneidensis* and the more recently discovered *Cable Bacteria* demonstrate remarkable electrical transport properties. These electroactive bacteria are receiving growing attention from diverse research fields, motivated by a fundamental interest in the underlying long-range transport mechanisms and in the potential future role in emerging domains such as bio-electronics, biodegradable electronics, and electronic biological materials (e-biologics). In the long-term these materials could open novel avenues for the growing problem of electronic waste in the upcoming era of ubiquitous electronics (cfr. the *Internet of Things*). Moreover, the emergence of biological electronic materials could play a role next to synthetic organic electronic materials in the diverse *"More than Moore"* technology platforms for future electronic applications, where new materials and heterogeneous integration technologies are indispensable for future breakthroughs and towards next generation sustainable electronics. The fundamental study of the electro-optical properties of biological nanofibers from Cable Bacteria and other electroactive microorganisms, and their behaviour in bio-hybrid electronic devices can therefore be situated in this broader technological context.

Cable Bacteria are filamentous microorganisms consisting of more than 10^4 cells, forming unbranched filaments of up to several centimeters long, characterized by a distinct morphology with parallel ridges along the length of the filament. They have developed a unique energy metabolism which requires charge transport over centimeter distances. Electrical measurements at X-LAB on 'dry' cable bacteria filaments out of their wet natural aquatic habitat provided the first direct evidence of intrinsic electrical conductivity through the use of electrical probe measurements, with nanofiber conductivity values over 10 S/cm and an exceptionally long electron transport distance in the order of 1 cm. While nanometer-scale electron transport is known to occur in prokaryotes, chloroplasts and mitochondria, and micrometer-scale electrical currents are measured in the nanowire appendages of bacteria and archaea, the centimeter-scale electron transport by cable bacteria extends the known length scale of biological transport by several orders of magnitude.

To disclose the underlying electrical transport mechanisms occurring in Cable Bacteria several techniques are being introduced. Impedance spectroscopy provides an equivalent electrical circuit model, which indicate that dry Cable Bacteria filaments function as resistive biological wires. Recently, proof-of-principle biohybrid demonstrators have been prepared to investigate the electrical signal transmission possibilities in a broad frequency range. Temperature-dependent electrical characterization reveals that the conductivity can be described with an Arrhenius-type relation over a broad temperature range (-195°C to +50°C) indicative for hopping transport. Furthermore, when cable bacterium filaments are utilized as the channel in a field effect transistor, they show n type transport with electron mobility values of ~ 0.1 cm^2/Vs at room temperature and display a similar Arrhenius temperature dependence as the earlier mentioned conductivity.
Overall, the obtained results so far demonstrate that the intrinsic electrical properties of the conductive fibres in Cable Bacteria are comparable to synthetic organic semiconductor materials, and so they offer promising perspectives for both fundamental studies of biological long-range electron transport as well as alternative organic electronic materials for the emerging field of bioelectronics, biohybrid electronics and for visionary technologies such as biodegradable electronics and other *"More than Moore"* technology platforms.

11:45 AM SB06.04.11
Spatially resolved charge transfer kinetics at the quantum dot-microbe interface using fluorescence lifetime imaging microscopy Mokshin Suri, Farshid Salimi Jazi, Jack C. Crowley, Youngchan Park, Bing Fu, Peng Chen, Warren R. Zipfel, Buz Barstow and Tobias Hanrath; Cornell University, United States

Microbe-semiconductor biohybrids formed by integrating complex microbial enzymatic machinery with programmable optoelectronic properties of semiconducting quantum dots (QDs) have introduced compelling prospects for future photosynthetic solar-to-chemical transformations. Bringing these prospects to fruition requires a firm foundational understanding of charge transfer mechanisms at the nano- bio interface. One challenge is that the transfer of photoexcited carriers from a QD to drive redox reactions in a proximate microbe involves a complex interplay of photochemical and physiochemical sub-processes, and the governing thermodynamic and kinetic factors are just beginning to emerge. The inherent heterogeneities of both the microbe and QD ensemble presents additional challenges challenge to establishing robust mechanistic understanding and to ultimately translate basic insights to design principles for advanced biohybrids. In this study, we leveraged advanced spectroscopic imaging tools (fluorescence lifetime imaging microscopy, FLIM) to interrogate charge transfer kinetics at the interface of a CdSe quantum dot (QD) film and *Shewanella oneidensis* microbes with sub-cellular spatial resolution. We focused on electron transport under fumarate-rich conditions and observed that both the intensity and lifetime of the QD's photoluminescence decrease at on-cell and inter-cell positions relative to the off-cell background. These trends provide a map of electron transfer rates (in the range of 10^8 to 10^9 s^{-1}) from QDs to the *S. oneidensis* cells for terminal reduction of fumarate. Our analysis of spatially resolved charge transfer rates reveals the role of cooperative effects in small groups of microbes, i.e., working together, small communities *S. oneidensis* exhibit faster charge transfer than isolated microbes. We attribute the cooperative effects to nanowire extrusions from *S. oneidensis* that facilitate charge uptake. Light driven electron transfer rates define the photo-chemical efficiency limits of photosynthetic semiconductor biohybrids, and this study provides important progress towards characterizing these electron transfer rates with enhanced spatial resolution.

SESSION SB06.05: Living Materials II
Session Chairs: Angela Tino and Claudia Tortiglione
Wednesday Afternoon, April 24, 2024
Room 427, Level 4, Summit

1:45 PM *SB06.05.01
Growth and Distribution of Microalgae in Photosynthetic Living Hydrogels Marie-Eve Aubin-Tam; Delft University of Technology, Netherlands

Engineered living materials are functional materials that encapsulate living components within a polymer matrix. Understanding the physical, chemical and biological factors affecting the spatial organization and growth of cellular populations within the matrix is key to predicting and improving the materials' functionality and responsive potential. We study the motility, growth, spatial distribution, and photosynthetic activity of eukaryotic microalga *Chlamydomonas reinhardtii* in a hydrogel matrix. 3D printing is used to control the shape of the biohybrid hydrogel material as a whole, while light exposure and access to carbon source controls the growth and location of the cells within the material. I will present a strategy to control cell growth for higher productivity of photosynthetic living materials that resembles the established adaptations found in multicellular plant leaves.

2:15 PM SB06.05.02
Green Algae-Based Microrobots for the Active *In Vivo* Delivery Zhengxing Li; University of California, San Diego, United States

Green algae-based microrobots display diverse advantageous features concerting consistent self-propulsion and their functionalization capabilities. The long-lasting swimming behavior of natural microalgae offers excellent motion behavior, which provides remarkable potential as the carrier for gastrointestinal (GI) tract delivery. When orally administered in vivo into mice, our green algae-based microrobots substantially improved GI distribution of the payload compared with traditional magnesium-based micromotors, which are limited by short propulsion lifetimes. Such appealing motion behavior and extended lifetime of green algae-based microrobots allow precise GI localization and enhanced cargo deliveries in GI tissue for practical biomedical applications. Taking one specific example, green algae-based microrobots can be equipped with macrophage membrane-coated nanoparticles to efficiently capture pro-inflammatory cytokines 'on-the-fly'. The dynamic green algae-based microrobots outperform static counterparts by enhancing cytokine removal through continuous movement, better distribution, and extended retention in the colon to ease inflammatory bowel disease free from side effects. The advantages are not restricted to GI applications, as green algae-based microrobots also excel upon treating the mouse model of acute pseudomonas aeruginosa pneumonia, where the algae microrobots effectively reduce bacterial burden and substantially lessen animal mortality, with negligible toxicity. Overall, these findings highlight the attractive functions of green algae-based microrobots for the active in vivo delivery.

2:30 PM BREAK

3:30 PM *SB06.05.04
Photosynthetic Bacteria-based Biohybrid Materials for Energy and Sensing Matteo Grattieri[1,2], Jefferson Franco[1], Pierluigi Lasala[1], Dario Lacalamita[1], Paolo Stufano[2], Rossella Labarile[2], Danilo Vona[1], M. Lucia Curri[1,2], Elisabetta Fanizza[1,2], Massimo Trotta[2] and Gianluca Maria Farinola[1]; [1]Università degli Studi di Bari Aldo Moro, Italy; [2]Consiglio Nazionale delle Ricerche, Italy

Photosynthetic bacteria can utilize sunlight, the most abundant energy resource on Earth, to sustain their metabolism by means of the photosynthetic process. Scientists and engineers have mimicked this fascinating process developing artificial systems that allow converting sunlight into electrical and/or chemical energy.[1] In recent years, the possibility to couple abundant and sustainable photosynthetic biological catalysts with electrodes has called particular interest to harvest solar energy without the need of platinum group metals or other critical raw materials.[2,3] However, bacterial cells did not evolve to exchange electrons with an external electron acceptor/donor, making the transfer of photoinduced electron to (and from) an electrode the most critical challenge to be overcome.[4]
The talk will focus on the approaches that we are currently investigating to tailor the bacteria/electrode interface, specifically by (i) developing polydopamine-purple bacteria-based redox-adhesive matrices;[5] (ii) modifying the cellular membrane of photosynthetic bacteria with inorganic nanoparticles; and (iii) developing bio-based electrode materials using polyhydroxybutyrate for enhanced bacteria colonization.
Application of the biohybrid materials obtained with these approaches for the development of sustainable biosensors and the production of energy carriers will be discussed, together with the challenges and outlook of this fascinating technology.

An n-Type Conjugated Oligoelectrolyte Mimics Transmembrane Electron Transport Proteins for Enhanced Microbial Electrosynthesis Glenn Quek[1], Guillermo C. Bazan[1], Ricardo J. Vázquez[2], Samantha R. Mccuskey[1] and Fernando L. Garcia[1]; [1]National University of Singapore, Singapore; [2]Indiana University Bloomington, United States

Interfacing bacteria as biocatalysts with an electrode provides the basis for emerging bioelectrochemical systems that enable sustainable energy interconversion between electrical and chemical energy. Electron transfer rates at the abiotic-biotic interface are, however, often limited by poor electrical contacts and the intrinsically insulating cell membranes. Herein, we report the first example of an n-type redox-active conjugated oligoelectrolyte, namely **COE-NDI**, which spontaneously intercalates into cell membranes and mimics the function of endogenous transmembrane electron transport proteins. The incorporation of **COE-NDI** into *Shewanella oneidensis* MR-1 cells amplifies current uptake from the electrode by 4-fold, resulting in the enhanced bio-

electroreduction of fumarate to succinate. Moreover, **COE-NDI** can serve as a "protein prosthetic" to rescue current uptake in non-electrogenic knockout mutants.

4:15 PM SB06.05.06
Bacteriophage-based self-propelled catalytic biohybrid nanomotor Xi Ding, Marina Achterman and Elaine D. Haberer; University of California, Riverside, United States

Self-propelled biohybrid materials have potential applications in fields from drug delivery to environmental remediation. Microorganisms, such as bacteriophage, provide unparalleled targeting and assembly. Their structure and surface, including exact shape and site-specific functional groups, are genetically encoded and known with atomic scale precision. Synthetic inorganic nanoparticles facilitate superdiffusive motion. Their interactions with chemical fuels or physical fields convert energy into locomotion. Of specific interest, here, are viruses with asymmetric capsid proteins, like the M13 bacteriophage, that can serve as programmable low-symmetry templates for autonomous biohybrid materials. The M13 is a high aspect ratio, 880 nm long and 6.5 nm diameter filamentous virus. It contains approximately 2700 copies of p8 major coat protein along its length and 5 copies of p3 minor coat protein at the proximal end of the filament. Each of these proteins can be modified to promote motor form and function. In this work, the asymmetric structure and functionality of the M13 bacteriophage capsid was used to create nanoswimmers. A cysteine-rich peptide fusion was inserted into the minor coat protein (p3) at the virus tip and Pt nanoparticles were attached via metal-thiol bonding. The viral-based Janus particles were fluorescently tagged and exposed to low concentrations of H_2O_2 to fuel self-propulsion. Using confocal fluorescence microscopy, nanomotor trajectory and motion were evaluated.

4:30 PM *SB06.05.07
In situ control of cells and multicellular structures by two-photon lithography Christine Selhuber-Unkel; Heidelberg University, Germany

In vivo, the tissue environment often provides strong confinement to cells and multicellular assemblies, particularly in cancer. Therefore it is highly important to mimic such confined environments, in order to investigate the impact of confinement on cellular systems. Here, we employed two-photon lithography, which allows to print directly into and next to multicellular assemblies. For example, we printed dome-shaped confinements with micrometer-sized openings to confine cancer spheroids in order to investigate the migration behavior of the cancer cells and also to study the effects of confinement on the spheroid. We have shown that confinement of the spheroids leads to a decreased cell migration speed and affects actin alignment and dynamics. Furthermore, in situ two-photon lithography provides a novel way of analyzing the behavior of specific regions of multicellular structures, by enabling the separation of multicellular structures from a spheroid. This is possible, as the laser used for printing can reach into the almost transparent multicellular structure and the used material is biocompatible. Hence, two-photon lithography is suitable for controlling the growth, migration and morphological cues of live cells, which is highly relevant to study the impact of the physical microenvironment on biosystems.

SESSION SB06.06: Plants—Environment
Session Chairs: Pengju Li and Eleni Stavrinidou
Thursday Morning, April 25, 2024
Room 427, Level 4, Summit

8:45 AM SB06.06.02
The Multifunctional Use of an Aqueous Battery for a High-Capacity Jellyfish Robot Xu Liu, Shuo Jin, Yiqi Shao, Autumn Pratt, Duhan Zhang, Jacqueline Lo, Yong Joo, Lynden Archer and Robert Shepherd; Cornell Unversity, United States

The batteries that power Untethered Underwater Vehicles (UUVs) serve a single purpose—to provide energy to electronics and motors; the more energy required, the bigger the robot must be to accommodate space for more batteries. This size dependency is further exacerbated by the high gravimetric density of batteries, requiring bigger hulls to displace water the equivalent weight of the batteries. With the increased size, comes increased moments of inertia, reducing maneuverability. By choosing batteries that are primarily liquid (i.e. Redox Flow Batteries, RFBs), the increased weight can be distributed for improved capacity with reduced inertial moment; and, when also being used as hydraulic fluid, reduce the overall weight of the AUV. In this paper, we formed an RFB into the shape of a jellyfish, using two redox chemistries and architectures: (i) a secondary $ZnBr_2$ battery with high power density, and (ii) a hybrid primary/secondary ZnI_2 battery with high capacity. Our choice of a Jellyfish shape demonstrates a low inertial moment architecture, a hemisphere, facilitated by the easy shaping of fluid batteries. In our robot, the RFB electrolyte also provides hydraulic force transmission to control the shape of the jellyfish's bell, causing it to sink or swim. Finally, our choice of catholyte to fill the bell allows us to quickly recharge the battery by emptying the fluid and replacing it with pre-charged electrolyte (analogous to a gas station).

9:00 AM SB06.06.03
Communication with Plants Using Wearable Electrophysiology Sensors Yifei Luo[1], Yi Jing Wong[1,2], Wenlong Li[1], Xian Jun Loh[1] and Xiaodong Chen[2]; [1]Agency for Science, Technology and Research, Singapore; [2]Nanyang Technological University, Singapore

Different parts and organs of a plant communicate using various forms of signals to optimize resource allocation and coordinate systemic responses to environmental stimuli for survival and growth. Investigating these communication processes is important to understanding plants' perception of environments and well-being as well as engineering approaches to improve plant health or induce desired behaviors. We aim to achieve this through electrophysiology, the study of electrical signals in plants, due to the simplicity of sensor design and rich biological insights buried in the signals.
In this talk, I will share my work on developing plant-interfacing materials for high-fidelity signal acquisition from plants having complex surface topography (e.g., hairy, rough, superhydrophobic), as well as achieving long-term stability during plant growth. The conformal adhesive attachment of the devices on plants makes them resistant to motion artifacts, and the noninvasive wearable form factor promises the potential for real-world deployment in farms and gardens.
I will discuss possible applications of this technology in plant health monitoring, environment optimization, crop breeding, and robotic control, by giving examples. Electrophysiology sensors, together with other modes of plant wearable sensors, will play a role in the sustainable development of human society.

9:15 AM *SB06.06.04
Engineering Nanotechnology for Precision Sensing and Targeted Delivery in Living Plants Tedrick Thomas Salim Lew; National University of Singapore, Singapore

Plant engineering plays a pivotal role in enhancing the productivity and resilience of future agricultural practices. Nevertheless, current efforts in plant engineering are hampered by the lack of universal and efficient techniques that can be applied across various plant species. In this talk, I will present the development of nanoparticle-mediated biomolecule delivery and analytical tools which can be interfaced with living plants of different species to enable diverse plant biotechnology and agricultural applications. First, I will describe the engineering of nanomaterials as optical nanosensors to monitor plant defense signaling pathways elicited by environmental stresses. By embedding nanosensors within plant tissues, the plant internal state can be accessed with portable electronics in a non-destructive and species-independent manner – a combination of features currently unattainable with existing analytical approaches. The optical sensing strategy is versatile and can be expanded for selective detection of abiotic and biotic stressors. Additionally, I will also present recent efforts in our group developing functionalized nanomaterials for targeted delivery to specific plant organs. These advances highlight the potential of nanomaterial-enabled platforms to engineer high-yielding and climate-resilient agriculture for our food security.

Real-Time Monitoring of Iron Uptake and Transport in Plants with Optical Nanosensor Thinh D. Khong[1], Javier Jingheng Tan[2,1], Raju Cheerlavancha[1], Benedetto Marelli[3,1], Urano Daisuke[2,1] and Michael Strano[3,1]; [1]Singapore-MIT Alliance for Research and Technology, Singapore; [2]Temasek Life Sciences Laboratory, Singapore; [3]Massachusetts Institute of Technology, United States

Iron deficiency is a major global health concern, and dietary iron from plant consumption is a primary source for most people worldwide. However, the iron content in plants is heavily affected by various environmental and agronomic factors, including climate change such as rising temperature, water scarcity, and elevated atmospheric CO_2 level. Therefire, it is a pressing need to develop effective strategies to combat iron deficiency and ensure food security for the global population. Conventional analytical techniques to investigate the efficacy of foliar iron fertilization are not optimally suited to observe the nuances of foliar absorption, translocation, and iron speciation. This lack of information hampers the optimization of fertilization strategies and the development of more effective nutrient formulations.

In this work, we introduce a highly sensitive fluorescence iron nanosensor for elucidating the biochemistry of iron in plants, thereby enabling the formulation of precise fertilization strategies. This nanosensor can be easily incorporated into living plant species to monitor real-time iron uptake via both foliar and soil-based fertilizations. Our sensor, fabricated by conjugating a synthetic conjugated polymer onto single-walled carbon nanotubes, is designed to exhibit a unique orthogonal optical response that enables differentiation between Fe(II) and Fe(III).

Using hydroponically grown lettuce as a model for iron foliar application study, our sensor provides the means to monitor iron uptake, metabolism, and transport with high spatial and temporal resolution in the leaf tissues in real time. Our findings demonstrate that the plant's mechanistic responses to the source of iron species depend on the chelation state rather than the oxidation state. Under conditions of iron deficiency or simulated abiotic stress, such as drought or salt stress, the diffusion and transport rate of iron species are also affected. We also observe a shared mechanistic response to chelated iron species across various plant species, hinting at the existence of conserved foliar iron homeostatic mechanisms.

With its ability to offer detailed insights into the dynamics of iron uptake and transport in real-time, we believe this sensor technology has the potential to revolutionize the study of iron uptake and distribution in plants. This advancement can lead to improved plant growth and yield through the development of more precise and efficient micronutrient management strategies.

10:30 AM SB06.06.06
Microfluidic Microbial Fuel Cell Based Biosensors for Copper Ion and Formaldehyde in Water Monitoring Hao Ren; ShanghaiTech University, China

In this abstract, we present microfluidic microbial fuel cell (MFC) biosensors, which are based on biohybrid materials of microorganisms living on electrodes, for monitoring toxic chemical in water. We have built microfluidic MFCs with anode and cathode chambers of 100μL. Start-up process of the microfluidic MFC biosensors takes 3-5 days and we utilize the MFCs for copper ion and formaldehyde in water monitoring. It is found that for copper ion in water monitoring characterization, a linear relationship between the output current and the copper ion concentration is observed, while the MFC biosensor can recover after the initial current drop caused by the copper ion in water. However, when the MFC biosensor is exposed to formaldehyde in water, a sigmoid relationship is observed and the MFC biosensor cannot recover after formaldehyde causes the current to drop. The experimental results may further the development of microfluidic MFCs for toxic chemical in water monitoring.
Water pollution is a global health threat affecting 2 billion people, causing significant health issues. Traditional non-real-time methods such as atomic spectrometry are time-consuming and expensive. Therefore, many studies have been performed to monitor toxic substances in water with MFCs due to their real-time measurement and low cost. However, the state-of-the-art MFC biosensors are non-reusable and take at least 3 minutes. Therefore, a real-time MFC biosensor for toxic chemical in water monitoring is needed.
The microfluidic MEMS MFC biosensor is composed of anode, cathode and proton exchange membrane (PEM) with a chamber volume of 100 μL. The anode/cathode are 100nm-thick Pt thin films deposited by magnetic sputtering. The start-up process of the MFC biosensor takes approximately 3-5 days and the polarization curve confirms its normal operation. Firstly, we measure the response of the MFC biosensors to copper ion in water. The MFC biosensors are exposed to 0.2-1.6mg/L copper ion respectively. The current is first inhibited and then recovers, demonstrating the reusability of the MFC biosensor for copper ion in water monitoring. The biosensor linearity characterization demonstrates a strong linear correlation between the current inhibition percentage and copper ion concentration with an R^2 of 0.997. The accuracy of the biosensor is calculated as 3.54% by testing a concentration of 1.3 mg/L, which is the EPA standard for the maximum allowable copper ion concentration in water. The average measurement time for the MFC biosensor is only 48 seconds. Afterwards, we measure the response the MFC biosensor to formaldehyde. When the MFC biosensor is exposed to a large formaldehyde concentration range from a low concentration of $1x10^{-3}$ mg/L to a high concentration of 3 mg/L in water, a sigmoid dose–response relationship of normalized current inhibition percentage versus formaldehyde concentration in water is observed, in agreement with traditional toxicology dose–response curve obtained by other measurement techniques. In addition, the current cannot recover after the inhibition due to the toxicity of the formaldehyde. We believe the different response of the MFC biosensors to copper ion and formaldehyde in water can help to improve the specificity of the MFC biosensors for toxic chemical in water monitoring.

SESSION SB06.07: Bioinspired—Biomimetics
Session Chairs: Pengju Li and Eleni Stavrinidou

EcoRobotics: bioinspired and biohybrid soft robots for environmental monitoring and preservation Barbara Mazzolai, Fabian Meder and Emanuela Del Dottore; Istituto Italiano di Tecnologia, Italy

Meeting the global challenges of climate change represents one of the most important frontiers for science and sustainable technologies. With this ambition, our research activity envisions environmentally responsible, bioinspired systems that can grow, adapt, and are built with recyclable, or biodegradable, or biohybrid materials. We refer to them as 'ecorobots'. These ecorobots are designed to imitate the adaptability of living organisms, allowing them to navigate and function effectively in complex and unpredictable environments. They are also designed to seamlessly integrate into natural ecosystems.
We primarily draw inspiration from soft invertebrates, such as cephalopods and earthworms, as well as plants, as they exhibit remarkable adaptive capabilities with smart, effective, and efficient strategies. Specifically, when studying plants, we can develop innovative ecorobots featuring structural-functional materials, distributed sensing and intelligence systems, and biohybrid energy-harvesting mechanisms. Much like their natural counterparts, these machines are envisioned to possess the ability to biodegrade at the end of their lifecycle, promoting sustainability.
In this presentation, I will outline our approach to designing and developing ecorobots inspired by the characteristics of plants. Our primary objectives are twofold: first, to identify and extract the fundamental principles that underlie the biological functions of plants and translate them into technological solutions; and second, to advance our scientific understanding of the biological systems we draw inspiration from.
Our examples will include the following ecorobots: the Plantoid robot, the pioneering plant-root-inspired robot, equipped with artificial growing roots, distributed sensors, actuation mechanisms, and intelligence systems, designed for soil exploration and monitoring; the GrowBots, machines inspired by climbing plants that move by growing, tailored for various exploration tasks; the I-Seed robots, soft, biodegradable miniaturized robots inspired by the morphology and dispersion abilities of plant seeds, serving purposes in environmental monitoring, plant monitoring and drug delivery systems featuring natural plant hooks; biohybrid energy harvesting systems; as well as solutions inspired by plant communication and emerging collective behaviors, paving the way for a new paradigm of robot networks and embodied AI.
Our ecorobots have been designed for a wide range of applications, including exploration and monitoring of natural environments and infrastructures, archaeological research, space missions, and search-and-rescue operations. Beyond introducing innovative technologies, we also aspire to engage in "reverse biology" by using bioinspired robots as experimental tools for investigating biological behaviors.

11:15 AM SB06.07.02
Time-controlled nanoscale delivery system Jihyeon Park, Seoyeah Oh and Jiwon Kim; Yonsei University, Korea (the Republic of)

Molecular communication (MC), a bio-inspired technology, is emerging as an alternative way of communication by overcoming the limitations of conventional electromagnetic waves. As the demand for practical implementation of MC grows, physical components of MC (*e.g.*, transmitter and receiver) have been fabricated through the integration of nano-/micro-technology. However, challenges such as slow speed of information molecule (IM) transmission, dispersion of IMs into the surrounding medium, and interference between sequentially transmitted IMs persist in employing the transmitters. Furthermore, sequential delivery of multiple IMs with an adjustment of their time intervals to enhance the communication efficiency remains as a significant challenge. Herein, we report a time-controlled delivery system that utilizes nanomotors as transmitters achieving precise multi-cargo delivery with desired time intervals. Nanomotors consisted of multi-metal nanorod (*i.e.*, nickel head, gold bridge, silver flexible filament, and gold tail) are encapsulated with poly (N-isopropylacrylamide) (pNIPAm) based hydrogel, and nanomotors with various dimensions transport multi-cargo as IMs (*e.g.*, Indigo carmine and Carminic acid) at different speeds under the same magnetic field. Consequently, nanomotors release IMs on-demand at desired locations upon near-infrared (NIR) irradiation, leading to IM delivery with high spatiotemporal density. Continuous linear sweep voltammetry (LSV) confirmed the sequential delivery of multiple IMs with time intervals of several minutes, indicating that nanomotors can transport IMs at higher transmission rate compared to diffusion-based methods. Furthermore, IM delivery using nanomotors exhibited higher signal intensity and reduced intersymbol interference (ISI), which enables a continuous signal transmission with a lower error rate in communication. We believe our time-controlled multi-cargo delivery via nanomotors can serve as transmitters paving a way to realize practical MC systems, such as disease detection and monitoring. This will allow us to understand communications in biological/biomimetic systems or unexplored environments.

11:30 AM SB06.07.03
Computational Design of Solid-Binding Peptides for the Biohybrid Diagnostic Electronic Nose Oliver Nakano-Baker, Richard V. Lee, Shalabh Shukla and John D. MacKenzie; University of Washington, United States

Trained dogs can detect COVID-19 or cancer from the odor of exhaled breath. Could your phone do the same? Diseases create a distinct shift in the volatile compounds (VOCs) in human breath - a compact breathalyzer capable of detecting this "VOC fingerprint" of disease could provide rapid diagnoses for a wide range of conditions. We recently demonstrated a biohybrid sensor platform for targeted gas detection, combining carbon nanotube transistors with surface-binding peptide molecules derived from olfactory proteins. Here, we present a pipeline strategy for combining multiple biomimetic sensors into engineered multiplexes, eNoses capable of performing diagnostic tasks. Molecular machine learning and dynamics are used to predict and optimize the binding affinity of peptides to targeted disease-relevant VOCs. Then, computer simulations are used to evolve sets of peptides, bootstrapping the multiplex design towards peptide makeup that can classify VOC fingerprints efficiently. Finally, rapid experimentation with simulated breath validates and feeds back binding profiles to the computational pipeline, improving the toolset. The peptide-sensitized multiplex sensors created by this process could be the key to unlocking mobile breathomics - phone-sized breathalyzers capable of detecting viral and bacterial infections, blood glucose levels, early-stage cancers, and more from the chemical signatures in exhaled breath.

11:45 AM SB06.07.04
PEDOT:PSS Fiber-Based Highly Sensitive Strain Gauge Force Sensor for Biohybrid Robots Xinran Xie, Abhijith Surendran, Ruiheng Wu and Jonathan Rivnay; Northwestern University, United States

Integrating biological components of contractile living muscle tissues with careful microstructure design, biohybrid robots have realized various biomimetic behaviors and functions such as swimming, walking, and object manipulation. However, the inherent vulnerability to the stimulation and increased dexterity of biohybrid robots require perception of their function and surroundings for tissue protection and accurate control. Currently, most biohybrid robots are stimulated to output large forces without considering their health status, causing short lifetime and decreased performance. Therefore, biohybrid robots need to be equipped with sensors that can monitor muscle force and length similar to the Golgi tendon and muscle spindle in humans. The feedback signals would help with tuning stimulation parameters to better protect tissues from damage while generating stable and controllable force. This can be realized by incorporating a strain gauge force sensor within the muscle tissue to provide real-time strain and force information.

Poly(3,4-ethylenedioxythiophene):poly(styrene sulfonate) (PEDOT:PSS) is one of the most widely utilized conducting polymers with diverse applications

in bioelectronics, owing to its favorable electrical and mechanical properties, biocompatibility, stability, and commercial availability. By wet spinning of PEDOT:PSS into sulfuric acid bath, we successfully made fibers with diameters ranging 50-100 µm. These fibers remain elastic within 0-0.5% strain range, which is suitable for in vitro muscle strain monitoring. These fibers work like a resistive strain gauge and achieve a gauge factor of ~150 in the elastic range. The high gauge factor indicates a highly sensitive strain gauge from a single PEDOT:PSS fiber. We are able to incorporate the fiber-based strain gauge into a standard two-pillar muscle culture polydimethylsiloxane (PDMS) platform and calibrate it with a force transducer to generate the strain-force relationship. The PDMS platform can then be used to culture skeletal muscle tissues and measure the muscle strain and force production in real-time. This research sheds light on the perception and control of biohybrid robots.

SESSION SB06.08: Cells—Organoids Interface
Session Chairs: Maria Rosa Antognazza and Claudia Tortiglione

Room 427, Level 4, Summit

1:30 PM *SB06.08.01
Hybrid bioelectronic tissues: interfaces for monitoring and modulating function Brian Timko; Tufts University, United States

Hybrid bioelectronic systems offer a unique route toward two-way electronic communication with living cells and tissues. Recent advances in bioelectronics and bioactive materials have enabled multiplexed, stable and seamless interfaces with surrounding cells and tissues, representing a distinct advantage over conventional systems such as patch clamp and optical dyes.

We recently developed a multi-electrode array (MEA) platform that could integrate with cardiac monolayers at up to 32 spatially-distinct locations in vitro. In the first part of this talk we will discuss our recent heart-on-a-chip platform which integrated both extra- and intracellular recording elements for monitoring cardiac electrophysiology during episodes of acute hypoxia. This system allowed us to monitor not only cell-cell communication (e.g., wavefront propagation) but also action potentials (APs) at several spatially-distinct regions simultaneously. Our platform provided a unique route toward understanding the role of hypoxia on ion channel dynamics. For example, we found that APs narrowed during hypoxia, consistent with proposed mechanisms by which oxygen deficits activate ATP-dependent K^+ channels that promote membrane repolarization.

In the second part of this talk we discuss an integrated optogenetic and bioelectronic platform for stable and long-term modulation and monitoring of cardiomyocyte function. Optogenetic inputs were achieved through expression of a photoactivatable adenylyl cyclase (bPAC), that when exposed to blue light caused a dose-dependent and time-limited increase in intracellular cyclic AMP concentration and, subsequently, autonomous cardiomyocyte beat rate. Bioelectronic outputs from the MEA provided real-time readouts of cardiomyocyte behavior in response to optical modulation. Irradiation at 24 $\mu W/mm^2$ resulted in a ca. 17% increase in beat rate within 20-25 minutes of irradiation. Multiplexed readouts revealed that wavefront propagation rates throughout the monolayer remained constant between “on” and “off” states, demonstrating that optical modulation did not affect intercellular coupling. In addition, bPAC activation could be cycled through repeated “on” and “off” states via time-limited illumination or in a gradient fashion with 0.03-24 $\mu W/mm^2$ illumination. Cardiomyocytes could be modulated reproducibly over at least four days, demonstrating that bPAC expression as well as the bioelectronic interface were stable throughout that period.

Taken together, our studies demonstrate the feasibility of bioelectronic and optical techniques for monitoring and modulating cardiac function. We will discuss recent efforts in our lab toward 3D bioelectronics-embedded tissues and closed-loop feedback systems. We will also discuss potential clinical applications for cardiac regulation including arrythmia diagnosis and intervention.

2:00 PM SB06.08.02
Exploring 3D printed GelMA/hydroxyapatite scaffold from design to biological evaluation for bone tissue engineering Fabiola Hernández Rosas[1], Ana Paola Salgado Álvarez[1], José R. Alanis Gómez[1], Manuel Jaime Rodríguez[2] and Ximena Mejia Delgadillo[1]; [1]Universidad Anahuac Querétaro, Mexico; [2]Tecnológico de Monterrey, Mexico

Bone repair is a widely explored field in tissue engineering due to its significant impact on the human body's structural integrity. Biomaterials based on calcium phosphate, such as hydroxyapatite (HAp), have shown promise because of their ability to emulate the mineral composition and porous structure of bone. Additionally, the utilization of additive manufacturing has provided opportunities to create cellular scaffolds for bone grafts, allowing us to control properties like porosity, pore size, structural form, and mechanical characteristics. These designs are crafted using Computer-Aided Design (CAD) software. The primary objective of this project is to design, fabricate, characterize, and assess the bioactivity of 3D HAp scaffolds for tissue engineering applications. To achieve this, hydroxyapatite was initially synthesized using the microwave-assisted hydrothermal method. Consequently, HAp nanofibers acquired a hexagonal structure, enhancing their mechanical properties. Subsequently, the HAp nanofibers underwent characterization through X-ray diffraction (XRD) and Scanning Electron Microscopy (SEM) to determine dimensions, morphology, topology, orientation, and crystalline structure. In addition, various 3D bone scaffolds with interconnected pores, facilitating permeability similar to trabecular bone morphology, were designed using Rhinoceros 3D CAD software with the Grasshopper extension. These scaffolds were produced using a 3D bioprinter with methacryloyl (GelMA) and laminin as bioink. Gelatin methacryloyl (GelMA) hybrid hydrogel with hydroxyapatite has shown its ability to promote osteogenesis and enhance osseointegration, as supported by both in vitro and in vivo studies. In this research, 3D Voronoi bioprinted scaffolds with GelMA/HAp were designed and manufactured for in vitro biological evaluation using mesenchymal stem cells. Mesenchymal Stem Cells obtained through primary culture of pig bone marrow were cultured in DMEM medium with 10% inactivated fetal bovine serum at 37°C/5% CO_2. The study included two groups: one with the GelMA/HAp scaffold and another with a control group containing only GelMA hydrogel without hydroxyapatite. The scaffolds were maintained for 21 days under these conditions. Then, Alizarin red staining was done to reveal the osteogenic differentiation of Mesenchymal Stem Cells. Subsequently, RNA was extracted from the cell suspension, and osteogenesis was evaluated through RT-qPCR with markers BMP-2, OCN, COL1A1, and OPN. The mean cycle threshold (Ct) value for each target gene was normalized against the Ct value of a housekeeping gene to determine relative expression. To calculate the fold change, the DDCt method was applied, comparing mRNA expressions between the treated groups (with GelMA/HAp) and the negative group (cells cultured in complete culture medium only). Based on robust scientific evidence, this biomaterial is expected to demonstrate its bioactive functions without harming the cells, as intended.

2:15 PM SB06.08.03
Incorporation of Gentamicin-Encapsulated Poly (lactic-co-glycolic acid) Nanoparticles into Polyurethane/Poly (ethylene oxide) Nanofiber Scaffolds for Biomedical Applications Yu Sun[1], Jesse Heacock[1], Yan Li[1,1,1], Jiangguo Liu[1,1], Chuchu Chen[2] and Kaiyan Qiu[2]; [1]Colorado State University,

United States; [2]Washington State University, United States

The development of novel wound-dressing materials has attracted significant research interests in recent years. With the advancement of nanofabrication, the application of nanoparticles (NPs) in drug delivery systems has become feasible. However, most existing work focuses on incorporation of metal, metal/semi-metal oxide, or organic particles into nanofiber scaffolds. There has been a lack of work on incorporation of drug-encapsulated polymeric particles into nanofiber scaffolds. In this study, gentamicin-encapsulated poly (lactic-co-glycolic acid) (PLGA) NPs were synthesized via a double emulsion solvent evaporation method. Electrospinning was used to incorporate gentamicin-encapsulated PLGA NPs into nanofiber scaffolds. Atomic force microscopy (AFM), dynamic light scattering, scanning electron microscopy (SEM), ultraviolet-visible spectroscopy (UV-vis), and an agar diffusion method were utilized to characterize the morphologies, release profiles, and antibacterial activities of various gentamicin-loaded PLGA NPs incorporated nanofiber scaffolds. The results indicated the PLGA NPs had a spherical morphology with an average diameter of 130nm. Purification of PLGA NPs was essential to eliminate the residual polyvinyl alcohol (PVA) and to prevent particle agglomeration. The purified PLGA NPs were uniformly and individually incorporated into the polyurethane (PU)/ poly ethenyl oxide (PEO) or PEO-only nanofiber scaffolds, but nearly none into the PU-only fiber scaffolds. PEO served as a continuous phase in the PU/PEO mixture, which significantly improved the compatibility of PLGA NPs and PU, resulting in a well-dispersed distribution of PLGA NPs in the monolithic nanofiber scaffolds. Excellent antibacterial properties against *E.coli* were found in both PU/PEO and PEO nanofiber scaffolds. This study of incorporating gentamicin-encapsulated PLGA NPs into fiber scaffolds provides insights for achieving successful incorporation of drugs-encapsulated polymeric NPs into fiber scaffolds. This offers a promising microfabrication technology for delivery of therapeutic molecules with controlled release for biomedical applications.

2:30 PM BREAK

Kirigami electronics for chronic electrophysiological recording of human neural organoids Bianxiao Cui; Stanford University, United States

Neurons transmit information via electrical signals. Recent advancement in neural organoids and assembloid technologies, derived from human stem cells, have offered a promising avenue for modeling aspects of nervous system development. To understand brain development and develop effective disease models, it is crucial to enable long-term, minimally invasive recordings from these three-dimensional systems. Current technologies, such as patch clamp, penetrating microelectrodes, planar electrode arrays, and substrate-attached flexible electrodes, do not, however, allow chronic recording of neural organoids in suspension, which is necessary to preserve their 3D architecture. Inspired by the art of kirigami, we develop flexible electronics that transition from a flat 2D pattern to a 3D basket-like configuration to accommodate the long-term culture of human neural organoids in suspension. This platform, named kirigami electronics (KiriE), integrates with and enables chronic recording of intact cortical organoids for 170 days while preserving their morphology, cytoarchitecture and cell composition. KiriE detects disease-related hyperactive phenotype. Furthermore, KiriE is compatible with simultaneous recordings from individual organoids in an assembloid and can capture activity in emerging cortico-striatal circuits. Moving forward, this flexible electronics system holds the potential to unveil disease phenotypes and reveal the activity patterns underlying the assembly of the nervous system.

3:30 PM SB06.08.05
Microstructures printed via 2-Photon Polymerization (2PP) to mechanically stimulate 3D multicellular systems Federico Colombo, Mohammadreza Taale, Gent Dulatahu, Teresa Debatin, Philipp Kollenz, Maria Villiou, Fereydoon Taheri, Malin Schmidt and Christine Selhuber-Unkel; University of Heidelberg, Germany

In nature, cells live immersed in an extracellular matrix with other cells, forming tissues and organs. These three-dimensional environments are essential for a wide array of vital biological processes. As a result, many recent studies are now exploring the utilization of 3D multicellular systems such as spheroids, organoids, and organotypic cell cultures. These alternatives, when compared to conventional 2D cell culture methods, hold a significant advantage in closely resembling physiological conditions. Indeed, the mechanical forces acting upon cells can yield differing outcomes depending on whether the cells are in a 2D or 3D environment. Traditionally, most studies on mechanotransduction, especially in terms of the effects induced by mechanical stretching, have been conducted on two-dimensional cultures. This approach, however, has provided only a limited understanding of the effects within a 3D culture.
To address this limitation, we have developed a device for the mechanical stimulation of 3D multicellular systems using Two-Photon Polymerization (2PP). This device can be used to study the mechanical forces in the biological complexities of tissues at an exceptional micrometer-scale resolution. The design of the device allows the application of forces capable of stretching the encapsulated 3D multicellular systems with extreme precision, using a cantilever. Simultaneously, this system enables high-resolution imaging to assess the effects of stretching in vivo. Our findings have revealed that cyclic stretching over 30 minutes at a frequency of 0.5 Hz, and an average displacement of 0.22um, leads to noteworthy alterations in the morphology and orientation of actin within the 3D multicellular system. Furthermore, this device can be easily customized to mechanically stimulate various types of multicellular systems, accommodating differences in shape and cell types.

3:45 PM SB06.08.06
Novel Virus-Templated Engineered Material for Photodynamic Treatments Marika Iencharelli[1,2], Paolo Emidio Costantini[3], Vittorio De Felice[1], Roberto Saporetti[4], Angela Tino[1], Francesca Di Maria[2], Alberto Danielli[3], Matteo Calvaresi[4] and Claudia Tortiglione[1]; [1]CNR-ISASI Consiglio Nazionale delle Ricerche, Italy; [2]CNR-ISOF Consiglio Nazionale delle Ricerche, Via Piero Gobetti, Italy; [3]Alma Mater Studiorum—Università di Bologna, Italy; [4]Alma Mater Studiorum, Università di Bologna, Italy

Thiophene-based materials **TMs**, due to their excellent electron transport properties, optical properties, soft material nature, stability, solution processability, and water dispersibility, have demonstrated significant potential in photodynamic (**PDT**) therapies. To increase the cell uptake and the permeation of physiological barriers recent studies reported the use of proteins (human serum albumin, HSA) [1] or phages (M13 bacteriophage) [2,3] as natural carriers of different photosensitizers (rose bengal, chlorin e6, oligothiophene ECB04), able to induce cell death by apoptosis in a variety of cell lines. Here we propose a novel engineered living material for photodynamic therapy, i.e. a virus-templated platform, based on the M13 bacteriophage**,** engineered to display targeting ligands on its surface. By covering the surface of the M13 phage with oligothiophene molecule, a 1-D thiophene nanoplatform, M13EGFR(TNP) was synthetized and tested in vitro and in vivo. Cell culture experiments were carried out to validate the ability of the biohybrid material to maintain the EGFR-targeted tropism of the phage and to demonstrate photoactivity. The tissue-like animal model Hydra was employed to further confirm the possibility to use these engineered materials for photodynamic treatment and to screen for targeting properties. The transparency, softness and body simplicity together with the lack of ethical issue make *Hydra* a suitable model for this type of studies, enabling fast screening of cytotoxicity and identification of molecular pathways underlying necrosis or apoptosis pathways. Our work provides valuable insights into the potential of M13EGFR(TNP) for targeted photodynamic therapy, laying the groundwork for further exploration of this innovative living material in **nanotheranostic** applications.

Using Metamaterials and Cardiac Tissue Engineering to Engineer Robust and Contractile Cardiac Tissue Patches Lewis S. Jones[1], Hector Rodriguez[2], Omer Dzemali[2] and Robert Katzschmann[1]; [1]ETH Zurich, Switzerland; [2]Universitätsspital Zürich, Switzerland

Ventricular Septal Rupture (VSR) is a challenge in cardiac medicine with a high mortality rate of 45-60%. Current treatment methods use bovine pericardial patches (BPPs), which are non-contractile, tend to calcify over time, and fail to integrate effectively with the myocardium. Therefore, patients do not tend to fully recover cardiac function. To address these limitations, we are engineering a cardiac tissue patch that uses human stem cell-derived cardiomyocytes in hydrogel, reinforced with a metamaterial lattice. This approach allows us to tune the patch mechanical properties and contractility, while enabling stable implantation within the intraventricular space. Here, we will showcase our current results on metamaterial design and manufacturing, mechanical characterization (tunable stiffness and anisotropic ratio), and biological characterization (biocompatibility, cell maturation, and tissue contractility). In summary, we will show how metamaterials can be combined with engineered cardiac tissues to fabricate centimeter scale, three dimensional, and implantable cardiac tissues.

4:15 PM SB06.08.08
Ion Detection in a DNA Nanopore FET Device Purun (Simon) Cao[1], William Livernois[1], Quanchen Ding[1], Soumyadeep Saha[2] and M. P. Anantram[1]; [1]University of Washington, United States; [2]University of Waterloo, Canada

Significant strides have been made to integrate biotechnology with semiconductor nanotechnology, but the ability to directly interface with living cells is still an emerging area of research. Such devices are being developed for interfacing directly with neurons, which can help monitor and treat chronic pain and Parkinson’s disease. In this pursuit, an ion detection device that combines a DNA-origami nanopore and a field-effect transistor (FET) was designed and modeled to determine the sensitivity of the nanodevice to the local cellular environment.
Our design employed an "artificial gap junction" constructed using a DNA origami nanopore on a CMOS device as a direct interface between the cell and the electronic device. Inspiration for using a DNA Nanopore comes from naturally occurring transmembrane nanopores, such as the protein Gramicidin, which have been modeled as ion channels. In this work, we have modeled a synthetic nanopore pore that uses a six-helix bundle of DNA that has been previously synthesized as a cylindrical nanopore structure that spans a bilipid membrane. The DNA-origami structure is bio-compatible and can also be modified with ligands to anchor to the lipid bi-layer on a cell. This self-assembling structure would be compatible with the living system and convert signals generated by ionic currents directly into an electrical signal using a gated ion-selective field effect transistor. While typical nanopore sensors detect single molecules and ions by measuring the change in ion flow across a membrane, the proposed device would detect the ions as a buildup of charge across the gate of the FET. A blanket of ions (electrical double layer) would form on the nanopore inner wall and over the gate oxide in a manner dependent on the local environment, and the resulting source-drain current can be used to measure the presence of ions in the cell.
A continuum model was used to account for the ions in the electrolyte. Modeling of an electron distribution with the electric double layer theory was applied to verify the applicability of the model to a bio-sensing environment. The FinFET architecture was shown to increase sensitivity to ions even with a low drain-source bias. The device combined with the nanopore is shown to have high sensitivity to ion concentration and nanopore geometry, with the electrical double layer behavior governing the device characteristics. The logarithmic relationship found between ion concentration and FET current generates almost a microampere of current difference across varying concentrations with a small applied bias.
Our findings illuminate a promising pathway for refining cellular interfacing, potentially catalyzing advancements in in-vivo sensing technologies for biomedical applications.
We acknowledge the NSF SemiSynBio 2027165 grant.

4:30 PM *SB06.08.09
Measuring Transmembrane Ion Channel Activity Using Biomembrane Bioelectronic Circuits Susan Daniel; Cornell University, United States

Despite advancements in transmembrane protein (TMP) structural biology and a growing interest in their applications, this class of proteins remains challenging to study. Progress has been hindered by the complex nature of TMPs and innovative methods are required to circumvent significant technical hurdles. We offer two new approaches that facilitate the study of the activity of ion channel proteins based on a bioelectronic biomembrane platform we developed. First, we harvest materials from plasma cell membranes that contain the ion channel of interest and coat our electrodes with these “cellular biopsies.” Second, we use cell-free protein synthesis using reconstituted components of the cellular transcription and translation machinery in vitro for integrating TMPs directly into a membrane coating the electrode. In this talk, I will highlight both approaches for functionalizing electrodes with biological materials and measuring their activity. The bioelectronic biomembrane platform used in these studies is made possible by using a biocompatible conducting polymer film that supports a lipid bilayer. Specifically, PEDOT:PSS films on electrodes, which are both transparent and electrically conductive, allow the assessment of protein activity by optical and electrical means. Here, fluorescence microscopy and electrochemical impedance spectroscopy (EIS) are used to characterize the ion channels in these devices. Examples of activity measurements from the human, plant, and bacteria world will be given with implications in health, agriculture, and sensing.

SESSION SB06.09: Poster Session II
Session Chairs: Eleni Stavrinidou and Claudia Tortiglione
Thursday Afternoon, April 25, 2024
Flex Hall C, Level 2, Summit

5:00 PM SB06.09.02
Force-Triggered Self-Destructive Hydrogels Tharindu R. Rajasooriya[1], Hiroaki Ogasawara[1], Yixiao Dong[1], Joseph Mancuso[1] and Khalid Salaita[1,2]; [1]Emory University, United States; [2]Georgia Institute of Technology, United States

Self-destructive polymers (SDPs) are defined as a class of smart polymers that autonomously degrade upon experiencing an external trigger, such as a chemical cue or optical excitation. Because SDPs release the materials trapped inside the network upon degradation, they have potential applications in drug delivery and analytical sensing. However, no known SDPs that respond to external mechanical forces have been reported, as it is fundamentally

challenging to create mechano-sensitivity in general and especially so for force levels below those required for classical force-induced bond scission. To address this challenge, the development of force-triggered SDPs composed of DNA crosslinked hydrogels doped with nucleases is described here. Externally applied piconewton forces selectively expose enzymatic cleavage sites within the DNA crosslinks, resulting in rapid polymer self-degradation. The synthesis and the chemical and mechanical characterization of DNA crosslinked hydrogels, as well as the kinetics of force-triggered hydrolysis, are described. As a proof-of-concept, force-triggered and time-dependent rheological changes in the polymer as well as encapsulated nanoparticle release are demonstrated. Finally, that the kinetics of self-destruction are shown to be tuned as a function of nuclease concentration, incubation time, and thermodynamic stability of DNA crosslinkers.

5:00 PM SB06.09.03
Label-Free Laser-Induced Ni/AuNPs Micropore Reusable Electronic Sensor for Rapid Bacteria Detection and Quantification Wing Yan Poon and Mitch Guijun Li; The Hong Kong University of Science and Technology, Hong Kong

The advancement of biosensors for microbes, especially pathogenic bacteria has been an important research area aiming to develop rapid and accurate detection, with its crucialness to various applications in healthcare, food safety and environmental monitoring. Laser-induced nanoparticles have emerged as a viable solution to stimulate and identify electrochemical properties of bacteria. In this study, we propose a label-free laser-induced Ni/AuNPs reusable electronic sensor that enables fast and precise detection of pathogenic bacteria.

The rapid bacteria sensor is achieved by two major innovative laser applications. The sensor is firstly fabricated by a laser-drilled micropore sized at approximately 1 μm on double sided laser-induced graphene (LiG) polyamide film. The size of the micropore is utilized to conduct selective resistive pulse analysis which allows identifications across different pathogenic bacterial species along with machine learning. It is then followed by controlled potential amperometric analysis of different pathogenic bacteria using Ni/AuNPs modified LiG as electrode, providing quantitative details of bacteria present in the sample solution. The Ni/AuNPs modified LiG is efficiently manufactured by laser ablation of Ni-consisting crystal and Au thin film to laser-induced graphene. This novel bacteria sensor requires no additional coating of antibodies and non-reversible conjugations between bacteria and ligands, enabling its robust reusability on bacteria detection and quantification.

This novel approach demonstrates simple yet highly functional applications for the detections and quantification of bacteria, microorganisms or even viruses. Through the techniques of laser-induced nanomaterials and micropores, the manufacturing of microbes related sensing instruments would be immensely enhanced in terms of time efficiency as well as financial cost. With indications of such capabilities, it is assured that the future of microbial diagnosis will be optimized with next generation rapid sensors developed from laser evolved technologies, paving ways for further applications in fields of food safety, epidemiology and Point-Of-Care testing.

5:00 PM SB06.09.04
Pushing the Limit of Self-Assembly Ultrashort Peptides Minimum Gelation Concentration for Advanced Biomedical Applications Panagiotis Bilalis, Dana Alhattab, Cynthia Juarez, Abdulelah Alrashoudi, Manola Moretti and Charlotte A. Hauser; King Abdullah University of Science and Technology, Saudi Arabia

Ultrashort amphiphilic peptides, characterized by a distinct sequence motif and comprising up to seven natural amino acids, display self-assembling dynamics under physiological conditions. Despite their small size, these peptides can adopt α-helical, β-sheet, and β-turn secondary structures in aqueous solutions. At higher concentrations, they spontaneously organize into nanofibers, resulting in hydrogels characterized by an exceptionally high water content (>99% w/w). Notably, these hydrogels exhibit biocompatibility, biodegradability, and low immunogenicity, making them versatile for various biomedical applications such as 3D cell culture, bioinks for 3D bioprinting, hemostatic agents, drug delivery systems, and materials for soft tissue repair. By strategically substituting certain amino acids in the sequence with non-natural counterparts, we achieved the lowest reported minimum gelation concentration for self-assembling peptides, thereby expanding their potential applications. In-depth analyses using 2D-NMR, Raman spectroscopy, and molecular dynamic (MD) simulations were conducted to further elucidate the self-assembly process. These peptides serve as scaffolds capable of supporting cellular viability and proliferation without compromising the mechanical properties of the hydrogel. The results demonstrate the potential of these scaffolds for advanced biomedical applications. Specifically, we demonstrated the capability of the developed peptide scaffolds to be combined with human platelet lysate up to 40% of its volume without compromising the self-assembly process. This forms a hydrogel scaffold that can self-sustain and promote cellular growth under xenofree 3D culture conditions. The hybrid peptide and platelet lysate hydrogel developed in this study holds immense promise for clinical applications in the field of regenerative medicine.

5:00 PM SB06.09.05
Engineering Cellular Alignment in Contractile Cardiac Tissues Using Coherent Light Biofabrication Lewis S. Jones[1], Miriam Filippi[1], Mike Yan Michelis[1], Aiste Balciunaite[1], Oncay Yasa[1], Gal Aviel[2], Maria Narciso[1], Eldad Tzahor[2] and Robert Katzschmann[1]; [1]ETH Zurich, Switzerland; [2]Weizmann Institute of Science, Israel

Biofabricating three-dimensional cardiac tissues that mimic the native myocardial tissue is a pivotal challenge in tissue engineering. In this study, we fabricate three-dimensional cardiac tissues with controlled cellular alignment and directed contractility. We use coherent light biofabrication with optically tuned bioinks of high cell density (15-60 million cells/mL) to fabricate hydrogel microstructures for cardiac cell alignment. Cardiac tissues with microstructures expressed higher levels of protein alpha 1 (GJA1) (1.6x) and exhibited higher uniaxial contractility (3.8x) relative to unstructured tissues. Tissues that were bioprinted at high cell density (30-60 million cells/mL) contracted synchronously (27 μm uniaxially). However, cell-induced light scattering hinders microstructure formation and cellular alignment at increased light propagation depth (> 400 um). Furthermore, cell-induced light attenuation caused anisotropic tissue remodeling and contractility. We mitigated these limitations by projecting light bidirectionally. This approach minimized the light propagation depth and allowed us to rapidly bioprint larger tissues with microstructures (ø 0.6 mm x 2 mm). Our approach provides a new strategy for engineering cellular alignment in cardiac tissues used for drug screening, regenerative medicine, and biohybrid robots.

5:00 PM SB06.09.06
Multi Electrophysiological Signal Collecting E-Textile System by Sponge Electrode Chansoo Kim, Junyi Zhao and Chuan Wang; Washington University in St. Louis, United States

Wearable electrophysiological signal sensors are essential for long-term health monitoring applications, and these electrodes lead us to pre-diagnose lots of diseases such as a cardiac disorder and muscle or nerve disorders before the diseases move to more dangerous step. However, most of the reported wearable sensors have collected signals individually or integrated into patch for multi-signal collection. As a result, the practical implementation is hampered by challenges such as process complexity, durability, and user experience.
Here, we introduce an interesting approach for long-term and multi-electrophysiologic signal collecting electrode by E-textile system. This system is composed of simply screen printed textile electrodes with Poly(3,4-ethylenedioxythiophene)polystyrenesulfonate (PEDOT:PSS) and carbon black mixed

conductive PDMS sponge electrode. The porous structure of soft and conductive sponge electrode provides pressure sensitivity by changing the void (air gap) structure inside of the sponge. So, it shows sensitive resistance and capacitance change under small pressure changes (Under 300 Pa).
For the electrophysiological signals, the sponge electrode can drastically increase the contact area between skin and electrode in water and gel condition. In addition, it also keeps the water or gel longer time compared to the planner electrode. So, to overcome the hydrophilicity of PDMS and carbon black, and maximize the absorption of water or gel into the sponge electrode, layer-by-layer (LbL) coating is utilized with poly-L-lysine.
Eventually, we achieve 1.2×10^4 Ω*cm^2 skin contact impedance and 30 dB signal-to-noise ratio (SNR) for the electrocardiogram (ECG) and electromyography (EMG). Furthermore, the carbon black sponge electrode demonstrates better wet condition stability compared to other coated sponge electrodes. Finally, we utilized this E-textile system for the patient study to collect uterine contraction signals and predict childbirth (Washington University Institutional Review Board, IRB 201612140). We strongly believe that this E-textile system will lead to a new opportunity for stable long-term electrophysiologic signal collecting applications.

5:00 PM SB06.09.07
Colorimetric and Photothermal Dual-Mode Apta-Sensor for Selective Detection of Kanamycin Using Chitosan-Stabilized Platinum Nanozymes
Han Been Lee, Sung Min Jeon, Dayeong Choi and Gi Hun Seong; Hanyang University, Korea (the Republic of)

Addressing bacterial infections, kanamycin (KAN) finds extensive use in aquaculture, livestock husbandry, and agriculture. Nevertheless, the overuse of KAN leads to an excess of biological residues in the environment and food, resulting in potential nephrotoxicity, ototoxicity, and other harmful side effects for humans. Consequently, it becomes imperative to develop a rapid, selective, cost-effective, and sensitive detection system for KAN to safeguard human health and ensure food safety.
Colorimetric assays employing antibodies have garnered significant attention due to their noticeable color change discernible by the naked eye, swift observation, cost-effectiveness, and ease of operation. Nonetheless, antibodies come with drawbacks such as high cost, sensitivity to storage conditions, and variability in quality from batch to batch, leading to decreased reproducibility. To address these challenges, we opted for aptamer molecules. These functional, single-stranded nucleic acids possess the ability to fold into specific 3-D structures, exhibiting high specificity for target molecules, whether they are small molecules, or even proteins.
Nanozymes, nanomaterials exhibiting natural enzyme-like activities, have been recognized as viable substitutes to emulate natural enzymes such as horseradish peroxidase (HRP). This is attributed to their advantages of low cost, straightforward preparation, easy modification, excellent stability, and remarkable catalytic activity. Platinum nanoparticles (PtNPs), in particular, have found extensive use in bioanalytical applications due to their superior peroxidase-like activity, biocompatibility, and high chemical inertness. The choice of suitable stabilizing reagents is crucial in the synthesis of efficient nanozymes, as stabilizers significantly impact the physicochemical and biological properties of nanoparticles. In our study, chitosan (CS) was employed. The positively charged nature of CS facilitates the electrostatic binding of the negatively charged KAN binding aptamer (KBA) to chitosan-stabilized platinum nanoparticles (CS/PtNPs).
Traditionally, immunoassays operate by detecting the target in a single mode. However, outcomes obtained through a single-mode signal readout can be susceptible to variations stemming from differences among operators, equipment disparities, and non-standard analytical protocols. In contrast, dual-mode sensing platforms not only possess the intrinsic characteristics of each response mode but also offer mutual validation of detection results obtained through diverse modes. Recent efforts have been directed towards establishing analytical methods that incorporate temperature changes as a signal, in addition to the colorimetric method, in immunoassays. Among various photothermal agents, oxidized TMB (TMB_{ox}) has emerged as a promising photothermal sensor due to its high photoconversion efficiency in near-infrared (NIR)-induced photothermal applications. TMB_{ox} exhibits distinct absorbance at UV-visible (652 nm) and NIR (808 nm) wavelengths, making it suitable for use as a probe in both colorimetric and photothermal detection.
In this work, CS/PtNPs and TMB_{ox} were used to construct a dual-mode colorimetric and photothermal aptasensor designed for the selective detection of KAN, relying on the KBA-derived enhancement of peroxidase activity in CS/PtNPs and its subsequent inhibition by KAN. The developed dual-mode colorimetric and photothermal aptasensor exhibited a linear detection range of 0.1–50 and 0.5–50 μM, with respective limits of detection (LOD) of 0.04 and 0.41 μM. Furthermore, the aptasensor effectively identified KAN concentrations in spiked milk samples, confirming its reproducibility and reliability in practical applications. Crucially, the proposed aptasensor eliminates the need for a washing step and demonstrates robust selectivity for KAN. These characteristics position the aptasensor as a versatile tool for the detection of small molecules with known aptamers.

5:00 PM SB06.09.08
Nanocarrier Incorporating Fucoidan/Chitosan for Co-Encapsulation of TMB, Glucose Oxidase and Prussian Blue: Applications in Chemotherapy, Photothermal Therapy and Glucose Starvation Treatment Dayeong Choi, Han Been Lee, Sung Min Jeon and Gi Hun Seong; Hanyang University, Korea (the Republic of)

Fucoidan, a naturally occurring sulfated polysaccharide derived from marine brown algae, has been explored as a promising therapeutic nanoparticle for cancer treatment. Effective strategies such as chemotherapy, photothermal therapy, and glucose starvation can create a conducive environment for successful cancer eradication. Harnessing the potential of functionalized fucoidan nanoparticles in combination with chitosan, acting as a nanocarrier, presents an opportunity for biological activation, particularly in abnormally acidic extracellular environments. In this study, we developed a fucoidan (Fu)-chitosan (CS) nanocarrier through a self-assembly technique and encapsulated it with 3,3′,5,5′-tetramethylbenzidine (TMB), prussian blue (P), and glucose oxidase (GOx) (Fu/CS@TPGOx). The synthetic multi-stimuli-responsive Fu/CS@TPGOx nanoparticles were characterized using dynamic light scattering (DLS), zeta potential, UV absorption, scanning electron microscopy (SEM), and transmission electron microscopy (TEM) analyses. DLS analysis indicated an average particle size of 440 nm, consistent with the spherical morphological structures observed in TEM results. Moreover, the positive zeta potential of 22.9 mV affirmed the stability of the synthesized particles.
The catalytic efficacy of Fu/CS@TPGOx nanoparticles is confirmed through UV absorption studies, revealing specific absorbance spectra at 652 nm. Additionally, a prominent peak at 810 nm signifies substantial absorption in the near-infrared (NIR) range, rendering it particularly suitable for photothermal treatment. The photothermal performance of the newly developed Fu/CS@TPGOx nanoparticles was assessed by subjecting them to an 808 nm NIR laser at concentrations of 7.7, 3.85, and 0.77 μg/mL, with a power density of 0.75 W/cm^2. Results indicated a proportional increase in temperature with nanoparticle concentration. Notably, at 7.7 μg/mL Fu/CS@TPGOx nanoparticles, the temperature reached 55.2 °C, providing an optimal condition for the targeted destruction of breast cancer cells (MDA-MB-231) following a continuous 10 minute exposure to an 808 nm laser with a power density of 0.75 W/cm^2.
The WST-1 assay, a live-dead cell staining method, validates the anticancer properties of Fu/CS@TPGOx in MDA-MB-231 cancer cells. Fu/CS@TPGOx exhibited 40% cytotoxicity in MDA-MB-231 cells under chemodynamic treatment and glucose starvation conditions at a dose of 0.77 μg/mL. Furthermore, the cytotoxicity increased to 55% during photothermal effects with chemodynamic treatment and glucose starvation by exposing Fu/CS@TPGOx to an 808 nm laser at 0.75 W/cm^2 for 10 minutes. The live-dead cell staining experiment yielded similar results, highlighting Fu/CS@TPGOx's significant potential as a cancer therapeutic. Moreover, DCFH-DA analysis confirms that under photothermal conditions with chemodynamic therapy and glucose starvation, the generation of reactive oxygen species was higher in the 0.77 μg/mL Fu/CS@TPGOx treatment. This suggests that Fu/CS@TPGOx played a crucial role in activating OH^- in cancer cells.
The flow cytometry study provides evidence supporting the cytotoxic effects of 0.77 μg/mL Fu/CS@TPGox under laser conditions, yielding the highest rate of apoptosis (84.5%) compared to glucose starvation and chemodynamic treatment (60%). The utilization of three anti-cancer strategies—

chemotherapy, photothermal treatment, and glucose starvation—is evident in the findings, showcasing Fu/CS@TPGox's substantial anti-cancer impact at low concentrations. This research holds the potential to contribute to the development of more effective anticancer therapies for cancer treatment. A comprehensive investigation of these novel materials will be conducted to assess their in vivo efficacy and toxicity in comparison to other anti-cancer drugs in the future.

Keywords: Fucoidan, Chitosan, Photothermal therapy, Chemodynamic therapy, Glucose starvation

5:00 PM SB06.09.09
The Photothermal Efficacy of Silver and Rhenium Disulfide Nanoparticles for Cancer Eradication Sesha Subramanian Murugan[1,2], Venkatesan Jayachandran[1,2] and Gi Hun Seong[1]; [1]Hanyang University, Korea (the Republic of); [2]Yenepoya Deemed to be University, India

Cancer is a deadly disease that usually manifests in its later stages or whenever medicinal treatments become ineffective. Tumor cell suppression in the malignant microenvironment is a significant impediment to anticancer therapy. Photothermal characteristics of nanomaterials are being investigated as a potential new cancer treatment. Rhenium disulfide (ReS_2) nanosheets were created in this work by liquid exfoliation with gum arabic (GA), and then coated with AgNPs to produce reactive oxygen species that destroy cancer cells. The developed AgNP-GA-ReS_2 NPs have been studied by photothermal, UV, DLS, SEM, and TEM assessments.UV analysis shows that produced AgNP-GA-ReS_2 NPs has significant responses to NIR irradiation at 808 nm which could potentially utilized for photothermal cancer treatments. The dynamic light scattering (DLS) results showed that the NPs had a zeta potential of +76 mV and were around 216 nm in size. The transmission electron microscopy (TEM) and scanning electron microscopy (SEM) analyses indicated that the AgNP-GA-ReS_2 produced single-layered nanosheets on which the AgNPs were scattered. Following 5 minutes of laser irradiation, the photothermal effects of 50 µg/mL AgNP-GA-ReS_2 NPs were investigated using 808 nm laser, operating at 1.2 W cm^{-2} and temperature increased to 55.8 °C .This temperature represents the ideal death point for tumor cells. Within comparable testing settings, AgNP-GA-ReS_2 at 25 µg/mL had an average temperature of “40.71 °C”, indicating an evident link between the concentration and the substance's photothermal abilities.
The anticancer activity of the novel AgNP-GA-ReS_2 NPs was investigated in MBA-MB-231 cells for five minutes with and without laser irradiation to determine dose-dependent cytotoxicity, and the results confirmed that higher concentrations (50 µg/mL) of AgNPs-GA-ReS_2 are effective at killing cancerous cells. Calcein and EtBr staining confirmed the cytotoxic nature of AgNP-GA-ReS_2 NPs in laser conditions, with more dead cells in the laser boundary region stained with red EtBr. In addition, AgNP-GA-ReS_2 nanosheets exposed to NIR irradiation produce Reactive Oxidation Species (ROS) with strong anticancer activity, as confimed by the DCFH-DA and flow cytometry investigations, along with photothermal effects.
Key Words: Cancer, Photothermal effects, Rhenium Disulfide and Silver nanoparticles

5:00 PM SB06.09.10
A Conformal Second Skin for Long-Term Electrophysiology Monitoring of Plants Yi Jing Wong[1,2], Xiaodong Chen[1] and Xian Jun Loh[2]; [1]Nanyang Technological University, Singapore; [2]Agency for Science, Technology and Research, Singapore

Electrophysiological (EP) signals are important plant health indicators as they are pivotal in the growth development and plants’ response to environmental stimuli or stresses. Long-term plant health monitoring through analysis of EP signals has become increasingly important with the growing risk of global agriculture instability. However, the long-term attachment of wearable electrodes has always been hindered due to hydrogel dehydration or poor conformability with plant surfaces.
In this presentation, I will share my work on the development of a long-term coupling layer to achieve stable monitoring of plant EP signals. The high conformality of the coupling layer allows the non-invasive recording of EP signals for a month with superior signal-to-noise ratio and minimal drift. This work investigates the coupling mechanism and demonstrates potential applications, with the objective of laying the foundation for use of wearables in understanding plants' long-term responses to environmental changes.

5:00 PM SB06.09.11
A Fibrous Matrix Immobilized with Milk Exosomes for Improved Wound Healing Hoai-Thuong Duc Bui[1], Gayeon You[2], Hyuksang Yoo[1] and Hyejung Mok[2]; [1]Kangwon National University, Korea (the Republic of); [2]Konkuk University, Korea (the Republic of)

This study aims to provide an advanced therapy for wound recovery by immobilizing pasteurized bovine milk-derived exosomes (mEXO) onto a polydopamine (PDA)-coated hyaluronic acid (HA)-based electrospun nanofibrous matrix (mEXO@PMAT) using a straightforward dip-coating technique. The goal of this study is to create a wound-healing biomaterial that is composed of mEXO-immobilized mesh. mEXOs that have been purified and measured at approximately 82 nanometers contain a number of microRNAs (miRNAs) that are associated with collagen synthesis, cell proliferation, and anti-inflammatory properties. These miRNAs include let-7b, miR-184, and miR-181a. These miRNAs are responsible for eliciting increased mRNA expression of keratin5, keratin14, and collagen1 in human keratinocytes (HaCaTs) and fibroblasts (HDF). During the course of fourteen days, the mEXOs that have been immobilized onto the PDA-coated meshes are progressively freed from the meshes without experiencing a burst-out effect. In the cells that have been treated with HaCaTs and HDF, the degree of in vitro cell migration is greatly increased in the cells that have been treated with mEXO@PMAT. This is in comparison to the cells that have been treated with unmodified or PDA-coated meshes. A further benefit of the mEXO@PMAT is that it facilitates substantially quicker wound closure in vivo without causing any noticeable toxicity. Therefore, the prolonged liberation of bioactive mEXO from the meshes has the potential to significantly promote cell proliferation in vitro and accelerate wound closure in vivo. This has the potential to be utilized by mEXO@PMAT as a promising biomaterial for wound healing.

5:00 PM SB06.09.12
Functionalization of Gold Electrodes with Aptamers for Impedimetric Biosensor for Detection of *Brucella Abortus* Merylin S. Jiménez[1,2], David Monge Castillo[1,2,3], Daniela Zuñiga Rivera[1,2], Leonardo Lesser Rojas[4,5], Giovanni Sáenz Arce[6,7], Caterina Guzmán Verri[8] and Claudia Villarreal[1,2,9]; [1]Escuela de Ciencia e Ingeniería de Materiales, Instituto Tecnológico de Costa Rica, Costa Rica; [2]Centro de Investigación y Extensión en Ingeniería de Materiales (CIEMTEC), Instituto Tecnológico de Costa Rica, Costa Rica; [3]Maestría Ingeniería en Dispositivos Médicos, Instituto Tecnológico de Costa Rica, Costa Rica; [4]Centro de Investigación en Ciencias Atómicas, Nucleares y Moleculares, Universidad de Costa Rica, Costa Rica; [5]Escuela de Física, Universidad de Costa Rica, San Pedro de Montes de Oca, Costa Rica; [6]Centro de Investigación en Óptica y Nanofísica, Departamento de Física, Universidad de Murcia, Spain; [7]Departamento de Física, Facultad de Ciencias Exactas y Naturales, Universidad Nacional, Costa Rica; [8]Programa de Investigación en Enfermedades Tropicales (PIET), Escuela de Medicina Veterinaria, Universidad Nacional, Costa Rica; [9]Laboratorio Nacional de Nanotecnología (LANOTEC), Centro Nacional de Alta Tecnología (CENAT), Costa Rica

Brucella Abortus is a bacterium that causes brucellosis, considered one of the main causes of economic losses in the livestock sector, also causing a zoonotic risk. It’s estimates that about half a million new cases of human brucellosis occur each year worldwide. Biosensors offer the necessary criteria to perform an early, accurate and efficient detection of *Brucella abortus*, to prevent the spread of the disease and minimize its effects on human and animal health, due to their ease of use and portability for complex samples. The objective of this work is to develop a selective platform for the detection of *Brucella abortus*, to be implemented in a microfluidic device based on an impedimetric aptasensor. The aptamers are covalently functionalized on the gold

electrodes via glutaraldehyde and cysteamine. The electrodes were characterized by Fourier transform infrared spectroscopy (FTIR) to confirm the presence of aptamers on the surface; scanning electron microscopy (SEM) Energy Dispersive Spectroscopy (EDS) and atomic force microscopy (AFM) were used to image the aptamer layer on the electrode surface and evaluate the morphology, quality, homogeneity, uniformity, and thickness. Electrochemical Impedance Spectroscopy (EIS) and Cyclic Voltammetry (CV) are applied to observe the biological interaction response and interfacial properties of the functionalized electrode.

5:00 PM SB06.09.13
TD-DFTB Investigation and Deposition of Au onto Ag Nanocubes for Enhanced Stability and Sensing Ayomide D. Oluwafemi, Tim Kowalczyk and Ying Bao; Western Washington University, United States

Silver nanocubes are appealing to scientists and significant in technology due to their optical, electric, and chemical properties. However, there are limitations to chemically modifying silver nanocubes and they are susceptible to oxidation leading to the loss of their shape, stability, and quality. A solution is to deposit a metal like gold on silver nanocubes that is resistant to oxidation and chemically modifiable. This prevents silver nanocube deterioration, ensuring their stability and modification potential. Unfortunately controlling the synthetic parameters that shape gold-coated silver nanocubes is difficult. The galvanic replacement reaction between gold and silver can erode, hollow, or disintegrate silver nanocubes. We conducted several tests to create a viable and reproducible gold-coated silver nanocube synthesis process. This research employed both thermodynamic and kinetic control to prevent galvanic replacement reaction by decreasing the gold precursor's reduction potential with potassium iodide and adjusting the pH to regulate the reduction power of the reducing agent. We also evaluated various experimental settings and parameters vital to the synthesis. The refractive index sensing potential of gold-coated silver nanocubes was assessed and chemically treated with MUTAB ((11-Mercaptoundecyl)-N, N, N-trimethylammonium bromide). The Time dependent density theory functional (TD-DFTB) computational methodology was used to better understand the synthetic process and the atomic system, focusing on gold and silver electronic interactions and the effects of Iodide (I^-), Chlorine (Cl^-), and Sulphite ions (SO_3^{2-}) on the galvanic replacement reaction, nanostructure geometry and stability. Overall, this study expands on gold-coated silver nanocube research. It gives more insights on how gold-coated silver nanocubes are synthesized, maintains their shape, improves stability, and functionality.

5:00 PM SB06.09.14
***In Situ* Cell Purification by Biomolecule Induced Peptide Self-Assembly** Cheuk Yin Li, Zhenghua Liang and Yi Kuang; Hong Kong University of Science and Technology, Hong Kong

Synthetic mRNA switches have emerged as valuable tools for the cell sorting in culture condition, particularly for purification of stem cell-derived cells. The efficiency of recovering target cells is however hindered by the undesired expression of toxic proteins, and the removal of non-target cells is also limited due to the absence of signal amplification. To address these challenges, we developed an innovative approach utilizing synthetic mRNA switches sensing intracellular marker molecule, that control the formation of an extracellular toxic assembly. Since this approach does not involve in expression of toxic proteins, it ensures a high effectiveness in recovering target cells. Furthermore, we implemented multi-level signal amplification to enhance the elimination effectiveness of non-target cells. This novel approach can be customized to suit diverse in situ cell purification requirements, offering a promising solution for achieving effective and efficient in situ cell purification in a broad biological and clinical applications.

5:00 PM SB06.09.15
Thermodynamically Stable Nanotubular mRNA Carriers made of Self-Adjusting Peptide Building Blocks Youjin Jung; Yonsei University, Korea (the Republic of)

While mRNA delivery technology holds significant promise, storage and safety-related problems still exist, which arise from the inherently low thermodynamic stability of conventional mRNA carriers. The existing mRNA carriers have generally spherical structures. Considering the filamentous nature of mRNAs and the exceptional thermodynamic stability associated with nanotubes among nano-assemblies, we could dramatically enhance the thermodynamic stability by developing mRNA carriers in the form of nanotubes. Through cooperative interactions, mRNA and peptides were fabricated into rigid nanotubes that resemble tobacco mosaic virus. The fluttering and irregular mRNA strand was coated by a single layer of peptide building blocks. The crucial factor in developing the mRNA nanotube lies in designing self-adjusting supramolecular building blocks (SABs). SABs contain α-helical coiled coils, that incorporate two contrasting properties, namely dynamic flexibility and stiffness, within a single molecule. mRNA nanotubes with bound ligands for targeting exhibited high uptake efficiencies and the tunable transfection efficiencies in mammalian cells. Consequently, mRNA nanotubes will provide underlying technology in advancing the development of more stable and safe mRNA vaccines and therapeutics.

SESSION SB06.10: Biosensing
Session Chairs: Matteo Grattieri and Tedrick Thomas Salim Lew

Genetically Encoded Nanoparticles Synthesized Intracellularly Or Shemesh[1,2], Krishnashis Chatterjee[2], Pururav Ramakrishna[2] and Amanda Lin[2]; [1]The Hebrew University of Jerusalem, Israel; [2]The University of Pittsburgh, United States

Despite major advances in detection and therapy, multiple cancers are still aggressive and incurable. Metal nanoparticles are being tested and used for tumor imaging, radiotherapy, and hyperthermia. However, using nanoparticles in living specimens is impeded as they often fail to reach the target cell or desired subcellular organelle, causing insufficient efficacy and safety concerns. Sophisticated chemical coatings and targeting aids such as vesicles and antibodies designed to address these pitfalls, provide only a partial solution, as they either increase off-target activity or hinder the clinical function of the nanoparticles. To solve this, we had the nanoparticles of interest made by the tumor cells, using their own genetic machinery. We expressed genes that encode nanoscale protein cages, able to stabilize metal ions inside tumor cells. The expressing tumor cells were presented with subtoxic concentrations of salts containing metal ions, which were stabilized to form metal nanoparticles. We are now testing the hypothesis that creating Genetically Encoded Nanoparticles Synthesized Intracellularly (GENSIs) can yield high-efficiency cancer therapy. We optimized the formation of GENSIs in glioma cell cultures and confirmed the formation of metal GENSIs by optical microscopy, transmission electron microscopy (TEM) and elemental analysis (EDX). We anticipate tumor cell photothermal killing, by expressing GENSIs in cancer cell lines and exposing them to near-infrared laser light. These studies will unlock the immense potential embedded in genetically encoded nanoparticles for cancer therapeutics and diagnostics applications.

8:30 AM SB06.10.03
Nanopillar Devices for Single Molecule Sensing in The Clinic Alain Wuethrich, Junrong Li, Selvakumar Edwardraja, Christopher Howard, Richard Lobb and Matt Trau; The University of Queensland, Australia

The precise and early detection of biomarkers serves as molecular evidence for managing emerging diseases, enabling timely interventions, and potentially saving lives. Nanomaterials and nanostructures, with their unique physico-chemical properties, can be harnessed to develop innovative sensing systems for multiplex biomarker detection, generating patient-specific molecular profiles from a simple blood sample. At the Centre for Personalised Nanomedicine at UQ, our focus is on developing translational nanotechnologies. We explore nanomaterials and nanostructures to design highly sensitive and multiplex sensing systems for profiling circulating biomarkers in the clinic. In this presentation, we will highlight our recent adventures into single molecule sensing and show how these sensing systems can provide a new window into complex diseases. We will introduce a nanopillar sensing device with single molecule sensitivity for monitoring the human immune system [1], cancer [2, 3] and post-acute sequelae of COVID-19 (unpublished). Furthermore, we exemplify the design of novel biohybrid nanoprobes for sensing of emerging infectious diseases [4].

Rapid miRNA Detection Enhanced by Exponential Hybridization Chain Reaction in Graphene Field-Effect Transistors Zhaoli Gao and Ting Huang; Department of Biomedical Engineering and Shun Hing Institute of Advanced Engineering, The Chinese University of Hong Kong, Hong Kong

Point-of-care nucleic acid testing with speed, accuracy, and precision is crucial for early detection and timely treatment of diseases. Electronic biosensors that utilize target recycling and hybridization chain reaction (TRHCR) in combination with graphene field-effect transistors (GFETs) show great promise for highly sensitive diagnostics of nucleic acid, reaching the limit of detection down to 100 aM. However, a challenge arises from its linear kinetics, which results in prolonged sensing times for lower concentration oligonucleotides, e.g., approximately 15 hours for 100 aM oligonucleotides. Here, we report a 30-fold reduction in sensing time, from 15 hours to a mere 30 minutes, for detecting 100 aM miRNA, which is achieved by developing an exponential amplification reaction pathway, synergistically compatible with GFETs. This enables the target miRNA to exponentially trigger TRHCR, leading to long-nicked double-stranded polymers that can be detected by GFET through chemical gating. Consequently, our approach facilitates the detection of 22 mer miRNA at concentrations as low as 100 aM in human serum samples, achieving a time frame congruent with point-of-care testing and superior specificity against single-base mismatched interfering oligonucleotides. Our work paves the way towards highly precise, efficient, and label-free nucleic acid testing, thus facilitating early-stage detection of cancer and other diseases at the point of care.

Superstrong Electronic Hydrogel Actuators (ECO) Max M. Hamedi; KTH, Sweden

Superstrong Electronic Hydrogel Actuators (ECO)

Intelligent systems combine sensing, actuation, and computation to achieve complex tasks and functions. Soft electrically controlled multifunctional materials, especially hydrogels, are the most promising materials for such systems as they are as adaptable as biological systems yet compatible with advanced systems through electronics.
We describe an electroactive hydrogel fabricated from cellulose nanofibrils from trees, and conductive nanomaterials, like CNTs or 2D MXenes.[1][2] These nanoparticles self-assemble into an anisotropic composite networks with an open mesoporous structure that can hold lots of water and be highly permeable to substances in their surroundings. The anisotropy of the network allows high expansion in one direction while maintaining very high strength and high electric conductivity in the other.
The electrochemical charge/discharge of the conductors in the hydrogels controls the internal salt concentration and consequently their osmotic swelling.[3] This allows direct electrically controlled actuation where around 700 water molecules expand/contract the structure for each ion/electron pair inserted/de-inserted at only ±1 volt, resulting in up to 300% electroosmotic expansion, with very high pressures reaching 1 MPa.

This mode of electronic actuation has not been shown before. We call these electroosmotic (ECO) actuators. Our ECO hydrogel actuators have emergent properties not present in any previously known soft material.
ECO actuators represent a new form of smart soft material, opening possibilities not achieveable with other materials systems: as they enable monolithic integration of sensors and many other functions into the same composite, for example using 3D printing techniques.

A Breakthrough in Nanotechnology-Enhanced Glucose Sensors Yuan-Hao Hsiao, Rajan D. Chakravarthy, Yu-Hsiang Hsiao and Hsin-Chieh Lin; National Yang Ming Chiao Tung University, Taiwan

According to the International Diabetes Federation (IDF), 537 million adults worldwide suffered from diabetes in 2021, and it is expected that by 2045, one out of every eight adults will have diabetes. As a result, monitoring blood glucose concentrations is essential.

Recent breakthroughs in materials science have led to the creation of nanozymes, which mimic the catalytic functions of natural enzymes, typically comprising metals, metal oxide or metal-organic frameworks (MOFs), offering benefits of stability, precision, and rapid reaction rates for blood glucose measurement.

Nanozymes, though versatile, tend to lack the specificity of natural enzymes, limiting their practicality, and some may exhibit low biocompatibility.

Hence, we created enzyme nanoparticles, fusing nanomaterial attributes with enzyme benefits to preserve natural enzyme advantages and compensate for nanozyme limitations like reduced catalytic activity, specificity, and biocompatibility, tailored for utilization in glucose sensors.

The findings illustrate that by incorporating organic enzyme-based nanoparticles, the electrode can attain outstanding glucose detection capabilities through the utilization of nanotechnology, enabling reduced enzyme dosage, heightened reaction efficiency, and enhanced stability, thus presenting a promising prospect for the future development of a novel blood glucose sensor.

10:15 AM SB06.10.07
MXene-Based 3D-Nanomaterials Printed Wearable System: A Self-Powered Solution for Continuous Physiological Biosignal Monitoring Rahim Esfandyarpour; University of California, Irvine, United States

The development of sustainable, self-powered wearable sensing systems capable of recording physiological biosignals is pivotal for personalized health monitoring, but such devices have remained elusive. In this study, we introduce a novel, self-powered, MXene-based 3D-nanomaterials printed flexible wearable system tailored for continuous, real-time physiological biosignals monitoring. This integrated system combines power-efficient triboelectric nanogenerators (TENG), highly sensitive pressure sensors, and multifunctional circuitry. MXene, a two-dimensional (2D) transition material known for its unique electronegative, conductive characteristics, and triboelectric properties, serves as the foundation of our device and is ideally suited for 3D-printing. We paired MXene with a skin-mimicking Styrene-ethylene-butylene-styrene (SEBS) substrate, which boasts a positive triboelectric characteristic and exceptional stretchability. Our wearable, MXene-based, self-powered physiological sensing system delivers an output power of ~816.6 mW m−2 for its TENGs, with a sensor sensitivity of ~6.03 kPa−1, a low detection limit of ~9 Pa, and a rapid response time of ~80 ms. This makes it possible to continuously monitor the radial artery pulse (RAP) waveform in real-time, without reliance on external power sources. Furthermore, the system's capabilities extend to on-demand RAP monitoring and wireless data and power transmission via near-field communication. This development represents one of the inaugural wearable systems for real-time physiological biosignal monitoring, fully powered by human motion, showcasing its tremendous promise in the field.

10:30 AM SB06.10.08
Artificial intelligence-powered electronic skin for stress monitoring Changhao Xu and Wei Gao; California Institute of Technology, United States

Stress and mental disorders have become a leading contributor to the global burden of disease, especially given that there is a sharp increase in anxiety and depression in the aftermath of the COVID-19 pandemic. While current stress assessment relies on subjective questionnaires and clinical surveys, there is an unmet need for continuous and precise quantification of stress response evaluations. While progress has been made in the development of wearable sensors and continuous health monitoring, these devices can only monitor a limited set of physical signals and suffer from poor operational stability in biofluids. To meet the demand for reliable long-term continuous monitoring and objective stress assessment, we developed a consolidated artificial intelligence-reinforced electronic skin (CARES) platform that deconvolutes the biological mechanism behind stress responses. Integrated with miniaturized iontophoresis module, microfluidic channels and system-level engineering, the platform is capable of monitoring three key vital signs as well as six molecular biomarkers in human sweat. To enable continuous long-term daily monitoring, we developed a general material strategy for biochemical sensors by introducing analogous composite materials into the sensor interface that achieves an unprecedented long-term sweat biomarker analysis of over 100 hours with high stability. The high performance of CARES platform was evaluated through continuous multimodal physicochemical monitoring over 24-hour real-life activities, and can differentiate physiological and psychological stressors, as well as quantification of psychological stress responses with a high accuracy and confidence level. Such fully-integrated CARES platform can be adapted to monitor a broad spectrum of disease diagnosis and pave the way for numerous practical wearable applications such as intelligent healthcare and personalized medicine.

10:45 AM SB06.10.09
Development and Characterization of Flexible PVDF-TrFE-BaTiO3-Ti3C2 MXene-Based Composite Multi-Morphs: towards The Development of Electro-Active Biomedical-Wearable Devices Derek Xiong[1], Kaiyu Vang[1], Parshwa Khane[1], Prakhyat Gautam[1], David Ryman[1], Edbertho Leal-Quiros[2], Saquib Ahmed[3,3] and Sankha Banerjee[1,4]; [1]California State University, Fresno, United States; [2]University of California, Merced, United States; [3]Buffalo State College, United States; [4]University of California, Davis, United States

Lead-based perovskite oxides have been used as sensors, actuators, and transducers, for sound generation and detection, and also in optical instruments and microscopes. Electro-polymers such as PVDF, and PVDF-TrFE based structures have also been used in several applications towards the development of flexible electroactive multi-morph systems for biomedical applications. but the systems have lower piezoelectric strain coefficients as compared to those of their lead-based piezoceramics. Though lead-free-based ceramic and electroactive polymer composites have been explored their property-performance characteristics are not comparable to that of the electro-active ceramics. The following work looks into the fabrication of non-toxic PVDF-TrFE-BaTiO3-Ti3C2 MXene-based lead-free alternatives to perovskite oxides application in stacked biomedical wearable devices. Three-phase, PVDF-TrFE-BaTiO3-Ti3C2 electroactive nanocomposite thin films were fabricated. The volume fraction of the MXene phase was held constant at 1%, while the volume fraction of the BaTio3 phase varied from 20–70%. The dielectric constant, capacitance, impedance, and piezoelectric properties of the samples were measured using an impedance analyzer, and a piezotester. The results were compared as a function of the volume fraction of BaTiO3 to understand the electron transport performance of these thin films. The impedance and dielectric spectra of the nanocomposites were recorded over a frequency range of 20 Hz to 10 MHz. The microstructural properties and cross-section of the thin films were analyzed using a Scanning Electron Microscope. The high sensitivity and electron transport properties of the composite could be potentially utilized in biomedical devices at low- and high-frequency ranges.

DNA-based Immunostimulatory Hydrogel Loaded with Nanoparticle-detained Toxins as a Toxoid Vaccine against Bacterial Infection Zhongyuan Guo, Ronnie H. Fang and Liangfang Zhang; University of California San Diego, United States

Vaccines have been highly successful in protecting against many different types of infections. Unfortunately, there are still many high-priority pathogens for which there are no clinically approved formulations. Recently, nanoparticle-based strategies have been explored for more effective antigen delivery to the immune system. Nanotoxoids are an emerging platform that leverages cell membrane coating technology to safely deliver toxic bacterial antigens in their native form for antivirulence vaccination. In order to further boost their immunogenicity, we have formulated nanotoxoids against staphylococcal α-hemolysin by embedding them into a DNA-based hydrogel with immunostimulatory CpG motifs. The resulting nanoparticle–hydrogel composite is injectable and improves the in vivo delivery of the bacterial toxin while stimulating nearby immune cells. This resulting in elevated antibody production and stronger antigen-specific cellular immune responses. In mouse models of pneumonia and skin infection caused by methicillin-resistant *Staphylococcus aureus*, mice that are vaccinated with our new hybrid vaccine formulation are better protected. Our work highlights the benefits of combining nanovaccines with immunostimulatory hydrogels into a single platform. We believe that the approach can be readily generalized to a range of infectious diseases.

11:15 AM SB06.11.02
Advancing smart materials with cell-free synthetic biology Marilyn Lee; US Army DEVCOM CBC, United States

Cells are a basic building block of biology, but what can transcription and translation processes do when we think outside the cell? Cell-free biological systems provide an open environment that illuminates new opportunities, particularly in field-based sensing, biosynthetic prototyping, and biomaterials science. This presentation will outline progress in scaling and processing of cell-free systems for the functionalization of smart materials, highlighting the advantages of enhanced stability and biosynthesis unbounded by a cellular format. We extend synthetic biology into solvent and heat cast polymer plastics, with potential applications in coatings, wipes, wearables, and personalized hazard detection, and other biologically driven devices.

11:30 AM SB06.11.03
Alginate-based Material System for Medical Applications: From Multipurpose Phantom to Chronic Disease Treatment Haoyi Qiu, Fabian Schuett, Leonard Siebert and Rainer Adelung; Kiel University, Germany

Phantoms are specialized models designed to mimic the properties of human tissue or body structures for use in various medical and healthcare applications. These phantoms are usually made for single application. For example, calibration phantoms usually contain materials with known density, size, or other physical properties e.g., polyethylene, acrylic, and polycarbonate, which can be used in computed tomography (CT), magnetic resonance imaging (MRI), and ultrasound (US) to calibrate the imaging equipment, ensure accurate measurements, and detect potential issues or deviations. They are not applicable for utilization in surgery training. Phantoms for surgery training are usually made from soft materials like silicones, utilized for educational and skill development purposes. They replicate anatomical structures and allow medical students and professionals to learn basic surgical techniques, honing advanced skills, and improving the dexterity and coordination. However, these phantoms exhibit limited suitability for hands-on surgical training. Surgical practice inherently involves destructive procedures, thereby precluding the subsequent reutilization of the phantoms. Materials like silicones owing to their resistance to natural degradation processes, exhibit persistence in the environment over an extended period, thereby constraining its applicability in the context of surgical training. These commercial phantoms have relatively high cost, which limits their use, especially in developing countries.

Another type of phantom is the so-called multipurpose phantom, which integrates multiple imaging modalities and allows for surgery practice within a single construct. For example, these phantoms can be measured under CT and US, after which the students or surgeons can be trained to identify the tumor from the CT and US images and then practice removing the tumor. However, the cost of making such phantoms is usually extremely high due to the materials and complicated fabricating process. In this work, we have developed a facile material system based on alginate and vegetable fat for fabricating the multipurpose phantom. The mechanical, US and CT properties of the materials can be tuned independently to achieve the desired properties of the individual organ and tissue within one material system. The used materials are cheap and easy to obtain even in resource-constrained or developing countries. Moreover, they are 100% vegan, food safe and biodegradable, which is highly suitable for surgery practice that is destructive. These advantages also make it the perfect material system for fabricating patient-specific phantoms for difficult surgery planning and practicing.

In addition to the medical phantoms, the alginate-based hydrogel can be further functionalized with nanoparticles for cardiovascular and musculoskeletal disease treatment. By incorporation of nanoparticles, the injectability or printability of the hydrogels can be modified and the release of the bioactive substances can be achieved under controlled conditions.

Ultrashort Self-Assembling Peptide Hydrogels Provide Mechanical and Adhesive Support for Tissue Engineering and Coral Restoration Manola Moretti, Sherin Abdelrahman, Maria Hountondji, Rui Ge, Panagiotis Bilalis and Charlotte A. Hauser; KAUST, Saudi Arabia

Ultrashort peptides that self-assemble into hydrogel matrices can provide mechanical and adhesion cues by a slight change in their sequence. Here we report two examples of specific sequence designs for tissue engineering and coral restoration applications.
Cells' interactions with their microenvironment influence their morphological features and regulate crucial cellular functions including proliferation, differentiation, metabolism, and gene expression. Most biological data available are based on *in vitro* two-dimensional (2D) cellular models, which fail to recapitulate the three-dimensional (3D) *in vivo* systems. This can be attributed to the lack of cell–matrix interaction and the limitless access to nutrients and oxygen, in contrast to *in vivo* systems. Despite the emergence of a plethora of 3D matrices to address this challenge, there are few reports offering a proper characterization of these matrices or studying how the cell–matrix interaction influences cellular metabolism in correlation with gene expression. In this study, two tetrameric ultrashort self-assembling peptide sequences, FFIK and FIIK, were used to create *in vitro* 3D models using well-described human dermal fibroblast cells. The peptide sequences are derived from naturally occurring amino acids that are capable of self-assembling into stable hydrogels without UV or chemical cross-linking. Our results showed that 2D cultured fibroblasts exhibited distinct metabolic and transcriptomic profiles compared to 3D cultured cells. The observed changes in the metabolomic and transcriptomic profiles were closely interconnected and influenced several important metabolic pathways including the TCA cycle, glycolysis, MAPK signaling cascades, and hemostasis. Data provided here may lead to clearer insights into the influence of the surrounding microenvironment on human dermal fibroblast metabolic patterns and molecular mechanisms, underscoring the importance of utilizing efficient 3D *in vitro* models to study such complex mechanisms.

Coral reef survival is threatened globally. One way to restore this delicate ecosystem is to enhance coral growth by the controlled propagation of coral fragments. To be sustainable, this technique requires the use of biocompatible underwater adhesives. Hydrogels based on rationally designed ultrashort self-assembling peptides (USP) are of great interest for various biological and environmental applications, due to their biocompatibility and tunable mechanical properties. Implementing superior adhesion properties to the USP hydrogel compounds is crucial in both water and high ionic strength solutions and is relevant in medical and marine environmental applications such as coral regeneration. Some marine animals secrete large quantities of the aminoacids dopa and lysine to enhance their adhesion to wet surfaces. Therefore, the addition of catechol moieties to the USP sequence containing lysine (IIZK) should improve the adhesive properties of USP hydrogels. However, it is challenging to place the catechol moiety (Do) within the USP sequence at an optimal position without compromising the hydrogel self-assembly process and mechanical properties. Here, we demonstrate that, among three USP hydrogels, DoIIZK is the least adhesive and that the adhesiveness of the IIZDoK hydrogel is compromised by its poor mechanical properties. The best adhesion outcome was achieved using the IIZKDo hydrogel, the only one to show equally sound adhesive and mechanical properties. A mechanistic understanding of this outcome is presented here. This property was confirmed by the successful gluing of coral fragments by means of IIZKDo hydrogel that are still thriving after more than three years since the deployment. The validated biocompatibility of this underwater hydrogel glue suggests that it could be advantageously implemented for other applications, such as surgical interventions.

10:30 AM SB06.05.03
Living Material Architecture as the Reciprocal Interactions Between Materials and Embedded Cells Salman Karim and Nakhiah Goulbourne; University of Michigan, United States

The interface between biomaterials and synthetic biology leads to engineered living materials that have superior properties such as tunability, programmability, growth, self-healing, disturbance sensing, and adaptation to their surroundings, etc. This three-dimensional interaction between cells and hydrogels made from synthetic polymers or nature-derived biopolymers gives rise to a smart, complex, dynamic, and stimulus-responsive system which opens up a new frontier for tissue engineering, regenerative medicine, self-healing materials, and sustainable building materials. However, the engineering of living materials is still in its infancy as the control of the properties including mechanical properties such as elasticity, stiffness, plasticity; swelling behaviour, microscale architecture, biological signalling, response sensitivity, stability, and deformation etc, is not well understood. Additionally, advancements in the 3-D printing, manufacturing, and assembly of material architecture are required to engineer functional materials. Our focus is on the engineering of load-bearing structures by cell embedding during scaffold fabrication using 3-D bioprinting in a spatially organised manner. An attempt has been made to engineer living materials of distinctive chemical and physical living structures by developing algae-laden hydrogel motifs to gain mechanistic insights into their morphology, pattern formation, and stability. The encapsulation of microalgae *Chlamydomonas reinhardtii* in 3D hydrogel scaffolds with predesigned geometries was carried out to examine different parameters such as material composition and its effect on bioprinting structures, mechanical properties of hydrogel such as swelling and stability in culture, pattern geometry, cell survival during the plotting, cell viability and growth by measuring oxygen release and chlorophyll, spatial distribution of cells within the matrix, and build structure stability. Further, the relationship between printing parameters and plotting material composition will be tested. Overall, the purpose of this study is to identify the mechanism of failure in 3-D living materials by identifying the role of algae-hydrogel interactions during the growth, stability, and deformation of *Chlamydomonas reinhardtii* in a hydrogel medium. The results from this study will facilitate the transition from microscale to macroscale living architecture.

Enabling Atomistic Modeling and Simulation of Complex Lipid Structures and Cellular Membranes with xMAS Builder Noah Trebesch and Emad Tajkhorshid; University of Illinois, United States

As more powerful HPC resources are becoming available, there is a new opportunity to bring the unique capabilities of molecular dynamics (MD) simulations to cell-scale systems. Lipid bilayers forming cellular and organelle-level membranes are ubiquitous within cells and are responsible for a diverse set of essential biological functions, but building atomistic models of cell-scale membranes for MD simulations is immensely challenging because of their vast sizes, complex geometries, and complex compositions. To meet this challenge, we have developed xMAS Builder (E**x**perimentally-Derived **M**embranes of **A**rbitrary **S**hape **Builder**), which is designed to take experimental lipidomics and structural (e.g., electron microscopy and tomography) data as input and use them to build MD-ready models of cellular membrane systems. To test xMAS Builder's capabilities, we have used it to build two large models (each ~12.0 million atoms) of a test system with a representative complex lipid composition and geometry. The two models, which differed only in their lipid packing densities, both maintained their membrane integrity during an extended MD simulation (on the order of 100s of nanoseconds), but their highly divergent relaxation dynamics indicate that the proper packing density of curved membranes is determined by leaflet volume rather than surface area. These results suggest that xMAS Builder's algorithms produce high quality models and that simulation of these models will provide profound biophysical insights into the behavior of cellular membranes.

11:00 AM SB07.01.02
Coarse-Grained Simulation of RNA-Containing Lipid Nanoparticle Self-Assembly via Dissipative Particle Dynamics Douglas Grzetic[1], Nick Hamilton[1,2] and John Shelley[1]; [1]Schrodinger Inc., United States; [2]The University of Vermont, United States

Ionizable lipid-containing lipid nanoparticles (LNPs) have enabled the delivery of RNA for a range of therapeutic applications. In order to optimize safe, targeted and effective LNP-based RNA delivery platforms, an understanding of the role of composition and pH in their structural properties and self-assembly is crucial, yet there have been few computational studies of such phenomena. Here we present a coarse-grained dissipative particle dynamics model of ionizable lipid and mRNA-containing LNPs. Our model allows access to the large length- and time-scales necessary for LNP self-assembly, and is automatically mapped and parameterized with reference to all-atom structures and simulations of the corresponding components at compositions typical of LNPs used for mRNA delivery. Our simulations reveal insights into the dynamics of self-assembly of such mRNA-encapsulating LNPs, as well as the subsequent pH change-driven release of mRNA.

11:15 AM *SB07.01.03
Dynamics of Fluid Bilayer Membranes: Insights from GUV Flickering and Electrodeformation Petia M. Vlahovska; Northwestern University, United States

A lipid bilayer is the main component of the membranes that envelope cells and cellular organelles. While the fluidity of the bilayer is known to control lateral mobility of embedded biomolecules, its importance in membrane shape transformations is less appreciated. In this talk, I will discuss the significant role played by membrane viscosity in the bending dynamics of highly-curved structures such as liposomes and sub-cellular organelles. We extend the model of Seifert and Langer [Europhys. Lett, 1993] for the dynamics of a planar viscous bilayer to a quasi-spherical vesicle. The theory predicts a slower relaxation rate, ~q^4, for a spherical harmonic mode q, a drastic change from the classic result ~q^3. Flickering spectroscopy, which is the analysis of experimentally recorded thermally-driven shape fluctuations of giant vesicles (GUVs), confirm the theoretical results in the case of phospholipid/cholesterol mixtures and, for the first time, demonstrate that membrane viscosity slows down bilayer undulation dynamics giving the appearance of an effectively stiffer membrane. For scattering techniques such as Neutron Spin Echo, the theory predicts an anomalous diffusion exponent of 1/2 governing the Dynamic Structure Factor instead of the commonly used 2/3 [Zilman and Granek, Phys. Rev. Lett. (1996)]. Furthermore, we extend the theory to viscoelastic membranes motivated by the flickering dynamics of block-copolymer vesicles and recent electrodeformation experiments that show a two-time scales response, consistent with Kelvin-Voigt viscoelastic material, in the transient ellipsoidal deformation induced by an applied uniform AC electric field of DMPC vesicles near the melting transition.

This research was supported by NIGMS award 1R01GM140461

11:45 AM SB07.01.04
Impact of Structurally Active Lipids on Lipid Nanoparticle Delivery Processes Lining Zheng and Cecilia Leal; University of Illinois, United States

RNA therapeutics have the potential to treat many diseases that are not targetable by small molecules. One of the biggest challenges in RNA therapy is RNA delivery. Lipid nanoparticles(LNPs) is one of the most successful RNA delivery systems to date, however the delivery efficiency of LNP systems is still hindered by inefficient endosomal escape. How LNPs impact the endosomal escape process is still poorly understood. In this work, we explore how structurally active lipids that can form bicontinuous cubic and inverse hexagonal phases impact the properties of active model endosomal membranes, to better understand the change of endosomes when lipids from LNPs diffuse into the endosomal membrane. We formed giant unilamellar vesicles (GUVs) with different molar percentages of structurally active lipids, and with fluctuation analysis showed that the bending modulus of the membrane reduces with the increase in structurally active lipid content. The presence of membrane protein can greatly impact endosomal membrane properties, so GUVs with V-ATPase, a membrane protein that is essential to the endosomal escape process, were also formed to model active endosomal membranes.

SESSION SB07.02: Phase Separation in Lipid Materials and Membranes
Session Chairs: Elizabeth Kelley and Cecilia Leal
Tuesday Afternoon, April 23, 2024
Room 439, Level 4, Summit

1:45 PM *SB07.02.01
Liquid-Liquid Phase Separation in Membranes is a Product of Universal Material Properties and Specific Biological Functions Sarah Keller; University of Washington – Seattle, United States

Many lipid membranes reversibly phase separate to form large (micron-scale) liquid domains. These systems vary widely, from simple membranes

composed of only three lipid types to complex membranes of living yeast cells or giant plasma membrane vesicles. Independent of the source of the phase-separating membrane, the size, shape, and behavior of the resulting liquid domains is governed by the membrane's material properties and the physical conditions under which it is held. For example, small domains in flaccid vesicles grow larger as membrane tension increases and as temperature decreases. Similarly, the temperature at which a membrane undergoes liquid-liquid phase separation is influenced by its lipid composition and the surfaces it touches. In simple membranes, these experimental conditions are imposed by researchers. In contrast, yeast cells actively regulate their lipid composition to achieve a particular biological outcome, namely, to maintain an offset between their growth temperature and their membrane transition temperature.

2:15 PM *SB07.02.02
Monolayer Domain Shapes - Equilbrium or Kinetically Controlled? Joseph A. Zasadzinski[1], Cain Valtierrez-Gaytan[1], Zachary McAllister[1] and Benjamin Stottrup[2]; [1]University of Minnesota, United States; [2]Augsburg University, United States

Lateral phase separation of lipid monolayers and bilayers into domains of different composition or local order is the basis of the "raft" hypothesis of cell membrane organization in which sub-micron domains, or rafts, of different local composition or order nucleate and grow from a continuous phase within the cell membrane. These physical and chemical inhomogeneities within the membrane provide sites for multiple different proteins to localize and carry out complex cell functions. Phase separation and domain formation is also important to the dynamic spreading and surface tension lowering ability of native and clinical lung surfactants (LS) used to treat neonatal respiratory distress syndrome (NRDS) in premature infants.
The relative simplicity of two-dimensional lipid monolayer films makes them ideal systems to study the fundamental issues that govern lateral phase separation, the evolution of domain microstructure, and the effects of this microstructure on interfacial dynamics. Here we show that a myriad of domain morphologies that occur during monolayer compression are the result of the classic Mullins-Sekerka growth instability (1) that occurs during crystallization from a multicomponent melt. On compression of dipalmitoylphosphatidylcholine-hexadecanol (DPPC-HD) monolayers with 1-5 mol% cholesterol, originally circular domain develop finger-like growth patterns as the surface pressure is increased. The finger widths and number vary with compression rate and quench depth with semi-quantitative agreement with the predictions of the Mullins-Sekerka theory. The Mullins-Sekerka theory postulates a diffusion front instability that predicts that the finger widths are set by a balance between line tension, crystallization rate, and the local variation in chemical potential between crystal and melt. The fingers are purely kinetically driven but eventually evolve into equilibrium extended stripe domains whose width depend only on surface pressure and temperature. The stripe width in independent of the route by which the morphology is approached, suggesting thermodynamic equilibrium. These observations help explain the wide variety of domain shapes observed in lipid monolayers that depend on compression rate and monolayer history.

2:45 PM SB07.02.03
Tiny Forces from Flow Transport Membrane Proteins on Cell Surfaces Aurelia Honerkamp-Smith; Lehigh University, United States

Many cells sense and respond to flow in their environment, and flow responses regulate important physiological processes such as blood pressure. A paradox in cardiovascular flow sensing is that shear forces applied by blood flow are extremely small, and it is currently unknown how cells detect them. We propose a mechanical solution to this problem: lipid-anchored membrane proteins can be rearranged even by tiny shear forces. We have previously shown that avidin linked to biotinylated lipids in supported membranes forms micron-scale concentration gradients in response to femtonewton-sized shear forces. We observe that in both living cells and glass-supported lipid bilayers, proteins move downstream when flow is on, forming a concentration gradient, and that the gradient disappears when the flow is turned off. This gradient is responsive to flow magnitude and direction and disappears when flow stops. We estimate protein diffusion constants and hydrodynamic areas by observing the gradient dynamics. Our recent work demonstrates the sensitivity of our method for measuring these forces, allowing us to correlate hydrodynamic force with the folded shape of lipid-anchored proteins, distinguish membrane drag on different lipid anchors, and demonstrate that similar protein transport can occur on the surface of living cells. Our results support the hypothesis that lateral transport of membrane proteins may contribute to flow sensing.

3:00 PM BREAK

3:30 PM *SB07.02.04
The Biophysical Tight Rope of Cell Membranes: Lessons Learned from Extreme Lipidome Adaptation in The Deep Ocean Itay Budin; University of California, San Diego, United States

Lipid bilayers are the universal structure of all cell membranes and depend on the propensity of specific phospholipid classes to form fluid lamellar phases. However, no biological membranes are composed entirely of bilayer-forming lipids, instead balancing species with low and high intrinsic curvatures. I will describe how this dynamic plays out in organisms that have adapted to hydrostatic pressure, which increases by 1 atmosphere every 10m in the water column. Small angle x-ray scattering of lipid suspensions from deep sea comb jellies (ctenophores) collected at depths up to 4km revealed a remarkable ability to access non-lamellar lipid phases, which are inhibited by pressure. Lipidomic analysis across a wide range of species identified phospholipids with large, negative spontaneous curvature as a depth-specific adaptation across the phylum. High pressure molecular dynamics of lipidome-derived bilayers supports this adaptation. Using engineered bacterial strains, we found that lipid spontaneous curvature can modulate pressure tolerance. Based on these results, we propose a homeocurvature adaptation model for cell membranes, in which the effect of pressure on lipid shape can contribute to both fitness and specialization in the deep oceans.

4:00 PM SB07.02.05
Nanoscale Molecular Organization in Polymer-Lipid Hybrid Systems using Cryo-Electron Microscopy Analysis of Nanoparticles (NPs) Nurila Kambar and Cecilia Leal; University of Illinois at Urbana-Champaign, United States

Membranes play an essential role in diverse engineering fields such as biomedicine, energy generation and water treatment. Thus, development of new types of membranes with tailored properties has been an active area of research. Two–component hybrid materials where phospholipid (PL) membrane stacks are hybridized with synthetic block copolymers (BCP) are of great interest due to their ability to combine the unique properties of two different materials. Hybrid membranes can demonstrate a wide range of self-assembled structures and properties that can be tailored to specific applications. The nanoscale arrangement of hybrid membranes into distinct lateral domains with varying structures and compositions is considered crucial for membrane functionality. The precise understanding of this organization has been challenging, primarily due to the absence of direct methods for probing nanoscale membrane features. Utilizing machine learning for the domain analysis of hybrid multilamellar nano-sized vesicles in cryo-TEM images, we are able to precisely generate detailed high-resolution 2D thickness maps of the membranes. These maps provide insights into the distribution of polymer-rich, lipid-rich, and well-mixed domains within the vesicles. Despite the optical microscopy indicating homogeneous mixing in the hybrid membranes, we reveal the coexistence of two distinct membrane structures within homogeneously mixed lipid-polymer hybrid vesicles. In this study, we highlight the significance of our semi-automated technique for directly iamging nanodomains in both biomimetic and biological membranes.

SESSION SB07.03: New Structures in Lipid Materials and Membranes

Wednesday Morning, April 24, 2024
Room 439, Level 4, Summit

9:00 AM *SB07.03.01
From 2D to 3D: Non-Trivial Membrane Transformation in a Flat World Irep Gozen; Oslo University, Norway

Synthetic cell studies conventionally focus on freely suspended lipid compartments, e.g. micelles and vesicles. This approach is simple and largely satisfactory, but misses the full potential of the 2D fluidic lipid material. On many solid interfaces, non-trivial transformations of biomembrane assemblies occur autonomously. Lipid membrane patches develop into a variety of astonishing morphologies, ranging from unilamellar compartment networks interconnected with nanotubes to densely packed microbial colony-like structures.
In my talk, I will explain how we exploit the tiny energy gain arising from contact of molecular lipid films with solid interfaces to drive the transformation from 2D to 3D assemblies, their architecture, communication and transport properties. The presentation will highlight the implications of the new findings for synthetic cell design, and argue that materials properties-driven autonomous processes on solid interfaces might have had a greater role in the development of life than currently considered.

9:30 AM SB07.03.02
Lipid Cubic Phase Films: Fundamentals and Applications Adam Squires; University of Bath, United Kingdom

We present work on films of lipid cubic phases: 3D periodic nanomaterials that spontaneously self-organise in the presence of water. We form these films at the solid-liquid and solid-vapour interface, and probe their structures using grazing-incidence small-angle X-ray and neutron scattering. We present fundamental work understanding the orientation of the films; and show how we use them in different applications, including templates for high area metal nanomaterials, matrices for biosensors, and as a method to probe curvature-driven localisation of membrane-incorporated molecules.

9:45 AM SB07.03.03
Molecular Structure and Dynamics of Lipid Nanoparticles via Small-Angle Scattering Shayna Hilburg and Lilo D. Pozzo; University of Washington, United States

Lipid nanoparticles have revolutionized human health outcomes, as evidenced by the mRNA vaccines used to combat COVID-19. Despite the success of these self-assembled nucleic acid therapeutics, the physicochemical fundamental properties of the non-viral delivery vectors must be better understood to be more easily tuned and optimized. In this work, we use small-angle X-ray (SAXS) and neutron scattering (SANS) to provide a nanoscale picture of the lipid nanoparticles. Specifically, we investigate how the environmental changes lipid nanoparticles experience during storage and delivery and the fundamental properties of macromolecular cargo impact particle structure and dynamics. The effects of lipid charge state and nucleic acid properties are studied through static SAXS and SANS measurements as well as time-resolved SANS, which provides insight into molecular exchange. Such information demonstrates what drives degradation in storage, what parameters can be changed to improve component dissociation allowing more efficient endosomal escape, and how nucleic acid properties can impact lipid formulation selection.

10:00 AM BREAK

10:30 AM SB07.03.04
How an Extra Terminal Group on Fatty Acids Leads to The Formation of Nanostructured Langmuir Films? Honghu Zhang[1], Benjamin M. Ocko[1], Alexei V. Tkachenko[1], Guangcui Yuan[2] and Sushil K. Satija[2]; [1]Brookhaven National Laboratory, United States; [2]National Institute of Standards and Technology, United States

A characteristic of fatty acids (FAs) covalently associated with fur and hair is two terminal methyl groups rather than the single methyl group found in simple FAs. When these FAs form Langmuir monolayers, the geometric constraint of the extra methyl group leads to periodic lateral nanostructures, a feature that doesn't appear in simple FAs. To unravel the nature of these nanostructures on aqueous surfaces we use in-situ surface X-ray scattering techniques directly on Langmuir monolayers. In our experiments, we investigate surface films prepared using 19-methyleicosanoic acid (19MEA) at different surface pressures with X-ray reflectivity (XRR) and grazing-incidence small-angle and wide-angle X-ray scattering (GISAXS/GIWAXS) methods. Our in-situ results reveal that interfacial 19MEA molecules self-assemble into two-dimensional (2D) hexagonal lattices of objects that resemble squished half hemispheres with a lateral lattice constant of 40-50nm. Surprisingly, this length uncovered by the GISAXS measurements is nearly 100 times that of the molecular width. Complementary GIWAXS studies show that the lateral order between the individual hydrocarbon chains is similar to simple FAs. With increasing of surface pressure, the lattice constant shrinks and the surface roughness measured by XRR increases from that found for simple FAs to a value which is 3 times larger. We have also measured the phase diagram of mixtures of 19MEA with arachidic acid, a simple FA. With increasing of the arachidic acid composition, we have found a cross-over from a hexagonal to a 1D nanostructure. A real-space model and a theoretical framework have been developed to explain the self-assembly behavior of the FAs that have two terminal methyl groups. This combined experimental and theoretical work provides a basis for understanding the unusual nanostructures which form in these simple molecular systems.

10:45 AM SB07.03.05
Nanoscale Confinement of Dip-Pen Nanolithography Written Phospholipid Structures on CuZr Nanoglasses Srivatsan K. Vasantham[1], Evgeniy Boltynjuk[1], Harald Fuchs[2], Horst W. Hahn[1,3] and Michael Hirtz[1]; [1]Institute of Nanotechnology, Germany; [2]Universität Münster, Germany; [3]The University of Oklahoma, United States

In the realm of materials science, nanoglasses have intrigued researchers due to their unconventional properties. However, their interaction with biomaterials and their effects on living cells remain insufficiently understood. Previous studies hinted at proliferation effects, but distinguishing these from other material or topography effects has been challenging. In this research, we explored how nanoglass surfaces interact with phospholipids, crucial components of cell membranes. Our study uncovered a distinctive confinement effect exhibited by nanoglasses on lipid structures patterned with dip-pen nanolithography. Dip-pen Nanolithography with phospholipids (**L-DPN**) utilizes the fine tip of an atomic force microscope, covered with phospholipid mixtures, for writing nanostructures of lipid membranes onto various substrates. These structures are used as probes for the lipid/nanoglass interaction. Our study revealed distinct differences between homogeneous (regular) metal glasses and their nanoglass counterparts of same chemical composition in regard to lipid spreading and membrane organization. Our findings show that nanoglasses interact profoundly different with L-DPN written membranes, which suggests a potential influence on cell membrane structures. The results can shed light on a possible mechanism for their impact on cell behavior and can inform future studies on nanoglass/cell interactions.

SESSION SB07.04: Lipid Nanoparticles for Drug and Gene Delivery

Acid Degradable Lipid Nanoparticles Efficiently Deliver mRNA to The Liver, Lung, Spleen and Multiple Other Organs Niren Murthy[1,2]; [1]University of California, Berkeley, United States; [2]U.C. Berkeley, United States

The development of acid degradable linkers that rapidly hydrolyze at endosomal pHs is a central problem in the field of drug delivery. Acid degradable linkages are challenging to develop because of their instability. In this report we present a new acid degradable linker based on an azide-acetal, which rapidly hydrolyzes at endosomal pHs but has exceptional stability at pH 7.4. The azide-acetal linkage hydrolyzes via a two-step mechanism that requires reduction and acid hydrolysis and has a unique combination of stability and rapid triggerable hydrolysis. The azide-acetal has a hydrolysis half-life of days at pH 7.4 and can be conveniently synthesized and incorporated into delivery vectors, however after in situ reduction with DTT it hydrolyzes with a t1/2<15 minutes at pH 6.0. We used the azide-acetal linker to synthesize acid degradable analogs of the lipid components of lipid nanoparticles and demonstrate that these new lipids are significantly better at delivering mRNA to mice than traditional lipids. Lipid nanoparticles containing acid degradable lipids transfected multiple non-liver organs after an intravenous injection and efficiently transfected brain tissue after an intracranial injection. The azide-acetal linkage has the potential to solve the instability problems associated with acid degradable linkers and has numerous applications in drug delivery.

2:00 PM *SB07.04.02
Preformed Vesicle-Mediated Delivery of Messenger RNA for Retinal Gene Therapy Gaurav Sahay; Oregon State University, United States

Quantitative nucleic acid encapsulation by lipid-based nanoparticles (LNPs) is often thought to be one of the main prerequisites for successful cargo delivery, as the lipid environment protects mRNA from degradation by external nucleases and assists in initiating delivery processes. However, here we report the delivery of mRNA via preformed vesicle approach (PFV-LNPs) that defies this precondition. PFV-LNPs possess superficial mRNA localization that proved exceptionally beneficial in delivering mRNA to the back of the eye. Successful delivery of GFP mRNA to retinal pigment epithelium and photoreceptors was observed in mice, non-human primates, and human retinal organoids. This approach was generally beneficial as indicated by improved EGFP transfection with PFV-LNPs containing benchmark lipids (We posit that the PFV architecture may be beneficial to transfect local targets like the back of the eye. We will also discuss the impact of surface modifications for LNP mediated gene editing.

2:30 PM BREAK

3:30 PM *SB07.04.03
Stimuli-Responsive Liposomes for Triggered Cargo Release and Activated Cell Delivery Michael Best and Jinchao Lou; University of Tennessee Knoxville, United States

Liposomal nanocarriers are effective for the encapsulation and delivery of a wide range of therapeutic cargo in a manner that improves drug pharmacokinetic properties. However, liposome therapeutic properties could be advanced by enhancing control over cell delivery as well as cargo release. This presentation will describe the development of stimuli-responsive liposomes designed to achieve both of these goals. One approach employs synthetic lipid switches engineered to modulate lipid membrane properties upon contact with disease-associated conditions, such as through programmed chemical reactions and/or conformational changes. In particular, we will focus on encapsulated cargo release triggered by the binding of chemical agents/molecules that are commonly upregulated in diseased cells. A second strategy involves chemically triggering of cell entry. In this design, liposomes are masked as neutral carriers until they encounter stimuli that generate cationic lipids, thereby activating cell entry. The presentation will include the design and synthesis of stimuli-responsive lipid switches, analysis of selectivity of cargo release in the presence of different stimuli, investigation of changes to liposome membrane properties, and evaluation of cellular delivery properties triggered by disease-associated stimuli.

4:00 PM SB07.04.04
Poly(N-Vinyl Amide)-Lipid Conjugates as Poly(Ethylene Glycol) Alternatives for The Modification of Lipid-Based Nanocarriers Antoine Debuigne, Manon Berger, François Toussaint, Sanaa Ben Djemaa, Christine Jerome, Anna Lechanteur, Denis Mottet and Geraldine Piel; University of Liege, Belgium

Pegylation of drug nanocarriers, and of lipid-based vectors in particular, is a common strategy to grant them stealth properties and promote their prolonged circulation in the blood stream. However, PEG is also associated to the accelerated blood clearance (ABC) effect, leading to the fast elimination of the medicine from the body, and to the PEG *dilemma*, which consists in uptake issues due to the presence of the polymer layer around the carrier. For these reasons, the search for PEG alternatives in drug delivery systems is timely.
This work explores the potential of poly(*N*-vinyl amide)s, including poly(N-vinyl pyrrolidone) (PNVP), as PEG alternatives for the development of non-toxic, efficient and less immunogenic lipid-based carriers, in particular siRNA-loaded lipoplexes and lipid nanoparticles dedicated to gene therapy.[1,2] For this purpose, novel poly(*N*-vinyl amide)-lipid conjugates were synthesized by reversible deactivation radical polymerization. This strategy allowed to control the molar mass of the hydrophilic polymer sequence and to functionalize its extremity with lipids, such as 1,2-distearoyl-sn-glycero-3-phosphoethanolamine (DSPE), to ensure their anchoring at the surface of the lipid carriers. The surface active properties of these poly(N-vinyl amide)-lipid conjugates and their interaction with phospholipid bilayers were studied by Langmuir film balance and quartz crystal microbalance with dissipation monitoring (QCM-D), respectively. The anchoring of the poly(N-vinyl amide)-lipid compounds at the surface of siRNA-loaded lipid nanocarriers and their ability to prevent protein adsorption were demonstrated by dynamic light scattering, zeta potential and nanoparticles tracking analyses. *In vitro* and *in vivo* studies demonstrated the non-toxicity, stealth properties and transfection efficiency of the accordingly modified siRNA-loaded lipid nanocarriers. Importantly, compared to their pegylated counterparts, lipid nanocarriers decorated by poly(N-vinyl amide)s showed lower immunogenicity in particular after the second injection which constitutes a key step to the development of safer lipid-based carriers.

4:15 PM SB07.04.05
Biodegradable Polymer-Lipid Nanoparticles for Effective *In Vivo* mRNA Delivery Yiyan Yang[1] and James Hedrick[2]; [1]Bioprocessing Technology Institute, Agency for Science, Technology and Research (A*STAR), Singapore; [2]IBM Almaden Research Center, United States

Currently, only 2 mRNA Covid-19 vaccines from Moderna and Pfizer-BioNtech have been approved by the US FDA for human use. Both vaccines utilize SARS-CoV-2 mRNA as the antigen and lipids as the carrier. The lipids consist of 3 different types of lipids (PEG-lipid conjugate, ionizable lipid and helper lipid) and cholesterol. The ionizable lipid condenses mRNA into lipid nanoparticles (LNPs) through electrostatic interaction and self-assembly. The mRNA-loaded LNPs stimulate the immune cells for prophylactic response against the SARS-CoV-2 virus. The use of PEG-lipid (ALC-0159) makes the LNPs unstable *in vivo*, leading to delivery of mRNA primarily to the liver after *i.v.* injection of mRNA LNPs. In this study, we synthesize amphiphilic block copolymers of PEG and biodegradable polycarbonate with varying chain length and urea moiety to replace PEG-lipid conjugate. Urea functional groups are used to form hydrogen-bonding interactions within the LNPs to further increase the stability of LNPs. Luciferase-encoded mRNA is loaded into lipid nanoparticles by using a microfluidic device. Use of amphiphilic polycarbonate block copolymers enhances the stability of mRNA-loaded nanoparticles in serum-containing medium while yielding high transfection efficiency of mRNA in mice. The introduction of polycarbonates alters their biodistribution *in vivo*. The polymer-lipid nanoparticles with enhanced stability may be used to deliver mRNA to T cells for cancer therapy.

4:30 PM SB07.04.06
Membrane Fusion Mediated Drug Loading in Exosomes Hojun Kim; Korea Institute of Science and Technology, Korea (the Republic of)

Exosome-based drug delivery gaining a significant interest from bioindustry. Compared with conventional delivery vehicles, exosomes offer minimized immunogenicity, increased circulation stability, and exceptional permeability across various biological barriers. Such distinct characteristics make exosomes as a promising next-generation delivery platform. Despite of the therapeutic potential, however, there are multiple challenges remained. Among many, drug loading in exosome is recognized as one of the major challenges. This is because current approaches not only show poor drug loading efficiency but lead to side effects such as hemolysis due to foreign components. In addition, the size of therapeutic molecules is also limited with conventional approaches. Therefore, developing a new way of loading technology in exosome is in urgent need.

Here we devised a novel drug loading approach utilizing a highly fusogenic lyotropic liquid crystal nanoparticles. We inspired from the fact that endosome and exosome share its biological origin. Because lipid-based lyotropic liquid crystal nanoparticles are known to easily fuse with endosome, we hypothesized that it can also easily fuse with exosome thereby delivering its cargo. Our synchrotron SAXS and FRET based study revealed that fusion-mediated drug loading shows a high loading efficiency with only innate materials. Our results indicate that the fusion-mediated loading method can be a fruitful approach for exosome therapeutics.

4:45 PM SB07.04.07
Block Polymers of Acryl Derivatives Using Raft Polymerization as PEG Alternatives for mRNA Delivery Hema Choudhary, Rohit Sharma and Niren Murthy; University of California Berkeley, United States

Lipid nanoparticles (LNPs) have emerged as an important class of non-viral delivery methods for mRNA delivery for various applications including, gene editing, vaccine development, and protein replacement therapy. The performance of LNPs is influenced by several factors including stability to proteases, protein absorption, pharmacokinetics, and immunogenicity. Poly (ethylene glycol) (PEG) is the most used polymer in nanomedicine and is a gold standard for improving LNP performance. Nevertheless, this overwhelming use of PEG for biomedical applications is resulting in anti-PEG antibody formation in PEGylated drug-treated patients. This presents an immense challenge in mRNA-based vaccine development and protein replacement therapies which requires muti-dosage delivery over a period. Consequently, there is a great need to explore alternative polymers that mimic the physiochemical properties of PEG.
Here, we present a simple approach to synthesize PEG alternative polymers for mRNA delivery. Our approach involves a synthesis of block polymers with acryl derivatives monomers using a reversible addition–fragmentation chain transfer (raft) polymerization strategy. We have synthesized a library of hydrophilic polymers with various functional groups on the polymer backbone using commercially available monomers such as N-(2-Hydroxypropyl) methacrylamide (HMPA), acrylamide, (Hydroxyethyl)methacrylate as well as in lab synthesized sugar methacrylamides. To test the drug efficacy of these polymers, LNPs were formulated by complexing mRNA with standard lipids (Dlin-MC3, DOPE, cholesterol), and stabilized using our block hydrophilic polymers. These LNP/mRNA complexes were investigated *in-vitro* (HEK293 cells) and *in-vivo* in mice. Data from these studies will be presented in this talk.
We expect these functional groups on the polymer backbone to attribute interesting behavior to the LNPs. In this regard, our mannose-polymer stabilized LNPs showed spleen-targeted delivery of luciferase mRNA in comparison to PEG-stabilized LNPs.

SESSION SB07.05: Poster Session
Session Chairs: Shelley Claridge and Cecilia Leal

5:00 PM SB07.05.01
Angiopep2-Functionalized Lipid Cubosomes for Blood-Brain Barrier Crossing and Glioblastoma Treatment Xudong Cai, Jiali Zhai, Nhiem Tran and Calum Drummond; RMIT University, Australia

Background: Glioblastoma multiforme is an exceptionally aggressive form of brain cancer known for its high malignancy and resistance to traditional treatments, leading to a bleak prognosis for patients. Various treatment methods, such as surgery, radiotherapy, and chemotherapy, have been developed to address brain diseases; however, they often come with significant side effects on healthy tissues. Additionally, delivering drugs from the bloodstream to the brain is hindered by the presence of the blood-brain barrier (BBB). Lipid nanoparticles have gained substantial interest because of their inherent benefits,

including biocompatibility, facile surface functionalization for targeted drug delivery, and improved solubility for poorly soluble drugs. These distinctive features make them promising carriers for bioactive agents to cross the BBB.

Aims: In this study, we have pioneered the development of Ang2-conjugated cubosomes, an approach aimed at enhancing BBB penetration and improving the uptake of glioblastoma cells. Our previous research successfully yielded a range of amphiphilic block copolymers, synthesized through RAFT polymerization, which included polyethylene glycol (PEG), poly(2-(dimethylamino)ethyl methacrylate) (PDMAEMA), and poly(4-(4,4,5,5-tetramethyl-1,3,2-dioxaborolan-2-yl)benzyl acrylate) (PTBA). These polymers served as effective stabilizers for monoolein cubosomes with pH nad H_2O_2 responsiveness. In this study, we selected PEG114-b-PDMAEMA17-b-PTBA9-RAFT polymer to craft Ang2-conjugated monoolein-based cubosomes, loaded with the anti-cancer drugs cisplatin (CDDP) and temozolomide (TMZ), which are known for their poor solubility.

Methods: A comprehensive analysis of these developed nanoparticles was conducted to assess their particle size, surface charge, and internal structures through dynamic light scattering and synchrotron Small-Angle X-ray Scattering. Furthermore, their potential to enhance BBB penetration was evaluated using three in vitro models: a Transwell BBB model based on the hCMEC/D3 human brain endothelial cell line, a 3D hCMEC/D3 spheroid model, and an innovative microfluidic BBB/GBM-on-a-chip model. This microfluidic model featured a unique setup with hCMEC/D3 cells in one channel (representing the blood channel) and U87 glioblastoma cells in an adjacent, interconnected channel (representing the brain channel). This design enabled the simultaneous investigation of the cubosomes' ability to cross the BBB and enter U87 cells. To further evaluate the anticancer effectiveness of CDDP/TMZ-loaded cubosomes, in vitro cytotoxicity studies on U87 glioblastoma cells was conducted.

Results: These developed lipid cubosomes exhibited a particle size of approximately 300 nm, possessed an internally ordered inverse primitive cubic phase, achieved a high conjugation efficiency of Ang2 on the particle surface, and displayed an encapsulation efficiency exceeding 70% for both CDDP and TMZ. We employed various in vitro BBB models, including hCMEC/D3 cell Transwell assays, 3D spheroid cultures, and microfluidic BBB/GBM-on-a-chip models, to evaluate the effectiveness of these cubosomes in crossing the BBB. The results demonstrated that Ang2-functionalized cubosomes exhibited superior BBB penetration. Furthermore, these modified cubosomes exhibited significantly increased uptake by U87 glioma cells, with a notable three-fold enhancement observed in the BBB/GBM-on-a-chip model compared to unmodified cubosomes. Moreover, CDDP-loaded Ang2-functionalized cubosomes exhibited a heightened toxic effect on U87 glioma spheroids.

Coclusion: These findings suggest that the Ang2-functionalized cubosomes hold great promise for improving BBB penetration and enhancing the delivery of therapeutics to glioblastoma.

5:00 PM SB07.05.02
Electrokinetic Enhancement of Membrane Techniques for Efficient Nanoparticle Separation and Enrichment Ji Hyo Park[1,2], Jae Sung Yoon[1,3], Do-Hyun Kang[1], Yeong-Eun Yoo[1,3] and Kwanoh Kim[1]; [1]Korea Institute of Machinery and Materials, Korea (the Republic of); [2]Seoul National University, Korea (the Republic of); [3]University of Science and Technology, Korea (the Republic of)

Separation and preconcentration of colloidal nanoparticles are pivotal in various biomedical applications, notably bioprocessing and biochemical detection. While membrane-based techniques are recognized for their efficiency and versatility, diminishing particle sizes pose challenges such as increased flow resistance, escalated back pressure, and issues with particle retrieval due to adsorption onto membranes. In this study, we introduced an electric field-assisted membrane system, integrating conductive metal-coated membranes. By leveraging the electrokinetic effects from voltage application to the membranes, our system adeptly separated and retrieved nanoparticles even finer than the membrane pores. Experiments with polystyrene nanoparticles demonstrated separation efficiencies surpassing 95% and enrichment factors approaching 1.8 folds within 10 minutes. The pressure drops measured across the membranes were significantly lower than that observed in conventional systems with narrower pore sizes, particularly at elevated flow rates. Moreover, the pressure drop exhibited consistent stability over time, suggesting reduced membrane fouling. This approach offers an energy-efficient, high-throughput method for nanoscale particle separation and enrichment, holding promise for point-of-care diagnostics and progressive biomanufacturing.

5:00 PM SB07.05.03
Diet-Induced Obesity Modulates Close-Packing of Triacylglycerols in Lipid Droplets of Adipose Tissue Kyungwon Ko[1], Sarith R. Bandara[1], Weinan Zhou[1], Leo Svenningsson[2], Marilyn Porras-Gomez[1], Nurila Kambar[1], Julia Dreher-Threlkeld[1], Daniel Topgaard[2], Diego Hernandez-Saavedra[1], Sayeepriyadarshini Anakk[1] and Cecilia Leal[1]; [1]University of Illinois at Urbana-Champaign, United States; [2]Lund University, Sweden

Adipose-derived lipid droplets (LDs) are rich in triacylglycerol (TAGs), which regulate essential cellular processes such as energy storage. Although TAG abundance in adipocytes has been linked to metabolic disorders, including obesity and metabolic syndromes, how LDs dynamically package TAGs in response to excessive nutrients remains elusive. Here, we found that LD lipidomes display a remarkable increase in TAG acyl chain saturation under calorie-dense diets turning them conducive to close-packing. Using high-resolution X-ray diffraction, solid-state NMR, and imaging, we show that beyond size expansion, LDs from mice under varied obesogenic diets govern fat accumulation by packing TAGs in different crystalline polymorphs. Consistently, LD membrane tension and tissue elastic modulus in high-calorie-fed mice doubled compared to normal diet. Our data suggest that in addition to expanding, adipocyte LDs undergo structural remodeling in response to caloric overload, close-packing rigid and highly saturated TAGs. This work could enable the development of new therapeutics for LD-involved pathologies.

5:00 PM SB07.05.04
Outer Membrane Vesicles as a Multicomponent Lyme Disease Vaccine Stephanie Curley, David Krimer and Bennett Beaulieu; Union College, United States

Lyme disease, caused by the bacteria Borrelia burgdorferi (Bb), is the most common vector-borne disease in the United States. It is transmitted by ticks, causing symptoms ranging from mild (fevers, headaches, and the characteristic erythema migrans rash), to severe (arthritis, carditis, and neuroborreliosis) if left untreated. Although mainly prevalent in the northeastern U.S., due to the changing climate, Lyme is expected to become even more widespread in the coming decades. Current treatment is limited to antibiotics, which often do not fully treat the infection. While there previously was an FDA-approved vaccine for human use, it was withdrawn from the market because of low sales due to high consumer cost and unfounded public fear of side effects. Development of a cheap and effective alternative vaccine for Lyme is needed.
Outer membrane vesicles (OMVs), spherical lipid bilayers naturally produced by bacteria, may provide the simple, cost-effective platform necessary to develop an effective Lyme vaccine. OMVs hold a plethora of macromolecules in their membranes that can enhance the immune response to the antigen of interest when co-delivered. There have been two previous studies on an OMV-based vaccine against Lyme Disease using meningococcal OMVs carrying the *Bb* antigen outer surface protein A (OspA). However, research suggest that a multi-antigenic approach for Lyme disease vaccination may be crucial for proper immune recognition.
Here, we investigated whether Lyme antigens could be effectively expressed on the surface of OMVs derived from a strain of Clearcoli that have been genetically modified to hypervesiculate. Bacterial surface protein cytolysin A (ClyA) was used as a fusion partner to assist in surface presentation of the

antigen proteins. Three outer surface proteins from Bb (RevA, OspC, and OspA) were successfully expressed as fusion partners to ClyA, as shown by SDS PAGE and western blot. After efficient expression was confirmed, OMVs expressing ClyA-Lyme antigen fusion proteins were produced from Clearcoli. OMVs expressing fusion proteins were evaluated using dynamic light scattering, and showed an average size of ~140 nm, which is slightly larger than OMVs that did not contain the fusion proteins. Furthermore, surface presentation of the ClyA-Lyme antigen proteins was confirmed using the protease accessibility assay. Future work will focus on evaluating the adaptive immune response of these vaccine platforms an animal model.

5:00 PM SB07.05.05
Bioinspired Glycolipids - Applications for Mitigating Airborne Dust Pollution Damask Grinnell, Taehee Lee, Raina Maier, David Hogan and Minkyu Kim; The University of Arizona, United States

Airborne dust particulates are a major constituent of total atmospheric pollution affecting global environmental and human health that must be urgently mitigated. Particulate matter (PM) with diameter < 10 μm is deeply inhaled into the lungs, causing significant human health risks particularly for cardiovascular and respiratory health. PM is also environmentally harmful, affecting global biogeochemical cycles, polluting water bodies and air masses, and impacting global climate. Control of fugitive dust emissions is a major operational challenge to various industries including construction, agriculture, transportation, energy, and mining. Previous dust suppressant materials have included amphiphilic synthetic polymers as water additives, which interact with dust particles after water evaporation due to their amphiphilic properties and encourage particle agglomeration, thus suppressing dust generation. However, these synthetic polymers and other conventional dust suppressant materials have short-term effectiveness, are corrosive to machinery, and increase toxicity concerns to both humans and the environment.

Herein, bioinspired glycolipids are being investigated as alternative dust suppressants to conventional amphiphilic polymers. Glycolipids are naturally-occurring molecules consisting of sugar and lipid moieties, thus making them amphiphilic molecules with both hydrophobic and hydrophilic properties. While glycolipids can be extracted from bacterial membranes, there are issues with batch size and ill-defined and inconsistent mixtures, causing further problems for quality control. By synthetically manufacturing glycolipids, quality control issues are mitigated, and the processing provides the ability to modify their molecular structures and physiochemical properties.

We have investigated the relationship between dust suppression performance and molecular structures of glycolipids by varying (1) sugar head type, (2) sugar head number, (3) lipid tail length and (4) lipid tail number. Static and dynamic characterization methods have revealed that specific sugar heads, lipid tail lengths, and number of sugar heads/lipid tails influence the self-assembled structures of glycolipids and their interactions with dust particles, resulting in enhancing or diminishing of dust suppression capabilities. Specifically, glycolipids with single rhamnose and xylose sugar head demonstrated up to 90% better dust suppression performance compared to the water control, and both types also produced further enhanced dust suppression properties as their lipid tail lengths increased. Furthermore, those glycolipids with double lipid tails demonstrated excellent dust suppression performance > 95% better than the water control, indicating that the addition of a second lipid tail may enhance the wetting interaction of the glycolipids with small particles. This was further investigated through ATR-FTIR, DLS and SEM, and specific details will be discussed. Additionally, thermal characterization via DSC shows that several glycolipid types undergo a phase change to liquid at approximately 50°C and maintain the liquid phase at normal temperature. Our previous work with liquid amphiphilic polymers has shown that they are highly effective dust suppressants because their liquid phase facilitates more efficient physical interactions between the polymer and small particles, and this glycolipid phase change mechanism appears to follow a similar mechanism to those previously observed.

This work presents that bioinspired glycolipids are promising dust suppressant materials, and the ability to tune their molecular structures allows us to further enhance their dust suppression performance. Our findings are expected to facilitate the development of highly-efficient glycolipid structures to effectively reduce airborne dust levels contributing to enhanced human health and environmental safety.

SESSION SB07.06: Lipid Materials and Membranes in Living Systems
Session Chairs: Aurelia Honerkamp-Smith and Cecilia Leal
Thursday Morning, April 25, 2024
Room 439, Level 4, Summit

9:00 AM *SB07.06.01
How to Build a Synthetic Virus without a Living Host for Vaccination Susan Daniel[1], Neha Kamat[2], Hector Aguilar-Carreno[1], Ekaterina Selivanovitch[1], Vivian Hu[2] and Shahrzad Ezzatpour[1]; [1]Cornell University, United States; [2]Northwestern University, United States

There are 1.6 million mammalian and waterfowl viruses (Bull.WHO, 2018; 96:292). Even though only a miniscule set of these are known to infect humans, the potential that additional zoonotic viruses exist is high. Moreover, the natural evolution of viruses is rapid and hard to predict. Our best defense against viral illness is to train our immune system to recognize a threat before we are exposed to it. While vaccines address this need, we are largely ill-prepared to design, manufacture, and distribute vaccines rapidly during a pandemic outbreak. To stay abreast of viral threats, we must transform our approach to vaccine science and engineering. mRNA vaccines are one approach, as are “virus-like particle (VLP) vaccines. Our team takes another approach; we use synthetic biology and engineering to build a proteo-lipid nanoparticle vaccine that is easy to synthesize, tunable in antigen(s) presentation, nonvirulent, and eliminates cell production currently required to generate both VLP vaccines or the expression of the antigen from mRNA lipoparticles. We have achieved the successful cell-free synthesis of Nipah virus viral coat proteins embedded into lipid vesicles using our synthetic biology approach and show that the nanoparticles we created elicit neutralizing antibodies in mice. We have also successfully synthesized into lipid vesicles the full transmembrane Spike protein from coronavirus and hemagglutinin from influenza into lipid nanoparticles using cell-free approaches. This synthetic approach enables molecular-level modification that can be guided by computational and data-driven design approaches, leading to a modular approach to vaccine optimization. New insights into fundamental mechanisms of immune response will be enabled by unprecedented homogeneity of the particle structure possible with this approach.

Probing The Physical Properties of Therapeutic Carriers that Modulate Uptake by Clathrin-Mediated Endocytosis Grant Ashby and Jeanne C. Stachowiak; The University of Texas at Austin, United States

Cell surface receptors facilitate signaling and nutrient uptake. These processes are dynamic, requiring receptors to be actively recycled by endocytosis. Due to their differential expression in disease states, receptors are often the target of drug-carrier particles, which are adorned with ligands that bind specifically

to receptors. These targeted particles are taken into the cell by multiple routes of internalization, where the best-characterized pathway is clathrin-mediated endocytosis. Most studies of particle uptake have utilized bulk assays, rather than observing individual endocytic events. As a result, the detailed mechanisms of particle uptake remain obscure. To address this gap, we have employed a live-cell imaging approach to study the uptake of individual liposomes as they interact with clathrin-coated structures. By tracking individual internalization events, we find that the size of liposomes, rather than the density of the ligands on their surfaces, primarily determines their probability of uptake. Interestingly, targeting has the greatest impact on endocytosis of liposomes of intermediate diameters, with the smallest and largest liposomes being internalized or excluded, respectively, regardless of whether they are targeted. These findings, which highlight a previously unexplored limitation of targeted delivery, can be used to design more effective drug carriers. Our ongoing work is examining the coupling between multiple physical parameters – size, targeting, rigidity, surface charge – during individual particle uptake events, toward a better understanding of the design space for effective particle-based delivery of therapeutics to cells.

Smart Blood: Red Blood Cell based Drug Carriers Maikel Rheinstadter; McMaster University, Canada

The era of one-disease-one-pill is long gone. We are now tackling complex diseases such as Alzheimer's disease, cancer, and infectious diseases. With moderate progress, it has become clear in recent years that complex diseases require sophisticated solutions. A significant hurdle in this process is the effective delivery of drugs to specific targets within the patient's body to increase the drug's efficacy and reduce the side effects common with conventional drugs. To accomplish this goal, drugs are encapsulated in or conjugated to nanocarriers and selectively delivered to their targets. Potential applications include immunization, delivering anti-cancer drugs to tumors, antibiotics to infections, targeting resistant bacteria, and delivering therapeutic agents to the brain. Despite this great promise and potential, drug delivery systems have yet to be established, mainly due to their limitations in physical instability and rapid clearance by the host's immune response. Recent interest has focused on using red blood cells (RBC) as drug carriers due to their naturally long circulation time, flexible structure, and direct access to many target sites. This includes coating nanoparticles with the membrane of red blood cells and the fabrication and manipulation of liposomes made from the red blood cells' cytoplasmic membrane. The properties of these erythrocyte liposomes, such as charge and elastic properties, can be tuned through the incorporation of synthetic lipids to optimize physical properties, loading efficiency, and retention of different drugs. Specificity can be established through the anchorage of antigens and antibodies in the liposomal membrane to achieve targeted delivery. Although still at an early stage, this erythrocyte-based platform shows promising results in vitro and in animal studies. A large part of the challenge is related to material science, involving the manipulation of biological materials at the molecular level. I will review the current status and recent progress in the field.

11:00 AM SB07.06.04
Erythro-PmBs: A Selective Polymyxin B Delivery System using Antibody-Conjugated Hybrid Erythrocyte Liposomes Hannah Krivic, Sebastian Himbert and Maikel Rheinstadter; McMaster Unviersity, Canada

Due to the growing worldwide antibiotic resistance crisis, many currently available antibiotics have become ineffective as bacteria develop resistance mechanisms. Only a limited number of potent antibiotics can successfully suppress microbial growth; however, these are often considered a last resort due to their toxicity. We have developed a novel PmB delivery system by conjugating hybrid erythrocyte liposomes with antibacterial antibodies to combine high loading efficiency with targeted delivery [1,2]. The retention of PmB is enhanced through the incorporation of the negatively charged lipid, DMPS, into the red blood cell's cytoplasmic membrane through electrostatic interactions. Molecular dynamics (MD) simulations reveal an optimal fraction of DMPS in the hybrid erythrocyte membranes that allows for complete anchorage of PmB by inserting their acyl tail into the hydrophobic membrane core. Anti-Escherichia coli antibodies are attached to these hybrid erythrocyte liposomes using DSPE-PEG maleimide linkers. Our studies demonstrate that these erythro-PmBs have a loading efficiency of approximately 90% and effectively deliver PmB to E. coli, with minimum inhibitory concentration (MIC) values comparable to those of free PmB. However, the MIC values for Klebsiella aerogenes significantly exceeded the resistance breakpoint, indicating that the inclusion of anti-E. coli antibodies enables erythro-PmBs to selectively transport antibiotics to specific targets. MD simulations further suggest a fusion or lipid exchange mechanism between erythro-PmBs and the outer membrane of E. coli.

How Anisotropic Surface Chemistry Changes The Nano-Biomembrane Interaction: From Janus Nanoparticles to Viruses Yan Yu; Indiana University-Bloomington, United States

The non-uniform surface chemistry is ubiquitous for both naturally occurring and engineered nanoparticles. Microbes, such as viruses, are known to have anisotropic presentation of proteins on their surfaces. Engineered nanoparticles are often designed to have heterogeneous surface chemistries to enable novel applications. How does the anisotropic chemistry of nanoparticles impact their interactions with biological membranes and cells? More importantly, can we take advantage of the anisotropic surface chemistry to reverse-engineer nano-bio interactions? In this talk, I will present my group's recent research progress toward addressing those questions. On the one hand, using engineered "two-faced" Janus nanoparticles with different surface chemistries on two hemispheres, we demonstrated that spatially separating charges and hydrophobicity on the nanoparticles renders them more potent in perforating lipid membranes and thereby in killing a broad range of bacteria. On the other hand, using non-enveloped viruses, we found that the partial hydrophobicity on the viral capsid enables the viruses to deform and penetrate the lipid membrane, leading to their infection of host cells. Our studies from both living and non-living worlds provide direct evidence that the spatial distribution of surface functionalities, rather than just its overall surface chemistry, on a nanoparticle, plays a crucial role in determining its interaction with biomembranes.

11:45 AM SB07.06.06
Multicellular Lipid Compartments for Scalable Micro-Compartmentalization with Environmentally Responsive Release. Richard Archer, Tsuyoshi Inaba and Shin-Ichiro M. Nomura; Tohoku University, Japan

Smart drug release systems have gained attention as a method of using existing medicines in a more effective manner. However, topically applied medicines still rely on uncontrolled diffusion for delivery. Here we propose the use of multicellular lipid compartments (MCLCs) to encapsulate, regulate and control the release of encapsulated drugs. MCLC systems are lipid-based, semi-solid, high internal phase emulsions (HIPEs) with an aqueous dispersed phase pressed into tightly bound micro-compartments with a multicellular-like morphology. The resulting micro-compartments are typically between 20-200 µm and delineated by a continuous lipid-hybrid membrane. The lipid membranes show high stability over months of observations and have semi-

permeable properties, allowing water and other small molecules across while retaining larger target molecules. MCLC systems are easily formed on milliliter scales within seconds from desired aqueous solutions by simple application of “lipid-inks”. These lipid-inks are formed from a mixture of natural phospholipids, commercial surfactants, and oils. We show that phospholipids play a crucial role in driving the distinctive cellular morphologies while the surfactants help increase the stability of the system.
To create properties for real-world applications, we encapsulate MCLC systems within polysaccharide hydrogels to improve their stability and enable their use as practical, tangible devices. Using these MCLC-hydrogels we demonstrate the release of the encapsulated contents into external aqueous environments using membrane solubilization strategies. Release rates from the membrane are shown to be related to compartmentalization conditions due to sequential membrane breakdown. Additionally, we show membrane breakdown can be triggered and enhanced by introducing ionic species, leading to environmentally sensitive release conditions. The compartmentalization strategy also allowed for heterogenous cellular mixing, creating single MCLC systems consisting of multiple different types of separated drugs, and multiple release conditions leading to multi-step or sustained delivery outputs. We believe this work could lead to medical patches for smart and customizable trans-dermal drug delivery. Their environmental sensitivity could lead to smart-release capabilities capable of modulating drug release depending on skin conditions, further increasing their effectiveness by introducing conditional delivery.
Beyond drug delivery, we also hope to develop MCLC systems into simple cell models, communicating permeable networks and bio-inspired soft-robots.

SYMPOSIUM SB08

Advanced Biomaterials and Bioelectronics for Neural Interfacing
April 22 - April 25, 2024

Designer Nanomachines for Biological Targets: The Case of Magneto-Genetics (MG) Jinwoo Cheon[1,2]; [1]Yonsei University, Korea (the Republic of); [2]Institute for Basic Science, Korea (the Republic of)

Nanochemistry has been essential to create ”designer nanomachines” that come with mechanical functions in nanoscale precision for next-generation biomedical sciences for identifying and executing desired missions. In this talk, I will discuss ”magneto-mechanical nanoparticles” as core platform materials and tools for a variety of functionalities such as targeting and signaling of cells and live animals in a selective and efficient way. These tools serve as a modulator for cell signaling of neurons via “magneto-mechanical-genetics (MMG)” for the behavior control of live animals. MMG serves as one of the most advanced technologies in controlling neurons for brain stimulations via remote and wireless fashion.

SESSION SB08.02: Bioelectronic Interface I
Session Chairs: Alina Rwei and Huiliang Wang
Tuesday Morning, April 23, 2024
Room 433, Level 4, Summit

10:30 AM *SB08.02.01

Pushing Limits of Neural Electrodes for Intracortical Recording and Stimulation Chong Xie; Rice University, United States

I will present our efforts in ultraflexible neural electrods and recent progress in scaling-up their channel count and density. I will also discuss using these electrodes for recording and stimulation in animal models.

11:30 AM SB08.02.04
High-Density Flexible Neural Electrode and Application in Neurological Disease Monitoring Siting Yang; Mechanical Engineering, China

Neurological disorders have become the most common diseases affecting human health, such as epilepsy, Parkinson's disease and aphasia. Measuring the neuro-electrophysiology signals is the gold standard for characterizing brain activity. Long-term tracking of the electrophysiological signals and timely feedback for intervention is a promising therapeutic approach for some of these brain diseases. Currently, traditional rigid neural electrodes, dominated by silicon-based electrodes and microwire electrodes, will inevitably induce immune responses due to the significant mechanical mismatch between the rigid materials and the brain tissue. As a result, it is challenging to form a long-term stable neural interface between the electrode and the neurons. In contrast, flexible neural electrodes with small size and low Young's modulus can form a seamless interface with the brain, thus enable long-term signal detection. To date, however, it is still difficult to precisely implant flexible neural electrodes with large amount of electrodes into multiple deep brain regions. It is one of the factors that restricts the large-scale implantation of flexible neural electrodes.
Here, we demonstrated a multi-shank high-throughput 120-channel flexible neural electrode based on polyimide thin polymer substrate, which consists of 6 shanks. The thickness of the electrode is 4 micrometers, and the width of the electrode is only 100 micrometers. At the same time, we used tungsten wire with a diameter of 20 microns as an auxiliary implant shuttle to minimize brain damage. In addition, we designed a reliable and controllable plug-in shuttle device to perform implantation of electrode and retraction of shuttle which can not only completes high-density implantation of multi-shank electrodes, but also able to operate at different approaching and retraction speed. We demonstrated that the prepared high-density flexible electrodes can be implanted in multiple brain regions and deep brain regions and it demonstrated stable in vivo action potential signal detection for up to 6 months. At the same time, immunological tissue section also showed that the prepared high-density neural electrodes cause lower acute immune responses and long-term immune responses. With this technology, long-term brain-computer interfaces based on high-density neural electrodes can be realized in the near future, will benefit to patients with serious brain diseases.

SESSION SB08.03: Bioelectronic Interface II
Session Chairs: Guosong Hong and Alina Rwei
Tuesday Afternoon, April 23, 2024
Room 433, Level 4, Summit

2:00 PM *SB08.03.01
Nonfibrotic Bioelectronic Interfaces with Diverse Organs Xuanhe Zhao; Massachusetts Institute of Technology, United States

Implanted biomaterials and devices face compromised functionality and efficacy in the long term due to foreign body reactions and subsequent formation of fibrous capsules at the implant-tissue interfaces. Here, we demonstrate that an adhesive implant-tissue interface can mitigate fibrous capsule formation in diverse animal models, including mice, rats, humanized mice, and porcine models, by minimizing the establishment of the inflammatory microenvironment and subsequent infiltration of inflammatory cells at the implant-tissue interface. Histological analysis shows that the adhesive implant-tissue interface does not form observable fibrous capsules on diverse organs, including the abdominal wall, colon, stomach, lung, peripheral nerves, and heart, over 12 weeks in vivo. In vitro protein adsorption, multiplex Luminex assays, quantitative PCR, immunofluorescence analysis, and RNA sequencing are additionally performed to validate the hypothesis. We further demonstrate long-term bi-directional electrical communication enabled by implantable electrodes with an adhesive interface over 12 weeks in a rat model in vivo. This finding may offer a promising strategy for long-term anti-fibrotic implant-tissue interfaces.

2:30 PM SB08.03.02
Microelectrode Arrays for Electrophysiology of Astrocyte Lineage Cells Misaki Inaoka, Nataly Hastings, Elise Jenkins, Sagnik Middya, Filip Wronowski, Mark Kotter and George G. Malliaras; University of Cambridge, United Kingdom

Astrocytes, a type of glial cell present in the central nervous system, play a crucial role in brain information processing together with neurons. These cells prominently exhibit Ca2+ excitations and are also characterised by electrophysiological activities that derive from voltage-gated ion channels on their membranes. However, there are few tools specifically optimised to detect their low-amplitude and low-frequency membrane oscillations from the extracellular environment, despite the intrinsic benefits these recordings provide for long-term recording and network studies. In this report, we developed an in vitro 64-channel microelectrode arrays (MEAs). To reduce impedance, our MEAs incorporate a larger electrode size (100 µm in diameter) compared to those designed for neurons and features a coating of PEDOT:PSS on a gold electrode. PEDOT:PSS offers notable biocompatibility and electrical properties. We cultured rat cortical astrocytes on this device and subsequently conducted electrophysiological recordings. The results demonstrated that the device could detect low-amplitude activities in the low-frequency range, which were absent in control recordings both without cells and after cell fixation. Moreover, leveraging the transparency of PEDOT:PSS, we carried out simultaneous recordings of calcium dynamics and electrophysiology in astrocytes and human glioblastoma cells, which are cancer cells that originate from astrocytes. The comparison of results from these two different cell types suggests that the frequency of calcium events in astrocyte lineage cells correlates with the signal intensity of electrophysiological recordings.

2:45 PM SB08.03.03
A Multimodal Neural Probe for Seizure Signals Monitoring and Optical Stimulation Treatment to Epilepsy Na Xiao[1,2,3], Tao Zou[1,2], Ruihong Weng[2], Chung Tin[3] and Paddy K. L. Chan[1,2]; [1]The University of Hong Kong, China; [2]Advanced Biomedical Instrumentation Centre, China; [3]The City University of Hong Kong, China

Epilepsy is a central nervous system disorder which affects more than 65 million people worldwide. Seizures are often accompanied by abnormal discharges of a large number of neurons overall the brain, causing periods of unusual behavior, sensations, loss of awareness and even death. Electrical stimulation to deep brain regions has been demonstrated to be effective methods of seizure control for patients with drug-resistant seizures. However, the metal neural probes used in clinical applications for monitoring the neural signal or delivering electrical stimulation have significant disadvantages in the poor conformability, risk of tissue damage, long term stability issue and etc. Soft-material based electrode array has emerged as a promising alternative to metal probes for their small size, biocompatibility, and more importantly, their flexibility and conformability.

Here we demonstrated a soft multimodal device that contains 16-channel depth electrodes and 16-channel ECoG electrodes. The electrodes were fabricated with gold as conducting layer and parylene-C as the supporting layer, coated with PEDOT:PSS and pHEMA to reduce the impedance and enhance the bio-compatibility. By using a 50 um diameter thin optical fiber as shuttle, the depth electrodes were implanted to the focal region of seizure, meanwhile, the ECoG electrodes were placed on the surface of the brain cortex of a half-hemisphere. This design allows us to monitor the LFP signals from the seizure source region, such as hippocampus, and spreading ECoG signals from the brain surface, simultaneously. The optical fiber shuttle was also served for delivering light stimulation to the source region. Data analysis results show that when we input both of the ECoG and LFP signals recorded with our device into a seizure detection computer model, the detection accuracy is high then only use one of them. The correlation coefficient and phase locking value analysis between the LFP channels and ECoG channels further demonstrated the functional connections between the seizure focal region and different spreading regions. We also found that the optical stimulation delivered to the hippocampus region of AAV-ChR2-infused animals effectively suppressed the seizures signals at both LFP and ECoG levels.

3:00 PM BREAK

5:00 PM SB08.05.01
Biocompatible Lactulose based Resistive Random Access Memory for Bio-Implantable Electronics Beom Soo Kim, Jong Bin An, Hyung Tae Kim, Dong Hyun Choi, Moon Ho Lee, Sun Min Song and Hyun Jae Kim; Yonsei University, Korea (the Republic of)

The growing interest in digital healthcare has spurred research into the development of bio-implantable devices capable of detecting various biosignals for convenient daily use. Non-volatile memory is an important component of these bio-implantable devices, especially the resistive random-access memory (RRAM) device, which is attracting attention due to its low power consumption, fast switching, and low fabrication cost. In general, RRAM for processing biosignals is often made of inorganic materials, which are not suitable for bio-implantable devices that require biocompatibility. Therefore, numerous studies on organic-based RRAM, which offers several advantages over inorganic-based RRAM, including biocompatibility, low power consumption, and high flexibility, are in progress.
To fabricate bio-implantable organic-based RRAM, we propose Lactulose as a suitable material for the switching layer of RRAM among biocompatible organic materials that are not harmful to the human body. Lactulose has proven its efficacy and safety, as it is registered on the World Health Organization (WHO) list of essential drugs and has the unique characteristic of not being digested or decomposed in the stomach or small intestine. Based on these properties, we determined that Lactulose could be used as a switching layer of bio-implantable RRAM that has a characteristic of biocompatibility.
In order to make a Lactulose -based RRAM device, a series of processes are required. The first step is to prepare a Lactulose solution, which is made by dissolving Lactulose powder (Sigma-Aldrich, USA) in deionized (DI) water as a solvent with a concentration of 3 wt%. Lactulose is completely dissolved by stirring the solution for 24 hours. Simultaneously, prepare a p^+-Si wafer to deposit the solution. After cleaning process, the wafer undergoes hydrophilic treatment through O2 plasma to help the Lactulose solution adhere well to the wafer's surface during the spin-coating process. The next step is to deposit the Lactulose solution on the prepared wafer through spin-coating at 3,000 rpm for 30 s. After deposition, the sample is annealed at 80 °C for an hour. Finally, the top electrode, Magnesium (Mg), is deposited on the device after annealing is complete. Since the switching layer is an organic material, an E-beam evaporator is used to minimize damage to the switching layer, and an Mg thin film of about 120 nm is deposited. This results in the fabrication of a two-terminal RRAM having a p^+-Si /Lactulose/Mg structure.
Fabricated Lactulose-based RRAM had stable bipolar resistive switching properties with a set/reset behavior between the LRS and HRS. When a voltage sweep is applied to a fabricated Lactulose-based RRAM to check the current change, a set behavior was observed at approximately 3.1 V under positive bias, and a reset behavior was observed at approximately -2.8 V under negative bias. The conversion between the LRS and HRS was also verified through the log-scale I-V curve, which indicated that the switching mechanism of the device is likely due to the formation and rupture of conductive filaments in the switching layer. The device also exhibited a stable resistive switching window over 250 cycles without degradation when resistive switching operations in the LRS and HRS regions were performed. The device also shows a retention time of over 8,000 s. Through these endurance and retention results, it was confirmed that Lactulose-based RRAM exhibits high reliability as a memory device. Therefore, the results suggest that Lactulose can be a strong candidate for a bio-implantable RRAM with its performance. Building upon these characteristics and stability, Lactulose-based RRAM demonstrates its potential for use as bio-implantable devices.

5:00 PM SB08.05.02
Effect of Magnesium-Doped Hyrosyapatite Nanofibers on The Growth and Regeneration of Cortical Neurons in Fibroblasts Primary Cultures and its Biological Characterization Fabiola Hernández Rosas[1], Rafael Rangel Ibarra[1], José R. Alanis Gómez[1], Juan David Olivares Hernández[2] and Rodrigo Velazquez Castillo[3]; [1]Universidad Anáhuac Querétaro, Mexico; [2]Universidad Nacional Autónoma de México, Mexico; [3]Universidad Autónoma de Querétaro, Mexico

Hydroxyapatite (HAp) is frequently employed in various biomedical applications due to its chemical composition, making it one of the predominant calcium phosphate bioceramics in the tissue engineering field. Magnesium-doped synthetic hydroxyapatite (HAp-Mg) is a variant of hydroxyapatite bioceramic in which magnesium has been introduced in these crystalline structures. This allows it to obtain additional properties and characteristics that

may have specific benefits at the cellular level, such as stimulation of cell growth, differentiation, and regeneration. This study used an in vitro model of fibroblasts obtained from chicken embryos to investigate the effect of hydroxyapatite nanoparticles doped with magnesium on the growth and regeneration of cortical neurons. HAp doped with 2% magnesium was synthesized by the Microwave Hydrothermal Assisted Method. Subsequently, for its characterization, X-ray diffraction analysis was performed to characterize the HAp-Mg samples. The morphological and microstructural characterization and the chemical analysis of the HAp-Mg were carried out using Scanning Electron Microscopy and Energy Dispersive Spectroscopy. To evaluate the effect on cortical neurons, the primary culture of chicken embryo cortical neurons was carried out in Nb-B27 medium with 10% inactivated fetal bovine serum. These neurons were treated with different concentrations of HAp-Mg in the range of 0.1-100 ug/ml and incubated at 37°C and 5% CO_2 for 24 and 48 hrs. Subsequently, morphometric analysis was stained with β-III-tubulin and for dendritic length analysis, individual neurons were selected and drawn using the Simple Neuro Tracer plugin of FIJI-ImageJ software to evaluate neurite outgrowth and neuronal branching; also, RNA was obtained to perform real-time PCR experiments to assess the ability of HAp-Mg to stimulate the regeneration of cortical neurons to molecular level. This study suggests that HAp-Mg nanoparticles may positively affect the growth and regeneration of cortical neurons. These findings provide a promising basis for future research on the potential use of HAp-Mg in neuronal regeneration and central nervous system repair therapies.

5:00 PM SB08.05.03
FIB-SEM Investigation for Neurons-Electrode Interface Characterization and 3D Reconstruction Claudia Latte Bovio[1,2], Csaba Forro[3] and Francesca Santoro[4,1,5]; [1]Italian Institute of Technology, Italy; [2]Università degli Studi di Napoli Federico II, Italy; [3]Stanford University, United States; [4]RWTH Aachen University, Germany; [5]Forschungszentrum Jülich GmbH, Germany

The interaction between biological cells and non-biological surfaces plays a pivotal role in influencing cell attachment, shaping long-term tissue responses, and ultimately determining the success of medical implants and biosensors[1]. The cell-chip electromechanical coupling plays a key role in ensuring a long-term and stable interaction between the neurons and the active elect of the neuroelectronic devices[1, 2]. In this work we investigated the primary cortical neurons response to the biomimetic microelectrodes designed through two-photon lithography technique. The goal strategies involved the use of the Focus Ion Beam – Scanning Electron Microscopy (FIB-SEM) assisted milling and imaging. The technique used is called “salami slicing” technique, or Slice and view; it allows to mill and to save the whole neuron without loss resolution at a nanometer length scale (about 5nm) and stable alignment. Importantly, the procedure used, the ultra-thin plasticization (UTP)[3–5], required different steps allowing the preservation of the integrity of the neuron structure. Firstly, the chemically fixation, then the heavy metal embedding by osmium and uranyl based to stain the membrane and protein; and at the end the resin embedding and polymerization. By coupling these two techniques we bypassed the substrate removal since the cut can be applied to any type of material, preserve the subcellular structures due to the plastic layer embedding, moreover we obtained the 3D reconstruction of the neurons deform around microelectrodes allowing the quantify of the cleft between the neurons and the electrodes. This was instrumental in providing a comprehensive and precise representation of complex biological structures. It allowed to visualize intricate details that might be overlooked in conventional representations. By embracing this advanced imaging technique, we aim to deepen our understanding of cell-material interactions and their implications for medical implants and biosensors, ultimately advancing the field. Through our investigations into how cell membranes engage with topographical features, such as nanoscale protrusions and invaginations, a remarkable discovery has emerged. Neurons membranes exhibit a pronounced tendency to deform inward and conform to protruding structures, while displaying limited outward deformation when encountering invaginating features. This intriguing asymmetry in membrane response significantly influences the width of the cleft between the cell membrane and the nanostructure's surface.

5:00 PM SB08.05.04
Point-Of-Care Detection of Alzheimer’s Disease Biomarkers using Reduced Graphene Oxide Reza Mahmoodi; University of Denver, United States

In recent years, significant advancements in biosensing technologies have revolutionized the development of diagnostic tools, offering rapid and precise results that are vital for timely medical intervention. Gold, with its remarkable attributes encompassing high electrical conductivity, biocompatibility, and facile surface modification capabilities has emerged as a pivotal element in transducing complex biological interactions into quantifiable signals. The integration of gold electrodes has further enriched the immobilization of biomolecules, capitalizing on their substantial surface area-to-volume ratio to achieve heightened sensitivity in the detection of target molecules. Gold’s innate inertness ensures minimal interference from non-specific binding events, rendering biosensing platforms precise and reliable even within intricate biological environments.
The integration of reduced graphene oxide (rGO) into gold-based biosensors represents a notable advancement, driven by rGO's outstanding electrochemical properties and expansive surface area. This synergistic combination not only accelerates electron transfer kinetics but also enhances biomolecular immobilization, leading to a substantial boost in sensitivity and specificity. Furthermore, rGO's intrinsic structural flexibility and robustness fortify the stability and durability of biosensing platforms, establishing their versatility across a broad spectrum of applications.
The methodology involves the immobilization of antibodies using 1-Ethyl-3-(3-dimethylaminopropyl) carbodiimide (EDC) and N-Hydroxysuccinimide (NHS) coupling with a primary focus on detecting Brain-Derived Neurotrophic Factor (BDNF) and Amyloid Beta (ab) from clinical human samples. The detection of change in ab and BDNF levels is crucial providing insight into the state of the nervous system. ab is a peptide that plays a major role in the development of Alzheimer's disease (AD) and BDNF is involved in learning, memory, and cognitive functions. Point-of-care detection of BDNF and Aβ biomarkers offers the potential for earlier and more effective diagnosis and management of neurodegenerative diseases like AD. It can improve patient outcomes, reduce healthcare costs, and advance research in the field.
Its levels have been linked to several psychiatric and neurological conditions, including depression, schizophrenia, and neurodegenerative diseases. Overall, detecting BDNF and Amyloid Beta levels can assist in the early identification of neurodegenerative disorders. Early detection is fundamental for effective treatment and management of these conditions, potentially leading to improved patient outcomes and quality of life.
The electrochemical sensor results were benchmarked against the Enzyme-Linked Immunosorbent Assay (ELISA) technique. This integrated approach holds significant promise for rapid and label-free electrochemical biosensing, ultimately contributing to the amelioration of diagnostic capabilities in biomedical and environmental fields. Furthermore, this research initiative strives to democratize lab-quality testing by increasing access to reliable point-of-care diagnostics, thus empowering individuals with more accessible and accurate healthcare options.

A Highly Stretchable and Conductive PEDOT:PSS/PEG-Coated Au Nanoparticle Nanomembrane for a Low-Impedance Biointerface Yoona Lee[1,2] and Dae-Hyeong Kim[1,2]; [1]Seoul National University, Korea (the Republic of); [2]Center for Nanoparticle Research, Institute for Basic Science, Korea (the Republic of)

A biointerface, which denotes the interface between human biological systems and devices, plays an important role in the field of wearable and implantable electronics since mechanical mismatch leads to low signal-to-noise ratio, delamination of devices, and even tissue damage. However, achieving a conformal contact between the device and the tissue remains challenging due to its difficulty in simultaneously satisfying high stretchability, high conductivity, low impedance, and biocompatibility. Herein, we present a novel material of coating an Au nanoparticle nanomembrane (Au NP NM) with a mixture of polyethylenedioxythiophene:polystyrene sulfonate (PEDOT:PSS) and polyethylene glycol (PEG) to fabricate a biointerface with ultrathin thickness, low impedance, high elasticity, and metal-like conductivity. Au NP NM, made of the float assembly with gold nanoparticles partially embedded on a styrene-ethylene-butylene-styrene (SEBS) substrate, forms a conductive percolation pathway that remains intact even in 200% tensile stretching. Then, the interaction between PEDOT:PSS/PEG and Au NP NM creates optimal contact, which improves the conductivity and durability while stretching (400%). Therefore, the coating of PEDOT:PSS/PEG does not disturb the Au percolation pathway rather, it reinforces its connectivity, thus improving stretchability, resulting in a biointerface with high charge storage capacity and high conductivity. This material could be incorporated into brain interfaces to facilitate efficient stimulation and monitoring of electrophysiological signals.

5:00 PM SB08.05.06
Materials Strategies to Fabricate Metal-Like Stretchable Nanocomposites Using Locally-Bundled Nanowires for Wearable Devices Hyunjin Lee[1,2] and Dae-Hyeong Kim[1,2,1]; [1]Seoul National University, Korea (the Republic of); [2]Institute for Basic Science (IBS), Korea (the Republic of)

Stretchable conductive nanocomposites are a key focus in the field of wearable bioelectronics. Achieving a balance between metal-like conductivity (over 100,000 S/cm) and significant stretchability (more than 100%) for advanced skin-compatible devices remains a formidable task. This paper introduces a method for creating such a nanocomposite, employing locally clustered silver nanowires, which are stabilized using a combination of 1-propanethiols and 1-decanethiols. The process involves solidifying the nanocomposite through solvent evaporation in a highly humid environment, which clusters and stabilizes the nanowires within the organic solution. This local bundling reduces contact resistance and preserves the percolation network, enhancing conductivity. The use of both 1-propanethiol and 1-decanethiol further enhances this effect. Consequently, a nanocomposite is produced with exceptional conductivity (approximately 122,120 S/cm) and stretchability (around 200%). These outstanding electrical and mechanical properties are vital for various skin-like electronic applications. The paper showcases the application of this material in a wearable thermo-stimulation device.

5:00 PM SB08.05.07
Investigating Biocompatibility of PEDOT-based Biopolymers for Enhanced Integration into Neuronal Networks Nevena Stajkovic[1,2], Isabela Berndt Paro[2,1], Janic Töx[2,1], Valeria Criscuolo[2,1] and Francesca Santoro[1,2]; [1]Institute of Biological Information Processing – Bioelectronics, IBI-3, Forschungszentrum Jülich GmbH, Germany; [2]Faculty of Electrical Engineering and IT, RWTH, Aachen, Germany, Germany

In the neuroelectronics field, neuromorphic devices based on organic electrochemical transistors (OECTs) are important, as they emulate neuronal features such as short- and long-term synaptic plasticity and adaptivity[1] because of the characteristic mixed ionic-electronic conduction mechanism of conjugated polymers like poly(3,4 ethylene dioxythiophene) – PEDOT:PSS. Depending on the application, aside from PSS^-, PEDOT can be doped with negatively charged counterions such as hexafluorophosphate (PF^{6-}) or perchlorate (ClO_4^-).[2,3] Moreover, functionalization of PEDOT:PSS with azobenzene group *via* click chemistry produces photo-responsive azo-PEDOT:PSS biopolymers.[4] To achieve full integration of OECT-based neuromorphic devices into neuronal networks, the interface between biological cells and biopolymers is critical.[5] The surface geometry, biomaterial roughness, and its chemical composition can affect the neuron-material interfaces, neuron morphology, and network development. Developing new biomaterials with improved features in terms of stability and conductivity are in demand to achieve seamless integration and broaden the biological applications of OECTs considering also the potential role of different counterions in triggering neuronal outgrowth at the cell-chip interface.

In this work, the interfaces of cells and semiconductive PEDOT-based biopolymers—PEDOT:PSS, PEDOT:PF_6, PEDOT:ClO_4, and modified PEDOT-crown:ClO_{46} are investigated. The PEDOTcrown:ClO_4 is interesting owing to its ability to bind Na^+, which can mimic sodium channels that are abundantly expressed in the nervous system. The interfaces of cells and N_3-PEDOT:PSS, N_3-PEDOT:PF_6, and N_3-PEDOT:ClO_4, which can be functionalized into photo-responsive azo-PEDOT, are also studied. The biocompatibility of the biopolymers is investigated by assessing the viability and morphology of HT22 neuronal cells on each material. To assess the HT22 survival rate and cytotoxicity, standard *in vitro* assays (Live/Dead, MTT, and cellular ROS) are used. Cell morphology is assessed by labeling the actin cytoskeleton. The focused ion beam/scanning electron microscopy (FIB/SEM)[7] is used to gain a deeper insight into cell-biomaterial interfaces. Currently, biocompatibility assays and FIB/SEM are being carried out to investigate primary neuron-biomaterial interfaces. Also, neuron overgrowth on biopolymers is being studied by actin labeling in the growth cones and by immunostaining of axons and dendrites.

The results of this study are of importance since they will provide a characterization of new semiconductive biomaterials with potential applications in the neuro- and optoelectronics fields.

8:45 AM *SB08.06.01

Miniaturised, Flexible Deep Brain Probes Noaf Alwahab and Stephanie P. Lacour; Ecole Polytechnique Federale de Lausanne, Switzerland

Microfabricated brain electrodes offer a distinctive method for directly interfacing with individual neurons in vivo. However, their long-term reliability is compromised by the formation of scarring tissue around them. A primary factor contributing to this issue is the mechanical disparity between the electrode and the surrounding biological tissue, prompting the exploration of more adaptable neuroelectronic interfaces. Advances in soft coatings that mirror the brain's elasticity, along with the introduction of compact, flexible designs, are paving the way for enhanced compatibility and durability of these implants. In our research, we fine-tuned a micrometric zwitterionic hydrogel coating for neural implants, leveraging its softness and minimal fouling characteristics while minimizing the implant size. This specialized coating was incorporated into microfabricated polyimide neural probes. These were chronically implanted into deeper brain regions prone to micromotion. Consistent weekly recordings from freely moving rats demonstrated an enduring capability to record for a minimum of 8 weeks, showcasing a high signal-to-noise ratio.

9:15 AM SB08.06.02
Biomimetic Dendritic Electrodes Tune The Neural Network Behavior and Communication Claudia Latte Bovio[1,2], Anna Mariano[3] and Francesca Santoro[4,5,1]; [1]Italian Institute of Technology, Italy; [2]University of Naples Federico II, Italy; [3]Istituto Italiano di Tecnologia, Italy; [4]RWTH Aachen University, Germany; [5]Forschungszentrum Jülich GmbH, Germany

The interaction between electrogenic cells and external devices is indispensable for tasks like cell recording and stimulation. In particular, the physical cell-chip coupling has a crucial impact on the electrical conduction mechanism. A deepened comprehension of how cells interact with artificial materials is of utmost importance in the quest for effective interfaces. The process of cells adhering to and spreading on pseudo 3D micro-structures, is a well-coordinated mechanism that hinges on cell adhesion and the cell's capacity to adapt its cytoskeletal architecture to conform to vertically aligned structures[1, 2]. This scenario highlights a knowledge gap in our understanding of how to modulate neural network development and how cell membranes conform to protruding vertical electrodes, particularly for creating an effective 3D representation of the cleft to be integrated into the cell-electrode equivalent circuit for recording and stimulation modeling. On this purpose a biomimetic dendritic electrode[3] has been fabricated by using the two-photon polymerization lithography[4]. Firstly, three structures' geometry have been identified: thin that can initiate contacts with presynaptic terminals and are therefore essential in the initial stages of spinogenesis; the mushroom shape as a result of the plastic and dynamic reshaping of the neuronal circuits during synaptic development and the stubby. The experimental approach involved the primary cortical neurons. In our work, we've demonstrated the mechanical interactions occurring at focal adhesion sites. These interactions oversee the continuous remodeling and adjustment of cells on the material's surface and have the capacity to generate localized traction forces on the substrate. Neurons can utilize these forces to facilitate directed movement through contact guidance. Additionally, this mechanism promotes the engulfment event by facilitating membrane invagination, leading to the precise localization of transmembrane proteins, including integrins. This localization helps induce a specific cytoskeletal arrangement. Furthermore, our results indicate how microelectrodes can impact directionality and influence the remodeling of the neural network, particularly affecting the growth cone phase, shifting from pausing to a resting state. Importantly, we've demonstrated that the growth cone rate changes in response to different pitch configurations. Significantly, our research has revealed that biomimetic topographical cues can swiftly impact membrane adhesion proteins and enhance the efficiency, as demonstrated through the 3D reconstruction integrated into an electrical equivalent model. With an eye toward future applications in controlling signal dissipation, this work has the potential to enhance the recording of electrogenic cells.

9:30 AM SB08.06.03
Ultra-Compliant and Biodegradable Stem Cell-Embedded Hydrogel Microelectrode Arrays Applied for Combined Neural Signal Diagnosis, Electrically Neuromodulation and Cell Therapy Wei-Chen Huang; National Yang Ming Chiao Tung University, Taiwan

Biohybrid neural interfaces (BHNIs) are a new class of neuromodulating devices that integrate neural microelectrode arrays (MEAs) and cell transplantation to improve treatment of nerve injuries and disorders. However, current BHNI devices are made from abiotic materials that are usually bio-passive, non-biodisintegratable, or rigid, which restricts encapsulated cell activity and host nerve reconstruction and frequently leads to local tissue inflammation. Herein, we propose the first MEA composed of all biodisintegratable hydrogel tissue scaffold materials with synergistic performances of tissue conformal adhesiveness, MEA technologies, tissue scaffolding and stem cell therapy on a time scale appropriate for nerve tissue repair. The device substrate is made of an enzyme-crosslinked gelatin/silk (GS) hydrogel with adhesiveness and controllable degradability that benefit nerve tissue integration and neural progenitor cell (NPC) transplantation. MEA circuits composed of graphene oxide (GO)/PEDOT/gelatin-based ECHs were designed with a double-crosslinked architecture to confirm robust ionic/electroconductive properties. With seamless lamination around peripheral nerve fibers, the device permits successive neural signal monitoring for wound condition evaluation, while demonstrating synergistic effects of spatiotemporally controlled electrical stimulation and cell transplantation to accelerate restoration of motor function.

10:15 AM *SB08.07.01
Optoelectronic Biointerfaces: From Random-Access Photostimulation to Neuromodulation Bozhi Tian; University of Chicago, United States

The development of new neural interfaces necessitates innovative materials and advanced device concepts. Our lab has introduced a monolithic system designed for optoelectronic interfaces that effectively interact with neural and cardiac systems. Utilizing semiconductor-enabled biomodulation interfaces, we have enhanced the capabilities of random-access photostimulation. The devices demonstrate significant translational potential for medical applications, ranging from cardiac system modulation to peripheral nerve stimulation. In this talk, I will also introduce a new electrochemical system for neuromodulation. Our lab's future focus will be on refining the performance and reliability of the random access systems. We aim to expand the range of medical applications, improve device efficiency, and ensure seamless integration into clinical practices.

10:45 AM *SB08.07.02
Implantable Photoacoustic and Microwave Neural Interface Chen Yang; Boston University, United States

High precision neuromodulation is a powerful tool for fundamental studies in neuroscience and potential treatments for neurological disorders. Here we report new developments in implantable non-genetic photoacoustic and microwave neural interfaces for high precise neuromodulation in retina and brain. First, we will discuss our design of biocompatible soft photoacoustic retina protheses. We confirmed successful blind retina stimulation through a PDMS-based photoacoustic film safely with a spatial resolution of 50 microns ex vivo and in vivo. These results show the potential of using optoacoustic signal to drive activity in photoreceptor-damaged retinas. Second, we will report an implantable miniaturized multifunctional fiber integrating with electrodes for simultaneous stimulation and recording in brain in vivo. Successful electrophysiology recording upon photoacoustic stimulation has been demonstrated in mouse brain acutely as well as up to 1 mon after implantation of the stimulator. Such devices open up potential for improved closed-loop stimulation in deep brain stimulation without the interference between the conventional electrical stimulation and recording. Lastly, we will discuss a miniaturized millimeter size microwave antenna as a wireless implantable neural interface to inhibit neural activities in vitro, ex vivo and in vivo. Suppression of seizure activities in brain in an epileptic rodent model has been achieved using low intensity microwave together with the implanted microwave antenna 6-10 time less than the FDA microwave threshold.

11:15 AM SB08.07.03
Flexible and Biocompatible Photoacoustic Film for Vision Restoration at Ultrahigh Spatial Resolution Yueming Li[1], Audrey Leong[2], Hélène Moulet[3], Jean-Damien Louise[3], Serge Picaud[2] and Chen Yang[1]; [1]Boston University, United States; [2]Sorbonne Université, France; [3]Axorus, France

Retinal degenerative diseases represent a major factor leading to irreversible blindness. Despite extensive research efforts, a definitive curative treatment remains elusive. The development of retinal prostheses, encompassing bionic and photovoltaic devices, has aimed to address this unmet clinical need. However, these technologies face inherent issues such as crosstalk from current leakage impacting spatial resolution, limitations in electrode numbers limiting the visual angle, and difficulties related to internal strain during fabrication. To address these challenges, we introduce a novel solution utilizing a uniform and flexible photoacoustic film composed of candle soot and polydimethylsiloxane for high-precision retinal stimulation as a subretinal implant. This approach leverages on the advantages of light patterning flexibility to overcome the limitations of unit spacing, electrode numbers, and internal strain observed in other devices. Our experiments demonstrate that this photoacoustic film effectively stimulates the retinas of blind rats ex vivo, achieving a spatial resolution of 50 µm. Moreover, upon implantation in rats, this flexible photoacoustic film exhibits superior biocompatibility. Significantly, the photoacoustic stimulation induced visual responses that were recorded in the rat brain's visual cortex. These findings hold promise for the restoration of vision in individuals suffering from age-related macular degeneration and retinal dystrophy, offering a potential solution with improved spatial resolution and better biocompatibility.

11:30 AM SB08.07.04
Fabrication, Characterization and *In Vivo* Validation of Flexible Optical Cortical Probe Amélie Albon[1], Emma Butt[2], Keith Mathieson[2] and Charles Rezaei-Mazinani[1]; [1]EMSE, France; [2]University of Strathclyde, United Kingdom

Mechanically-flexible neurotechnologies based on soft and biocompatible organic materials have significant advances for neuroscience applications. However, integrating active electronic components into polymer-based neurotechnologies is still a challenge. This is particularly important for optogenetic applications where, despite important advances in light delivery technologies (such as optical fiber or inorganic µLED-based optoprobes) they mostly rely on rigid substrates. This is a key obstacle to their successful integration with neural tissue. In this work, we focus on the development of a novel optical cortical-probe (optoprobe), seamlessly integrating high performance inorganic µLEDs for optogenetic stimulation, along with organic electrodes for electrical recording. This optoprobe offers a plastic and conformable interface with the cortex. Here, we present our fabrication method for the integration of 4 µLEDs (100x100 µm, λ = 450 nm) and 4 PEDOT:PSS based electrodes (50x50 µm) and fully characterize the optoprobe for optogenetic stimulation and electrical recording. This includes analysis of the electrical crosstalk between the drive currents for the µLEDs and the electrical recording component (sensitive to 10s of microvolts). Driving the µLEDs can also increase the optoprobe's temperature profile and influence the long-term stability of the optoprobe – both of these effects have been studied in accelerated testing. Furthermore, we show validation of the optoprobe performance in mouse auditory cortex *in vivo*. Integrating electrodes and µLEDs on a common transparent substrate has the potential to improve stimulation control by facilitating real-time adjustments based on observed neuronal responses through a closed-loop system. Moreover, our results demonstrate the scalability of this fabrication process to a large µLED arrays. This technology marks a significant step forward in the development of flexible optogenetic devices.

11:45 AM SB08.07.05
Non-Invasive and Programmable Molecular Manipulation for Deep Brain Modulation Using Focused Ultrasound Wenliang Wang[1], Yanshu Shi[2], Wenrui Chai[1], Kai Wing K. Tang[1], Banglin Chen[2] and Huiliang Wang[1]; [1]The University of Texas at Austin, United States; [2]The University of Texas at San Antonio, United States

The precise control of mechanochemical activation within deep tissues via non-invasive ultrasound holds profound implications for advancing our understanding of fundamental biomedical sciences and revolutionizing disease treatments. However, a theory-guided mechanoresponsive materials system with well-defined ultrasound activation has yet to be explored. Here we present the concept of using porous hydrogen-bonded organic frameworks (HOFs) as toolkits for focused ultrasound programmably triggered drug activation to control specific cellular events in the deep brain, through on-demand scission of the supramolecular interactions. A theoretical model is developed to visualize the mechanochemical scission and ultrasound mechanics, providing valuable guidelines for the rational design of mechanoresponsive materials at the molecular level to achieve programmable and spatiotemporal activation control. To demonstrate the practicality of this approach, we encapsulate designer drug clozapine N-oxide (CNO) into the optimal HOF nanoparticles for FUS gated release to activate engineered G-protein-coupled receptors in the mice and rat ventral tegmental area (VTA), and hence achieved targeted neural circuits modulation even at depth 9 mm with a latency of seconds. This work demonstrates the capability of ultrasound to precisely control molecular interaction and develops ultrasound-programmable HOFs to minimally invasive and spatiotemporally control cellular events, thereby facilitating the establishment of precise molecular therapeutic possibilities. We anticipate that this research could serve as a source of inspiration for precise and non-invasive molecular manipulation techniques, potentially applicable in programming molecular robots to achieve sophisticated control over cellular events in deep tissues.

SESSION SB08.08: Magnetic Stimulation II
Session Chairs: Alina Rwei and Huiliang Wang
Wednesday Afternoon, April 24, 2024
Room 433, Level 4, Summit

1:30 PM *SB08.08.01
Magnetoelectric Metamaterials for Remote Control of Neural Activity Jacob T. Robinson; Rice University, United States

Magnetoelectric materials have applications in wireless data transmission, electronics, sensing, data storage, and biomedical applications. Recently there has been interest in using magnetoelectric materials for direct neuromodulation, but existing magnetoelectric materials struggle to provide millisecond-precision remote stimulation due to the high resonant frequencies of magnetoelectric materials. Here we discuss how we can engineer composite materials that display magnetoelectric properties not found in nature including magnetoluminescence and strong non-linear magnetoelectric coupling. These meta-atoms have magnetic coupling that enables precise activation of nerves and remote control of cell activity.

Specifically, we introduce the concept of self-rectifying magnetoelectric metamaterials (MNMs) that rely on nonlinear charge transport across semiconductor layers in a trilayer laminate consisting of a piezoelectric layer and two magnetostrictive layers. This innovation enables us to generate arbitrary electrical pulse sequences with a time-averaged voltage exceeding 2 V. Consequently, we can remotely stimulate peripheral nerves with repeatable latencies of less than 5 ms, a significant improvement over previous neural stimulation approaches relying on magnetic materials. This achievement holds promise for applications requiring fast neural signal transduction, such as sensory or motor neuroprosthetics.

Our work showcases the potential of rational design to introduce nonlinearities into the magnetic-to-electric transduction pathway, opening doors to diverse MNM designs tailored for applications spanning electronics, biotechnology, and sensing. Ultimately, this breakthrough in remote neural stimulation can be used for medical therapies, facilitating less invasive treatments and advancing neuroscience research in freely behaving animals.

2:00 PM SB08.08.02
Probing The Origin of Alternating Field Induced Magnetic Heating with Lithographically Fabricated Collodial Solutions of Compensated Ferrimagnets Noah Kent, Daniel Suzuki, Byunghun Lee, Geoffrey Beach and Polina Anikeeva; Massachusetts Institute of Technology, United States

Magnetic nanoparticles (MNPs), used as alternating magnetic field (AMF) transducers, are currently actively being researched as a non-invasive way of manipulating biological systems. The nanomagnetic transducers turn the AMF into a force or field that can interact with biology. Most ubiquitous is the use of AMF transducers to generate heat. This heat can be used to ablate cancer cells, trigger ion channels, or open the blood brain barrier. Optimizing the heating from MNPs allows one to reduce the amount of MNPs used for medical treatment or to selectively heat on a cellular scale due to better local heating.
Current theory says that the heating from a MNP in an AMF is proportional to the area of the hysteresis loop swept by the MNP. While this is an excellent approximation there have been some noticeable discrepancies observed in the current literature with this theory; it has been observed quite often that superparamagnetic nanoparticles have significant heating, but have no hysteresis loop area. Additionally, the Hamiltonian used when calculating energy loss in this theory lacks a term for ferromagnetic exchange.
We instead turn to theory that describes accurately the switching of a MNP dynamically and includes ferromagnetic exchange. This theory predicts the heating induced in a magnet in an AMF is proportional to the sum of the speed of all the spins squared ($|d\mathbf{M}/dt|^2$). Intuitively one could think of this as a magnetic friction. This explains why superparamagnets have heating that is nearly the same as ferromagnetic nanoparticles but paramagnets do not. This also agrees with the previously put forward theory that larger anisotropy and larger hysteresis loops lead to larger heating.
To confirm this theoretical framework we consider a system which, under the old theory should not heat but, with the accurate nanomagnetic heating theory, should heat: compensated ferrimagnets. Compensated ferrimagnets are ferrimagnets where the magnetization of the two sublattices are nearly the same, and therefore, below spin flip fields, have near zero net magnetization, have no hysteresis loop area, but still have two dynamically switching magnetic sub lattices.
Turning films of magnetron sputtered amorphous near compensation GdCo (Gd = 25%) into colloidal solutions of lithographic microdisks we observe a net magnetization of 1.1emu/g (very small compared to 100emu/g for magnetite), and a near zero area hysteresis loop. However, we observe non-trivial AMF induced heating of 240 w/g (350w/g for magnetite in the same field conditions). These results demonstrate that magnetic heating is not purely proportional to hysteresis loop area but is a result of rapid, ferromagnetic exchange induced, magnetic motion.

2:15 PM SB08.08.03
Controlling Neuronal Cell Signaling within Three-Dimensional Magnetic Nanocomposites Dekel Rosenfeld; Tel Aviv University, Israel

Iron oxide magnetic nanoparticles (MNPs) with diameter of 20-25 nm dissipate heat when exposed to weak alternating magnetic fields (AMFs) with amplitudes <50 mT and frequencies of 100-600 kHz. This heat can be exploited to activate cells that have thermally sensitive ion channels on their membrane via magnetothermal modulation. AMF has a high penetration rate with no deleterious effects, and therefore suitable for the activation of cells within deep organs in the body. Iron oxide nanoparticles are biocompatible and being utilized in different biomedical applications, including drug delivery, cell signaling and imaging.
We exploit the magnetothermal approach to control calcium signaling in cells within deep organs and with a minimally invasive scheme. While the common approach of magnetothermal stimulation exploits MNPs in the form of ferrofluid, my lab recently pioneered a new design of a three-dimensional nanocomposite that can examine cell signaling under thermal effects in microenvironment that is suitable for cell organization and functionalities. We introduce a novel concept for the field of bioelectronic medicine with new materials design and in-depth nanocomposite characterization. One intriguing target of the magnetothermal approach is the heat sensitive ion channel, the transient receptor potential vanilliod 1 (TRPV1), the capsaicin receptor. TRPV1 is a non-selective cation channel that is calcium-permeable and can be activated by heat with temperature threshold above 42 Celsius. Previous studies have demonstrated the expression of TRPV1 in various peripheral organs as well as sensory neurons. We use this model to demonstrate our approach of cells activation in three-dimensional magnetic nanocomposites.

3:30 PM *SB08.09.01
Piezoionic Currents: Mechanical Deformation of Hydrogels Induces Ionic Currents that Stimulate Nerves John D. Madden[1] and Yuta Dobashi[2]; [1]University of British Columbia, Canada; [2]University of Toronto, Canada

The nervous system operates at tens of millivolts and employs ionic currents. Similar voltages and ionic currents are generated when hydrogels are compressed. This opens the possibility of stimulating the nervous system directly using the electrical energy produced when ionically conductive materials are deformed. To demonstrate this effect, a finger was firmly tapped on a slab of polyacrylamide hydrogel containing 1.5 M of sodium chloride solution. The resulting current was fed into PEDOT-coated Pt-Ir electrodes wrapped around a rodent peripheral nerve, The mechanical input produced currents of 10 μA at voltages of less than 100 mV. Hhindlimb twitches were produced. This 'self-powered' sensing interfaces with nerves without any signal conditioning or amplification. We dub the underlying mechanims "piezionic", in loose analogy to piezoelectrics. A pressure gradient applied to the hydrogel produces a flow of electrolyte and ions within it. Some ions displace faster than others as they translate through the nanopores of the hydrogel, likely due to differences in size between anions and cations. Similar effects are seen in other ionically conducting polymers including conjugated polymers and ionically conductive membranes. Response times can be quite fast (~30 ms) when thin gels are used, which create large pressure gradients around the indentation area, and fast transport. The piezonionic effect creates the possibility of a fully ionic artificial mechanoreceptor that can interface with the nervous system - though long distance, high density signal conduction may be best achieved using thin metal wires.

4:00 PM *SB08.09.02
Flexible Transducers for Ultrasound Neuromodulation Sang-Mok Lee, Taemin Lee, Seunghyeon Nam and Hyunjoo J. Lee; KAIST, Korea (the Republic of)

Wearable ultrasound patches possess the potential to transform conventional medical ultrasound applications by enabling hands-free, prolonged, and uninterrupted diagnostic and therapeutic procedures. However, current flexible ultrasound transducers often lack the ability to govern their curvature and are limited in terms of production throughput and design flexibility. In this work, we present a method for fabricating flexible ultrasound transducers with controllable curvature, utilizing high-yield silicon microfabrication and employing flex-to-rigid structures. The transducer's curvature is modulated through Joule heating, utilizing a low-melting-point metal alloy. The transducer demonstrates remarkable electrical and acoustical performance at central frequencies of 1.5 MHz and 3.4 MHz when immersed. We deploy this flexible transducer to induce neuromodulation of immune responses within an internal organ, illustrating the potential for continuous therapeutic interventions via a wearable ultrasound patch.

4:30 PM *SB08.09.03
Deep Brain Stimulation by Blood–Brain-Barrier-Crossing Piezoelectric Nanoparticles Generating Current and Nitric Oxide under Focused Ultrasound Won Jong Kim; POSTECH, Korea (the Republic of)

Neurodegenerative diseases entail the gradual breakdown of the central nervous system, leading to involuntary movements, cognitive decline, and memory issues. Deep brain stimulation (DBS), a successful treatment, uses implanted electrodes to modify neural signals and neurotransmitter release, though invasive electrode insertion poses side effects. Therefore, a wireless, non-invasive approach is essential. Piezoelectric materials generate electrical output when mechanically stimulated. Combining these materials with focused ultrasound might non-invasively stimulate localized neurons. However, the blood-brain barrier (BBB), a critical CNS barrier, limits nanoparticle delivery to the brain. A strategy to modulate BBB is crucial for effective treatment. Nitric oxide (NO), a vital gas molecule, shows potential in disrupting BBB, but the mechanism remains unclear. A NO release in response to specific stimuli could temporarily open BBB, facilitating nanoparticle accumulation in target areas. This study introduces a multifunctional system, combining ultrasound-responsive NO donors with piezoelectric nanoparticles for non-invasive neural stimulation. These nanoparticles release NO and direct current only under ultrasound, temporarily disrupting BBB for nanoparticle accumulation. The piezoelectric nanoparticles stimulate dopaminergic neurons. In an animal model, systemically administered nanoparticles under high-intensity focused ultrasound alleviated Parkinson’s disease symptoms without toxicity. In conclusion, this innovative approach offers promise for non-invasive, wireless neural stimulation.

SESSION SB08.10: Non-Invasive Bio-Interfaces

Room 433, Level 4, Summit

8:30 AM *SB08.10.01
Sensing Applications of Conformable Organic Imagers Tomoyuki Yokota and Takao Someya; The University of Tokyo, Japan

Optical-based 3-axis pressure sensors, with delicate imaging systems, can offer detailed tactile pressure data vital for robotics and human interaction. However, their bulkiness complicates mounting and integra-tion. We present a thin and flexible sensor construction approach to realize detection of 3-axis pressure distribution on a large area with wide sensing range and high accuracy. The sensor can detect the distribution of 3-axis pressure on an area of 3 cm × 4 cm, with a high-accuracy normal and tangential pressure sensing up to 360 and 100 kPa, respectively. A porous rubber is used as a 3-axis pressure-sensitive optical modulator to omit the thick and rigid focusing system without sacrificing the sensitivity. In addition, by integrating thin and flexible backlight and imager, the sensor has a total thickness of 1.5 milimeter, making it function properly even when bent to a radius of 18 mm. The flexible imager uses a combination of organic photo diodes (OPDs) and low-temperature polycrystalline silicon (LTPS)–based thin-film transistors (TFTs) fabricated on a film substrate. The imager has a pixel size of 235 μm, and a total of 126 × 168 pixels are formed on a 3 cm × 4 cm area. The organic photodiode designed for NIR light detection, optimized for maximum sensitivity at a wavelength of 850 nm, exhibits excellent air stability due to the implementation of an inverted structure.

9:00 AM SB08.10.02
Noninvasive E-Textile System for Long-Term Multimodal Electrophysiological Monitoring in Sports and Clinical Healthcare Junyi Zhao and

Chuan Wang; Washington University in St. Louis, United States

Textile-based electronic systems have emerged as a promising platform for creating noninvasive and comfortable human-machine interfaces across various domains, including sensing, display, and communication, which aligns with the contemporary drive for enhanced miniaturization and multifunctionality. This work presents a novel E-textile system comprising in-plane electrode layout and bioinspired conductive microfibers. This configuration allows for gel-free and motion-artifact-tolerant recording of multiple physiological signals, including electrocardiography and electromyography, capturing muscle activity triggered by motor neurons. More specifically, The base layout features a screen-printed array of poly(3,4-ethylenedioxythiophene) polystyrene sulfonate (PEDOT:PSS), with PEDOT:PSS-coated fluffy microfibers stacked on top. The vertically oriented hairy microfiber conductors ensure exceptional conformal and robust skin contact, while the dispersed microfiber electrodes substantially increase the effective contact area, significantly reducing the contact impedance between the electrode and skin. This feature enables comfortable all-day wear under dry conditions without the need for ionic gels. To ensure the durability and functionality of the textile in harsh conditions, a self-assembled monolayer (SAM) of trichloro(1H,1H,2H,2H-perfluorooctyl) silane is vaporized as a superhydrophobic coating. This treatment preserves the natural texture of the textile while maintaining the intrinsic conductivity of the electrodes. Additionally, portable miniaturized circuitry was meticulously designed and manufactured to enable multi-channel recording, signal processing, and wireless communications.

These advancements facilitate the seamless integration of the E-textile system into everyday life, broadening its potential applications. This study explores the application of E-textile systems in real-life scenarios, including strenuous exercise and clinical studies. We commence by demonstrating the robustness and stability of the E-textile system during professional cycling training sessions. Remarkably, the recorded signals remained clear and free from motion artifacts, even in the presence of intense sweating, maintaining a signal-to-noise ratio of approximately 30 dB. Real-time monitoring facilitated on-the-spot data analysis, including heart rate and muscle output. Next, we tested the waterproof capability of the system by integrating it into an E-textile-equipped swimsuit. Throughout the professional swimming training, the fully submerged E-swimsuit consistently delivered reliable electrocardiography recordings, demonstrating its resilience and suitability for aquatic environments. Even when encountering water flows, the E-swimsuit showcased robust performance, making it ideal for water sports. Finally, the textile-based E-patch with electrode arrays was employed in clinical studies to monitor maternal/fetal health. Multiple pregnant subjects were involved for capturing multichannel maternal-electrocardiography and uterine-electromyography signals. The recorded multichannel uterine-electromyography signals were further processed to generate noninvasive and high spatiotemporal resolution three-dimensional (3D) electromyometrial images with a fast frame rate. This groundbreaking achievement offers unique insights into neural activities within the uterus, aiding in the diagnosis of abnormal obstetrics symptoms and predicting the risk of potential preterm birth. These findings underscore the versatility and potential of wearable E-textile systems across a wide range of real-world applications, paving the way for professional sports tracking and personalized advancements in healthcare.

9:15 AM SB08.10.03
Development of Human-Scale Dry EEG based on 2D MXene and Benchmarking Against Clinical Gelled Electrodes Sneha Shankar, Doris Xu, Francesca Cimino, Ashley Koluda, Eugenia Angelopoulos, Kathryn Davis and Flavia Vitale; University of Pennsylvania, United States

Electroencephalography (EEG) is a valuable tool for non-invasive monitoring of electrical activity from the scalp for clinical monitoring of neurological disorders. Clinical EEG typically involves gel-based electrodes, whose application is time-consuming and requires skin-irritating abrasives and pastes. Recently, we have introduced dry EEG electrodes based on Ti_3C_2 MXene materials. These electrodes offer enhanced comfort and ease of use, requiring minimal skin preparation. Furthermore, they are conformable to the scalp, providing a comfortable fit for users. Here, we advance this technology towards research and clinical use by fabricating two different configurations of EEG headsets. The first configuration is a reduced-montage headband consisting of 8 channels placed at equal spacing on FP1, FP2, F7, F8, T3, T4, T5. The second configuration is a standard 10-20 montage with 21 recording sites at the canonical scalp locations. In both devices, the dry electrodes are fabricated from porous pillars infiltrated with Ti_3C_2 MXene (diameter: 8 mm, height: 6 mm), enabling access to the scalp through hair without the need for gel or pastes. The electrodes are connected to the recording amplifiers via snap connectors attached to snap leads. Owing to the high electrical conductivity ($155 \pm 4\ \Omega$, n= 5 electrodes) and surface area, the average 10 Hz impedance with the scalp of these dry porous MXene-infused electrodes is $2.1 \pm 1.8\ k\Omega$ (n=5 subjects). To further validate the dry MXene EEG technology, we have benchmarked it against clinical gelled cup Natus electrodes. Briefly, we have recruited patients in the outpatient epilepsy clinic at the Hospital of the University of Pennsylvania. For each participant, we recorded EEG with the reduced-montage headset and MXene electrodes for 20 minutes prior to clinical EEG. We recorded EEG in the following conditions: resting state, eyes open/closed, and sleeping, which corresponded to the same tasks used during clinical EEG acquisition. A preliminary analysis of the recordings shows comparable quality of the EEG signals acquired with the dry MXene and clinical gelled electrodes, while the duration of the skin prep and electrode placement operation reduced by ~2X. In conclusion, we have developed and validated a novel dry EEG technology that can improve user comfort, reduce electrode placement and skin preparation time, and reliably transmit signals of interest, providing a comfortable and efficient solution for EEG monitoring.

9:30 AM SB08.10.04
Detect The Undetectable in Wearables and Brain-Machine Interfaces: pM-Level Biomolecular Detection with Fast-Scanned Aptamer-OECT Xinyu Tian and Shiming Zhang; The University of Hong Kong, Hong Kong

Biomolecular detection is the next goal for wearable devices. The lower limit of detection (LoD) is a critical metric for wearable biosensors. In this study, we demonstrate that aptamer-based Organic Electrochemical Transistors (OECTs) can detect concentrations in the picomolar range (close to the dissociation constant, K_d) in a fully-integrated wearable context [1], which is not achievable with a standard electrochemical sensor. The high transconductance (g_m) of OECTs allows for a more significant variation in current, making the sensor highly resistant to ambient noise.

Specifically, we observed that a high scanning rate improves LoD to values close to the theoretical limit (K_d) of the aptamers. This improvement is achieved by operating OECTs at optimal high frequency range where the leaking reaction resistance most vibrates with the binding of the molecules [2]. Thus, microscale OECTs are essential for achieving a higher cutoff frequency for rapid scanning purposes.

3D Printed Flexible and Stretchable Tissue-Like Electronic Devices for Neural Recording Tao Zhou; The Pennsylvania State University, United States

The utilization of neural recording technology has significantly transformed our comprehension of the brain, spinal cord, and other nervous systems. These technologies have provided essential insights into neural activity, hence facilitating the development of groundbreaking therapeutic approaches. Nevertheless, the development of neural recording devices that can match the properties of neural tissues remains a significant challenge. Furthermore, commonly used neural recording devices are usually time-consuming to fabricate and costly. This research presents a novel strategy to tackle the aforementioned obstacle, wherein we propose the utilization of 3D printable flexible and stretchable tissue-like electronic devices for the purpose of neural recording. The device exhibits a unique structure that offers remarkable characteristics like flexibility, stretchability, and conformability. These properties facilitate the seamless integration of the device with the brain and spinal cord. In addition, the 3D printing manufacturing process can allow rapid fabrication of designed neural electronic devices and is less costly than lithography-based manufacturing methods. This innovation exhibits remarkable ramifications, presenting significant prospects for the fields of brain-computer interfaces, neuromodulation, and neural prosthetics.

10:45 AM SB08.11.02
Aerosol Jet Printing Enabled High-Density and Customized Neural Probe Integration Xiaokang Bai[1], Priyan Pathirana[2], Efrain Brizuela[1], Angel Nunez[1] and John Seymour[1,2]; [1]The University of Texas Health Science Center at Houston (UTHealth), United States; [2]Rice University, United States

Advanced packaging and integration techniques play a pivotal role in the development of next-generation medical devices. These devices demand high-density and complex-shaped substrate integration, which poses challenges to traditional packaging methods. Aerosol jet printing (AJP) offers a novel solution to the packaging of thin film arrays and convenient customization through AutoCAD. To achieve consistent and precise structures with AJP, design of experiments (DOE) is often necessary to establish optimal printing parameters. In this report, we present an approach to packaging flexible, tubular circuits, including high-density neural probes for neurosurgery or smart catheters for medical diagnostics. We demonstrated the effective utilization of the DOE method on a 400 μm step structure while maintaining high-density connections (64- to 128- channels) and achieving fine features with linewidths of ≤ 60 um and pitch sizes of ≤ 4 mils. Our method is versatile and can be easily adapted to various smart catheter and neural probe integration requirements. Furthermore, it has the potential to be extended to broader packaging and integration applications, such as ASIC integration, printed electronics, and various medical devices.

3D Printable Bioresorbable Electronics Jared Anklam, Kyle Harshany, Breanna Wong, Sammi Yu, Eric K. Tokita, Samuel H. Hales, Aarav Parikh and Yong Lin Kong; University of Utah, United States

The ability for bioelectronics to be resorbed to the body can obviate the need for surgical extraction, reducing potential complications and clinical burden in bioelectronics implantation. Advances in bioresorbable electronics have enabled a broad range of transient electronics, yet achieving three-dimensional integration with bioresorbable electronics remains a challenging goal. Microextrusion-based 3D printing can create freeform wireless electronics that can be directly integrated with a broad range of three-dimensional biomedical devices and biological constructs. Nevertheless, formulating a 3D printing ink that simultaneously possesses the rheological properties and electronics properties necessary for high-performance wireless electronics has not been demonstrated. Here, we developed a 3D printable ink that is bioresorbable and electrical conductive ink. Our ink demonstrates excellent electrical conductivity (3×10^4 S/m) and possesses rheological properties that allow the preservation of geometrical fidelity. We envision that our work can enable the direct integration of transient bioelectronics into a broad range of biomedical devices and biological constructs, improving the potential clinical outcome in 3D-printed bioelectronics.

11:15 AM SB08.11.04
3D Printing of Nanomaterial-Based Bioelectronics with a Metamaterial-Inspired Near-Field Electromagnetic Structure Samuel H. Hales[1], Jared Anklam[1], Xin Yang[2], John S. Ho[2] and Yong Lin Kong[1]; [1]University of Utah, United States; [2]National University of Singapore, Singapore

3D printing of nanomaterials can enable the creation of freeform architectures and multifunctional devices with unprecedented versatility. The full potential of this technology, however, has so far been limited by the inability to selectively anneal the printed nanomaterials, a critical step to enhance performance. Here, we demonstrate the ability to selectively and locally anneal 3D printed nanomaterials *in situ* on a broad range of temperature-sensitive substrates by focusing near-field electromagnetic waves using a metamaterial-inspired near-field electromagnetic structure (Meta-NFS). The near-field microwave 3D printing (NFP) enables exceptional control of printed nanomaterial annealing parameters, allowing the creation of spatially freeform microstructure where the electronic and mechanical properties can be locally programmed. NFP significantly broadens the possible class of materials compatible with an additive manufacturing process, enabling the creation of hybrid multi-functional constructs and printing of functional electronics even on temperature-sensitive substrates.

11:30 AM SB08.11.05
Multifunctional Fluorinated Coating for Improving Neural Implant Biocompatibility May Yoon Pwint, Paige Martin and Xinyan T. Cui; University of Pittsburgh, United States

Although implantable neural electrode devices have been used in animals and human for neuroscience research and clinical applications, they face the challenge of signal degradation due to a myriad of reasons including implantation trauma, glial scarring, biofouling, and loss of signal-generating neurons. During implantation, the neural probe inflicts injury to the brain tissue by breaking blood vessels and inducing mechanical stress to the surrounding tissue. The implantation then triggers a cascade of immune response involving non-specific protein adsorption, inflammatory cell adhesion followed by the encapsulation of the probe by glial sheath. The disrupted blood flood may cause hypoxia, which along with the trauma and inflammation may compromise neuronal survival and function.
Here, we used chemically and biologically inert perfluorocarbon (PFC) as a multi-functional coating for implantable neural interfaces providing 1) lubrication during insertion to reduce insertion trauma, 2) anti-fouling surface, and 3) oxygen supply to the injury site. Preliminary data shows that the PFC coating can reduce peak insertion force of a single-shank silicon probe by at least 50%, translating to less acute trauma. The PFC coating also effectively decrease non-specific protein adsorption and inflammatory cell attachment. In addition, the same coating is capable of carrying oxygen and passively

releasing it over at least six hours. We also studied the effect of the coating on the interfacial impedance of platinum electrodes and found no significant difference in impedance between the bare and PFC coated electrodes. Combined, these functionalities of the PFC coating showed great potential for reducing implantation trauma and improving neuronal survival near the neural electrode implants.

1:30 PM *SB08.12.01
Development of Highly Biocompatible Ultra-Low Fouling Zwitterionic Materials, Coatings and Nanoparticles Shaoyi Jiang; Cornell University, United States

An important challenge in many applications is the prevention of unwanted nonspecific biomolecular and microorganism attachment on surfaces. We have shown that zwitterionic materials and surfaces are highly resistant to nonspecific protein adsorption and microorganism attachment from complex media. Typical zwitterionic materials include poly(carboxybetaine), poly(sulfobetaine), poly(trimethylamine N-oxide), and glutamic acid (E) and lysine (K)-containing poly(peptides). Unlike poly(ethylene glycol) (PEG), there exist diversified zwitterionic molecular structures to accommodate various properties and applications. Furthermore, zwitterionic materials are super-hydrophilic while their PEG counterparts are amphiphilic.
In this talk, I will discuss the application of zwitterionic materials to implants, medical devices, stem cell cultures, and drug delivery carriers. With zwitterionic materials, coatings, hydrogels or nanoparticles, results show no capsule formation upon subcutaneous implantation in mice for one year, expansion of hematopoietic stem and progenitor cells (HSPCs) without differentiation, no anti-coagulants needed for artificial lungs in sheep, and no antibodies generated against zwitterionic polymers. I will also discuss a newly developed drug delivery system to delivery mRNAs or small molecules through the blood-brain barriers into the brain.

2:00 PM SB08.12.02
Tailoring Thermogels: A Versatile Strategy for Functionalized Injectable Hydrogels and Controlled Drug Release Joey H. Wong[1], Belynn Sim[1,2], Jason Y. Lim[1,3], Xian Jun Loh[1,4,2] and Rubayn Goh[1]; [1]Institute of Materials Research and Engineering, Singapore; [2]Nanyang Technological University, Singapore; [3]National University of Sciences & Technology, Singapore; [4]National University of Singapore, Singapore

Biocompatible injectable hydrogels provide a minimally invasive strategy for biointerfacing. Depending on the encapsulated payload, these hydrogels can serve as a low-modulus interface for neural electrodes, provide localized and sustained delivery of drugs, or offer structural support to cells during proliferation and tissue regeneration. One strategy used to develop injectable hydrogels involves copolymerizing thermally-responsive blocks with a hydrophilic polymer (e.g. pluronics). These thermally responsive injectable hydrogels, known as thermogels, undergo a sol-gel transition above a critical gelation temperature, such as when being warmed to 37°C. This is triggered by the formation of micellar crosslinks of the thermo-responsive domain.

In this study, we have developed a versatile synthetic strategy for creating a library of functionalized thermogels and have investigated the three-way interactions between functional groups, gel scaffolds, and encapsulated drugs. Our work will illustrate the impact of these functional groups on the sol-gel transition, the physical properties of these gels, and the sustained release of drug analogs. As a proof of concept, we were able to achieve sustained release of anionic orange II and cationic crystal violet of 5 to 6 months, with release profiles varying depending on the functionalized moieties.

2:15 PM SB08.12.03
Advanced Microfabrication Strategies for Neuro-Inspired 3D Conductive Polymers Valeria Criscuolo[1,2], Claudia Latte Bovio[3], Kevin Lengefeld[1,2] and Francesca Santoro[1,2,3]; [1]RWTH Aachen University, Germany; [2]Forschungszentrum Jülich GmbH, Germany; [3]Istituto Italiano di Tecnologia, Italy

Neuroelectronic platforms aim at recapitulating neuronal communication and functions to monitor and eventually restore lost functionalities. Indeed, engineering neuroelectronic devices that can be smoothly interfaced with brain and neurons can provide a step forward in a better understanding of hampered electrical communication in e.g., neurodegenerative diseases. In this scenario, conductive polymers, such as PEDOT:PSS, have gained a prominent position in the realization of seamlessly integrated bioelectronic devices and soft flexible probes.[1] However, existing polymer-based devices are not yet able to effectively mimic and reproduce the complex neuronal environment, being flat and bidimensional. Neurons indeed interact with and respond to a great variety of mechanical and topographical stimuli; thus it is imperative to take inspiration from the extremely complex architecture of the brain.[2] Moreover, the cell-device interface plays a crucial role for an effective electrical coupling between the cell and the device.[3] Indeed, a cleft is typically formed between the cell and the electrode. For this reason, recent approaches demonstrated that non-planar substrates, featuring 3D and 2.5D structures,[4] result in the reduction of the cleft and in an improvement of cell-device electrical coupling.[5]
In the light of the above, here we introduce innovative microfabrication strategies for the realization of neuroelectronic platforms based on PEDOT that can recapitulate distinctive morphological neuronal features such as dendrites and dendritic spines.
Dendrites were reproduced by the formation of PEDOT:PF_6 fibers by using AC electro polymerization[6] on a multi electrode arrays (MEAs). By changing the parameters of the applied signal and the geometric relationship between the electrodes, the growth and morphology of the fibers was altered. Additionally, the fibers geometry and branching was tuned by changing the shape of the applied AC-signal and the manipulation of the electrical field. The so obtained dendrite-like fibers were morphologically characterized by means of scanning electron microscopy (SEM) and atomic force microscopy (AFM) and the neurite elongation and branching was compared to real neurons. Additionally, electrochemical properties as well as long term stability in aqueous media was investigated via electrochemical impedance spectroscopy (EIS) and cyclic voltammetry (CV).
On the other hand, dendritic spines, biological structures essential in synaptic communication, were recreated by means of 2-photon polymerization (2PP) lithography, given its high resolution, versatility, and design freedom[2] both achieving non-conductive and conductive material patterning via electropolymerization. The resulting 3D microstructures were characterized by SEM and electrochemical measurements (CV and EIS) .
Finally, biocompatibility assays were carried out for both dendrites- and dendritic spines-like structures with neuronal cells, and the local adhesion processes to the 3D structures was characterized by means of optical and electron microscopy.
Overall, the proposed strategies allow for the fabrication of 3D/2.5D electrodes with different levels of complexity that can effectively mimic neuronal features and enhance the cell-chip interface. Such systems will open the way to the possibility of sensing and/or stimulating cells and tissues in a more realistic environment.

2:30 PM SB08.12.04
A Simple Animal Model to Discover Neuroactive Function of Semiconducting Oligomers Claudia Tortiglione[1], Giuseppina Tommasini[1], Mariarosaria De Simone[1], Silvia Santillo[1], Marika Iencharelli[1], Gwennaël R. Dufil[2], Daniele Mantione[3], Eleni Stavrinidou[2] and Angela Tino[1]; [1]Istituto di Scienze Applicate e Sistemi Intelligenti, Italy; [2]Linköping University, Sweden; [3]University of the Basque Country, Spain

Modulating neural activity with electrical or chemical stimulus can be used for fundamental and applied research. Beside intracellular and extracellular electrodes delivering brief electrical pulses for neural stimulation, wireless methodologies based on functional materials may represent superior alternatives to modulate neuronal function. Here we show that the organic semiconducting oligomer ETE-S induces precise behaviors in the freshwater polyp *Hydra*, a small invertebrate with a nerve net controlling a limited repertoire of behaviors. Through pharmacological and electrophysiological approaches we found that the ETE-S induced behavioral response relies on the presence of head neurons and calcium, and is prevented by drugs triggering ionotropic channels and muscle contraction [1]. Moreover, ETE-S affects *Hydra*'s electrical activity enhancing the contraction burst frequency. The unexpected neuromodulatory function played by this conjugated oligomer on a simple nerve net opens intriguing research possibilities on fundamental chemical and physical phenomena behind organic bioelectronic interfaces for neuromodulation, and on alternative methods that could catalyze a wide expansion of this rising technology for clinical applications.

2:45 PM SB08.12.05
Polymer-Based Transparent Brains for 3D Evaluation of Brain Tumors without Tissue Sectioning Maryam Golshahi, Hamed Arami and Layla Khalifehzadeh; Arizona State University, United States

Conventional tissue sectioning, staining, and optical microscopy are used as standard clinical methods for diagnosis of the brain tumors (i.e., glioblastoma multiforme or GBM), studying their anatomical phenotypes and evaluating their response to therapies. Sectioning of the tissues is destructive and stained and analyzed tissues cannot be re-used for evaluation of additional biomarker. Also, histological microscopy data obtained from each tissue section are limited to that area of the tumor and are not ideal representatives of the whole tumor mass, especially for highly heterogeneous tumors such as GBM. Here, we will discuss a method for transforming the whole brain tumor tissues to optically transparent hydrogel masses without losing any anatomical, extracellular or sub-cellular features within the tissues. Different types of orthotopic brain tumors (e.g., human-derived U87 GBM with GFP signal) were generated in mouse brains (n=3-5) and analyzed using magnetic resonance and bioluminescent imaging (MRI and BLI). Brains were excised and immersed in an acrylamide monomer solution, followed by the polymerization of these monomer molecules within the entire brain tissue at 37°C. Brains were clarified by removing the lipid molecules from the tissue microenvironment. Transparent brains were analyzed using confocal and light-sheet microscopy techniques after being immersed in Focus Clear solution to adjust their refractive index for optimized microscopy. Three-dimensional macroscopic and microscopic maps were generated from the whole brains for analyses of the tumor growth pattern and their response to therapies, without losing the intactness of the proteins and tissue structure. Using various monomer derivatives enabled the tuning of the cross-linking rate and optical transparency of the hydrogels for improved analysis of heterogeneous tumor masses. This method enabled series of reversible staining de-staining, and re-staining of the tissues for clinical analysis of different brain tumors and a variety of neuropathological biomarkers.

What Happens When We Stimulate Cells with Electricity? George G. Malliaras; University of Cambridge, United Kingdom

Electrical stimulation of cells can elicit a variety of biological outcomes, e.g. the firing of action potentials in neurons, or the promotion of apoptosis in dividing cells. Clinical uses of electrical stimulation include the treatment of cardiac arrhythmia, profound deafness, movement disorders and different forms of cancer. Still, a unified description of the phenomena elicited by electrical stimulation does not exist and different communities focus on particular aspects within the general field (electrophysiology, tissue engineering, electroporation, tumour treating fields). I will discuss a generalised framework for discussing these phenomena, starting with experimental ways to avoid the production of chemical species at the electrodes, following with a review of the physical phenomena that take place upon electrical stimulation and ending with the elicited biological outcomes.

11:00 AM SB09.01.02
Investigating Electrical Stimulation to Mitigate The Foreign Body Response in Neural Implants Filip Wronowski and George G. Malliaras; University of Cambridge, United Kingdom

This research addresses a critical challenge in the field of neural interfaces: the foreign body response (FBR). Neural interfaces hold tremendous promise for treating neurological disorders and enhancing therapeutic outcomes, but the FBR often limits their long-term effectiveness.

The FBR is primarily driven by non-neuronal glial cells and results in chronic inflammation and fibrosis, ultimately compromising neural recording and stimulation capabilities. This study focuses on the potential of electrical stimulation to mitigate the FBR and enhance the performance and longevity of neural implants.

Preliminary findings indicate that electrical stimulation can influence astrocytes, fibroblasts, and other cell types involved in the FBR. The parameters of stimulation, including timing, intensity, and frequency are being investigated and can influence the glial response, ranging from driving cell alignment, affecting cell division and to exerting anti-inflammatory to pro-inflammatory effects.

To this end, we employ two novel in vitro platforms, followed by advanced microscopy techniques and cytokine assays. These insights will be further complemented by RNA sequencing. Our ultimate aim is to extend our findings to an in vivo context, enabling us to refine our understanding and improve strategies for addressing the foreign body response in neural implants.

This research sheds light on these complex interactions, offering potential strategies to enhance the effectiveness of neural interfaces and reduce the impediments caused by the FBR. Ultimately, this work has the potential to significantly impact the field of neural implant technology and improve patient outcomes in the treatment of neurological disorders.

Quantum biological tunnelling for electron transfer (QBET) is involved in controlling essential functions for life such as cellular respiration and homoeostasis. Understanding and controlling the quantum effects in biology has the potential to modulate biological functions. Here we merge wireless nano-electrochemical tools with cancer cells for control over electron transfer to trigger cancer cell death. Gold bipolar nanoelectrodes functionalized with redox-active cytochrome *c* and a redox mediator zinc porphyrin were developed as electric-field-stimulating bio-actuators, termed bio-nanoantennae. We show that a remote electrical input of alternating current (A.C.) at high frequency (3MHz) and low voltages (0.65V/cm) regulates electron transport between these redox molecules, which results in quantum biological tunnelling for electron transfer to trigger apoptosis in cancer cells from various hard-to-treat tumors. Transcriptomics data show that the electric-field-induced bio-nanoantenna targets the cancer cells in a unique manner, representing electrically induced control of molecular signaling. Arrhenius-kinetics confirmed the occurrence of moderate QBET in the system. *In vivo* studies in tumor bearing rats are underway to demonstrate first example of quantum medicine to treat cancers.

1:30 PM *SB09.02.01
Organic Neuromorphic Bioelectronics Paschalis Gkoupidenis; Max Planck Institute for Polymer Research, Germany

Neurons are the fundamental elements of the nervous system, coping with a great diversity of electrobiochemical signals. Neuronal function is an archetype for biomimicry with neuromorphic electronics. However, artificial neurons based on electronics are insufficiently capable of operating in situ in biological environments, thus hampering the seamless sensing and biointerfacing as well as the biorealistic neuronal emulation. A few examples of soft-matter artificial neurons are based on conventional circuit oscillators and therefore require many elements for their implementation. An organic artificial neuron consisting of a compact non-linear electrochemical element will be presented. The artificial neuron displays in situ operation in biologically relevant environments that displays spiking dynamics sensitive to common ions of the biological aqueous milieu, within physiopathological concentration ranges (~5-150mM), and with ion specificity. Small-amplitude (~1-150 mV) electrochemical oscillations and noise in the electrolytic medium shape the neuronal dynamics, while changes of ionic (≥ 2% over physiological baseline) and biomolecular concentrations (≥ 0.1 mM dopamine) modulate the neuronal excitability. The artificial neuron operates synergistically with bio-membranes, forming real-time biohybrid interfaces. This electrochemical artificial neuron opens new possibilities for the seamless communication and the realistic emulation of biology with electronics.

2:00 PM SB09.02.02
Ultrathin TiO_2 ALD Coatings Enhance Properties of Biomaterials used in Medicine Jana Bacova[1], Kaushik Baishya[2], Jan Capek[1], Raul Zazpe[1,2], Hanna Sopha[1,2], Lina M. Sepulveda[1], Tomas Rousar[1] and Jan M. Macak[1,2]; [1]University of Pardubice, Czechia; [2]Central European Institute of Technology, Brno University of Technology, Czechia

TiO_2 surfaces are in general recognized as excellent biocompatible materials owing to their resistance to body fluid effects, low ion release, high stability, antibacterial properties, and wetting ability. Various TiO_2 nanostructured surfaces show great properties enhancing cell interactions. Anodic TiO_2 nanotube (TNT) layers have emerged as extremely suitable and effective substrates for cell growth and proliferation. A pioneering study demonstrated that TNTs with a diameter of 15 nm are the most suitable surface for the growth of cells [1]. Several papers also showed that anodization is a great tool for surface modification of various materials used in biomedical applications, especially TiAlV.
Recently, we demonstrated that ultrathin coatings by metal oxides (e.g. TiO_2) using Atomic Layer Deposition (ALD) on TNT layers enhance cell adhesion, growth, and proliferation [2]. These properties make them excellent as the uppermost surfaces for bone and dental implants. The presentation deals with the comparison of the biological effect of ultrathin TiO_2 ALD coatings achieved by various numbers of TiO_2 ALD cycles on planar and nanotubular surfaces. For that Ti sheets and anodized TNT layers with a distinct inner diameter of 12 nm and 15 nm, were used as substrates, as they appear to be the most suitable for cell growth in general. We evaluated the cell adhesion, proliferation, and density of fibroblast, osteoblast, and neuroblast cells on these substrates [2,3].
Moreover, the single-cell adhesion of the cells to the TNT layers modified using ALD method was studied by the bio-Atomic Force Microscopy (bio-AFM) technique [3]. Finally, the biological effect of black form of TiO_2 nanotubes in comparison to their classical counterparts was investigated for the first time. The black TiO_2 nanotubes with TiO_2 ALD coating can be considered as a potential candidate in various applications due to the disappearance of mild toxic effects of white and black TiO_2 nanotubes due to the shading of carbon and fluorine species incorporated within the TiO_2 nanotube walls [4].

Microalgal Growth Assessment using Fluorinated Ethylene Propylene Microcapillaries Raquel Amaral[1], David M. Silva[1], Nuno M. Reis[2] and Paulo R. Rocha[1]; [1]University of Coimbra, Portugal; [2]University of Bath, United Kingdom

Efficient microalgal bioanalytical microsystems are becoming crucial to address the industrial, agricultural and environmental increasing demands. Most microalgae farming continues to depend on a significant amount of manpower in monitoring and measuring growth of microalgae in open ponds and/or photo-bioreactors. This requires specialized operators, regular sampling from open ponds or photo-bioreactors, and the use of in bulky laboratory equipment. In addition, many open ponds and water reservoirs are exposed to environmental factors such as temperature, nutrients or pH changes which may trigger algal blooms or cause difficulty in predicting microalgal growth, a critical challenge in the water industry.
In this work we demonstrate the use of a melt-extruded fluorinated ethylene propylene (FEP) Teflon microfluidic film coated with PVOH as a hydrophilic “dip-stick” microcapillary for *in-situ* power-free sampling and optical monitoring of microalgal growth. We ascertained the growth of *Chlorella* for 22 days in the ‘dip stick’ microfluidic strips matched well the growth in an aerated Erlenmeyer, yielding a logistic growth with a growth rate of 0.35 day^{-1} and similar to large industrial bioreactors, without the need of nutrient renewal. The optical transparency of the ‘dip stick’ strip combined with good permeability enabled simultaneous tracking of cell cycle and growth rate using simple image analysis, which can easily be carried out with a smartphone camera.
Our new microanalytical solution enables micro-cultivation and individual cell monitoring over time, which may pave the way to innovative biocompatible materials for water management and also high throughput microalgal productivity assessment.

3:00 PM *SB09.03.01
Mechano-Electrical Coupling in Neurons Sonia Contera; University of Oxford, United Kingdom

We have become used to studying the different aspects of biological function in isolation; biochemical, genetic, mechanical or electrical properties of

biomolecules, cells and organisms are studied by different fields. Yet, it is precisely the coupling of the different aspects inside “a living shape” that underlies the functional diversity and the information processing capacity of living systems. By coupling their properties, biological systems can induce behaviours acting against the direction imposed by thermodynamic forces, which are characteristic of *being alive*. For example, a protein is able to work with great efficiency because it couples electrostatics, mechanics and chemistry; an embryo grows its shape by coupling mechanical, chemical, genetic and electrical oscillations.
In neurons, evidence gathered over half a century shows that local mechanical changes in the membrane propagate along with the action potential in neurons. These observations effectively point towards the hypothesis that the action potential is not merely an electrical pulse, but a complex multiscale electro-mechanical “multiphysics” process that affects and is affected by all components of the membrane [1]. Due in part to the emergence of experimental techniques such as atomic force microscopy (AFM) that allow to measure and alter the mechanical properties of membranes and living cells in physiological environments, research interest in the role of mechanics of the neuronal membrane has grown, essentially driven by its potential in medical applications, e.g in ultrasound neuromodulation (expected to find applications in the treatment of epilepsy and chronic pain, to promote neuroplastic repair mechanisms for post-stroke recovery).
Using new techniques that allow us to apply mechanical signals to living neurons from the Hz to the 100s of KHz range and to quantify correctly viscoelastic properties from these measurements [2], and coupling them to electrophysiological and fluorescence measurements, our work shows that alterations of electrophysiological activity (e.g., with anaesthetics or electrical potential) correlate linearly with a change in viscoelastic properties such as the loss tangent, the ratio of mechanical energy stored and dissipated in the cell [3]. And the other way around, ultrasound stimulation alters neuronal firing. I will discuss these results in the context of building a “multiphysics” nonequilibrium framework to study neurons that allows us to create models to predict/interpret the oscillatory systemic behaviours of physical/chemical properties of neuronal networks [1].

3:30 PM *SB09.03.02
Bioactive Piezoelectric Nanofibers for Electromechanical Stimulation and Neuronal Regeneration Leyla Esfandiari[1,2]; [1]University of Cincinnati, United States; [2]Cincinnati Children Hospital, United States

One of the important signaling networks in embryonic development, regeneration, and homeostasis of tissue is the endogenous bioelectricity. It has been observed that electric fields can promote axonal regrowth in nerve injury and bioelectric stimuli can be crucial to induce regeneration in peripheral and central nervous systems. Severe peripheral nerve injuries disrupt nerve pathways, connections, and the extracellular matrix (ECM) surrounding the nerve, which affects distal innervation targets. If the injury gap is large enough, functional recovery is extremely limited and adequate clinical therapies don’t exist. A key reason for poor functional recovery is that neurons lack the proper guidance, alignment, and signaling from the damaged ECM to allow for targeted growth across injured tissue.
We have developed an ultrasound-mediated, bioactive scaffold that addresses these challenges by offering controllable electrical, physical, and chemical signaling capabilities. Piezoelectric poly(vinylidene fluoride-co-trifluoroethylene)(PVDF-TrFE) is integrated with decellularized ECM through electrospinning fabrication technique. The bioactive piezoelectric nanofibers are capable of producing controllable electrical stimulation in response to cellular mechanobiology and remote ultrasound activation without the need for electrodes due to its piezoelectric capacity. The tissue-specificity of the ECM combined with the piezoelectric scaffold improved the cell-biomaterial interactions and host immune response. Extensive characterization of material properties was conducted on resultant bioactive scaffolds. The bioactive scaffold's piezoelectric nature remained intact, and cell-material interactions showed enhanced cell viability, proliferation, and adhesion. This new and multi-parametric biomaterial is envisioned to be used as next-generation nerve guidance conduits (NGCs) and will be tested for its efficacy in the future.

4:00 PM SB09.03.03
Observation of Cell Behavior by Waveform Measurement using Lithium Niobate-Based Surface Acoustic Wave Device Shun Koda[1], Takahiro Yamada[2], Hiroaki Onoe[3], James Friend[2] and Yuta Kurashina[1]; [1]Tokyo University of Agriculture and Technology, Japan; [2]University of California, San Diego, United States; [3]Keio University, Japan

Introduction: Highly matured cells and tissues are essential to improve the quality of regenerative medicine and drug discovery research. Fluorescence observation by immunostaining with antibody labeling of maturation makers is one of the gold standards for evaluating such cells and tissues. To deliver antibodies to antigens in the cell membrane, fixation and permeabilization of cells are necessary for fluorescence observation. Recently, living cells can be observed by gene transfer (Kasahara et al., ***Sci. Adv.***, 2023), but with the risk of altering the cellular morphology. That is, observation of living cells is difficult without damaging cells.
Here, we propose a non-invasive evaluation method of cultured cells using surface acoustic waves (SAW) for sensing cell behavior without administering any invasive chemicals to the cells or altering their genetic traits. For cell behavior observation, a cell evaluation system with surface acoustic waves transmitted from a SAW device to the cells was fabricated. The SAW device consists of lithium niobate (LN) substrates having a high mechanical quality factor. Thus, LN is suitable for the material of the SAW device because of its low elastic loss and low attenuation of surface acoustic waves.
Materials and methods: The waveform information from the transmitted and received waves was measured to observe cell behavior by this cell evaluation system. The cell evaluation system was composed of the SAW device and energizing probes. The SAW device was fabricated by a lift-off method using an LN substrate with chromium and aluminum deposited to form IDT fingers. To micropattern the cells to the measurement spot, the seeding area was limited by the dimethylpolysiloxane (PDMS) chamber sandwiched between acrylic covers to adhere the chamber to the SAW device. The slit surface was then cleaned using peracetic acid and plasma. The cells were incubated for 6 hours after modifying fibronectin on the surface of the SAW device. After incubation, the acrylic cover and cell-seeding chamber were removed from the cell evaluation system. After seeding cells, an alternating current of around 40 MHz band was applied to the IDT to measure the received wave with an oscilloscope.
Results and discussion: The resonance frequency of the SAW device on the transmitter side of the fabricated cell evaluation system was measured with an impedance analyzer at 37.8 MHz. The SAW devices freely control the frequency band of irradiating SAW by changing the design of the distance between the interdigital transducer (IDT) fingers. In this study, by setting the distance between the IDT fingers to 25 μm, the target resonance frequency of the SAW device was 40 MHz. From the measurement of the impedance analyzer, the SAW device with a resonance frequency close to the target resonance frequency was successfully fabricated. This reproduces a wavelength (= ~100 μm) that provides sufficient resolution for observing cell behavior. The cell seeding area was a 1 mm × 5 mm slit area considering that the attenuation length of the SAW surface displacement at the LN-water interface is 1.24 mm. The SAW was irradiated by applying an alternating current at around 40 MHz band to the IDT fingers of the SAW device on the transmitting side. Waveforms were measured at two different cell counts. The ratio of the amplitude of the received wave to the amplitude of the transmitted wave was 0.88

when the cell density was 627 cells/mm^2, and 0.97 when the cell density was 83 cells/mm^2, respectively. Comparing them, the surface acoustic waves were attenuated as the number of cells increased. These results suggest that this system is effective in measuring cell counts. Since ultrasound is capable of reaching deep into tissues, measuring waveforms using this system could be applied to the development of more effective biomaterials including 3D cellular tissues.

SESSION SB09.04: Bioelectronic Interfaces for Monitoring and Modulating Cells
Session Chairs: Frankie Rawson and Paulo Rocha
Tuesday Afternoon, April 23, 2024
Flex Hall C, Level 2, Summit

5:00 PM SB09.04.01
PEDOT:PSS Porous Electrodes for Probing Cohort Signaling in Escherichia Coli Felipe L. Bacellar[1], Francisco C. Cotta Jr[1], Raquel Amaral[1], Nuno M. Reis[2] and Paulo R. Rocha[1]; [1]University of Coimbra, Portugal; [2]University of Bath, United Kingdom

Bacteria are known to coordinate gene expression to control their phenotypic characteristics to the most favourable condition in harsh environments. This smart communication mechanism enables the bacteria cells to efficiently manage the behaviour of their surrounding community. One important mediator of communication processes in bacteria is the dynamics of their membrane potential, mainly studied through single-cell patch-clamp - which is difficult due to bacteria small size, and through the use of genetic modified bacteria that produce changes in fluorescence intensity as a function of membrane polarization. Despite being a direct response to the external electric stimuli and chemical agents (such as ion channel inhibitors, stimulants or antibiotics) these fluorescence methods usually require toxic fluorescent probes hindering stress-free long-term recordings and fail to probe important sub-thresholds regimes in the measuring cell or cellular cohort.
Non-invasively sensing the minuscule electrical activity of bacteria populations is therefore a major challenge in bioelectronics and microbiology. To overcome this challenge, we have devised a highly sensitive transducer based on Au/Polyurethane(PU)/poly(3,4-ethylenedioxythiophene) polystyrene sulfonate (PEDOT:PSS) electrodes, to visualize the electrogenic activity of cohorts of bacteria without the need of gene modification or the use of stimuli to address intercellular communication.
For the first time, the electrical activity of large *Escherichia coli* populations is directly measurable. By submerging the recording electrodes into LB broth with the model bacteria *E. coli* MG1655, we were able to sense the bacterial electrical behaviour without any physical disruption or interference into their physiology. *E. coli* demonstrated fluctuations of their basal voltage level, which is much higher in amplitude than the background acquisition noise of about 1 µV. The extracellular analysis reveals asynchronous and synchronous electrical spikes, with amplitudes ranging from 10 µV up to 100 µV, spike widths from 50 ms to 2 s and sporadic events of quasi-periodic bursts with interspike intervals mostly between 0.5 to 10 s, which can be attenuated by using a protonophore carbonyl cyanide m-chlorophenylhydrazine (CCCP).
The electric noise analysis combined with compound screening indicated that the *E. coli* likely communicate through a diffusion-limited paracrine signalling mechanism where the diffusion of H^+ plays an important role.
Our ultra-sensitive transducer is a unique screening tool to study the electrophysiological properties of large bacterial populations under different pharmacological compounds effects and metabolic states contributing to more effective drug developments.

5:00 PM SB09.04.02
Bioelectricity in Diatom Phaeodactylum Tricornutum *C*ohorts Raquel Amaral, Francisco C. Cotta Jr, Felipe L. Bacellar and Paulo R. Rocha; University of Coimbra, Portugal

Diatoms are a large and highly diverse group of photosynthetic microalgae, mostly oceanic, with a major environmental role on the planet due to a significative contribution to global fixation of carbon and to the biogeochemical cycling of silica. The peculiar evolutionary history of diatoms equipped them with a unique genetic and metabolic makeup which likely contribute to their ecological success in the contemporary oceans. The presence of intracellular signaling and intercellular communication mechanisms in diatoms upon stress plays a role in the acclimatory response to (a)biotic stressors. Diatoms thrive and may proliferate into pernicious harmful algal blooms through their resourceful communication mechanisms, not yet fully understood. We demonstrate that a population of diatoms under darkness show electrical oscillations. Cells of model diatom *Phaeodactylum tricornutum* were left to settle on planar gold printed electrodes. The setup was in a Faraday's cage connected to instrumentation tailored to record minute electric fluctuations stemming from extracellular signaling. Recordings of voltage as a function of time show fast signals, preceded by voltage elevation, which resemble neurons' "firing" action potential. The mean magnitude of these spikes was 0.0404 mV, with a mean duration of 0.444 s, they are possibly a result of collective participation of several cells as a response to voltage fluctuation. Since diatoms are not synaptically interconnected in a network as neurons are, signal transmission likely occurs by paracrine signaling, in which one cell diffuses a messenger molecule to nearby cells, causing a cascade effect by consecutive voltage-gated diffusion of ions through membrane channels. Slower signals were also recorded with a speed of 201.9 µm/s across the 1.4 mm diameter electrode, similar to previously determined for another diatom species. These signals have an atypical shape resembling random telegraph noise. Messenger Ca^{2+} ions are involved in the mechanism, since their diffusion characteristics match those of the intracellular waves.
The translation of microalgal cooperative signaling paves the way for early detection and prevention of harmful blooms and an extensive range of stress-induced alterations in the aquatic ecosystem.

5:00 PM SB09.04.03
Cyanobacteria Growth Assessment using Fluorinated Ethylene Propylene Microcapillaries David M. Silva, Raquel Amaral and Paulo R. Rocha; University of Coimbra, Portugal

Due to global warming and other human-derived nutrient rich discharge, nutrient availability increases, causing anomalous proliferation of bloom-forming phytoplankton. This leads to eutrophication and the deoxygenation of bottom waters, with a dramatic toll on the affected food web and ecosystems. Cyanobacteria, also known as blue-green algae, are the main bloomers in freshwater ecosystems, including species of *Oscillatoria*, known to produce algal toxins with an unpleasant earthy/moldy taste and odor, contaminating water sources and drinking waters.
The study of filamentous cyanobacteria is hampered by technical problems stemming from the slow growth observed *in vitro*, even with nutrient-rich culture media. Their maintenance in laboratory conditions is demanding and requires frequent nutrient refreshing to prevent culture loss. Moreover, the conventional methodologies used to study growth over time, such as cell counting, are not applicable due to cells being packed into filamentous morphology. Also, dry weight estimations are inconsistent due to the presence of various filament sizes in culture.
To overcome the technical limitation of assessing the filamentary growth of cyanobacteria, we developed a transparent fluorinated ethylene propylene (FEP) microcapillary strips to sample, cultivate and monitor the loaded filaments of *Oscillatoria* over time.

Geosmin producer strain *Oscillatoria* sp. UHCC 0332 was cultivated in BG11 medium during 3 weeks, in a growth chamber. Filaments were dip-loaded into 3 cm long strips that were then cultivated in standard conditions for 2 weeks for image assessing and then up to 15 more weeks for confirming survival. The growth of two filaments was determined after 1 and 2 weeks. The estimation of growth was achieved by determining the area occupied by the filaments over time, with image analysis. This enabled the observation that filaments elongate over time with growth rates reaching up to 0.40 day^{-1}. Also, it was possible to estimate the number of cells which corresponded to elongation. Our microanalytical solution enables long-term micro-cultivation and individual *Oscillatoria* monitoring over time, which may pave the way to pioneering biocompatible materials for water management and productivity assessment.

5:00 PM SB09.04.04
A PEDOT:PSS Porous Electrode for Real-Time Monitoring of Microalgae Growth using Electrochemical Impedance Spectroscopy Francisco C. Cotta Jr, Raquel Amaral, Felipe L. Bacellar and Paulo R. Rocha; University of Coimbra, Portugal

Microalgae are early Jurassic unicellular microorganisms globally used as sentinels to examine water ecosystems due to their ability to grow in most humid environments and quickly react to environmental stressors. Monitoring microalgal growth is currently an important area in water resource management and remains hindered by non-efficient measurements of, for instance, N and P nutrient fractions, temperature, and dissolved oxygen, or even biomass. Here, we show that electrical impedance spectroscopy (EIS) can be used as a non-invasive and real-time tool to probe microalgal growth, from the linear to stationary phases, on metal/polyurethane/poly (3,4- ethylenedioxythiophene) polystyrene sulfonate (PEDOT: PSS) electrodes.
A highly mucilaginous culture of *Chlamydomonas* was selected to promote cell adhesion to our Au/PU/PEDOT: PSS porous electrode. The cells were seeded on our transducer, within a homemade cultivation well and inside a standard algal growth chamber from ARALAB. The EIS recordings were continuously monitored inside the ARALAB, for 14 days, during which the cells grown from linear to stationary phases - as confirmed by our parallel and conventional cell counting methods. Contrary to the high frequency regime where minor changes occurred, at low frequencies, below the Maxwell-Wagner relaxation frequency at 0.1 mHz, a substantial change in impedance of over 3 kΩ was observed with culture time.
Interestingly, the EIS data and equivalent circuit modeling are consistent with standard microscopy analysis, cell-counting and extracellular matrix development. The growth followed a logistic function with exponential phase from day 2 until day 6 followed by a linear growth and then cell density started to decline at day 10. A growth rate of k=0.85 cells/day was extracted from standard growth curves. The EIS at 0.1 mHz followed a similar trend to the standard growth curve, with an Impedance increase at the beginning of the growth curve coinciding to the exponential and linear phase of growth, followed by an electrochemically stable stationary stage. By following the extracellular polymeric substances (EPS) formation in *Chlamydomonas* cells over time, we ascertained that the high production of EPS by each cell in the initial growth phase is quite significant and contributes to a higher Impedance, at the beginning of growth. In fact, by considering that the cells and EPS are both occupying the sensor surface area and causing the impedance to change, a growth curve obtained with the total area occupied by cells and EPS was by normalized with the corresponding EIS, which resulted in a near overlapping of the fitted logistic functions.
Here we show that Au/PU/PEDOT:PSS porous electrodes can be applied to sense, characterize and model microalgae growth with EIS, which may open new avenues for more effective and predictive water resource management.

SESSION SB10.01: Organic Electrochemical Transistors—Fundamentals and Materials I
Session Chairs: Hans Kleemann and Sihong Wang
Tuesday Morning, April 23, 2024
Room 429, Level 4, Summit

10:30 AM *SB10.01.01
Novel Approaches for High-Performance Organic Transistors Lukas M. Bongartz, Matteo Cucchi, Anton Weissbach, Ali Solgi, Hans Kleemann and Karl Leo; IAPP, Germany

The first organic transistors reported were organic electrochemical transistors (OECT, 1984) historically before the organic field effect transistor (OFET, 1986), the organic inversion transistor (2011), and the organic bipolar transistor (2022). After a longer phase of limited interest, OECT have recently been investigated intensively since they offer switching and sensing functionality in an electrolytic environment compatible with biological systems. The mixed electron-ion transport of the devices has consequence for many parameters of the devices including dynamics and hysteresis. In this talk, our recent work on a better understanding of OECT operation is discussed. Recently, we have shown that the so far used electrostatic "FET-like" description of OECT is needs to be extended to a model including entropic and enthalpic terms. The model elegantly describes a multitude of effects, including bistability and a peculiar temperature behavior of subthreshold slopes. Besides offering new insight into the basic operation, it also allows novel device applications.

11:00 AM *SB10.01.02
Novel Material for n-Type Organic Electrochemical Transistors Thuc-Quyen Nguyen; University of California, Santa Barbara, United States

Organic electrochemical transistors (OECTs) are attractive for applications in chemical and biological sensors, neuromorphic computing, and reconfigurable electronics. An OECT consists of three electrodes (source, drain, and gate), an organic mixed ionic-electronic conductor (OMIEC) channel connecting the source and the drain, and an electrolyte between the gate and the channel. The development of OECTs has been strongly linked to advances in OMIECs. The OECT active material needs to accommodate ion transport, electronic transport, ion-electronic coupling, and air stability. For these reasons, early development of OMIECs has focused mostly on p-type polymer materials because of their superior air-stability and processability. As for n-type OECT polymer active materials, the bottle-neck is usually air-stability because n-type polymers with lowest unoccupied molecular orbital (LUMO) higher than -4.0 eV react with oxygen at ambient condition. In this work, we report an approach to make n-type OECTs from a solution-processable perylene diimide-based material. Our model material shows good n-type electronic transport, ionic transport, ion-electronic coupling, and air-stability. Via device engineering, we achieve n-type OECTs with high transconductance (49 mS) and good stability (stable after hundred-cycle weekly operation across five weeks stored in ambient air). We demonstrate the use of n-type perylene diimide-based OECTs in glucose sensors.

11:30 AM SB10.01.03
Electric Field Contributions to Ion Motion in Organic Electrochemical Devices Loren G. Kaake; Simon Fraser University, Canada

Organic electrochemical devices include biosensors, transistors, electrochromic displays, and light emitting electrochemical cells. One key step in device operation is the movement of ions within the electronically conductive π-conjugated material. The mechanisms of ion motion and the structure-property relationships that govern those mechanisms continue to be a source of keen interest. One important vantage point to understanding this motion is through the fundamental equations of mass transport (the drift-diffusion equation). Because both electronic charge carriers and ions are in motion, the details of this coupling can, in principle, be quite complex. In order to develop a first order model that encapsulates typical behavior in the most common systems, we performed spectroelectrochemical measurements on thin films of PEDOT:PSS, a common mixed conducting material. Specifically we examined what role, if any, applied electric fields have on the transport of ions in PEDOT:PSS. This was accomplished by comparing a device with potential applied at the electrolyte interface to a device where a potential is applied across the PEDOT:PSS thin film, in an attempt to use fields to draw the ions more rapidly through the bulk of the material. No discernable difference in the electrochemical charging dynamics was observed, demonstrating that macroscopic fields are not an important influence in ion motion. To better rationalize this result, finite element simulations were performed. These simulations highlight the importance of local fields as established by both the electronic charge carriers and the intermolecular forces between the ions and the polymeric medium in which it is embedded.

11:45 AM SB10.01.04
Stable Organic Electrochemical Neurons Based on p-Type and n-Type Ladder Polymers Han-Yan Wu, Jun-Da Huang, Chi-Yuan Yang and Simone Fabiano; Linköping University, Sweden

Organic electrochemical transistors (OECTs) are a rapidly advancing technology that plays a crucial role in the development of next-generation bioelectronic devices. Recent advances in p-type/n-type organic mixed ionic-electronic conductors (OMIECs) have enabled power-efficient complementary OECT technologies for various applications, such as chemical/biological sensing, large-scale logic gates, and neuromorphic computing. However, ensuring long-term operational stability remains a significant challenge that hinders their widespread adoption. While p-type OMIECs are generally more stable than n-type OMIECs, they still face limitations, especially during prolonged operations. Here, we demonstrate that simple methylation of the pyrrole-benzothiazine-based (PBBT) ladder polymer backbone results in stable and high-performance p-type OECTs. The methylated PBBT (PBBT-Me) exhibits a 25-fold increase in OECT mobility and an impressive 36-fold increase in μC* (mobility × volumetric capacitance) compared to the non-methylated PBBT-H polymer. Combining the newly developed PBBT-Me with the ladder n-type poly(benzimidazobenzophenanthroline) (BBL), we developed complementary inverters with a record-high DC gain of 194 V V^{-1} and excellent stability. These state-of-the-art complementary inverters were used to demonstrate leaky integrate-and-fire type organic electrochemical neurons (LIF-OECNs) capable of biologically relevant firing frequencies of about 2 Hz and of operating continuously for up to 6.5 h. This achievement represents a significant improvement over previous results and holds great potential for developing stable bioelectronic circuits capable of in-sensor computing.[1]

1:30 PM *SB10.02.01
Electrochemical Transistors Monolithically Integrated for Sensing Arrays Antonio Facchetti[1,2]; [1]Georgia Institute of Technology, United States; [2]Northwestern University/Flexterra Inc, United States

Organic electrochemical transistors (OECTs) have stimulated new research in biosensor, wearable/e-textile, and neuromorphic applications. However, limitations in micro/nanopatterning of organic semiconductors and topological irregularities often limit their implementation in monolithically integrated circuits as is common in silicon-based electronics. In this presentation we first report on a new vertical OECT architecture (vOECT) enabling excellent and

balanced behavior. Next, we demonstrate the successful realization of high-density (up to ~7.2M OECT/cm^2) and mechanically flexible vOECT arrays and circuits via facile and generalizable micropatterning of the semiconductor materials by electron-beam lithography. The resulting p- and n-type vOECT active-matrix arrays exhibit excellent electronic characteristics with transconductances of 0.08 – 1.7 S, fast transient times (<100 um) and ultra-stable switching properties (>100k cycles). Furthermore, we demonstrate vertically stacked complementary logic circuits, including NOT, NAND, and NOR gates, which are essential components for digital processing and logic operations.

2:00 PM *SB10.02.02
Organic Electrochemical Transistors Based on Polymer Blends Shunsuke Yamamoto; Tohoku University, Japan

We examine the organic electrochemical transistors (OECTs) based on polymer blends of a mixed conductor (PEDOT:PSS) and an ion conductor (PSSNa) or other functional polymers, including thermoresponsive PNIPAM. The phase separation structures, especially surface segregation, were examined to discuss the distribution of PEDOT and other components in the channel layers. For example, we found that the blend films of PEDOT:PSS and PNIPAM have a surface skin layer of PNIPAM on top of the PEDOT layer. This talk will cover the tendency and driving force of the surface segregation phenomena in PEDOT:PSS-based blend films for a rational design of functional OECT devices.

Physical Reservoir Computing with Dendritic Polymer Structures – Understanding Internal Dynamics, Scale-up and Integration in All-Solid-Systems Anton Weissbach, Peter Steiner, Lukas M. Bongartz, Richard Kantelberg, Peter Birkholz, Karl Leo and Hans Kleemann; Technische Universität Dresden iAPP, Germany

Physical Reservoir Computing is an emerging field of research as such recurrent neural networks offer power-efficient real-time classification on edge devices thereby utilizing the inherent temporal dynamics of the underlying physical, chemical or biological system. In particular, the use of organic mixed ionic-electronic conductors enables a close connection to biological systems due to the strong coupling between ionic and electronic conduction as well as the possibility to chemically modify the polymer to interact with bio-molecules. Previously, we have shown a first realization of a physical reservoir composed of polymer dendrites integrated onto a flexible substrate for on-chip heartbeat classification. However, the these systems was limited due to an insufficient complexity and the use of an external delayed feedback line (single-node reservoir), requiring significant data pre-processing and increasing the power consumption.
In this contribution I will discuss the internal dynamics of such dendritic reservoirs and how we tuned them by external parameters such as the ion conductivity or ion mobility. Furthermore, I will demonstrate the integration of such reservoirs into a solid-state electrolyte, which allows us to scale-up the network to a large number of nodes covering the bandwidth relevant for bio-signal processing. The scale-up results in an improvement of the classification accuracy up to 95% without any silicon-based component. Moreover, the scale-up study shows us that the classification accuracy and power consumption can be decoupled in sparse network configurations, enabling us to achieve such a high accuracy with a power consumption of only 100nW. This integration strategy of sparse networks into a solid-state electrolyte opens up new perspectives to further increase the efficiency of intelligent edge devices based on organic semiconductors.

Coordination Compound Materials for Neuromorphic Computing and Brain-Computer Interfaces Alec Talin; Sandia National Laboratories, United States

As we near the limits of conventional digital Si based transistor technology, neuromorphic computing using analog devices based on functional materials that emulate neuronal and synaptic characteristics has emerged as a powerful approach to realize the energy efficiency and dynamic adaptability of animal brains. While most efforts have focused on inorganic materials due to their compatibility with Si CMOS processing and scalability, a wide range of neuromorphic functionality has also been demonstrated in devices based on organic polymers, coordination polymers and molecular coordination complexes. In my presentation I will give a snapshot of how these different materials are being explored for analog neuromorphic computing, and then focus on our recent work with the mixed valence coordination polymers like the Prussian blue analogues (PBAs), attractive because they have an open framework structure and ability to conduct both ionic and electronic charge. Using inkjet-printing, we demonstrate flexible artificial synapses that reversibly switch electronic conductance by more than four orders of magnitude based on electrochemically tunable oxidation state. Retention of programmed states is improved by nearly two orders of magnitude compared to the extensively studied organic polymers, thus enabling in-memory compute and avoiding energy costly off-chip access during training. We demonstrate dopamine detection using PBA synapses and biocompatibility with living neurons, evoking prospective application for brain-computer interfacing. By application of electron transfer theory to in-situ spectroscopic probing of intervalence charge transfer, we elucidate a switching mechanism whereby the degree of mixed valency between N-coordinated Ru sites controls the carrier concentration and mobility, as supported by DFT.

4:00 PM SB10.03.03
Large-Scale Stretchable Neuromorphic Computing Circuits for Acute Disease Detection and Soft Robotics Songsong Li[1], Max Weires[1], Zixuan Zhao[1], Fangfang Xia[2] and Sihong Wang[1]; [1]The University of Chicago, United States; [2]Argonne National Laboratory, United States

Developing wearable edge computing electronics with skin-like stretchability has a significant impact on precision medicine and soft robotics. To implement edge computing function, integrated neuromorphic systems with artificial synapses and neuron functionalities are necessary, which can emulate biological neural networks and enable the replication of complex cognitive abilities within an artificial system. Recent explorations have identified organic electrochemical transistors (OECTs) as a promising device platform for stretchable neuromorphic computing. However, challenges remain in the scalable fabrication of stretchable large-scale synaptic arrays and additional stretchable components, such as artificial neurons. In this work, we develop intrinsically stretchable integrated neuromorphic systems by fabricating stretchable 10 x 10 neuromorphic arrays via a standard cleanroom microfabrication process, subsequently constructing artificial neurons to realize neuromorphic activation functions. Various machine learning algorithms are deployed using our

neuromorphic integrated system to detect acute disease and regulate the movement of soft robotics. Overall, this work will shed light on the promising pathway toward realizing wearable on-body edge computing.

4:15 PM *SB10.03.04
Structural Plasticity with PEDOT-Based Dendritic Electropolymerization for Neuromorphic Engineering Kamila Janzakova[1], Corentin Scholaert[1], Ismael Balafrej[2], Ankush Kumar[1], Dominique Drouin[3], Jean Rouat[2], Sébastien Pecqueur[1], Yannick Coffinier[1] and Fabien Alibart[1,3]; [1]IEMN-CNRS, France; [2]University of Sherbrooke, Canada; [3]CNRS, Canada

Neuromorphic computing and engineering is capitalizing heavily on the new physical properties offered by nantechnologies to engineer biological processes. At the frontiers in between bio-mimetism and bio-inspiration, various solutions have been proposed for synaptic plasticity or neuronal features based on discrete memory elements, bistable switches or transistors circuits. One missing element that has been missing in the neuromorphic toolbox is the ability to reproduce the complex 3D interconnections observed in biological neural networks. Here, we propose to take advantage of bipolar electropolymerization of PEDOT dendritic fibers to reproduce the ability of neural networks to generate complex topologies. The electropolymerization mechanism is used to realize structural plasticity based on Hebbian-like plasticity rules. We explore how such bottom-up process can find optimal topologies for specific computing tasks. We demonstrate that such optimal topologies results in a drastic reduction of interconnects for classification and reconstruction tasks, thus offering an interesting option for neural network design.

4:45 PM SB10.03.05
Ladder-Type Conjugated Polymers: Synthesis and Their Application in Organic Electrochemical Transistors/Artificial Neurons Chi-Yuan Yang[1,2] and Simone Fabiano[1,2]; [1]Linköping University, Sweden; [2]n-Ink AB, Sweden

Organic electrochemical transistors (OECTs) are a rapidly advancing technology that plays a crucial role in the development of next-generation bioelectronic devices. Recent advances in p-type/n-type organic mixed ionic-electronic conductors (OMIECs) have enabled power-efficient complementary OECT technologies for various applications, such as chemical/biological sensing, large-scale logic gates, and neuromorphic computing. However, ensuring both high performance and long-term operational stability remains a significant challenge that hinders their widespread adoption. Ladder-type conjugated polymers, with their rigid backbone structure composed of double-strand chains linked by condensed π-conjugated units, can sustain high electrochemical doping levels without any conformational disorder, which leads to exceptional operational stability, high charge carrier mobility, and large volumetric capacitance. In this report, we demonstrate our recent development on ladder-type conjugated polymers, with p-type/n-type high mixed ionic-electronic conducting performance and high stability in long-term OECT operation. Reasonable molecular design and improvement of synthesis methods have enabled the synthesis of high-performance p-type/n-type ladder polymers with mobility increased by more than 10 times. Their unique ladder-type structure enables them to have long-term stability within >90% current remain after 6 hours continues operation, and enables them to accommodate more carrier injections with of up to two charges per repeat unit. Density of states filling and opening of a hard Coulomb gap around the Fermi energy at high electrochemical doping levels enable the ion-tunable antiambipolarity in these ladder polymers. The development of ladder-based polymer ink formulations has also enabled printed electronics. With these ladder-type polymers, we developed complementary inverters with a record-high DC gain of 194 V/V and excellent stability. We report the first organic electrochemical neurons (OECNs) with ion-modulated spiking, based on all-printed complementary organic electrochemical transistors. We demonstrate facile bio-integration of OECNs with Venus Flytrap (Dionaea muscipula) to induce lobe closure upon input stimuli. We report a biorealistic conductance-based organic electrochemical neuron (c-OECN) using a mixed ion–electron conducting ladder-type polymer with stable ion-tunable antiambipolarity. The latter is used to emulate the activation/inactivation of sodium channels and delayed activation of potassium channels of biological neurons. These c-OECNs can spike at bioplausible frequencies nearing 100 Hz, emulate most critical biological neural features, demonstrate stochastic spiking and enable neurotransmitter-/amino acid-/ion-based spiking modulation, which is then used to stimulate biological nerves in vivo.[1-5]

Manipulating Physicochemical Properties of Biosensor Platform with Polysuccinimide-Silica Nanocomposite for Enhanced Protein Detection Rabi Saleh Ibrahim and Chaenyung Cha; Ulsan National Institute of Science and Technology, Korea (the Republic of)

As point-of-care testing (POCT) is becoming the new paradigm of medical diagnostics, there is a growing need to develop reliable POCT devices that can be conveniently operated in a minimally invasive manner. However, the clinical potential of POCT diagnostics is yet to be realized, mainly due to the limited and inconsistent amount of collected samples on these devices, undermining their accuracy. This study proposes a new biosensing platform modified with a functional polysuccinimide (PSI)-silica nanoparticle (SNP) composite system that can substantially increase the protein conjugation efficiency by modulating physicochemical interaction with proteins by several hundred percent from an unmodified device. The efficacy of this PSI-SNP system is further validated by applying it on the surface of a microneedle array (MN), which has emerged as a promising POCT device capable of accessing interstitial fluid through minimal penetration of the skin. This PSI-SNP MN is demonstrated to detect a wide array of proteins with high sensitivity on par with conventional whole serum analysis, validated by in vivo animal testing, effectively displaying broad applicability in biomedical engineering.

5:00 PM SB10.04.02
Polypyrrole/ Hydrogel Hybrid Films as Biomimetic Self-Sensing Macromolecular Motors Yahya Ahmed-Ismail, Shabeeba Aranhikundan and Lijin

Rajan; University of Calicut, India

Conducting polymers can be regarded as the simplest model materials that can be used to fabricate biomimetic sensing motors (intelligent devices) mimicking biological functions in which the driving and sensing signals can be read at any time, through the same two connecting wires. With a view to fabricate more flexible and mechanically robust conducting polymer-based sensing motors, polypyrrole/hydrogel hybrid films were fabricated through in-situ chemical polymerization. Like natural muscles, the reversible redox reactions of the hybrid films respond, adapt and sense, any variation in chemical, electrical and thermal working energetic conditions using electrical energy and/or electrical charge as the sensing parameters. The single faradaic electrochemical reaction of polypyrrole was responsible for the self-sensing property. Under galvanostatic conditions, the hybrid films modify the consumed electric energy to self-adapt the newly imposed energetic conditions and respond to the electrical, thermal and chemical energetic conditions. Under potentiodynamic conditions, the extension of the faradaic reaction defined by the coulovoltammetric charges senses the working electrical, chemical and thermal ambient. The conformational and structural changes occurring through *n* consecutive steps of one electron extraction per step arises due to the cooperative actuation of the constitutive polypyrrole chains (the chemical machines) driven by the oxidation/reduction reactions make the coulovoltammetric charge a self-sensor of the working energetic conditions. Accordingly, we have fabricated a self-sensing supercapacitor device using the hybrid film capable of sensing its working condition at any reaction moment, without physical separation through the same two connecting wires. The similarity of cooperative actuation of the polypyrrol/hydrogel hybrid film with natural muscles in simultaneously sensing the working energetic condition can serve as the foundation for the construction of biomimetic multifunctional devices.

5:00 PM SB10.04.03
Rapidly Deployable, Compact Airborne Detection Platform Using Bio-Inspired Molecular Probes to Counter Infectious Disease and Evolving Threats Richard V. Lee, Oliver Nakano-Baker, Shalabh Shukla and John D. MacKenzie; University of Washington, United States

Rapid detection of VOC signatures from exhaled breath provides a simple and non-invasive way for determining states of health by assessing the breathomics signatures of conditions, diseases and chemical toxins that can endanger human performance and health. In response, we are advancing the fundamental science and engineering of biologically-inspired molecular probe-based sensing towards developing a compact, multiplexed sensor that can be rapidly deployed to detect and quickly diagnose existing and emerging infectious disease threats, toxicants, and biomarkers at low cost. The key to our approach is computationally-engineered chimeric peptides and modified protein biomolecules derived from computational derivation of target molecule binding sites and homology from natural odorant-binding olfactory receptor protein libraries. These bioinspired molecules are multifunctional and bind to specific airborne volatile and dissolved targets whose binding events are transduced directly into electrical signals in carbon-based field effect transistor (FET) sensors. These probes create a selective, compact, and customizable platform to directly sense disease or identify the human body's response following exposure to a toxin. For complex VOC profiles such as the trace components of human breath, multichannel FET sensor chips can be functionalized with sets of peptide or protein probes to sensitize the transistor array to a disease, condition or intoxicant's multicomponent signature thereby creating high selectivity. The FET sensor allows for detecting voltage threshold shifts versus target exposure and the gate voltage tuning of the sensor bias to achieve maximum sensitivity. The transistor-based biosensor identifies diseases and human body responses to antagonists using machine learning (ML) trained on typically multicomponent target profiles, recognizing their often complex volatile organic compound (VOC) signature profile in exhaled breath or ambient air using computationally designed and optimized sets of solid-binding peptides and protein probe molecules that can achieve high selectivity and exclude confounding factors. The platform technology could be deployed as handheld, wearable, or drone-mounted eNoses and as broadly capable chemical sensors. We have demonstrated the ability of our system to directly detect VOCs indicative of COVID-19 infection in simulated breath as well as sensing of human stress biomarkers in solution using sensor-adapted cortisol-binding proteins. Solution titration studies of protein-functionalized carbon nanotube FET sensors have enabled the determination of a target detection threshold of at least 10 parts per trillion (10 femtomolar) in a simple, direct chemical/electronic transduction signal. We are currently exploring the targeted detection of biotoxins, such as saxitoxin, with our molecular-probe functionalized FET sensor platform.

5:00 PM SB10.04.04
Zwitterion Dielectric Materials for Low Voltage Organic Field Effect Transistors Jasleen Kaur and Loren G. Kaake; Simon Fraser University, Canada

Achieving low voltage operation in organic thin film transistors (OTFTs) is crucial for their integration into sensing devices, smart packaging, and the internet of things. This is often accomplished through the use of liquid electrolytes which intercalate into the organic semiconductor film. However, this strategy can lead to undesirable structural changes and charge trapping phenomena. Inspired by polyelectrolyte dielectric materials, we explored solution processable zwitterion-based dielectric materials for OTFT applications. Zwitterion-based films are prepared using 4-(3-butyl-1-imidazolio)-1-butane sulfonate in poly (vinyl alcohol) (PVA) polymer matrix. Top gate bottom contact p-type OTFTs gated via zwitterion-based dielectric are fabricated using poly(3-hexylthiophene-2,5-diyl) (P3HT) as organic semiconductor and electrical characteristics are studied under dry and humid conditions. The operating voltage is found to be strongly humidity dependent with humidified devices operating below -1.2 V. Further, electrochemical impedance spectroscopy of zwitterion-based dielectric films confirmed that increased dielectric response with humidity aids in lower voltage operation in OTFTs. Impedance data is fitted with the Havriliak-Negami model and indicates that only one polarization mechanism is responsible for the electrostatic double-layer like capacitance. The simple formulation and tunable capacitance of zwitterion-based dielectric materials hints at a rich line of research where the interplay of intermolecular forces and applied field leads to materials with exceptional properties.

5:00 PM SB10.04.05
Machine-Learning Assisted Micropillar Assay for High-Throughput *In-Situ* Functional Analysis of Patterned Organoids Shuai Wu; Auburn University, United States

An organoid is a 3D multicellular tissue structure cultivated in vitro, designed to closely mimic its corresponding in vivo organ. This enables the study of various aspects of that organ within the controlled environment of a tissue culture dish. Although 3D tissue culture techniques have been in use for decades. The detection and quantification of protein biomarkers in-situ is hampered by challenges in its sampling and analysis. Here we report the use of a micropillar-based patch for fast in vivo sampling and on-pillar quantification of target protein biomarkers in organoid. We used the micropillar patch functioned with different size nanoparticles-antibody conjugates to detect the cytokines in a multiplex way with machine learning assisted image process. Micropillar patches for the minimally invasive collection and analysis of biomarkers in organoids might facilitate point-of-care diagnostics and longitudinal monitoring.

5:00 PM SB10.04.06
Intrinsically Stretchable Subthreshold Organic Transistors for Highly Sensitive and Extremely Low-Power e-Skin Temperature Sensors Phuong N. Vo[1], Jun Su Kim[1], MinWoo Jeong[1], Tae Uk Nam[1], Kyu Ho Jung[1], Tae Il Lee[2] and Jin Young Oh[1]; [1]Kyung Hee University, Korea (the Republic of); [2]Gachon University, Korea (the Republic of)

Body temperature is a vital physiological parameter used for health monitoring and early detection of infectious diseases or changes in one's physical

condition. The growing importance of continuous health monitoring has led to an increased demand for swift and accurate temperature measurement. To address this need, researchers are rapidly developing skin-mounted or wearable sensors that provide real-time insights into an individual's well-being. Nonetheless, challenges like the tradeoff between power consumption and responsiveness, as well as sensitivity to strain, continue to pose significant obstacles for electronic skin (e-skin) sensors. Recently, researchers have made substantial progress in the development of organic thin-film field-effect transistors (OTFTs) using inherently stretchable organic semiconductor materials. These advancements hold promise for OTFTs to serve as skin-like sensors, capable of offering low power consumption, exceptional responsiveness to physiological signals, skin-like flexibility, and maintaining stability in the face of strain, while also delivering strong electrical properties and sensing capabilities. This work introduces an intrinsically stretchable subthreshold OTFT designed for a highly sensitive and low-power active-matrix temperature sensor array, closely resembling human skin. The OTFT exhibited an impressively steep subthreshold slope at low voltage, leading to a high transconductance efficiency. Consequently, it achieved exceptional temperature sensitivity (9.4% $°C^{-1}$) with ultra-low power consumption (less than 1 nW, with a maximum of 670 pW), rapid response times (0.3 seconds), a minimal threshold voltage deviation (within ±0.5 V), and high sensing accuracy (0.5 °C) even when subjected to a 100% strain. Additionally, we successfully created a skin-like subthreshold organic transistor active-matrix array, which accurately detected surface temperature variations even under three-dimensional deformations.

5:00 PM SB10.04.07
Development of a Minimally Invasive Flexible Continuous Glucose Sensor Anthony Fontana and Ahyeon Koh; Binghamton University, United States

Every year, hundreds of millions of people worldwide are affected by diabetes mellitus. While the symptoms and treatment regimens vary from each individual, a lifelong commitment to monitoring and balancing blood glucose concentration can be expensive and psychologically exhausting. To provide patients with an increased ability to control this disease, continuous blood glucose biosensors are used to provide on demand measurements of relevant biomarkers. This allows users to readily regulate the concentration of glucose in their blood. Traditional sensor devices analyze small samples of blood, requiring invasive techniques of obtaining the sample. There is also a lack of continuous glucose measurements in these devices, as fluctuating analyte concentrations during day-to-day activities cannot be monitored. To address these limitations, a device that utilize soft and flexible materials that can integrate with the skin and offer a minimally invasive method to continuously detect glucose concentration is proposed. A temporary tattoo platform that incorporates a sensitive electrode system can provide the patient with the ability to comfortably monitor their condition. Flexible bioelectronics has emerged as a promising platform to develop biosensors because of their seamless integration into biological systems. The abundance of soft and flexible tissues within the body interacts well with other flexible systems, hence the need to develop devices that interact with the body in the same way.

This glucose sensor device extracts interstitial fluid from below the skin through reverse iontophoresis, a process by which low current is precisely applied to the epidermis. Following this extraction process, the fluid interfaces with a three-electrode system that utilizes a substrate-enzyme interaction to detect glucose through a hydrogen peroxide intermediate. The electrodes were fabricated utilizing a PCB printer to extrude conductive inks onto a flexible polyimide substrate. The system was created from a carbon-graphite Prussian blue mediator paste which contains redox active molecules necessary for detection of the hydrogen peroxide intermediate. Onto the surface of the working electrode, the glucose oxidase enzyme was immobilized along with a solution of single walled carbon nanotubes and chitosan. Upon binding of glucose within the interstitial fluid to the glucose oxidase enzyme, the hydrogen peroxide by-product can be measured in terms of current by the working electrode.

To determine electrochemical function of the sensors, a variety of experiments including cyclic voltammetry, linear sweep voltammetry, amperometry, and chronography were used. These techniques demonstrated the performance of the Prussian blue working electrode by recording oxidation and reduction peaks, which align precisely with commercially available alternatives. Additionally, characterization of the reference and counter electrodes indicate proper electrochemical function of the entire sensor system. Following this analysis, the ability for the electrode to detect the hydrogen peroxide intermediate was evaluated. In target concentrations ranging from 2mM/L to 12mM/L of hydrogen peroxide, the device clearly possesses the ability to systematically and consistently respond to various H_2O_2 concentrations. The current density response is then used to develop a linear response curve to correlate H_2O_2 with electrical output.

Within this flexible biosensor system, hydrogen peroxide concentration was related to electrical output quantitatively. Hydrogen peroxide's direct relationship with glucose upon binding with glucose oxidase suggests this platform can provide a promising alternative from conventional methods of detecting glucose within the blood.

5:00 PM SB10.04.08
Surface Electromyography Controlled Human-Machine Interface Using Upcycled Compact Disc Electrodes Pauline Faith A. Macapinlac, Matthew Brown and Ahyeon Koh; Binghamton University, United States

In efforts of relieving the ever-amassing amounts of electronic waste produced a year, researchers are looking for ways to repurpose discarded devices into new technologies for biomedical purposes. Promising methods of repurposing compact discs (CDs) into stretchable and flexible biosensors called upcycled compact disc electrodes (UCDEs), have opened up new possibilities for providing accessible and affordable biotechnology for a variety of applications. One application is the implementation of UCDEs in human machine interfaces (HMI). Human controlled robotic interfaces have garnered growing interest in recent years due to its potential use in aiding disabled and elderly individuals or augmenting the performance of everyday tasks and occupations. This study focuses on creating an HMI to simulate hand movement based on surface electromyography (EMG) conducted with UCDE applications. The UCDEs are specifically designed and patterned to mimic the mechanical properties of the skin above the targeted muscles and are used to detect the electroactivity during contraction and relaxation. When integrated into an HMI, UCDEs have proven to be capable of consistent and reliable measurements of muscle detection capable of controlling the robotic interface.
To begin the UCDE fabrication process, Verbatim UltraLife Gold Archival Grade DVD-R CDs were soaked in acetone for 30 seconds to break down the polycarbonate substrate and release the metal layer. The metal was then mechanically harvested by adhering polyimide tape followed by a layer of water-soluble tape to the surface of the exposed metallic surface. At this stage, the metal is patterned using a Cricut Fabric Cutter and prepared to be integrated into the machine interface. Mechanical properties of the UCDEs were evaluated using tensile testing with a 25 N load at a 5.1 mm/min to failure and cyclic bending with a strain rate of 300 mm/min held at a bending radius of 3.5 mm. The Quad BioAmp PowerLab system was used to examine the material's capability of EMG measurements and find optimal UCDE placement for the machine interface. The HMI used in this study was built using the InMoov open-source 3D printed hand and forearm, powered by an Arduino Nano and wirelessly controlled with a nRF24 module. MyoWare 2.0 Muscle Sensors attached to the UCDE sensors were used for measuring and processing muscle activity that can then be used to control movement of the robotic hand and designed into a wireless wearable electronic device. The machine interface was connected and coded to utilize the signals from the muscle sensors using Arduino Software (IDE).
The polymeric-metal layers of the UCDE were patterned with ease using the mechanical cutter down to feature sizes of 25 μm capable of up to 20% strain. Once patterned, the UCDEs demonstrated an elastic modulus of 5.59 ± 0.16 MPa and elongation of 62.35 ± 1.81% when tested to failure. Cyclic bending for 100 cycles with a radius of 3.5 mm demonstrated a 0.29% increase in UCDE resistance. The performance of the UCDEs have proved to be comparable to commercial electrodes when measuring EMG of various muscle groups. When integrating UCDEs with the HMI, the wearable electronic system and

UCDEs were attached in ideal placement on the forearm. UCDEs proved capable of controlling all five robotic fingers in three distinct motions by detecting EMG signals from three different muscle groups simultaneously within a small surface area. Performance of the machine interface was comparable between the use of UCDEs and commercially available electrodes.
UCDEs proved to be capable of controlling complex systems such as HMIs through the constant measurement of EMG signals. This discovery demonstrates the promising potential of this sustainable solution for upcycling electronic waste and the possibility of creating more accessible and affordable HMIs with the use of commonly available materials.

5:00 PM SB10.04.09
Artificial Intelligence-Enhanced Flexible Biocompatible Triboelectric Nanogenerator Mohammad Abrar Uddin, Barrett Burgess and Taeil Kim; Baylor University, United States

Triboelectric nanogenerators (TENG) have emerged as a promising technology for energy harvesting in wearable devices and self-powered sensors. However, the effective utilization of TENGs in practical scenarios faces several challenges including limited power output, complexity of material combinations, wear and tear issues, complex integration into systems, sensitivity to frequency ranges, and miniaturization. A lot of work is being done addressing these challenges, however, the use of artificial intelligence in design optimization can pave new ways to reduce experimentation and can identify the optimal design parameters to obtain the best possible output from a range of variables. To unlock the full potential of TENGs, we propose a novel approach that integrates artificial intelligence (AI) techniques with the design of experiment (DOE) method to optimize the design and performance of TENGs. A microcavity-nanoparticle assembled microstructure with one triboelectric layer composed of porous polydimethylsiloxane (PDMS) sandwiched between a second triboelectric layer has been chosen as the initial prototype design. The use of porous PDMS in the structure with nanofillers allows the increase in surface area without the need for a spacer structure between the triboelectric films. This design structure can be well integrated with the human body motion in day-to-day life and provide improved energy conversion. A novel biogel material has been used as electrodes to ensure the biocompatibility of the TENG with the human skin along with flexibility. This study includes variation of key parameters or factors such as material combinations, porosity in PDMS, surface area, thickness, frequency of applied force or pressure, and applied force to prepare different sample prototypes and identify the optimal combinations for TENG performance. The frequency of the applied force mimics the human motion frequency range, which is from 0 to 20 Hz. The data generated from the prototype design with a range for each independent data point is analyzed by statistical tools and software to identify significant factors or parameters, and interactions between these factors are evaluated. After that, the optimization algorithms are applied to find the optimal levels of significant factors. Additional experiments are thereby conducted to validate the predicted performance and find the accuracy of the optimization. Finally, by refining the design parameters and conducting iterative experiments, a final optimized contact separation mode TENG design has been generated that is flexible, biocompatible, and efficient to power wearable biosensors for health monitoring. By harnessing energy from human motion, this AI-enhanced TENG offers a sustainable, reliable, and biocompatible power source for wearable healthcare applications.

5:00 PM SB10.04.10
The Importance of Electrode Material in Bioelectronic Electrophoretic Ion Pumps Tiffany Nguyen, Narges Asefifeyzabadi, Houpu Li, Le Luo and Marco Rolandi; The University of California, Santa Cruz, United States

Bioelectronic ion pumps deliver ions and biomolecules from a source to a target biological system with high spatiotemporal control for bioengineering and regenerative medicine applications. A voltage between a working electrode and a reference/counter electrode delivers the charged ions and biomolecules from a source to the desired target. The source and the target are separated by an ion exchange membrane so that only the charged molecules of interest are delivered. Future wearable and implantable applications require high efficiency of delivery to minimize power consumption. The majority of recent efforts on improving ion pump efficiency have focused on optimizing the ion exchange membrane. However, the contribution of the working electrode material to the ion pump efficiency has been mostly overlooked. This work identifies how changing the working electrode material greatly affects the efficiency of delivery in ion pumps. With an electrical circuit model analysis, voltammetry studies on silver, platinum, and palladium hydride working electrodes, and implementation of the Butler–Volmer equation, results show that the material-dependent equilibrium potential at the working electrode surface has a large impact on ion pump efficiency. With this knowledge, a simple predictive model to optimize the working electrode material for delivering each specific ion or molecule of interest is designed.

5:00 PM SB10.04.11
Synthetic Smart Hydrogels Tailored for Sensing in Gaseous Environments Sitao Wang[1], Gerald Gerlach[1] and Julia Koerner[2]; [1]Technische Universität Dresden, Germany; [2]Leibniz University Hannover, Germany

Stimulus-responsive, i.e. smart, hydrogels are polymers capable of exhibiting a reversible volume change in response to external physical and chemical influences, for example pH value, light, temperature or specific analyte molecules. This makes the material a very interesting candidate for novel sensing elements, especially since the properties can be tailored for specific applications from a wide variety of monomers and mixtures thereof, as well as additives [1,2].
The smart hydrogel's volume change is usually mediated by the uptake and release of liquid and consequently, most applications are centered on liquid environments. However, the hydrogel's capabilities for selective and sensitive analyte detection hold great potential beyond that and we have therefore started to explore how to harness the material's properties for sensing in gaseous media. The specific target application of our research is volatile organic compound (VOC) detection in exhaled breath to enable monitoring of disease biomarkers such as acetone.
For this purpose, synthetic acrylamide-based hydrogels were chosen as the model material. In a first step, different polymers comprising polyacrylic acid (PAA), polyacrylamide (PAM), poly(*N*-isopropylacrylamide) (PNiPAAm) and their co-polymer combinations were investigated with respect to their ability of maintaining a measurable volume change in air with relative humidity variation from 0% to 100%. These studies were performed without and with added acetone gas as test VOC (concentrations: 20 ppm - 100 ppm) and the hydrogel's swelling response was characterized by gravimetry and piezoresistive pressure sensing. PNiPAAm showed the best responsiveness in terms of humidity range, dependence of swelling response on the target analyte concentration and potential for selectivity [3].
However, these studies also revealed a significant challenge for using hydrogels in a gaseous atmosphere: A large surface area is crucial for a strong and fast response in VOC detection, hence the hydrogel should ideally feature a very porous structure (surface and bulk). While the porosity can be adjusted by the use of pore-forming additives or by ice-templating during polymerization, the pores are likely to collapse after polymerization and subsequent drying in air.
To address this challenge, the second step of our research focused on the development of a procedure enabling the creation of defined porosity which is maintained under the conditions of a gas atmosphere with varying humidity conditions. We found that templating with PEG during polymerization, followed by freeze drying (either at -196°C or -20°C, depending on the desired pore size) and subsequent conditioning in high relative humidity (90 – 100 %) is the key to achieve stable porosity.
The material properties were characterized and compared in scanning electron microscopy and FT-IR analyses, and the volume change performance again evaluated by gravimetry and piezoresistive pressure sensing [4].
These investigations have been conducted for PNiPAAm which was identified as the most promising material candidate for our target application.

However, the developed process for tailoring and stabilizing a porous polymer structure in gaseous environments is of general nature and can easily be applied to other types of hydrogel since there are no components or steps specific for PNiPAAm.
To enhance the responsiveness (i.e. swelling strength, time constants, reversibility) of the smart hydrogel even further, the focus of our future work is on the integration of additives such as graphene- and MXene-based materials.

Mechanically Heterogeneous Silk Fibroin Film for Wireless Hybrid Electronics Yanling Wang and Xiaodong Chen; Nanyang Technological University, Singapore

Hybrid electronics that integrate rigid silicon-based electronic modules and stretchable sensors have been demonstrated through the combination of rigid islands and stretchable interconnects, which offer enhanced functionality and conformability with human body. However, mass production of these devices utilizing conventional synthetic materials contributes to the burgeoning electronic waste predicament. The fabrication process, involving intricate procedures such as photolithography, not only amplifies complexity but also consumes substantial power, thereby impeding sustainability and ecological equilibrium. Furthermore, the limited electrical stretchability of these hybrid sensors compromises the system's robustness. Consequently, there is an imperative need to explore sustainable materials capable of substituting or complementing synthetic counterparts in stretchable hybrid electronics, aiming to mitigate their environmental footprint while upholding performance and functionality.
Here, we developed a mechanically heterogeneous silk fibroin film as the platform for a wireless hybrid electronic system which can be attached on skin to collect biological signals with simple manufacturing. By virtue of the solution-processibility and tunable mechanical property of silk fibroin, the $CaCl_2$ plasticized silk fibroin film is fabricated by solvent casting and the effective strain isolation is achieved by locally hardening with methanol treatment. The considerable contrast in Young's modulus between rigid and soft parts, reaching approximately ~100, arises from the conformational transition of silk induced by methanol, which can be verified by both experimental structural analyses and molecular dynamic simulations. Combined with printing technology, the trace printed on our plasticized silk film exhibit consistent conductivity even at 100% strain, maintaining a low resistance. Besides, the interconnected resistor on the treated area sustains functionality when subjected to a 50% strain, showcasing the suitability of our designed structure for integrating hybrid electronics. Lastly, a wireless hybrid electronic system has been developed to facilitate on-skin sensing. The system comprises stretchable interconnects with high printing resolution and rigid microelectronics dedicated to signal processing and data transmission on a mechanically heterogeneous silk fibroin film. The proposed methodology, involving the fabrication of the heterogeneous biomaterials merged with thin-film technology, presents a promising pathway toward establishing on-skin hybrid electronic systems tailored for real-time physiological detection.

5:00 PM SB10.04.13
Highly Stable Ladder-Type Conjugated Polymer Based Organic Electrochemical Transistors for Low Power and Signal Processing-Free Surface Electromyogram Triggered Robotic Hand Control Zhongliang Zhou and Wei Lin Leong; Nanyang Techonological University, Singapore

Organic electrochemical transistors (OECTs) based complementary inverters have been considered as promising candidates in electrophysiological amplification, owing to their low power consumption, and high gain. To create complementary inverters, it is important to use highly stable p-type and n-type polymers with well-balanced current. In this work, we improved the electrochemical stability of p-type ladder-conjugated polymer based OECT through an annealing process where it maintained its doped-state drain current from 76 % to 105 % after 4,500 cycles in ambient environment. We next present an OECT-based complementary inverter made from p-type and n-type ladder-conjugated polymers (PBBTL and BBL) that possess ultra-low power consumption (~170 nW), high gain (67 V/V) and high noise margin (92%) with full rail-to-rail swing. Furthermore, we demonstrate its potential in amplifying the envelope of surface electromyography (EMG) for robotic hand control. The high variation in the output (0.35V) allows the amplified EMG signals to be directly captured by commercial analog-to-digital converter, which in turn controls the robot hand to grasp different objects with low delay and low noise. These results demonstrate the capability of OECT inverter based amplifier in future signal processing-free human machine interface, particularly useful for prosthetic control and gesture control applications.

SESSION SB10.05: Biosensing and Bioelectronics I
Session Chair: Sahika Inal
Wednesday Morning, April 24, 2024

8:15 AM SB10.05.01
Organic Mixed Ion-Electron Conductors for THz Metadevices Federico Grandi[1,2], Cristiano Bortolotti[1,3], Francesco Modena[3], Lorenzo Gatto[2], Matteo Butti[3], Iain McCulloch[4], Caterina Vozzi[2], Mario Caironi[3], Giorgio Ernesto Bonacchini[3] and Eugenio Cinquanta[2]; [1]Politecnico di Milano, Italy; [2]CNR-IFN, Italy; [3]Istituto Italiano di Tecnologia, Italy; [4]University of Oxford, United Kingdom

In the last decades, materials that can efficiently transport ionic and electronic charges become key in advancements in the fields of bioelectronic devices, energy storing or harvesting, and healthcare. Organic mixed ionic-electronic conductors (OMIECs) are organic materials that can transport both ionic and electronic charge[1]. The large variety of organic molecules that can be synthesized and the number of ways in which they can be arranged provide a great number of degrees of freedom that influence the OMIECs' properties and device functionalities. Recent progress in the design and synthesis of organic mixed ion-electron conductors is actively contributing to developing exciting new technologies based on organic electrochemical transistors (OECTs). Among recent applications, OECT-based resonant devices have been proposed in the microwave spectral region showing excellent amplitude and frequency tuning performances in the sub-5GHz range[2]. In these devices, the 3-dimensional charge modulation capabilities of OMIECs are key in achieving excellent tunability of both individual and arrays of microwave resonators, hence leading to a novel class of microwave photonic devices based on organic materials. The next step is to explore the applicability of this approach toward the THz frequencies, as well as the investigation of the OMIEC charge transport properties in this spectral range.
In this work, we study the far-infrared conductivity of a state-of-the-art OMIEC, namely p(g2T-TT), with field-assisted THz Time Domain Spectroscopy (THz-TDS). Through this technique, we non-destructively investigate the dielectric and electronic properties of the OMIEC during operation, thus gaining crucial insights for the physical modeling of charge transport at high frequencies. By varying the applied voltage bias from -800 to 600 mV, we modulate

the dielectric response of the polymer and obtain information about the charge injection and its effect on the polymer conductivity. We observe an increased conductivity by tuning the bias from 600 to -800 mV indicating an increase of the injected charge. More in detail, we report a positive real accompanied by a negative imaginary part of the conductivity, as already shown in the literature[3]. This behavior is well described by the Drude-Smith model that considers charge localization effects due to the finite polymer chain size and the energetic disorder. From the fit, we extract the charge density injected in the OMIEC as a function of the applied voltage bias and its carrier mobility.
To demonstrate the effectiveness of the charge carrier screening effects in p(g2T-TT) at THz frequencies, we investigate the amplitude modulation performances of a THz metadevice based on this OMIEC. The prototypical device is based on metallic Split Ring Resonators with a resonance at 0.7 THz, which are electrostatically tuned with the p(g2T-TT). We show that despite the relatively low mobilities of the charge carriers, their large density modulation leads to excellent modulation depth – exceeding 60% - with polarization voltages below 1 V.
Our results highlight the potential of organic THz devices based on OMIECs, for instance as optical modulators for telecom applications. Further research efforts in this direction could lead to a new generation of reconfigurable photonic technologies that take benefit of the many desirable properties of organic semiconductors, such as the ease of processability on large-area flexible substrates.

8:30 AM *SB10.05.02
Translational Neuroelectronics Dion Khodagholy; Columbia University, United States

Our understanding of the brain's pathophysiology relies on discoveries in neuroscience and neurology fueled by sophisticated bioelectronics enabling visualization and manipulation of neural circuits at multiple spatial and temporal resolutions. In parallel, to facilitate clinical translation of advanced materials, devices, and technologies, all components of bioelectronic devices have to be considered. Organic electronics offer a unique approach to device design, due to their mixed ionic/electronic conduction, mechanical flexibility, enhanced biocompatibility, and capability for drug delivery. We design, develop, and characterize conformable, stretchable organic electronic devices based on conducting polymer-based electrodes, particulate electronic composites, high-performance transistors, conformable integrated circuits, and ion-based data communication.
These devices established new experimental paradigms that allowed monitoring of the emergence of neural circuits during development in rodents and elucidated patterns of neural network maturation in the developing brain. Furthermore, the biocompatibility of the devices also allowed intra-operative recording from patients undergoing epilepsy and deep brain stimulation surgeries, highlighting the translational capacity of this class of neural interface devices.
In parallel, we are developing the fully-implantable, conformable implantable integrated circuits based on high-speed internal ionic gated organic electrochemical transistors that can perform the entire chain of signal acquisition, processing, and transmission without the need of hard Si-based devices. This multidisciplinary approach will enable the development of new devices based on organic electronics, with broad applicability to the understanding of physiologic and pathologic network activity, control of brain-machine interfaces, and therapeutic closed-loop devices.

9:00 AM *SB10.05.03
Organic Neuromorphic Electronics for Sensory Coding and Biohybrid Systems Yoeri van de Burgt; Eindhoven University of Technology, Netherlands

Neuromorphic engineering takes inspiration from the efficiency of the brain and focusses on how to utilise its functionality in hardware. Organic electronic materials have shown promising solutions for the manipulation and the processing of biological signals, with applications ranging from bioinformatics to brain-computer-interfaces and smart robotics.

This talk describes state-of-the-art organic neuromorphic devices and provides an overview of the current challenges in the field and attempts to address them. I demonstrate two device concepts based on novel organic mixed-ionic electronic materials and show how we can use these devices smart robotics and at the interface with biology. This can pave the way for novel architectures with bio-inspired features, offering promising solutions for the manipulation and the processing of biological signals and potential applications ranging from brain-computer-interfaces to bioinformatics and neurotransmitter-mediated adaptive sensing. I will highlight our recent efforts for such hybrid biological memory devicesand artificial neurons.

9:30 AM SB10.05.04
Zwitterionic Hydrogel Design of PEDOT:PSS Suppresses The Foreign Body Response against Bioelectronic Conductors Shinya Wai, Nan Li, Seounghun Kang, Yahao Dai, Lavoie Tera, Wei Liu, Matthew V. Tirrell and Sihong Wang; The University of Chicago, United States

Implantable medical devices (IMDs) are playing an increasingly important role due to an aging population and the associated increasing prevalence of chronic diseases. However, the foreign body response (FBR) has limited IMDs from realizing their full potential. The FBR is characterized by inflammatory and fibrotic processes that surround the implanted material. Degradative chemicals and enzymes produced in the process can damage the implant. Fibrotic encapsulation is particularly detrimental for biosensors and electrophysiological devices because it would impede the diffusion of analytes and ions. A class of materials with promising FBR suppressing properties are zwitterionic polymers which have been shown to nearly eliminate the FBR for at least a year in mice. As electronic materials for IMDs, poly(3,4-ethylenedioxythiophene):poly(styrene sulfonate) (PEDOT:PSS) is of interest because it is chemically stable, highly processable, non-cytotoxic, and has good mixed ion-electron conducting properties. Nonetheless, previous work addressing the FBR against PEDOT:PSS did not place their focus on long-term solutions or did not carry out FBR-specific characterization methods. We hypothesize that by combining PEDOT:PSS and a zwitterionic polymer into a double-network hydrogel and carefully tuning its phase separation morphology, the conductivity can be increased and the FBR can be suppressed indefinitely. In this work, we demonstrate a process for inducing PEDOT:PSS network formation *in situ* in a zwitterionic hydrogel matrix, which significantly improves its conductivity and reduces FBR-associated fibrosis. Our work demonstrates that controlling the phase separation morphology of composite materials can be an effective strategy for suppressing the FBR.

9:45 AM SB10.05.05
Potentiometric Wearable Sensors with a Laser Engraved Graphene Layer as Transducer Farbod Amirghasemi, Abdulrahman Al-Shami, Victor Ong and Maral Mousavi; University of Southern California, United States

Laser-induced graphene has gained great attention recently for sensing devices. LIGs are generated through the process of irradiating carbon-rich polymers, primarily polyimide, using a laser beam. This procedure induces localized photothermal reactions, resulting in the conversion of SP3 carbon atom

hybridization into a three-dimensional graphitic-like structure. This maskless, scalable, simple, reproducible, cost-effective, and fast technique produces high-quality graphene layers with outstanding flexibility, electrical conductivity, and electrocatalytic properties instead of using the conventional time-consuming, expensive, and complicated methods such as wet chemistry, ink-jet printing, and chemical vapor deposition (CVD). In this work, we discuss surface modification and properties of graphene for achieving a stable interfacial potential in contact with a lipophilic sensing membrane, in a potentiometric readout mode. Specifically, surface topography and hydrophilicity of the material impacts the long-term and short-term properties of the wearable sensors. We will show how the engraving conditions impact water layer formation and drift of sensors, and how a highly stable readout can be achieved through surface modification. We use bio-inspired organic receptors to achieve ion specific binding at the electrode surface and generate biomarker specific signal.

10:00 AM BREAK

10:30 AM *SB10.05.06
Controlling The Optical Properties of Near-Infrared Nanotube Sensors through Bioengineering Ardemis A. Boghossian; Ecole Polytechnique Federale de Lausanne (EPFL), Switzerland

Single-walled carbon nanotubes (SWCNTs) emit fluorescence that is ideal for a breadth of optical sensing applications. The near-infrared emissions are minimally absorbed by biological tissue, biofluids, and other visibly opaque materials. This property motivates their use for packaging and deep-tissue applications. The indefinite photostabilities and optical sensitivity to changes in their environment further justify the use of SWCNTs for continuous optical monitoring. However, SWCNTs require surface functionalizations to control the selectivity of their interactions and the specificity of the resulting sensors. Biomolecules like proteins and DNA show unparalleled molecular specificity towards various bioanalytes. Although they are commonly functionalized onto various surfaces to control the specificity of these surfaces towards analytes, their interactions with the surfaces themselves are often suboptimal. In the case of SWCNTs, these sub-optimal interactions limit sensor performance and response. This presentation highlights recent advancements that rely on bioengineering strategies, including directed evolution, mutagenesis, and xeno nucleic acids, for tuning the performances of bio-based optical SWCNT sensors.

11:00 AM *SB10.05.07
Ultra-Sensitive and Selective Ionic Sensors based on Vertical Organic Electrochemical Transistors for *In-Situ* Body Fluid Monitoring Wei Huang; University of Electronic Science and Technology of China, China

Ions are ubiquitous biological and physiological regulators, while abnormal ion concentrations in human body fluids are often fingerprints of ongoing pathological states, diseases, and even organ malfunctions (such as heart or kidney failure, and dehydration). Therefore, accurate and timely detection/monitoring of various vital ion concentrations in body fluids is highly desired. Here, we demonstrate ultra-sensitive and selective ionic sensors based on vertical organic electrochemical transistors (vOECTs). By combining the advantage of high transconductance (g_m > 0.2 S) and small footprint (< 30×30 μm) of the vOECTs with specific ionic selective membranes, ultra-high sensitivities up to 13.9 mA/dec (for Na^+), 2.2 mA/dec (for K^+), and 187 mA/dec (for Ca^{2+}) are achieved, along with decent selectivity, stability, and reproducibility. Such sensitivities are the highest values among reported ion-sensitive transistors (including ISFETs, EGOFETs, and OECTs). By integrating different vOECT-based ionic sensors in an array, in-situ monitoring of the ionic level in the externally circulated bold fluid or the dialysate during an active continuous renal replacement therapy (CRRT) is demonstrated with high accuracy and reversibility. This work demonstrates the great potential of OECT-based sensors for complex sensing scenarios.

11:30 AM *SB10.05.08
Shape-Actuated Bioelectronics Christopher M. Proctor; University of Oxford, United Kingdom

Significant advances have been made in the last two decades in interfacing electronic devices with the nervous system. To that end, research efforts are being pursued to develop minimally invasive, implantable bioelectronic devices integrating sensing, stimulating, and dynamic control of geometry. Here we report recent developments towards such multimodal devices for neural interfacing that take full advantage of the favorable properties offered by flexible electronics, conducting polymers and polymer substrates. It is shown that thin, flexible devices can incorporate microfluidic channels to enable new sensing and therapeutic functionalities. One such technology leverages the mixed conducting properties of conducting polymers and molecularly imprinted polymers for real time sensing of cortisol. Furthermore, we show fluidic components can open the door to novel implantation strategies that can reduce the surgical footprint required for implantation of widely used bioelectronic devices. We anticipate this work will accelerate the development of a new generation of bioelectronic devices for diagnostics and therapy.

SESSION SB10.06: Biosensing and Bioelectronics II

1:30 PM *SB10.06.01
Biointegrated Living Electronics for Healthcare Bozhi Tian; University of Chicago, United States

The emerging field of living bioelectronics aims to seamlessly integrate electronic devices with biological tissues, offering transformative solutions in healthcare diagnostics and therapeutics. In this talk, I will begin by discussing our earlier efforts centered around engineered tissue-integrated bioelectronics and the construction of tissue-mimetic materials. Progressing from these foundational works, I will transition into our latest explorations that harness the synergy between biology and electronics to address intricate biomedical challenges. Specifically, we present the active biointegrated living electronics platform. This unique interface, integrating a bioelectronics framework with a bacteria-laden hydrogel composite, facilitates dynamic signal transduction between microbial and mammalian systems. This platform has demonstrated its potential by monitoring microbial interventions in several skin conditions. As we forge ahead, our focus will be on optimizing device longevity, enhancing efficiency, and unveiling novel therapeutic solutions.

2:00 PM *SB10.06.02
Organic Optoelectronic Neurohybrid Devices Francesca Santoro[1,2]; [1]Forschungszentrum Jülich GmbH, Germany; [2]RWTH Aachen University, Germany

Exploiting the light–matter interplay to realize advanced light responsive multimodal platforms is an emerging strategy to engineer bioinspired systems

such as optoelectronic synaptic devices. However, existing neuroinspired optoelectronic devices rely on complex processing of hybrid materials which often do not exhibit the required features for biological interfacing such as biocompatibility and low Young's modulus. Recently, organic photoelectrochemical transistors (OPECTs) have paved the way towards multimodal devices that can better couple to biological systems benefiting from the characteristics of conjugated polymers.
Neurohybrid OPECTs can be designed to optimally interface neuronal systems while resembling typical plasticity-driven processes to create more sophisticated integrated architectures between neuron and neuromorphic ends. Here, an innovative photo-switchable PEDOT:PSS was synthesized and successfully integrated into an OPECT. The OPECT device uses an azobenzene-based organic neuro-hybrid building block to mimic the retina's structure exhibiting the capability to emulate visual pathways. Moreover, dually operating the device with opto- and electrical functions, a light-dependent conditioning and extinction processes were achieved faithful mimicking synaptic neural functions such as short- and long-term plasticity.

2:30 PM BREAK

3:30 PM *SB10.06.03
Self-healing, Stretchable and Tissue-Adhesive Materials for Stable Bioelectronics Donghee Son; Sungkyunkwan University, Korea (the Republic of)

Conventional flexible/stretchable devices capable of monitoring bio-signals and delivering the feedback information have been considered as essential functional components in realizing the stable closed-loop bioelectronics. Despite such significant progress, their mechanical and electrical instability, originating from materials fatigue and the absence of tissue adhesion, still remains a challenge in pursuit of strain-durable tissue-interfacing capability. Here, we report optimal stretchable materials design strategies and device fabrication/integration technologies for the two different kinds of self-healing tissue-adhesive bioelectronics: i) A patch-type platform for either facile peripheral nerve repair (neurorrhaphy) in rodents and nonhuman primates or large-scale conformal cardiac interfacing; ii) A syringe-injection-type platform for instantaneous closed-loop rehabilitation. The patch-type self-healing bioelectronics consists of ionically conductive hydrogel adhesive and tough composite electrodes with solid and liquid micro-/nano-fillers, enabling both on-tissue strain-insensitive electrical performance and mechanical adaptation. In terms of the injectable type, tough hydrogel with irreversible yet freely rearrangeable biphenyl bonds and reversible coordinate bonds with conductive gold nanoparticles was applied to injured nerves/muscles for realizing immediate closed-loop robot-assisted rehabilitation and effective tissue regeneration.

4:00 PM *SB10.06.04
Thin-Film-Based Soft Electronic/Photonic Devices for Conformable Contact with Organs Kenjiro Fukuda[1] and Takao Someya[2,1]; [1]RIKEN, Japan; [2]The University of Tokyo, Japan

Electronic/photonic devices that are conformable to biological organs basically need to have extremely soft properties. Such devices usually have a multi-stack structure consisting of several functional layers, and can usually be realized using thin film devices. It is possible to reduce flexural rigidity and buckling load by simply reducing the film thickness of the device as well as reducing Young's modulus of each layer. This approach creates a system that does not inhibit the movement of organs. becomes possible.
One example of our recent achievements is the establishment of a method for mounting ultrathin-film organic solar cell films on insect abdomens [1]. The abdominal segments consist of multiple segments, abdominal deformation is achieved through the overlap of the segments. To not inhibit the movement of the abdomen, we developed an adhesive method in which part of the films have adhered to abdominal surfaces, and the unbonded area secures the room for deformation during the bent of the abdomen. In the case of polymer films with Young's modulus on the order of GPa, there is a tolerance threshold of around 5-10 μm in thickness to secure the basic motion ability of a specific insect, which was quantitatively clarified from the correlation with the bending load. Through such evaluations, we created a system of cyborg insects that can be recharged with ultra-thin organic solar cells adhered to abdominal surfaces.
Another example is the construction of stretchable electrode systems for stimulation and sensing on PDMS [2]. The use of extremely thin PDMS (approx.. 1 μm), improves its adhesion to living organisms. We developed a stretchable conductor using micro-crack structured gold onto such thin PDMS films, which contributes to nerve stimulation with lower power than thicker film-based electrodes. In addition, by combining it with conductive polymers, stable adhesion on the skin is achieved, making it possible to construct systems that enable daily activities such as hand washing and swimming.

4:30 PM SB10.06.05
Plant Electrophysiology with Organic Electronics Eleni Stavrinidou; Linköping University, Sweden

Electrical signals in plants are mediators of long-distance signalling and correlate with plant movements and responses to stress. These signals are studied with single surface electrodes that cannot resolve signal propagation and integration, thus impeding their decoding and link to function. We developed a conformable multielectrode array based on organic electronics for large-scale and high-resolution plant electrophysiology. As a model system we studied the generation and propagation of the action potential (AP) in the carnivorous plant Venus flytrap. The AP in VFT is one of the fastest electrical signals in plants and it is generated when the mechanosensitive hairs in the trap are triggered. When two AP are generated within thirty seconds the trap closes. With organic bioelectronics we performed precise spatiotemporal mapping of the action potential in Venus flytrap and found that the AP actively propagates through the tissue with constant speed and without strong directionality. We also found that spontaneously generated APs can originate from unstimulated hairs and that they correlate with trap movement. Last, we demonstrate that the Venus flytrap circuitry can be activated by cells other than the sensory hairs. Our work reveals key properties of the AP and establishes the capacity of organic bioelectronics for resolving electrical signalling in plants contributing to the mechanistic understanding of long-distance responses in plants.

4:45 PM SB10.06.06
Chemical and Biosensing Using Enzyme Inspired Electropolymerized MIPS and Devices Rigoberto C. Advincula; The University of Tennessee/Oak Ridge National Laboratory, United States

Bioinspired macromolecules can be prepared by bio-conjugation or de-novo biopolymer substitutes. The lock-and-key templating process can mimic molecular complexes inspired by biological enzyme-substrate interactions. Using functional monomers that can be electrochemically polymerized enables the formation of cross-linked polymer films with cavities that enable high-binding assays of chemical and biological analytes. This talk will show the effective and bio-inspired artificial enzymes for detecting chemical and biological analytes. We will focus on demonstrating electropolymerized molecularly imprinted polymer (E-MIP) sensor elements and their ability to utilize transduction methods such as surface plasmon resonance (SPR) spectroscopy to enable high sensitivity and selectivity. The monomer and molecular design for optimized analyte interaction enables effective templating protocols in an electrically conducting polymer matrix with tunable redox states to enable a high volume of analyte-cavity sites. Optimized electropolymerization methods are important for film deposition and surface characterization based on SPM, XPS, and other microscopic and spectroscopic

methods to confirm surface specificity. Several analytes, including drugs, organic pollutants, nerve agents, and epitopes of larger proteins. This was recently demonstrated in the detection of dengue-expressed proteins for disease diagnostics.

SESSION SB10.07: Poster Session II
Session Chairs: Simone Fabiano and Naoji Matsuhisa
Wednesday Afternoon, April 24, 2024

5:00 PM SB10.07.01
Electropolymerized Organic Mixed Ionic-Electronic Conductors Arnel Besic and Connor G. Bischak; University of Utah, United States

Organic mixed ionic electronic conductors (OMIECs) are conjugated polymer systems that conduct both ions and electrons. These materials are promising for applications in healthcare and energy technologies, including biosensors and batteries. An obstacle for these novel materials is a lack of understanding behind the fundamental principles that underlie operation, particularly the coupled ion motion dynamics, electron transport, and morphological changes. This work presents the electropolymerization and characterization of several thiophene-based polymers and copolymers. An advantage of electropolymerization is the monomers do not require bulky side-chains to be made soluble in organic solvents, which allows these materials to pack more charge per unit volume. Using electropolymerization, we synthesize several polythiophenes with different side chain chemistries. We investigate ion injection kinetics in these materials using spectroelectrochemistry and find that injection kinetics depend on the identity of the electrolyte. We also characterize their morphology with atomic force microscopy (AFM), scanning electron microscopy (SEM), and Grazing-Incidence Wide-Angle X-ray Scattering (GIWAXS). Electropolymerized OMIECs may play an important role in the advancement of OMIEC-based technologies due to their unique morphologies which stem from this new synthesis method.

5:00 PM SB10.07.02
Amplifying Biosensor Sensitivity through Chitosan-Coated Nanoparticles Ariadna Schuck and Yong-Sang Kim; Sungkyunkwan University, Korea (the Republic of)

Chitosan, a biocompatible polymer derived from chitin, enhances biosensor sensitivity by facilitating precise recognition element immobilization and protecting against interference [1], [2]. When combined with chitosan-coated nanoparticles, it further amplifies sensitivity by increasing the surface area for binding and signal output, improving biosensor performance [3], [4]. To verify the effect of the chitosan-coated gold nanostructures on the surface of a screen-printed carbon electrode (SPCE) sensor, we modified gold nanoparticles and nanostars with chitosan and performed several morphological and electrical characterizations. Uniformity, diameter size, and dispersion of the nanostructures were investigated with atomic force microscopy (AFM), UV-Vis spectroscopy, and scanning electron microscopy (SEM) images. The electrical analysis was performed after electrodepositing the coated nanostructures on the working electrode of the SPCE sensor. First, the cyclic voltammetry (CV) technique was measured with a buffer solution where the peak currents were amplified after the functionalization step. The Nyquist plots were also recorded to verify the charge transfer resistance based on the equivalent circuit. To verify the nanostructures' performance for the detection of biochemicals, we decided to immobilize specific antibodies (100 ng/mL) over the nanostructures and detect apolipoprotein E4 (APoE4), a specific allele of the APoE gene associated with Alzheimer's disease. We performed differential pulse voltammetry measurements to quantify the biomarker (ranging from 0.41 to 40 ng/mL) in human serum samples (less than 20 μL). The current peak variations showed high linearity, with a linear regression coefficient (R^2) of 0.9841, corresponding to the levels of ApoE4. Further studies will involve validation and interference tests, including the detection of other Alzheimer's disease (AD) biomarkers, such as Amyloid-β 42.

5:00 PM SB10.07.03
Superelastic Hydrogels for Mechano-Electric Sensing Stephan Foerster, Tulika Sharma, Martin Dulle, Jürgen Allgaier and Guido Vehres; Forschungszentrum Jülich, Germany

Hydrogels are materials that can retain large amounts of water, making them broadly applicable to many areas, including wound care, tissue engineering, and soft electronics. Conventional hydrogels usually possess limited mechanical strength. The current concept of double network hydrogels provides largely increased mechanical stability, thus allowing also mechano-electrical sensing. However, the chemical and structural complexity of many double network hydrogels complicate understanding and tailoring their mechanical and electrical properties over a broad range.

We synthesized a new class of elastic and mechanically stable hydrogels based on alternating amphiphilic copolymers that in water spontaneously form physical networks that constitute the hydrogels, with no crosslinking chemistry required. The hydrophobic copolymer blocks consist of alkyl chains that form well-defined nanodomains acting as dynamic crosslinks. The mechanical and dynamic properties of the hydrogels can be directly controlled by the lengths of the alkyl chains and the hydrophilic repeat units. The highly elastic hydrogels allow elongations of more than 10000%, with tensile moduli in the kPa-range to MPa-range, adjustable to the range of moduli and deformation of skin at joints. We demonstrate *in situ* X-ray diffraction under tensile stretching and compression, together with conductivity measurements to relate the nanodomain structure directly to the mechano-electrical properties.

The intrinsic ion conductivity of the hydrogels allows mechano-electrical sensing of stretching and compression from very small to large deformations for thin films, over a broad range of frequencies, suitable to sense joint motion and speech.

5:00 PM SB10.07.04
Naturally Derived Chlorophyll Absorption Layers for RGB Color Recognition in IGZO Phototransistors Hyunji Son[1,2], Dong Hyun Choi[1], Kyungho

Park[1], Jusung Chung[1] and Hyun Jae Kim[1]; [1]Yonsei University, Korea (the Republic of); [2]LG Display Co., Korea (the Republic of)

With the continuous growth of various Internet of Things (IoT)-based industries – including mobile smart devices, autonomous vehicles, and medical equipment – there has been a sustained interest in the technologies that recognize and communicate information in real-time. Particularly, as a significant portion of information processing is visual, the study of optoelectronic devices, such as photosensors that detect visual information, has become increasingly important. Metal-oxide semiconductors have been a focal point as potential optoelectronic devices due to their advantages, such as high uniformity over large areas, high optical transparency, high mobility, and low off current. Past research has primarily aimed to expand the inherently limited light absorption range(ultraviolet and blue light) of these semiconductors, which results from their wide bandgap (>3.0 eV). This was usually achieved by introducing light-absorbing layers or by forming subgap states. However, most strategies focused merely on broadening the detection range into the visible or infrared spectrum without the ability to distinguish specific wavelengths of the absorbed light. It has been shown that even when absorbing different wavelengths of light, a consistent photo-response is generated based on its intensity, making it impossible to identify the specific wavelength of absorbed light. Therefore, conventional photosensor devices need additional color filters to identify different wavelengths, increasing costs and complicating high-density integration.
In this study, we propose an indium-gallium-zinc oxide (IGZO) phototransistor integrated with naturally derived chlorophyll as the light-absorbing layer to differentiate between different wavelengths without needing for color filters. Chlorophyll's characteristic green hue arises from its predominant absorption of blue and red light, while reflecting much of the green light. Utilizing the unique absorption properties of chlorophyll, we enhanced the light response range of the IGZO phototransistor. Specifically, absorption in the chlorophyll layer produces electron-hole pairs. These generated electrons then migrate to the IGZO channel layer, altering the transistor's electrical characteristics. For a chlorophyll concentration of 0.06 M, we measured the phototransistor's characteristics under red (635 nm), green (532 nm), and blue (405 nm) light irradiation. At an intensity of 1 mW/mm^2, results indicated photoresponsivity of 1607/641/3881 AW^{-1}, photosensitivity of $5.80 \times 10^7/3.51 \times 10^5/2.35 \times 10^8$, and detectivity of $3.86 \times 10^{12}/1.63 \times 10^{11}/3.58 \times 10^{13}$ Jones for red, green, and blue wavelengths, respectively. This is in contrast to conventional photodetectors, which typically show a light responsivity order of blue>green>red; our findings presented an order of blue>red>green. Exploiting this distinctive characteristic, combining a conventional phototransistor with our chlorophyll-induced version allows the design of an NMOS (N-type metal oxide semiconductor) inverter logic circuit capable of differentiating between 3 colors of blue, green, and red without color filters. Using SPICE (Simulation Program with Integrated Circuit Emphasis) simulations and the phototransistor's experimental results, we demonstrated that within a light intensity range of 0.1~5 mW/mm^2, the output voltage responded with low, high, and mid-values for red, green, and blue light inputs, respectively.
In conclusion, the IGZO phototransistor utilizing chlorophyll as an absorption layer has demonstrated the potential to differentiate between red, green, and blue light. This suggests the possibility of simplifying the actual fabrication process by eliminating color filters in the sensor. Moreover, it implies the potential for various applications, such as light-controlled logic circuits.

5:00 PM SB10.07.05
Ultrathin, Self-Adhesive, Sweat-Absorbing Janus Membrane Epidermal pH Sensor Wenqing Wang[1,2], Suksmandhira Harimurti[1], Kenjiro Fukuda[2], Sunghoon Lee[2], Tomoyuki Yokota[1] and Takao Someya[1]; [1]The University of Tokyo, Japan; [2]RIKEN, Japan

Wearable biomedical sensors have enabled non-invasive and continuous physiological monitoring for daily health management and early detection of chronic diseases [1,2]. Among the biomedical sensors, wearable pH sensors attracted significant interest as pH influences most biological reactions [3,4]. However, the conformable pH sensor which can be self-adhesive to human skin, has sweat-wicking ability and gas permeability remains largely unexplored. Here, we present a novel approach to this problem through the development of a Janus membrane-based pH sensor with self-adhesive on the skin. The sensor consists of a hydrophobic polyurethane-polydimethylsiloxane (PU-PDMS) porous nanometer-thick film and a hydrophilic polyvinyl alcohol-polyacrylic acid (PVA-PAA) nanofiber film. This Janus membrane exhibits a thickness of a few micrometers, providing a firm and comfortable adhesion to the skin. The sensor demonstrates fast-responsive, accurate, and long-term pH measurements, enabling reliable wearable applications. The simultaneous realization of solution absorption, gas-permeability, and self-adhesiveness, make it suitable for long-term, continuous monitoring without compromising wearer comfort. The pH sensor has been tested successfully for continuous monitoring over an hour, demonstrating its potential for stable analysis of skin health conditions. This innovative Janus membrane-based pH sensor holds significant promise for comprehensive skin health monitoring and wearable biomedical applications.

Breathable, Structure-Gradient Pressure Sensing Textile for Rehabilitation Assistance Jinxing Jiang and Qiyao Huang; The Hong Kong Polytechnic University, Hong Kong

Triboelectric pressure sensing textile shows great potential in various wearable applications such as healthcare monitoring system due to their light weight, high permeability and flexibility. However, it's difficult to achieve high sensitivity and large pressure sensing range simultaneously. Here, we innovatively crafted a skin-inspired fiber mat (SIFM) with a gradient structure using a template-assisted layer-by-layer electrospinning technique. Drawing inspiration from the human skin, our SIFM mimics its natural micro-bump texture, gradually transitioning from soft to rigid as one moves from its outermost surface towards its core. The distinct structural design of SIFM has led to the development of a breathable, structure-gradient pressure sensing textile (PSPST) with simultaneously high sensitivity, wide detection range and high breathability. In comparison to conventional pressure sensing textiles constructed from homogeneous fiber mats, our PSPST exhibits a substantial enhancement in pressure sensing performance. Finally, We demonstrate its ability for rehabilitation assistance, including monitoring the quadricep, pulse and plantar pressure simultaneously.

Tissue-Like Skin-Device Interface for Wearable Bioelectronics by Using Ultrasoft, Mass-Permeable and Low-Impedance Hydrogels Yoonsoo Shin and Dae-Hyeong Kim; Seoul National University, Korea (the Republic of)

Hydrogels are composed of a cross-linked porous polymer structure with water molecules distributed within the gaps of the polymer chains. This unique composition renders hydrogels soft and hydrated, sharing mechanical and physical characteristics akin to human tissues. Consequently, hydrogels have the potential to emulate a tissue-like environment within the minuscule spaces between wearable devices and the human skin. In this study, we introduce

strategies at both material and device levels to establish a quasi-solid, tissue-mimicking interface between wearable bioelectronics and human skin. A crucial element of this approach involves an ultra-thin functionalized hydrogel exhibiting exceptional properties like high mass-permeability and low impedance. This specialized hydrogel acts as a liquid electrolyte on the skin, creating a highly conformal and low-impedance interface suitable for wearable electrochemical biosensors and electrical stimulators. Moreover, its porous structure and ultra-thin profile enable efficient transport of target molecules across the interface, thereby maximizing the performance of diverse wearable bioelectronics.

5:00 PM SB10.07.08
Highly Elastic and Ultrathin Nanomembrane Using Kinked Ag Nanowires for Epidermal Electrode Minseong Kim[1,2] and Dae-Hyeong Kim[1,2,1]; [1]Seoul National University, Korea (the Republic of); [2]Institute for Basic Science, Korea (the Republic of)

Skin electronic devices require a flexible conductor with properties such as metal-like conductivity, high flexibility, extremely thin thickness, and the ability to create simple patterns. Achieving these characteristics simultaneously has proven to be quite challenging. Previous research introduced a nano-membrane fabrication method using a float assembly technique to successfully address a significant portion of these challenges in creating electrodes for skin electronic devices. However, conventional nano-membranes often struggle to precisely control conductivity and flexibility due to the dense packing nature of nanowires. In this study, an innovative approach is presented to create highly flexible nano-membranes using twisted nanowires. Incorporating twisted nanowires in the nano-membrane fabrication process facilitates the formation of percolation networks at low concentrations. Furthermore, the use of twisted nanowires not only enhances flexibility but also reduces the likelihood of nanowire breakage during vertical deformation. This innovation advances the development of skin electronic devices and holds significant potential for improved flexibility, conductivity, and durability in various applications.

5:00 PM SB10.07.09
Recognitive Tactile Sensor System Inspired by Human Skin Mechanoreceptors Kyoung-Yong Chun, Seunghwan Seo and Chang-Soo Han; Korea University, Korea (the Republic of)

The human skin is an astonishing sensory organ that provides extensive information about our surrounding environment. It can detect various stimuli such as pressure, vibration, texture, temperature, and even chemical substances. Taking inspiration from ion channels and receptors, which are key components of cutaneous sensory organs from a biological perspective, a new approach is being pursued to address the limitations of conventional touch sensors and enable machines to interact with the world in a more human-like manner. Specifically, skin sensory organs perceive tactile sensations through the simultaneous and complex reactions of diverse and abundant receptors. Each receptor possesses a unique working mechanism that selectively responds to specific stimuli. Unfortunately, prior research has overlooked the significance of this aspect and instead focused on independent studies or functions of individual receptors, neglecting to mimic structure of the skin or incorporate it adequately.
The skin encompasses numerous transmission networks that detect stimuli and relay information to the brain. These networks consist of receptors that detect stimuli, ion channels that generate action potentials, and nerves that transport the electrical signals to the brain.Specifically, in the context of sensing physical stimuli, mechanoreceptors are generally classified into four types: Merkel discs (MD), Meissner corpuscles (MC), Ruffini endings (RE), and Pacinian corpuscles (PC). These mechanoreceptors play a crucial role in collecting information about the physical properties of objects we encounter in the environment, enabling us to perceive their shape, weight, texture, etc.
To truly mimic human skin functionality, it is essential to design and manufacture a diverse array of sensors capable of obtaining various information such as pressure, sheer force, and tension from a limited size. This will allow for more accurate and diverse collection of mechanical stimuli from the surrounding environment. For instance, in our case, to emulate the vibrational touch sensing function observed in dermal papillae where MC is located, a bump-like structure and piezoelectric characteristics can be utilized for implementation. Additionally, to mimic the positional and functional features of piezo2, found in the MD, a cone-shaped ion gel and piezo gel can be employed. As for the RE, which has a dendritic branch form within the capsule and participates in stretch detection, this can be emulated using carbon nanotubes (CNTs) sheet with properties of tensile resistance within viscoelastic materials. Simulating the functions and features based on these receptor structures represents a future challenge that artificial skin should strive towards. This study aims to develop a tactile sensor system that recognizes objects by mimicking the mechanoreceptors present in human skin. The sensor system is designed by emulating the unique structures and functionalities of three types of receptors (MD, ME, RE) crucial for object recognition. These sensors are embedded in a material with similar elasticity to human skin. The integrated sensors are arranged in a way that separates receptors (stimulus detectors) and ion channels (signal generators), enhancing selectivity to specific stimuli. The manufactured sensors exhibit stretchability similar to human tactile organs and demonstrate trends comparable to biological touch experiments. Furthermore, to achieve effective object recognition, an AI-based signal processing algorithm is employed to analyze and learn from the data generated by the sensors. The material design for the object recognition sensor incorporates materials such as piezo gels and non-hydrogel ion gels, as well as substances like carbon nanotubes to control mechanical and electrical properties. The integrated sensor system successfully recognizes surface textures and various objects that are difficult to analyze using only one or two types of sensors.

Multiple Recycled Triboelectric Nanogenerators for Smart Waste Management Nikhil R. Patra, Yuvraj S. Negi and Kaushik Parida; IIT Roorkee, India

The last decade has seen a mammoth rise in the progress of polymer electronic devices. This has in turn lead to the accumulation of non-degderable plastic material which has led to the degdration of the enviournment. Thus, for the sustainable progress of mankind, there is a need to recyle these polymer electronic devices. Although there has been reports on recycled nanogenerator, there is a need to develop nanogenerator which can be recylcled multiple times. A multiple recycled triboelectric nanogenerator (MRTENG) derived from mixed plastic waste has been fabricated to achieve an environmentally sustainable energy harvesting device with an increase in lifetime in an order of magnitude[1]. The triboelectric layer is prepared from plastic waste using a novel material design in the presence of a compatibilizing agent derived from e-waste for high stability and mechanical performance. This increases the lifetime of the energy harvester for ten rounds of recycling. The current collector is extracted by high-temperature pyrolysis of segregated mixed plastic waste, depolymerized polyester, and multiple recycled triboelectric layer that acts as a conducting layer in the single-electrode triboelectric nanogenerator[2,3]. The fabricated device shows high performance even after multiple rounds of recycling, hence providing a sustainable solution in reducing environmental pollution. The device is installed in smart dustbins for digitalizing waste management using machine learning. As a waste disposal sensor the MRTENG monitors filling of bins and and also identifies the type of waste disposed to alert and optimize the waste collection and segregation process, from the homes to the recycling industries.

5:00 PM SB10.07.12
Conductive Carbon Fiber-Hydrogel-Composites for Functional Tissue Engineering Sebastian Bihler and Julia Koerner; Leibniz University Hannover, Germany

Materials for tissue engineering rely on the mimicry of extracellular matrix environments, easily achievable biocompatibility and favorable mechanical properties. Hydrogels are a type of polymer that incorporate these properties and are widely used as tissue scaffolds [1]. In general, hydrogels are a non-

conductive material and therefore tailoring their electrical properties to enhance conductivity opens the possibility of extending their applications to include sensing and actuation.
One technique to tailor and modify the conductivity and mechanical properties of hydrogels is to embed carbon fibers in the polymer matrix. To date, carbon fiber-hydrogel-composites (CHC) with random fiber distribution within the hydrogel have been used as flexible and biocompatible sensors [2]. In addition, composites of epoxy-based polymers and unidirectional fiber bundles have been investigated for their properties under high strain and have shown piezoresistive behavior [3,4].
Our work targets the application of unidirectional carbon fibers as a novel approach for tailoring the hydrogel's electrical conductivity. The aim of this research is to study the capabilities of CHCs for directed electric signal transmission along the fibers which could be a first step towards applications as bioelectrical elements, e.g. in nerve grafts. In this regard, two forms of current flow inside the CHC need to be considered: electron- and ion-based for the carbon fibers and hydrogel matrix, respectively. The initial investigation focused on studying the interplay between these two types of conductivity and how they influence the general electric signal transmission capabilities of CHCs.
Therefore, cylindrical polyacrylamide hydrogels containing a bundle of polyacrylonitrile carbon fibers (~1000 filaments) in the middle were fabricated by molding and UV photopolymerization, with the fiber ends protruding from the hydrogel for electrical connection. Two different types of samples were defined: Sample group (SG) 1 features a continuous fiber bundle throughout the hydrogel and SG2 a cut fiber bundle inside the matrix with a gap of a few millimeters. This enables the investigation of the transition between electron- and ion-based current flows. Furthermore, samples from both groups were stored in different concentrations of phosphate buffered saline (PBS) solution to study the influence of the hydrogel's ion concentration on signal transmission capabilities. Prior to the electrical measurements, the samples were immersed in PBS solutions ranging from 1x to 5x in increments of 1x for at least 24 hours. Please note that the CHC samples were always stored in PBS solution between experiments but the measurements itself were conducted in air.
Predefined signals with a frequency of 1 kHz were applied at one end of the CHC sample and the voltage at the other end captured with a digital oscilloscope. The received signal was evaluated for change in amplitude and phase with respect to the input.
SG1 showed no relation between ion concentration and amplitude or phase but good overall conductivity (~100 S/mm). SG2 samples showed a variation in signal phase shift as a function of increasing ion concentration.
These experimental results were accompanied by the electrical properties of the CHCs being modeled in a circuit model in order to gain insight into the causes of the different transmission behavior. This is a very first step towards characterizing and ultimately utilizing the properties of CHCs for active signal transmission. Further work will focus on different fiber bundle distributions and the influence of mechanical stress on the electrical properties.

5:00 PM SB10.07.13
Fluorescence Imaging of Self-Assembled Peptides on h-BN Using Thioflavin-T Hiroki Maeda and Yuhei Hayamizu; Tokyo Institute of Technology, Japan

Peptides possess the capability to self-assemble into well-ordered structures on two-dimensional (2D) materials, such as graphene, rendering them promising candidates for biosensor applications owing to their design flexibility and biocompatibility [1]. Recent research has highlighted the potential of graphene biosensors functionalized with peptides, emulating olfactory receptors for applications in odor sensing [2,3]. Investigating the surface structure of self-assembled peptides on 2D material-based biosensors is crucial for comprehending their performance. Atomic force microscopy (AFM) with high spatial resolution has conventionally been employed for the precise observation of these peptide structures [4].
Nevertheless, due to its limited field of view, AFM is unsuitable for the in-situ observation of macroscopic structures of self-assembled peptides with sizes ranging in the hundreds of micrometers. This study focuses on the in-situ observation of macroscopic structures of self-assembled peptides on hexagonal boron nitride (h-BN) surfaces using fluorescence imaging with Thioflavin-T (ThT) as a fluorescent marker. h-BN, transparent in the visible region, is well-suited for fluorescent microscopy as a transparent substrate. ThT is known to exhibit strong fluorescence when attached to β-sheet structures, commonly found in amyloid fibers associated with diseases like Alzheimer's. Given that the peptides in this study are expected to form β-sheet structures, we assessed the feasibility of using ThT for real-time observation of the macroscopic surface self-assembly process [5].
AFM measurements unveiled that peptides formed long-range ordered structures on h-BN. Subsequently, under fluorescent microscopy, we observed strong fluorescence in regions where the ordered peptide structures existed. The size of the domain of ordered peptides on the surface spanned over a few tens of micrometers in length. This size exceeds the field of view of AFM measurements, and the fluorescent measurement with ThT molecules enables us to visualize the macroscopic self-assembled structures of peptides. Furthermore, weak fluorescence was also detected on partial surfaces of h-BN containing amorphous peptides. These findings underscore the potential of ThT as a tool for assessing the macroscopic self-assembly of peptides over a wide area. The ability to monitor these processes in real-time under liquid conditions using fluorescence microscopy provides insights into the spatial uniformity of molecular thin films, a critical aspect for enhancing the activity of peptide-based bio-probes on graphene biosensors. This methodology opens avenues for the development of improved peptide biosensors with enhanced functionality and performance.

Synthesis of Shape-Programmable Elastomer for a Bioresorbable, Wireless Nerve Stimulator Chan-Hwi Eom; Korea University, Korea (the Republic of)

Materials that have the ability to manipulate shapes in response to stimuli such as heat, light, humidity and magnetism offer a means for versatile, sophisticated functions in soft robotics or biomedical implants, while such a reactive transformation has certain drawbacks including high operating temperatures, inherent rigidity and biological hazard. Herein, we introduce biodegradable, self-adhesive, shape-transformable poly(L-lactide-co-ε-caprolactone) (BSS-PLCL) can be triggered via thermal stimulation near physiological temperature (~38 °C). Chemical inspections confirm the fundamental properties of the synthetic materials in diverse aspects, and study on mechanical and biochemical characteristics validates exceptional stretchability up to 800 % and tunable dissolution behaviors under biological conditions. The integration of the functional polymer with a bioresorbable electronic system highlights potential for a wide range of biomedical applications.

Keywords: biodegradable polymers; shape-transformable elastomers; shape memory; self-adhesion; nerve stimulators

NIH Brain Behavior Quantification and Synchronization Program: Next Generation Sensor Technology and Related Materials Science Development Yvonne M. Bennett; NIH, United States

This session will highlight several Notice of Funding Opportunities (NOFOs) from the National Institutes of Health (NIH) Brain Research through Advancing Innovative Neurotechnologies® (BRAIN) Initiative that are intended to support the development of next generation sensor technologies and bioelectronic devices to further the goals of the Brain Behavior Quantification and Synchronization (BBQS) program. The BBQS funding opportunities broadly support 1) development of tools for simultaneous, multimodal measurement of behavior and synchronization of these data with simultaneously-recorded neural activity; and 2) development of novel conceptual and computational models that capture dynamic behavior-environment relationships. More information about the BRAIN Initiative including existing Notices of Funding Opportunities for the BBQS program can be found at www.brainitiative.nih.gov (search "BBQS") and there is a BBQS Sensors Request for Information at NOT-MH-24-125. The BBQS Program invites researchers in materials science to contribute to upcoming projects (large and small scale, and future sensor hubs) to develop next generation sensor technologies at the micro and nano scales, which must feature wireless, lightweight, compact designs with energy harvesting capabilities. Sensors must be noninvasive or minimally invasive in design. Sensor developer teams in a future Consortium will promote rigorous technology design, fabrication, testing, validation, and dissemination of information regarding sensors and bioelectronics toward improving our understanding of human and organismal behavior.

SESSION SB10.08: Flexible and Stretchable Electronics
Session Chairs: Sihong Wang and Cunjiang Yu
Thursday Morning, April 25, 2024
Room 429, Level 4, Summit

8:15 AM SB10.08.01
Wearable On-Skin Chemo-Sensors Le Yang[1,2]; [1]Institute of Materials Research and Engineering A*STAR, Singapore; [2]National University of Singapore, Singapore

In an increasingly health-aware population and a move towards remote diagnostics, remote healthcare monitoring and cloud-based med-tech, we tap on the ubiquitous and unlimited reservoir of on-skin biomarkers, including sweat metabolites, in developing a wearable, non-invasive, continuous and real-time sensor – a printed, multiplexed biosensor. Such a device can be colorimetric or electrochemical in its sensing mechanism. Our integrated devices are designed and developed with scalability and translation in mind – ensuring printability (for scalable manufacturing), ease of fabrication routes, and solid-state and miniaturised prototype.[1-8]

In particular, firstly, we introduce a newly-published fully-printed paper-based patch, printed from our development of a ceramic-based ink along with nanoparticle-functionalisation, for multi-metabolite and sweat rate monitoring.[1]

Next, we highlight the importance of enzymes in such enzymes-based biosensors (enzymatic reactions to detect target analytes), where their intrinsic instability poses a bottleneck in practical long-term use. Previous methods at enhancing enzyme stability had always been met with a trade-off in sensitivity, selectivity or performance/efficacy. Herein, we showcase a novel materials-based approach, a one-pot synthesis of co-encapsulating enzymes and carbon-dots in a metal-organic framework, overcoming the aforementioned compromise. We achieve an electrochemical highly-stable and highly-sensitive device, and demonstrate it as a touch-based sweat sensor. [2]

Lastly, we briefly highlight an even more holistic approach in developing a printable, non-invasive, real-time and continuous electrochemical sensor for sweat-based and 'dry-skin' based on-skin chemosensing. [3-7]

8:30 AM SB10.08.02
Breathable Electrode based on Hydrophobic-Hydrophilic Membranes with Water Stability for Stable Biosignal Monitoring on Wet/Sweaty Skin Suksmandhira Harimurti[1], Wenqing Wang[1,2], Sunghoon Lee[2], Tomoyuki Yokota[1] and Takao Someya[1,2]; [1]The University of Tokyo, Japan; [2]RIKEN, Japan

Realizing a breathable electrode, which can reliably monitor biosignal after being exposed to water or sweat is challenging. Depending on the stability of its polymer chain backbone towards water or sweat, some of the electrodes could be damaged when exposed to water or sweat. Besides, sweat could also introduce undesired noise artifacts, which lowers the quality of the acquired biosignal. Here, a water- and sweat-stable breathable electrode was demonstrated by utilizing a stack layer of ultrathin hydrophobic microporous Au/polyurethane-polydimethylsiloxane (Au/PU-PDMS) membrane and water-stable hydrophilic poly(vinyl alcohol)/poly(acrylic acid) (PVA/PAA) nanofibers membrane. The hydrophobic membrane was fabricated by dip-coating the PU nanofibers into PDMS-hexane solution. By controlling the dip-coating withdrawal speed, PU-PDMS membrane with pore density of 39% was achieved. Despite having pores on its surface, the PU-PDMS membrane exhibited hydrophobicity with a water contact angle (WCA) of ~108°. Meanwhile, the hydrophilic nanofibers membrane was fabricated using electrospinning followed by a partial crosslinking process to achieve the water stability yet maintain the hydrophilicity. The total thickness of the stack layer was below 15 µm. Along with its porous structure, the electrode exhibited an

excellent breathability equal to the open bottle with a water vapor transmission rate (WVTR) of 0.58 kg/m^{2}day.

Moreover, the stack of these two membranes facilitated a spontaneous water/sweat pulling, of which the water/sweat could be pulled up vertically in antigravity direction. As a result, when the sweat was secreted to the skin surface, the sweat was spontaneously pulled away from the skin surface. Consequently, the skin-electrode interface could be kept dry, ensuring reliable biosignal monitoring. In addition, the hydrophilic membrane showcased an excellent stability in water that it did not break even after being continuously immersed in deionized (DI) water or phosphate-buffered saline (PBS) solution for up to 1 month. PBS solution was used in this study to simulate the ions contained in the sweat. More importantly, even after continuous immersion in both liquids, the hydrophilic membrane could maintain its hydrophilicity. From the WCA measurement at 37 s, the WCA of the membrane after the immersion in DI water remained stable at ~23.5^o while after the immersion in PBS solution the WCA decreased to 14.4^o, indicating that the membrane became more hydrophilic. Furthermore, electrocardiogram (ECG) signal was measured at rest (dry skin) and after doing a physical exercise (sweaty skin) to evaluate the biosignal acquisition stability against sweat. Exhibiting a sweat pulling property, the electrode was able to maintain a high signal-to-noise ratio (SNR) of 30 dB on the sweaty skin. This result could potentially provide more insight for the medical doctors, especially when evaluating cardiovascular health of a subject that may require the subject to do physical exercise or under a dynamic ambient (temperature/humidity) conditions.

8:45 AM SB10.08.03
Intrinsically Stretchable Subthreshold Polymer Transistors for Highly Sensitive Low Power Skin Like Temperature Sensors Jin Young Oh, MinWoo Jeong, Phuong N. Vo and Kyu Ho Jung; Kyung Hee University, Korea (the Republic of)

Stretchable wearable sensors ultimately require low power consumption and high response to physiological signals with skin conformability. However, power response tradeoff and strain dependent sensing instability remain key challenges for electronic skin (e skin) sensors. In this talk, I will adrress an intrinsically stretchable organic subthreshold transistor operating at low voltage (−1 V) is presented, leading to ultralow power consumption (<1 nW) for highly sensitive skin like temperature sensory devices. The highly temperature dependent hopping transport of the fully stretchable subthreshold transistor exhibits high temperature sensitivity (9.4% °C^{-1}) and excellent sensing stability up to 100% strain. A skin like subthreshold organic transistor active matrix array is successfully fabricated that sensed the surface temperature distribution under a 3D deformation.

9:00 AM *SB10.08.04
Biomimetic Rubbery Synaptic Electronics and Integrated Systems Cunjiang Yu; The Pennsylvania State University, United States

Synapses are unique and critical biological structures that allow for the transmission of electrical or chemical signals thus to enable neurons to communicate with each other. Embodied within human or animals, the synapse is usually soft and able to accommodate various forms of mechanical deformations. Artificial synapse electronics that can be stretched similar to those appearing in human or animals could be seamlessly integrated other soft functional systems towards enabled neurological functions. This presentation will show our recent efforts on developing stretchable synaptic electronics fully made out of rubbery electronic materials. Rubbery synaptic devices are enablers for various soft systems with implemented neurologic functions. Examples including soft neurorobots, cognitive smart skins, neuromorphic imaging devices will be introduced.

9:30 AM *SB10.08.05
Nature and Human-Inspired Sensing Devices Benjamin C. Tee; National University of Singapore, Singapore

B10- Bioinspired Organic Materials and Devices for Sensing and Computing

Sensing systems provide timely[1] and requisite data for machines to operate in physical environments. Often, natural biological systems provide optimized concepts that could be applied to design and engineer artificial sensor systems. Novel organic-based materials can even provide self-healing capabilities to such sensor devices[2]. In this talk, I will discuss our recent advances in nature- and human-inspired materials for designing high performance sensor devices[3,4]. The exciting cross-disciplinary interplay of physical interfaces, materials chemistry and electronics become essential for optimizing sensitivity, linearity and speed for the sensor system.

10:00 AM BREAK

10:30 AM *SB10.08.06
Self-Healing, Stretchable and Recyclable Electronics Fabio Cicoira; Polytechnique Montréal, Canada

Materials able to regenerate after damage have attracted a great deal of attention since the ancient times. For instance, self-healing concretes, able to resist earthquakes, aging, weather, and seawater are known since the times of ancient Rome and are still the object of research.
While several mechanically healable materials have been reported, self-healing conductors are still relatively rare, and are attracting enormous interest for applications in electronic skin, wearable and stretchable sensors, actuators, transistors, energy harvesting, and storage devices, such as batteries and supercapacitors.[1] Self-healable and recyclable conducting materials have the potential to reduce electronic waste by enabling the repair and reuse of electronic components, which can extend the lifespan of electronic devices. Furthermore, they can be used for wearable electronic and biomedical devices, which are often subject to mechanical stress causing damage to their components.
Conducting polymers exhibit attractive properties that makes them ideal materials for bioelectronics and stretchable electronics, such as mixed ionic-electronic conductivity, leading to low interfacial impedance, tunability by chemical synthesis, ease of process via solution process and printing, and

biomechanical compatibility with living tissues. However, they show typically poor mechanical properties and are therefore not suitable as self-healing materials.
In our group, we produced several self-healing and stretchable conductors by mixing aqueous suspensions of the conducting polymer poly(3,4-ethylenedioxythiophene) polystyrene sulfonate (PEDOT:PSS) with other materials providing the mechanical characteristics leading to self-healing, like for instance polyvinyl alcohol (PVA), polyethylene glycol, polyurethanes and tannic acid. [2-10] In this talk, various types of self-healing will be presented and correlated with the electrical ad mechanical properties of the materials. The use of the self-healing gels and films as epidermal electrodes and other devices will be also discussed.

Integrated Biodevices for Smart Contact Lenses Takeo Miyake; Waseda University, Japan

Smart contact lenses—contact lenses with built-in electronics—are a next-generation wearable product with capabilities beyond simple vision correction. Since the electrical lenses are in continuous contact with the eyeball surface, they have three main applications: (i) biomedical sensing of tears and intraocular pressure to monitor health conditions, (ii) wearable displays for augmented reality (AR), and (iii) actively regulating eye accommodation to ensure perfect vision. Thus, a smart contact lens has substantially greater functionality than an electrical eyeglass. We have developed several prototypes of an ultrasensitive diagnostic smart contact lens [1-5] with high sensitive biosensors and high efficient parity-time (PT) symmetric wireless transfer systems, a wireless electrochromic lens using conductive polymer-based film, and multi-electrode electroretinogram (ERG) lens system. I will present a detail in my invited talk.

11:30 AM *SB10.08.08
Tissue-Interfaced Electronics for Directing Biological Functions Toshinori Fujie; Tokyo Institute of Technology, Japan

Integration of flexible electronics into the living system is expected for advancing medical diagnostics and therapeutics. Such devices should be seamlessly conformed to the physical and mechanical environment of living body, in which acquired biosignals are expected to be transmitted wirelessly to external device. In this regard, we envisage the development of tissue-interfaced electronics for wearable and implantable applications based on polymer nanosheet technology. The polymer nanosheet shows tens- to hundreds-of-nanometer thickness close to the scale of biomembranes, in which various types of polymers (e.g., biodegradable polymers, conductive polymers, and elastomers) are formed into the ultra-thin structure. Free-standing polymer nanosheets showed flexible and adhesive properties derived from their ultra-small flexural rigidity ($< 10^{-2}$ nN m). In this talk, polymer nanosheet (or thin film)-based devices are introduced by combining polymer nanosheet and printing technologies with variety of unique inks. A microgravure coater was employed for the preparation of flexible substrates or electrodes, an inkjet printer allowed for the tailor-made design of multielectrode array, and a laser processing machine was used for making the microchannels for insulating the circuit. The ultra-conformable structure has been utilized as tissue-interfaced electronics to direct biological functions in the applications of healthcare and medicine, represented by the wirelessly-powered light emitting device for photodynamic cancer therapy, and the flexible, thin-film neural electrode for diagnosis and treatment of epileptic seizure.

SESSION SB10.09: Neuromorphic Computing II

1:30 PM *SB10.09.01
Organic Neuromorphic Electronics for Emulating and Interfacing Biological Systems Paschalis Gkoupidenis; Max Planck Institute for Polymer Research, Germany

Neurons are the fundamental elements of the nervous system, coping with a great diversity of electrobiochemical signals. Neuronal function is an archetype for biomimicry with neuromorphic electronics. However, artificial neurons based on electronics are insufficiently capable of operating in situ in biological environments, thus hampering the seamless sensing and biointerfacing as well as the biorealistic neuronal emulation. A few examples of soft-matter artificial neurons are based on conventional circuit oscillators and therefore require many elements for their implementation. An organic artificial neuron consisting of a compact non-linear electrochemical element will be presented. The artificial neuron displays in situ operation in biologically relevant environments that displays spiking dynamics sensitive to common ions of the biological aqueous milieu, within physiopathological concentration ranges (~ 5-150mM), and with ion specificity. Small-amplitude (~ 1-150 mV) electrochemical oscillations and noise in the electrolytic medium shape the neuronal dynamics, while changes of ionic ($\geq$ 2% over physiological baseline) and biomolecular concentrations ($\geq$ 0.1 mM dopamine) modulate the neuronal excitability. The artificial neuron operates synergistically with bio-membranes, forming real-time biohybrid interfaces. This electrochemical artificial neuron opens new possibilities for the seamless communication and the realistic emulation of biology with electronics.

2:00 PM *SB10.09.02
Thiophene-Based Trimers *In-Vivo* Polymerizes to Form Substrate-Free Organic Bioelectronics on Living Cell Systems Magnus Berggren; Linkoping University, Sweden

An array of different thiophene trimers have been synthesized to form bioelectronics that is amalgamated with living cell systems. Depending on the trimer composition and attached side groups, we can control the ionization potential, aggregation characteristics and the affinity to different cell system components. To fuel the polymerization, we take use of metabolic components, naturally available of the biological system, and various shapes of conducting and electroactive structures are formed. From here, we aim at establishing fundamental electrode and device architectures to enable novel routes to record and trigger cell functions, especially targeting the nervous system. The chemical, physical and electrical characteristics of different polymerized structures formed on cells and within tissues will be reported along with microscopy images.

2:30 PM SB10.09.03
From a Single Dendrite to Dendritic Networks: Towards Multi-Terminal OECTs Corentin Scholaert[1], Kamila Janzakova[1], Yannick Coffinier[1], Sébastien Pecqueur[1] and Fabien Alibart[1,2]; [1]CNRS IEMN, France; [2]CNRS - Laboratoire Nanotechnologies & Nanosystèmes (LN2), Canada

In the quest to change the way we envision computing, the ability to create connections in between computing nodes on demand offers the very exciting possibility to explore bottom-up strategies when it comes to thinking the design of electronic devices and circuits.
Recently, the growth of conductive polymer fibers via electropolymerization (most notably poly(3,4-ethylenedioxythiophene) doped with poly(styrenesulfonate), abbreviated as PEDOT:PSS) was employed in the realm of neuromorphic hardware, first as a way to tune the resistance of a connection,[1] and then to perform computing tasks, such as biosignal classification trough reservoir computing,[2] thus establishing the advantages of the method.

In this work, we propose to demonstrate that electropolymerization is a useful tool for the creation of sensors that are able to realize computing tasks in an aqueous environment. By taking advantage of the morphology of the fibers, we show that PEDOT:PSS dendrites can discriminate between different types of voltage pulses emitted in their vicinity by a local gate electrode, thus performing *in materio* classification.[3]
In addition, we discuss the growth of networks of polymer fibers on 2D substrates. The ability to create structures that cover several microelectrodes allows us to study the behavior of the whole system instead of a single dendrite, and it highlights the relationship that relates the morphology of the object and its electrical properties. In particular, we show that dendrites present an asymmetric non-linear behavior due to the volume of polymer that increases the capacitance of the device albeit not participating in conduction. Moreover, because of the ionoelectronic coupling that exists within an electrolyte, two active devices working concomitantly will influence one another. We demonstrate that it is a blessing for the realization of computing tasks, such as logic, and that it can also be used to program the dendrites into non-volatile conductance states. Therefore, dendritic networks could constitute a new building block for non-conventional information processing that fits into the larger framework of brain-inspired computing.

2:45 PM SB10.09.04
Face-On Orientation Matches Vertical Organic Electrochemical Transistors for High Transconductance and Superior Non-Volatility Bingjun Wang[1], Yuxin Kong[2], Sen Zhang[1], Ziang Wu[3], Shijie Wang[1], Jiaqi Ren[2], Han Young Woo[3], Yuxiang Li[2] and Wei Ma[1]; [1]Xi'an Jiaotong University, China; [2]Xi'an University of Science and Technology, China; [3]Korea University, Korea (the Republic of)

The recently developed vertical structure of organic electrochemical transistors (OECTs) can integrate volatile (sensing) and non-volatile (memory) functions into one reconfigurable device, making it highly promising. However, compared with the conventional planar OECT (c-OECT), the understanding of vertical OECT (v-OECT) working principles and device engineering strategies is still lacking, impeding rational optimization. Since a major difference between c- and v-OECTs is their charge transport directionality, which is highly influenced by crystallite orientations, the orientation–device structure match thus becomes an important yet outstanding topic for OECTs. Herein, using a newly synthesized n-type small molecule IDIC-MEG, we investigate how much impact such a match can have on OECT performance. The IDIC-MEG c-OECT fails to work due to the seriously hindered in-plane electron transport by face-on orientation. Surprisingly, simply changing the device structure from planar to vertical allows the resultant v-OECT to exhibit the highest reported transconductance (46.3 mS) among all small-molecule OECTs, thanks to the match between face-on orientation and the vertical structure. Such a match also leads to excellent non-volatility, including good conductance state retention, highly predictable programmability, and nice operational stability. This work, for the first time, explicitly demonstrates the significance of orientation–device structure match for OECT optimization. We envisage that this device engineering strategy may provide a new pathway to achieve high-performance, reconfigurable v-OECTs for homogenous in-memory sensing and computing systems, which entail volatile and non-volatile functions alike.

3:30 PM *SB10.09.05
Artificial Organic Afferent Nerves with Tactile Enhancement for Closed-Loop Feedback of Intelligent Robot Wei Lin Leong; Nanyang Technological University, Singapore

In biological tactile somatosensory system, the cooperation of mechanoreceptors, neurons and synapses allows human to efficiently detect, transmit and process the tactile information. Emulation of the tactile sensory nerve to achieve advanced sensory functions in robotics with artificial intelligence is of great interest. Here, we report an artificial organic afferent nerve (AOAN) by integrating novel pressure-activated organic electrochemical synaptic transistor (OEST) and artificial mechanoreceptors. Owing to the effect of electrochemical ion doping and ion trapping in bulk conjugated semiconductor, external mechanical stimulation enables activation and modulation of OEST, endowing the system with the recognition/sensation of spatiotemporal tactile information and a low retention loss during signal transmission. Dendritic integration function for neurorobotics is achieved to perceive directional movement of object. An intelligent robot with our system, coupling with a closed-loop feedback program is demonstrated for slip detection and prevent slippage of objects. This work provides a promising approach towards next-generation intelligent neurorobotics and low power biomimetic electronics.

4:00 PM SB10.09.06

Environment-Adjustable Bilingual Synaptic Functions in Bio-Synaptic Transistors Moon Jong Han[1] and Vladimir V. Tsukruk[2]; [1]Gachon University, Korea (the Republic of); [2]Georgia Institute of Technology, United States

The transmission of signals in the nervous system is controlled by neurotransmitters. Neurons can be either stimulated or suppressed depending on the specific neurotransmitter released by the sending neurons. It is crucial for the nervous system to maintain a balance between these excitatory and inhibitory responses in order to be versatile, flexible, and capable of parallel processing. One way to achieve the brain's adaptability and flexibility is by replicating this balance between excitatory and inhibitory responses. Despite extensive efforts to study how the nervous system achieves this balance, it has been challenging to simulate the intricate connections between excitatory and inhibitory synapses. Herein, we propose an optoelectronic synapse that achieves a balance between excitatory and inhibitory responses with color recognition. This is accomplished by utilizing the humidity-sensitive helical arrangement of chiral nematic phases within cellulose nanocrystals (CNCs). The level of absorbed water molecules fine-tunes the polarization of the CNC complex films, resulting in diverse hysteresis effects and subsequent excitatory and inhibitory nonvolatile behavior in bio-electrolyte-gated transistors. By applying voltage pulses and stimulating with chiral light, the artificial optoelectronic synapse not only adjusts synaptic functions but also enhances learning behaviors and the ability to recognize color signals. Through the interdisciplinary collaboration between CNC bio-nanotechnology and functional optoelectronics systems, the versatile synaptic transistors exhibit potential for applications in highly efficient parallel neuromorphic computing and advanced robot vision technology.

4:15 PM SB10.09.07
A Fully-Integrated Wearable In-Sensor Computing Platform based on Intrinsically Stretchable Organic Electrochemical Transistors Dingyao Liu and Shiming Zhang; The University of Hong Kong, Hong Kong

Organic electrochemical transistors (OECT) have emerged as a promising technology paradigm for in-sensor computing and wearable healthcare applications [1]. However, several major challenges limit their widespread adoption in real-world applications: 1) the lack of conformable and stretchable OECT units to reduce the mechanical mismatch between devices and the soft human body; 2) the lack of reliable fabrication methods to enable scalable manufacturing of intrinsically stretchable OECT arrays with smaller feature sizes and high density; and 3) the lack of miniaturized readout systems to enable wearable-sized assembly [2]. In this work, we present a wearable, integrated, and soft electronic (WISE) platform based on intrinsically stretchable OECT arrays, addressing all these challenges. The WISE-platform achieves: 1) intrinsically stretchability (>50%) by implementing a new material protocol for device assembly and improving strain-robustness at interfaces with a tough adhesive supermolecular buffer layer; 2) a scalable fabrication of stretchable OECTs arrays with feature size down to 100 μm using a high-resolution 6 channel inkjet printing system; and 3) a customized, coin-sized data readout system for easy acquisition of biosignals at their origin. As an example, we demonstrate the use of the coin-sized, smartwatch-compatible electronic module for wearable in-sensor computing at the edge, but other application scenarios can be easily imagined.

4:30 PM *SB10.09.08
Synaptic Plasticity on Demand for Neuromorphic Computing and Bio-Inspired Artificial Nerve Dae-Gyo Seo, Gyeong-Tak Go, Min-Jun Sung and Tae-Woo Lee; Seoul National University, Korea (the Republic of)

Biological nervous systems possess versatile attributes, serving diverse functions; for instance, the central nervous system (CNS) governs learning and memory, while the peripheral nervous system (PNS) is responsible for sensory perception. Consequently, there is a need to engineer artificial synapses tailored to adapt to performance requirements in various applications. Brain- inspired neuromorphic computing aims to emulate the learning and memory capabilities of the CNS, being inspired from the long-term potentiation (LTP) observed in biological synapses. The application of artificial synapses in the fields of nervetronics and neuroprosthetics requires the emulation of the short-term plasticity (STP), enabling the rapid signal transmission and fast responses akin to those in the biological PNS. To demonstrate the broad applicability, spanning areas including neuromorphic computing and bio-inspired nervetronics, our study has explored the modulation of STP and LTP using ion-gel gated polymer synaptic transistors (IGPSTs). We have modulated the polymer semiconductor (PSC) film’s crystallinity through post-deposition film annealing, self-assembly monolayer treatment, and the introduction of various sidechain length, leading to the conversion between STP and LTP properties in IGPSTs. Moreover, we have utilized a straightforward yet effective approach by blending two PSCs with the same backbone but different sidechains. This blend strategy has led to a substantial improvement in LTP characteristics, whereas IGPSTs employing each PSC individually show only STP properties. IGPSTs with enhanced LTP properties demonstrate their potential as neuromorphic computing devices, effectively simulating learning processes in artificial neural networks. Concurrently, IGPSTs featuring STP capabilities are used to demonstrate various artificial nervous systems, such as artificial reflex arcs, neuromuscular systems, and neuro-prosthetic nerves incorporating artificial proprioceptors. These pioneering studies on neuromorphic devices have expanded the scope of applications for artificial synapses and validate the feasibility of these innovative technologies.

SESSION SB10.10: Bioelectronic and Neuomorphic Systems

Friday Morning, April 26, 2024
Room 429, Level 4, Summit

8:30 AM SB10.10.01
Colloidal Electronic Matter Jihpeng Sun and Albert T. Liu; University of Michigan–Ann Arbor, United States

Arming nano-electronics with mobility extends artificial systems into traditionally inaccessible environments. Carbon nanotubes (1D), graphene (2D) and other low-dimensional materials with well-defined lattice structures can be incorporated into polymer microparticles, granting them unique electronic functions. The resulting colloidal electronic 'cells', comprised of microscopic circuits connecting artificial 'organelles' (e.g., generators, sensors, logic gates, etc.), combine the modularity of modern electronics with the characteristic mobility found in dispersive colloidal systems. In this talk, I will discuss our efforts to fabricate colloidal electronic systems that perform autonomous functions integrating energy harvesting, chemical detection and digital memory recording - all within a form-factor no larger than biological cells.

8:45 AM SB10.10.02
A Purely Electronic Analog Memristive Device Based on a Squaraine Nanowire Mesh Gareth Redmond; University College Dublin, Ireland

Analog memristors offer the ability to gradually increment device conductance, akin to synaptic weight updating the human brain, and a path toward emulation of brain-like functionality on a chip. Specifically, purely electronic resistive switching device operation may provide good device stability, fast

device response, and microelectronics fabrication compatibility. In this context, nanowires (NWs) based on 2,4-bis[(4-diethylamino)-2-hydroxyphenyl]squaraine were prepared by non-solvent-induced precipitation and characterized in detail. Symmetric, unipolar (hole-only) metal−insulator−metal-type devices were formed by simple deposition of NW meshes on interdigitated gold electrodes. The DC I−V characteristics acquired from devices displayed pinched hysteretic I−V loops indicative of memristive behavior. Analysis of I−V data indicated Ohmic transport at low bias with carrier extraction facilitated by thermionic emission. At high bias, devices exhibited trap-limited space-charge-limited conduction in the presence of traps distributed in energy, which was enhanced by a Poole−Frenkel effect, with carrier extraction facilitated by Fowler−Nordheim tunneling. Overall, the data were consistent with purely electronic conduction. This hypothesis was further supported by DC measurement data acquired from devices under illumination, by AC impedance data acquired in both dark and light conditions, and by variable temperature transport measurements. During voltage sweeps applied to NW mesh devices, I−V hysteresis was observed, consistent with modifications to current flow caused by carrier trapping/detrapping. Device conductance could be increased sweep by sweep, giving conductance tuning through distinct states, with wait time- or voltage-erase options, consistent with trap filling/emptying effects. On this basis, trap-enabled analog memristive device functionality was demonstrated in both rigid and flexible device formats by applying various voltage waveforms. Repeated erase-write-read of multiple distinct states over many voltage cycles during continuous use in air was demonstrated. Also, synaptic functions, e.g., pulse-dependent plasticity, and short- to long-term memory transition, were successfully emulated. Finally, the stable, repeated erase−write−read of multiple distinct conductance states over hundreds of voltage cycles during hours long periods of continuous use in an ambient atmosphere was demonstrated. Overall, squaraine NW mesh devices appear to exhibit many attractive characteristics that make them potential candidates for neuromorphic computing applications.

9:00 AM SB10.10.03
Paper-Based Electronic Tongue for Rapid and Reusable Quantitative Sensing of Water in Organic Solvents Using Principal Component Analysis
Gregory Moore and Anthony Dichiara; University of Washington, United States

Rapid and quantitative recognition of trace amounts of water in organic solvents is of great importance in industrial operations. Currently the standard methods of determining water content in such cases include the Karl Fischer (KF) titration and fluorescence colorimetry, which are expensive, time consuming, and require skilled operators to perform. Electronic tongues are sensor systems with the ability to analyze and classify complex samples by their chemical composition [1]. Principal Component Analysis (PCA) is a multivariate statistical technique used to reduce the dimensionality of data while retaining as much of the initial variation as possible and is commonly used in electronic tongue applications [1], [2]. In this work, a multifunctional liquid sensing and classification system was developed based on paper comprising pulp fibers adsorbed with multi-walled carbon nanotubes. Papertronics is a field of increasing interest due to the biodegradable nature, flexibility, and light weight of lignocellulosic paper and its ability to be produced at large scale using well-established and cost-effective manufacturing processes [3]. The hygroscopic nature of cellulose fibers causes them to swell radially in response to water molecules, which alters the conductive pathway within the percolated carbon nanotube network present on their surface, leading to a significant change in the paper resistance when wet. Importantly, the swelling behavior strongly depends on the nature of the solvent, which makes it an exceptional material for liquid sensing applications [4]. The electrical response of the sensor was tested and replicated for several liquid solutions of different solvents, concentrations of water in solvents, and ionic strengths of water. Specific features were identified from the response profiles, generating over 800 data points which were implemented in the PCA and used to differentiate between the liquids. The sensing platform can quantify the amount of water in the organic solvent with a sensitivity below 100 ppm and high resolution which makes it competitive with the KF titration. The proposed paper-based electronic tongue demonstrates the ability to rapidly differentiate low concentrations of water in organic solvents, provides an economic alternative to current methods, and enables future discoveries in biosensing and bioelectronics.

9:15 AM SB10.10.04
Untethered Cardiac Stimulation and Pacing Enabled by Ultra-Thin Rubbery Bio-Optoelectronic Stimulators Zhoulyu Rao, Faheem Ershad and Cunjiang Yu; The Pennsylvania State University, United States

Untethered electrical stimulation or pacing of the heart is of critical importance in addressing the pressing needs of cardiovascular diseases in both clinical therapies and fundamental studies. However, existing devices to provide untethered electrical stimuli are typically rigid, bulky, and complex in system architecture thus it is challenging to seamlessly integrate them with soft, deformable, and dynamic organs and tissues, which unavoidably causes device failure or tissue damage. Alternatively, light illumination induced electrical stimulation via the photoelectric effect without any genetic modifications to the beating cells/tissues or the whole heart has profound benefits. However, a critical bottleneck lies in the lack of a suitable material/device with tissue-like mechanical softness and deformability and sufficient optoelectronic performances towards effective cardiac stimulation and pacing. Specifically, concurrent deformation (i.e. ~ 20% strain) of a stimulating device with a beating heart during the stimulation while not constraining its beating is of paramount importance. However, materials and devices with these collective properties have never been developed. Here we introduce an ultra-thin (<500 nm), stretchy, and self-adhesive rubbery bio-optoelectronic stimulator (RBOES), in a bilayer construct of a rubbery semiconducting nanofilm and a transparent, stretchable gold nanomesh conductor. The RBOES can produce a potential response as high as 150 mV from the semiconductor-electrolyte interface under light illumination (2.8 mW/mm^2) and could maintain its optoelectronic performance when it was stretched by 20%. The RBOES was validated to effectively synchronize the beating and pace the cultured human induced pluripotent stem cell-derived cardiomyocytes under optoelectronic stimulation with variable target beating rates (from 20-30 bpm before stimulation to 30, 48, and 72 bpm after stimulation). Furthermore, optoelectronic pacing of ex vivo perfused rat hearts with the self-adhered RBOES was achieved with repetitive pulsed light illumination. Systematic investigations on the materials strategy, device design, and biological validations illustrated the key aspects of the RBOES and its capabilities in cardiac stimulation and pacing. This work exploits an unprecedented cardiac stimulator in a rubber format developed through material engineering to form a unique rubbery semiconducting nanofilm based bio-optoelectronic interface for non-genetic biological stimulation. The RBOES is applicable to various electrically excitable tissues and organs, such as the brain, spinal cord, peripheral nerves, and skeletal muscles, which paves the way towards non-genetic, untethered stimulation for both fundamental biological studies and clinical therapy.

9:30 AM SB10.10.05
Flow-Cell Sensor for Bacteria Detection Using Gate-Modified Organic Electrochemical Transistor Jingchu Huang, Daewoo Han and Andrew J. Steckl; University of Cincinnati, United States

Organic electrochemical transistors (OECT) have been previously demonstrated in the sensing of cells and metabolic products. In this study, we report a

novel approach on the universal detection of bacterial contamination in home-liquid-goods through the utilization of a microfluidic flow-cell that has been integrated with OECT technology. The flow-cell device has been developed for the purpose of detecting minimal concentration (~10^3 CFU/ml) of several bacterium types (*Escherichia coli, Pseudomonas fluorescens and Staphylococcus aureus*) in various commercial household liquid product blends (cf. Air Febreze, Tide, Old Spice bodywash). This process can be completed in a testing period of one hour or less and does not require amplification or a designated binding agent. The flow-cell configuration uses a microporous filter membrane (Au coated PETE, 0.2 µm pore diameter) designed to concentrate the bacteria within the chamber. The membrane also functions as a gate electrode for the operation of OECT. The presence of bacteria on the gate filter membrane leads to an increase in the total effective gate voltage (V_{eff}), which in turn causes a decrease in the OECT source-drain channel current (I_{DS}). Based on the shift of I_{DS}, the OECT provides good discrimination between bacteria and sterile solutions (0.4 mA difference). The OECT transconductance (g_m) exhibits a maximum value at different levels of V_{GS} for sterile and bacteria solutions. g_m shifts to positive value at lower gate operating voltage due to bacteria attachment on Au gate. The flow-cell filtration and OECT gate sensing approach has the capability to identify a diverse range of bacteria, encompassing both gram-positive and gram-negative strains, across multiple testing media.This approach exhibits potential for biosensing systems that will enable real-time monitoring at the production line.

9:45 AM SB10.10.06
3D-Printed Epidermal Microfluidic Systems: Opportunities to Expand Access to Personalized Health Monitoring Tyler Ray; University of Hawaii, United States

Persistent disparities exist in access to state-of-the-art healthcare and disproportionately affect underserved and vulnerable populations. Advances in wearable sensors enabled by additive manufacturing (AM) offer new opportunities to address such disparities and enhance equitable access to advanced diagnostic technologies. Additive manufacturing processes, particularly stereolithography (SLA)-based printing, offer powerful pathways for circumventing existing barriers to innovation for resource-limited settings by providing significant reductions in prototype development cost and cycle time while substantially expanding device capabilities with fully 3D device designs. Here, we present a simplified 3D-printing prototyping process to fabricate flexible, stretchable, epidermal microfluidic devices ('3D-epifluidics') suitable for direct on-body interfacing. These wearable sweat sensors integrate microfluidic channel networks with biochemical sensors and flexible electronics to enable the noninvasive, real-time monitoring of sweat-based biochemical signals associated with health and wellness. By reducing fabrication time to [O]min, this approach enables the integration of spatially-engineered features including 3D-structured passive capillary valves, monolithic channels, and reservoirs with spatially-graded geometries. With geometric features comparable to established epifluidic devices (channels >50 µm), benchtop and on-body testing validate the performance of 3D-epifluidic devices. We utilize these platforms to showcase how these devices hold the potential for addressing some of the formidable obstacles to delivering comprehensive medical care in under-resourced settings, especially in remote or geographically isolated areas.

Transfer-Printed PEDOT:PSS on Stretchability-Enhancing, Biodegradable PVA Substrates towards Stretchable OECTs Carla Volkert[1], Renan Colucci[1], Mateusz Brzezinski[1], Pablo Gomez Argudo[1], Jasper Michels[1], Pol Besenius[2], Paul W. Blom[1] and Ulrike Kraft[1]; [1]Max Planck Institute for Polymer Research, Germany; [2]Johannes Gutenberg University, Germany

Extensive efforts have been invested in advancing flexible devices[1], including biosensors, optoelectronic devices, organic field effect transistors (OFETs), light emitting diodes (LEDs) and organic electrochemical transistors (OECTs)[2]. Building on these achievements, stretchable electronic devices have evolved within the last decade[3,4]. To further advance and fully exploit the next generation of stretchable electronics, the innovation of novel device fabrication processes and materials is needed. Poly(3,4-ethylenedioxythiophene): poly(styrenesulfonate) (PEDOT:PSS) stands out as a popular material in bioelectronic applications due to its high conductivity, optical transparency, mechanical resilience, commercial availability and biocompatibility. Consequently, significant efforts have been undertaken to transform PEDOT:PSS from a brittle into a flexible and stretchable material. Conventional approaches involve the addition of chemicals such as ionic liquids[5], surfactants, plasticizers and other organic additives[6].
Here, we propose an alternative approach towards stretchable electronics: rather than inducing stretchability through such additives, we demonstrate that the mechanical properties of PEDOT:PSS can be adjusted by utilizing diffusion-active substrates. The substrates are infused with a plasticizer that diffuses into the PEDOT:PSS, modifies its glass transition temperature and consequently leads to an enhanced stretchability and an increased conductivity. Chain-alignment and -mobility during elongation are evidenced by a higher crack-on-set-strain (>150%) and an increased conductivity upon strain. A comprehensive (concentration-dependent) analysis, including electrical measurements, atomic force microscopy, and Raman spectroscopy, was undertaken to study the substrate- and PEDOT:PSS-chain alignment upon strain and was correlated with the concentration-dependent diffusion of the plasticizer.
This novel approach towards stretchable electronics is furthermore compatible with our recently developed transfer-printing method for (plasma-patterned) electronic devices and finally led to the successful fabrication of intrinsically stretchable organic electrochemical transistors on biodegradable substrates.

Edible Logic Circuits Giulia Coco[1,2], Valerio F Annese[2], Valerio Galli[1,2] and Mario Caironi[2]; [1]Politecnico di Milano, Italy; [2]Istituto Italiano di Tecnologia, Italy

As single-use and disposable electronic devices are becoming widespread for food and gastrointestinal tract monitoring, safe and sustainable materials development is emerging as a fundamental objective for technological innovation. The EU-funded ROBOFOOD project explores food-derived materials - an unprecedented and unconventional approach – to fabricate robots that could be metabolized (or degraded) in the body (or environment) after performing their function. In this perspective, the challenge consists of realizing stable edible electronic circuits that can provide synchronization, perform simple computation, and serve as memory, starting from notoriously unstable materials.
Here we present the fabrication and characterization of edible logic circuits. For this aim, a printed edible electrolyte-gated transistor with a lateral gate configuration was fabricated using food-based inks. A comprehensive characterization was carried out revealing performance comparable with state of the art. Hence, edible logic gates operating at low voltage (< 1 V) were demonstrated, integrating the transistor in unipolar configurations. Different edible materials and fabrication techniques compatible with the proposed transistor were also explored for implementing the required resistive load. Edible NOT and NAND gates were successfully fabricated and characterized using well-established metrics. More complex circuits, such as an edible ring oscillator working at a frequency around 1 Hz and a set/reset latch, were demonstrated. We believe that this work leads the way to edible logic circuits performing complex functions and to their integration into devices that can interact safely with humans and animals.

11:00 AM SB10.10.09

A Fingertip Force Microscope (FFM) for Micro-Scale Morphology Characterization Jiaqi Tu and Xiaodong Chen; Nanyang Technological University, MSE, Singapore

Texture sensing is an essential part of tactile sensing, which extracts morphology, roughness, and hardness information during object manipulation. However, biological texture sensing is only a qualitative description of object features and shows low spatial resolution. Current research on artificial tactile sensing systems mainly focuses on machine learning-based qualitative comparison of different surfaces with different roughness. Here, we present a wearable artificial fingertip consisting of two piezoelectric vibration tips for quantitative morphology characterization. Two sensing tips with fixed spacing will bend and recover while sliding the artificial fingertip over uneven surfaces. Piezoelectric films on the tips transform vibrations into voltage signals. The two-tip design enables the identification of instantaneous speed. By correlating voltage signals with the actual moving condition and the calculated instantaneous speed, the time-domain information indicates the groove width, bar width, and groove depth of the grating texture. Therefore, textures with height of 1μm~3mm and distances beyond 200 μm can be detected without the need for controlled speed and pressing force. Further, the artificial fingertip can be worn on fingers and generates micro-scale morphology information. The artificial fingertip was further integrated into a robotic hand for obtaining morphology information from multiple slides. Three-dimensional (3D) reconstruction of fine micro-scale patterns can be generated through a quick sweep in real time.

QuantumDock: An Automated Computational Framework for Wearable Sensor Design Daniel Mukasa, Minqiang Wang, Jihong Min, Yiran Yang, Samuel A. Solomon, Hong Han, Cui Ye and Wei Gao; California Institute of Technology, United States

Wearable sweat sensors have the potential to revolutionize precision medicine as they can non-invasively collect molecular information closely associated with an individual's health status. However, the majority of clinically relevant biomarkers cannot be continuously detected in situ using existing wearable approaches. Molecularly imprinted polymers (MIPs) are a promising candidate to address this challenge but haven't yet gained widespread use due to their complex design and optimization process yielding variable selectivity. Here, QuantumDock is introduced, an automated computational framework for universal MIP development toward wearable applications. QuantumDock utilizes density functional theory to probe molecular interactions between monomers and the target/interferent molecules to optimize selectivity, a fundamentally limiting factor for MIP development toward wearable sensing. A molecular docking approach is employed to explore a wide range of monomers, and to identify the optimal monomer/cross-linker choice for subsequent MIP fabrication. We further employ a molecular generation scheme that allows us to generate molecules with much higher sensitivities and selectivities than traditionally used monomers. Using an essential amino acid phenylalanine as the exemplar, experimental validation of QuantumDock is performed successfully using solution-synthesized MIP nanoparticles coupled with ultraviolet–visible spectroscopy. Moreover, a QuantumDock-optimized graphene-based wearable device is designed that can perform autonomous sweat induction, sampling, and sensing. For the first time, wearable non-invasive phenylalanine monitoring is demonstrated in human subjects toward personalized healthcare applications.

11:30 AM SB10.10.11
Development of Water-Resistant Au-PVA/WBPU Nanomesh Electrodes for Stable Monitoring of Skin Impedance Maho Mimuro, Sunghoon Lee, Tomoyuki Yokota and Takao Someya; The University of Tokyo, Japan

Electrodermal activity, which is known to vary due to various factors such as psychological states like stress level [1], and environmental factors like temperature [2] and humidity [3] is one of the important biological signals for early detection of disease and preventive healthcare. Previously, ultrathin and lightweight Au-PVA nanomesh electrode which does not cause discomfort when they were attached on skin has been developed [4] and continuous measurement of skin resistance and skin impedance were achieved by using the nanomesh electrodes [5, 6]. However, these electrodes were vulnerable to water and prone to damage, requiring careful handling during attaching to the skin and being susceptible to breakage with slight movements or sweat. To address this issue, we developed nanomesh electrodes with excellent water resistance and stable measurement capabilities by mixing hydrophobic WBPU (waterborne polyurethane) with the conventional material PVA (polyvinyl alcohol). The Au-PVA/WBPU nanomesh electrodes were fabricated by following method. First, a mixture of a 15 wt% PVA aqueous solution and a 30 wt% WBPU solution in 2:1 ratio was made into a nanofiber sheet by electrospinning method. And then, a heat-press treatment was applied to the nanofiber sheet to improve the inner connect between fibers. After a heat-press treatment at 150°C for 1 minute, a 100 nm thick layer of gold was deposited by vacuum evaporation method. To check the water resistivity of the nanomesh electrode, we conducted a water immersing test. After a 1-minute stirring test in the pure water, the conventional Au-PVA nanomesh electrodes completely disappeared from the artificial skin, whereas Au-PVA/WBPU nanomesh electrodes remained more than 95% area on the artificial skin. In addition, we checked the stability of the nanomesh electrodes on the skin. After attaching the electrodes on the skin for 2 hours, the resistance of the Au-PVA/WBPU nanomesh electrodes were almost constant while that of conventional nanomesh electrodes showed a deterioration, increasing by 3 to 4 times.

Elastic Metal Microtube for Flexible Ultralow-Hysteresis Tactile Sensor Yanzhen Li and Xiaodong Chen; Nanyang Technological University, Singapore

Low-hysteresis and fast-response tactile sensors that mimic the human sense of touch can empower robotic systems to manipulate diverse objects rapidly and accurately. However, current tactile sensors, which mostly rely on viscoelastic polymers as functional materials, suffer from high hysteresis and slow response time, limiting their applicability in intelligent robotics. Here, we introduce an elastic metal microtube enhanced (EMME) tactile sensor with ultralow hysteresis and fast response. The microtube structure is achieved by utilizing the inner stress of thermally evaporated metal films after dissolving a sacrificial layer. The superior elasticity of the metal microtubes minimizes energy dissipation during deformation under external mechanical stimuli, contributing to ultralow hysteresis and fast response of EMME tactile sensor. Furthermore, the positive correlation between hysteresis and energy dissipation is theoretically and experimentally established in capacitive tactile sensors based on parallel plate structure. Our flexible EMME tactile sensor possesses ultralow hysteresis (~0.8%), fast response time (<1 ms), high endurance (10000 cycles), and the ability to keep up with high-frequency vibration. Upon integration with the robotic hand, accurate and autonomous manipulation of shape-changing objects with a feedback loop is achieved, mimicking air pressure monitoring via balloon volume change in chemical experiments, exhibiting its potential in future intelligent and autonomous laboratory robotic systems.

10:30 AM *SB11.01.01
Leveraging Biological Motor Control for Soft Robotics Ritu Raman; Massachusetts Institute of Technology, United States

Human beings and other biological creatures navigate unpredictable and dynamic environments by combining compliant mechanical actuators (skeletal muscle) with neural control and sensory feedback. Abiotic actuators, by contrast, have yet to match their biological counterparts in their ability to autonomously sense and adapt their form and function to changing environments. We have shown that engineered skeletal muscle actuators, controlled by neuronal networks, can generate force and power functional behaviors such as walking and pumping in a range of untethered robots. These muscle-powered robots are dynamically responsive to mechanical stimuli and are capable of complex functional behaviors like exercise-mediated strengthening and healing in response to damage. Our lab uses engineered bioactuators as a platform to understand neuromuscular architecture and function in physiological and pathological states, restore mobility after disease and damage, and power soft robots. This talk will cover the advantages, challenges, and future directions of understanding and manipulating the mechanics of biological motor control.

11:00 AM ^SB11.01.02
Vapor-Deposited Polymeric Biointerface to Direct Living Behavior Rong Yang; Cornell University, United States

Polymer is often considered one of the most prevalent materials in the modern age. The interactions between polymers and a highly ubiquitous living system – bacteria – are of great interest in applications ranging from fouling control to living materials, but details of those interactions are poorly understood. The sub-micron size of most bacteria, whose sensory apparatus often operates on the nanoscale, requires precise placement of chemical functionalities and nanostructures at the synthetic-living interface. The need for nanoscale resolution challenges most traditional synthesis and processing approaches, which have been predominantly performed in solution. Recent advances in vacuum-based synthesis technologies, such as the initiated Chemical Vapor Deposition (iCVD), have enabled a new mode of control over polymeric material properties during polymerization. Distinct from prior research that has placed strong emphasis on the design of monomer molecular structure and controlled polymerization, the all-dry synthesis enables manipulation of the physical phenomena, such as nanoscale dewetting, Knudsen diffusion, and molecular complexing, to achieve programmable material properties. In this talk, we will discuss several strategies to achieve the nanoscale control over the vapor-deposited polymeric biointerface. Such control in turn led to improved understanding and manipulation of bacteria-material interactions, such as suppression of virulence. Taken together, the synthetic advances are poised to open up a new dimension in the design of polymeric materials for the programmable material-bacteria interactions, which extend beyond “kill or repel” towards signaling and control.

11:15 AM SB11.01.03
Programmable Tissue Folding in Magneto-Active Structured Hydrogels Zenghao Zhang, Avinava Roy, Claudia Loebel and Abdon Pena-Francesch; University of Michigan–Ann Arbor, United States

Biological tissues are structurally complex and heterogeneous, making the in vitro recapitulation challenging if using a traditional flat cell-culture substrate. Although recent development in engineering tissue patterns has been achieved through top-down approaches including micro-molding and 3D bioprinting, reversible and on-demand dynamic patterning is still underdeveloped. Among soft actuation systems, magnetic actuation shows little toxicity to cells, and can penetrate tissue and media to generate pulling forces and torques remotely, enabling fast and reverse untethered actuation. In this study, we developed hydrogel cell-culture systems based on bilayer folding hydrogels composed of a rigid hyaluronic acid (HA) hydrogel and a stretchable double-network (DN) with ferromagnetic particle dopants. Building upon recent advances in the design of magnetoactive soft materials, our approach further uses magnetoactive hydrogels to provide dynamic patterning upon applying magnetic fields. Using this method, we generated cell-laden hydrogel substrates that display on-demand folding/unfolding reversible shape transformations, providing a culture system for mimicking dynamic tissue folding in vitro and

recapitulating 3D complex structures to probe cellular mechanisms.

1:45 PM *SB11.02.01
The Synergy of Electronic Polymers and Self-Driving Laboratories for Innovations in Soft Robots Jie Xu; Argonne National Laboratory, United States

In the realm of soft robotics, electronic polymers have emerged as important materials owing to their unique combination of mechanical viscoelasticity and electronic properties. These materials, including conductive and semiconductive polymers, are instrumental in crafting flexible coverings that empower soft robots to sense intricate environments and relay information to human counterparts. However, the quest to identify electronic polymers capable of realizing desired functionalities remains a formidable challenge. Traditional, manual methods, relying solely on human expertise, could entail decades of arduous research and development. In this context, self-driving laboratories, leveraging robotic automation and artificial intelligence, are revolutionizing the exploration and development of electronic polymers and soft devices tailored for soft robotics. In this presentation, I will begin by introducing our autonomous laboratory, aptly named 'Polybot.' Subsequently, I will delve into recent research, exemplifying autonomous electrochromic polymer discovery for applications in optical communication and autonomous polymer electrochemical sensor discovery, with the potential to serve as bio-sensing platforms within soft robotic systems.

2:15 PM SB11.02.03
Liquid-Metal-Based All-Soft Pressure Sensor and Machine Learning Application for Multidirectional Detection Osman Gul[1,2], Jeongnam Kim[2,3], Yulim Min[2,3], Hye Jin Kim[2,3] and Inkyu Park[1]; [1]Korea Advanced Institute of Science and Technology, Korea (the Republic of); [2]Electronics and Telecommunications Research Institute, Korea (the Republic of); [3]University of Science and Technology, Korea (the Republic of)

Electronic skin needs to be able to sense different types of pressures, such as radial pressures, which require the development of a soft multidirectional pressure sensor. Although previous studies have developed multidirectional pressure sensors, the investigation into discerning the direction and magnitude of applied pressure remains an unexplored domain in multidirectional pressure sensor research. Multidirectional pressure sensors have been extensively developed in literature due to their vast application opportunities. Recently, the trend has shifted towards developing soft sensors with a focus on the design of the structure and sensing materials. The four-element sensing structure is the most commonly used structure for multidirectional sensors. In the case of the four-element sensing structure, the four sensing element is positioned at 90-degree intervals from one other, forming a cube-like structure. The four-element sensing structure facilitates the measurement of multidirectional forces. Wide-ranged 3D bump structures are used at the top of the four-element sensing materials to identify the applied multidirectional forces effectively. Lee et al. demonstrated trapezoid structure and CNT array as the sensing material. Jung et al. proposed a multidirectional force sensor with the sensing materials placed on the sidewalls of the 3D bump structure. Vogt et al. and Kim et al. presented liquid-metal-based multidirectional sensors with rigid pressure transmission structures on the top of the liquid metal channels. In these sensors, the multidirectional force is generated by applied shear pressure to the four-sensing structure of the sensor. Nevertheless, extracting directional information from a four-sensing element-based sensors' setup when exposed to applied radial pressure remains a formidable challenge, because the four-sensing element method is primarily designed for shear force-based applications.
In the present study, we present a new solution to address the limitations of existing multidirectional sensors. Our approach involves the development of a soft sensor using liquid metal with a dome-shaped design that enables discrimination of directional pressures. Additionally, we leverage machine learning algorithms to identify the direction and magnitude of applied pressure. The microchannels of the soft pressure sensor were created using fused deposition modeling (FDM). A 3D printed mold made of poly(vinyl alcohol) (PVA) was embedded into the elastomer and dissolved with water to create the microchannels. The empty microchannels were filled with liquid metal, and a vacuum process was applied to create the dome structure for multidirectional pressure sensing. The microchannels within the liquid-metal-based soft pressure sensor exhibit a transient response when pressure is applied. Specifically, each direction of the sensor indicates a distinct transient response when the pressure is applied, which helps to differentiate between different directions of pressure. The machine learning technique, we have implemented is based on dual-task 1D convolutional neural networks (CNN). This approach allows for real-time classification and regression of the magnitude of pressures applied on different directions of the sensor. We achieved direction identification in real-time using the transient response data from the soft pressure sensor. The developed liquid-metal-based soft pressure sensor can detect the direction (classification accuracy of 99.1%) and magnitude (regression error of 20%) of the multidirectional pressure in real-time pressure prediction through a 1D CNN algorithm. The effectiveness of the sensor and algorithm is demonstrated with a human-machine interface application where the sensor is used to control an RC model car. The machine learning predictions, including the direction and magnitude of the pressure, are used to control the vehicle's real-time movement.

2:30 PM +SB11.02.04
Ultra-Tough Ionogels for Stretchable Ionic Devices Michael Dickey and Meixiang Wang; North Carolina State University, United States

Ionogels are compelling materials for energy storage devices, ionotronics, and actuators due to their excellent ionic conductivity, thermal and electrochemical stability and nonvolatility. However, most existing ionogels suffer from low strength and toughness. Here, we report a simple one-step method to achieve ultra-tough and stretchable ionogels by randomly copolymerizing two common monomers in ionic liquid. Copolymerization leads to a single covalent network with controllable polymer- and solvent-rich phases that form in situ due to the phase behavior of the polymer in ionic liquid. The polymer-rich phase forms hydrogen bonds that dissipate energy and thereby toughen the ionogel during extension, while the solvent-rich phase remains elastic to enable large strain. The copolymer ionogels composed of acrylamide and acrylic acid exhibit extraordinary mechanical properties, including fracture strength (12.6 MPa), fracture energy (~24 kJ m-2), and Young's modulus (46.5 MPa), setting new records among reported ionogels. The tough ionogels are highly stretchable (~600% strain) and possess good self-recovery, as well as excellent self-healing and shape-memory properties. This concept extends to other monomers and ionic liquids, which offers a promising and general way to tune microstructure in situ during one-step polymerization that solves the longstanding mechanical challenges in ionogels.

3:00 PM BREAK

SESSION SB11.03: Stimuli-Responsive Soft Robots
Session Chairs: Danielle Mai and Abdon Pena-Francesch
Tuesday Afternoon, April 23, 2024
Room 430, Level 4, Summit

3:30 PM +SB11.03.01
The Design, Fabrication and Structural Modeling of Biomimetic Soft Materials for Robotic Applications Qing Chen; EMPA, Switzerland

The prospects of endowing soft actuators with biomimetic functions are promoting the development of intelligent robotics. Harnessing the energy from the ambient environmental conditions, various stimuli-responsive soft robots have been fabricated and applied in artificial muscles, human-machine interfaces and smart wearable devices. For example, a humidity-responsive actuator based on a mono-layered [1], and a multi-stimuli-responsive actuator based on a double-layered conducting polymer thin film have been fabricated [2], which demonstrated an outstanding actuation force and sensitive responses to their respective stimuli. The actuation behavior of soft actuators largely relies on their energy conversion and the underlying structural reconfiguration ability of stimuli-responsive materials. More importantly, these two processes are also essential for the reorganization of their intrinsic structural network, which is the key to self-healing ability of the material. Despite the tremendous advances in stimuli-responsive soft actuators, it is still a challenge to incorporate multiple-stimuli sensitivity and self-healing ability into a single material system. To solve this problem, great efforts have been devoted to develop structural-reconfigurable materials based on dynamic non-covalent crosslinking. For sample, a cellulose-based packaging paper have been fabricated, of which the humidity-responsiveness and hydration-induced self-healing ability depends on reversible hydrogen crosslinking of cellulose [3]. In another case, two stimuli-responsive and structural-reconfigurable layers with complimentary thermal expansion and compatible mechanical properties are combined as a bi-layered actuator *via* hierarchical assembly. The actuator is self-healing through a sequential treatment of heating and humidifying as each of the bi-layer is healable with the aid of either of these two energy inputs. Moreover, by combining various analytical techniques, we introduced the models for structural reconfiguration of these stimuli-responsive materials at multiple length scales, which could be used as the design platform for more biomimetic materials. Based on these achievements, we anticipate that these actuators hold great promise in a plethora of fields wherever programmable structural reconfigurations are needed, such as applications in space explorations and intelligent robotics.

4:00 PM SB11.03.02
Soft Sensory Robots based on Stimuli-Responsive Hydrogels for Electronic Implants Wubin Bai; University of North Carolina, Chapel Hill, United States

Living organisms with motor and sensor units integrated seamlessly exhibit effective adaptation to dynamically changing environments. Taking inspiration from coherent integration between skeletal muscles and sensory skins in human, we present a design strategy for soft robots, primarily consisting of an electronic skin (e-skin) and an artificial muscle, that naturally couples multifunctional sensing and on-demand actuation in a soft, biocompatible platform. here, we will describe an *in situ* solution-based method to create the e-skin layer with a series of sensing materials (e.g., silver nanowires, reduced graphene oxide, and poly(3,4-ethylenedioxythiophene) polystyrene sulfonate) incorporated within a polymer matrix (e.g., polyimide and polydimethylsiloxane), imitating human skin with complex receptors to perceive various stimuli. Biomimicry designs (e.g., starfish and chiral seedpods) of the soft robots enable various active motions (e.g., bending, expanding, and twisting) on demand and realize good fixation and stress-free contact with tissues. Furthermore, integration of a battery-free wireless module into these soft robots enables robotic operation and communication without tethering, thus enhancing safety and biocompatibility of the soft robots as minimally invasive implants. Demonstrated examples range from a robotic cuff enclosing around a blood vessel for precise detection of blood pressure, a robotic gripper holding onto a bladder for accurately tracking bladder volume, an ingestible robot residing inside stomach for pH sensing and on-site drug delivery, to a robotic patch wrapping onto a beating heart for quantifying cardiac contractility, temperature and applying cardiac pacing, highlighting the application versatilities and potentials of the bioinspired soft robots. Our designs of soft robots could establish a promising strategy to integrate a broad range of sensing and responsive materials, for forming highly integrated systems for medical technology and beyond.

4:15 PM SB11.03.03
Printable Liquid Metal Foams that Grow when Watered Febby Krisnadi[1], Seoyeon Kim[2], Sooik Im[1], Dennis Chacko[1], Man Hou Vong[1], Konrad Rykaczewski[3], Sungjune Park[2] and Michael Dickey[1]; [1]North Carolina State University, United States; [2]Jeonbuk National University, Korea (the Republic of); [3]Arizona State University, United States

Pastes and “foams” containing liquid metal as the continuous phase (LMFs) exhibit metallic properties while displaying paste or putty-like rheological behavior. These properties enable LMFs to be patterned into soft and stretchable electrical and thermal conductors through processes conducted at room temperature, such as printing. The simplest LMFs, featured in this work, are made by stirring liquid metal in air, thereby entraining oxide-lined air “pockets” into the liquid metal. Here, we report that mixing small amounts of water (as low as 1wt%) into such LMFs gives rise to significant foaming by harnessing known reactions that evolve hydrogen and produce oxides. The resulting structures can be ~4-5x their original volume and possess a fascinating combination of attributes: porosity, electrical conductivity, and responsiveness to environmental conditions. This expansion can be utilized for a type of 4D printing in which patterned conductors “grow”, fill cavities, and change shape and density with respect to time. Excessive exposure to water in the long term ultimately consumes the metal in the LMF. However, when exposure to water is controlled, the metallic properties of porous LMFs can be preserved. We characterize the physical changes of water-containing LMFs and explore prospective applications including a “growing” conductor that fills a gap in a circuit and an untethered pressure-driven actuator. We also demonstrate the printability of LMFs and present a printed pattern that changes shape over time.

4:30 PM *SB11.03.04
Fast and Autonomous Soft Robots enabled by Snap-Through Instabilities Shu Yang; University of Pennsylvania, United States

Soft robots offer a myriad of potentials due to their intrinsic compliance and adaptivity to unpredictable environments. However, most of them have limited actuation speeds and require complex control systems to maneuver various tasks. Inspired by the snap-through instabilities utilized by Venus flytrap to catch prey, the hummingbird’s beak to catch insects, and corkscrew-like stalk of Erodium seed, we combine materials intrinsic anisotropy and mechanical

metastructures to program the snapping behaviors, enabling several autonomous and unprecedented soft robotic functionalities. Specifically, I will discuss the design and performance of several examples of soft robots, including a centimeter-sized, sensor-less metacap gripper that can grasp objects in 3.75 ms upon physical contact or pneumatic actuation, lobed loops made from liquid crystal elastomer fibers capable of gait-like synchronization and directed locomotion, and laminated wood enabled seed carrier with helical tails capable of soil drilling with high success rate upon exposure to water.

SESSION SB11.04: Self-Healing Soft Robots
Session Chair: Minkyu Kim
Wednesday Morning, April 24, 2024
Room 430, Level 4, Summit

8:30 AM SB11.04.01
Self-Healing Semiconducting Polymers for Uses in Soft Robotics via Coordination Chemistry Yun Liu and Bob C. Schroeder; University College London, United Kingdom

Robots are increasingly assisting humans in performing various tasks. The requirement for safe physical human-robot interactions has led to the emergence of the field of soft robotics. Typically, soft robots consist of flexible and deformable materials such as elastomeric polymers, which have an inherent compliance comparable to biological tissues (10^5 to 10^9 Pa), greatly enhancing human interaction safety.[1, 2] Their intrinsic softness and compliance further endow them with features such as resilience to impacts and collisions due to shock absorbance, making soft robots an ideal candidate for handling delicate tasks in uncertain and unstructured environments.[3]
Despite the many advantages of soft materials, their usage in robotics does present challenges in terms of damage resistance. Synthetic soft polymers are highly susceptible to fatigue, overload and cuts, tears and perforation by sharp objects arising from uncontrolled working environments, which would induce irreversible damage to the material, massively reducing the functional performance of robots.[3] Inspired by a powerful feature of living organisms, an economic and ecological solution to this vulnerability is to construct future soft robotic systems out of self-healing semiconducting polymers, permitting the healing of microscopic and macroscopic damages as well as recovering material functionalities.
Various strategies have been applied to synthesise self-healable semiconducting polymers via non-covalent interactions such as hydrogen bonding, π-π stacking, host-guest interactions and ionic interactions.[5, 6] Multiple advantageous features are associated with metal-ligand complexes, in general, most coordination complexes can chelate spontaneously, resulting in easily processable materials.[7] However, achieving high mechanical strength within self-healing semiconducting polymers remains a crucial challenge. Due to the broad variety of possible metal and ligand combinations, the coordination bonds are highly tuneable, with accessible bond energies ranging from strong covalent to weak supramolecular forces such as van der Waals.[8] By tuning the coordination bond strengths, the presence of metal-ligand complexes in the polymer matrix could result in a synergistic effect on mechanical toughness and self-healing efficiency, offering new insights into the design of self-healing soft robotics.
Herein, we describe a new self-healing semiconducting polymer system based on metal-ligand coordination between transition metal ions (Cu^{2+}, Zn^{2+}) and bipyridine moieties incorporated in the cyclopentadithiophene-derived (CPDT) conjugated polymer backbone. Drastic changes to the polymer structure have been observed through spectroscopic measurements with varying ratios of bipyridine. Upon addition of the metal ions, a noticeable change in viscosity implied successful cross-links among polymer chains. Thermal analysis has revealed the stability temperature of the polymers to be as high as 400°C, giving the materials the potential to withstand extreme environments. In this presentation, we will discuss the self-healing and mechanical properties of the polymers from a coordination chemistry point of view, probing an understanding of the healing mechanism. Through the findings of our research, we hope that this creative combination of self-healing materials with robotics can present many opportunities for the future development of soft robotics.

Untethered, Autonomously Self-Healable, and Self-Powered Actively-Perceiving and Energy-Harvesting Triboelectric Skins and Their Applications in Soft Robotics Ying-Chih Lai; National Chung Hsing University, Taiwan

Soft robots with organism-like adaptive bodies have shown great potential in vast robot-human and robot-environment applications. Developing skin-like sensory devices (that are e-skins) enables them to naturally sense and interact with environment. It would be better if the capabilities to feel can be active like real skin. However, conventional e-skins are developed using passive sensing technologies, including resistive, capacitive, and optical types. Such passive sensors suffer from limited materials, poor scalability, complicated architectures, scant stretchability, large driving-voltage, and huge power dissipation in large-area uses. Those drawbacks greatly hinder the development of untethered and deformable robotic skins.
In this talk, we will present diversified cutting-edge self-powered triboelectric skins (tribo-skins) [1-6] with various fascinating attributes, including autonomous ability of self-healing (30 min, 100% efficiency at 900% strain) [3], omnidirectional stretchability (>900%) [1-4, 6], transparency (88.6%) [3], environmental-inert (−30 to 60 °C) [4, 6], and electromagnetic and biomechanical energy-harvesting ability [5]. The tribo-skins can actively sense proximity, contact, and pressure to external stimuli via self-generating electricity. The driving-energy comes from natural triboelectrification effect involving a cooperation of contact electrification and electrostatic induction. We will demonstrate the first actively perceivable and responsive soft robots using the untethered and ultra-stretchable tribo-skins.[1,2] The perfect integration of the tribo-skins and soft actuators enables soft robots to perform various actively sensing and interactive tasks including actively perceiving their muscle motions, working states, textile's dampness, and even subtle human physiological signals. The diversified self-powered tribo-skins with various desired attributes will be introduced. Last, we will demonstrate a transparent, self-healing, and self-powered perceiving soft robotic hand. These works will inspire lots of great ideas and show tremendous potentials of wearable/stretchable/deformable electronics, artificial e-skins, smart interfaces, and soft robots.

Autonomous Self-Aligned Multilayer Self-Healing Polymers and High Energy Density Artificial Muscle based on Periodic Non-Covalent Dynamic Polymer Networks Zhenan Bao; Stanford University, United States

Polymer networks formed through dynamic noncovalent or covalent bonds exhibit a range of interesting and tunable mechanical properties (e.g., tough, elastic, self-healable, stimuli-responsive, and reconfigurable). In nature, hierarchically ordered structures are formed through weak but cooperative interactions to perform precise functions. Learning from nature, we designed and investigated flexible polymer chains linked with periodically placed and directional dynamic bonds. Through understanding the structure property relationships, we discovered unique applications of designing such polymers for self-healing electronic materials, “morphing” electronics, artificial muscle and reconfigurable soft robots.

10:00 AM *SB11.05.01
Bioinspired Protein Materials for Self-Healing Robotics Abdon Pena-Francesch; University of Michigan, United States

Recent progress in soft robotics has motivated the search for new robotic materials and actuators that can replicate biological functions and behaviors (such as sensing, healing, power, etc.) with various degrees of autonomy and complexity. Proteins are uniquely well-positioned to bring new solutions to these challenges, as they offer high versatility, specificity, and control in their self-assembly to regulate their emergent structures and properties. In this talk, we will introduce cephalopod-inspired proteins with a segmented block design that self-assemble into β-sheet nanocrystalline structures. These β-sheet nanocrystals act as physical and reversible crosslinking structures in supramolecular protein networks that regulate the physical properties. We demonstrate the dynamic properties of squid-inspired polypeptides in self-healing protein networks with healing strength and kinetics surpassing those typically found in other natural and synthetic soft polymers. This family of cephalopod proteins and their biosynthetic derivatives have opened new opportunities in bioinspired design for adaptive functional materials and soft devices with enhanced autonomy and durability, and we will demonstrate their implementation in self-healing and reconfigurable soft actuators and in self-powered microrobots for aquatic locomotion.

10:30 AM SB11.05.02
Harnessing Protein-Based Motors and Liquid Crystal Networks for Bioinspired Locomotion Control of Small-Scale Soft Robots Chuqi Huang[1], Natalie Pinchin[2], Chia-Heng Lin[1], Hamed Shahsavan[2] and Abdon Pena-Francesch[1,1,1]; [1]University of Michigan–Ann Arbor, United States; [2]University of Waterloo, Canada

The miniaturization of untethered robots poses new challenges in powering, actuation, and control since traditional electro-mechanical mechanisms are not applicable due to their inherent size and weight limitations. While different strategies based on different stimuli have been developed, there is a rising need for new biocompatible methodologies to power and control small-scale robots. Inspired by the surface locomotion of aquatic insects, we propose the use of structural proteins as a porous matrix for the development of surface tension-propelled micromotors. These protein motors can change their nanostructure and nano-porosity to regulate the diffusion of chemical fuel and thus regulate the propulsion. We integrated these protein motors into photomechanical liquid crystal networks to provide steering control via bending and surface deformation, mimicking the posture change of swimming insects. We demonstrated diverse locomotion control and active direction transition in milli swimmers across length scales. This new strategy offers orthogonal power and control solutions for autonomous swimming soft robots.

10:45 AM SB11.05.03
Engineering Biomolecular Actuators from Calcium-Responsive Repeat Proteins Marina P. Chang, Alana P. Gudinas, Kenny M. Hernandez and Danielle J. Mai; Stanford University, United States

Protein-based hydrogels provide a platform for functional, biocompatible materials in soft robotics. Stimuli-responsive protein hydrogels can function as soft actuators by transforming environmental signals into mechanical motions without the need for an external power source. For soft robotics systems to interface or integrate with biological systems, they must respond to physiological stimuli. Calcium ions act as critical signaling molecules for a wide variety of biological functions, including muscle cell contraction, cell replication, and neurotransmitter release. Calcium-responsive actuators would enable broad biomedical applications, such as artificial muscles and implantable, responsive materials.

The diverse functionality of naturally occurring proteins offers bioinspiration to develop engineered proteins that respond to specific stimuli. Calcium responsiveness emerges in a class of “Repeats-in-Toxin” (RTX) protein domains that undergo reversible conformation changes from random coils to β-roll structures upon binding to calcium. We characterize the changes in the overall size and tertiary structure of RTX domains in the presence and absence of calcium using small angle x-ray scattering (SAXS). The addition of calcium results in a 70% decrease in volume of an RTX domain, representing a large contractile range. To harness this mechanical response, we genetically fused RTX domains between hydrogel-forming associative domains. The mechanical properties of the resulting hydrogels were characterized using shear rheology, which revealed calcium-dependent increases in hydrogel stiffness. By incorporating RTX domains in hydrogel systems, we demonstrate a tunable platform for calcium-responsive biomolecular actuators. RTX-based biomolecular actuators are poised to enable the development artificial muscles to aid in the repair or replacement of injured muscle.

11:00 AM *SB11.05.04
Overcoming Challenges in Processing Biobased Materials for Soft Robotics Blair K. Brettmann; Georgia Institute of Technology, United States

Electronic materials and robotic devices are pervasive throughout modern society and with increasing demand comes a growing interest in improving the sustainability of these products. One of the most promising methods to improve sustainability is to replace key components with biobased materials, which are derived from renewable biomass sources. However, these materials are often very challenging to process due to a large degree of heterogeneity, impurities from the feedstock, batch-to-batch variation, and abundance of functional groups with strong molecular interactions. This becomes even more important for applications such as soft robotics where small changes in microstructure can lead to large changes in performance. Applying systematic study of the formulation and the processing conditions in tandem, we can provide insights into how to overcome these unique challenges in biobased materials, working with materials from cellulose nanocrystals to sodium alginate to silk fibroin. Strong hydrogen bonding and the presence of charged functional groups leads to changes in rheology that require adjustments in processing parameters, while impurities from the biomass source lead to inconsistency in the materials and development of additional purification schemes to reduce variability in the output product and improve quality. Underlying the design of these soft materials from biobased sources is a strong link between the formulation and the process and only with this vision towards manufacturability can we realistically improve the sustainability of these complex products.

11:30 AM SB11.05.05
Biomimetic Nanostructures Incorporated with Synthetic Melanin for Advanced Soft Robot Materials Suyoung Lee, Damask Grinnell, Mark Van Dyke, Roberto Guzman and Minkyu Kim; The University of Arizona, United States

Soft robotics opens up new opportunities in a variety of fields, including biotechnology, agriculture, manufacturing, and defense, by replacing traditional rigid robots in complex scenarios. Soft robots are designed to imitate the flexibility and adaptability found in natural systems. Moreover, the materials employed in soft robotics typically require durability, with the necessity of biocompatibility, contingent upon the desired performance. Keratin, a fibrous protein comprising a major biomatrix in hair, skin, nails, wool, and feathers, can be an ideal candidate for soft robotics. The natural keratin-based materials offer biocompatibility and attractive mechanical properties, such as high tensile strength, hardness, toughness, and flexibility. However, materials developed from extracted keratin from natural sources often exhibit inferior mechanical properties compared to their natural counterparts, limiting their application in soft robotics.
In natural keratin-based biomatrix, melanin is commonly observed, and its catechol groups are known for their contributions to self-healing, enhanced mechanical properties, and chemical stability, in addition to their primary role as pigments. Polydopamine (PDA) has garnered attention as an artificial melanin due to its similar chemical structure and properties to its natural counterpart. The customizable design parameters of melanin-like PDA particles (MLPPs) make them even more intriguing than natural melanin. In this study, we introduced MLPPs into the keratin biomatrix to investigate the relationship between MLPP design parameters and the mechanical properties of the biomatrix. Specifically, we synthesized MLPPs using PDA alone or by coating PDA onto various particles and then incorporated these MLPPs into the keratin matrix. We correlated the mechanical properties of the biomatrix with PDA coating thickness, particle sizes, and concentrations of embedded MLPPs. We anticipate that the improved mechanical properties of keratin-based materials achieved through the integration of MLPPs, along with the multifunctional capabilities offered by diverse MLPPs, will not only render them suitable for soft robotics but also broaden their potential applications, including light harvesting, 4D printing, color-switching, and metal scavenging.

11:45 AM SB11.05.06
Phase Transition in Polymeric Systems for Biomimetic Materials Working with Water Kosuke Okeyoshi, Taisuke Hatta, Yuto Watanabe, Reina Hagiwara, Thi Kim Loc Nguyen and Leijie Wu; Japan Advanced Institute of Science and Technology, Japan

Inspired by history of natural environment and biomaterials, we are designing and fabricating functional soft materials through organizing polymeric materials [1-3]. To propose advanced energy converting systems, materials living with water are the target. From a viewpoint of biomimetics, the air-water interface is expected to play an important role in establishing a universal model of dissipative structures. Viscous fingering, as an example of nonlinear fluidic flow, is an unstable situation that is widely known as *tears of wine*. This has been explained through the Marangoni effect, coffee ring effect, Saffman-Taylor instability, etc. However, due to the transitional nature of these phenomena, there are few strategies for immobilizing such fluidically regulated interfaces. Recently, such phenomena have been applied successfully to an immobilized structure by controlling the evaporation of a mixture of biopolymer and water.
In this study, we present a brief discussion of nonequilibrium phenomenon, “meniscus splitting”. More precisely, an air-liquid interface is divided into multiple interfaces to partition a space. By using a mixture of polysaccharides and water, a macroscopic pattern following a specific rule could be confirmed. When the mixture is dried from a top open cell, the polymer forms deposits at specific positions to split the meniscus by bridging a millimeter-scale gap. Because water irreversibly evaporates from the liquid phase to the air phase through a gap, the air-liquid interface is in a nonequilibrium state between polymer deposition and water evaporation. The interfacial instability is comparable to the mechanical instability of gels at the phase transition or to the skin layer of gel surfaces during shrinking. Furthermore, by controlling the deposition, the polymeric self-assembly could acts as vapor-sensitive materials or super moisturizing materials [1-2]. Here, the phenomenon and the material’s behaviour would be discussed from physicochemical viewpoints.

3:30 PM *SB11.06.01
Charge and Energy Transfer Dynamics in Organic Solar Cells Using Extracts of Algae Mmantsae M. Diale; University of Pretoria, South Africa

The relationship between photosynthesis and photovoltaics is often viewed from different positions by researchers, whilst in fact, these two are related. Photovoltaics is a direct copy of photosynthesis, where the green leaf is the oldest solar cell with almost 100% photo conversion efficiency. The mechanism of solar energy conversion in photosynthesis is sustainable and environmentally safe, has a great potential as an example of renewable energy device. The efforts to collect all photons in the visible light has been unsuccessful due to bandgap limitations of inorganic materials. Recent advances in the design of optimal organic solar cells include the creation of converters in which thylakoid membranes, photosystems and cyanobacteria immobilized on nanostructured electrodes are used. Application of carotenoids and thylakoids pigments has extended light absorption from ultraviolet to infra-red photons,

an effort to improve solar cell performance and photo conversion efficiency. This presentation aims review charge and energy transfer dynamics in organic solar cells to produce maximum efficiency using algae-related matter.

4:00 PM SB11.06.02
Microstructures of Anisotropic pH-Responsive Chitosan Hydrogels prepared by Meniscus Splitting Method Thi Kim Loc Nguyen and Kosuke Okeyoshi; School of Materials Science, Japan Advanced Institute of Science and Technology, Japan

Polysaccharides have been expected to be a useful material in wide fields of food packaging, drug delivery, cosmetics, etc., toward a sustainable society. In addition, numerous natural polymers, like chitosan and cellulose, have also demonstrated pH-responsive swelling behavior. However, the hierarchical structures have not been used for materials under physiological conditions. In this study, to reorganize the polymeric systems, aqueous mixtures of chitosan as viscous fluid are used through the meniscus splitting method, for preparation of a chitosan membrane. To understand the factors on the specific deposition in the meniscus splitting, the nucleus position is analyzed thoroughly verifying the effect of the cell width. Furthermore, the dried chitosan membrane shows anisotropic pH-responses as a hydrogel because of the oriented structures in submicron scale.
To clarify the characteristic anisotropy in ion- or pH-sensitive hydrogels, the pH-dependence of three-dimensional swelling ratios and the cyclic pH-changes were validated. Especially, the dried membrane was directly immersed into each buffered solution in a wide range of pH (pH2.2–pH8.0). Under the acidic conditions, the protonation allowed the water molecules to penetrate the interspace not only among the fibers but also among the chains in fibers. As a result, some of the crosslinking points by the hydrogen bond should be dissolved. Besides, toward the use of the membrane in the physiological pH condition, like pH7.4, the repeatability of swelling/deswelling as the hydrogel was validated. In the pH cyclic changes between pH8.0 and pH2.2, the gels showed no reversibility. Through a repeat test of stepwise pH-changes between pH8.0 and pH2.2, it was clarified that the sample continued swelling and redispersed into the aqueous solution, suggesting that the chitosan chain had irreversibly dissolved crosslinking points. In the pH2.2, the protonation of the chitosan chain would induce the dissolution of the hydrogen bonds between the hydroxyl groups and exchange of the citric acid. Interestingly, in the cyclic pH changes between pH8.0 and pH5.0, the chitosan gels had reversibility both in the *Y*- and the *Z*-directions. This result suggests that the water molecules can go in and out of the interval of the oriented structure without dissolution of the crosslinking points. The membrane would have a hierarchical architecture: nanofiber as a molecular bundle, and microfibers as a nanofiber bundle. In the presentation, to clarify the nano-/micro anisotropic structure in DRY/WET states, the surface and cross-section positions of the chitosan membrane will be discussed.

4:15 PM SB11.06.03
Soft Robots Meet Bioelectronic Interfaces: A Promising Use-Case of Bio-Based and Biomimetic Polymers for Minimally Invasive Implantable Devices Sukho Song[1,2], Florian Fallegger[1], Alix Trouillet[1], Kyungjin Kim[1,3] and Stephanie P. Lacour[1]; [1]École Polytechnique Fédérale de Lausanne, Switzerland; [2]Empa Swiss Federal Laboratories for Materials Science and Technology, Switzerland; [3]University of Connecticut, United States

This presentation shares an emerging research field of minimally invasive implantable devices that utilize soft robotics, which offers promising applications for bio-based and biomimetic polymers. The talk first highlights a recent work published in Science Robotics (*1*) concerning the development of deployable electrocorticography (ECoG) electrode arrays enabled by soft robotic sensing and actuation. ECoG is a minimally invasive method commonly used to map epileptogenic regions of the brain. It aids in lesion resection surgery and is increasingly explored in brain-machine interface applications. However, current devices present limitations, leading to trade-offs in cortical surface coverage, spatial electrode resolution, aesthetics, and risk factors. These limitations often restrict the use of the mapping technology to the operating room.

The presented work introduces a scalable technique for fabricating large-area soft robotic electrode arrays. These arrays can be deployed on the cortex through a square-centimeter craniotomy using a pressure-driven actuation termed "eversion". The design of these eversion-based electrode arrays is akin to a rubber glove with finger-shaped air pockets. To prepare for deployment, this glove is inverted and folded within a cylindrical loader. During deployment, liquid is introduced into each "finger," enabling the array to revert and expand over the brain. Each section incorporates soft, microfabricated electrodes and strain sensors for real-time deployment monitoring. In a proof-of-concept acute surgery, the soft robotic electrode array was successfully deployed on a minipig's cortex to record sensory cortical activity without causing significant morphological damage.

The talk will also discuss insights into the future prospects of soft robotic implant technologies, which hold potential for multifunctional chronic health monitoring and treatment. Beyond the everting actuation mentioned, there are opportunities to explore various soft robotic actuation to adapt to the geometries and movements of specific target organs, such as bending, unfurling, coiling, and undulating. Additionally, there are promising applications for these robotic implants to deploy a diverse range of sensing or stimulating components. Examples include strain sensors for cardiac activity monitoring, microfluidic systems for drug delivery, and optical elements for optogenetic stimulation. Bio-based and tissue-mimetic soft polymers are especially significant, ensuring the implants' long-term biocompatibility and reliability. While the deployable ECoG arrays mentioned above utilized a soft polydimethylsiloxane (PDMS) matrix—comparable in mechanical properties to the brain's dura mater—employing even softer and more flexible polymers like hydrogels can decrease mechanical irritation on tissues, thus minimizing immune responses. Furthermore, antifouling materials like zwitterionic polymers can inhibit protein adhesion on the implant surface, a key factor in mediating immune responses. The integration of soft robotic implants with bio-based and bio-mimetic materials can open high-impact avenues in active implantable device technologies, enabling minimally invasive, chronic health monitoring and therapeutic applications previously deemed impossible.

4:30 PM *SB11.06.04
Bioderived and Biodegradable Materials for Sustainable Soft Robotics Martin Kaltenbrunner; Johannes Kepler University, Austria

Soft robotics provides unique opportunities in our quest for a more sustainable future. Among the key issues to overcome are the search for high performance green materials, end-of-lifetime considerations in complex (soft) systems, and their energy efficiency. This talk aims at suggesting solutions for some of these grand challenges. We introduce bioderived materials and fabrication methods for soft robots that biodegrade, yet are of high resilience. Based on highly stretchable biogels and degradable elastomers, our soft robots are designed for prolonged operation in ambient conditions without fatigue, but fully degrade after use through biological triggers. Electronic skins provide sensory feedback, while stretchable and biodegradable batteries enable autonomous operation. 3D printing of biodegradable hydrogels enables omnidirectional soft robots with multifaceted optical sensing abilities. Going beyond, we introduce a systematically-determined compatible materials systems for the creation of fully biodegradable, high-performance electrohydraulic soft actuators. These embodiments reliably operate up to high electric fields, show performance comparable to non-biodegradable counterparts, and survive over 100,000 actuation cycles. We elucidate their fundamental operating principles and provide materials combinations that enable power-efficient electrohydraulic actuators void of detrimental interfacial charging. Finally, concepts for energy-autonomous soft aquatic robots and aerial drones are introduced.

SESSION SB11.07: Poster Session
Session Chairs: Minkyu Kim and Danielle Mai
Wednesday Afternoon, April 24, 2024
Flex Hall C, Level 2, Summit

5:00 PM SB11.07.01
Biomimmetic Phenolic Hydrogels Faisal Ali and Kwang Su Seo; Chemence, United States

Hydrogels with versatile properties have undergone extensive research for applications in surgical adhesives, soft robotics, and wearable device development. These materials must be biocompatible, non-toxic, and have minimal foreign body reactions. However, several challenges such as poor adhesion, excessive swelling, undesirable degradation rate, and extensive preparation before application persist.

PEG (polyethylene glycol)- based hydrogels stand out as promising candidates for these applications. Nevertheless, many commercially available PEG-based adhesives or gels demand extensive on-site preparation and special storage conditions prior to use. The adhesion is often inadequate, and swelling rate cannot be controlled.

To that effect, here we report a non-toxic biomimetic hydrogel based on PEG polymer chains functionalized with phenolic functional groups (Gallol and Catechol) developed for robust adhesion and with customizable properties (for example, modulus, degradation and swelling rate). Our two-part device simplifies on-site preparation prior to administration, making it also suitable for use as a surgical adhesive. The hydrogel network consists of 4-arm PEG chains grafted with either catechol or gallol units, crosslinked using Ferric ions or sodium periodate as agents. Other polymer backbones like Polyethyleneimine (PEI) have also been investigated. The concentration of crosslinking agents with respect to that of phenolic groups' dictate the dominant mode of interaction, either coordination or covalent crosslinking. Furthermore, the overall self-healing ability, adhesive strength, and cohesive strength are tunable by the crosslinker's concentration relative to the PEG chains. Likewise, various findings have suggested that incorporating nanocomposite clay into the network can enhance the gel's cohesive strength.

In a comparative adhesion study, our optimal formulations, when tested alongside commercial PEG based adhesives on leather, exhibited shear strength of up to 253kPa, which was almost 12 times higher than Coseal™s shear strength of 22kPa after two hours of application. No delamination from the substrates (e.g., pig skin, leather, or collagen) was observed.

5:00 PM SB11.07.02
Wirelessly Actuated Soft Miniature Robots with Integrated Microfluidic Modules for Targeted Drug Delivery Emily Buckner[1,1,2], Boyang Xiao[1,1,1], Yilan Xu[1,1,1] and Xiaoguang Dong[1,1,1]; [1]Vanderbilt University, United States; [2]The University of Tennessee, Knoxville, United States

The inherent softness of soft robots offers unique advantages in medical applications where safe interaction with surrounding biological tissues is crucial. Soft robots made of smart soft materials allow for programmable functionalities by spatially patterning material properties. More recently, magnetic actuation has gained significant attention due to its ability to wirelessly control soft robots for medical operations. Despite recent advances, the development of wireless soft robots for minimally invasive medical procedures that can traverse complex terrains remains challenging. In this study, we propose an untethered soft robot actuated by magnetic fields and integrated with microfluidic channels to achieve on-demand and targeted drug delivery in complex, confined environments within the body, such as the gastrointestinal (GI) tract. The robot, constructed at the millimeter scale through laser lamination and layer-by-layer assembly, boasts optimized material properties and dimensions to facilitate multi-modal locomotion and targeted drug delivery functions. By employing a tailored magnetization profile design, the robot exhibits various modes of locomotion, including crawling and climbing. Furthermore, the integration of microfluidic channels into the robot body, along with an origami-inspired self-folding pump and flexible valve, enables precise control of drug delivery. To actuate the robot's movement, we have designed a customized electromagnet array that accurately directs and regulates the magnitude of the applied magnetic field. Finally, we experimentally validated the robot's locomotion and drug delivery capabilities in phantom structures. This novel soft robot design holds great potential to navigate complex terrains and serve therapeutic functions in biomedicine as well as on-demand and targeted drug delivery, minimizing the side effects of overdosing during medical treatments.

5:00 PM SB11.07.03
Silica Percolated Ionic Dielectric Elastomer with High Electromechanical Energy for Soft Robotic Application Hanbin Choi[1], Yongchan Kim[2], Seonho Kim[3], So Young Kim[1], Joo Sung Kim[4], Eseudeo Yun[2], Hyukmin Kweon[1], Minjeong Kim[1], Vipin Amoli[5], U Hyeok Choi[3], Hojin Lee[2] and Do Hwan Kim[1]; [1]Hanyang University, Korea (the Republic of); [2]Soongsil University, Korea (the Republic of); [3]Inha University, Korea (the Republic of); [4]RIKEN, Japan; [5]Rajiv Gandhi Institute of Petroleum Technology, India

Efforts to introduce soft actuators based on ionic electroactive polymer (i-EAP) in futuristic soft robotic systems are steadily underway. The i-EAPs offer many advantages for improving the performance of soft actuators through lightweight, flexibility, a straightforward manufacturing process, and low power consumption. Despite these advantages of i-EAPs, there are some limitations to their use in various soft robotic applications. Among them, a critical limitation is that i-EAP based actuators have low actuation force due to the flexibility of the material. To overcome this limitation, many studies have been attempted to improve the mechanical modulus of i-EAPs. However, improved modulus of materials reduces the flexibility, which inevitably decreases actuation strain. Therefore, these endeavors have delayed their implementation into soft robots due to the conflicting relationships between force and strain of i-EAP actuators.
In this study, we introduced an innovative approach to overcome the trade-off relationship between force and displacement in soft actuators based on ionic electroactive polymers (i-EAP). We present a novel material referred to as an ions-silica percolated ionic dielectric elastomer (i-SPIDER), which exhibits ionic liquid-confined silica microstructures that effectively resolve the chronic issue of conventional i-EAP actuators. Furthermore, by incorporating resistive polymers (PEDOT:PSS) and using ionic liquids and DMSO as additives, we could control the interface between ionic polymers and electrodes. The i-SPIDER is combined with ionic liquid-confined silica microstructures, thus enhancing electromechanical conversion capabilities at low voltage, thanks to improved ion accumulation facilitated by interpreting electrode polarization at the electrolyte-electrode interface. Through these characteristics, we successfully demonstrated that i-SPIDER containing IL-confined silica microstructures shows simultaneous improvement in both force and strain of electrically driven soft actuators by overcoming the chronic conflicting inverse relationship between them. As a result, ion accumulation was improved on the i-SPIDER -electrode interface, achieving a unique combination of high strain (by approximately 1.52%) and force (by roughly 1.06 mN) even at low Young's modulus (merely 5.9 MPa) based on high electromechanical energy density at a low voltage (2 V) compared to conventional i-EAP soft actuators.

Additionally, by demonstrating arachnid-inspired soft robots endowed with user-desired tasks through control of various form factors, we have demonstrated the potential for i-SPIDER-based soft robots to concomitantly enhance strain and force, ushering in the next generation of miniaturized, low-powered, low-voltage soft robotics.

5:00 PM SB11.07.04
Flexible Bacterial Cellulose Substrates Coated with Chlorophyll Dye for Photoelectrochemical Water-Splitting Nteseng D. Mosalakgotla and Mmantsae M. Diale; University of Pretoria, South Africa

In this study, flexible silver nanowire bacterial cellulose membranes have been fabricated to serve as conducting substrates for a chlorophyll dye. The structural properties and crystallinity of the prepared thin films were examined using X-ray diffraction (XRD). The surface morphology of the prepared thin films was investigated using the Field Emission Scanning Electron Microscope (FE-SEM). Ultraviolet–visible spectroscopy (UV-Vis) was used to study the photoabsorbance of the films and the existence of chlorophyll was confirmed using Fourier Transform Infrared Spectroscopy (FTIR). Lastly the thin films were used as photoelectrodes in a three-electrode electrochemical system to study their PEC properties. The obtained photocurrent response of the films is attributed to the strong photoabsorbance of the chlorophyll, and low resistance of the transfer of charge carriers at the solid/liquid interface of the films. This study promotes the use of cellulose based membranes as low-cost, lightweight, and durable substrates for PEC applications. Furthermore, it demonstrates the promise of incorporating organic materials on PEC systems to enhance the production of hydrogen.

Stimuli-Responsive, Morphing Liquid Crystal Elastomer Structures for Intelligent Systems Xueju (Sophie) Wang; University of Connecticut, United States

Intelligent systems with capabilities of sensing, actuation, and closed-loop control are promising for many applications such as augmented reality, rehabilitation, and soft robotics. In this talk, I will present our work on stimuli-responsive materials, structures, and electronics toward this effort. I will start with our study on liquid crystal elastomers (LCEs), a type of smart material that has capabilities of soft elasticity and large, reversible shape-changing behaviors due to liquid crystal-polymer network couplings. Through introducing a versatile mechanical programming technique, previously inaccessible reconfigurable three-dimensional structures made of LCEs and their magnetic composites are created and their potential applications in soft robotics are demonstrated. I will further present our facile strategy to locally tailor the stiffness and the morphing behavior of these reconfigurable LCE structures by harnessing molecular-material-structure interactions, i.e., locally controlled mesogen alignment and crosslinking densities. Selective photopolymerization of spatially aligned LCE structures yields well-controlled lightly and highly crosslinked domains of distinct stiffness and selective permanent mesogen programming, which enables various previously inaccessible stiffness-heterogeneous geometries, as demonstrated in diverse morphing LCE structures via integrated experimental and finite element analysis. Furthermore, reprogramming of the non-photopolymerized regions allows for reshaping, as shown in a sequentially shape morphing LCE rod and “face”. The heterogenous morphing LCE structures have the potential for many applications including in artificial muscles, soft robotics, and many others. In addition, a simple strategy for creating 3D thermochromic LCE structures with synchronous shape-morphing and color-changing capabilities for biomimetic robotics will also be introduced. I will conclude my talk with soft sensing devices for in situ pressure measurements, beyond the actuation capabilities enabled by LCEs. The introduced actuation and sensing strategies and concepts are promising for many intelligent platforms.

Design Optimization of The Directly 3D-Printed Jamming Structure Using Machine Learning Models Yuna Yoo, Zeqing Jin and Grace Gu; University of California, Berkeley, United States

Modifying the stiffness of soft robots presents a significant challenge, with the goal of enabling free deformations at low stiffness, while increasing the robustness of grasping at high stiffness values. Among the promising approaches, the utilization of jamming structure stands out for its ability to achieve high stiffness modification with minimal volume variation. However, most of the jamming structures require a complicated fabrication process, which limits the prototyping speed, repeatability, and reliability. To address this issue, attempts have been made to directly 3D-print jamming structures; however, these attempts were limited to 3D-printing the standardized jamming structures and the optimized designs relied on heuristic searches based on trial-and-error experiments. In this study, we introduce a directly 3D-printed jamming structure with optimized design through machine learning. The stiffness of the generated jamming structure design is estimated by finite-element-based simulations and the design is optimized using machine learning models. To validate the optimization results, benchmark designs and the optimized design are fabricated and the stiffness of the designs are compared. Finally, the feasibility of the optimized 3D-printed jamming structure is verified by grasping demonstrations, including its implementation into a pneumatically actuated soft gripper.

A Self-Healing Electrically Conductive Organogel Composite Yongyi Zhao[1,2] and Carmel Majidi[1]; [1]Carnegie Mellon University, United States; [2]Massachusetts Institute of Technology, United States

Self-healing hydrogels use spontaneous intermolecular forces to recover from physical damage caused by extreme strain, pressure or tearing. Such materials are of potential use in soft robotics and tissue engineering, but they have relatively low electrical conductivity, which limits their application in stretchable and mechanically robust circuits. Here we report an organogel composite that is based on poly(vinyl alcohol)–sodium borate and has high electrical conductivity (7×10^4 S m^{-1}), low stiffness (Young’s modulus of ~20 kPa), high stretchability (strain limit of >400%) and spontaneous mechanical and electrical self-healing. The organogel matrix is embedded with silver microflakes and gallium-based liquid metal microdroplets, which form a percolating network, leading to high electrical conductivity in the material. We also overcome the rapid drying problem of the hydrogel material system by replacing water with an organic solvent (ethylene glycol), which avoids dehydration and property changes for over 24 h in an ambient environment. We illustrate the capabilities of the self-healing organogel composite by using it in a soft robot, a soft circuit and a reconfigurable bioelectrode.

5:00 PM SB11.07.08
Fabrication of Reentrant Micromesh Suspended by Shape Memory Polymer for Liquid-Repellency Ga-in Lee, Moon Kyu Kwak, Minsu Kim, Han Jun Park and Dokyung Kyeong; Kyungpook National University, Korea (the Republic of)

Omniphobic surfaces, which are referred as having both hydrophobic and oleophobic behaviors under environments involving interaction with liquids, have been vigorously studied due to its robust liquid-repellency. By its non-wetting properties, the liquid-repellent surfaces have potential to be utilized in various applications such as self-cleaning, oil/water separation, droplet manipulation, and antifouling. Accordingly, scientists are developing the liquid-repellent surface by forming microscale structures with a specific functional morphology. Among the representations of the morphology, reentrant topography inspired by springtail in nature have enormous influences on microstructure engineering fields for its exceptional wetting resistance even under

liquids with low surface tension than water. Reentrant structures show an overhanging profile, by which a surface can uphold liquids so as to have liquid-repellency. Surface engineers have been consistently trying to imitate the reentrant topography by 3D printing, capillary interaction, self-assembly, photolithography, and imprint lithography ever since the studies of omniphobic surfaces have manifested. Among the aforementioned methods, imprint lithography by the UV light is one of the most commonly employed techniques due to its ability to achieve micro/nanoscale resolution affordably and rapidly. However, imprinting has limited feasibility in complex topography due to the difficulties in demolding process, for which 3-D structures with a semi-freestanding feature that below the surface is excavated and penetrated can be hard to be achieved. This shortcoming limits the practical realization of functional structures present in nature such as springtails, gecko, and so forth. Shape memory polymer (SMP) is a switchable material that has double states which are defined as a permanent shape and a temporary shape. Through manipulation of the shape under external stimuli such as heat or light, the temporary shape can be newly formed and fixed. Then SMP switches back to the permanent shape if triggered again by a stimulus. Recently, scientists have been utilizing SMP's unique property in developing functional surfaces including wetting controllable structures, diffractive optical elements, and dry adhesive surfaces. Herein, we fabricated suspended micromesh structures along with three different periods of the meshes. The meshes were imprinted on temporary-shaped flattened SMP and recovered to its permanent pillar shape when heat was applied above the glass transition temperature. Accordingly, the meshes were suspended as SMP recovered to its initial pillar shape and reentrant topography was formed consequently. In comparison with simple meshes, suspended micromeshes can realize the Cassie-Baxter state even with a liquid that has the intrinsic contact angle under 90 degrees by the geometry of the reentrant structure. Also, the apparent contact angle of suspended micromeshes increased compared to the simple meshes because of the created air fraction of the surfaces. Considering the reentrant geometry, we calculated the breakthrough pressure of suspended micromeshes based on the Laplace pressure and compared its values to the measured breakthrough pressure. In addition, drag reducing effect of suspended micromeshes were also evaluated to prove its robustness in liquid-repellency. In this work, we proposed a new method to fabricate the reentrant topography with the meshes by a combination of imprint lithography and SMP's own property. Wettability and hydrostatic robustness of fabricated suspended micromeshes were investigated via measurements of the contact angle, and breakthrough pressure, by which it is demonstrated that the reentrant topography was successfully established based on the comparison between the calculated values and the measured values. In addition, slip lengths were measured to further present the liquid-repellency of the structures owing to its created air layers.

5:00 PM SB11.07.09
Multifunctional Droplet Manipulation of Heterogeneous Structures using Magnetic Responsive Shape Memory Ridge Arrays and Superhydrophobic Silicon Thin Film Seungbeom Kim, Sangyeop Lee, Junhyung Kim, Uhyeon Kim and Seok Kim; Pohang University of Science and Technology, Korea (the Republic of)

The manipulation of droplets finds applications across diverse fields such as materials synthesis, healthcare, and chemistry. Traditional methods for droplet manipulation involve techniques such as electrowetting and fluidic-based platforms. In this study, we propose a novel approach to induce multifunctional droplet manipulation by utilizing nanostructured superhydrophobic silicon thin films integrated on magnetic particle-embedded SMP (Shape Memory Polymer) ridge arrays. Our approach capitalizes on the inherent Laplace pressure gradient resulting from the interaction between a created heterogeneous structure's ratchet surface and the droplet, overcoming challenges like biofouling associated with externally applied forces. The incorporation of SMP introduces elastic properties, while the silicon thin film contributes superhydrophobicity, optimizing both mechanical characteristics and hydrophobicity of overall platform.

Our choice of SMP is deliberate, as it allows for diverse functionalities through controlled magnetic torque. Unlike traditional magnetic responsive polymers, we employ SMP to perform various functions with partial heating and cooling of the platform. The heterogeneous structure comprising SMP exhibits shape fixing without the need for continuous external stimuli, enhancing energy efficiency.

We believe that this heterogeneous structure, exploiting Laplace pressure gradient, holds promise for applications beyond our study, extending to fields such as digital microfluidics, potentially impacting technologies like lab-on-a-chip devices. The unique combination of SMP and superhydrophobic silicon thin film offers a versatile and energy-efficient platform for advanced droplet manipulation.

5:00 PM SB11.07.10
Universal Anipulation of Macro-To-Microobjects by Controlling Adhesion of Nanotip Shape Memory Polymer Surface Junhyung Kim, Sangyeop Lee, Seungbeom Kim, Uhyeon Kim and Seok Kim; Pohang University of Science and Technology, Korea (the Republic of)

Shape memory polymer (SMP) possesses the capability to undergo dynamic variations in stiffness when subjected to external stimuli such as heat or light. It exhibits the unique ability to be shape-fixed into desired shapes and can revert to its original from through the shape memory effect. Exploiting these attributes, SMP serves as smart adhesives in applications like soft grippers and transfer printing, providing a solution to challenges posed by the adhesion paradox, a feature distinct from traditional elastomer adhesives.
Here, we report a nanotip SMP surface with extreme reversible adhesion, demonstrating its adeptness in manipulating objects across a spectrum ranging from macro-scale (≥10cm) to micro-scale (≥5μm). This innovative approach leverages the distinctive features of SMP to effectively resolve challenges related to the adhesion paradox, while also capitalizing on the adhesion paradox through a return to the original rough surface, thereby achieving excellent reversible adhesion. The nanotip SMP surface, characterized by an RMS roughness (R_q) exceeding 100nm, mitigates surface adhesion to zero through its rough topography. In its rubbery state, this surface allows for conformal contact with the object by reducing roughness, while transitioning to a glassy state results in increased adhesion due to shape-locking effect. Then, to release the object, the SMP surface is reverted to its original nanotip surface through the shape memory effect, inducing a return to a rough state and enabling easy release.
This mechanism underscores the achievement of great adhesion reversibility across varying scales, marking the capability of programmable and precise large-scale transfer printing at the 5μm level chips. The applications of this approach, such as micro LED transfer and repair are showcased, suggesting its potential as a next-generation display solution with enhanced yield and precision.

5:00 PM SB11.07.11
Layer Jamming Enhanced by Micro-Structured Biomimetic Adhesive Sheets for Soft Robotics Applications Shima Jalali, Hyun J. Chung and Dan Sameoto; University of Alberta, Canada

Layer jamming, in which the shape and the stiffness of a micro-structured sheets is modulated by regulating the friction force between layers, is a promising technology in the field of stiffness-tunable soft robotics. Biomimetic dry adhesive technologies utilizing the distinctive microstructures found on a gecko's foot, have been applied in applications ranging from climbing robots, pick and place assembly, skin-adhesives, and microfluidics. The biomimetic dry adhesive technology can be utilized to augment the friction force that induces layer jamming in reversible manner without the need of vacuum.
In this project, we create dry adhesive sheets employing Kraton G1645 - a styrene-ethylene-butylene-styrene (SEBS) thermoplastic elastomer. G1645 is used as the primary structural material and then modified by blending different weight percentages of polypropylene (PP) which is miscible and lower cost than SEBS. The blend is then used for micro-molding using a modified recipe of our previously reported compression molding processes.

The Setex gecko adhesive materials (DA910B) has proven to be a promising candidate for jamming applications, demonstrating favorable results as a layer jamming actuator in prior studies. While the material composition remains proprietary, it seems to be a relatively viscoelastic cured polyurethane. Our objective is to transition from the proprietary Setex adhesive to a more cost-effective and customizable alternative by employing a blend of SEBS (a recyclable, easy process and low-cost thermoplastic elastomer) and PP. Despite SEBS exhibiting commendable dry adhesive properties and strength on smooth surfaces which makes it an excellent reversible adhesive, challenges arise due to its low melt flow index, hindering the production of ultra-thin sheets through micro-molding techniques. Furthermore, its strength may not be sufficient to endure numerous cycles of attachment and detachment, as it is prone to mechanical tearing in low thickness and deformation of micro features under shear stress during detachment processes. Polypropylene (PP) as a cost-effective thermoplastic offers chemical compatibility for blending, and may increase the mechanical stability of individual fibers, allowing taller fibers to space out jammed layers which should in theory increase the effectiveness of the sheets at stiffness switching. Previous reports have also used PP microfibers for self-cleaning and directional adhesion properties which inspires the idea of using it in a blend with SEBS to improve mechanical properties and preserve adhesion ability of SEBS simultaneously.
The manufacturing process of gecko adhesive layers with a mushroom-shaped microstructure (the same structure as the Setex commercial type) involves the hot embossing technique using negative PDMS molds replicated from Setex masters. The SEBS/PP blends are produced using a single-screw extruder and then, using a hydraulic hot press, compressed into thin sheets with approximately 60µm thickness. The SEBS/PP blends are compared to pure SEBS using microscale tests based on JKR models to measure the adhesion properties of the samples. Additionally, mechanical tests are conducted to provide a complete comparison with commercial samples and to identify the optimum composition of SEBS/PP for maximum repeatability and longevity of the adhesive layers. The experimental results demonstrate good compatibility between SEBS and PP and the adhesive layers can be thermally bonded to thin PP films to complete a jamming actuator. These research results hold promising implications for the large-scale production of low-cost materials suitable for various applications, especially as stiffness tunable actuator in soft robotics.

SESSION SB11.08: Sensing, Actuation and Reconfiguration in Soft Robots
Session Chairs: Qing Chen, Stephan Roth, Newayemedhin Tegegne and Jie Xu

The Hole Dynamic in PEDOT:PSS/Bacterial Cellulose Actuators Sukesh Kumar[1,2], Aimin Yu[2] and Mudrika Khandelwal[1]; [1]Indian Institute of Technology Hyderabad, India; [2]Swinburne University of Technology, Australia

Actuators are one among numerous applications that have emerged from the utilization of conducting polymers. This class of material has attracted wide interest in the field of electronics, because they conduct both electronic and ionic charges through the bulk of their volume. This makes possible the application of electronic devices as electrochemical devices, which are termed as organic electrochemical transistor (OECT).
Despite the extensive use as OECTs, there are still numerous discrepancies in the descriptions of the fundamental physics underlying the performance of these devices. Therefore, there is a growing emphasis on modeling the ion-electron interaction within conducting polymers. Recent publications have contributed fresh insights into the conduction mechanisms. However, the actuator community has yet to fully integrate these newfound understandings into their efforts to comprehend and model the mechanical response of conducting polymer actuators. Existing models for these actuators have primarily focused on ionic diffusion, which falls short of explaining all the existing experimental observations.

This study draws from three distinct bodies of literature, comprising the most pertinent existing model for conducting polymer actuators, advancements in the comprehension of ionic-electronic conduction in conducting polymers, and empirical observations that defy current models for conducting polymer actuators. Also, Electrochemical Impedance Spectroscopy (EIS) is used extensively to understand the actuation mechanism under dynamic conditions, considering the progress made in comprehending the physics of conducting polymers as previously mentioned.

The conducting polymer actuator is prepared using PEDOT:PSS and bacterial cellulose (BC) (as a substrate), which is operated in both depletion mode and enhancement mode, for different time scales. The doping (compensation) and dedoping (displacing) in PEDOT:PSS (using an electrolyte) results in displacement of the PEDOT:PSS/BC bi-layer. Notably, the actuator displacement is found to be asymmetric, contingent on the polarity, magnitude, and frequency/time period of the applied potential. The observed asymmetry in displacement as a function of these parameters remains unaccounted for by existing models for conducting polymer actuators.

Experimental Process
Electrochemical Impedance Spectroscopy (EIS) is performed on a PEDOT:PSS/Bacterial cellulose bi-layer actuator, while the actuator is subjected to various electrostatic potential. The displacements of the actuator under these potentials are also recorded for different time periods. The EIS data is used to model electrical circuit for actuators under given potentials. Mott-Schottky analysis is performed to understand the energy band structure of the actuator-electrolyte system. Density Functional Theory simulations are performed to aid the conclusions derived from experimental data.

Significance
The results and discussion which follows in this paper is significant in deriving an updated model for conducting polymer actuators, delving into quantum capacitance effects given the low charge density in conducting polymer, which is essential for reliable device performance and in defining the operating ranges for such actuators. This study becomes significantly important in the background of the development happening in the field of OECT, as it brings in the mechanical deformation corresponding to those findings.

9:00 AM SB11.08.02
Fabrication of Responsive 4D Micro-Structures for Dynamic Structural Color and Optical Sensing Teodora Faraone[1], Jing Qian[2], Louise Bradley[2], Larisa Florea[1,3] and Colm B. Delaney[1,3]; [1]Trinity College Dublin, Ireland; [2]Trinity College Dublin, The University of Dublin, Ireland; [3]Centre for Advanced Materials and BioEngineering Research, Ireland

Self-assembly of colloidal particles into crystalline colloidal arrays have attracted great interest from chemists, physicists and materials scientists alike due to their broad applications in the fields of optics and photonics[1]. In particular, application of colloidal crystal arrays offers a means for controlling and manipulating light flow, and gives rise to some of the most brilliant structural colors. This phenomenon is also present in nature, where many species of birds, insects, butterflies, fish and even flowers, owe their vivid color to hierarchical assemblies of photonic structures.

Changing the structural color of photonic crystalline structures typically requires the synthesis of different size particles, in order to modulate inter-particle distance[2]. This can add different degrees of difficulty as precise control of particle size and inter-particle distance in the self-assembly process can be time-consuming. In this work, we prove how using just one size polymer particle spheres, a wide gamut of reflected colours can be obtained in a range of different polymer matrices.

Using direct laser writing (DLW) in nanocomposite photoresists (at particle concentrations conducive to self-assembly), we can fabricate complex 3D microstructures with sub-micron feature sizes. Furthermore the DLW fabrication technique allows for fine control over a series of fabrication parameters, such as laser power, structure slicing and hatching, thereby providing minute control over the inter-particle distance in all 3 dimensions, to obtain hierarchically ordered nanocomposite microstructures showing a wide gamut of color.

We present the expansion of this work to encompass soft, stimuli-responsive polymers in which an external stimulus can be further used to vary periodicity of the ordered nanocomposite, thereby further changing the reflected colour in and out of the visible spectrum. We will show routes of exploitation for this approach which span sensing and encryption.

In conclusion, the strategy presented herein offers a novel and efficient route for creating responsive photonic microstructures that can be used qualitatively (for analyte determination) or qualitatively (for go/no go interventions).

Functional Hybrid Materials on Bio-Basis for Sensors and Actuators Stephan V. Roth[1,2]; [1]KTH Royal Institute of Technology, Sweden; [2]Deutsches Elektronen-Synchrotron DESY, Germany

Cellulose nanofibrils (CNFs) are an abundant, bio-based, and renewable material with excellent mechanical properties. They show highest strength and allow for light-weight applications. In order to functionalize this sustainable material par excellence, the fabrication of hybrid materials is mandatory. These hybrid materials include functional polymers as well as advanced core-shell and metallic nanoparticles. Here, the knowledge of the nanostructure is crucial for its application. Starting from thin film technology, spray deposition is a scalable, facile, and industrially used method for fabricating tailored nanostructures with specific applications. To start with, sprayed CNF templates themselves act as nanoporous templates for optoelectronic applications. They comprise non-swelling polymer electrodes[1], sensor materials[2], flexible electrodes[3], and tunable amorphous photonic crystals[4]. Being all water-based, the interaction with water is crucial[5]. Using water-based polymers and CNF in a hybrid material and facile solution casting, internal stresses and humidity sensitivity is exploited to fabricate self-healing actuators[6].
In my talk I will present the fundamental aspects of using CNF and characterizing its response to water and humidity. The nanoporous structure of CNF thin films is the key-point for their functionalization. The nanostructure is extracted using advanced X-ray and neutron scattering methods, which allows to understand and exploit the interaction with water of the hybrid materials applied in soft robotics.

Artificial Sharkskin: Fabrication of Staggered Overlapped Microdenticles Jeong Jae Wie[1,2]; [1]Hanyang University, Korea (the Republic of); [2]State University of New York College of Environmental Science and Forestry, United States

In liquid crystalline elastomers, anisotropy in molecular alignment governs direction of mechanical actuation upon exposure to external stimuli.[1] Similarly, the arrangement direction of magnetic particles determines magnetomechanical actuation of polymer composites. In micropillar arrays, chain-like arrangement of magnetic particles can induce bending or twisting actuation of micropillars under linear external magnetic field.[2] When magnetic particles are arranged along the principal axis of the micropillar, the perpendicular external magnetic field produces bending actuation. In the same magnetic field condition, twisting actuation is induced with magnetic particles arranged along the short-axis of micropillars.[2] The strain responsivity of magnetic actuation can be enhanced by employing anisotropic micropillar geometry for anisotropic stress distribution.[3] Based on the manetic bending actuation of anisotropic microdenticles, staggered-overlapped three-dimensional microarchitectures are constructed to mimick artificial sharkskin, a feat difficult to achieve by conventional microfabrication techniques.[4] In this presentation, various anisotropic functionalities of this artificial sharkskin will be discussed.

Micro-Robots with Fast and Reversible Actuation via Two-Photon Polymerization Yekaterina Tskhe[1], Srikanth Kolagatla[1], Alex J. Thompson[2,2], Colm B. Delaney[1] and Larisa Florea[1]; [1]Trinity College Dublin, Ireland; [2]Imperial College London, United Kingdom

The additive manufacturing and its application in micro-robotics have demonstrated the high potential for the fabrication of tiny smart devices.[1] These microscale tools can be used in surgeries to manipulate objects with precision and control while reducing damage and making patient recovery faster. The key element for the movements and actuation of such microsystems is stimuli-responsive material.

In this work, we present functional microgrippers fabricated by direct laser writing via two-photon polymerization (2PP). This technique allows the creation of complex 3D structures on a microscale by scanning a polymer hydrogel with the femtosecond laser, building the structure layer by layer.[2] By tuning the fabrication parameters such as slicing and hatching as well as laser power and scanning speed it is possible to adjust the mechanical and chemical properties for the desired application.

The actuation of the microgripper is controlled by pH-responsive polymer materials which react to the pH changes of the environment. Their shape-morphing feature is inspired by the artificial muscles which can contract and expand in response to pH changes.[3] The microgripper is powered by this type of responsive polymers that can move its arms to reversibly close and open. The actuation takes a few seconds due to the minuature scale of these devices. By mimicking the blood vessels, we can implement such microgrippers as valves and use them in the pH sorter microsystem. The characterization of such microstructures was complemented by optical microscopy, atomic force microscopy (AFM), and scanning electron microscopy (SEM). We showcased the effect of structure design, hydrogel composition and writing parameters on the performance of microgrippers.

These types of micro-robots open new opportunities for minimally invasive surgeries, sensing and photonics. [4,5,6] We can incorporate multiple functionalities into a single microdevice by adapting the design and adjusting fabrication parameters. It offers a high degree of flexibility and presents a wide range of potential applications for 2PP-fabricated micro-robots.

Flexible Electronic Skins for Sensing and Haptic Actuation John A. Rogers; Northwestern University, United States

Mechanoreceptors in the skin present compelling targets for selective and noninvasive neural interfaces. This presentation summarizes our recent work in systems for independently rendering sensations in these afferent channels using miniaturized mechanical actuators configured in programmable, dense arrays as untethered, wearable devices. The actuators combine with the skin as an elastic, energy storing module to support bistable, self-sensing modes for inducing controlled deformations at the surface of the skin. The result renders both dynamic and static stimuli, through either normal or shear forces. Studies in the context of rehabilitation with human subjects demonstrate this wireless, skin-conformable haptic array as an interface to a physical environment, reconstructed and tracked from an advanced suite of smartphone-based sensors. The diversity in modes of engagement, the density of power delivery, and the efficiency in operation of these small-scale mechanical transducers represent key, enabling advances over alternatives based on electrostatic, pneumatic, and electromagnetic approaches.

Bioinspiration from Photosynthetic Light-Harvesting Protein Complexes Tjaart Krüger; University of Pretoria, South Africa

Proteins execute their programmed functions in a finely regulated way with extraordinary efficiency, despite ample environmental disorder and densely crowded, heterogeneous environments. These capabilities serve as a useful source of inspiration for polymer design. The way in which photosynthetic light-harvesting proteins establish robustness to conformational disorder is particularly meaningful for conjugated polymers where such disorder gives rise to spatial localization of excitons and the formation of electronic traps, whereby exciton lifetimes and charge diffusion lengths are significantly reduced. In photosynthetic light-harvesting proteins, these limitations are largely overcome by the binding of chromophores in dense arrangements, allowing the formation of molecular excitons that are coherently shared across a number of neighboring chromophores. Having a significantly reduced susceptibility to structural disorder, these spatially delocalized excitations offer various functional benefits such as faster energy transport and less trapping and ensuing loss of excitation energy. These functions are often enhanced by mixing of the excitons with charge-transfer states. In the first part of the presentation, I will discuss molecular design strategies of conjugated polymers with enhanced robustness to static disorder. I will also show how subunit aggregation types can be quantified, using as an example the application of three computational methods to the experimental absorption and photoluminescence spectra of a benzodithiophene-isoindigo copolymer. In the second part of the presentation, I will discuss how the photosystem organization of cyanobacteria serves as inspiration for the design of conjugated terpolymers whereby the use of one donor and two acceptor units mimics the design of one main type of light-

harvesting complex channeling excitation energy to two different types of photosystems.

11:00 AM *SB11.09.02
Shape Change Mechanisms in Biological Materials Peter Fratzl; Max Planck Institute, Germany

The shape change of plant and animal tissues fulfills a variety of functions from organ growth to locomotion or seed dissemination. Various physical mechanisms, from fiber contraction to osmotic pressure and atmospheric dehydration, are at the origin of such shape changes. Fiber orientation distributions control the geometry of shape change and constitute, therefore, the alphabet for such programmed transformations. The talk reviews recent work on seed locomotion and capsule opening, on collagen fiber contraction as well as fiber tension-controlled tissue growth.

11:30 AM *SB11.09.03
Shaping Soft Matter: From Live Cell Tattoos to Hydrogel Transformers David H. Gracias; Johns Hopkins University, United States

Micro and nanopatterning of rigid materials such as semiconductors, metals, and dielectrics has revolutionized human life by enabling integrated circuits, microsensors, and smart phones. Imagine applying the same micro/nano patterning principles and multi-scale integration to hydrogels and living materials. We could then create adaptable implants, living robots, microphysiological systems, and homeostatic materials.
This talk will describe our efforts to apply micro and nanoscale patterning and heterogeneous integration to hydrogels and living cells/organoids. I will describe the first demonstration of the patterning of live cells with nanolithographic arrays of gold dots and wires using a biocompatible biotransfer process. Integrating lithographic patterns on live cells offers the potential to create living material interfaces and incorporate electronic/optical tattoos. I will also describe shape-changing temperature responsive and DNA polymerization gels that display diverse functions such as gripping, locomotion, and complex programmable shape change. I will give examples wherein such hydrogel transformers can be applied widely, including for adaptive implants, soft-robots, digitally programmable materials, and automata. These studies indicate the potential for the design of a range of intelligent materials, robots, and integrated devices that have the touch and feel of biological matter.

12:00 PM SB11.09.04
Ultra-Thin Graphene Oxide Composite DNA Polymerization Gels Ruohong Shi, Qi Huang, Rebecca Schulman and David H. Gracias; Johns Hopkins Univerisity, United States

DNA polymerization gels exhibit high swelling, as high as a 100-fold volumetric increase, based on the sequential insertion of DNA hairpins. They offer programmability based on DNA hybridization with high specificity and the potential for the integration of biomolecular circuits, which is of broad relevance to tissue engineering and soft robotics. Here, we incorporated graphene oxide (GO) nanosheets into the polymerization gels to enhance functionality. The composites are stiffer and enable the gels to be structured in significantly thinner films, as thin as 8 µm. We observe that the GO-DNA polymerization gel composites retain their sensitivity to DNA-induced shape transformation, such as swelling and shrinking, akin to controls without GO, but with accelerated shrinking rates. We anticipate that the combination of thinner gels with more rapid shrinking, combined with the functionality of GO (such as optical absorbance), enhances their potential for use in flexible devices, soft robotics, and drug delivery. The study also highlights the potential to incorporate other nanoparticles (e.g., noble metal, semiconducting, ferromagnetic) into DNA polymerization gels to enhance optical, electronic, and magnetic functionality.

12:05 PM SB11.09.05
Harnessing Gradients for Self-Assembly of Peptide-Based Nanocapsules Xuliang Qian[1], Haopeng Li[1], Harini Mohanram[1], Xiao Han[1], Huitang Qi[2], Guijin Zou[3], Fenghou Yuan[2], Ali Miserez[1], Qing Yang[4], Tian Liu[2], Huajian Gao[1] and Jing Yu[1]; [1]Nanyang Technological University, Singapore; [2]Dalian University of Technology, China; [3]A*STAR, Singapore; [4]Chinese Academy of Agricultural Sciences, China

Biological systems ingeniously craft materials with complex structures for specialized functions, a feat often challenging to replicate in man-made materials. We report a serendipitous discovery where insect cuticle peptides (ICPs) spontaneously form nanocapsules through a single-step solvent exchange process. This phenomenon occurs as a concentration gradient, arising from the mixing of water and acetone, drives the localization and self-assembly of the peptides into hollow nanosized capsules. The intrinsic affinity of these peptides for specific solvent concentrations, coupled with the diffusion-driven gradient interface, triggers their localization and self-assembly. This gradient-mediated self-assembly process not only mimics biological systems in its simplicity and efficiency but also paves the way for next-generation drug delivery systems using ICP nanocapsules. Furthermore, it showcases the potential of protein/peptide-based materials in self-healable robotic skin, and stimuli-responsive sensors and detectors.

SYMPOSIUM SF01

High Entropy Oxides and Related Materials
April 23 - May 7, 2024

SESSION SF01.01: Local Characterization of High Entropy Materials
Session Chairs: Christina Rost and T. Zac Ward
Tuesday Morning, April 23, 2024
Terrace Suite 1, Level 4, Summit

10:30 AM *SF01.01.01
Investigations of Local Structure in High Entropy Oxides Christina Rost; Virginia Tech, United States

Many properties we observe in materials are a direct consequence of their composition and local structure. High entropy oxides are a unique class of systems that do not have a primary composition; rather they contain a near-equimolar distribution of several elements— where no single element serves as host. Such compositional disorder is accompanied by a unique distribution of localized structural distortions which may affect properties such as thermal conductivity, magnetic interaction, diffusion, and more. A key point of interest in these high entropy systems is the implied breadth of property tunability, which ranges in compositionally dependent functionalities from amorphous-like thermal conductivities to exotic magnetic states. In this talk, we review the beginnings of high entropy oxides then present ongoing work on the local characterization of several high entropy compositions exhibiting numerous crystal structures. X-ray absorption fine structure (XAFS), both near-edge and extended, is demonstrated to aid in understanding such chemical and structural disorder. The strengths and challenges of such characterization are discussed.

11:00 AM *SF01.01.02
Atomic Level Structural and Chemical Characterization of High-Entropy Oxides using Advanced (S)TEM Techniques Di Wang[1], Kai Wang[1,2], Abhishek Sarkar[1,2], Gleb Iankevich[1], Ziming Ding[1,2], Zhibo Zhao[1], Robert Kruk[1], Horst W. Hahn[1], Xiaoke Mu[1], Ben Breitung[1] and Christian Kuebel[1,2]; [1]Karlsruhe Inst of Technology, Germany; [2]TU Darmstadt, Germany

High entropy oxides (HEOs) exhibit unconventional properties, which have attracted intensive interest for a wide variety of applications such as electrochemical energy storage [1,2] and (electro) catalysis [3] as well as in fundamental studies on strongly correlated materials with competing magnetoelectric phases [4] giving rise to interesting properties such as colossal magnetoresistance (CMR) and metal-insulator transitions (MIT). The recent advances in (scanning) transmission electron microscopy (S)TEM have enabled a detailed structural analysis of HEOs providing atomic level chemical and oxidation state information together with local structural distortion and strain analysis as basis for a fundamental understanding of structure property correlations allowing to disentangle the complex high-entropy and 'cocktail' effects.
In this presentation, I will illustrate some of these advanced TEM capabilities for a detailed analysis of HEOs. I will discuss how this information enabled deciphering the synergistic effects of the cations in a $Mg_{0.2}Co_{0.2}Ni_{0.2}Cu_{0.2}Zn_{0.2}O$ electrode in lithium ion batteries [2] as well as the correlation between composition, oxidation state, structural distortions and magnetoelectric properties in strongly correlated high entropy manganates [4].
The TEM investigation of a $Mg_{0.2}Co_{0.2}Ni_{0.2}Cu_{0.2}Zn_{0.2}O$ electrode during various charging stages [3] revealed a nanoscale phase segregation during the initial discharging of the homogenous HEO into a metallic CoNiCu alloy phase, a Zn(Li) and a Mg oxide phase, which forms a highly defective, semi-coherent fcc composite structure. Although the material appears X-ray amorphous, 4D-STEM crystal orientation analysis shows that the composite structure extends throughout the originally single crystalline domains. Segregation of the metallic alloy at the grain boundaries gives rise to an interconnected conductive network throughout the composite particle. During recharging, Zn and partially Co are reoxidized (electrochemically active elements) forming a mixed fcc oxide with Mg (providing the structural stability) while the metallic NiCu(Co) phase (providing electrical conductivity) is maintained. This self-assembled nanostructure enables stable cycling of micron-sized particles and bypasses the need for nanoscale pre-modification required for conventional metal oxides. It demonstrates that the elemental diversity with a defined role of each element is key for optimizing these multi-cation electrode materials.
In a series of single-phase orthorhombic $(Gd_{0.25}La_{0.25}Nd_{0.25}Sm_{0.25})_{1-x}Sr_xMnO_3$ (x=0-0.5) HE-manganites, which combines the high entropy (HE) concept with property control by Sr^{2+} (hole) doping, we extend the HE approach to design strongly-correlated systems. [4] Using atomic resolution STEM imaging, an orthorhombic distortion has been identified for x=0, which is reduced with increasing Sr concentration to pseudo-cubic for x=0.5. Atomically resolved elemental maps reveal a homogenous distribution of the rare-earth cations and Sr on the A-site and Mn on the B-site sub-lattice. The oxidation state change of Mn has been evaluated by EELS using the O K and Mn L-edge features, unambiguously confirming that the Sr^{2+} doping results in increased Mn^{4+}. These electronic and structural changes correlate with a transition of the magnetoelectric properties from an insulting antiferromagnetic to a metallic ferromagnetic phase with good CMR values. This initial study signals the excellent potential to achieve complex magnetoelectric phase diagrams with unique temperature dependencies that stem from competing magneto-electronic interactions, which can be tuned by merging high entropy design with strongly correlated electron systems.

11:30 AM *SF01.01.03
Short Range Ordering in Entropy Stabilized Oxides with the α-PbO_2 Structure Solveig S. Aamlid[1], Sam Mugiraneza[1,1,2], Mario Ulises Gonzalez Rivas[1,1], Joerg Rottler[1,1] and Alannah Hallas[1,1]; [1]The University of British Columbia, Canada; [2]University of California, Santa Barbara, United States

The four-component medium entropy oxide (Ti, Zr, Hf, Sn)O_2 crystallizes in the α-PbO_2 structure. The formation of this structure type is interesting since it is distinct from the ground state structure of any of its precursor oxides. In itself, this is an indication that (Ti, Zr, Hf, Sn)O_2 might be an entropy stabilized compound. Conveniently, the two-component low entropy oxide (Ti, Zr)O_2 crystallizes in the same crystal structure, and is verified experimentally to be entropy stabilized.

Short range ordering (SRO) is an elusive phenomenon to characterize and quantize, but also potentially pivotal for the emergence of superior functional properties in high entropy materials. (Ti, Zr)O_2 possesses a well-characterized type of ordering where Ti and Zr cations order in alternating slabs. The degree of ordering can be controlled by the cooling rate and monitored through a simple measurement of the lattice parameters. In this work, we aim to

quantify and compare the degree of SRO in the two-component (Ti, Zr)O_2 and the four-component (Ti, Zr, Hf, Sn)O_2.

Pair distribution function measurements reveal large changes in the local structure of (Ti, Zr)O_2 depending on whether the sample has been quenched or slowly cooled, while (Ti, Zr, Hf, Sn)O_2 displays no discernible changes after heat treatments. In order to explain these observations and quantify the true configurational entropy of these materials, we use a computational approach based on density functional theory, cluster expansions, and Metropolis Monte Carlo simulated annealing. The calculations are able to reproduce the type of ordering and temperature range experimentally observed for (Ti, Zr)O_2. The same calculations are performed for (Ti, Zr, Hf, Sn)O_2, where the order-disorder phase transition temperature is lowered by hundreds of degrees relative to the two-component compound. Sluggish diffusion kinetics keep the cations frozen in place regardless of cooling rate, effectively hindering any degree of SRO or even a reversible phase transition, explaining the lack of changes in the pair distribution functions. The two-component compound on the other hand, shows signs of SRO even at synthesis temperature, indicating that the ideal configurational entropy state is never reached. As the energetics of cation-cation interactions are similar in these two materials, it is the increase in configurational entropy that causes the suppression of SRO. Finally, we introduce the possibility of heterovalent substitutions within this framework. In this case, short range order is expected to be strong due to the strong and long-ranged electrostatic forces involved.

SESSION SF01.02: Functional Properties of High Entropy Materials I—Batteries
Session Chairs: Ben Breitung and Torsten Brezesinski
Tuesday Afternoon, April 23, 2024
Terrace Suite 1, Level 4, Summit

1:30 PM *SF01.02.01
From High-Entropy Solid Electrolytes to Batteries Torsten Brezesinski; Karlsruhe Institute of Technology, Germany

Solid-state batteries represent a promising next-generation energy storage technology, with the prospect of delivering higher energy densities and exhibiting better safety characteristics than conventional liquid-electrolyte-based batteries, but are currently limited by short cycle life, among others because of electro-chemo-mechanical degradation. Especially superionic lithium thiophosphate solid electrolytes are being considered for use in bulk-type solid-state batteries. Nonetheless, many of the solid electrolytes reported in the literature tend to lack in room-temperature ionic conductivity and stability; thus, the continuous search for materials with improved properties. High-entropy conductors may offer a potential solution by enabling tailorable properties through compositional design. However, the correlation between configurational entropy and ion mobility is largely unexplored.
In this presentation, I will show recent findings on the effect that configurational entropy has on charge transport in chemically complex lithium thiophosphates for solid-state battery applications. In addition, I will demonstrate that performance improvements of high-entropy hexacyanoferrate cathodes are mainly due to suppression of phase transitions and gas evolution during cycling.

2:00 PM SF01.02.02
Entropy-Mediated Stable Structural Evolution of Prussian White Cathodes for Long-Life Na-Ion Batteries Yueyue He[1], Sören L. Dreyer[1], Yin-Ying Ting[2], Yang Hu[3], Thomas Diemant[3], Maximilian Fichtner[3], Horst W. Hahn[1], Jasmin Aghassi-Hagmann[1], Torsten Brezesinski[1], Yanjiao Ma[4] and Ben Breitung[1]; [1]Karlsruhe Institute of Technology, Germany; [2]RWTH Aachen University, Germany; [3]Helmholtz Institute Ulm (HIU) for Electrochemical Energy Storage, Germany; [4]Nanjing Normal University, China

The high-entropy approach is applied to monoclinic Prussian White (PW) cathode materials for sodium-ion batteries to address the issue of unfavorable multilevel phase transitions, leading to structural degradation and poor cycling stability. A series of Mn-based PWs was prepared, composed of up to six metal atoms sharing the N-coordinated positions (with Mn predominating), endowing the materials with unique structural properties. The high-entropy PW material of composition $Na_{1.65}Mn_{0.4}Fe_{0.12}Ni_{0.12}Cu_{0.12}Co_{0.12}Cd_{0.12}[Fe(CN)_6]_{0.92}\blacksquare_{0.08}$ was found to exhibit superior cyclability over medium-entropy, low-entropy and conventional single-metal PWs. In addition to the promising electrochemical performance, we report, to our knowledge for the first time, that the high-symmetry crystal structure (cubic form in this study) is favorable for high-entropy PWs during battery operation. Computational comparisons of the formation enthalpy of high-, medium- and low-entropy materials show that the compositionally less complex samples are prone to phase transitions that negatively affect the cyclability, especially in the deep de-/sodiated state. Based on data from complementary *operando* and *ex-situ* characterization techniques, an intrinsic mechanism for the stability improvement of the disordered PW structure during Na^+ insertion/extraction is proposed, namely the dual effect of suppression of phase transitions and gas evolution.

2:15 PM *SF01.02.03
High-Entropy Disordered Rock-Salt Cathodes for Lithium-Ion Batteries Bei Zhou[1], Elmar Kataev[2], Götz Schuck[2], Matteo Bianchini[1,3] and Qingsong Wang[1,3]; [1]Bavarian Center for Battery Technology, Germany; [2]Helmholtz-Zentrum Berlin für Materialien und Energie GmbH, Germany; [3]University of Bayreuth, Germany

Traditional layered oxides consist of well-ordered alternating Li and transition metal (TM) with Li transport in two-dimensional (2D). In the disordered rock-salt (DRX) structure, Li and TM cations are randomly distributed at the 4a sites in the cationic sublattice.[1] The three-dimensional (3D) DRX cathodes are considerably more stable than the conventional layered oxides which often suffer from collapse of the interlayer spacing upon Li extraction at high voltages. The disordered arrangement of Li and TM opens the possibility of using a variety of TMs. The high-entropy DRX oxyfluorides, firstly reported by our group[2,3], of which the underlaying reaction mechanism has been intensively investigated recently especially by synchrotron-based techniques, including *operando* soft/hard X-ray absorption spectroscopy (XAS) and *ex situ* resonant inelastic X-ray scattering (RIXS).

2:45 PM SF01.02.04
Segregation Phenomena in Rock-Salt High Entropy Oxides for Lithium Battery Applications Studied by *In Situ* Annealing in a Scanning Transmission Electron Microscope Albina Borisevich[1], Craig A. Bridges[1] and Sheng Dai[1,2]; [1]Oak Ridge National Laboratory, United States; [2]The University of Tennessee, Knoxville, United States

Recently high-entropy oxides were proposed as promising materials for lithium battery anodes, with reports showing improvements in the storage capacity and cycling ability of the rock-salt type materials attributed to entropic stabilization due to random distribution of metal cations within the lattice (see e.g. [1]). However, multiple further studies suggested that these materials are not behaving as a homogenous mix of cations: in situ XAS investigation showed that lithiation-delithiation follows a multistep path, with some irreversible processes taking place [2], and recent localized spectroscopy results showed nanoscale segregation and differential movement of the constituent cations during charging and discharging [3]. It is therefore very important to evaluate the compositional stability of these materials at different elevated temperatures, given that charge/discharge processes can be highly exothermic.
In this study we are exploring the elemental distribution in the equimolar rock-salt high-entropy oxide of Li, Mg, Mn, Co, Ni, Cu and Zn using compositional mapping with Electron Energy Loss spectroscopy in a Scanning Transmission Electron Microscope using *in situ* Protochips Aduro platform to heat the powders to temperatures ranging from 500°C to 950°C. The initial powders are either the mixture of initial oxides or pre-annealed *ex situ*, ball-milled before the *in situ* heating experiment.
Our results suggest that, even with a highly homogenized precursors, the most uniform distribution of cations is only achieved at high annealing temperatures, such as 950°C, and thermal treatment much below that temperature results in swift segregation of primarily Cu into distinct agglomerates. It takes as little as 1.5 hours at 500°C for the powder pre-annealed at 950°C to show Cu segregation. We also find that the reducing vacuum atmosphere inside the microscope contributes to the driving force for the segregation; while the powders annealed at 950°C inside the microscope from the precursors are the most homogeneous, they still show some segregation compared to powders annealed *ex situ* at the same temperature which do not.
These results confirm earlier findings about differential behavior of cations in these materials as they undergo thermal treatment and chemical transformations and suggest that controlling heat distribution within these anodes during charging and discharging can be very important for cycling stability [4].

SESSION SF01.03: Novel Magnetic and Electronic Properties of High Entropy Materials
Session Chairs: Alannah Hallas and Alessandro Mazza
Tuesday Afternoon, April 23, 2024
Terrace Suite 1, Level 4, Summit

3:30 PM *SF01.03.01
Accessing Novel Phase Space by The High Entropy Approach Alessandro R. Mazza; Los Alamos National Laboratory, United States

Disorder and defects often dictate emergent phenomena in materials – such as electronic phase, magnetic ordering, and mechanical strength. Traditional thought pushes our understanding of phase order to rely on the idea of uniformity in materials, with disorder and defects resulting in lower ordering temperatures and prevention of long-range percolation. However, high entropy materials are challenging this understanding and disorder is emerging as a parameter which drives the local microstates into globally ordered behaviors. We demonstrate that this seemingly counterintuitive statement is not only true but that it simplifies the prediction of predominant functional phase in high entropy oxides. As a result, we design, grow, and characterize high entropy perovskite oxide films demonstrating the utility of this predictive materials approach.

We present these theoretical and experimental results on two classes of single crystal epitaxial films. Magnetism and charge disorder of the high entropy ABO_3 perovskite $La(Cr_{0.2}Mn_{0.2}Fe_{0.2}Co_{0.2}Ni_{0.2})O_3$ is a representative case, demonstrating how a seemingly chaotic landscape of spin and charge disorder can yield an ordered state. Second, to explore electronic phase, we demonstrate realization of extreme *A*-site cation disorder in $(Y_{0.2}La_{0.2}Nd_{0.2}Sm_{0.2}Gd_{0.2})NiO_3$, whose parent ternary oxides each have a large range of electronic (metal to insulator transition) and structural phase transition temperatures. These results suggest cation variance and disorder, such as that accessible only in high entropy oxides, can be a critical order parameter in the design of correlated oxides, and that this parameter can more broadly provide continuous tunability to emergent phenomena.

Brown[1], Sangheon Oh[1], Catalin Spataru[1], Eli Kinigstein[2], Jinghua Guo[2], Joshua D. Sugar[1], Arantzazu Mascaraque[3], Enrique G. Michel[4], Alison Shad[1], Jacklyn Zhu[1], Matthew Witman[1], Suhas Kumar[1], Alec Talin[1] and Elliot J. Fuller[1]; [1]Sandia National Laboratories, United States; [2]Lawrence Berkeley National Laboratory, United States; [3]Universidad Complutense de Madrid, Spain; [4]Universidad Autónoma de Madrid, Spain

There is growing interest in material candidates that provide knobs to tune their properties beyond traditional limits. Compositionally complex oxides, often called high entropy oxides, are excellent candidates, wherein a lattice site shares more than four cations, forming single-phase solid solutions with unique properties. Here, we demonstrate compositional complexity as a tunable parameter in a spin-transition oxide semiconductor $La_{(1-x)}(Nd,Sm,Gd,Y)_xCoO_3$, by varying the population x of rare earth cations. As the compositional complexity increases with x, localized and uniform lattice distortions occur that have profound effects on the material's semiconductor-to-metal spin transition and carrier type. Experimental measurements, together with first-principles calculations, demonstrate that atomic-range distortions from the varying rare earth radii induce a crossover from hole-majority to electron-majority conduction at $x = 0.8$ without the introduction of electron donors. Thus, we show that control of localized lattice distortions through compositional complexity is a facile knob to tune oxide semiconductors and spin transitions beyond traditional means.

4:15 PM *SF01.03.03
Magnetic-Electric Properties of High-Entropy Oxides Horst W. Hahn[1,2], Zhibo Zhao[2], Robert Kruk[2] and Abhishek Sarkar[3,2]; [1]The University of Oklahoma, United States; [2]Karlsruhe Institute of Technology, Germany; [3]IIT Kharagpur, India

The quest for artificial, heterostructured magneto-electrics is driving the search for new magnetic materials that can exhibit enhanced sensitivity to external

stimulation. In principle, the system of choice for this purpose can be the new class of materials known as High Entropy Oxides (HEOs). HEOs are single phase solid solutions consisting of five or more elements in equiatomic or near-equiatomic proportions incorporated into the cationic sub-lattice(s). What sets HEOs apart is their remarkable chemical complexity, encapsulated within a single crystallographic structure, often resulting in unique functionalities. From a local structure standpoint, HEOs exhibit an exceptionally large number of distinct metal-oxygen-metal pairings. Consequently, the magnetic correlations in HEOs, influenced by the coordination geometry, valence, spin state, and type of hybridized metal cations, are naturally influenced by an extensive variety of neighboring ionic configurations. These conditions give rise to a complex magneto-electronic free-energy landscape within HEOs, potentially leading to the stabilization of unconventional spin-electronic states. This form of inherently imbalanced magnetism has the potential to be influenced by external stimuli, such as voltage, presenting opportunities for the development of artificial magneto-electrics. Examples of these systems, including perovskites and spinels, will be discussed in the context of their magneto-electronic properties, which are a consequence of the extreme local chemical disorder.

4:45 PM SF01.03.04
Correlated Electron Metals with High Entropy: Thin Film Growth and Properties Saeed S. Almishal[1], Pat Kezer[2], Jacob Sivak[1], Sai V. Ayyagari[1], Francisco Marques dos Santos Vieira[1], Christina Rost[3], Vincent Crespi[1], Venkatraman Gopalan[1], Nasim Alem[1], Ismaila Dabo[1], Susan B. Sinnott[1,1], John T. Heron[2] and Jon-Paul Maria[1]; [1]The Pennsylvania State University, United States; [2]University of Michigan, United States; [3]Virginia Tech, United States

Novel conducting complex oxides with high electron correlation are of keen interest for UV-transparent applications, and as hosts for fundamental studies of correlated electron systems and spin-hall effect. Sr based cubic perovskite oxides are appealing to explore due to their heavy cation solubility and tunable electrical conductivity and transparency. Utilizing a high configurational entropy formulation, the high symmetry perovskite phase can be stabilized with five cations on the perovskite B-site. Our results show that $Sr_x(Ti,Nb,Cr,Mo,W)O_3$ thin films grown by pulsed laser deposition are stabilized as single-phase perovskite. Derivative systems with four B-cations instead of five, exhibit chemical and/or phase segregation. Contributions from individual B-cations and their interactions result in unique overall transport properties. For instance, Cr markedly influences electrical transport. A-site vacancies and doping, too, influence electronic and optical properties, and structure stability. The experimental findings are supported by first principles calculations that highlight the cation coexistance effect on octahedral tilting, tolerance factor, band structure and orbital filling.

SESSION SF01.04: Poster Session: High Entropy Materials
Session Chairs: Ben Breitung, Alannah Hallas, Scott McCormack and T. Zac Ward
Tuesday Afternoon, April 23, 2024
Flex Hall C, Level 2, Summit

5:00 PM SF01.04.01
Potentiodynamic Polarization and Electrochemical Impedance Behavior in Co-Rich $Co_{40}Cr_{20}Ni_{15}Fe_{15}Mo_{10}$ High Entropy Alloy Moonkyu Lee[1], Zakiyuddin Ahmad[2] and Kwangmin Lee[1]; [1]Chonnam National University, Korea (the Republic of); [2]University of Indonesia, Indonesia

This study aims to investigate the corrosion characteristics of a high entropy alloy (HEA) composed of $Co_{40}Cr_{20}Ni_{15}Fe_{15}Mo_{10}$, which is designed as a metallic biomaterial. The Co-HEA was synthesized using vacuum arc remelting (VAR). To gain insights into the detailed mechanisms of corrosion reactions, we performed potentiodynamic polarization (PDP) and electrochemical impedance spectroscopy (EIS) experiments in Ringer's solution. The PDP analysis revealed an I_{corr} value of 1.358×10^{-8} A/cm^2 for $Co_{40}Cr_{20}Ni_{15}Fe_{15}Mo_{10}$, which was lower than that of 316L stainless steel and L605 Co-alloy. To further understand the corrosion behavior, we employed an electrical equivalent circuit (EEC) to extract fitting parameters from Nyquist plots at various time points after the EIS test. The Nyquist plot exhibited a gradual increase in the size of the semicircular radius with increasing immersion time, indicating the growth of the passive film. Notably, the Co-HEA consistently displayed higher R_{ct} values at all time points compared to 316L and L605, representing its superior corrosion resistance attributed to their excellent passivation ability. The passive films formed on $Co_{40}Cr_{20}Ni_{15}Fe_{15}Mo_{10}$ were primarily composed of oxides and hydroxides of Co, Cr, and Fe, with the highest $Cr_2O_3/Cr(OH)_3$ ratio observed. These findings suggest that the $Co_{40}Cr_{20}Ni_{15}Fe_{15}Mo_{10}$ HEA, with its robust and stable passive film, demonstrates better corrosion and electrochemical properties when compared to 316L stainless steel and L605 Co-alloy, suggesting that it is a promising candidate for future biomaterial applications.

5:00 PM SF01.04.02
The Investigation of Electrochemical Properties Using High-Entropy Spinel-Oxide as an Anode for Lithium-Ion Batteries Chia-Chien Ma, I-Han Lee and Tri-Rung Yew; National Tsing Hua University, Taiwan

The global demand for lithium-ion batteries (LIBs) is increasing, primarily because they can be used for various applications. To improve the energy density of LIBs, transition metal oxides are potential candidates for anodes owing to their high capacity and earth abundance. However, the issues such as low ionic conductivity, low Coulombic efficiency, and structural degradation during charge/discharge cycles limit the development of transition metal oxides in LIBs applications.

High-entropy oxides exhibit new chemistries and outstanding cycling stability for developing electrode materials. Nevertheless, they often contain expensive raw materials, and their effects on the application of LIBs are still unclear. In this work, a novel spinel-structure AMFCZ-based high-entropy oxide with five cost-effective and non-toxic oxides consisting of aluminum, manganese, iron, copper, and zinc ions is synthesized using a solid-state method with an ideal capacity of ~1000 mAh/g. Its cycling performance, electrochemical properties, and reaction mechanisms are investigated, showing good rate capability.

The slurries containing the AMFCZ-based active materials, carbon black (Super P), carboxymethyl cellulose (CMC), and styrene-butadiene rubber (SBR) are coated on a copper foil by using a doctor-blade process to form an electrode. After that, the electrode is dried in a vacuum oven, followed by assembling half-batteries in a glove box. The crystal structure of AMFCZ-based anode is characterized by X-ray diffraction (XRD) analysis. Scanning electron microscopy (SEM) and energy-dispersive X-ray spectrometry (EDX) are used to analyze the morphology and composition distribution of AMFCZ-based anodes. Galvanostatic charge/discharge (GCD), electrochemical impedance spectroscopy (EIS), and X-ray photoelectron spectroscopy (XPS) are used to analyze the cycling performance and electrochemical properties. This work reveals a novel high-entropy oxide as an anode and demonstrates its electrochemical properties as an anode for LIBs.

Inhibition Effect of Segregation and Chemical Order on Grain Boundary Migration in NbMoTaW Multi-Principal Element Alloy Xiao-Tong Li,

Xiaozhi Tang and Ya-Fang Guo; Beijing Jiaotong University, China

Wide-range applications of high entropy materials (HEA) requires their superior mechanical properties, which essentially relies on grain boundary (GB) stability for sustaining plastic deformation. While the fundamental mechanisms of GB migration in HEA differ from the ones in conventional materials due to lattice distortion and local chemical environments. Particularly the GB segregation in HEA always accompanies local chemical order (LCO) variations. To quantificationally and efficiently investigate the impacts of solute segregation and chemical order on GB migration, we applied atomistic simulations for the NbMoTaW multi-principal element alloy. Assisted by a contrived Nb-rich model, it is found that solute segregation and chemical order synergistically inhibit GB migration. Nb segregation increases the critical stress for GB migration, and the presence of chemical order further enhances the resistance of GB to plastic deformation. The destruction of local ordering structures is responsible for the difficult GB migration. Transition pathway analyses show that GB modified with both Nb segregation and chemical order requires high migration barrier, and the prior migration of GB sites tends to avoid regions with heavier chemical order. These results provide new insight into how chemical complexity affects elementary GB motion and contribute to manipulating the stability of MPEAs.

Theory-Guided Searching for Ductile Single-Phase Refractory Multi-Principle-Element Alloys Hailong Huang, Rameshwari Naorem, Prashant Singh and Nicolas Argibay; Ames Laboratory, United States

The pursuit of materials exhibiting good high-temperature mechanical behavior has never faded. Multi-principal-element alloys (MPEAs, also called compositionally complex alloys) with nearly infinite design space which deviate from conventional design philosophy offer great potential. Refractory MPEAs(RMPEAs) are promising for aerospace and related industries usage due to their excellent mechanical performance and superior resistance to softening at elevated temperatures. Nevertheless, a great majority of such RMPEAs developed up to date suffer from poor room-temperature ductility, which makes them difficult to be processed and thus limits their practical applications. Here we proposed a density-functional theory (DFT) guided searching for single-phase RMPEAs with tensile ductility and high strength.

5:00 PM SF01.04.05
Tough NiTi-Based High-Entropy Intermetallic Compounds: Uniform Plastic Deformation and Small-Scale Defects Ya-Jing Lee, Chun-Cheng Chen, Cheng-Yuan Tsai and Shou-Yi Chang; National Tsing Hua University, Taiwan

Owing to the advantages of superior elevated-temperature strength and good thermal stability compared to traditional engineering alloys, intermetallic compounds with an ordered structure are of great potential for applications in extreme high-temperature environments. However, the detrimental brittleness due to strong bonding-caused low plasticity is concerned. In this study, based on the synergy of the chemical ordering of intermetallic compounds and the active defects in high-entropy alloys, NiTi-based, ordered B2 medium- and high-entropy intermetallic compounds were thus developed. Substitutional elements to Ni or Ti lattice sites were selected in consideration of thermodynamic parameters and electronegativity. Their microstructures were characterized, macro-to-microscale mechanical behaviors were investigated, and defect activities were experimentally examined and molecular-dynamics simulated. Experimental results indicated that the medium- and high-entropy intermetallic compounds presented a much higher strength, plasticity and resistance to high-temperature softening as compared to the traditional binary NiTi low-entropy one (in the condition without martensitic transformation). The quaternary intermetallic compound with Zr showed a high yield strength of 2000 MPa at room temperature and 400 MPa at 800°C (only 60 MPa for NiTi), while the one with Hf showed a compressive strain of 18% before fracture at room temperature (5% for NiTi). The quinary intermetallic compound with both Hf and Zr showed a retained yield strength of 1600 MPa, improved plastic strain of 20% and enhanced softening resistance of 600 MPa at 800°C. With further addition of Fe, the senary intermetallic compound became harder and more brittle due to the precipitation strengthening of Fe_2Zr but much more softening-resistant with 900 MPa at 800°C. The micropillar compressive tests of the binary, quaternary (the harder one with Zr) and senary (prepared from the single-phase, solid-solution region without Fe_2Zr) samples revealed that the low- and medium-entropy micropillars catastrophically fractured in a rapid slip way, whereas the high-entropy ones plastically barrel-like deformed with high work hardenability. Additionally, both microscopic observations and molecular dynamics simulations suggested that, instead of the long-distance planar gliding of long dislocations, short-range randomly-oriented activities of abundant tangled small-scale dislocations dominated the uniform plastic deformation of the high-entropy intermetallic compound.

Investigating The Phase Stability and Thermal Properties of Compositionally Complex Titanate Pyrochlores Joshua Safin, Xin Wang and Katharine Page; University of Tennessee at Knoxville, United States

In multicomponent ceramics there are varying factors that determine the phase selection and stability such as the configurational entropy of the system or the ionic radii of the constituent cations. The influence of each of the aforementioned factors can vary based on the complexity of the crystal structure of the material. Stability rules based on ionic radius ratios are well established for rare earth pyrochlores ($RE_2^{3+}B_2^{4+}O_7$). From these rules, members of the titanate pyrochlore family have been synthesized from the Lanthanide series (La to Lu, large to small) that take advantage of the wide range of ionic radii and stable +3 oxidation state across the majority of the series to create a series of samples with different combinations and distributions of cations as well as including cations that are not normally stable as pyrochlores in single component systems based on known stability rules. The trends in the crystal structure were studied through the use of X-Ray diffraction and Rietveld refinement. Thermal properties were investigated using the Transient Plane Source method and dilatometry. Altogether, the impact of the higher entropy configurations and the distribution of constituent cations on pyrochlore radius ratio rules, thermal properties, and other potential crystal-chemical effects will provide deeper understanding of possible design considerations for intrinsic property tuning in these and other multicomponent complex ceramics. In particular, tunable rare earth titanate pyrochlores would have a wide range of applications in various fields such as in magnetic materials because of the spin ice properties, in thermal barrier coatings due to low thermal conductivity and good coefficients of thermal expansion, and in ionic conductors.

5:00 PM SF01.04.07
A Phonon-Unfolding Based Method for Quantitative Assessment of Thermal Conductivity of High Entropy Ceramics Yuxuan Wang, Guoqiang Lan and Jun Song; McGill University, Canada

Thermal barrier coating materials have been extensively used in fields of aerospace and power industry. It can protect the underlying substrate against hot gas streams while effectively isolating the heat flow. High entropy ceramics, with their unique disorder lattice structures, exhibit ultra-low thermal conductivity and good high temperature stability, which make them promising candidate materials for next generation thermal barrier coatings (TBCs). Unlike the conventional ceramic materials where the intrinsic thermal resistance largely comes from phonon-phonon interactions, the thermal resistance in high entropy ceramics predominantly arises from phonon-disorder scattering. In this study, we propose a new method based on the supercell phonon unfolding (SPU) technique to predictively assess the thermal conductivity of high entropy ceramics, focusing on the high entropy rocksalt oxide group as the representation. We demonstrated that our method could obtain an indicator in direct correspondence to the thermal conductivity, thus allowing quantitative comparison of the thermal conductivities of different high entropy ceramics. A good agreement has been found between our model predictions

and the experimental measurements, confirming the validity of our method. The method provides a valuable predictive tool for screening and design of high entropy ceramics for TBCs.

5:00 PM SF01.04.08
Development of High Entropy Perovskite Oxide Electrocatalysts for the Oxygen Evolution Reaction: A Combined Experimental, Density Functional Theory (DFT) and Machine Learning Approach to Predicting Oxygen Vacancy Formation Energies Panesun J. Tukur[1], Jianjun Wei[1], Yirong Mo[1], Hanning Chen[2], Wei Yong[3] and Yinning Zhang[4]; [1]UNC Greensboro, United States; [2]The University of Texas at Austin, United States; [3]High Point University, United States; [4]University of West Georgia, United States

This research explores the design and development of high entropy perovskite oxide electrocatalysts for the oxygen evolution reaction (OER) through a comprehensive approach that integrates experimental investigations, density functional theory (DFT) calculations, and machine learning techniques. By harnessing the potential of high entropy materials, we aim to enhance the catalytic activity of perovskite oxides for the critical OER process. We investigate the formation energies of oxygen vacancies and molecular adsorption energies on these catalyst surfaces using state-of-the-art DFT simulations. Additionally, machine learning models are employed to predict these critical properties, providing insights into catalyst performance across a wide compositional space. The synergistic combination of these methods promises to accelerate the discovery of advanced OER electrocatalysts with improved efficiency and sustainability, contributing to the advancement of renewable energy technologies.

5:00 PM SF01.04.09
Predicting The Synthesizability of High-Entropy Rare Earth Disilicates by First-Principles Calculations with Machine-Learning Debanjan Sarker and Cormac Toher; The University of Texas at Dallas, United States

Silicon carbide based ceramics are promising alternatives to the conventional nickel-based superalloys to be used in hot temperature sections of the turbines for their low density, and outstanding resistance to creep and oxidation at high temperature. However active reaction with water vapor in high-velocity combustion environments degrade the stability of Si-based ceramics thereby reducing its strength. To increase the durability, environmental barrier coatings (EBC) can be used as a protective layer for silicon-based CMCs by limiting the chemical reactions between environment and the CMC. The current state-of-the-art EBC candidate materials are rare earth silicates, due to their good corrosion resistance and a coefficient of thermal expansion similar to that of SiC. However, rare earth disilicates display several different polymorphs, and undergo phase transitions with changing temperature. To increase the thermodynamic stability of these compounds, tune their CTE and elastic modulus and reduce the lattice thermal conductivity, high-entropy rare earth disilicates are being developed. To predict which compositions are most likely to form a high entropy single-phase, we are combining first-principles calculations using the AFLOW framework with experimental data and machine-learning to develop models and find descriptors to predict phase formation in these materials.

5:00 PM SF01.04.10
Ultra-Fast Synthesis of High Entropy Boride Layers and Their Characterization Merve Uysal Komurlu and Ali Erdemir; Texas A&M University, United States

In this study, we used an ultra-fast boriding process to quickly and uniformly produce thick boride layers on high entropy refractory alloys consisting of W, Re, Nb, Zr, Ta, and V. Boriding is performed at 1000°C and for 1 hour. Chemical, structural, and mechanical characterization of the boride layers was carried out using relevant test methods and confirmed that W and Re-containing alloys were among the very best in terms of boride layer thickness of 40 µm and hardness. While, Nb, Ta, and V containing alloys attained thickness values of around 3 µm. Nano hardness profiles across the boride layers revealed that W and Re-containing alloys possessed exceptional hardness, i.e., around 40 GPa. In the cases of other alloys, hardness values of boride layers fell between 18.5 GPa and 8 GPa. Such significant variations in thickness and hardness highlight the need for a more systematic and predictive modeling approach that can provide critical information on the selection of constituent refractory metals in high entropy alloy systems as well as desirable boride phases with superior mechanical, thermal, and oxidative properties.

5:00 PM SF01.04.11
Microwave Plasma Synthesis of MoNbTaVW High Entropy Alloy: A Novel Approach Bria C. Storr and Shane A. Catledge; University of Alabama at Birmingham, United States

We investigate a novel approach for synthesis of the high entropy alloy MoNbTaVW from metal oxide precursors via microwave-induced plasma. The process involves ball milling of the metal-oxides, followed by microwave plasma annealing at 1800°C for a duration of 1 hour. Hydrogen is used as the plasma feedgas for efficient reduction of metal-oxides. Analysis through X-ray diffraction, scanning electron microscopy/energy dispersive x-ray analysis, and Vickers hardness testing has revealed the characteristic structure/properties of high-entropy alloy. This includes a single-phase body-centered cubic structure with a uniform distribution of all five metals, and measured hardness of 6.8 ± 0.9 GPa. This hardness aligns closely with findings reported in literature for high entropy alloys sharing the same five-metal configuration. In addition to rapid volumetric heating enabled by interaction of microwaves with the dielectric precursors, the microstructure exhibits clear evidence of localized microwave sintering. The outcomes highlight the promising potential of microwave plasma as a rapid, cost-effective, and versatile processing tool for the production of high entropy alloys.

8:30 AM *SF01.05.01
The Crystal Chemistry in Two Families of Compositionally Complex Oxide Electrocatalysts Katharine Page[1,2]; [1]The University of Tennessee, Knoxville, United States; [2]Oak Ridge National Laboratory, United States

Integration of renewable feedstocks into the current energy infrastructure drives the development of electrocatalysts that can maintain high surface areas and selective electrocatalytic activities under a variety of challenging chemical and environmental conditions. Recently, several compositionally complex oxides (CCOs) have been reported with intriguing and tunable electrocatalytic properties. We present recent studies on compositionally complex Rare Earth cerate oxygen evolution reaction (OER) electrocatalysts and bifunctional OER and oxygen reduction reaction (ORR) spinel ferrite electrocatalysts. A

combination of local to long-range electron, x-ray and neutron scattering probes are employed to investigate their complex configurational diversity and associated structure-property trends. Relationships are explored between the cation site preferences, chemical-short-range order, and promising electrocatalytic properties achieved in the families through compositional tuning and variation in synthesis/processing conditions. Experimentally derived models are supported by Density Functional Theory calculations employing Special Quasirandom Structure models. This work highlights the importance of studying structure-property characteristics under reaction conditions and hints at the exquisite level of detail that may be required in computational and experimental approaches to guide structure-property tuning in emerging CCO OER and ORR electrocatalysts. Current challenges and future opportunities in this arena will be discussed.

9:00 AM SF01.05.02
Synthesis and Fundamental Studies of $Ce_{1-x}(YLaPrSm)_xO_{2-\delta}$ as Ionic Conductors Billy E. Yang[1], Saeed S. Almishal[1], Mary Kate Caucci[1], Sai V. Ayyagari[1], Nasim Alem[1], Christina Rost[2], Susan B. Sinnott[1,1] and Jon-Paul Maria[1]; [1]The Pennsylvania State University, United States; [2]Virginia Tech, United States

High entropy oxide $Y_{1/5}La_{1/5}Ce_{1/5}Pr_{1/5}Sm_{1/5}O_{2-\delta}$ (F1) with both +3 and +4 preferred cations is considered a promising candidate for oxygen ion conduction since the anion sublattice will contain up to 25% unoccupied sites in a fluorite structure. However, depending on the thermal and kinetic history during its synthesis, F1 may exhibit local chemical ordering and form an unwanted bixbyite-like structure. Therefore, it is crucial to investigate the conditions that lead to the phase transformation and the stabilization of the desired fluorite symmetry in high entropy sesquioxides. In this work, we synthesized a series of bulk F1-derived systems with varying the Ce concentration ($Ce_{1-x}(YLaPrSm)_xO_{2-\delta}$) to investigate the structural dependence on composition. The XRD patterns indicate when the cation mixture is equimolar; the system favors bixbyite structure up to 1500 °C. As the Ce concentration increases beyond 20%, the material transitions into a single-phase fluorite structure without evidence of a bixbyite-like phase. The SEM images reveal that all synthesized $Ce_{1-x}(YLaPrSm)_xO_{2-\delta}$ bulk samples have consistent grain size with no significant chemical segregation, as evident from EDS. Moreover, the bandgap and oxidation states of $Ce_{1-x}(YLaPrSm)_xO_{2-\delta}$ were investigated by UV-Vis and XPS and supported by first-principles calculations.

Electrocaloric Performance of High-Entropy Oxides from First Principles Ismaila Dabo and Tara Karimzadeh Sabet; The Pennsylvania State University, United States

The electrocaloric effect holds significant promise for advancing sustainable solid-state refrigeration technologies. High-entropy oxides [1] are potentially advantageous due to the thermal stability of their polar phases. In this work, we evaluate the phase stability and electrocaloric performance of the high-entropy perovskite $(Na,Bi,Sr,Ba,Ca)TiO_3$. A pivotal parameter in evaluating electrocaloric performance is the dependence of adiabatic electrocaloric temperature change as a function of temperature, which is intricately linked to the change of polarization with respect to temperature under a constant electric field [3]. To predict this parameter, we developed models for the temperature-dependent polarization $P(T)$ of high-entropy oxides taking into account chemical disorder and local distortions.

Mir[3], Ritesh Sachan[4], David Mandrus[1], Yanwen Zhang[5,1] and Veerle Keppens[1]; [1]University of Tennessee, United States; [2]Los Alamos National Laboratory, United States; [3]University of Huddersfield, United Kingdom; [4]Oklahoma State University, United States; [5]Idaho National Laboratory, United States

High-entropy oxides (HEOs) have recently gained recognition for their low thermal conductivity and tunable mechanical capabilities, but little is known about their response to high energy heavy ion beams. In this work, the heavy-ion irradiation response of HEOs with the pyrochlore and perovskite structures has been investigated. The damage accumulation behavior at 300 K due to 4 MeV Au ion irradiation of a <100>-oriented HEO titanate pyrochlore single crystal has been investigated by Rutherford backscattering spectrometry in channeling geometry and transmission electron microscopy (TEM). In addition, in situ TEM irradiation using 600 keV Xe ions has been employed to reveal the dose and temperature dependence of amorphization in a HEO pyrochlore with the same composition. In another single-crystal HEO titanate pyrochlore composition, amorphization due to 23 MeV Ni ions has been characterized by Raman spectroscopy, which indicates a much higher dose for amorphization, suggesting significant athermal recovery during irradiation due to the high electronic energy loss of the Ni ions. Ion tracks formed in a HEO perovskite structure irradiated with 774 MeV Xe ions have been characterized by TEM, and the stability of these ion tracks under electron beam irradiation has been evaluated. The results obtained on these HEO structures are compared to those of their single-component counterparts.

Reaction Pathway in The Formation of Rocksalt Entropy-Stabilized Oxides Avery-Ryan E. Ansbro[1], Akira Miura[2], Wenhao Sun[1] and John T. Heron[1]; [1]University of Michigan, United States; [2]Hokkaido University, Japan

High entropy oxides (HEO) are characterized through the effects of configurational disorder. The wide combinatorial space offered by complex materials, however, challenges our ability to predict reaction dynamics leading to entropy stabilization. We investigate (MgCoNiCuZn)O and establish the importance of kinetics in single phase formation. Rapid movement and diffusion between 800 °C and 870 °C indicate a eutectic copper oxide transition

phase mediates the formation of the entropy-stabilized complex by solvating and localizing metal cations. Larger, constituent particles remain inactive until 1020 °C, where it then dissolves the liquid phase to form an entropy stabilized oxide. Modifying the composition and phase of the binary mixture, we find that the liquid copper phase is essential to the development of a single phase. We propose the possibility that engineered, selective melting may be utilized to realize and design other ESO and oxide phases.

11:15 AM SF01.06.03
High Temperature Decomposition of Entropy-Stabilized Oxide (MgCoNiCuZn)O Matthew J. Webb[1], Mike Gerhart[2], Avery-Ryan E. Ansbro[1], Peter Meisenheimer[3], Tony Chiang[1], Christina Rost[4,2] and John T. Heron[1]; [1]University of Michigan, United States; [2]James Madison University, United States; [3]University of California, Berkeley, United States; [4]Virginia Tech, United States

Entropy-stabilized oxides represent a unique class of single-phase, multicomponent oxides that achieve stability through a substantial configurational entropy, ΔS_{conf}, which counters a positive, unfavorable enthalpy. Although it is generally postulated that entropy-stabilized oxides will exhibit robust thermal stability due to the presence of the $-T\Delta S_{conf}$ term in Gibbs' free energy, their behavior at high temperatures remains largely unexplored. In this presentation, I will discuss the stability of the prototypical entropy-stabilized oxide, rocksalt (MgCoNiCuZn)O, in the 1300-1700 °C range in air. As temperatures exceed 1300 °C, a gradual reduction in the Cu and Zn content within the rocksalt phase is observed. We pose that the correlated partial loss of these elements is mediated by local distortions and defects that facilitate greater diffusion rates for these ions at elevated temperatures.

11:30 AM SF01.06.04
High-Entropy Layered Double Hydroxides as Precursors for High-Entropy Oxides Sujeong Lee[1], Juhwan Noh[2] and Ho Jin Ryu[1]; [1]Korea Advanced Institute of Science and Technology, Korea (the Republic of); [2]Korea Research Institute of Chemical Technology, Korea (the Republic of)

Layered double hydroxides (LDHs) consist of positively charged metal cation layers with anion interlayers and water molecules, as following by formula, $M_{1-x}^{2+}M_x^{3+}(OH)_2[A^{n-}]_{x/n}\,zH_2O$. This material has advantages such as tunable metal composition layers, exchangeable interlayer anions, and memory effect, actively applying to the research fields of catalysts, batteries, drug delivery, and adsorption.
Through the flexible design of tunable metal layers, LDHs can be expanded to a high entropy system. The reported high entropy system exhibits a lower adsorption activation in energy in comparison to conventional systems. This resulted from the various adsorption activation energy spectrums and the availability of multiple binding sites because of the mixing of multiple elements. Furthermore, high entropy LDHs can be easily transformed into high entropy layered double oxides (LDOs) through calcination. Nevertheless, there is a scarcity of research on high-entropy LDHs and high-entropy LDOs. To address this gap, 120 binary, and ternary LDHs were synthesized through co-precipitation, serving as a database for expanding to the quaternary and quinary systems with a machine-learning-based approach. Out of the 120 LDHs, 47 cases were successfully formed as LDH crystal structures, while 10 cases showed mixed phases with less than half consisting of the secondary phases, and the remainder failed to crystallize as LDHs. The thermal stability of synthesized 57 cases was conducted and the evaporation temperature of the parent interlayer anions varied depending on the combination of metal elements. Lastly, the order of iodate adsorption capacity within the ternary system was as follows: Mg-based, Mn-based, Co-based, Cu-based, and Ni-based. Furthermore, 70% of the ternary system showed an improvement in adsorption capacity compared to simple binary cases, underscoring the importance of expanding the high entropy LDH system. Moreover, the exploration of high entropy LDHs might be the role of precursors for expansion into the high entropy oxide research area.

11:45 AM SF01.06.05
Growth of High-Entropy Oxide Single Crystals by means of Floating Zone Technique Dongjoon Song and Alannah Hallas; The University of British Columbia, Canada

The high-entropy materials (HEMs) have been dealt with as a new play ground of the material engineering, since the functionality of the materials is expected to enhance by controlling the new degrees of freedom. Also, the field flips traditional condensed matter physics paradigms on their head by seeking to understand what properties arise in the presence of profound configurational dis[1]order. However, the fundamental physics governing these materials, including the true degree of configurational entropy, its role in stabilizing the structure, and its effect on other physical properties such as magnetism and electrical transport all remain open questions. A key roadblock towards achieving a deeper understanding of HEMs has been the inability to study these materials in single crystal form. Although the imperative to study HEMs in single crystal form are clear, many crystal growth methods are excluded because the synthesis of HEMs requires high levels of both thermodynamic and kinetic control. We suggest that floating zone growth is the optimal method to unlock this new frontier. In this talk, we will report several high-entropy oxide single crystals grown by the floating zone technique and discuss the advantages of this method in achieving high quality crystals of HEMs.

SESSION SF01.07: Machine Learning and Data Driven Approaches
Session Chairs: Scott McCormack and Simon Schweidler
Wednesday Afternoon, April 24, 2024
Terrace Suite 1, Level 4, Summit

1:45 PM *SF01.07.01
Accelerating Material Discovery of New High-Entropy Materials through High-Throughput Synthesis, Characterization and Machine Learning Methods Simon Schweidler[1], Anurag D. Khandelwal[1], Jan Schützke[1], Leonardo V. Valesco[2], Pascal Friederich[1], Markus Reischl[1], Ben Breitung[1], Horst W. Hahn[1] and Jasmin Aghassi-Hagmann[1]; [1]Karlsruhe Institute of Technology, Germany; [2]Universidad Nacional de Colombia Sede La Paz, Colombia

New materials are synthesized and optimized with the explicit intention of enhancing current state-of-the-art materials in various fields of application, addressing the continually growing societal demands. In this context, high-entropy materials (HEMs) offer a huge research area for the development of novel material compositions and potential applications, e.g. as electrodes in batteries or fuel cell or in the field of electrochemical catalysis.[1] Unlike "classical" materials, HEMs intentionally maximize configurational entropy by increasing the number of elements to reduce free formation energy and stabilize a single-phase crystal structure. In addition, the "cocktail effects" describing the interactions between different elements often lead to partially unexpected properties, which may affect potential application areas. Therefore, the advantage of using HEMs lies in the possibility of influencing their elemental composition and electronic structure through the choice of design parameters. This flexibility offers the possibility to create materials with unique surface properties by changing the size of the e.g. catalytic centers and/or the electronic structure, as well as by selectively creating defects (e.g. oxygen vacancies). However, exploring the vast compositional space of high-entropy materials in a conventional approach, i.e., one experiment at a time is prohibitive in terms of cost and time. Consequently, the development of high-throughput experimental methods supported by machine learning and

theoretical predictions will facilitate the search for HEMs in their compositional diversity. This talk will therefore focus on the establishment of automated high-throughput methodologies in the field of synthesis and characterization for metallic and non-metallic (ceramic) HEMs, allowing the creation of material libraries of material properties.[2–4] This facilitates the analysis of material properties in terms of the overall composition, the effect of individual elements, morphological and/or structural differences. Machine learning-based data analysis and theoretical approaches also provide opportunities for virtual development of novel materials for functional and structural applications.

High-Entropy Oxides for Electronic Applications: Present and Future Jasmin Aghassi-Hagmann, Ben Breitung, Yueyue He, Hongrong Hu and Anurag D. Khandelwal; Karlsruhe Institute of Technology, Germany

HEMs represent a class of materials characterized by the incorporation of a minimum of five distinct elements within a single-phase lattice structure. This incorporation serves to elevate configurational entropy, a measure of entropy arising from the mixing of dissimilar elements, thereby engendering the emergence of unique material properties. There exist various subtypes, with high-entropy alloys and high-entropy ceramics being the most prominent among them. While alloys are typically unified within a single lattice structure, ceramics exhibit a more complex arrangement, often comprising multiple sublattices, including cationic and anionic sublattices. Consequently, when evaluating configurational entropy, one must scrutinize these sublattices independently. The combination of dissimilar elements or ions, characterized by disparities in size, electronegativity, and other factors, induces lattice distortions and intricate inter-element interactions. This interplay initiates a cascade of electronic, physical, chemical, and structural effects within the material.
Given that the synthesis of many high-entropy materials typically results in powders, and the production of well-ordered crystalline layers is possible only in specific cases or with significant effort, a structuring technique capable of yielding the desired results with powders is imperative.
This presentation introduces printing techniques as a versatile technique for structuring high-entropy materials and delves into current applications in electronic devices and systems. More specifically the talk will discuss the properties of semiconducting high entropy oxides as revealed by Hall mobility measurements of flurite structures. While the mechanism is still unknown we show that mobility can be improved by the number of constituent elements. These materials can have a great potential for high performance absorbance layers. As a second example we will show HE Metal organic frameworks (HEMOFs) displaying interesting properties as active materials in memristive devices. Wet chemistry approaches at room temperature are used to fabricate Prussian blue HE MOFs with at least five different elements. The HE MOFs can easily be inkjet printed and keep their molecular structure after pattering which is important for device fabrication.
In conclusion we believe that while many mechanisms underpinning the enhancement of various properties remain to be discovered, there exist great prospects for employing high-entropy materials as active materials in components of electronic systems

Enhanced Electrical Conductivity caused by Phase Transformation and Interfacial Segregation in an Entropy Stabilized Oxide Hasti Vahidi, Alexander Dupuy, Benjamin Lam, Justin Cortez, Pulkit Garg, Timothy Rupert, Julie Schoenung, William J. Bowman and Huiming Guo; University of California, Irvine, United States

Research on entropy stabilized oxides (ESOs) has primarily focused on exploring new structures, chemistries, dislocations [1], or unique properties. However, few studies discuss the impact of secondary phases on functionality. Here, electrical transport mechanisms in the canonical ESO (Co,Cu,Mg,Ni,Zn)O were assessed as a function of secondary phase content [2]. When single-phase, the oxide is a small polaron electronic conductor. After heat treatments, Cu-rich tenorite particles form at grain boundaries, which enhances the grain interior rocksalt oxide electronic conductivity due to increased Cu cation vacancies and compensating small hole polarons. While Cu depletion tailors grain interior the conduction mechanism, Cu-rich tenorite grain boundary phases create a pathway for Cu^{2+}/Cu^{3+} small hole polarons after longer heat treatment times. The ability to selectively grow secondary phases nucleated at grain boundaries enables tuning of electrical properties in entropy-stabilized and complex concentrated oxides using microstructure design, nanoscale engineering, and heat treatment, paving the way to develop many novel materials.

Functional High Entropy Oxides: From Electronic to Magnetic Properties David Berardan, Adrien Moll, Claudia Decorse and Nita Dragoe; University Paris-Saclay, France

Since their first report by Rost et al. in 2015 [1], Entropy Stabilized Oxides and High Entropy Oxides (HEOx) have become a hot topic in the field of functional oxides, with many papers devoted to the synthesis of new compositions and structures and to the study of various functional properties.
In the past few years, many compositions have been obtained with different crystal structures, with both entropy-stabilized and thermodynamically stable compounds. Some of them exhibit promising functional properties, among other: superionic Li conductivity or fast ionic conductivity, colossal dielectric constants, photocatalytic properties, unexpected magnetic ordering, (...). Although no clear link has been made to date between these properties and the possible role of entropy-stabilization (or even high-entropy nature), cocktail effects have been reported in some cases with functional properties of the multicomponent compounds significantly different from that of their single-cation counterparts.
In this talk, I will give an overview of the electronic and magnetic properties of various systems studied in our group, and discuss the perspective they open for applications.

Entropy-Stabilized Oxide Memristors Sieun Chae[1], Sangmin Yoo[2], Emmanouil Kioupakis[2], Wei Lu[2] and John T. Heron[2]; [1]Oregon State University, United States; [2]University of Michigan, United States

Memristor arrays have emerged as a promising hardware platform for efficient machine learning tasks. Traditional amorphous oxide-based memristor materials, however, suffer from device stochasticity and a lack of tunability which hinder applications requiring adaptive networks. Here I will present a study on tunable carrier transport and dynamics in single crystalline (MgCoNiCuZn)O entropy-stabilized oxide (ESO) thin films. We find that the ESO undergoes composition tunable hopping conduction in agreement with the composition dependent point defect formation and electronic structure from first principles calculations. Notably, the transport is bulk and non-filamentary. Pulsed measurements reveal a low resistance state with a short, composition-tunable retention time that can be harnessed for memristor function via temporal data processing. We interpret the carrier dynamics in terms of voltage modulated filling of deep level defects states that are controlled by composition as predicted by theory. The precise tunability of carrier transport in this ESO make it an excellent candidate for "task specific" neural network systems with record energy efficiency for temporal data processing.

SESSION SF01.09: High Entropy Perovskites
Session Chairs: Alan Farhan and T. Zac Ward
Thursday Morning, April 25, 2024

8:30 AM *SF01.09.01
Element Sensitive Characterization of High-Entropy Oxide Perovskite Thin Films Alan Farhan; Baylor University, United States

Employing the entropy-driven stabilization concept into the perovskite structure showed first promising results demonstrating the potential unlimited freedom in designing ferroic properties in high-entropy oxide perovskite (HEOP) thin films [1]. Here, I will show how element-sensitive characterization with x-ray absorption spectroscopy (XAS), employing x-ray magnetic circular- and linear dichroism (XMCD and XMLD) can shed light into how each transition metal element contributes to the overall ferroic order in HEOP thin films with a primary focus on rare-earth-based $R(Ni_{0.2}Co_{0.2}Fe_{0.2}Mn_{0.2}Cr_{0.2})O_2$ (R: Tb, Lu and Dy). The results highlight the important role of elevated Co^{2+} concentrations, likely iduced via strain, in introducing long-range ferromagnetic order [2, 3] and the occurrence of spin-reorientations in Dy-based HEOPs [4].

Growth and Characterization of High Entropy Perovskite $(La_{0.2}Nd_{0.2}Gd_{0.2}Sm_{0.2}Y_{0.2})MnO_3$ Thin Films on Cubic and Orthorhombic Substrates Maximilian Mihm, Aladin Ullrich, David Stein, Christian Holzmann, Helmut Karl and Manfred Albrecht; Institute of Physics, University of Augsburg, Germany

With the discovery of high entropy oxides in 2015 many different oxides have been synthesized using the high entropy strategy [1]. Since 2018 many different high entropy perovskites have been synthesized, some of them contain five elements on the A- or the B-site [2]. Some high entropy perovskites were synthesized with ten different elements, five on the A-site and five on the B-site [2]. Most of them were produced as polycrystalline powders, only a few oft them have been grown as thin film [2-5]. In the recent research, the focus has shifted to high entropy manganites-perovskites, because of their interesting magnetic properties, where the Mn-O-Mn exchange dominates the magnetic properties and the rare earth ion radii influences the strength of the exchange [3,4]. One high entropy manganite-perovskite is $(La_{0.2}Nd_{0.2}Gd_{0.2}Sm_{0.2}Y_{0.2})MnO_3$ which was previously produced as a powder [2].
We have grown thin films of $(La_{0.2}Nd_{0.2}Gd_{0.2}Sm_{0.2}Y_{0.2})MnO_3$ via pulsed laser deposition on three different substrates, one with a cubic structure $SrTiO_3$ (001) and two with an orthorhombic structure, $NdGaO_3$ (001), and $YAlO_3$ (001). All films were subsequently annealed. X-ray diffraction data confirmed epitaxial growth of $(La_{0.2}Nd_{0.2}Gd_{0.2}Sm_{0.2}Y_{0.2})MnO_3$ on all substrates. Wide-range reciprocal space mapping and electron-backscattered diffraction revealed,

that $(La_{0.2}Nd_{0.2}Gd_{0.2}Sm_{0.2}Y_{0.2})MnO_3$ has three different crystal orientations on $SrTiO_3$ and two on $NdGaO_3$ and $YAlO_3$. On $SrTiO_3$ $(La_{0.2}Nd_{0.2}Gd_{0.2}Sm_{0.2}Y_{0.2})MnO_3$ grows in two different directions (001) and (110). The (001) orientated crystals are rotated by 45° with respect to the substrate, while the (110) crystals are aligned either to the substrate lattice or are also rotated by 45°. On $NdGaO_3$ we observed only (001) orientated crystals, but with two different in-plane orientations, either (001) or (110). On $YAlO_3$ two crystal orientations were observed (110) and (001), both are aligned to the substrate lattice. High-resolution transmission electron microscopy confirmed the perovskite structure and the epitaxial growth. All surfaces showed a grainy structure which was observed by atomic force microscopy. Zero-field-cooled and field-cooled measurements revealed a magnetic transition temperature around 38 K for $(La_{0.2}Nd_{0.2}Gd_{0.2}Sm_{0.2}Y_{0.2})MnO_3$ grown on $SrTiO_3$, which is lower compared to most of the parent compounds. This is in good agreement with the magnetic measurements on corresponding powder. Below 25 K the rare earth elements couple antiferromagnetic to the manganese, which is indicated by a decrease of the magnetization in the field-cooled curve. All samples showed a small coercive field and a small remanent magnetization, which indicates a soft magnetic behaviour.

Synthesis and Characterization of Multifunctional High-Entropy Perovskite Oxides Rubayet Tanveer, William J. Weber and Veerle Keppens; University of Tennessee, United States

The scientific community has taken a keen interest in perovskite oxides (ABO_3) due to their unique electrical, magnetic, thermal, and optical characteristics with diverse potential applications. The addition of compositional diversity or “high entropy” in these oxide perovskites with five or more cations on a given lattice site offers the opportunity for property engineering by taking advantage of the high compositional disorder, large lattice distortion tunability, huge mass fluctuation, expansion in cation size variance and integration of diverse cation species <!--[endif]----->[1-3]. High entropy perovskites have the potential to revolutionize applications in areas including energy storage, electronics, and photonics, however, designing such compositionally complex multifunctional perovskite oxides is challenging and needs to take into account several factors, including e.g. cation choice for property integration, tolerance factor of the desired structure, high mixing enthalpy, and changing oxidation states. Herein, we present the synthesis of a group of new entropy-stabilized perovskite oxides with a series of alkaline and rare earths on the A site and five transition metals on the B site in equimolar amounts. Such compositions are interesting due to their high cation size variance, and diversity in cation species. Energy dispersive X-ray spectroscopy (EDS) and room temperature X-ray diffraction (XRD) were used to confirm the elemental distribution and single-phase compositions. Electrical, magnetic, and optical properties will be presented for various cation combinations to explore possible multifunctionality.

Vacancy-Ordered Halide Perovskites for High Entropy Semiconductors Seán R. Kavanagh[1], Shanti Liga[2], Aron Walsh[3], David O. Scanlon[4] and Gerasimos Konstantatos[2]; [1]Harvard University, United States; [2]ICFO–The Institute of Photonic Sciences, Spain; [3]Imperial College London, United Kingdom; [4]University of Birmingham, United Kingdom

Due to their quasi-0D / molecular-aggregate type crystal structure, vacancy-ordered double perovskites (VODPs) with the chemical formula A_2BX_6, exhibit unusual material properties associated with both zero-dimensional and three-dimensional materials.[1–4] These include low thermal conductivity, high compressibility, and strong exciton binding despite relatively small semiconducting band gaps, making them potential candidates for a range of alternative applications, such as thermoelectrics, white-light emitters/phosphors, photocatalysts, non-linear optics and more.

In this study, we report a combined experimental and computational investigation on the mixing behavior of cations in this system. Remarkably, we find ultra-low enthalpic costs to cation mixing, resulting in entropy dominance and ideal mixing behavior. This facilitates the room-temperature and low-temperature synthesis of high-entropy materials (high-entropy semiconductors) from these compounds, as demonstrated experimentally by Folgueras et al in *Nature*, 2023.[5] We elucidate the underlying structural and electronic origins of this facile cation miscibility in these systems, and analyze the resulting optical, thermodynamic and structural changes upon cation mixing.

Our work demonstrates that vacancy-ordered perovskites present an exciting new class of high-entropy semiconductors, synthesisable at much milder conditions than typical high-entropy materials. Moreover, we elucidate the origins of this behavior, allowing the extraction of general design rules for high-entropy semiconductors with tailored properties.

An Insight into The Functional Properties of High-Entropy Perovskite Oxides Anurag D. Khandelwal, Piyush Sharma, Simon Schweidler and Ben Breitung; Karlsruher Institut für Technologie, Germany

In recent years, there has been a surge of research interest in high entropy materials, driven by the potential to engineer their functional properties. High entropy materials, with their diverse elemental compositions, exhibit distinctive characteristics compared to conventional materials due to the intricate interplay of inter-elemental interactions, some of which cannot be predicted.

Among these materials, oxide perovskites stand out as a versatile material class with applications ranging from catalysis and solid-state fuel cells to oxide solar cells, rendering them particularly captivating for high-entropy investigations. Noteworthy studies have already shown the exceptional performance of high-entropy perovskite oxides in critical applications such as electrochemical catalysis, high-energy-density capacitors, and thermoelectric systems. The extensive array of perovskite systems, coupled with the immense spectrum of high-entropy cation combinations within them, opens up a vast domain of possibilities for such diverse applications.

In this talk, a comprehensive study of lanthanum-based perovskite-type oxides containing various compositions of transition elements (Co, Cr, Cu, Fe, Mn, Ni and Zn) at the B site is given, with the aim of studying the effects of the different cations on the properties of these materials. Various analysis techniques are used to characterize the optical and electronic behavior of these materials and thus enable further optimization for specific applications.

10:30 AM *SF01.10.01
High-Pressure Synthesis of High-Entropy Spinel-Type Semiconducting Manganates and Perovskite-Type Ferroelectric Niobates Ayako Yamamoto[1], Haruka Yokoyama[1], Tomoki Nakayama[1], Riki Maeda[1], Kimitoshi Murase[1], Anna Laila[1], Yann-Andrev Kerneur[2] and Nita Dragoe[2]; [1]Shibaura Institute of Techology, Japan; [2]Université Paris-Saclay, France

We have studied high-entropy (HE) chalcogenides[1] and oxides prepared at high pressure. The high-pressure method has several advantages in stabilizing HE compounds; for example, enclose the volatile elements and quick-quench from high temperature. Here, we report our recent study on HE spinel-type manganates as a thermistor and HE perovskite-type niobates, possibly as ferroelectric relaxors.

We focused on $NiMn_2O_4$ as a pristine that is a typical NTC (Negative Temperature Coefficient) thermistor compound. $NiMn_2O_4$ and partially (minor component) substituted ones show proper resistivity for monitoring temperatures between 300–500 K in various electric devices. The efficiency of a thermistor is evaluated with the B constant (corresponding to sensitivity) in general. Most commercial ones show B = 3,000–4,000 K. Our objective of this HE-spinel project is to expand the temperature range up to 700 K while keeping B = 3,000–4,000 K by controlling temperature dependence of resistivity with the HE techniques.

Two types of crystal systems appear in AMn_2O_4 (A=Mg, Co, Ni, Cu, and Zn) spinel: cubic in A=Ni and Co and orthorhombic in A=Mg, Cu, and Zn. It is interesting to see which structural system is stable in HE spinels and how to change a temperature dependence of resistivity depending on the composition and structure. We mixed up equal molar selected 2–5 elements among Mg, Co, Ni, Cu, Zn, plus Ti in assuming A site. $TiMn_2O_4$ could not be stabilized in spinel since tetravalent Ti in ilmenite-type $MnTiO_3$ and rutile-type TiO_2 are stable in the ambient condition. However, we expected Ti would be included in the spinel structure with the HE stabilized effect if we were starting from TiO with divalent in a closed golden cell of high-pressure synthesis assembly. We prepared a single phase of tetragonal spinel (Mg, Co, Ni, Zn, Ti)Mn_2O_4 with sintering at high pressure (4 GPa) and quenched from ca. 1250 K to 350 K in several seconds. In contrast, samples sintered in the air were a mixture of tetragonal and cubic phases or two sets of tetragonal phases, whether quench (liquid nitrogen) or slow cooling. The temperature dependence of resistivity showed semiconducting behavior with B= 5,000–5,500 K at 300-700 K. In addition, resistivity's absolute value is higher than conventional ones, an advantage in sensitivity at higher temperatures. Ti may be located in the B site, and part of Mn moved to the A site. The Cu version (Mg, Co, Ni, Zn, Cu)Mn_2O_4 showed lower B=3,000 K at 300-700 K and lower resistivity. The properties look sensitive to cooling processes and oxygen deficiency. We are also preparing A and B double sites' HE spinel.

Another HE project is to obtain a ferroelectric relaxor in perovskite-type niobates. $ANbO_3$(Li, Na, K, and Ag) are well-known ferro(antiferro)electric compounds. Structure types and or distortion types of these compounds differ depending on the A element; however, they allow partial substitution of each other. For example, in $KNbO_3$, Li and Ag could be substituted 5-10 % of K, and $NaNbO_3$ makes a complete solid solution with $KNbO_3$. In this study, we adapted $KNbO_3$ as a pristine and prepared HE niobates with equal molar selected 2–5 elements among Li, Na, K, Ag, and others in A site at ambient and high pressure. The high-pressure method effectively suppresses alkaline metals' vaporization (Li, Na, and K). We found $LiNbO_3$ is more stable in a $LiNbO_3$-type structure at high pressure. Therefore, equal molar HE compounds may be challenging in this system. Once it stabilized in a single phase, even if Li concentration is lower than other metals, it expected a ferroelectric relaxor in the temperature dependence of dielectric constant.

We also present our progress in XAS and XPS studies in HE pyrite (Fe, Co, Ni, Cu)X_2 (X = S and Se). It investigates a local configuration and interaction difference by comparing A element in a single metal AX_2 (A=Fe, Co, Ni, and Cu).

11:00 AM SF01.10.02
Influence of Synthesis Method on The Properties of The Spinel High Entropy Oxide Mario Ulises Gonzalez Rivas[1], Solveig S. Aamlid[1], Megan R. Rutherford[1], Edgar E. Villalobos-Portillo[2], Hiram Castillo-Michel[2], Ronny Sutarto[3], Ning Chen[3], Robert J. Green[4] and Alannah Hallas[1]; [1]University of British Columbia, Canada; [2]European Synchrotron Radiation Facility, France; [3]Canadian Light Source, Canada; [4]University of Saskatchewan, Canada

Understanding and controlling sample dependence is a critical step towards any material achieving widespread use in applications. High entropy oxides (HEOs) are a class of materials with immediate potential for an array of applications but whose sample dependence has the potential to be particularly profound due to their high degree of configurational disorder. In this work, we seek to clarify the extent of sample dependence in HEOs by directly comparing the structural, magnetic, and electronic properties of an HEO with the spinel structure synthesized by five distinct methods. These methods (solid state, high pressure, hydrothermal, molten salt, and combustion) each provide distinct levels of kinetic and thermodynamic control in the growth process. The spinel HEO’s ferrimagnetic structure was determined from neutron diffraction, whilst the site distribution of the cations in each sample was calculated using x-ray absorption spectroscopy. This thorough structural and magnetic characterization allowed us to identify the likely origins of variation in the magnetic behavior of our samples. We find that while distinct differences in homogeneity, sharpness of the magnetic ordering transition, and cation

distribution are apparent, the most technologically important properties, including ordering temperature (» 400 K) and saturated moment (» 1.8 μB/F.U.), are highly robust to preparation method, with the most extreme cases remaining within 10 % of one another. On the other hand, we observe a 500% variation in the sharpness of the onset of magnetic order between the most and least spatially homogenous samples. Likewise, we observe a 250% variation in coercive field, highlighting the effect of spatial homogeneity in the properties of HEOs. We conclude that this overall robustness to synthesis method make HEOs excellent candidates for a variety of industrial processes.

11:15 AM SF01.10.03
Rapid Synthesis of Entropy Stabilized Oxides Using Radio Frequency Heating Aniruddh Vashisth; University of Washington, United States

Entropy-stabilized oxides (ESOs) represent an exciting new category of hybrid materials and single-phase metal oxides, composed of multiple ions, exhibiting material characteristics that lie between those of their constituent oxides or occasionally showcasing entirely novel properties. One drawback of ESOs is their energy expensive manufacturing process, which has hindered the pace of their development and scaling. In this study, we introduce an innovative, energy-efficient method for synthesizing ESOs. This approach leverages the rapid heating capability of carbonaceous materials when exposed to radio frequency (RF) fields within the 1–200 MHz range. By employing carbon fibers and graphene as RF susceptors, we successfully achieved the synthesis of $(MgCoNiCuZn)_{0.2}O$ through RF-triggered combustion synthesis, achieving heating rates of 203°C/s with a 20 W input power. This technique reduces the ESO formation time to less than a minute, significantly enhancing fabrication efficiency. The morphology and composition of the resultant ESO-carbon fiber and ESO-graphene composites were comprehensively examined using spectroscopy and characterization techniques. Moreover, single carbon fibers coated with ESO underwent testing for tensile strength and modulus, revealing minimal changes in mechanical properties compared to pristine fibers. In this study, for the first time, a new method for producing ESO-carbon composites has been demonstrated using out-of-oven electromagnetic heating using radio frequencies in the range of 1–200 MHz at low input power (less than 25 W).

11:30 AM SF01.10.04
High-Entropy Spinel Ferrite Nanoparticles via Low-Temperature Synthesis for The Oxygen Evolution Reaction Judith Zander, Julia P. Wölfel and Roland Marschall; University of Bayreuth, Germany

High-entropy oxides are a material class that is currently receiving rapidly increasing attention due to the large variety in composition and adjustable properties. Cooperative effects between different metal cations in the crystal structure in addition to entropic phase stabilisation have proven beneficial for electrocatalytic applications. Most synthesis methods, however, require high synthesis temperatures and long synthesis times, and often only yield selected samples in good phase-purity.
We herein present for the first time a microwave-assisted low temperature synthesis of earth-abundant high-entropy oxide nanoparticles. Phase-pure spinel ferrites (AFe_2O_4) of various compositions ranging from one to seven different A-cations were successfully obtained after only 30 min synthesis time at 225 °C. A detailed characterisation of their properties in relation to their composition was performed, and they were also employed for the alkaline oxygen evolution reaction (OER).
A partial replacement of Fe by Co moreover shows the high versatility of the synthesis that also allows for the simultaneous variation of the B-ion.

11:45 AM SF01.10.05
Designing Nanostructure Exsolution-Self-Assembly in a Complex Concentrated Oxide Huiming Guo[1], Christopher Mead[2], Marquez Balingit[1], Soham Shah[3], Xin Wang[1], Mingjie Xu[4], Ich Tran[4], Toshihiro Aoki[4], Jack Samaniego[1], Kandis Abdul-Aziz[3], Lincoln J. Lauhon[2] and William J. Bowman[1,4]; [1]University of California, Irvine, United States; [2]Northwestern University, United States; [3]University of California Riverside, United States; [4]Irvine Materials Research Institute (IMRI), United States

Complex concentrated oxides (CCOs) are an emerging material class that includes high-entropy oxide (HEOs) and entropy-stabilized oxides (ESOs), whose unprecedented properties stem from disorder-induced distributions in electronic structure and chemistry caused by stabilizing many-cation (typically > 5) solid solutions[1-3]. Integrating these materials into composites with nanoscale tunability will enable tailored (multi)functionality beyond what is possible in a single phase[4-6]. Here, we demonstrate a novel, highly extensible approach, *exsolution self-assembly* (ESA), to realize CCO-based nanocomposite thin films with intricate multi-element nanostructures. Using pulsed-laser deposition (PLD), we selectively reduce cations in a model perovskite CCO $LaFe_{0.7}Ni_{0.1}Co_{0.1}Pd_{0.05}Ru_{0.05}O_{3-\delta}$, inducing defect-interaction-driven exsolution and simultaneous self-assembly of metal nanorods and metal-oxide core-shell nanoparticles, depending on oxygen partial pressure (P_{O2}). A correlated analysis using aberration-corrected scanning transmission electron microscopy (STEM) imaging, energy dispersive X-ray spectroscopy (EDS), electron energy-loss spectroscopy (EELS), geometric phase analysis (GPA) strain mapping, atom probe tomography (APT) with 3D mass spectrometry, and X-ray photoemission spectroscopy (XPS) was performed to characterize the ESA nanostructures and elucidate the nanostructure formation mechanisms underlying the highly tailorable synthesis approach.

With decreasing P_{O2} from 3 mtorr, 0.15 mtorr, to 0.015 mtorr, concentration of oxygen vacancy increases, which tunes the extent of exsolution for different ESA nanostructures. At P_{O2} of 3 mtorr, the $LaFeO_3$-based CCO thin film matrix shows uniform cation distribution. When P_{O2} drops to 0.15 mtorr, ESA Pd nanorods grow from bottom of the thin film to top surface, with growth restricted by compressive stress exerted by the matrix in the in-plane direction and Pd availability in surroundings. When P_{O2} further reduce by 10 times to 0.015 mtorr, Pd-$Ni_xCo_{1-x}O$ metal-oxide core-shell nanoparticles embedded in the matrix form via seed growth effect triggered by growth of Pd followed by subsequent exsolution of Ni^{3+} and Co^{3+} in the CCO matrix. ESA is expected to synthesize complex and multi-dimensional nanostructures for electrochemical devices via integration of novel compositions and crystal structures of CCOs as well as PLD conditions.

1:30 PM *SF01.11.01
Entropy-Maximized Materials for Catalysis Applications Sheng Dai[1,2]; [1]Oak Ridge National Laboratory, United States; [2]The University of Tennessee, Knoxville, United States

Until recently the design and synthesis of heterogeneous catalysts have been dominated through enthalpic factors (e.g., charge-charge interactions, charge-transfer interactions). With emergence of high entropy materials (HEMs), another avenue to design and synthesize catalytic materials has opened up. The definition of HEMs is any material that consists of the solid solution of more than five components that allow great flexibility in tuning surface compositions and interfacial functionalities. Here we present the synthesis of high entropy electrocatalysts that potentially outperform the traditional catalysts in energy-related catalysis reactions. The synthesis strategies through entropy maximization will be discussed.

2:00 PM SF01.11.02
Sol-Gel-Derived Ordered Mesoporous High Entropy Spinel Ferrites and Assessment of Their Photoelectrochemical and Electrocatalytic Water Splitting Performance Marcus Einert[1], Arslan Waheed[1], Stefan Lauterbach[1], Maximilian Mellin[1], Marcus Rohnke[2], Lysander Wagner[2], Julia Gallenberger[1], Chuanmu Tian[1], Bernd Smarsly[2], Wolfram Jaegermann[1], Franziska Hess[3] and Helmut Schlaad[4]; [1]Technical University of Darmstadt, Germany; [2]Justus-Liebig-Universität Giessen, Germany; [3]Technical University Berlin, Germany; [4]University of Potsdam, Germany

With the introduction of high-entropy oxides (HEO) as a novel class of materials, unexpected and interesting properties have emerged and are currently under investigation. A HEO consists of five or more ions occupying a single crystallographic site and inducing a high degree of configurational disorder, which increases the entropic contribution to the Gibbs free energy of formation. This extra gain of energy stabilizes the formation of single-phase structures showing unique and, so far, unpredictable properties. Significant efforts have been devoted to the development of new HEO phases; however, the large majority of synthetic approaches are based on solid-state, rather than sol-gel chemistry allowing only the preparation of micrometer-sized, low-surface-area particles.

With respect to sol-gel synthesis, the precise control of hydrolysis and condensation reactions of the complex precursor is important in order to form uniform structures. The whole reaction system becomes even more complex when an additional component – such as a structure-directing agent – is added. This intricate interplay of reactants, such as control of reaction kinetics, is most likely the reason why the sol-gel preparation of highly ordered mesoporous HEO thin films by the well-established soft-templating and evaporation induced self-assembly (EISA) approach has not been reported yet.

For the first time the design of periodically ordered mesoporous high-entropy-assisted (CoNiCuZnMg)Fe2O4 spinels prepared by dip-coating and EISA process is reported. A synthetic route was developed, utilizing the unique diblock copolymer (poly(ethylene-co-butylene)-block-poly(ethylene oxide), known as KLE, in order to obtain periodically ordered and 15−18 nm sized mesopores within the high-entropy ferrite (HEF) network. The mesostructured HEF electrodes were found to be crack-free on the nano- and macroscale. Time-over-flight secondary ion mass spectrometry (ToF-SIMS) and electron microscopy analysis verified a homogenous distribution of all elements within the thin film structure. The mesoporous HEF electrodes were used to study the fundamental impact of a nanoscale framework on the electrocatalytic and photoelectrochemical properties. Hence, the HEF electrodes were investigated as oxygen evolution catalyst and n-type photoanode for solar water oxidation. For both applications the near-metallic electric conductivity, which was related to an electron hopping mechanism induced by the interaction of 3d-states of the inserted transition metals, was found to improve the performance. The photoresponse of HEF photoanodes is limited owing to severe surface recombination as evidenced by intensity-modulated photocurrent spectroscopy.
This novel high entropy oxide class can be considered as interesting candidate and nanostructure for energy applications where high surface-areas offering a large number of (catalytically) active reaction sites are advantageous. [1]

Size Controlled Monodisperse Alloy Nanocrystals via Colloidal Synthesis, from Medium to High Entropy and Their Excellent Catalytic Properties Jasper Clarysse, Yunhua Xing and Vanessa Wood; ETH Zürich, Switzerland

High entropy alloy (HEA) nanocrystals (NCs) are solid solutions of 5 or more elements, while medium entropy alloy (MEA) NCs are solid solutions of 2 to 4 elements. Entropy alloy nanocrystals are an emerging class of materials which show intriguing properties such as enhanced resistance to oxidation and mixing of immiscible elements within nanocrystals. Furthermore, HEA NCs have recently been demonstrated as catalysts in various important reactions (e.g., water splitting and oxygen reduction reaction) with record or near-record activities, attributed to “synergistic” and “cocktail” effects originating from the combination of multiple metals within the NCs. Yet, the exact structure-activity relationships, leading to the excellent performance of high-entropy alloys in applications such as catalysis remain poorly understood. Furthermore, no synthesis method for highly monodisperse and size-controlled medium and high entropy alloy NCs exists yet. Here we show the colloidal synthesis of highly monodisperse entropy alloy NCs [1-2], employing oleylamine as a suitable reaction solvent and non-poisoning L-type ligand. Furthermore, we extend our synthetic method to achieve MEA NCs constituting of non-precious, environmentally benign metals (e.g., Ni-Zn) and we report the first size-tunable synthesis of HEA NCs (e.g., 1.8 nm, 2.5 nm, and 3.5 nm HEA NCs) [3]. The synthesis method is facile and easily scalable. We demonstrate that the resulting nanocrystals possess size-dependent catalytic properties and exhibit better catalytic performance compared to monometallic nanocrystals. We achieve MEA and HEA nanocrystals with excellent catalytic properties and study these for different reactions (e. g. semihydrogenation of alkynes and hydrogen-evolution reaction). We understand the crystallographic and electronic structure of the nanocrystals using a range of advanced characterization techniques (high resolution transmission electron microscopy and synchrotron-based X-ray diffraction, total X-ray scattering and X-ray absorption spectroscopy) and using density functional theory calculations and reveal the relationships between catalytic performance and structure of the MEA and HEA NCs.

Entropy-Inspired Materials Design for Novel Electronic Materials: $A_6B_2O_{17}$-Form (*A* = Zr, Hf; *B* = Nb, Ta) Oxides Robert J. Spurling and Jon-Paul Maria; The Pennsylvania State University, United States

In this work, we apply an entropy-inspired materials design approach to study the class of compositionally complex, disordered $A_6B_2O_{17}$ (*A* = Zr, Hf; *B* = Nb, Ta) family of phases. The availability of multiple local coordination sites on the cation sublattice coupled with substantial tolerance for extended chemical solubility makes this a unique system for studying the interplay between configurational entropy (controlled across multiple structural hierarchies) and properties. This work focuses on both the thermodynamic consequences of configurational entropy on phase stability as well as property characterization, with particular focus on dielectric and candidate ferroelectric behavior. This work spans studies in both the bulk and thin film regimes. First, we confirm the stability of ternary and quinary $A_6B_2O_{17}$ phases at high temperatures as well as substantial inherent cation sublattice disorder; moreover, we observe enhanced solid solubility in multi-constituent systems commonly associated with high-entropy material behavior. We develop a sintering procedure for producing dense ternary $A_6B_2O_{17}$ phases for use as both sputtering targets for thin film preparation and bulk dielectric measurements. Furthermore, we characterize the effect of sputter deposition conditions (i.e. O_2 partial pressure and total pressure) on film quality (crystallinity, roughness, and density); we also relate these parameters to observed dielectric performance. Collectively, this study leverages a range of advanced characterization techniques, including both *ex situ* and *in situ* X-ray diffraction, scanning electron microscopy, atomic force microscopy, and X-ray photoelectron spectroscopy. These results support continued interest in such unique structures with substantial configurational entropy and suggest new opportunities for research probing structure-property relationships in high-entropy systems.

2:45 PM SF01.11.05
Computational Design and Experimental Validation of Ductile Refractory Metal-Based High Entropy Materials Kate Elder[1], Brandon Bocklund[1], Adam M. Krajewski[2], Joel Berry[1], Benjamin Ellyson[1], Connor Rietema[1], Jibril Shittu[1], Hunter Henderson[1], Alexander A. Baker[1], Thomas Voisin[1], Scott McCall[1], Aurelien Perron[1] and Joseph McKeown[1]; [1]Lawrence Livermore National Laboratory, United States; [2]The Pennsylvania State University, United States

The vast design space of high entropy materials allows the tuning of designer materials with enhanced properties. The subset of high entropy materials consisting of refractory metals with a body centered cubic (BCC) structure are known to maintain a high yield strength at elevated temperatures. However, just tailoring refractory metal-based high entropy materials to be strong and BCC stable is insufficient and ductility, which is challenging to model, must be incorporated into any alloy design process. Ductility models are compared with experimental compression and elongation data to determine which model accurately predicts ductility in refractory metal-based high entropy materials. Through analytical calculations, we investigate high entropy alloys from the Hf-Mo-Nb-Ta-Ti-V-W-Zr element palette to identify ductile candidates and understand which compositional combinations, with varying entropy, lead to novel properties. The design strategy is then expanded to rapidly explore the space of high order non-equiatomic refractory metal-based high entropy materials by leveraging machine learning and high-performance computing capabilities. Selected compositions predicted to maintain high strength, BCC phase stability and acceptable ductility are manufactured and tested to validate the search for refractory metal-based high entropy materials with designer properties. Prepared by LLNL under Contract DE-AC52-07NA27344.

SESSION SF01.12: Thermal and Mechanical Properties of High Entropy Materials
Session Chairs: Lavina Backman and Scott McCormack
Thursday Afternoon, April 25, 2024
Terrace Suite 1, Level 4, Summit

3:30 PM *SF01.12.01
Synthesis and Characterization of High Entropy Carbonitrides Lavina Backman, James Tsai, Heonjune Ryou, Eric Patterson, Sara Mills, James Wollmershauser, Edward Gorzkowski III and Jesse Maxwell; US Naval Research Laboratory, United States

The high temperature (T>1700°C), highly chemically reactive environments encountered during hypersonic flight present unique design challenges for materials scientists. Requirements for these materials include melting temperatures greater than 3000°C, high thermal and dimensional stability, good thermal shock resistance, low reactivity and low coefficients of thermal expansion. Before 2015, less than 15 elements or compounds were considered to have the thermochemical stability to be viable material system candidates for this application and development of materials with coincident mechanical stability (e.g. ductility, toughness) has lagged. The recent advent of the high entropy design paradigm has expanded the composition space for UHTCs significantly and provided unprecedented tunability of mechanical and chemical properties. This is of particular interest for hypersonic vehicle designs requiring both high temperature oxidation resistance as well as maintaining structural and dimensional integrity to maximize aerodynamic performance. This presentation will review design strategies for performance in high temperature environments and discuss material system candidates, with a special focus on carbonitride high entropy ceramics. Experimental work on the synthesis and characterization of high entropy carbonitrides will also be presented.

4:00 PM SF01.12.02
Rapid Down-Selection of Novel High-Entropy Materials and Insights into their Characteristic Energy Scales from Temperature-Dependent Elastic Properties Christopher Mizzi[1], Tannor Munroe[1], Osman El-Atwani[2], Saryu Fensin[1] and Boris Maiorov[1]; [1]Los Alamos National Laboratory, United States; [2]Pacific Northwest National Laboratory, United States

High-entropy materials have generated much interest owing to their exceptional performance and high tunability. However, there are significant challenges in optimizing high-entropy compositions for tailored applications, such as in nuclear reactors, stemming from the immense size of the high-entropy design space. There is a pressing need for rapid, quantitative property assessments to identify promising high-entropy candidates, down-select compositions for further study, and provide experimental inputs to facilitate model development. One enticing property to examine in this context is elasticity. Elastic constants describe the extent to which materials resist elastic deformation, providing important information on mechanical performance as well as microscopic details about the nature of bonding and characteristic energy scales in materials. These features mean elastic constants naturally connect experiment and theory, making them prime candidates to serve as a benchmark for materials design, model development, and model validation.

In this talk, I will share elastic constant measurements on a range of refractory high-entropy alloys at ambient conditions to exemplify how elastic constants and ultrasonic attenuation can be used to rapidly identify promising high-entropy compounds for further study. Then, I use elastic constant determination down to 2K to explore the effects of composition on characteristic phonon energy scales (*e.g.*, Debye temperature), anharmonicity, and mechanical performance. These results are compared with theoretical predictions. Resonant ultrasound spectroscopy (RUS) is used for these experiments because of its ability to non-destructively determine the entire elastic constant tensor from a single measurement with high accuracy and precision. This approach, which entails extracting elastic constants from mechanical resonant frequencies, is amenable to all high-entropy materials, from metals to ceramics, compatible with any amount of crystalline anisotropy or texture, and capable of providing rapid feedback on novel high-entropy materials. As such, elastic constant determination with RUS is ideal to rapidly identify promising high-entropy materials, examine their functional properties, and determine key energy scales to incorporate in predictive models.

4:15 PM SF01.12.03
Critical Assessment of Mass and Lattice Disorder in Thermal Conductivity Prediction for Medium and High Entropy Ceramics Yuxuan Wang, Guoqiang Lan and Jun Song; McGill University, Canada

Medium and high entropy ceramics, with their distinctive disordered structures, exhibit ultra-low thermal conductivity and high temperature stability. These properties make them strong contenders for next generation thermal barrier coating (TBC) materials. However, predicting their thermal conductivity has been challenging, primarily due to their unique phonon scattering mechanisms. Apart from the conventional phonon-phonon scattering mechanism, the phonon-disorder scattering, comprising both mass and force disorder, are also expected to make significant contribution in determining the thermal conductivity of medium and high entropy ceramics. However, it remains challenging to quantify the phonon-disorder contribution, particular in the aspect of force disorder. Here we demonstrated a relationship between the lattice disorder, a quantity more readily calculable, with force disorder, rending it possible to substitute the force disorder by lattice disorder. Based on this relationship and drawing inspiration from Klement's equation of static imperfection, we have developed a model that quantitatively assess the connection between disorder and thermal conductivity. Applying our model to the medium/high entropy rocksalt and pyrochlore oxides as the representative, we found good alignment between the theoretical predictions and experimental measurements of thermal conductivities, confirming the validity of our model. The model developed offers a critical predictive tool for rapid screening of TBC materials based on medium and high entropy ceramics.

4:30 PM SF01.12.04
Local Chemical Fluctuation and Lattice Thermal Conductivity of High-Entropy Thermoelectric Materials Wu Wang, Shixuan Liu, Yan Wang and Jiaqing He; Southern University of Science and Technology, China

High-entropy materials, which consist of multiple elements occupying the same crystallographic site, have emerged as the promising materials for a variety of applications [1,2]. With the mutual interaction of different elements, local chemical fluctuation arises in high-entropy structures and largely enhances the properties of various materials included metallic alloys [3], Li-ion batteries [4], and catalysts [5]. Recently, this high-entropy strategy has also been applied to enhance the performance of thermoelectric materials with the combination of multiple elements [6,7]. The local chemical fluctuation could dampen the propagation of heat-carrying phonons and thus largely reduce lattice thermal conductivity of thermoelectric materials.

However, these studies of high-entropy materials have lacked the attention on the role of each constituent elements on local chemical fluctuation, which is crucial for tailoring the local chemical fluctuation by selecting specific element. Herein, we have identified the respective contributions of the element characteristics (atomic mass, radius, and electronegativity) on the local chemical fluctuation by determining atomic-scale distributions and concentrations of various elements in GeTe, SnTe and PbTe-based high-entropy thermoelectric materials. The electronegativity is found to have a comparable influence with the mass on the elemental fluctuations while the slight contribution is from the radius. The local chemical fluctuation is further tailored by selecting specific elements to induce large lattice distortion and strong strain fluctuation in the GeTe-based high-entropy materials for lowering lattice thermal conductivity independent of the increased entropy by adding more elements. With the comparison of GeTe-AgSbX (X=Sn, Mn and Pb) high-entropy materials, we have also identified the noticeable contribution of electronegativity difference to the lattice thermal conductivity in addition to the known effect of mass and size differences. Our findings of local chemical fluctuation and lattice thermal conductivity provide the basis for tuning the structure and property of high-entropy materials by selecting specific elements.

Investigating High Temperature Thermal Properties of Rare Earth Oxides for Thermal Barrier Coatings William T. Riffe, Hunter Schonfeld, Kristyn Ardrey, Prasanna Balachandran, Beth Opila, Patrick E. Hopkins and Saman Zare; University of Virginia, United States

Rare earth oxides (REOs) show promising thermal properties required of next generation thermal barrier coatings (TBCs) for ultrahigh temperature applications (1500 ºC+). TBCs mitigate conductive heating between hot components by reducing thermal conductivity through increased phonon-phonon scattering. New research aims to explore the fundamental mechanisms for this reduction and explore other properties of interest such as melting temperature and emissivity.

In this work, we perform a series of thermal and optical studies via pump-probe thermoreflectance, laser radiometry, and spectroscopic ellipsometry to elucidate temperature-dependent thermal properties of REOs. With a novel laser-based metrology, thermal conductivities, melting temperatures and emissivities of ceramics over 2000 ºC can be measured nondestructively. Understanding these trends is of utmost importance in choosing REOs that can endure cycling to operating temperatures. Additionally, through ellipsometry, the lifetimes of optical phonons can be understood. Anharmonic scattering dominates thermal transport at high temperatures so measuring lifetimes with changing temperature is important to understand fundamental energy transport in REOs. By investigating pertinent physical scattering mechanisms at relevant temperatures, we deconvolute key design considerations for next generation TBCs.

SESSION SF01.13: High Entropy Carbides, Borides, and Silicates
Session Chairs: Theresa Davey and Scott McCormack
Friday Morning, April 26, 2024
Terrace Suite 1, Level 4, Summit

8:30 AM *SF01.13.01
First-Principles Calculations of Structural Transitions within Multi-Principal Component Transition Metal Carbides Theresa Davey[1,2] and Ying Chen[2]; [1]Bangor University, United Kingdom; [2]Tohoku University, Japan

High-entropy or multi-principal component ultra-high temperature ceramics (UHTCs), such as rocksalt structured MC_{1-x} (where the cation M is an equiatomic or non-equiatomic mixture of metallic elements including Ti, Zr, Hf, Nb, and Ta, and the anion C is carbon), have recently generated significant interest due to their potential improved or tuneable properties such as melting point, hardness, ductility, and oxidation resistance. The single metallic element UHTC carbides, such as zirconium carbide, are known to have a wide range of stoichiometry facilitated by significant numbers of carbon vacancies (up to around 50% of the carbon atoms), where in different parts of the phase space, the vacancies exhibit long-range ordering, short-range ordering, or are randomly distributed. Until now, there have been no systematic investigations varying carbon stoichiometry in multi-principal cation carbides, either experimentally or theoretically.

Individually, all the MC_{1-x} carbides have a tendency to form long-range vacancy-ordered phases at low temperature, although these are extremely challenging to experimentally synthesise. In single cation transition metal carbides (e.g. ZrC_{1-x}, HfC_{1-x}), the short- and long-range carbon vacancy ordering is driven by differing local bonding surrounding different vacancy cluster configurations. However, similar but slightly different trends are observed in group IV and group V transition metal carbides, resulting in different symmetries, for example low temperature M_2C (M = Ti, Zr, Hf) has a cubic Fd-3m structure, whereas M_2C (M=Ta) has a trigonal P-3m1 structure.

This work uses first-principles calculations to explore multiatomic mixing (binary, ternary, quaternary, and quinary) on the metallic element lattice at different carbon stoichiometries. Within this, disordered vacancies, and various vacancy-ordered structures were considered. Special Quasirandom Structures (SQS) were generated for each composition, to provide a supercell approximation of random mixing. Density functional theory (DFT) calculations were used to obtain the ground state energy and structural and electronic properties. The atomic bonding is investigated, and trends are identified by considering the local atomic environments and cluster configurations.

The effects that the multi-principal cation lattice has on the carbon vacancy ordering on the anion lattice are explored, at absolute zero and considering finite temperature effects. The most stable crystal structures are identified for various multi-cation systems at different carbon stoichiometries. Miscible and immiscible mixtures are identified, where approximate temperatures of miscibility gaps are determined using the Bragg-Williams configurational entropy approximation for ideal mixtures. The tendency for phase separation is compared in equivalent composition multi-cation vacancy-disordered and vacancy-ordered carbides. Approximate order-disorder transition temperatures are obtained for mixed-cation substoichiometric carbides and compared with the miscibility gaps in the same system. On this basis, the possibility of synthesising certain vacancy-ordered multi-principal cation compounds is revealed, alongside the required range of synthesis temperatures.

9:00 AM SF01.13.02
Computational Investigation into Synthesis of Transition Metal Borides Himanshu Shekhar and Aravind Krishnamoorthy; Texas A&M University, United States

Borides of transition metals and high-entropy alloys offer novel opportunities to design materials that demonstrate phase stability, high strength, and thermal oxidation resistance at high temperatures and under extreme conditions. Identifying mechanically strong and chemically inert transition metal borides requires an understanding of the synthesizability of different transition metal borides, as well as their mechanism of growth during boriding of such metals. We performed *ab initio* Density Functional Theory simulations to quantify phase stability, formation energies of point and extended defects, and point defect migration barriers in crystalline borides of transition metals and their alloys. A point defect model based on the computed defect concentrations and ionic mobilities was used to explain the experimentally observed thicknesses of boride films formed by the boriding of different transition metals and alloys. Thermodynamic (formation energies and stability) and kinetic (energy barriers and mobilities) data from these ab initio simulations were also used to create a graph neural network model for the screening of compositional phase space of high-entropy borides to identify promising candidates with high phase stability and synthesizability.

9:15 AM *SF01.13.03
Predicting The Synthesizability and Properties of Disordered Materials from First-Principles Cormac Toher; The University of Texas at Dallas, United States

The successful development and manufacturing of new materials, for applications ranging from wear resistant coatings for cutting tools and thermal protection barriers in aerospace engineering to new catalysts and photovoltaics, as well as materials for batteries and electronics, depends on computational thermodynamics to predict synthesizability and stability. Thermodynamic models for synthesizability must incorporate entropy, which is particularly important at high temperature for multi-element materials [1, 2]. Descriptors and thermodynamic models have been developed based on the thermodynamic density of states extracted from ensembles of ordered calculations in the AFLOW repository [3, 4] to predict the synthesizability of new disordered materials such as high entropy carbides [5, 6]. Similar methods are now being combined with machine-learning to investigate high-entropy rare-earth silicates for thermal and environmental barriers in gas turbines [7].

9:45 AM SF01.13.04
***In-Situ* SEM Tensile Characterization of High Entropy MXenes** Yuxiang Gan, Congjie Wei, Jiaoli Li and Chenglin Wu; Texas A&M University, United States

The synthesis of high-entropy (HE) MXenes as a new emerging member of the MXene family was reported by implementing four transition metals. The resultant HE MXenes, $TiVNbMoC_3T_x$ and $TiVCrMoC_3T_x$ have great potential in the thermoelectricity, magnetic, and superconductivity fields due to their diverse compositions. The stability and reliability of these applications largely depend on the mechanical properties of HE MXenes. However, the tensile strength as a critical factor for its practical strength in engineering applications has not been investigated. In this paper, we employed an in-situ push-to-pull device under a scanning electron microscope (SEM) to measure the load-displacement data of suspended HE MXene films and observed an exciting tensile behavior during crack extension. When the number of HE MXene layers in a stack changes, the tensile strength variations can be recorded. Additionally, the crack tip behavior after fracture testing can be observed by transmission electron microscopy (TEM). Our combined experiment and modeling investigations have revealed that the tensile strength of HE MXene is much higher than that previously observed in MXene and other 2D Materials stacks. HE MXene can serve as an excellent structural reinforcement for multi-scale composite materials, as well as for other applications in which robust mechanical performance is required.

10:00 AM BREAK

SESSION SF01.14: High Entropy Intermetallics and Alloys
Session Chairs: Alannah Hallas and Cormac Toher
Friday Morning, April 26, 2024
Terrace Suite 1, Level 4, Summit

10:30 AM SF01.14.01
Boron Interstitial and Boride Strengthened Grain Boundary for Toughening Refractory High-Entropy Alloys Ping-Hsu Ko, Ya-Jing Lee and Shou-Yi Chang; National Tsing Hua University, Taiwan

Refractory high-entropy alloys exhibit a high mechanical strength and an excellent structural stability at elevated temperatures, and are of great potential for applications to aerospace and nuclear power components. However, the drawback of poor grain boundary cohesion and consequent early brittle interganular fracture renders their practical applications limited. According to the literature, boron interstitials (or borides) have been verified to improve the cohesion strength of grain boundaries and thus the ductility of some intermetallic compounds such as nickel aluminide(s). Introducing boron interstitials (or forming multicomponent borides) particularly at grain boundaries was hence considered in this study for enhancing grain boundary cohesion and toughening refractory high-entropy alloys. A very small amount (0.1 at.%) of boron was added in arc-melted $Hf_xMo_{0.5}NbTa_xTiV_{1.5-x}Zr_x$ refractory high-entropy alloys, and the microstructure, compositions and crystallographic orientations of the alloys were characterized. Macroscale compressive tests were conducted for measuring the stress-strain response of the alloys, and micropillar compressive tests and indentations were carried out for measuring the strength of grains and grain boundaries. Microstructure observations indicated that elemental boron was uniformly distributed in the refined single-phase, solid-solution grains, while some nanosized boride particles were dispersed at the grain boundaries. With the addition of boron, the hardness of weak grain boundaries (about 5.0 GPa) was markedly improved to the equivalent level of grain interiors (about 6.2 GPa). While the yield strength of the boron-added alloys did not change (about 1450 MPa), the ultimate compressive strength effectively increased from 1690 to 2240 MPa at a higher work hardening rate. The compressive strain increased from 20-25% to 35-40%, attributable to the inhibited boundary decohesion-caused brittleness as the distinct transition of interganular-to-transgranular fracture. Micropillar compression tests suggested that the grain boundaries of the alloys without boron early decohered at a stress of below 700 MPa, whereas those with boron did not fracture even after the adjacent grains yielded. Owing to the high charge density-enhanced grain boundary cohesion, the boron-added alloys also showed a high structural stability at elevated temperatures, with a retained strength of 1190 and 990 MPa at 600 and 800°C, respectively.

10:45 AM SF01.14.02
Predictive Modelling of The Structure and Phase Stability of High-Entropy Materials: Case Study of $Al_xCrFeCoNi$ Christopher D. Woodgate[1], Laura H. Lewis[2,2] and Julie Staunton[1]; [1]University of Warwick, United Kingdom; [2]Northeastern University, United States

Advancing both fundamental understanding and technological application in the rapidly developing field of high-entropy materials, computational-forward modelling approaches are an important tool to help guide experiment. Starting from a given combination of constituent elements, we would like to be able to predict a material's crystal structure, its thermodynamic stability, as well as the nature of emergent atomic short- and long-range order, as this will enable us to go on to predict subsequent macroscopic materials properties. Here we present results from a first-principles-based, all-electron Landau theory which has previously been used with success to study the Cantor alloy and its derivatives [1,2], as well as the refractory high-entropy alloys [3]. We study the $Al_xCrFeCoNi$ system for $0 \leq x \leq 2$ and demonstrate successful reproduction of the experimentally observed crystal structure and phase behavour of this material. We successfully predict the A1+B2 coexistence region of the phase diagram, explain the lack of observation of an atomically disordered A2 phase, and give insight into the preferred low-temperature atomic arrangements. As the methodology is first-principled, we are able to explain ordering tendencies in terms of materials' underlying electronic structure, and pull out qualitative rules to explain ordering tendencies in these complex systems.

Thin Film Combinatorial Sputtering of TaTiHfZr Compositionally Complex Alloys for Rapid Materials Discovery Reece Emery, Stephen B. Puplampu, Dayakar Penumadu, Eric A. Lass, Shakti P. Padhy, Zachary Sims and Philip D. Rack; The University of Tennessee, Knoxville, United States

Combinatorially sputtered thin films can be leveraged as a rapid, materials discovery process in mechanical alloy design. $Ta_wTi_xHf_yZr_z$ thin films were synthesized via combinatorial sputtering from pure Ta, Ti, Hf, and Zr targets. The substrate was not rotated to generate compositional gradients where $12.4<w<71.6$, $6.40<x<55.6$, $4.22<y<58.8$, $7.25<z<48.9$ over a 100 mm diameter substrate. The crystal structure, phase fraction, film morphology, mechanical (i.e. modulus and hardness), optical (i.e. n and k), thermal (i.e. phase stability, CTE, and thermal conductivities), and corrosion properties (i.e. corrosion current and rates) are all correlated to the $Ta_wTi_xHf_yZr_z$ composition. Temperature dependent x-ray diffraction (TDXRD) reveals the thermal stability of the material system. TDXRD has shown the as-deposited material library is primarily stable in a single HCP phase below 60 at. % Ta at room temperature but will form increasing amounts of a BCC phase at elevated temperatures. Nanoindentation of as-deposited films shows good agreement between experimental, solid solution estimations of hardness via a simple rule of mixtures from bulk elements, and correlated to a few up-scaled bulk samples. Thin film modulus shows good agreement with bulk rule of mixture estimations after accounting for thin film substrate effects via King's correction. As-deposited and annealed film properties are compared. Compositions with an optimal combinations of the aforementioned properties were then upscaled to bulk materials for further investigation.

Accelerated Discovery of Structural Materials for Harsh Environments Rameshwari Naorem[1,2], Hailong Huang[1], Gaoyuan Ouyang[1], Prashant Singh[1], Duane D. Johnson[1,2], Jun Cui[1], Ryan T. Ott[1], Iver E. Anderson[1,2], Nicolas Argibay[1] and Brandon Krick[3]; [1]Ames Laboratory, United States; [2]Iowa State University of Science and Technology, United States; [3]Florida A&M University, United States

Multi-principal-element alloys (MPEA) have emerged as a promising group of advanced materials with unprecedented combinations of mechanical properties compared to conventional alloys. Materials that can tolerate harsh environments and retain high strength at elevated temperatures are needed to enable greater efficiency in applications including nuclear reactors, hydrogen combustion turbines, bearings, and hypersonic vehicles. We will present results from materials design efforts focused on refractory alloys that rely on high-throughput synthesis and characterization methods like additive manufacturing, tribology-based mechanical testing, and electronic-structure modeling. Discussion topics will include rapid screening of thermomechanical properties using surface (scratch)-based techniques to assess hardness, fracture toughness, and tensile ductility. We will also present preliminary results from composition tailoring of MPEA to understand and control the impacts of hydrogen exposure on selected refractory MPEAs and to develop alloy design criteria for mitigating hydrogen embrittlement.

Bridging the Gap between Modeling and Characterization to Unravel Short-Range Order and Properties of Si-Ge-Sn-Pb Alloys Shunda Chen, Xiaochen Jin and Tianshu Li; George Washington University, United States

Group IV concentrated alloys composed of Si-Ge-Sn-Pb are promising candidates for mid-infrared photonics owing to their tunable band gaps, low-cost, and CMOS-compatibility. Although group IV alloys have been long conceived as a random solid solution, our recent ab initio-based statistical sampling predicted substantial short-range order (SRO) behaviors in group IV alloys [1–4]. The structural complexity was further shown theoretically to yield a substantial impact on the underlying electronic[1–3], topological[4], and transport properties of group IV alloys. Although SRO may have a complicated implication on material quality, it also opens an emerging opportunity for engineering SRO to harvest new functionalities that are challenging to achieve through traditional heterojunctions. Emerging characterization evidence based on EXAFS[5], Raman[6], APT[7] and 4D-STEM support our prediction of SRO, but important questions need to be addressed regarding the actual structures, spatial domain size and its distribution, and corresponding changes in the properties of SRO, before a practical strategy can be employed. The explicit answers to these questions require synergistic efforts from both characterization and modeling. Here I will discuss our ongoing theoretical effort to close the gap between theory and characterization to enable deciphering the fine structural details of complex alloys. We have developed a highly accurate, highly efficient machine-learning potential (MLP) based on neuroevolution potential framework for group IV system. The developed MLP is shown to reach a DFT-level accuracy by exhibiting a root mean squared error of energy < 1 meV/atom with respect to the DFT training data set and more importantly, enables a side-by-side comparison with APT and 4D-STEM on the same scale. Using this development, we discovered the spatial structural heterogeneity in group IV alloys. In particular, we show that structural details at a fine level, as reflected by the distributions of both atomic SRO parameter and spatial SRO domains, are vital for the underlying electronic structures of group IV concentrated alloys.

Fabrication and Characterization of Two-Dimensional High-Entropy Sulfides and Tellurides Yingchao Yang; University of Missouri, United States

Since the discovery of graphene monolayers by mechanical exfoliation in 2004, many other two-dimensional (2D) materials have been synthesized, such as transition metal dichalcogenides (TMDs), hexagonal boron-nitride (*h*-BN), black phosphorous. Another category of materials, high entropy alloys (HEAs) are constructed by the combination of multiple principal elements at an equimolar or near-equimolar fraction. HEAs offer an extensive combinatorial space facilitating superior functionalities that are generally lacking in conventional alloys composed only of one or two principal elements.
The combination between 2D materials and HEAs results in a new 2D high-entropy materials (2D HEMs). Even though 2D HEMs has significant potential towards catalysis and energy storage, the rationale and criterion for designing 2D HEMs and demonstration of feasibility in synthesizing 2D HEMs are still missing.
In this presentation, we will demonstrate the successfully synthesized five-metal-element sulfide and tellurides. Sulfides have been synthesized through

chemical vapor deposition (CVD) method and tellurides have been obtained via the conventional solid-state reaction (SSR) approach. Advanced characterization techniques have been performed to confirm that uniform element distribution and single phase 2D HEM have been achieved. The designed and fabricated 2D HEMs adds an exceptional family member to the fast-growing field of 2D materials.

High-Throughput Experimentation for The Exploration of High Entropy Materials: From Alloys to Oxides and Nitrides Alfred Ludwig[1,2,2]; [1]Ruhr-University Bochum, Germany; [2]Ruhr-Universität Bochum, Germany

Discovery of new materials is a key challenge in materials science. New materials for sustainable production/storage/conversion of energy carriers are necessary to improve existing and to enable future energy systems. Compositionally complex materials, frequently called high entropy materials, offer a vast multidimensional search space, which provides opportunities for discovering new materials. Next to alloys compounds such as oxides and nitrides are of interest. However, efficient methods for the exploration and exploitation of this multidimensional search space are necessary, especially as oxides and nitrides need more sophisticated synthesis methods such as reactive sputter deposition. Here, the integration of high-throughput thin-film combinatorial materials science methods with simulation and materials informatics (1) is presented as an effective means to produce large datasets on new materials, which enables mastering of this immense search space. The approach combines theoretical predictions from high-throughput computations with production of large, consistent and complete experimental datasets, which are used for materials informatics. Thin-film materials libraries are fabricated by (reactive) combinatorial sputter deposition and optional post-deposition treatments, followed by high-throughput characterization, and finally the organization of the acquired multi-dimensional data in adequate databases as well their effective computational analysis and visualization, e.g., of polyelemental systems in the form of composition-processing-structure-function diagrams, interlinking compositional data with structural and functional properties. The talk will discuss examples of high-throughput exploration of compositionally complex metallic solid solutions as well as oxide and nitride thin-film libraries for electrocatalysis and solar water splitting (2-7). In the case of compositionally complex perovskites, we recently discovered a new platform for materials discovery (8). Furthermore, a new approach (9) to accelerate atomic-scale measurements for complex materials and their oxidation (10) is presented.

Electrospun High-Entropy Spinel Oxides as Catalysts for as Electrocatalysts for Oxygen Evolution in Alkaline Environment Saveria Santangelo; Mediterranea University, DICEAM, Italy

The generation of H_2 via the electrochemical splitting of water is a promising and sustainable technology. Nonetheless, the oxygen evolution reaction (OER) still represents the bottleneck of the process. Spinel-structured transition metal (TM) oxides have shown great potential as an alternative to platinum group metal-based electrocatalysts as they are Earth-abundant, inexpensive and stable. Among them, those based on the high-entropy concept, benefiting from the synergy among their multiple-metallic components, are in focus due to their interesting performance in various energy applications [1,2], including the OER in alkaline environment.
This contribution focuses on the case of electrospun spinel-type high-entropy oxide (HEO) nanofibers (NFs), which thanks to their granular architecture are suitable to the preparation of ink-jet printable OER electrocatalysts [3]. It presents the results of the evaluation of a large set of HEO NFs with oxygen-deficient surface as electrocatalysts in alkaline medium. HEO NFs based on different equimolar TM combinations, are prepared under different calcination conditions and characterized by a combination of benchtop analytical techniques to investigate the complex and interdependent changes in the morphology of the fibers, crystallinity and inversion degree of the spinel oxide, concentration of the oxygen-vacancies, cation distribution in the lattice produced by the variation of HEO composition and calcination temperature (400-900 °C) and to identify the relationships with the different electrochemical properties of the fibers. The electrocatalytic performance of HEO NFs are discussed in terms of the most common descriptors, namely outer 3*d*-electron number, e_g filling and occupation of 16*d* sites.

Autonomous Discovery of Triple-Conducting High-Entropy Oxides for Protonic Ceramic Fuel Cells Ivano Eligio Castelli; Technical University of Denmark, Denmark

We develop and implement an autonomous multi-fidelity computational workflow to explore the chemical space of high-entropy perovskite oxide materials with general formula ABO_3, screening for stable, high-performance cathodes for low-temperature protonic ceramic fuel cells. The workflow, implemented in the framework of Density Functional Theory (DFT), is based on the calculation of thermodynamic, electric and kinetic properties, which include phase and electrochemical stability, electronic conductivity, and ionic diffusivity. To accelerate the calculation of the kinetic properties, we employ accelerated methods that leverage recent advances in machine learning for materials science to predict transition barriers for ionic diffusion. The

computational cost of the workflow is additionally decreased while retaining the quality of results through a thorough examination of the required level of theory for all descriptive properties. Moreover, the aim is a general and chemistry-neutral approach that can be applied to other crystal prototypes and materials screenings.

Micro-Focused X-Ray Absorption Spectroscopy Studies of Plutonium Materials Sarah Hickam[1], Arjen van Veelen[1], Daniel Olive[1], Kasey Hanson[1], Raymond Atta-Fynn[1], Nicholas Edwards[2] and Samuel Webb[2]; [1]Los Alamos National Laboratory, United States; [2]SLAC National Accelerator Laboratory, United States

Synchrotron X-ray absorption spectroscopy (XAS) is an established technique for studying the local structure of plutonium materials, including oxides and metals. Modern imaging and high-resolution techniques provide detailed information that may elucidate questions regarding the fate of impurities with different Pu oxidation conditions and may also find utility in nuclear forensics investigations. Combining XAS with x-ray fluorescence (XRF) mapping provides the ability to quickly locate particles or areas of interest with up to 1 μm spatial resolution and then obtain local structure information from individual points. In this work, we apply micro-focused XRF+XAS techniques to the study of common impurities in plutonium oxides, such as gallium, iron, and nickel. We investigate the distribution and local structure of these impurities in plutonium oxides made from various synthetic routes, including corrosion and high temperature calcination of Pu metal. The results show that for some impurities, like Ga, local structure and distribution are highly dependent on processing conditions, such as temperature. We also discuss developments in micro-focused high energy resolution fluorescence detection (HERFD) XAS techniques and their applications to Pu particulate samples. Using a HERFD spectrometer significantly increases the resolution of the near-edge spectrum, providing greater confidence in oxidation state determination, and combining this technique with a micro-focused beam enables the generation of oxidation state distribution maps. Here, we present results for heterogeneous plutonium samples, demonstrating the utility of this technique for distinguishing between phases of interest (e.g. oxide and metal) and their distribution within a sample. Characterization using these advanced methods provides insight into impurity fate with plutonium processing and possible nuclear forensics signatures of plutonium materials.

11:00 AM *SF02.01.02
The Auger Parameter and Plutonium Paul Roussel; AWE, United Kingdom

The Auger parameter, α', the sum of the binding energy of the most prominent core level transition and the kinetic energy of the Auger transition, as measured in a single X-ray Photoelectron Spectrum, can afford chemical state / chemical fingerprinting, non / local screening and initial / final state information. The use of the Auger parameter and the related chemical state plot offer advantages over chemical state / environment determination from the shift in binding energy of a single core hole transition as both charge referencing / binding energy scale calibration and work function corrections are not required, such that data from different laboratories can be easily compared. In the area plutonium XPS there are three separate reports on the Auger parameter and the associated chemical state plots [1-3]. The first two reports [1, 2] have both utilised the Pu P_1VV X-ray induced Auger transition combined with the Pu $4f_{7/2}$ peak and are very similar demonstrating reproducibility as the data were acquire at different laboratories using different samples. However, the most recent report uses the Pu N_7O_5V Auger peak with the Pu $4f_{7/2}$ core level, and the results are distinctly different [3]. The first two reports show that the Auger parameter for PuO_2 is approximately 2 eV higher than plutonium metal which is extremely unusual, indicative of enhanced screening / extra atomic relaxation behaviour in the oxide compared to the metal. In comparison, the most recent report [3] indicate that plutonium dioxide has a remarkably similar Auger parameter to plutonium metal, albeit this is based on an extremely limited data set. The object of this presentation is to investigate this discrepancy and if possible, to explain the differences by evaluating the key assumption used in the Auger parameter of equal binding energy shifts for all core levels involved in the definition of the Auger parameter. To enhance understanding the of the Auger parameter involving the Pu N_7O_5V transition the data set used has been expanded which has resulted in a greater understanding to the factors involved in measuring the Auger parameter on plutonium materials.

11:30 AM SF02.01.03
Extraction of Branching Ratios from HERFD Data James G. Tobin[1], Sophie Nowak[2], Sw Yu[3], R. Alonso-Mori[2], T Kroll[2], D. Nordlund[2], T.C. Weng[2] and Dimosthenis Sokaras[2]; [1]University of Wisconsin-Oshkosh, United States; [2]SLAC National Accelerator Laboratory, United States; [3]Lawrence Livermore National Laboratory, United States

Historically, Branching Ratio measurements with X-ray Absorption Spectroscopy (XAS) and related techniques have played a key role in the advancement of the understanding of 5f electronic structure. [1] Specifically, the transitions utilized were the N_4 and N_5 of the actinide elements, with electrons being moved from the occupied 4d states into unoccupied 5f states. For soft x-rays, the peak separations are small, allowing the doublet peaks to be collected together, in a single spectrum. The intensity calibration is intrinsic, within some small variations such as those due to storage ring beam current decay and fluctuations and other higher order effects. For tender and hard x-rays, the peak separations tend to be larger, often requiring two separate spectra and some sort of new normalization, especially for High Energy Resolution Fluorescence Detection (HERFD) XAS spectra. It will be shown that the step heights in the EXAFS regime can be used as a cross calibration between the M_4 and M_5 spectra, if two well characterized cases can be used as controls. (EXAFS is Extended X-ray Absorption Fine Structure, typically about 20 eV or more above the white-lines (sharp, intense peaks) at threshold, e.g. the 5f peaks.) Thus, a quantitative analysis method has been developed that allows the cross calibration of separate Uranium M_4 and M_5 X-ray absorption spectra (XAS), in particular those collected with the new High Energy Resolution Fluorescence Detection (HERFD) method. With this method, it is now possible to generate experimental Branching Ratio (BR) values from the U $M_{4,5}$ XAS HERFD data.

Rosas[1], Donya Servando-Williams[1], Vanna Som[1], Nicholas Cicchetti[2], Alexander Ditter[3] and David K. Shuh[3]; [1]Lawrence Livermore National Laboratory, United States; [2]University of Nevada, Las Vegas, United States; [3]Lawrence Berkeley National Laboratory, United States

Nuclear forensics requires accurate identification of distinguishing material characteristics to delineate the material's origin-to-interdiction information. We developed the focused ion beam (FIB) methodology to reveal entrapped material clues such as internal morphological and chemical features within the surface/subsurface and bulk of nuclear materials. Our recent effort also established the capability of using the FIB-based micromanipulation technique to select, isolate, and extract a site-specific microscopic feature from bulk plutonium (Pu) and uranium (U) materials. Using a combination of scanning electron microscopy (SEM), transmission electron microscopy, three-dimensional (3D) spatial modeling, and synchrotron-based X-ray spectromicroscopy, we identified distinguishing morphological and chemical characteristics that are attributable to the material's provenances. Variations in the internal chemical composition and morphological structure were found to occur between materials from different origin, processing, and environmental exposures. The information is of potential use in identifying material characteristics related to the provenance, process, and pathways of interdicted nuclear materials.

SESSION SF02.02: Advanced Characterization

1:30 PM *SF02.02.01
Application of Ultra-High Temperature XAFS Measurement System for Actinide Materials Tsuyoshi Yaita; Japan Atomic Energy Agency, Japan

In order to clarify accident progression scenarios in the Fukushima NPP accident, it is essential to evaluate the behavior of fuel heated to high temperatures, and information on fuel behavior in the "ultra-high temperature region (around melting point)" is required. However, there is little information on the structural and electronic properties of actinides in this high temperature region. In this study, we developed a new measurement cell that enables high-temperature heating and constructed an in-situ observation system using synchrotron radiation XAFS and XRD to obtain information on the structure and electronic state of materials around the melting point. The validity of machine learning was also verified by comparison with the structural and electronic state information predicted by theoretical calculations using NN potentials. In this study, we mainly report the results obtained by synchrotron radiation analysis of yttrium-stabilized zirconia around the melting point as first step. The measurements were performed at the JAEA beamline BL22XU at SPring-8. The incident light intensity was measured with an ion chamber placed just in front of the sample, a CCD detector and imaging unit for X-ray diffraction, and a silicon drift detector for XAFS, each of which was placed horizontally displaced from the optical axis downstream or upstream of the sample, taking into account the position of the window in the measurement chamber. The heating system was a pulsed current heating furnace using W as the electrode, which is capable of performing structural analysis experiments up to ~3500K. In the radial structure function by XAFS, the distance of the first peak originating from Zr-O tends to shorten as the temperature increases, especially around 2000 K. This indicates a phase transition of zirconia, corresponding to the phase transition of zirconia from Tetragonal to Cubic. On the other hand, the second peak originating from Zr-Zr shows a trend of increasing distance as a whole, and the peak became so small that its order is almost unobservable near the melting temperature. The energy of the absorption edge also showed a tendency to shift to the lower energy side with the structural change due to the temperature increase.

Actinide Photosensitization in Macromolecular and Nanocrystal Hybrids Rebecca Abergel[1,2]; [1]Lawrence Berkeley National Laboratory, United States;

[2]University of California, Berkeley, United States

The small absorption cross sections ($\varepsilon < 10\ M^{-1}\ cm^{-1}$) characteristic of Laporte-forbidden transitions in the f-elements have limited the practical implementation of lanthanide and actinide nanoparticles in devices for applications ranging from solar capture to sensing. While various strategies designed to circumvent the problems of low f–f oscillator strengths have been investigated, comparatively little work has explored the utility of organic ligands with high absorption coefficients ($\varepsilon \approx 10^3–10^5\ M^{-1}\ cm^{-1}$) in sensitizing excited states in f-element macromolecules and nanocrystals. Our approach investigates actinide hybrid architectures, in which sensitization is achieved with aromatic antenna functioning as terminal light absorbers to convert light into luminescence with unusually high external quantum yields. In addition, chiral constructs allow for luminescence circular polarization for sensing applications and forensics determination. Energy transfer mechanisms in these actinide compounds and particles will be discussed, with an emphasis placed on the generality of this material architecture for realizing ligand-pumped, photon conversion and polarization.

2:30 PM SF02.02.03
Elastic Properties of Pu Alloys using Resonant Ultrasound Spectroscopy Boris Maiorov; Los Alamos National Laboratory, United States

Determining the elastic properties of Pu alloys and their changes as a function of temperature and time is a powerful tool to study thermodynamic and dynamic changes. Temperature dependence informs the nature of the free energy of the different phases, as elastic moduli are fundamental thermodynamic susceptibilities and connect directly to thermodynamics, electronic structure, and mechanic properties. Changes occurring as a result of self-irradiation change the elastic moduli and affect thermodynamic phase transitions. In turn, these changes are translated to changes in the hardness and brittleness of the compound. Similarly, sound attenuation provides information about dynamic processes such as dissipation associated with defect movement, annealing or re-crystallization. Thus, measurements of elastic moduli and sound attenuation help determine the origin of the phenomena found in ^{239}Pu and its Ga alloys. By measuring the mechanical resonance frequencies of a sample, the Resonant Ultrasound Spectroscopy (RUS) technique can extract with extreme precision and accuracy the elastic moduli without corrections. Using RUS we perform time- and temperature-dependent measurements of the mechanical resonance frequencies of polycrystalline Pu with different Ga concentrations. From these measurements, elastic moduli and the sound attenuation can be extracted. I will show the changes in elastic moduli and sound attenuation with time for samples with different ages and Ga concentrations.

2:45 PM SF02.02.04
Soft and Tender X-Ray Synchrotron Radiation Spectromicroscopy for Nuclear Forensics David K. Shuh[1], Alexander Ditter[1], Nicholas Cicchetti[1,2], Joe Brackbill[1,3], Artem Gelis[2], Rachel Lim[4], Shohini Sen-Britain[4], Debra L. Rosas[4], Alexander A. Baker[4], Scott Donald[4] and Brandon W. Chung[4]; [1]Lawrence Berkeley National Laboratory, United States; [2]University of Nevada, Las Vegas, United States; [3]University of California, Berkeley, United States; [4]Lawrence Livermore National Laboratory, United States

The development of new methods and signatures is crucial to ensure that nuclear forensics activities remain effective. Synchrotron radiation analysis offers one way to extend the scope of nuclear forensics investigations in elemental, chemical, and structural analysis which all can be done in imaging modes that in some cases, reaches to the nanoscale. X-ray techniques are particularly useful because of their elemental specificity and non-destructive nature. The ability to use tunable, focused beams makes synchrotron radiation sources a potentially key tool for addition into the array of characterization techniques currently employed, particularly when it comes to the investigation of particles or areas of interest in very small specimens.

There have been recent efforts at the Advanced Light Source (ALS) conducting tender and soft spectromicroscopy using primarily x-ray fluorescence and chemical speciation coupled with selective X-ray absorption near-edge structure (XRF and XANES; Beamline 10.3.2); and with a scanning transmission x-ray microscope (STXM; Beamline 11.0.2). The tender XRF/XANES measurements provide elemental analysis at the low-single micron scale, whereas the STXM can probe electronic structure with ligand K-edge spectroscopy and chemical speciation via XANES with a spatial resolution of better than 25 nm. Several uranium, plutonium, and along with other relevant specimens, from both particle-based systems and monoliths fabricated by focused ion beam (FIB) methods, have been investigated utilizing these specific aforementioned techniques. The potential signatures obtained from this data, as well as the significance of the results, will be presented and discussed. The outlook for synchrotron radiation within nuclear forensics including the strengths and drawbacks of these techniques will also be discussed.

DMFT Theory of Elemental Actinides and Their Compounds Gabriel Kotliar[1,2]; [1]Rutgers University, United States; [2]Brookhaven National Laboratory, United States

Elemental actinides and their compounds have for many years posed a challenge to the electronic structure field, as their physical properties are not well described within density functional theory and its variants due to strong correlations. Dynamical mean field theory, on the other hand, has explained and predicted many suprising experimental features of these systems, as it captures non perturbative correlation effects. We will describe some of these, such as spectral features and magnetic moments. We will then go into more depth about why these features arise because multiple energy scales (crystal field, spin orbit coupling, Hunds rule coupling, Hubbard U and kinetic energy) are all important and have to be taken into consideration, as well as how it affects the physics of these compounds. Examples of the successes of DMFT + electronic structure will be drawn from a large number of materials. These include nuclear fuels such as UO2, the phase diagram of elemental Pu and why its beta phase is the most correlated of all, superconductors, such as PuCoGa5 and UTe2, and ferromagnets such as UGe2.

4:00 PM SF02.03.02
Strain Dependence of Phonons in α-Uranium Mark Mathis and Chris A. Marianetti; Columbia University, United States

The phonons in orthorhombic α-uranium have been well studied due to the charge density wave state, yet a systematic study of the phonons as a function of strain has yet to be accomplished. Here we compute the phonons and anharmonicity in α-uranium using the irreducible derivative method, guaranteeing the

highest computational efficiency for a finite displacement method. Various functionals within density functional theory are used to study the change in phonons with respect to the lattice parameters, with particular focus on changes in the soft-modes. Soft phonon modes other than the mode associated with the charge density wave are also found, which have not yet been identified in previous studies. Quartic phonon interactions associated with all soft modes are computed, allowing for the computation of thermal expansion within the Hartree-Fock approximation for phonons. Our findings are compared with existing experimental data.

4:15 PM SF02.03.03
Hydrogen and Oxygen Gas Dosing on α-Plutonium Using Time-of-Flight Secondary Ion Mass Spectroscopy and Density Functional Theory Sarah C. Hernandez, Raymond Atta-Fynn and Connor Dozhier; Los Alamos National Laboratory, United States

Plutonium metal is highly reactive towards environmental gases by immediately forming an oxide layer when exposed to air and quickly forming a hydride when exposed to hydrogen. Previous work has shown that the monoclinic α-Pu phase readily oxidizes quicker than compared to the face-centered-cubic δ-phase. By using ToF-SIMS in conjunction with DFT calculations, we exposed α-Pu to hydrogen and oxygen gas to determine the reactivity. ToF-SIMS is a highly surface-specific analytic technique that probes <1nm of the surface and can determine impurities at parts-per-million levels and chemical speciation, including hydrogen. After H_2 and O_2 gas exposures of an Ar^+ sputtered cleaned α-Pu metal, there was no apparent reaction to H_2 for up to 180 Langmuir (L), where at ~20-30L of O_2 exposure oxide formation was evident. This is indicated by the relativity intensities of the negative Pu-O ion fragments being PuO_3^- > PuO_2^- > PuO^- as the surface is approaching a "PuO_2" state. The experimental observations were supported by DFT studies, which indicated that H_2 physisorbs on the α-Pu surface at 0 K independent of coverage and partially dissociates at high surface coverage at 300 K, whereas O_2 strongly reacts to form oxide layers at 0 K at both low and high surface coverage.

4:30 PM *SF02.03.04
Electronic Structure of Uranyl Complexes probed by Valence and X-Ray Spectroscopy Valerie Vallet[1], Hanna Oher[2], Wilken Aldair Misael[1], Richard Wilson[3] and Andre Severo Pereira Gomes[1]; [1]Universite Lille, CNRS, France; [2]Univ. Rennes, CNRS, ISCR, France; [3]Argonne National Laboratory, United States

This presentation will showcase the capabilities of relativistic quantum chemistry approaches in exploring the electronic structure of actinide-containing compounds. The focus will be on luminescence properties and core-level spectroscopic observables of the uranyl moiety (UO22+) within both linear and bent uranyl complexes. Given the challenges associated with nuclear waste management and the environmental impact of fission products, efficient extraction and characterization methods for actinide-containing compounds are of great societal importance.

The electronic structure of actinide compounds remains poorly understood compared to other elements in the periodic table. Valence- and core-level spectroscopic techniques offer valuable insights into this complex subject. The presentation will demonstrate how luminescence spectroscopy and X-ray spectroscopies serve as sensitive tools for probing the electronic structure and bonding nature between the uranyl moiety and its coordinated ligands.

Specifically, the talk will cover the application of relativistic Time-Dependent Density Functional Theory (TDDFT) with the CAM-B3LYP functional. This method has proven effective in providing accurate excitation/emission energies and vibronic progressions for linear uranyl complexes ($UO_2Cl_4^{2-}$, $UO_2F_5^{3-}$, $UO_2(CO_3)_3^{4-}$, $UO_2(NO_3)L_2$), enabling the assignment of experimental data [1]. Additionally, the impact of bending the uranyl moiety on spectroscopy and observed vibronic progressions will be discussed [2].

The presentation will also delve into TD-DFT simulations of the core spectra of the uranyl tetrachloride dianion ($UO_2Cl_4^{2-}$) in the $Cs_2UO_2Cl_4$ crystal. These simulations align with previously reported angle-resolved near-edge X-ray absorption spectroscopy (NEXAFS) at the oxygen K-edge and high-energy resolution fluorescence detected (HERFD-XANES) at the uranium M_4- and L_3-edges [3].

***Ab-Initio* Spin-Fluctuation Hamiltonian for Delta-Pu at Finite Temperatures** Babak Sadigh, Kyoung Kweon, Per Söderlind, Michael Surh, Lorin Benedict and Fei Zhou; Lawrence Livermore National Lab, United States

Spin/orbital-polarized density functional theory has been used extensively in the past years to explore materials properties of the Pu metal, from its polymorphic phase diagram to energetics of formation and migration of lattice defects and impurities in the various Pu phases. Calculations to date have been conducted using one or other static low-energy spin configuration. The effect of allowing for non-collinear spin/orbital fluctuations is yet largely unexplored. We have thus developed a novel technique that allows for efficient calculations of adiabatic non-collinear spin/orbital excitations within spin-constraint density-functional theory. We use this technique to extensively explore the potential energy landscape of adiabatic spin fluctuations in delta-Pu. Several families of low-energy non-collinear spin configurations are found. We construct an effective Hamiltonian for thermal spin fluctuations in delta-Pu and study its statistical mechanics via Monte Carlo simulations. We report the impact of spin/orbital fluctuations on the structure and magnetic susceptibility of delta-Pu at finite temperatures.

This work was performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344.

9:00 AM SF02.04.02
Studying The Initial Corrosion of δ-Plutonium Through Density Functional Theory Charles H. Fricke and Sarah C. Hernandez; Los Alamos National Laboratory, United States

In this work, we will present results of density functional theory on the initial corrosion of δ-plutonium (Pu) due to hydrogen, oxygen, and water. We will explore the kinetics and energetics of water splitting on δ-Pu(100) and δ-Pu(111). Atomic oxygen and hydroxyl species are found to be strongly bound to the surface, with binding energies on the order of -2.2 eV for oxygen and -1.6 eV for the hydroxyl, when referenced to the chemical potential of water. In addition, we find that water and hydrogen have negative binding energies, but that the adsorption Gibbs free energies are highly sensitive to gas pressure and temperature variation. In the presence of water and oxygen gases, the metallic surface of the material is irreversibly coated in atomic oxygen, with energetic barriers for water splitting and oxygen dissociative adsorption low at room temperatures and pressures. A kinetic model was also developed, and when applied, oxygen is found to adsorb onto the surface close the experimentally defined Langmuir coverage for oxygen and plutonium surfaces. In addition, since hydrogen and oxygen are precursors to hydride corrosion and oxide formation, respectively, we will present results on surface to near-surface and bulk behavior of atomic hydrogen and oxygen. We find that the surface sites for oxygen and hydrogen are energetically preferred over the subsurface and bulk sites. Out of the two different interstitial sites in δ-Pu, the octahedral is significantly more stable that the tetrahedral interstitial site for oxygen and hydrogen. Gibbs free energies and the Sieverts constant for hydrogen will also be explored for these systems and compared to experimental values.

9:15 AM SF02.04.03
***Ab Initio* Studies of The Interaction of H with Pu_6Fe** Raymond Atta-Fynn and Sarah Hernandez; Los Alamos National Laboratory, United States

The corrosion of plutonium (Pu) by hydrogen (H) is rapid, however the mechanisms which dictate the hydride formation process is not fully understood. Iron (Fe) is a common impurity in Pu and segregates to the grain boundaries and triple points to form the intermetallic compound Pu_6Fe. To understand the role played by Pu_6Fe in the hydride formation process, density functional theory was employed to compute the energetics and electronic structure of H in interstitial and vacancy sites in Pu_6Fe. H binding was exothermic, with binding energies around -0.4 to -0.2 eV/H atom. With the aid of ab initio molecular dynamics, the interstitial diffusion of H was modeled and the crystal structure for bulk Pu_6Fe hydride was predicted. The role played by the Pu 5f electron states in the hydride formation process will be elucidated.

9:30 AM *SF02.04.04
***Ab Initio* Heavy Element Composite Methodologies** Bradley Welch[1], Sasha North[2], Nuno Almeida[1] and Angela K. Wilson[1]; [1]Michigan State University, United States; [2]Adrian College, United States

Providing the correct qualitiative description much less achieving quantitative accuracy for the prediction of energetic properties can become challenging for the lanthanides and actinides due to increasing computational costs and, typically, increasing complexity of the methodologies required. Developments by our group and applications that have provided insight about both energetic predictions for species of the lower part of the periodic table and the theoretical strategies used for the predictions will be highlighted. Specifically, we will discuss the heavy element correlation consistent Composite Approach (*f*-ccCA) and the super correlation consistent Composite Approach (s-ccCA), which have been designed for elements of the lower perioidic table. These methods are build upon the main group and transition metal correlation consistent composite approaches, which have been effectively utilized for many hundreds of species. Successes and challenges in describing heavy elements will be overviewed.

10:30 AM *SF02.05.01
Piezomagnetism in Uranium Dioxide: Actinide Science at High Magnetic Fields Krzysztof Gofryk[1], Marcelo Jaime[2], Daniel Antonio[1], Zahir Islam[3], Myron Salamon[4], Andres Saul[5], Rico Schönemann[4] and James Smith[6]; [1]Idaho National Laboratory, United States; [2]Physikalisch-Technische Bundesanstalt, Germany; [3]Advanced Photon Source, United States; [4]National High Magnetic Field Laboratory, United States; [5]Centre Interdisciplinaire de Nanoscience, France; [6]Los Alamos National Laboratory, United States

The spin-lattice coupling in uranium dioxide remains an unsolved puzzle resulting from the lack of a thorough understanding of the strong coupling between 5*f*-electron magnetism and lattice vibrations. Besides being the main nuclear fuel material, UO_2 is a Mott-Hubbard insulator with well-localized 5*f*-electrons (U^{4+} electronic configuration) and its magnetic state is characterized by a non-collinear antiferromagnetic structure of 3***k*** type and multidomain Jahn-Teller distortions. In the magnetic state, a UO_2 single crystal subjected to strong magnetic fields exhibits the abrupt appearance of positive linear magnetostriction leading to a trigonal distortion and piezomagnetism. This is the first example of piezomagnetism in the *f*-electron spin system. The unusually strong correlations between the magnetic moments in U-atoms and lattice distortions are a direct consequence of the non-collinear symmetry of the magnetic state that breaks time-reversal symmetry in a non-trivial way. The microscopic nature of these interactions, however, remains unclear. During the talk, we will demonstrate how detailed thermodynamic and structural measurements, performed in high and ultra-high magnetic fields, can be used to study these interactions and their couplings. We will discuss the implications of these results in the context of the origin of the piezomagnetic ground state in this material.

11:00 AM SF02.05.02
Strain-Driven Switching between Distinct Antiferromagnetic States in Frustrated Antiferromagnet UO_2 Evgenia Tereshina-Chitrova[1], Leonid Pourovskii[2,3], Sergii Khmelevskyi[4], Lukas Horak[5], Thomas Gouder[6] and Roberto Caciuffo[7]; [1]Institute of Physics, Czech Academy of Sciences, Czechia; [2]École Polytechnique, Institut Polytechnique de Paris, France; [3]Collège de France, Université PSL, France; [4]Vienna Scientific Cluster Research Center, Vienna Technical University, Austria; [5]Faculty of Mathematics and Physics, Charles University, Czechia; [6]European Commission, Joint Research Centre (JRC), Germany; [7]National Institute for Nuclear Physics, Italy

In materials containing magnetic atoms arranged in geometrically frustrated lattices, various magnetically ordered states can possess comparable energies with respect to the inter-site antiferromagnetic (AFM) exchange interactions. The concept of geometric frustration often intersects with broader phenomena in condensed matter physics, such as quantum spin liquids, topological states, and critical behaviour [1]. In recent decades, there has been a growing interest in intentionally manipulating magnetic states in collinear antiferromagnets, motivated by advancements in AFM spintronics [2]. In our study, we

demonstrate the fundamental potential to control spin orientations in frustrated antiferromagnets, pawing the way for their utilization in realms of spintronics.
Our research focuses on the interplay of magnetic and exchange anisotropy effects in artificial heterostructures based on a canonical frustrated **3-*k*** antiferromagnet, UO_2. We demonstrate that effective switching between the AFM states of different symmetries can be achieved by stretching the lattice of UO_2. The phenomenon is probed experimentally using the exchange bias (EB) effect in stoichiometric UO_2/Fe_3O_4 bilayers. By employing many-body first-principles calculations based on the charge self-consistent Hubbard-I approximation [3,4] we identify magnetic configurations in the UO_2 layers. We show that a minor tetragonal distortion induces a transition between antiferromagnetic states of different symmetries, driven by appearance of a robust single-ion anisotropy. This impacts the arrangement of magnetic moments at the UO_2/Fe_3O_4 interface and thus influences the magnitude of exchange bias. Our findings showcase how epitaxial strain enables the manipulation of antiferromagnetic states in frustrated antiferromagnets by controlling single-site anisotropy.

Thermal Expansion of α-U at Low Temperatures Volodymyr Buturlim[1], Xiaxin Ding[1], Sabin Regmi[1], Chris M. Marianetti[2], Michael Manley[3], Jason Jeffries[4] and Krzysztof Gofryk[1]; [1]Idaho National Laboratory, United States; [2]Columbia University, United States; [3]Oak Ridge National Laboratory, United States; [4]Lawrence Livermore National Laboratory, United States

Uranium is one of the only elemental metals in which charge density waves have been observed (the phases are labeled α_1, α_2, and α_3). The first transition takes place at 43 K (α_1), the second at 38 K (α_2), and the last one stabilizes below 25 K (α_3). The structure below the transition is complex, consisting of small displacements of the atoms along all three of the orthorhombic axes. Despite the large experimental and theoretical effort, the nature of these transitions is still elusive, but it is believed to be associated with the unique coupling of 5f states, residing in the vicinity of the Fermi level, and the lattice vibrations. Here we present detailed experimental and theoretical studies of low-temperature thermal, thermodynamic, and electronic transport properties of the high-quality single crystals of α-U, across the CDW transitions.

11:30 AM SF02.05.04
Phonon-Spin Scattering in U-Doped ThO_2 and its Suppression on Thermal Conductivity Zilong Hua[1], Saqeeb Adnan[2], Amey Khanolkar[1], Cody A. Dennett[3], James M. Mann[4], Marat Khafizov[2] and David Hurley[1]; [1]Idaho National Laboratory, United States; [2]The Ohio State University, United States; [3]Massachusetts Institute of Technology, United States; [4]Air Force Research Laboratory, United States

We report on an investigation of thermal conductivity suppression in thorium dioxide with low-level uranium doping. Thermal conductivity of 6%, 9%, and 16% uranium-doped thorium dioxide is experimentally measured using a spatial domain thermoreflectance technique in the temperature range of 77K-300K, and the results are compared to the predictions of an analytical Klemens-Callaway model. With the impacts from different phonon scattering mechanisms isolated in the analytical model, we observed that phonon-spin scattering, i.e., the lattice distortion induced by the spin of paramagnetic electrons, has a stronger impact than the Rayleigh-type point defect scattering on reducing the phonon-mediated thermal conductivity in this temperature range. Moreover, the relative thermal conductivities among our samples with different uranium doping percentages and pure uranium dioxide suggest that the intensity of phonon-spin scattering is not linearly correlated to the doping percentage. This work shows the profound effect of introducing atoms with 5f electrons, populated in uranium but not in thorium, on the thermal transport behavior of fluorite oxides.

SESSION SF02.06: Condensed Matter Physics II

Unusual High-Field Superconductivity in Uranium Ditelluride Nicholas P. Butch[1,2]; [1]NIST, United States; [2]University of Maryland, United States

Uranium ditelluride (UTe_2) hosts a rare form of low-temperature superconductivity that involves spin-triplet pairing and may be topologically nontrivial. Multiple superconducting phases can be stabilized through the application of large magnetic fields or modest pressure. A dramatic example of reentrant superconductivity, dubbed the "Lazarus" phase, is stabilized at fields greater than 40T, persisting to higher than 65T. In this talk, I will discuss recent experimental developments in the study of the high field superconductivity.

2:00 PM SF02.06.02
Lattice Dynamics and Thermodynamics for δ-Plutonium from *Ab Initio* Theory Per Söderlind; Lawrence Livermore National Laboratory, United States

We present results from density functional theory (DFT) calculations of the lattice dynamics (phonons) and thermodynamics for δ-phase plutonium. The fully relativistic electronic structure is calculated assuming a three-dimensional noncollinear magnetic structure in conjunction with DFT and the general gradient approximation for the electron exchange and correlation interactions. The electronic-structure model is further enhanced by addressing strong orbital-orbital coupling via the conventional orbital-polarization (OP) scheme as has been successfully done for plutonium. The temperature dependence of the phonons is calculated within the self-consistent *ab initio* lattice dynamics approach. The obtained phonons compare very well with measurements

although a modest overestimation of the transverse *L*-point [ξξξ] phonon is acknowledged. Calculated thermal vibration amplitudes and the associated Debye-Waller temperatures are close to experiments. Lattice, electronic, and magnetic contributions to the heat capacity are predicted and consistent to a few percent with that deduced from experimental data. Good agreement is only achieved when a magnetic contribution to the specific heat is recognized. The parameter-free DFT+OP electronic model is thus capable of predicting phonon properties and thermodynamic behavior of δ-phase plutonium rather accurately.
This work was performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract No. DE-AC52-07NA27344

2:15 PM SF02.06.03
5*f* and 4*f* States in Layered Zintl Phases: Half- and Semi-Metals Ladislav Havela[1], Martin Divis[1], Dominik Legut[1,2], Jindrich Kolorenc[3] and Volodymyr Buturlim[1,4]; [1]Charles University, Czechia; [2]VSB, Czechia; [3]Czech Academy of Science, Czechia; [4]INL, United States

The term Zintl phases denotes compounds of one electropositive element donating electrons to a complex anion with covalent bonding. We focus on layered compounds with the trigonal structure type $CaAl_2Si_2$, which are known both for actinides (U,Th) and divalent lanthanides (Eu, Yb). The lanthanide-based compounds are narrow-band antiferromagnetic semiconductors with transport properties very sensitive to magnetic fields. UCu_2P_2 is Ising-like ferromagnet. Its T_C = 216 K steeply increases with hydrostatic pressure. Calculations reveal that the spin splitting of the 5*f* band with only one spin direction at E_F brings to the Fermi level also practically full polarization of light electrons. Hence UCu_2P_2 is a combination of semi metal and half metal. High pressure experiments on $EuZn_2P_2$ indicate that the band gap is suppressed under hydrostatic pressure of 12 GPa. Interesting aspects is brought by the layered character of the crystal structure, with *f*-element basal-plane sheets distinctly separated by the anionic slabs. This gives much longer magnetic correlations length in the basal plane. There is a striking contrast between $EuZn_2P_2$ with practically no magnetic anisotropy due to the spin-only magnetism of the f^7 state and extremely strong ($E_a/k_B \approx 500$ K) in-plane 5*f* bonding induced anisotropy in UCu_2P_2 with the U moments locked into the *c*-axis.
The results illustrate how the *f*-systems are affected by the polar bonding. The potential of the band-gap engineering can be used for designing thermoelectrics or materials for spintronics.
This work was supported by the Czech Science Foundation under the grant No. 21-09766S.

2:30 PM BREAK

SESSION SF02.07: Radiation Effects
Session Chair: Nicholas Butch
Wednesday Afternoon, April 24, 2024
Terrace Suite 2, Level 4, Summit

3:30 PM *SF02.07.01
The Role of Radiation-Induced Non-Equilibrium Plutonium Oxidation States in Solution Gregory P. Holmbeck[1], Travis S. Grimes[1], Amy Kynman[1] and Stephen Mezyk[2]; [1]Idaho National Laboratory, United States; [2]California State University Long Beach, United States

Plutonium plays a key role in global actinide research and nuclear fuel cycle technologies, and yet, our fundamental understanding of its inherent radiation-induced chemical behavior is limited. These radiation-induced processes cannot simply be switched off, as they are as fundamentally inherent to plutonium as the impact of relativistic effects on its *f*-electrons. In less chemically complex actinide systems, such as aqueous solutions of neptunium and americium, both steady-state and transient radiolysis products play a significant role in the redox cycling of their oxidation states, which ultimately impacts their chemistry and transport. However, plutonium's multiple, coexisting, and chemically active oxidation states, which comprise of bare ions and dioxo cations, provide additional redox pathways that complicate the aforementioned radiation-induced competition kinetics. Mechanistically understanding the response of these multiple oxidation states, both equilibrium and non-equilibrium, to intense ionizing radiation fields is essential for predicting the behavior of plutonium under a host of conditions that support technological innovation in global nuclear energy and non-proliferation efforts. Here, advances in radiation-induced plutonium solution chemistry will be presented, including new results from time-resolved electron pulse and steady-state gamma and alpha irradiations.

4:00 PM SF02.07.02
Recovery in Stabilized Delta Pu and its Effects on Thermophysical Properties Najeb M. Abdul-Jabbar, Shane Mann and Jeremy Mitchell; Los Alamos National Laboratory, United States

Recent efforts at Los Alamos National Laboratory (LANL) have focused on thermodynamic measurements of aged and pre-conditioned delta alloys at temperatures in the vicinity of defect recovery and stored energy release. In both scenarios, quantifiable thermophysical property changes are observed across temperatures ranging from 125-225 °C. Analogous behavior in Pu has been observed via electrical resistivity measurements, which has been attributed to migration of point defects, dislocations, and vacancy clusters. Whether interactions between defects produced by pre-conditioning or natural aging can develop into alpha-like embryos, which can lead to decomposition of the delta phase, remains to be seen. Consequently, ongoing thermal analysis work is being conducted at LANL on a comprehensive series of pre-conditioned and naturally aged Pu-Ga alloys and the ensuing results in the context of delta phase stability will be discussed.

4:15 PM SF02.07.03
Effects of Repeated Alternating Temperatures Measurements on Lattice Behavior of δ-Phase ^{239}Pu-Ga Alloys Alice I. Smith, Franz J. Freibert, Sven C. Vogel, Jianzhong Zhang, Joan E. Siewenie, Scott Richmond and Michael Ramos; Los Alamos National Laboratory, United States

Elemental plutonium is an atypical element in the periodic table, highly unstable and presenting six allotropes from room temperature to its melting point: monoclinic α, body-centered monoclinic β, face-centered orthorhombic γ, face-centered δ, body-centered δ', and body-centered cubic ε. These phases are unstable with temperature, pressure, and time, affecting the crystallographic structure, thermodynamic and mechanical properties in ways that are still inconclusive. The high temperature face-centered cubic (fcc) δ-phase is stable in elemental Pu between 320 and 450°C, and it can be stabilized to room temperature and below by alloying it with small amounts of trivalent elements (i.e., Ga, Al, Ce, Am, or Sc). The resulting alloys are in a metastable state, of great interest for several applications and more easily worked metallurgically than the other phases, exhibiting intriguing behaviors and unusual properties, such as negative thermal expansion, large low-temperature electronic specific heat, high electrical resistivity.

Self-irradiation, "the inside out" aging in plutonium and its compounds[1], results in radiation damage which will affect the microstructure of the materials, with significant changes of their structure and physical and mechanical properties. X-ray diffraction and dilatometry studies have shown that the room temperature self-irradiation of δ-phase Pu-Ga alloys results in swelling of the lattice that saturates after 0.1-0.2 dpa of accumulated lattice damage. At low temperatures, self-irradiation results in significant lattice damage, but the mechanisms associated with the evolution of defects at sub-ambient temperatures are still not fully understood.

For a more complete picture of the poorly understood "aging" processes of defect accumulation and damage evolution in δ-phase ^{239}Pu-Ga alloys, we need to consider the radiation dose and rate, thermal history, and composition of the materials. This talk will present experimental results on the evolution of the average structure of δ-phase ^{239}Pu- Ga alloys when exposed to repeatedly alternating-temperatures between ambient and cryogenic values, investigated by time-of-flight neutron diffraction.

4:30 PM SF02.07.04
Defect Chemistry and Radiation Stability of (Gd & Zr) Co-Doped UO_2 Solid Solutions Ritesh Mohun; Bangor University, United Kingdom

The irradiation behaviour of pure UO_2 is well experimentally characterised, but little is known about the irradiation of UO_2 doped with fission products such as rare-earth elements that are formed during in-reactor operations where the fuels are exposed to extreme environments of intense radiation and high temperature. For this purpose, this study was carried out to investigate the effect of heavy Kr-ion irradiation of UO_2 (to simulate radiation damage within a reactor) when doped with both trivalent Gd (a common burnable poison) and tetravalent Zr (a high concentration fission product) at varied concentrations. The mechanisms by which the dopants incorporate the UO_2 lattice were explored experimentally. XRD measurements showed that Gd-addition creates an oxygen vacancy environment comparable to hypo-stoichiometric UO_{2-x}, and HERFD-XANES revealed the presence of U(V) species in proportion quantities to the trivalent dopant to compensate for the charge. Zr doping, on the other hand, induced a contraction of the unit cell and Raman characterisations showed the induction of a new defect species with O_h symmetry that includes the Zr cation in the 8-fold coordination of O^{2-} in the form of ZrO_8-complex clusters.
Kr-irradiation of the pristine samples showed that dopants modify the irradiation character of the UO_2 structure, with the undoped pellet accumulating the highest concentration of lattice disorder, indicating that the co-doped solid solutions are more radiation resistant. The cation Frenkel pair formation enthalpy was calculated using DFT+U, which revealed that uranium interstitials formed as part of displacement cascades in doped samples have a significant thermodynamic drive to displace Zr/Gd substitutional defects, increasing the defect recombination volume. This mechanism, however, is not observed in undoped UO_2. In this talk, the key mechanisms that occur near defect-boundary interfaces will be discussed to highlight the precise role of dopants in changing the lattice defects mechanisms in nuclear fuels.

SESSION SF02.08: Poster Session
Session Chairs: Edgar Buck and David Shuh
Wednesday Afternoon, April 24, 2024
Flex Hall C, Level 2, Summit

5:00 PM SF02.08.01
New Angles on Actinide Quantum Materials Rosalie Greer[1], Matthew Simmers[1], Lorianne R. Shultz-Johnson[1], Alex Bretaña[1], Binod K. Rai[1], Christopher Barrett[1] and Tina Salguero[2]; [1]Savannah River National Laboratory, United States; [2]University of Georgia, United States

While actinide materials have seen an enormous swell of interest in recent years due to the surprising and fascinating quantum properties of materials such as UTe_2, this interest has largely been confined to a small set of compounds. The intrinsic obstacles to research the actinides present has greatly limited broader explorations into novel materials, novel analytical methods, and manipulation of actinide isotopics. Savannah River National Laboratory, in light of its unique position ameliorating many of the difficulties of actinide research, has pursued a research effort to begin those broader explorations.

Utilizing primarily chemical vapor transport and flux synthesis methods, SRNL has generated a number of actinide-based quantum materials, both those subject to contemporary mainstream interest and those which have been neglected for decades with insufficient characterization. High-quality crystals of materials such as UTe_3 have been prepared and characterized at much higher levels of fidelity than possible at the time of their discovery, clarifying disagreements in the existing literature and revealing new and compelling magnetic features. SRNL also plans to prepare a series of UTe_2 samples with tailored uranium isotopics, including the use of highly enriched uranium, enabling an unprecedented investigation of the impact of nuclear spin on the unusual quantum properties of that material.

Most importantly, this work results from the establishment of an actinide-based quantum material synthetic capability which will allow the synthesis of entirely new materials, including with actinides other than uranium. The richly complex correlation effects endemic to actinide species will no doubt lead to novel and intriguing quantum properties, offering a whole new realm of investigation.

8:00 AM *SF02.09.01
Nuclear Nanotechnology: Mechanisms behind The Formation of Uranium Oxide Nanoparticles Liane M. Moreau; Washington State University, United States

Nanoparticles are interesting due to the unusual properties that they display based on quantum effects, which make their electronic structures intermediate between individual atoms and larger bulk materials. While nanochemistry has been well developed throughout the transition metals, little is known regarding how actinide materials behave when their sizes are reduced to the nanoscale. This is problematic due to the inherent relevance of nanoscale actinides to the nuclear fuel cycle. High burnup structure nuclear fuel results in nanometer-scale grain sizes, and it is well documented that nanoparticle

formation greatly affects actinide oxide corrosion and the ability of actinides to move through environmental systems. In order to elucidate size/property relationships in uranium oxides, we have developed procedures to control the size and morphology of uranium oxide nanoparticles through organic phase colloidal synthesis and seed-mediated anisotropic growth. Notably, we have learned the important role that water plays in UO_2 nanoparticle synthesis, which has important implications for nanoparticle synthesis throughout the periodic table. Methods will also be described towards scaling down organic phase colloidal synthesis to achieve actinide oxide nanoparticles that utilize less than 1 mg of precursor, making trans-uranium nanoparticles more feasible to study. Additionally, we demonstrate the formation of unusual uranium oxide nanoparticle 2D superlattices, and how this can be controlled by altering nanoparticle size and morphology.

8:30 AM *SF02.09.02
Nanoprecipitates and Nanostructures in Spent UO_2 Fuel Lingfeng He[1], Yunyuan Lu[1], Cameron Howard[2], Linu Malakkal[2], Chao Jiang[2], Sudipta Biswas[2], Dewen Yushu[2], Jatuporn Burns[2] and Wei-Ying Chen[3]; [1]North Carolina State University, United States; [2]Idaho National Laboratory, United States; [3]Argonne National Laboratory, United States

Spent nuclear fuel experiences substantial alterations in both its microstructure and chemical composition during its time in a reactor. While some fission products remain integrated within the UO_2 matrix, other inert gases like xenon (Xe) and krypton (Kr), as well as certain 4d group metals (molybdenum, technetium, ruthenium, rhodium, and palladium), form nanoprecipitates within the UO_2 matrix. In certain areas of the UO_2 fuel, these Kr/Xe precipitates and metallic precipitates can also come together to create paired structures at the rim regions. Furthermore, as the burn-up levels increase, grain subdivision within the UO_2 occurs, giving rise to a high burn-up structure (HBS) characterized by the presence of nanograins. This research aims to provide an in-depth examination of the in situ microstructural changes in nanoprecipitates and HBS in spent UO_2 fuel when subjected to Kr or Xe ion irradiation. To enhance our understanding of these changes, this study employs transmission electron microscopy techniques alongside density-functional theory and phase field modeling.

9:00 AM SF02.09.03
Solvent Directed Anisotropic Growth of Uranium Dioxide Nanoparticles Christian Wentzell; Washington State University, United States

Nanoparticles are of interest due to their unusual behavior as a result of having a high surface area to volume ratio. The nanoscale size regime results in increased surface energy due to steric strain and increased lattice vacancies. Still, certain surface facets are more stable than others, which are modulated as a function of particle size, leading nanospheres to be the preferred morphology. To stabilize higher energy surface facets and achieve anisotropic nanoparticle morphologies, either one of two approaches is typically employed: 1) a surface binding species is utilized that preferentially binds to certain surface facets over others or 2) trace elemental species are added to the species which cap high energy surface facets and slow their growth rate. While these two approaches have been widely observed for noble metal and to a certain extent transition metal nanoparticles, little research has considered anisotropic growth in underexplored materials such as uranium dioxide. Of particular interest, it is possible that solvent coordination may also play a role in anisotropic growth due to their differential charge distribution. To this end, our initial findings show that in fact solvents can play a role and control anisotropic growth in uranium dioxide. Specifically, we have investigated various high boiling point organic solvents, such as dibenzyl ether, dihexyl ether and dioctyl ether, which have all resulted in different nanoparticle morphologies. Additionally, we have explored the effects of mixed solvents and variable surfactant mixtures with different functional groups including ethers, amines, ketones, aliphatic and aromatic compounds, which therefore sample various surface binding possibilities. In order to probe anisotropic growth pathways, time course reactions using transmission electron microscopy along with small and wide-angle X-ray scattering have been conducted. Overall, this presentation will demonstrate initial and illuminating progress towards morphological control over actinide oxides.

9:15 AM *SF02.09.04
Spectroscopy for Plutonium Polynuclear Species in Solution and Application of Model Structures in Data Analysis Thomas Dumas[1], Matthieu Virot[2], Cyril Michaux[2], Manon Cot-Auriol[2], Julien Margate[2], Sandrine Dourdain[2], Sergueï Nikitenko[2], Kristina Kvashnina[3,4], Lucia Amidani[3,4], Pier Lorenzo Solari[5], Denis Menut[5], Philippe Moisy[1], Geoffroy Chupin[1], Christelle Tamain[1] and Dominique Guillaumont[1]; [1]Univ. Montpellier, France; [2]ICSM, Univ Montpellier, CEA, CNRS, ENSCM, France; [3]The Rossendorf Beamline at the ESRF, France; [4]Institute of Resource Ecology, Germany; [5]Synchrotron SOLEIL, MARS Beamline, France

Understanding the structure of polynuclear plutonium ions in aqueous solution is crucial to develop separations technologies, predict the long-term behavior of actinide materials in wet systems and model accurately solution to solid precipitation mechanisms. It is an euphemism to say that plutonium chemistry in aqueous solution is complex. Diverse and multifaceted species has been identified and, most often, several of which coexist with each other. In this context, the structural information provided by EXAFS measurements can be a lighthouse for the chemist and the rich visible/near infrared plutonium absorption properties is an excellent asset too. Nevertheless none of which are easy to interpret because few structural models are available for plutonium. This presentation aims to recall how multiple spectroscopic approaches can benefit from reference structures (crystallographic and/or theoretical) to identify plutonium compounds in solution focusing on plutonium hydrolysis compounds and polycondensation in aqueous solutions.

Single crystal X-ray diffraction and spectroscopies has been applied to describe small plutonium clusters in solution.[1-3] Apart from the structural description, this plutonium hexanuclear core resulted in a peculiar absorption spectrum in the visible range that is a valuable footprint to detect it in several systems. The other actinide cluster geometries known [4-7] are also useful to support spectroscopic analysis in complex plutonium solution including nanomaterials. EXAFS spectra derived from crystal structures and ab-initio calculations how the cluster geometry and nuclearity translates into EXAFS scattering paths and may help to identify the plutonium clusters in solution.[8] This approach is one among others that is used to study larger plutonium assemblies. Overall, several structural and electronic properties of the nanosized plutonium oxides and colloids may be compared and analyzed on the basis of molecular bonds from plutonium clusters.[9-10] And ultimately, in the plutonium ions route to from colloidal suspensions or PuO_2 nanoparticles, polynuclear plutonium clusters are found to be an intermediate species, that the appropriate spectroscopic tools may help to capture.

10:15 AM *SF02.10.01
Visualizing Non-Classical Growth of *f*-Element Oxalates with Cryo-TEM Karen Kruska, Gabriel Hall, Shalini Tripathi and Edgar C. Buck; Pacific Northwest National Laboratory, United States

Cryo-transmission electron microscopy (TEM) was utilized to observe the initial stages of *f*-element oxalate morphologies under varying solution conditions, tracking particle nucleation and growth. U and Pu nitrites were mixed with oxalic acid to produce their respective oxalates. The reaction was stopped by vitrification of the reactants on a TEM grid, enabling the examination of early, meta-stable particle stages. The size and shapes of precipitates were studied over different reaction durations. Chemical analysis of cryo-samples was conducted using EFTEM, while post-mortem STEM-EELS provided more detailed chemical insights into dried samples. Images taken after 10 seconds revealed larger particles formed by the aggregation of smaller particles through particle attachment. Cryo-TEM unveiled the intermediate phases of this non-classical growth process. These findings will be discussed as part of a comprehensive investigation into the complete growth cycle, utilizing a combination of optical and electron microscopy techniques.

10:45 AM SF02.10.03
Highly Stable and Hierarchical Porous Ce-Based MOF for Efficient Uranium Extraction from Seawater Muhammad Asim, Bhupendra K. Singh and Wooyong Um; Pohang University of Science and Technology (POSTECH), Korea (the Republic of)

Owing to rapidly growing world population and swift industrialization, there is an escalating global demand for a sustainable and environmentally friendly energy resource, triggering the exploration of uranium source for nuclear energy. Seawater with a vast and untapped uranium reservoir (4.5 billion tons) is a promising source and holds an immense potential for uranium mining over an extended period. However, efficient, and selective uranium extraction from seawater (UES) is profoundly challenging due to ultralow concentration of dissolved uranium in seawater (about 3.3 ppb), complex chemical matrix, harsh and corrosive marine environments as well as economic viability.
To overcome these challenges, various approaches have been explored so far including ion exchange, precipitation, membranes, and electrochemical methods. However, these methods often suffer due to high cost, low selectivity, inefficient uranium extraction, susceptibility to degradation, and environmental concerns. Among the various methods utilized for UES, application of metal organic frameworks (MOFs) has grabs significant attention due to their high surface area and selective reactivity, tunable pore structure, tailored functionality, and optimal structural stability in ocean water.
This study aims to boost the uranium extraction efficiency as well as chemical and structural stability in marine environment by fabricating a hierarchically mesoporous Ce-based MOF (CeHMMOF). Leveraging efficient coordination between Ce and the ligand (2-amino terephthalic acid) incorporated with soft template (Pluronic, F127), a superstructure CeHMMOF (particle size; 1.5 - 2 µm) was successfully synthesized via one pot solvothermal approach. The synthesized MOF was systematically characterized using X-ray diffraction (XRD), Fourier transform infrared spectroscopy (FTIR), and scanning electron microscopy (SEM) to ascertain its structural, chemical, and morphological attributes.
The stability test conducted in simulated seawater conditions (Na^+ = 23,000 mg/L, Cl^- = 35,500 mg/L, C_0 = 100 µg/L , pH = 8.0) revealed promising chemical stability and structural resilience of CeHMMOF during prolonged exposure to simulated seawater up to 21 days, signifying its potential for practical deployment of UES at a larger scale. In terms of affinity for uranium and extraction efficiency in simulated seawater conditions, CeHMMOF displayed robust uranium removal efficiency (>50% of 100 µg/L initial U concentration in 12 minutes), surpassing reported materials concerning the extraction efficiency, and thus affirming the outstanding capability and considerable scope of synthesized Ce-based MOF sorbent for UES application.
In this work, we have developed a highly stable hierarchically mesoporous Ce-based MOFs with an efficient uranium extraction performance in harsh seawater conditions and proposed as an emerging candidate material for a high-throughput and sustainable UES, aligning well with ongoing global efforts to develop a clean and renewable energy resource.
To ensure the practical utilization of CeHMMOF on commercial scale, our research is ongoing and in the subsequent phases of this study, firstly, we will comprehensively evaluate the irradiation stability of synthesized MOF to assure its material stability and structural integrity under induced irradiation for long term onshore UES applications. Thereafter, uranium removal mechanism will be investigated in conjunction with other parameters impacting UES performance, including regeneration rate and selectivity of fabricated MOF for uranium extraction in natural seawater.

11:00 AM SF02.10.04
Evidence for Particle Attachment of Plutonium Solids in TX-118 Hanford Tank Waste Edgar C. Buck, Dallas D. Reilly, Sergey I. Sinkov and Eugene S. Ilton; Pacific Northwest National Laboratory, United States

The accumulation of plutonium particles in waste tanks has been suggested as a process that could lead to a nuclear criticality event during the processing of wastes at the Hanford site, WA, USA. This concern was bolstered by the apparent discovery of a bismuth-plutonium phase in the wastes by Reynolds et al. Initial analyses of TX-118 solids with SEM-EDS matched the findings of Reynolds and co-workers with the observation of similarly large 5 to 10 micrometer particles of Pu-bearing particles that also appeared to contain bismuth and phosphorus. However, it was not clear from the SEM-EDS, how these elements were incorporated into the Pu-phase. We used Scanning Electron Microscopy, (SEM), Scanning Transmission Electron Microscopy (STEM) and found no evidence for a distinct plutonium (Pu) -bismuth (Bi) and phosphate (P) phase. The plutonium was present as PuO_2 with closely associated minor levels of Bi and P. Plutonium-bearing particles in Waste Tank TX-118 appeared to consist of agglomerates of nanoparticles of PuO_2 with other metal oxide nanoparticles that were both crystalline and amorphous. We propose a particle-particle attachment mechanism for the formation of the plutonium agglomerates in TX-118 wastes. Low solubility Pu-bearing solids formed in the highly alkaline tank waste conditions would have had extremely low particle growth rates through Ostwald ripening or similar mechanisms. We performed precipitation experiments and examined the resulting agglomerates with STEM showing a possible particle attachment mechanism of formation.

SESSION SF02.11: Chemistry II
Session Chairs: Marisa Monreal and Tsuyoshi Yaita

Thursday Afternoon, April 25, 2024
Terrace Suite 2, Level 4, Summit

1:30 PM *SF02.11.01
Exploring The Photochemistry and Bonding of Trivalent Americium within Metal–Organic Constructs Robert G. Surbella III[1], Ana Arteaga[1], Aaron Nicholas[1], Michael Sinnwell[2], Bruce K. McNamara[1] and Edgar C. Buck[1]; [1]Pacific Northwest National Laboratory, United States; [2]The University of Iowa, United States

Metal-organic frameworks (MOFs) are suitable platforms for studying the fundamental properties of the transuranium (TRU) elements. While the material properties that are common to MOFs, (e.g., structural variability, high surface area, and permanent porosity), are often exploited for their functionality, our motivations for studying TRU-MOFs are fundamental in nature. These robust, crystalline constructs are attractive hosts for immobilizing the scarce and often, highly radioactive isotopes of the TRU elements, providing both structural stability and a platform to explore structure–property relationships. The trivalent lanthanide (Ln(III)) containing MOF-76 family is of particular interest in this regard, given its high thermal stability and unique optical properties, which have been explored for use in color tuning and analyte sensing. The MOF-76 family is constructed from Ln(III) ions (where Ln = Eu, Sm, Tb, Nd…) and 1,3,5-tricarboxylic acid (BTC) ligands, forming a porous, three-dimensional architecture. Perhaps more importantly, the synthetic routes for preparing MOF-76(Ln(III)) are robust, being able to accommodate nearly all the 4f elements, and as such, is an ideal entry point for studying the trivalent actinides, like americium. An overview of this synthetic strategy and the crystal structure of MOF-76(Am) will be presented. Moreover, the utility of this platform for studying the optical properties of Am(III) will be highlighted. To this end, the focus will be in differentiating 4f vs. 5f element behavior with respect to ligand-to-metal resonance energy transfer and photoluminescence quenching.

2:00 PM *SF02.11.02
Protein Crystallization Provides Insight into Actinide Coordination Jennifer N. Wacker[1], Peter B. Rupert[2], Marc Allaire[1], Roland K. Strong[2] and Rebecca Abergel[1,3,3]; [1]Lawrence Berkeley National Laboratory, United States; [2]Fred Hutch Cancer Research Center, United States; [3]University of California, Berkeley, United States

The diverse implications in understanding the biological chemistry of the actinides are profound, demonstrated in both the decontamination efforts of individuals after a nuclear accident and the remedial use of radionuclides for cancer treatments and diagnostics. Underpinning these efforts aimed to address critical societal challenges is a thorough understanding of *f*-element binding and coordination behavior in the presence of biologically-inspired systems. Despite advances in probing the fundamental properties of the actinides through methods such as X-ray Absorption Spectroscopy, opportunities to expand our current understanding at the interface between small molecule actinide complexes and natural systems can be further aided by the use of macromolecular hosts. By combining hard oxygen-donor chelators that bind actinides with high-specificity and utilizing a protein called siderocalin, which has been shown to selectively bind a diverse range of actinide complexes, these 'actinide-chelator-macromolecule' constructs can be crystallized to reveal the fundamental bonding of even the rarest of actinide elements. Protein crystallographic measurements collected at the Advanced Light Source (Beamline 5.0.2) enable actinide coordination to be revealed in the solid-state, and more broadly can help probe the interactions between biological scaffolds and actinide materials.

Terrace Suite 2, Level 4, Summit

3:00 PM *SF02.12.01
Room Temperature Oxidation Kinetics of a U-Nb Alloy Scott Donald; Lawrence Livermore National Laboratory, United States

The reaction of atmospheric gases with metal surfaces plays a crucial role in driving many beneficial and detrimental processes such as heterogeneous catalysis, corrosion, protection from degradation, and environmental dispersal. The chemistry and kinetics of the oxide formed on uranium metal alloyed with 14 at.% Nb was investigated following exposure to dry and ambient air environments. Using a combination of x-ray photoelectron spectroscopy (XPS) and time-of-flight secondary ion mass spectrometry (TOF-SIMS), the evolution of the oxide as a function of time and oxygen partial pressure were determined. Segregation of the solute element was found to occur, resulting in the formation of a niobium rich oxide interfacial layer between the UO_2 surface and bulk metal. The potential role of this segregation on passivating the material against further oxidation will be discussed and comparisons will be made to the oxidation mechanism of unalloyed uranium under similar environments.
This work was prepared by LLNL under Contract DE-AC52-07NA27344. This support does not constitute an express or implied endorsement on the part of the government.

3:30 PM SF02.12.02
From Conversion to Fabrication and Fine Characterization of MOX Fuel Laure Ramond[1,2], Florent Lebreton[1,2], Julie Simeon[1,2], Paul estevenon[1,2], Anna Hautecouverture[1,2] and Guillaume Bernard-Granger[1,2]; [1]Commissariat à L'énergie Atomique et Aux Energies Alternatives, France; [2]Université de Montpellier, France

MOX fuel is an intimate mixture of PuO_2 in a uranium oxide matrix, with plutonium content ranging from a few percent (light water reactor fuel) to several dozen percent (fast reactor fuel). In addition to conventional powder metallurgy processes, CEA Marcoule is studying other innovative ways of preparing MOX, such as advanced thermal denitration, SCS (solution combustion synthesis) and freeze granulation. The sintering of these different types of powder is being studied at the CEA, with the development of sintering maps and activation energy calculations. A wide range of tools are used to characterize sintered MOX pellets, from scanning electron microscopy (SEM) to Raman spectroscopy and transmission electron microscopy (TEM).

3:45 PM SF02.12.03
Multimodal Analysis of UO_2 Corrosion enabled by a Microfluidic Electrochemical Cell Jennifer Yao[1], Eugene S. Ilton[1], Bianca Schacherl[2], Bruce K. McNamara[1], Tonya Vitova[2] and Edgar C. Buck[1]; [1]PNNL, United States; [2]Kalrsruhe Insitute of Technology, Germany

Understanding the corrosion kinetics and mechanisms of spent nuclear fuel (SNF) is crucial for accessing the long term risks associated with the geologic storage of SNF.[1] Traditional experimental approaches have posed serious challenges, given the need for substantial resources and access to shielded hot cell facilities to protect researchers from the intense radiation field. One response is to work with depleted UO_2, a close but ultimately unsatisfactory analogue to SNF. An alternative would be to downsize the amount of SNF required such that the need for shielded hot cell facilities would be diminished.

Indeed, an innovative solution has emerged—the Particle-attached Microfluidic Electrochemical Cell (PAMEC)--which has the proven potential to work with microgram quantities of material. Central to the PAMEC is the electrochemical method, which is widely employed for studying corrosion processes. With respect to UO_2 corrosion, the PAMEC electrode is a composite of microgram quantities of UO_2 powder, polyvinylidene fluoride (PVDF), and carbon black.[2 3] The PAMEC has already proven effective in studying UO_2 redox behavior, providing consistent results with those from traditional bulk electrochemical studies.[4]

In more detail, the PAMEC is a vacuum-compatible microfluidic platform that provides precise control over experimental conditions (e.g., flow rates, dissolved volatile concentrations such as H_2), minimal resource utilization, and the ability to observe redox reactions in real-time and in situ. PAMEC's in situ and real time analytic and imaging capabilities, made possible by an ultra-thin 50 nm detection window, include scanning electron microscopy (SEM) combined with Energy-dispersive X-ray spectroscopy (EDS). The same set up allows for operando high-resolution X-ray absorption near-edge structure (HR-XANES) spectroscopy, which we used to track U oxidation states during multiple cyclic voltammetry scans of UO_2. The compact nature of the PAMEC simplified shipping the loaded device to the Karlsruhe Institute of Technology (KIT) synchrotron facility CAT-ACT beamline in Karlsruhe, Germany for operando HR-XANES analysis.

Our research has showcased the ability of the PAMEC using UO_2 corrosion as an example. We envision this approach can greatly reduce the risk associated with studying the corrosion of SNF under conditions that resemble repository environments, as well as allow for multimodal analyses for acquiring complementary characterization and more in-depth understanding of the corrosion process.

4:00 PM *SF02.12.04
Improvement of The Fission Track Analysis Methods for Nuclear Forensics Simulation and Tools Itzhak Halevy[1], Rami Babayew[2], Yaacov Yehuda zada[2], Galit Katarivas Levy[3], Jan Lorincik[4], Itzhak Orion[1], Noam Elgad[1] and Aryeh Weiss[5]; [1]Ben-Gurion University of The Negev, Israel; [2]NRCN, Israel; [3]Ben-Gurion University of the Negev, Israel; [4]Research Centre Rez, Czechia; [5]Bar Ilan University, Israel

In order to address inquiries pertaining to nuclear forensics, our research endeavors involve the formulation of novel methodologies and strategies aimed at enhancing the dependability and precision of this analytical process.
At now, the analysis of microscope pictures is limited to individuals who have received formal training in research methodologies. Given that this analysis relies on the researcher's own aptitudes and competencies, it is evident that several researchers will yield slightly divergent outcomes.
At now, the analysis of microscope pictures is limited to individuals who have received formal training in research methodologies. Given that this analysis relies on the researcher's own aptitudes and competencies, it is evident that several researchers will yield slightly divergent outcomes.

The simulation of fission tracks was conducted using the Monte-Carlo software, GEANT4. This software incorporates various aspects of nuclear fission tracks, including thermal neutron flux, fission cross-section, radiation time, particle size, enrichment, and other relevant physics. The present investigation involves the utilization of Trainer2.0 software to compute the trajectories on our Lexan detector, as well as their corresponding projections. These calculations are based on many physical parameters, including neutron flux, particle size, isotope, and radiation duration. The outcome manifests as a "star" that is positioned at the center of the simulated particle. The entirety of our software is implemented using MatLab programming language.

The simulation of harsh conditions allows for the exploration of novel aspects inside the fission track technique. The simulation provides insights into determining the appropriate sample size for the FTA procedure.
The simulation has the capability to make predictions and may be compared to both the mini-bulk and micro-bulk analyses.
The novel concept of employing penetrating fluorescent colors provides the capability to perform three-dimensional (3D) scanning with our detector, as opposed to the conventional two-dimensional (2D) scanning. In this particular instance, the Dapi marker was employed as an initial approach. It is widely recognized in the field of biomedical research.

This new idea to investigate the FT Star more than just by his projection.
The determination of the source isotope in a given element can be achieved by analyzing the length and distribution of its tracks. This analysis involves examining the shape of the "fission products distribution" as well as the density of impurities present in the source.

4:30 PM *SF02.12.05
Examining Actinide-Molten Salts Across Length Scales: Local Structure, Thermal Properties Marisa Monreal, J. M. Jackson, Scott Parker, Alexander Long and Sven C. Vogel; Los Alamos National Laboratory, United States

Actinide-molten salts are complex systems central to pyroprocessing for actinide metal purification and recovery, to molten salt reactors (MSRs)--a next-generation nuclear reactor concept currently in rapid growth, and also to a growing number of new energy-related applications. There are gaps in the literature concerning the chemistry and thermal properties of these systems, especially in data collected with well-documented methodology and experimental detail, using salts with analytical data confirming purity, and reported with thorough error analysis and quantified uncertainty. With the overarching goal to contribute to a better understanding of these complex systems, enabling prediction of their behavior, a suite of advanced characterization techniques is being developed at Los Alamos National Laboratory for the accurate and precise measurement of actinide-molten salt thermochemical and thermophysical properties, and for the study of their local structure. The high-quality empirical data collected using these capabilities supports the optimization of pyroprocesses, the development of MSRs, and the validation and refinement of models. Efforts to examine actinide-molten

salts across length scales will be described, including recent results from studies both on local structure and on thermal properties of uranium- and plutonium-bearing chloride salts. A selection of techniques and results will be detailed, with a focus on pulsed neutron characterization at the Los Alamos Neutron Science Center (LANSCE), including progress using pair distribution function (PDF) analysis to gain insight into uranium-molten salt local structure, and recent results from measurements of the liquid density of uranium- and plutonium-molten chloride salts as a function of temperature and composition using neutron radiography.

Hafnium, Titanium and Zirconium Intercalation Kristie J. Koski, Kevin R. Rivera, Tiffany Teoh, Ethan Chen and Vicky Huynh; University of California, Davis, United States

We demonstrate an intercalation chemistry for titanium, hafnium, and zirconium in the highly oxidized state (Zr^{4+}, Hf^{4+}, Ti^{4+}) into 2D layered materials through formation of a soluble, molecular bis-tetrahydrofuran (THF) metal halide complex. This method overcomes challenges distinct to intercalation of highly oxyphilic group 4 metals through creation of a molecular species that is highly soluble in organic solvents and is kinetically competent in reactivity. Metal intercalation is demonstrated in several layered hosts including MoO_3, Bi_2Se_3, Si_2Te_3, and GeS. This strategy intercalates, on average, 3 atomic % or less of Hf, Ti, and Zr, limited by the high oxidation state and charge transfer with the host. MoO_3 is chemochromically switched from transparent white to dark blue through Zr^{4+}, Hf^{4+}, Ti^{4+} intercalation. Contrast with methods for intercalation of zero-valent metals in 2D layered materials is demonstrated. We believe that this bis-THF chemistry offers a unique way to ionically switch properties of 2D layered materials and achieves a route to intercalate otherwise elusive guests.

11:00 AM SF03.01.02
Controlling Composition and Stoichiometry of Co-Intercalated Chevrel Phase Sulfides via Electrochemical and Solid-State Synthesis Pathways Konstantina G. Mason; University of California, Davis, United States

Carbon dioxide levels (CO_2) in the atmosphere continue to rise exponentially as fossil fuels remain a primary energy source for many industrial processes. Consequently, alternative energy technologies, such as solar and wind, must be harnessed to convert CO_2 into liquid fuels through the development of electrocatalytic materials that exhibit high selectivity and efficiency for CO_2 reduction (CO_2R). One such class of materials that have shown promise for CO_2R are Chevrel phase sulfides (CPs), due to their ability to host a wide variety of metal cations that can alter the structural and electronic properties of the crystal framework and in turn CO_2 binding motifs. CPs with the general formula $M_aMo_6S_8$ (M = transition, alkali, alkaline, or post transition metals) are excellent materials to investigate ion (de)insertion mechanisms due to the channels and cavities formed by the extended array of Mo_6S_8 clusters. While electrochemical insertion of a single mono or multivalent metal cation into CPs has been thoroughly investigated, co-insertion of two or more metal cations remains underexplored, despite the potential to further stabilize binding intermediates for CO_2R. Alternate electrochemical synthesis pathways can be exploited to not only co-insert two or more metal cations into the CPs framework for CO_2R studies but to further understand the thermodynamics and kinetics of chemical and electrochemical processes occurring during co-insertion. Furthermore, insertion methods, such as open circuit potential (OCP) mechanisms, can be used to investigate the synergistic movement of metal cations throughout the channels formed in the extended Mo_6S_8 solid and their effect on the electronic properties of the crystal structure that could prove beneficial for understanding product selectivity in CO_2R and other catalytic reactions. Aside from electrochemical co-insertion in aqueous electrolytes, medium temperature solid-state synthesis can also be utilized as a synthesis pathway to CPs materials with multiple metal cations inserted. In this work, control of composition and stoichiometry of co-inserted transition metal CPs

was achieved through OCP and cyclic voltammetry (CV) electrochemical synthesis techniques, as well as medium temperature solid state synthesis methods. Materials were characterized with X-ray diffraction (XRD), scanning electron microscopy (SEM), energy dispersive spectroscopy (EDS), x-ray photoelectron spectroscopy (XPS), and x-ray absorption near edge structure spectroscopy (XANES).

11:15 AM SF03.01.03
Bulk Proton Acidity Modulates Structural Transformations in Hydrogen Titanates during Li^+-Insertion Coupled Electron Transfer Saeed M. Saeed[1], Takeshi Kobayashi[2], Noah Holzapfel[1], Eugene Mamontov[3], Naresh Osti[3] and Veronica Augustyn[1]; [1]North Carolina State University, United States; [2]Iowa State University, United States; [3]Oak Ridge National Laboratory, United States

Nanostructured TiO_2-based materials are of interest for energy storage and conversion applications due to their high abundance, low toxicity, and chemical tunability. Lithium titanium oxides, such as spinel-type $Li_4Ti_5O_{12}$ and ramsdellite-type $Li_2Ti_3O_7$, have been extensively studied as electrode materials for Li-ion batteries. The synthesis of nanostructured metal oxide materials with high surface area has been a promising path for achieving high specific capacity for electrochemical energy storage. As such, it is important to expand the materials design strategies to synthesize titanium oxide materials for high Li-ion energy storage applications. Here we explore a series of layered hydrogen titanates (HTOs), $H_2Ti_nO_{2n+1}\bullet xH_2O$ (n = 3, 4, and 5), with varying degrees of structural protonation and interlayer water. These HTOs are metastable materials prepared via acid etching of alkali titanates. The complexity of the interlayer environment motivated us to understand the role of water content and structural protons on Li^+-insertion coupled electron transfer from a non-aqueous electrolyte. We hypothesized that structural protons are necessary for high Li^+ intercalation capacity, while the mobility of these protons determines the degree of structural change that occurs during Li^+ insertion. To investigate these phenomena, we utilized electrochemistry as well as operando electrochemical XRD, ex situ solid-state NMR, and acid-base titrations. By employing these techniques, we correlated the relative acid strengths of the structural protons to the degree of structural change during Li^+ intercalation. Our findings show that HTOs with more acidic protons undergo rapid, irreversible structural changes due to hydrogen evolution of bulk protons. Long term electrochemical cycling reveals irreversible structural transformations of the HTOs to lithiated titanates. This work provides a comprehensive understanding of the relationship between bulk proton acidity and structural transformations during electrochemical Li^+ intercalation into titanates. In doing so, it informs the structural design of next generation ion-insertion coupled electron transfer materials for energy storage and conversion.

11:30 AM SF03.01.04
Medium Temperature Intercalation (MTI) through Microwave Irradiation to Access Catalytically Relevant Metastable Chevrel Phases, MMo_6X_8 (M = Ag, Sn; X = S, Se) Rose Smiley and Jesus M. Velazquez; University of California, Davis, United States

The demand for large scale sustainable energy solutions for an energy landscape evolving posthaste calls for the development of transformative materials with the ability to mediate sustainable renewable energy conversion. Chevrel phases (CPs), $M_yMo_6X_8$ (M = alkali, alkaline, transition, post-transition, and lanthanide metals; X = S, Se, Te) have shown promise as electrocatalysts for the hydrogen evolution reaction (HER), the reduction of carbon dioxide (CO_2R), and the oxygen reduction reaction (ORR). However, efficient, and selective electrochemical conversion is hindered by achieving controlled bonding affinity of key intermediates. CPs offer a unique platform to probe structure function relationships between active sites and key intermediates in part to their highly tunable framework. While classical high temperature synthesis methods can be used to access thermodynamically stable CPs, the same methods can yield impure material for metastable CPs. Medium temperature intercalation (MTI) can be used to diffuse cations of interest into existing Mo_6X_8 framework to access pure phase metastable CPs. This work reports a facile synthesis procedure developed using a commercial microwave to synthesize $SnMo_6X_8$ and $AgMo_6X_8$ (X = S, Se), full characterization of the materials, and highlight X-Ray Absorption Near Edge Structure (XANES) and Extended X-Ray Absorption Fine Structure (EXAFS) data to gain insight on local electronics and structure.

11:45 AM SF03.01.05
Ion Insertion into Confined Solid Ionic Channels for Separation of Rare Earth Elements Siqi Zou[1], Woo Cheol Jeon[2], Maoyu Wang[3] and Chong Liu[1]; [1]UChicago, PME, United States; [2]Northwestern University, United States; [3]Argonne National Laboratory, United States

Rare earth elements (REEs) play an indispensable role in the path towards a greener, renewable future. Despite its efficacy, the conventional industrial solvent extraction method suffers from substantial energy consumption and chemical intensiveness. Thus, there is an urgent need to develop sustainable methods for REEs separation. Ionic radius and Lewis acidity are the two key differences that have paved the way for many separation methods. Separation methods combining both size effect and binding affinity can promote selectivity among REEs, however, the effect of long-range confinement on separation is largely unexplored. Here we report a new method to achieve separation among REEs in aqueous systems without ligands via creating optimal long-range confinement to maximize the energy penalty among unfavored REEs. We observed two distinct group behaviors through ion insertion, based on which we achieved effective separation for cross-group elements. We further proposed a pinning strategy to boost the same-group separation by maintaining the confinement throughout the reaction process. As a result, we achieved a significant escalation in enrichment factors for La-Nd and La-Pr pairs from 1.6 ± 0.1 and 1.5 ± 0.1 without pinning, to 5.4 ± 0.1 and 4.2 ± 0.1 with pinning, respectively. This unique design delivers an impressive ~92.3% purity of Dy from a 1:1 Nd-Dy pair, and a ~97.0% purity of Nd from a 1:1 La-Nd pair, through a two-time separation process. Our work illuminates the potential of confinement design and its pivotal role in advancing sustainable REE separation methods.

SESSION SF03.02: Ion Insertion for Switching Devices

1:30 PM *SF03.02.01
Harnessing Ion Tuning Mechanisms for Neuromorphic Computing: From Artificial Synapses to Dynamically Reconfigurable Architectures Alec Talin; Sandia National Laboratories, United States

Non-von Neumann computing using neuromorphic systems based on analog synaptic and neuronal elements has emerged as a powerful approach, but its full potential has not been realized due to the lack of materials and devices with the appropriate attributes. Recently, solid state electrochemical ion-insertion, also known as electrochemical random access memory (ECRAM) has emerged as a promising approach realize the needed device characteristics. Unlike memristors which require large write currents to drive phase transformations or filament growth, every electron transferred through the external circuit in an ion tunable element corresponds to the migration of ~1 ion, which is used to store analogue information. Like static dopants in traditional semiconductors, electrochemically inserted ions increase or decrease the conductivity by locally perturbing a host's electronic structure but do so in a

dynamic and reversible manner. The resulting change in conductance can span orders of magnitude, from gradual increments needed for artificial synapses, to large, abrupt changes required for artificial neurons. In my presentation, I will briefly cover the history of ECRAM, the recent progress in devices spanning various types of materials, circuits, architectures, and discuss the rich portfolio of challenging, fundamental questions and how we can harness ECRAM to realize a new paradigm for low power neuromorphic computing.

2:00 PM *SF03.02.02
On-Chip Learning with Organic Neuromorphic Systems Yoeri van de Burgt; Eindhoven University of Technology, Netherlands

The process of neural network training can be slow and energy-expensive due to the transfer of weight data between digital memory and processor chips. Neuromorphic systems can accelerate neural networks by performing multiply-accumulate operations in parallel using non-volatile analogue memory. However, the backpropagation training algorithm in multi-layer (deep) neural networks requires information - and thus storage - on the partial derivatives of the weight values, preventing easy implementation in hardware.
In this talk I will highlight a novel hardware implementation of the well-established backpropagation algorithm that progressively updates each layer using *in situ* stochastic gradient descent, thus avoiding this storage requirement. We experimentally demonstrate the *in situ* error calculation and the proposed progressive backpropagation method using a multi-layer hardware implemented neural network based on organic EC-RAM, and confirm identical learning characteristics and classification performance compared to conventional backpropagation in software.

2:30 PM SF03.02.03
Tuning Resistive Switching in $ZrTaO_x$ Devices Matthew Flynn-Hepford[1], Reece Emery[1], Jack Lasseter[1], Anton Levlev[2], Olga Ovchinnikova[1] and Philip D. Rack[1]; [1]University of Tennessee- Knoxville, United States; [2]Center for Nanophase Materials Sciences, United States

TaO_x chemistries have been widely studied as candidates for memristive switching memory and computation due to the non-linear conductance state transitions observed in these materials when exposed to applied electrical fields. Less effort has been put into studying the effects of doping and alloying TaO_x chemistries in order to optimize the mechanism of resistive switching. $ZrTaO_x$ alloys offer promising properties for stable resistive switching devices due to tantalum's mixed oxide states and zirconium's flexible 5S outer valence bonding orbital. To explore this system, we have employed a combinatorial magnetron reactive sputtering of this $Zr_xTa_{1-x}O_y$ system over a 100 mm diameter substrate and achieved a composition gradient such that $0.15<x<0.9$. We confirm the composition via energy dispersive x-ray spectroscopy and generate a series of $Pt/Zr_xTa_{1-x}O_y/Pt$ memristors along the gradient and correlate the resultant I-V to the composition as-deposited and as a function of annealing temperature. To gain insight into the switching mechanisms of the effective chemistries we leverage a workflow that couples conductive scanning probe microscopy (SPM) and spatially resolved time-of-flight secondary ion mass spectrometry (ToF-SIMS). Additional defects can then be introduced to these oxide systems, in the form of He, Ne and Si focused ion beams, in order to further understand how intentionally induced defects affect the oxygen motion that drives these devices.

2:45 PM SF03.02.04
Toward Tunable Conductance States in Layered Materials for Neuromorphic Computing using Metal Intercalation Michelle A. Smeaton, Katherine L. Jungjohann and Lance M. Wheeler; National Renewable Energy Laboratory, United States

As computing needs and accompanying energy costs continue to rise exponentially, neuromorphic (brain-inspired) computing has the potential to provide crucial improvements to computing speed and efficiency over traditional CMOS technology. Metal-intercalated, layered van der Waals materials present a promising strategy for tuning conductivity and insulator-metal transitions in devices for neuromorphic computing. Ion-insertion materials have been well studied for energy storage applications; however, the field focuses on high, reversible loading of ion materials. Here, we investigate the intercalation of metal heteroatoms into layered chalcogenide and oxide host materials, with the goal of understanding the associated modulation of the host electronic structure. We measure electrical transport of bulk materials and provide local insight into the structural and chemical effects of intercalation using scanning transmission electron microscopy (STEM) techniques. We further discuss how these effects differ based on host and intercalant species and intercalant concentration. These findings help provide insight into the dependencies of the host/guest interactions to understand the modulation of conductance and insulator-metal transitions for neuromorphic devices.

3:00 PM BREAK

3:30 PM *SF03.02.05
Dynamics of Electrochemical Ionic Synapses to Emulate Spike Timing Depending Plasticity and other Bio-Realistic Learning Rules Bilge Yildiz; Massachusetts Institute of Technology, United States

In our research, we aim to reduce the energy consumption in analog, brain-inspired computing, by focusing on designing materials and devices that use ions to perform data storage and computation in a single architecture. In this talk, I will share our work on the ionic electrochemical synapses, whose electronic conductivity we can control deterministically by electrochemical insertion/extraction of dopant ions across the active device layer. We are exploring protons and magnesium ions, which bring different advantages to the operation of the device. The protons present very low energy consumption, on par with biological synapses in the brain. Magnesium ions present with better stability without the need for encapsulation. The modeling results indicate the desirable material properties, such as ion conductivity and interface charge transfer kinetics, that we must achieve for fast (ns), low energy (< fJ) and low voltage (1V) performance of these devices. We are also exploring ion dynamics in these materials to emulate bio-realistic learning rules deduced from neuroscience studies. These include spike timing dependence achieved by electrochemical ionic synapses, as well as a local learning rule describing how song birds learn to sing. Our findings provide pathways towards brain-inspired hardware that has high yield and consistency and uses significantly lesser energy as compared to current computing architectures.

4:00 PM *SF03.02.06
Various Functional Devices Created by Ionic Nanoarchitectonics, such as Neuromorphic Properties. Kazuya Terabe, Takashi Tsuchiya and Tohru Tsuruoka; NIMS, Japan

Today's semiconductor devices continue to make remarkable progress, supported by technological developments in miniaturisation and integration, but there are fears that this progress will slow down in the near future. In order to evolve into the next generation information society, it is necessary to actively develop high-performance devices and new functional devices that operate on different principles from conventional semiconductor devices. Among these, solid-state ionic devices, which operate by utilising local ion transfer in solids, are expected to be very promising candidates. To date, we have developed ionic nanoarchitectonic methods that combine ionics and nanotechnology to create novel ionic devices with various unique functions and performances [1,2]. The ionic nanoarchitectonics controls the transport of ions, which are much larger in mass and size than electrons, and thus can control not only the electronic state of materials but also the crystal structures of surfaces and interfaces. As a result, it has been found that various functions and performances can be realised that could not be achieved by conventional electron transport control in semiconductor devices. This talk will focus on the development of

memristive, neuromorphic and artificial intelligence related devices such as artificial synapses, artificial vision and physical storage devices created by the ionic nanoarchitectonics.

Exploring Bioinspired Information Pathways: Bridging The Gap Between Science and Technology with The Intercalation of Alkaline-Ions in 3D-Aeromaterial of MoS2 Pia Pooker, Soeren Kaps and Rainer Adelung; University of Kiel, Germany

The human brain works with an exceptionally low power consumption but high information output. Understanding the intricate information pathways found in nature, particularly in the human brain, has emerged as a pivotal source of inspiration for revolutionary technological advancements. This exploration into bioinspired information pathways has led to the development of artificial neurons, a key element in unraveling the mysteries of neural processes. This exploration extends its reach to various domains, including energy efficiency, information storage, and memristive systems, where the integration of bioinspired concepts promises transformative breakthroughs.
As the brain functions with a decentralized energy supply, there are some striking similarities to alkaline batteries as both function with a liquid electrolyte based electrochemical system and are able to store energy with different kinds of charge transport carriers. In order to mimic spatial arrangement of a neuron inside the brain, a 3D network with a spatial and highly scalable structure, inspired by the intricate architecture of the brain, is designed in this study.
Moreover, to mimic the function of the brain, researchers have turned to two-dimensional materials to display the working function of ion channels, an integral aspect of bioinspired information pathways. The application of (non)-equilibrium dynamics allows these materials to serve dual roles. They function not only as energy-efficient batteries but also as information storage devices, thus bridging the gap between energy and data storage.
Among the intriguing materials of bioinspired information pathways are Transition Metal Dichalcogenides (TMDs), such as molybdenum disulfide (MoS_2). As part of the broader bioinspired research, TMD materials enable not only efficient energy storage but also serve as a cornerstone for developing innovative information processing technologies. TMDs like MoS_2, with their atomically thin structure and tunable bandgap, play a pivotal role in the quest to mimic the remarkable capabilities of the human brain.
In this contribution an aero-material consisting of the exfoliated 2D-TMD MoS_2 and exfoliated graphene (EG) is used as the functional material. For the realization of the battery-like electrodes, the 3D-network is infiltrated with a dispersion of both, exfoliated MoS_2 and EG, before etching ZnO away, to have a light, mechanically stable and 3D shaped TMD.
In a quest to advance traditional lithium-ion batteries, we are exploring sodium (Na) as well as potassium (K) as a viable alternative as the intercalated species to expand the horizons of layered materials. This shift opens new possibilities for energy storage technologies and fosters sustainability in energy solutions.
For testing equilibrium dynamics with both, Li and Na, the battery-like aero material is incorporated as the anode material with metallic Li as the cathode. The electrolyte is varied with different conducting salts containing Na^+/K^+-ions. The different ion-radii lead to an expansion of the interlayer spacing and hence to higher capacities. For testing non-equilibrium conditions, a tuning of the intercalation pathway of the alkaline ions and hence a tuning of the resistivity of certain pathways can be reached, by contacting several points of the 3D structure and applying different signals. With this measurement, a training of the network can be achieved.

4:45 PM SF03.02.08
Phase-Field Modeling of 3-Terminal Protonic Transistor Switching Dynamics Michael L. Li and Martin Z. Bazant; Massachusetts Institute of Technology, United States

The need for increased computational efficiency for deep learning applications has led to interest in in-memory computing. One example, three-terminal synaptic transistors with ion or proton intercalation mechanisms [1,2], have been recently studied for their CMOS compatibility and relatively fast switching time. Given the young nature of this technology, there are fundamental unanswered questions about these devices, which creates a gap between the current available models and tools required to simulate and accelerate material and architecture design. Though ion-intercalation materials have been heavily studied in the context of batteries, the large applied voltages to trigger the resistance state switching and nanoscale structure of these films lead to uninvestigated effects on the material reaction and transport properties. Additionally, the impact of these devices' design and formation on performance is not fully understood. A fundamental investigation of the relationship between material properties and device performance metrics is needed.

Here we present a new phenomenological phase-field model to describe the resistance switching of WO_3 3-terminal protonic transistors [1] by extending multiphase polarization theory outline by Tian and Bazant [3]. Through this process, we determine relationships between the effective surface reaction and material transport parameters and device performance parameters, such as switching time and energy. We address the importance of the underlying model for the surface ion-intercalation reaction, comparing different the phenomenological Butler-Volmer and the coupled ion-electron transfer reaction model [4]. Additionally, we investigate the impact of phase separation on these devices, which, due to the large electric fields needed to switch between resistance states, is shown to occur even when the bulk concentration exists in a single-phase region. Finally, preliminary extensions to 3d device topologies are investigated. This model will be indispensable in predicting the impact of material properties and architecture on device performance, accelerating design of similar synaptic transistor technologies.

A GFP-Chromophore-Based C3V-Symmetric Tripodal Receptor Material with Selective Hg(II), Fe(III) and Cr(III) Ion Insertion Kuangsen Sung; National Cheng Kung University, Taiwan

A novel green-fluorescent-protein-chromophore-based tripodal receptor material is synthesized. Its single crystal X-ray diffraction structure looks like a straight, long tube with one end closed. The diameter of the inner cavity of the tripodal receptor material is 2.7 Å and its outer cavity is a little larger with the diameter of 3.5 Å. The three GFP chromophores in this material are packed like a propeller quite well and tightly through van der Waals forces. The tripodal receptor material selectively captures Hg^{2+}, Fe^{3+} and Cr^{3+} in its inner cavity through four binding sites (one tertiary amine and three amide groups) to form a 1 : 1 complex with the binding constant K of 2.6 x 10^4, 1.4 x 10^5 and 4.3 x 10^4, respectively. The fluorescence of the tripodal receptor material is quenched by Hg^{2+}, Fe^{3+} or Cr^{3+} through a heavy-atom or a paramagnetic quenching mechanism.

5:00 PM SF03.03.02
***In Situ* Studies of $SrCoO_x$ Heterostructures for Synaptic Memories** Tadesse Billo Reta[1], Daniel B. Durham[1], Yan Li[1], Jill Wenderott[2], Hua Zhou[1], Supratik Guha[1] and Dillon D. Fong[1]; [1]Argonne National Laboratory, United States; [2]Drexel University, United States

Varying the oxygen concentration in many transition metal oxides can be used to tailor electronic properties, making oxide heterostructures of great interest in ionotronics and novel memory devices. We investigate epitaxial $SrCoO_x$ heterostructures, depositing insulating $SrCoO_{2.5}$ and conducting $SrCoO_3$ layers and bilayers on $SrTiO_3$ (001) substrates. The resistive switching properties of the heterostructures depend on structural and electronic phase transitions as governed by ion insertion and extraction. The volume fraction of the different phases significantly influences switch behavior, affording fine control and revealing distinct traits in low-voltage I-V sweeps, especially during DC forming. We employ coherent synchrotron techniques such as X-ray Photon Correlation Spectroscopy (XPCS) during ionic liquid gating to shed light on the dynamics of oxygen ion insertion and extraction. We will discuss these results and findings from electrical device characterization, emphasizing the reliability and performance of these structures.

5:00 PM SF03.03.03
Broad-Range Modulation of Guest-Species Interactions in MoS_2 Transistors for Electrochemical Phase Transitions Jaeeun Kwon and Hanbin Cho; Ulsan National Institution of Science and Technology, Korea (the Republic of)

In the realm of two-dimensional (2D) transition metal dichalcogenides (TMDs), the utilization of ionic gating has emerged as a powerful means, advancing electrostatic and electrochemical manipulations in a wide range of electronic properties. In general, the conventional ionic gating approach is, however, performed within the conservative low-voltage regime, which cannot take advantage of its full range of gating power as well as electrochemical interactions. Herein, we present an all-inclusive ionic gating technique covering from electric-double-layer gating (low-voltage stage) to insulator-to-metal transition (high-voltage stage). In the latter, the structural/electronic phase transformation of MoS_2 is triggered by intercalation of guest ions, 1-Ethyl-3-methylimidazolium ([EMIM]+), which is one of the most conventional cation used in ionic gating devices and the greater details in its characteristics are studied as a versatile and fast-switching device. In such device operated under high-bias condition, it is critical to prevent undesirable chemical reactions, and so we introduce a very thin high-k dielectric passivation layer deposited through atomic layer deposition, strategically protecting the electrodes and also reducing leakage current (so, $I_{on/off} > 10^6$) while operating in liquid-based electrolytes at room temperature. In addition, to effectively accumulate the charge in the channel and control the voltage range in which phase transiton can occur, a dual gating method was introduced just adding simple process fabricating bottom gate using high-k dielectric and a way to effectively operate the device was explored. This work underscores the potential for phase-change-based devices and hybrid gating schemes as promising avenues for advancing the field of 2D materials and nanoelectronics, offering unprecedented control and functionality in future electronic systems.

SESSION SF03.04: Fundamentals of Ion Insertion Dynamics

8:00 AM *SF03.04.01
Materials Approach to Control The Properties of Electrochemical Artificial Neurons and Synapses Ilia Valov[1,2]; [1]Peter Grünberg Institute 7 and JARA-FIT, Germany; [2]Bulgarian Academy of Sciences, Bulgaria

Memristive devices have significantly developed in the last decade, expanding their application horizon much beyond memory applications. Especially important is their functionalities as artificial neurons and synapses, making them promising building units for the next generation bio-inspired neuromorphic hardware. Despite a lot has been learned about materials design and the operation principles of memristors, recent research has shown that fundamentals can still be significantly amended, demonstrating new operation principles and functionalities.
In this contribution, the common electrochemical fundamentals of biological and memristive artificial neurons and synapses will be discussed as well as new aspects on materials design and its influence on the physicochemical processes and resulting functionalities of both ECM (CBRAM) and VCM (OxRAM) devices. The effects of the materials and thicknesses of the capping layer appear of special importance and as well the thicknesses and combination of thicknesses of all involved layers. The selection of different materials is changing the electrochemical nanoionics processes and as well the performance of the memrsitors. For reliable performance the device stack should be considered as a whole, and materials used in the stack and their thicknesses should be coordinated and harmonised.
A special attention will be paid on controlling the energy barriers at the interface electrode / switching film, where Schottky barrier competes with the energy barrier of the redox reactions. A new switching mechanism will be presented, relying entirely on electrochemical processes of oxidation and reduction and depends on the valence state and thickness of filament. The ohmic memritsive devices, demonstrate a number of advantages compared to Schottky-based devices, such as combination of digital and analogue switching in same devices, higher voltage window of stability, lower operating currents, higher OFF to ON ratio, high endurance and retention, high temperature stability. The importance of fundamental research will be highlighted, allowing for new functionalities and opportunities for applications.

8:30 AM *SF03.04.02
Origin of The Time Relaxation of Volatile Valence Change Memory Regina Dittmann, Johannes Hellwig, Carsten Funck and Dimitris Spithouris; PGI-7, Germany

Memristive devices based on the valence change mechanism are highly interesting candidates for data storage and hardware representation of synapses in neuromorphic circuits. Although long-term retention is often required for data storage applications, a time decay of the resistance is advantegous for several applications where short-term plasticity is required. In this work, we investigate in detail the LRS relaxation of volatile $SrTiO_3$ devices. The decay is analysed in terms of the Schottky-Read-Hall model for the contribution of electron traps and in terms of the Gibbs free energy gradient for the contribution of oxygen ion migration. Based on this, we can exclude trapping effects as origin oft he LRS decay. In contrast, we could nicely model the device behaviour by oxygen ion migration considering four reservoirs within the devices, connected by oxygen exchange. Our model serves as a tool for developing guidelines and design rules for future volatile memristive technology based on Schottky barrier mediated electron transport. As an example, we demonstrate the acceleration of the decay over 3 orders of magnetide by modifying the microstructure oft he $SrTiO_3$ layer.

9:00 AM *SF03.04.03
Ionic Peltier Effect in Li-Ion Electrolytes David Cahill, Zhe Cheng, Yu-Ju Huang, Beniamin Zahiri, Patrick Kwon and Paul V. Braun; University of Illinois, United States

The insertion of an ion from an electrode to an electrolyte involves changes in the thermodynamics properties and the transport of charge and heat. The coupled transport of charge and heat provides fundamental insights on the microscopic thermodynamics and kinetics of this process. We describe a sensitive ac differential resistance bridge that enables measurements of the temperature difference on two sides of electrochemical cell with a resolution of better than 10 μK. We use this temperature difference metrology to determine the ionic Peltier coefficients of symmetric Li-ion electrochemical cells as a function of Li salt concentration, solvent composition, electrode material, and temperature. The Peltier coefficients Π are negative, i.e., heat is absorbed at the cathode and emitted at the anode, large in absolute magnitude, Π >30 kJ/mol, become less negative with increasing concentration, and becomes slightly more negative with increasing temperature. The Peltier coefficient is approximately constant on time-scales that span the characteristic time for mass diffusion across the thickness of the electrolyte, suggesting that the heat of transport plays a minor role in comparison to the changes in entropy at the interface between the electrode and electrolyte. Our work demonstrates a new platform for studying the non-equilibrium thermodynamics of electrochemical cells and provides a window into the transport properties of electrochemical materials through measurements of temperature differences and heat currents that compliment traditional measurements of voltages and charge currents.

Cation Insertion Characteristics of Mesoporous Titania-Silica Composite Layers Debargha Chakravorty[1,2,3], Nina Plankensteiner[1,2,3], Maarten Mees[2,3] and Philippe M. Vereecken[2,1,3]; [1]KU Leuven, Belgium; [2]Imec, Belgium; [3]EnergyVille, Belgium

Innovative approaches in materials and concepts will be key to address the energy transition challenge. A key area involves ion insertion materials which are not only interesting for energy storage but also for energy conversion and low power electronics and optoelectronics[1]. Titanium dioxide (TiO_2) is well known ion insertion electrode capable of accommodating lithium ions. The ion storage capacity and ion insertion/extraction rates can be enhanced significantly by nano structuring and doping[2,3]. For nanostructured TiO_2, insertion of other cations such as K^+, Ca^{2+}, Mg^{2+} and Al^{3+} has been shown[4]. The versatility and stability of titania chemistry lends itself to tuning of its morphology by simple fabrication methods. In this paper, mesoporous titania-silica composite thin films were fabricated by a facile sol gel approach. The thin film was spin-coated and cured onto a metal coated silicon substrate, which served as current collector and loaded in a three-electrode cell for electrochemical characterisation. A facile and reversible ion insertion and extraction of the titania-silica composites was found upon, respectively, reduction of Ti(IV) to Ti(III) and oxidation of Ti(III) to Ti(IV) from aqueous and non-aqueous solutions. Interestingly, the results show that next to Li^+, also facile reversible ion insertion/deinsertion can be carried with other monovalent cations and even bivalent cations. The morphology and composition of the thin films were determined before and after the ion insertion process using scanning electron microscopy and transmission electron microscopy, combined with EDS and EELS. These measurements provided insights into the charge-discharge characteristics of the composite material and the charge capacity was determined. Proton intercalation/extraction was found a competing reaction during the charge/discharge process in aqueous solutions and depend on the pH. The total charge capacity of the material is then the sum of proton and cation insertion charges. The electrochemical characteristics of the material thus can be tuned according to the application.

Collective Phenomena in Mixed Ionic & Electronic Conductors William C. Chueh; Stanford University, United States

Mixed ionic and electronic conductors underpin many energy storage and conversion mechanisms. The coexistence of ionic and electronic charge carriers gives rise to critical functionalities and mechanisms that do not exist in pure ionic and pure electronic conductors, such as ion insertion (intercalation). Fundamentally, mixed transport of ions and electrons involves collective phenomena, similar to many-body effects in condensed matter physics. At the atomic scale, mobile ions and electrons interact as they migrate in the solid-state, affecting both the equilibrium configuration and the kinetic pathway. At the mesoscale scale, a large ensemble of “wired” particles interact in non-trivial ways.

Historically, the electrochemistry community has largely taken a mean-field approach towards these collective phenomena, which is reflected in widely used reaction-transport models. In the solid-state ionics community, mobile ions and electrons are often dissociated under typical experimental conditions (i.e., higher temperatures). As such, the standard approach is to consider bulk ion-electron interaction through local and equilibrium charge neutrality.

In this talk, I will overview two bodies work at Stanford on collective phenomena in mixed conductors that goes beyond the mean-field and local charge neutrality approach. First, at the atomistic level, I will deconstruct the coupling between mobile ions and localized electrons (polarons) and show how the local chemistry is determined by such couplings. I will use two model solids, Li2-XMnO3 and Na2-XMnO7 as examples. Second, at the mesoscale, I will

show that reaction-diffusion and phase separation occurring in an ensemble of wired particles give rise are vastly different behavior than their bulk, single crystal counterpart. I will use two additional model solids, LiXCoO2 and LiFePO4 to showcase these unusual collective phenomena occurring at the mesoscale. To conclude my talk, I will describe the ten-year vision to advance the understanding of ionic and electronic transport by embracing emergent experimental and theoretical tool that tackle transport at the intrinsic time and length scales.

Switching the Properties of Layered Materials through Intercalation, Defects and External Fields from First Principles Diana Qiu; Yale University, United States

Layered van der Waals materials, such as transition metal dichalcogenides (TMDs), are a promising platform for applications as diverse as optoelectronics, energy storage, and quantum information in large part due to the tunability of their electronic, optical and structural properties. Both ground- and excited-state properties can be sensitively modified both during and after synthesis through methods such as ion intercalation, stacking and twisting, the introduction of defects, and coupling to external fields. In this talk, I will explore three different pathways for switching the properties of layered TMDs. Firstly, I will present our recent first principles work on ion intercalation induced phase transitions in different TMD heterostructures, including an intercalation-induced charge density wave (CDW) phase transition in WTe2. Secondly, we will explore structural defects present in TMDs, routes for passivating these defects, and magnetic order arising from defect complexes. Finally, we will explore how many-body effects modify the nonlinear optical response of 2D materials and the coupling to strong external fields beyond the perturbative regime.

Coupling Diffusion and Finite Deformation in Intercalation Materials Ananya Renuka Balakrishna, Tao Zhang and Delin Zhang; University of California, Santa Barbara, United States

We present a multiscale theoretical framework to investigate the interplay between diffusion and finite lattice deformation in intercalation materials. In this framework, we couple the diffusion of a guest species (Cahn-Hilliard type) with the finite deformation of host lattices (nonlinear gradient elasticity). We adapt this theory to $LiMn_2O_4$ to investigate the delicate interplay between Li-diffusion and the cubic-to-tetragonal deformation of lattices. Our computations reveal fundamental insights into the microstructural evolution pathways under dynamic discharge conditions, provide quantitative insights into the nucleation and growth of twinned microstructures during intercalation, and identify regions of stress concentrations (e.g., at phase boundaries, particle surfaces) that arise from lattice misfit. These findings suggest a potential mechanism for structural decay in $LiMn_2O_4$. More generally, we establish a theoretical framework that can be used to investigate microstructural evolution pathways, across multiple length scales, in first-order phase transformation materials.

Tailoring The Optical and Electrical Properties of $MoTe_2$ via Electrochemical Intercalation of Lithium Ions Alyssa Shiyu Xu; Cornell University, United States

Intercalation of lithium (Li) ions is one of the most effective methods to realize structural transformation and to tune the optical and electrical properties of two-dimensional transition metal dichalcogenides (2D TMDCs). Numerous studies have focused on the phase transition from semiconducting 2H phase to metallic 1T (or 1T') phase in MoS_2 and WS_2 induced by the intercalation of Li ions. However, few reports explore the effects of Li intercalation in other TMDCs, such as Mo- or W- ditellurides. In particular, novel electronic and energy devices can be achieved using the Li-intercalated $MoTe_2$ with its intriguing electrical, topological and catalytic properties.
Here, we report electrochemical Li intercalation into 1T'- $MoTe_2$ flakes. The 1T' phase is stable down to 0.9 V of the applied electrochemical voltage, and two new phases are observed at 0.7 V (phase I) and 0.4 V (phase II), respectively. The lightly Li-intercalated phase I is evidenced by the disappearance of the A_g peak at ~77.7 cm^{-1} and the appearance of a peak at ~86.9 cm^{-1} in Raman spectroscopy and a 10% increase of electrical resistance in two-terminal measurements. For the heavily Li-intercalated phase II, we observe a lattice expansion of ~7% in (001) direction in single-crystal X-ray diffraction, the emergence of new Raman peaks at 16.8 cm^{-1}, 109.0 cm^{-1} and 132.8 cm^{-1} in Raman spectroscopy and increase of electrical resistance for over 8 folds. *In situ* Hall effect measurements confirm the decrease in conductivity, which also decreases with decreasing temperature for the phase II, suggesting a semiconducting phase. The Hall carrier density falls from 10^{15} cm^{-2} in pristine 1T'-$MoTe_2$ to 10^{14} cm^{-2} in phase I and to 10^{12} cm^{-2} in phase II. Our results highlight the importance of electrochemical intercalation of Li ions as a powerful tool to manipulate phase stability and electron density of 2D TMDCs.

SESSION SF03.05: Characterization of Ion Insertion Dynamics

1:30 PM *SF03.05.01
***Operando* Dynamical Studies of Dynamics within Intercalated 2D Materials** Aaron Lindenberg; Stanford University, United States

I will describe two recent efforts probing the dynamics of ion transport and ion-induced metastable phases as probed by time-resolved optical, x-ray and electron scattering. In Li-intercalated WTe2, we find a new metastable phase featuring an anomalously large in-plane chemical expansion coefficient (expansion per unit lithium inserted). It is common for 2D materials to expand in the out-of-plane direction upon intercalation, but large tunable uniaxial in-plane expansion is much more rare. The unusual actuation of LixWTe2 is linked to the formation of a metastable crystallographic phase, potentially enabling novel means for strain modulation at high frequencies. In the second part of the talk I will describe recent efforts to visualize the dynamics of ion hopping in superionic materials.

2:00 PM SF03.05.02
***Operando* Optical Probes of Ion-Insertion-Driven Phase Change in Electrochemically Gated $La_{1-x}Sr_xCoO_{3-\delta}$ (LSCO) for Tunable Photonics** Rohan D. Chakraborty, Teslim A. Fasasi, Chris Leighton and Vivian Ferry; University of Minnesota-Twin Cities, United States

Electrolyte gating has enabled dramatic control of electronic, magnetic, and optical properties in materials *via* electrochemically driven ion insertion and extraction at the interface between electrolytes and active materials. In ion-gel-gated perovskite $La_{1-x}Sr_xCoO_{3-\delta}$ (LSCO) thin films with $x = 0.50$, strong interfacial electric fields can support sufficient oxygen vacancy formation/migration to drive a topotactic transformation from the as-grown metallic

perovskite phase to an insulating, oxygen-vacancy-ordered brownmillerite phase that extends from the surface through the depth of the film. Our recent *ex situ* refractive index studies uncovered large optical contrast before and after this electrochemically induced oxygen extraction, framing LSCO as an attractive phase change material for tunable photonics.

Here, we apply *operando* FTIR spectroscopy to ion-gel-gated LSCO films to carefully probe the reversibility and cyclability of the metal-insulator optical changes induced by oxygen insertion/extraction at the ion gel-LSCO interface. Specifically, we will show FTIR transmission measurements of $x = 0.50$ LSCO under ion-gel electrochemical gating that reveal a repeated opening and closing of an electronic bandgap by switching between the as-grown metallic perovskite phase and the voltage-induced insulating brownmillerite phase, over many cycles and at room temperature. The *operando* FTIR measurements of this electrochemically-mediated photonic switching are correlated with insights from XRD, spectroscopic ellipsometry, and electronic transport.

We find that the topotactic phase changes in ion-gel-gated LSCO films with $x = 0.50$ are nearly fully recoverable, with positive gate voltage driving oxygen extraction from the nominally metallic perovskite phase to form the insulating brownmillerite phase, and negative voltage driving oxygen reinsertion through the gel-LSCO interface to re-form the metallic perovskite phase. This opening and closing of an electronic bandgap is observed over many cycles in *operando* FTIR transmission measurements, with some hysteresis due to imperfect reconstruction of the original perovskite phase and asymmetric redox kinetics. These differences in electrochemical reduction *vs.* oxidation are further explored through *operando* measurements under different environments. A low-moisture environment further drives oxygen extraction in the brownmillerite phase of LSCO, while an ambient environment is preferred in the reverse direction to reinsert more oxygen through the LSCO-gel interface and recover the original perovskite phase. The enhanced ionic movement under these respective environments corresponds to lower optical loss in the insulating phase and higher loss in the metallic phase, widening the optical contrast in LSCO. Together, these findings answer important questions about the reversibility and endurance of the electrochemically driven optical changes in ion-gel-gated LSCO films, provide insight on how different environments affect ion insertion dynamics, and, combined with the nonvolatile and low-power nature of these optical changes, further highlight the powerful role that electrochemically driven ion insertion and extraction can play in developing tunable photonic devices for adaptive sensing, optical memories, and more.

2:15 PM SF03.05.03
Ion Exchange Pathways of Lithium and Sodium in Layered Oxides Yu Han and Chong Liu; University of Chicago, United States

Ion exchange in layered materials is one type of special ion transport process, which involves ion insertion and ion extraction simultaneously. This type of bi-directional ion transport requires the rearrangement of interlayer ions and will induce the phase evolution of layered host structures. More importantly, ion exchange is a powerful method to access metastable materials with advanced functionalities for energy storage applications. However, the ion exchange reaction pathways in layered materials remain elusive. Here, using layered oxides as model materials, we tracked the real-time phase evolution during Li-Na ion exchange in layered oxides. An interesting pseudo-charging behavior has been observed. Combining with the chemical composition information, the ion exchange pathway of phase separation between Li-rich and Na-poor phases was revealed. Depending on the chemical potential of exchange ions in the solution side, we identified two different exchange routes, the surface reaction-limited route and the diffusion-limited route. The phase separation behavior accompanied by the charge transfer is general in both ion exchange routes. Both DFT calculation and experiments point to that the co-existence of Li-rich and Na-poor phases is governed by thermodynamics. Besides, we demonstrate that structural vacancy level and lithium preference are critical in determining the feasibility of ion exchange. Guided by this understanding, Na_yCoO_2 was converted from the parent Li_xCoO_2 for the first time and $Li_{0.94}CoO_2$ was converted from Na_yCoO_2 at 1-1000 Li-Na (molar ratio) with electrochemical assisted ion exchange.

Tuning The Insulator Metal Transition in Rare Earth Nickelates through Dynamic Electrochemical Ion Insertion Alan Zhang, Catalin Spataru, Joshua D. Sugar, Alec Talin and Elliot J. Fuller; Sandia National Laboratories, United States

The rare earth nickelates have received renewed attention due to the discovery of superconductivity in infinite layered structures under substitutional doping[1] and the observation of widely tunable electronic behavior in perovskite structures for use in analog memory devices[2]. Recent work has demonstrated that interstitial dopants (H, alkali metals) can be introduced into nickelates to change the room temperature resistance by 10^6 -10^8. However, the evolution of the bond disproportionation transition as a function of interstitial dopants has not been reported and the doping fraction leading to rich correlated electronic behavior is often unknown. Therefore, the electronic phase diagram in nickelate compounds as a function of interstitial doping is of interest. Here, we carried out lithium doping of $PrNiO_3$ using a dynamic electrochemical process. We constructed electrochemical cells using epitaxial thin films as electrodes and then insert lithium using an electrolyte. For Li_xPrNiO_3, we find that increased lithium doping interrupts bond disproportionation causing a reduction in the ground state resistivity at small fractions $0<x<0.25$ with a successively smaller ON/OFF ratio. At larger fractions $x>0.25$ we observe the disproportionation transition to be destroyed and fully insulating type behavior is observed over T= 5-300K. Raman spectroscopy reveals that lithium introduces structural changes that affect A1g modes which are a sensitive probe of bond disproportionation. Density functional theory calculations confirm the disruption to bond disproportionation with an initial reduction in the bandgap at small fractions and an increase at larger fractions. The results point to interstitial doping as a powerful method to synthesize new phases in strongly correlated systems and for next generation memory devices.

3:45 PM SF03.05.05
Redox-Free Ion Insertion: Discovery of Electride Materials for Electron-Anion Exchange Rebecca Radomsky and Scott C. Warren; University of North Carolina at Chapel Hill, United States

In order to maintain charge neutrality, ion insertion is accompanied by reduction or oxidation of the host lattice. However, a class of materials called electrides, where vacant crystallographic lattice sites are instead occupied by a bare anionic electron, exhibits a fundamentally different mechanism. The mechanism for anion insertion into electrides—which we have named Electron-Anion Exchange (EAX)—allows for the one-to-one swap of anions and electrons as the anion hops between “vacant” electride sites. Because the participating anionic electrons are not associated with any atomic nuclei, the surrounding atoms do not experience any reduction or oxidation throughout the insertion process. The consequences of redox-free EAX are substantial. Due to the similar size and charge of anionic electrons and simple anions, the host lattice experiences virtually no electrostatic change during ion insertion and the reorganization energy becomes negligible. In order to fully exploit the effects of EAX, including little to no lattice expansion upon intercalation and exceptionally low activation energies for ion diffusion, we have designed and synthesized a novel electride material, Y_6S_4. Similar to previously known electrides such as Y_2C, Y_6S_4 has a layered structure with alternating layers of anionic electrons and host material. However, Y_6S_4 contains S pillars throughout the anionic electron layer that increase the interlayer spacing, causing the overlap with neighboring cations to be small. We predict the “pillared

layered" structure of Y_6S_4 to have not only a larger capacity, but also a significantly higher ionic conductivity than its layered electride analogs. We therefore anticipate Y_6S_4 to be one of the most efficient anion intercalation materials to date—with natural applications as an electrode in anion shuttle batteries or electrochemical capacitors.

4:00 PM SF03.05.06
Optical Properties and Applications of Molecular-Intercalated MoS_2 Bo-An Chen, Sylwia Ptasinska and Prashant Kamat; University of Notre Dame, United States

Two-dimensional (2D) transition metal dichalcogenides have demonstrated intriguing tunability in optical and electrical properties through the intercalation of ions within the van der Waals gap of their layered structure. In this study, we present a spectroelectrochemical method for electrochemically intercalating quaternary ammonium molecules into a MoS_2 thin film while monitoring the optical properties through absorption spectra. Throughout the intercalation process, we observed attenuation in both A and B excitonic peaks, with complete quenching achieved at a sufficient applied potential (E = -1.8 V vs. Ag). Raman spectra indicated that the as-intercalated MoS_2 remains in a semiconducting phase (2H), with an additional out-of-plane (A_{1g}) vibrational mode appearing. Additionally, both X-ray and ultraviolet photoelectron spectroscopy (XPS and UPS) results showed the metallic-like properties of the as-intercalated MoS_2, confirming successful intercalation of ammonium molecules and resulting in a high concentration of electron injection. In the second part, we demonstrate a potential application in solar energy storage using colloidal MoS_2 prepared through an electrochemical intercalation and exfoliation process. This study underscores the importance of further investigating ion intercalation in 2D materials and provides insights into the potential of Molecular-Intercalated MoS_2 for energy storage.

4:15 PM SF03.05.07
Implantation of Gallium into Layered Tungstene Disulfide Nanostructures is Facilitated by Hydrogenation Alex Laikhtman[1], Julio A. Alonso[2], Jose I. Martinez[3] and Alla Zak[1]; [1]Holon Institute of Technology (HIT), Israel; [2]University of Valladolid, Spain; [3]Institute of Materials Science of Madrid, Spain

In this work, experimental results and theoretical simulations for the implantation of Ga into WS_2 nanoparticles exposed to focused Ga^+ ion beams (FIB) with various doses are reported.
Multiwall WS_2 and MoS_2 nanotubes and polyhedral fullerene-like nanoparticles were discovered in the earlier 1990s. An efficient synthesis method for the scaled-up production of high purity inorganic fullerene WS_2 nanoparticles was later developed, which allows to produce tens of kilograms per day. Additional efforts resulted in renewed synthesis of highly crystalline WS_2 and MoS_2 nanotubes in pure phase and scalable fashion. The availability of these nanomaterials led to investigation of their properties, and stimulated numerous applications in photoelectronics and nano-optics, tribology, and hydrogen storage.
Implantation of atoms into solid materials provides a way to modify their properties. Doping of layered MoS_2 and WS_2 nanoparticles with alkali metal atoms, Re, Nb, and possibly other elements is a promising technique to change the electronic (semiconductor to metal), magnetic (diamagnetic to paramagnetic), and optical properties, the surface characteristics, and the mechanical and chemical behavior of these materials. The modified materials could be used in nanotechnology applications, catalysts and sensors, as well as in tribology and lubrication. However, the implantation processes often have a damaging effect on the materials structure.
Bombarding WS_2 multilayered nanoparticles and nanotubes with FIB of Ga^+ ions at high doses, larger than 10^{16} cm^{-2}, indeed leads to drastic structural changes and melting of the material. At lower doses, when the damage was negligible or significantly smaller, the amount of implanted Ga was very small. A substantial increase in the amount of implanted Ga, and not appreciable structural damage, were observed in nanoparticles previously hydrogenated by a radio-frequency activated hydrogen plasma.
Density functional theory calculations reveal that the implantation of Ga in the spaces between adjacent layers of pristine WS_2 nanoparticles is difficult due to the presence of activation barriers. In contrast, in hydrogenated WS_2 the hydrogen molecules are able to intercalate in between adjacent layers of the WS_2 nanoparticles, giving rise to the expansion of the interlayer distances, that in practice leads to the vanishing of the activation barrier for Ga implantation. This facilitates the implantation of Ga atoms in the irradiation experiments.

SESSION SF03.06: Dynamical Switching of Electrons, Spins and Phonons
Session Chairs: Iwnetim Abate and Judy Cha

9:00 AM *SF03.06.01
Dynamic manipulation of thermal & structural properties using electrochemical & electrical stimuli Aditya Sood; Princeton University, United States

Beyond energy storage, ion insertion has emerged as an powerful method to dynamically tune the physical properties of materials[1]. While there have been numerous examples of electrochemical tuning of optical and electronic properties, the dynamic manipulation of thermal and structural properties is relatively less explored. I will first describe our efforts to create "thermal switches" – materials whose thermal conductivity can be tuned in real-time – using ion insertion. We show that the reversible intercalation of Li+ into the van der Waals gaps in MoS2 induces a ~8-10x modulation in the cross-plane thermal conductance[2], opening avenues for dynamic thermal management. Interestingly, we find that micron-scale heterogeneities in ion concentration can be imaged using spatially-resolved measurements of thermal conductance, suggesting that heat current measurements could enable operando microscopy in
electrochemical systems. Next, I will briefly discuss how ion insertion can change the crystal structure and symmetry in layered crystals; in particular, we discover intriguing uniaxial in-plane lattice expansion caused by Li+ intercalation in WTe2, a finding that has potential applications in electrochemical actuators[3]. Finally, I will describe our recent efforts to visualize nanosecond-timescale and picometer-lengthscale structural dynamics in materials driven electrically[4]. Such ultrafast operando techniques could provide fundamental insights into field-induced intermediate states, metastable phases, and transport pathways in ionic systems.

9:30 AM SF03.06.02
Unlocking Exotic Charge and Spin States in Layered Materials: A Dynamic Approach via Ion-Insertion Iwnetim I. Abate; Massachusetts Institute of

Technology, United States

Layered two-dimensional (2D) and quasi-2D materials, along with their heterostructures, offer a diverse range of electronic, optical, and magnetic properties. The tunability of charge, spin, orbital, and lattice degrees of freedom in these materials, both through static and dynamic methods, provides numerous avenues for addressing fundamental questions and exploring diverse applications. Electrochemical ion-insertion in these van-der-Waals materials serves as a delicate tool to dynamically adjust their properties, potentially leading to the emergence of exotic electronic and spin states that might not be attainable through traditional synthesis methods. In this presentation, I will share our group's research on layered oxide materials where we induce exotic charge and spin states using electrochemical ion-insertion. These unique states challenge existing theoretical models and experimental observations. I will delve into the novel theoretical framework we have developed, underpinned by rigorous computational formalisms, and the distinctive magnetic, optical, and phonon properties observed experimentally.

9:45 AM SF03.06.03
***Operando* studies of mixed-conduction polymers: Microstructural effects and carrier-induced ordering** Alberto Salleo; Stanford University, United States

New families of conjugated polymers are being investigated as mixed conductors in applications as varied as biosensing, electrocatalysis and brain-like computing. Great advances are being made in developing materials properties and in device design and integration. A fundamental understanding of “how they work” is however still missing. In this talk I will show how we use a suite of state-of-the-art *operando* techniques, spectroscopic and diffraction-based implemented during electrochemical biasing to study organic mixed conductors and answer basic questions. In particular, we elucidate the effect of electrolyte and charge density on structure and properties, namely carrier mobility. Most of these materials are semicrystalline and microstructure has an effect on their operation. We find that charge density affects structure, which in turn affects the ability of the semiconductor to conduct charges
