Quasi two-dimensional perovskites in Ruddlesden-Popper phase (RPPs) are extensively studied for their flexible tunability of the optoelectronic properties by changing the number of layers, chemical composition and the organic spacer, which makes them particularly suitable for several applications in the field of photovoltaics and light emitters [1-4]. In fact, the reduced dielectric screening and the quantum confinement in a monolayer of RPP materials generate large bandgaps and stable excitons at room temperature with binding energies of the order of hundreds of meV similarly to other 2D semiconductors. Moreover, the physical properties of RPPs are strongly influenced by the number of layers that affects the electronic bandgap and the exciton binding energy which decreases as the number of layers increases. These properties are also correlated with the chemical composition and the structure of the organic spacer used as the interlayer material [5, 6].

In this developing framework, the photoexcited carrier dynamics in these materials is still far to be completely understood although the study of charge generation and recombination path can furnish key information for boosting the development of new materials for new generation optoelectronic.

Femtosecond Transient Absorption Spectroscopy (FTAS) has proven to be an important tool to investigate the ultrafast physics of halide perovskites having different dimensionality, morphology and architectures, giving insights into the band structure and the electronic states involved in the photoexcitation processes. Here, we present FTAS investigations on monolayer and multilayer of RPPs DAMAPI ($\text{DA}_2\text{MA}_{n-1}\text{PbI}_{3n+1}$, where $\text{DA}=\text{CH}_3-(\text{CH}_2)_{11}-\text{NH}_3^+$ is the spacer and n indicates the number of the layers). The FTAS measurements, performed at 77 K and room temperature using several different pump energies and excitation densities, allowed the observation of absorption bleaching energies corresponding to different excitonic and electronic transitions in DAMAPI. These results are compared with theoretical simulations based on DFT, the GW approximation and the Bethe-Salpeter equation for the calculation of the excitonic properties. In this way, we have assigned the transient absorption signals to electronic transitions related to the formation of excitons with principal quantum number 1s and 2s. The temporal analysis of these signals indicates the exciton-exciton annihilation process as the main relaxation mechanism in the first picoseconds after the excitation, while exciton radiative recombination is observed at longer time delays (>100 ps). This work demonstrates how transient absorption measurements not only allow the study of the dynamics of the excited carriers but, because of their high sensitivity to the changes of the carrier density induced by the excitation, they also allow the observation of spectral features otherwise not observable with steady-state measurements [7].

Tracking Spin and Charge in Time and Space in Halide Perovskite Films Sascha Feldmann; Harvard University, United States

Halide perovskites are promising semiconductors for next-generation optoelectronic and spintronic applications. Yet, we still don't fully understand what governs the charge and spin dynamics in these

materials. This is especially true when studying device-relevant thin films of halide perovskites, which lack single-crystalline perfection.

In this talk, I will give an overview of our recent efforts to understand the spin-optoelectronic performance of these films better by using time-, space- and polarization-resolved spectroscopy and microscopy. We will find that the energetically heterogeneous energy landscape in mixed-halide perovskites can lead to the local accumulation of charges, with unexpected consequences for devices [1]; how despite strong differences in vertical diffusivity and across grains charge extraction can remain very efficient [2], and how locally varying degrees of symmetry-breaking drive spin domain formation [3,4] in this fascinating class of solution-processable semiconductors.

Characterizing Spin and Orbital Ordering Effects in Hybrid Metal Halide Perovskites Towards Advancing Optoelectronic Properties Bin Hu; University of Tennessee, United States

Hybrid metal halide perovskites are known as emerging semiconducting materials with tunable structure-property relationships through solution-processing methods. Such solution-processing perovskites simultaneously carry spin and orbital momentum. Consequently, using spin and orbital momentum has become a critical approach to control the multifunctional properties. However, characterizing spin and orbital parameters still demands much effort to understand their underlying relations to materials properties. To respond to this demand, we have been using magnetic field effects and circularly polarized laser spectroscopy to experimentally investigate spin and orbital parameters in determining light-emitting, photovoltaic, and lasing properties in hybrid metal halides. Our magnetic field effects have shown that bright and dark excitons are having largely different outcomes when generating optic, electric, optoelectronic actions. Therefore, magnetic field effects provide an essential experimental tool to characterize spin effects in such solution-processing perovskites. Furthermore, we found that circularly polarized luminescence can be used as a convenient method to elucidate orbital dynamics within Rashba band structures. We discovered that the circularly polarized orbitals with right and left handedness in Rashba band structures can selectively interact with spin-up and spin-down spin dipoles, leading to a mutually selectivity between spin order and orbital order. Particularly, this selective interaction between spin order and orbital order can enable spin-switchable phenomena towards developing emerging functionalities in these solution-processing hybrid metal halide perovskites. This presentation will discuss the fundamental details on exploring spin and orbital parameters by using magnetic field effects and circularly polarized laser spectroscopy.

Role of Interconnectivity in Perovskite Nanocrystals: Charge Carrier Dynamics in Nanostructures Embedded in Porous Films David O. Tiede¹, Carlos Romero-Pérez¹, Katherine A. Koch², Mauricio E. Calvo¹, Juan F Galisteo-López¹, Ajay Ram S. Kandada² and Hernán Miguez¹; ¹Institute of Materials Science of Seville, Spain; ²Wake Forest University, United States

In the past years, halide perovskite-based devices are shifting towards low-dimensional functionalized structures and morphologies such as 2D, 2D/3D or perovskite nanocrystals (pNCs). For the latter, a common approach is to employ ligands, which ultimately determine the photophysical properties and in particular the interaction among individual NCs. As an alternative approach, mesoporous matrices can be employed to synthesize pNCs and have been established as a promising ligand free approach. [1,2] From a more fundamental perspective, this material system allows to study the interaction of excitations in pNCs with their neighbouring pNCs isolated from ligand or solvent induced effects characteristic of colloidal NCs. [3]

In this presentation, we employ FAPbBr₃ NCs of various sizes synthesized in porous matrices to determine the role of interparticle interaction on charge carrier recombination isolated from ligand and solvent induced effects. A broad photophysical characterization comprising time resolved absorption and emission spectroscopies as a function of temperature and fluence is employed to study the transition from isolated emitters to interconnected NCs array that preserves confinement effects while allowing for long range electronic transport. From a spectroscopic point of view, the effect of confinement is verified through thermalization dynamics. We demonstrate that interconnectivity determines charge carrier dynamics as it affects trap filling, radiative recombination and multiparticle interactions. We rationalize these findings by employing recombination and diffusion models for both the isolated and interconnected case and study the transition between these scenarios. Such transition regime is of great importance in terms of possible device performance, since the interplay of transport and (non) radiative recombination while maintaining confinement effects will determine its ultimate efficiency.

Multi-Band Electronic Structure and Carrier Dynamics in Formamidinium Lead Bromide

Perovskite Daniele Catone¹, Giuseppe Ammirati^{1,2}, Patrick O'Keeffe¹, Stefano Turchini¹, Francesco Toschi¹, Alessandra Paladini¹, Faustino Martelli¹, Fabio Matteocci², Jessica Barichello², Paolo Moras¹, Polina Sheverdyeva¹, Valeria Milotti¹, Daniel Ory^{3,4}, Phillippe Baranek^{3,4} and Aldo Di Carlo^{1,2};
¹Consiglio Nazionale delle Ricerche, Italy; ²Università degli Studi di Roma Tor Vergata, Italy; ³Electricité de France (EDF), Italy; ⁴Centre National de la Recherche Scientifique, Italy

In recent years, the scientific community has been captivated by the exceptional properties of halide perovskites. These materials have garnered significant interest due to their high absorption coefficients in the visible range ($\alpha > 10^5 \text{ cm}^{-1}$), ultralong carrier diffusion lengths, extended carrier lifetimes, remarkable defect tolerance, and tunable bandgaps [1-2]. Among these perovskites, lead bromide perovskites have emerged due to their relatively large bandgap of approximately 2.3 eV, making them ideal candidates for tandem applications and efficient semitransparent solar cells. In this context, one of the most promising materials is formamidinium lead bromide perovskite (FAPbBr₃) that exhibits remarkable stability under light exposure and possesses a carrier diffusion length that facilitates a straightforward planar heterojunction solar cell configuration [3, 4]. Despite its proven superiority in terms of semitransparency and stability, only a limited number of experimental and theoretical studies have been conducted to explore its properties. In particular, the knowledge of the electronic properties and of the dynamics of

photoexcited carriers in FAPbBr₃ remain incomplete. Understanding the charge generation and recombination is of paramount importance as it provides crucial insights for advancing the development and optimization of various technologies such as solar cells, lasers, and LEDs [5].

Here, we present the excited-state properties of a thin film of FAPbBr₃ studied combining steady-state light absorption, photoluminescence (PL), femtosecond transient absorption spectroscopy (FTAS), photoelectron spectroscopy (PES) with density functional theory (DFT) calculations. In this way, we give a complete description of the electronic properties of FAPbBr₃, assigning the electronic bands involved in the photoexcitation by UV-Vis radiation and the relative carrier dynamics. By integrating absorption, PL, PES, and DFT, we successfully assign the two photobleaching (PB) signals observed in the transient spectrum to specific electronic transitions. Specifically, the signal at 2.3 eV (PB1) originates from the transition between the first valence band (VB1) and the first conduction band (CB1) [6], while the signal at 3.4 eV (PB2) arises from the transition between the second inner valence band (VB2) and CB1. In the light of this assignation, the rise of the PB1 and PB2 signals were investigated as a function of the carrier density, in order to correlate their dynamics to the thermal relaxation processes involving the carriers excited in the VB1→CB1 and VB2→CB1 transitions. The PB1 signal shows a rise time that slows down with the increase of the carrier density indicating that the dominant processes influencing it are the thermalization and cooling of carriers in VB1 and CB1 [7, 8]. On the other hand, the rise time in PB2 accelerates as the excited carrier density increases, suggesting that this signal is strongly influenced by the thermalization of the hot holes in VB2. In fact, VB2 shows a quasi-flat band structure determining a localization near the band maximum of all the excited holes [9].

In summary, the combination of various spectroscopic techniques and theoretical calculations allows us to unravel the underlying carrier dynamics and establish correlations with thermal relaxation processes, providing valuable insights into the excited-state behavior of FAPbBr₃. These findings enhance our understanding of the material properties and pave the way for further advancements in its utilization for optoelectronic and photovoltaic applications.

Engineering of Solid-State Single-Photon Sources Based on Perovskite Quantum Dots in Perovskite

Matrix Hao Zhang¹, Altaf Pasha¹, Siraj Sidhik¹, Jia-Shiang Chen², Xuedan Ma² and Aditya D. Mohite¹;

¹Rice University, United States; ²Argonne National Laboratory, United States

Semiconductor quantum dots (QD) have emerged to be one of the promising candidates for on-demand single-photon emitters (SPE), which are one of the key units in quantum photonic circuits and quantum information processing. However, despite wide investigation of colloidal QDs, implantation of such SPE system in solid states for electrical excitation is less developed. Here, we have demonstrated the first solution-processed perovskite-based single-photon source in a solid-state medium, by embedding

perovskite emission centers into a wide-bandgap perovskite matrix. Such ‘dot-in-a-matrix’ system exhibits a clear photon-antibunching signature, with second-order correlation function ($g_2(0)$) to be ~ 0.1 at cryogenic temperatures. The photoluminescence (PL) spectrum exhibits narrow emissions lines at 1.8–1.9 eV with 2–3 meV FWHM at $T=6$ K, indicating high crystallinity of the localized emission centers. High-resolution transmission electron microscope (HR-TEM) confirms the presence of nanometer-sized domains, which indicates the formation of quantum dots during the rapid crystallization of the precursor solvent. Monitoring PL with time suggests blinking-free emission and spectral diffusion of <1 meV. PL spectra exhibits a linear dependence with excitation intensity, indicating the mono-recombination dominated by single exciton rather than bi-exciton or charged exciton states. Additionally, exciton fine structures have been detected, which are likely due to the anisotropic structures of individual emitters. Finally, we have demonstrated the capability of electrical luminescence by sandwiching the matrix between electron-transport and hole-transport layers. Such demonstration may pave the pathway of on-chip integration of single-photon sources for quantum optical systems.

New Insights into the Formation Mechanism and Electronic Structure of Alloyed $\text{Cs}_2\text{AgBiBr}_6$ Double Perovskites for Enhanced Visible Light Absorption Huygen J. Jöbsis¹, Kostas Fykouras², Joost W. Reinders¹, Ina Vollmer¹, Michal Andrzejewski³, Loreta A. Muscarella¹, Nicola P. Casati³, Linn Leppert² and Eline Hutter¹; ¹University of Utrecht, Netherlands; ²University of Twente, Netherlands; ³Paul Scherrer Institute, Switzerland

Halide double perovskite semiconductors such as $\text{Cs}_2\text{AgBiBr}_6$ are widely investigated as a more stable, less toxic alternative to lead–halide perovskites in photoconversion applications including photovoltaics and photoredox catalysis. However, the relatively large (~ 2.1 eV) and indirect bandgap of $\text{Cs}_2\text{AgBiBr}_6$ limits efficient sunlight absorption. Similar to lead–halide perovskites, the bandgap of double perovskites can be manipulated through (partial) substitution of metals or halides with similarly charged ions. However, commonly used solvent-based synthesis routes often lead to the formation of domains or side phases, rather than solid solutions with controlled properties. This results in an inhomogeneous electronic landscape which is detrimental for photoconversion applications.

Here, we show that mechanochemical synthesis methods, such as ball milling, are a valid route to synthesize phase-pure double perovskites. With the use of synchrotron radiation we followed the formation mechanisms during mechanochemical synthesis of $\text{Cs}_2\text{Ag}[\text{BiM}]\text{X}_6$ (with $\text{M} = \text{Sb, In, or Fe}$ or $\text{X} = \text{Cl, Br, or I}$), and identified new intermediate phases, providing insights into the reaction kinetics. We find that mechanochemical synthesis is a successful approach to make compounds that have not been reported via solution-based synthesis routes, such as $\text{Cs}_2\text{AgBi}_{0.5}\text{In}_{0.5}\text{Br}_6$, $\text{Cs}_2\text{AgBiBr}_{6-x}\text{I}_x$, and $\text{Cs}_2\text{AgBi}_{1-x}\text{Fe}_x\text{Br}_6$. Where substitution with In^{3+} increases the band gap energy, it is lowered when replacing Bi^{3+} with Fe^{3+} or Br^- with I^- .

Hence, the optical bandgap of $\text{Cs}_2\text{AgBrBr}_6$ can be tuned over the entire visible spectrum when partly substituting Bi^{3+} or Br^- . For instance, we find that controlled replacement of Bi^{3+} with Fe^{3+} via mechanochemical synthesis results in a remarkable tunability of the absorption onset between 2.1 to ~ 1 eV. Our first-principles density functional theory (DFT) calculations demonstrate that this bandgap reduction originates from a lowering of the conduction band minimum upon introduction of Fe^{3+} , while the valence band remains constant. Additionally, our DFT calculations suggest that the bandgap becomes direct when $>50\%$ of Bi^{3+} is replaced with Fe^{3+} . Finally, we find that the tunability of the conduction band minimum is reflected in the photoredox activity of these semiconductors.

The improved understanding of the reaction mechanism of alloyed-AgBi double perovskites might help to overcome the current challenges faced with solution processing methods. Hence, opening up new avenues for enhancing the visible light absorption of double perovskite semiconductors and for harnessing their full potential in sustainable energy applications.

Traps in the Spotlight: How Traps Affect the Charge Carriers Dynamics in Cs₂AgBiBr₆ Perovskite

Valentina Caselli¹, Jos Thieme¹, Huygen J. Jöbsis², Jiashang Zhao¹, Eline Hutter², Tom J. Savenije¹ and Julia Anthea Gessner; ¹Delft University of Technology, Netherlands; ²Inorganic Chemistry and Catalysis, Netherlands

Since their discovery as versatile semiconductors for photovoltaic applications, perovskite materials, with general formula ABX₃, have been intensively studied. Tuning of their opto-electronic properties make it possible to reach remarkable power conversion efficiencies, currently topping at 25.6%, in roughly a decade of development. However, a rising concern regarding the use of lead in the photoactive layer has pushed research into lead-free alternative candidates. Toxic lead can be substituted by combining monovalent and trivalent cations, such as in Cs₂AgBiBr₆. However, efficiencies of Cs₂AgBiBr₆-based photovoltaics are still modest. To elucidate the loss mechanisms, in this report we investigate charge dynamics in Cs₂AgBiBr₆ films in thin films by means of TRPL, TA measurements and double pulse excitation time-resolved microwave conductivity (DPE-TRMC). In DPE-TRMC the sample gets illuminated by two laser pulses arriving with a short time delay. By comparing the photoconductance traces induced by the second pulse in presence and absence of the first pulse, we are able to examine the effect of the long-lived species on the charge carrier dynamics. For these experiments we used identical excitation wavelengths for both laser pulses but varying intensities and delay times. We modelled the results introducing a comprehensive model, which accounts for the free carrier generation yield, localization of free carriers, electron trapping by color centers, and shallow trap states for holes. The iterative analysis of the DPE-TRMC experiments with different intensities and delay times reveals the presence of a high concentration of both electron (10^{15} cm^{-3}) and hole (10^{16} cm^{-3}) trap states. In addition, we show that both carriers are trapped on sub-ns timescales, while their depopulation occurs over tens of microseconds. Furthermore, we observe a higher mobility for holes compared to electrons, which amount to 5 and 0.01 cm²/(Vs) respectively, in agreement with the imbalance in their effective masses. Localization of holes causes an effective loss in mobility for the holes, dropping to ca. 1.7 cm²/(Vs), while no effect can be discerned for the electrons. Knowing these kinetic parameters allows us to predict the charge carrier dynamics under AM1.5, explaining the solar cell performance. Our new developed DPE-TRMC methodology gives direct insight on the timescales involved with population and depopulation of the various trap states in Cs₂AgBiBr₆, essential for the design of more efficient devices.

11:45 AM EN04.08.10

Transient Holographic Imaging of Spin Magnetic Moments in Perovskites Julia Anthea Gessner¹,

Martin Hörmann², Shangpu Liu¹, Giulio Cerullo², Franco Valduga de Almeida Camargo³ and Felix Deschler¹; ¹Universität Heidelberg, Germany; ²Politecnico di Milano, Italy; ³IFN-CNR, Italy

Hybrid metal halide perovskites have shown to be a promising class of materials for a variety of applications ranging from LEDs [1] to solar cells [2] due to their high quantum efficiency and tunability in the visible range. Compared to conventional semiconductors, perovskites exhibit strong spin-orbit coupling and spin-split Rashba bands, which allow an efficient optical spin manipulation and could

possibly extend the spin life-time of excitons. These features are particularly attractive for opto-spintronic applications and data storage [3].

A preliminary step towards the integration of perovskites in opto-spintronic devices is the time- and space-resolved optical study of their magnetic properties. In the present work, we study the spatio-temporal spin dynamics of Methylammonium Lead Tribromide (MAPbBr_3) by the unique combination of two spectroscopic methods: Faraday rotation spectroscopy and Ultrafast Holographic Transient microscopy (UHT) [4]. With our technique we get access to the polarization dependent carrier population as well as the Faraday angle, which is a measure for the spin-aligned magnetic moment. The UTH microscope, which works as a shot-noise limited, all-optical lock-in amplifier, has no upper limitations in the signal repetition rate and can resolve femtosecond dynamics with a sub-micrometre spatial resolution. By spatially mapping the transient Faraday angle at different temperatures and fluences, we are hence able to investigate the evolution of optically spin-polarized excitons in time and space and identify the dominating spin relaxation mechanisms. This information is essential for the optimization of the materials' properties and the future realization of opto-spintronic systems.

Improving the Efficiency and Stability of Perovskite Solar Cells using π -Conjugated Aromatic Additives with Differing Hydrophobicities Brian Saunders; University of Manchester, United Kingdom

Improving the efficiency and stability of perovskite solar cells using π -conjugated aromatic additives with differing hydrophobicities

Perovskite solar cells (PSCs) continue to excite the research community due to their excellent power conversion efficiency (PCE) and relative ease of preparation. Additive engineering has played a decisive role in improving PSC performance and stability. In particular, π -conjugated aromatic additives (CAAs) offer key advantages such as high charge transport. However, the roles of hydrophobicity and structure in determining CAA performance as additives are still being established. Here, we investigate the effects of two coumarin additives on the PCE and stability of PSCs based on $\text{Cs}_{0.05}(\text{FA}_{0.85}\text{MA}_{0.15})_{0.95}\text{Pb}(\text{I}_{0.85}\text{Br}_{0.15})_3$ perovskite. The CAAs are coumarin methacrylate (CMA) and coumarin hydroxyethyl (CHE) and were

added to the precursor perovskite solutions prior to film deposition with CMA being more hydrophobic than CHE. These additives increase the best PCE of 19.15% for the control to 21.14% and 21.28% for the best devices containing CHE and CMA, respectively. The stability of the devices with the additives are far superior to that of the control (CAA-free) system. The time lengths required for the PCE to decrease to 80% of the initial value for CMA- and CHE-containing devices are 98 and 38 days, respectively, compared to only 14 days for the control. The moisture and thermal stabilities of the systems containing CMA are markedly improved compared to those containing CHE and the control. Our results show that the extents of binding to Pb^{2+} and passivation increase as the coumarin's hydrophobicity increases which decreases recombination. Our findings show that adding CAAs with increasing hydrophobic character to the precursor perovskite solution is useful for achieving high-performance and long-term stable PSCs[1].

Unraveling Photoelectrochemical Degradation Pathways in Lead Mixed Halide Perovskites with Near Ambient Pressure XPS Michel De Keersmaecker, Neal Armstrong and Erin L. Ratcliff; The University of Arizona, United States

Long-term stability in metal halide perovskites has often been connected to defects in the electronic band gap, but rarely their (electro)chemical, physical and dynamic nature, as well as ion reactivity and mobility are considered. Interactions with O_2 and light excitation (i.e. from X-rays to UV-visible regions) have been suggested as culprits for bulk and interfacial degradation of perovskites and have been considered critical in the improvement of operational stability of photovoltaic devices and X-ray detectors.^[1-3]

Possible explanations for this irreversible degradation process, however, range from intrinsic defects and phase segregation to electrochemical reactions as well as electronic and interfacial property changes.^[4-6] In this work, *in situ* degradation of device-relevant triple cation mixed halide perovskite films using dry O_2 gas using a near ambient pressure X-ray photoelectron spectroscopy (NAP-XPS) characterization method reveals the formation of a weakly coordinated form of Pb (relative to corner-sharing $[\text{PbI}_6]^{4-}$ octahedra). Simultaneously, oxidized iodide species (I_3^-) are formed in the illuminated near-surface region causing the bromide enrichment, consistent with “de-mixing” under stress. Once UHV conditions are restored, a slow return to the initial perovskite stoichiometry is observed, suggesting “self-healing” of defects when the low stress environment is reestablished. In non-stoichiometric films degradation rates accelerate for FAI-rich stoichiometries, but, more importantly, PbI_2 -rich stoichiometries show reduced rates.

This NAP-XPS study demonstrates an important first step in a systematic approach to understanding the role(s) of ambient gases in conjunction with above band-gap illumination and other stressors that limit device stability. Prior to investing resources in high-throughput device construction, this NAP-XPS characterization technique will be an important asset in the investigation of interface engineering strategies for top contact (and bottom) modifications used as mitigation strategies in device optimization with focus on photoelectrochemical stability and energy level alignment if combined with UPS. Additionally, this work extends towards other semiconductive materials or material blends, where *in situ* chemical characterization will be essential to design and support next-generation electronics.

Resolving the Hydrophobicity of Me-4PACz Hole Transport Layer for Inverted Perovskite Solar Cells Dinesh Kabra; Indian Institute of Technology Bombay, India

[4-(3,6-Dimethyl-9H-carbazol-9-yl)butyl]phosphonic acid (Me-4PACz) self-assembled monolayer (SAM) has been employed in perovskite single junction and tandem devices demonstrating high efficiencies. However, a uniform perovskite layer does not form due to the hydrophobicity of Me-4PACz. Here, we tackle this challenge by adding a conjugated polyelectrolyte poly(9,9-bis(3'-(N,N-dimethyl)-N-ethylammonium-propyl-2,7-fluorene)-alt-2,7-(9,9-dioctylfluorene))dibromide (PFN-Br) to the Me-4PACz in a specific ratio, defined as Pz:PFN. With this mixing engineering strategy of Pz:PFN, the PFN-Br interacts with the A-site cation is confirmed via solution-state nuclear magnetic resonance studies. The narrow full width at half maxima (FWHM) of diffraction peaks of perovskite film revealed improved crystallization on optimal mixing ratio of Pz:PFN. Interestingly, the mixing of PFN-Br additionally tunes the work function of the Me-4PACz as revealed by Kelvin probe force microscopy and built-in-voltage estimation in solar cells. Devices employing optimized Pz:PFN mixing ratio deliver open-circuit voltage (V_{oc}) of 1.16V and efficiency >20% for perovskites with a bandgap of 1.6 eV with high reproducibility and concomitant stability. Considering significant research on Me-4PACz SAM, our work highlights the importance of obtaining a uniform perovskite layer with improved yield and performance.

Long-Lived Hot-Carrier Light Emission in Sn Halide Perovskites Maria Antonietta Loi; University of Groningen, Netherlands

A long-lived hot carrier population is critical in order to develop hot carrier photovoltaic devices with

efficiencies exceeding the Shockley–Queisser limit. Here, we report photoluminescence from hot-carriers with unexpectedly long lifetime (ns range) in tin triiodide perovskites. By correlating energy-resolved and time-resolved photoluminescence both at low and room temperature, with density functional theory calculations, we posit that this phenomenon is mostly associated with state-filling of band edge states. While phonon interactions have an effect, but minor. Measuring impulsive stimulated Raman scattering spectroscopy, we identify two coherent phonon modes (25 and 133 cm^{-1}) in FASnI_3 , where the 133 cm^{-1} mode shows a fast decay (< 1 ps) and large dependence on the excitation fluence and energy. We further show that the phonons in FASnI_3 decay much faster compared to CsSnI_3 , highlighting the stronger electron-phonon and phonon-phonon interaction in the hybrid compounds. This work is of fundamental importance for our understanding of Sn-based hybrid perovskites and for an eventual future development of hot carrier photovoltaics.

Influence of Methylammonium Chloride on the Formation and Properties of 3D Br-Rich Perovskites: an *In Situ* Investigation Ana Flavia Nogueira; University of Campinas, Brazil

Owing to their exceptional properties, metal halide perovskites have been incorporated in tandem solar cells. For silicon-perovskite tandem, Br-rich perovskites with a wide-bandgap are required. However, the increase in Br content causes halide distribution heterogeneities and photoinstability. Methylammonium chloride (MACl , $\text{MA} = \text{CH}_3\text{NH}_3^+$) is often added to the perovskite precursor solution to improve optoelectronic properties and performance. However, the effect of MACl additive on Br-rich perovskites is poorly understood.

In this presentation, we will summarize the previous studies from our group where *in situ* experiments coupled to synchrotron radiation were important to identify intermediate compounds, other metal halide phases during the steps of formation, crystallization and annealing.

In the second part of the talk, we will focus on metal halide perovskites with different amounts of Br and MACl using the N-methyl-2-pyrrolidone (NMP) solvent and the gas quenching deposition method. Simultaneous grazing-incidence wide-angle X-ray scattering (GIWAXS) and photoluminescence spectroscopy (PL) tracked perovskite crystallization and emission properties during the spin-coating and thermal annealing steps. For the perovskites without MACl , the formation of crystalline intermediates depends on the halide proportion. On the other hand, adding the MACl changes the formation mechanism inhibiting the formation of crystalline intermediates. Robust Pb-Cl bond formation decreased the interaction of PbX_6 octahedrons with solvent molecules, preventing the stabilization of intermediate phases containing the solvent. The destabilization of the intermediate phases promoted by the addition of MACl favored the formation of the better crystalline perovskite phase with preferential orientation in the [001] direction and inhibited the photoinduced halide segregation. Nano X-ray fluorescence (nano-XRF) mapping at identified transformations in the elemental distribution, recognizing Br-richer and poorer domains that are reduced for samples prepared with MACl .

Which Defects Matter in Photoactive Perovskites? Joanne Etheridge¹, Weilun Li¹, Mengmeng Hao², Qimu Yuan³, Jay Patel³, Michael Johnston³ and Lianzhou Wang²; ¹Monash University, Australia; ²The University of Queensland, Australia; ³University of Oxford, United Kingdom

Photoactive perovskites show great potential for applications in solar cell devices, achieving remarkable

power conversion efficiencies while using relatively low cost, low temperature production methods. However, there remain many challenges, from stability in air and under photon irradiation to ion migration and current density-voltage hysteresis.

In order to exploit the full potential of photoactive perovskites, it is critical to understand how macroscopic device performance depends on structure, from the micron to the atomic scale. Compared with the rigid diamond structure of silicon, the intrinsically flexible and versatile perovskite structure provides an entirely different structural landscape upon which to manipulate properties, such as optical bandgaps. Furthermore, it can accommodate a different class of structural defects which can influence performance.

Here we investigate the relationship between local crystal structure, defect structure and device performance in quantum dot and thin film photoactive perovskites and associated devices using carefully devised ultralow dose electron microscopy methods [1-3] correlated with device characterisation.

In high performance $\text{Cs}_{1-x}\text{FA}_x\text{PbI}_3$ quantum dot devices [4], we identify the presence of planar defects with face-sharing octahedra and show that removing them leads to significantly improved power conversion efficiency and carrier lifetime [5] (consistent with observations in hybrid organic-inorganic $\text{MA}_{1-x}\text{FA}_x\text{PbI}_3$ thin films [6]). We also identify the formation of FA^+/I^- vacancy pairs and elucidate their role in ion migration and A-site dependent structural phase changes [7].

In $\text{CsPb}(\text{I}_{1-x}\text{Br}_x)_3$ films, we identify the crystal structures and defect structures associated with different halide compositions and deposition parameters, including twin and antiphase boundaries. Using sub- 10\AA^2 atomic resolution imaging techniques, we identify the local atomic structure of these planar defects and consider their impact on device performance, providing insights into the structural environments necessary to optimise device performance [8].

Structural and Ionic Stability Challenges in Metal Halide Perovskites Laura Herz; University of Oxford, United Kingdom

Organic-inorganic metal halide perovskites have emerged as attractive materials for solar cells with power-conversion efficiencies of single-junction devices now exceeding 25%. However, the low hurdle for ionic migration, and the structural flexibility of the perovskite structure still pose both opportunities and challenges to their commercialization in light-harvesting applications.

We discuss the peculiar mechanisms underlying detrimental halide segregation in mixed iodide-bromide lead perovskites with desirable electronic band gaps for silicon tandems.^[1-4] Surprisingly, halide segregation results in negligible impact to the THz charge-carrier mobilities, but is impacted by remarkably fast, picosecond charge funnelling into the narrow-bandgap I-rich domains that enhances radiative recombination.^[2] Our combinatorial, in-situ photoluminescence and X-ray diffraction measurements^[3,4] reveal how such halide segregation is affected by A-cation choice^[3] and the presence of charge-extraction layers.^[4] We further demonstrate a temperature-dependent reversal of halide segregation at temperatures above ambient.^[5] We observe that, with increasing temperature, halide segregation in $\text{CH}_3\text{NH}_3\text{Pb}(\text{Br}_{0.4}\text{I}_{0.6})_3$ first accelerates toward 290 K, before slowing down again toward higher temperatures. Such reversal is attributed to the trade-off between the temperature activation of segregation, for example through enhanced ionic migration, and its inhibition by entropic factors. High light intensities meanwhile can also reverse halide segregation; however, we find this to be only a transient process that abates on the time scale of minutes.^[5]

In addition, we discuss the peculiar effect of “intrinsic quantum confinement” (QC) exhibited by FAPbI_3 perovskite, apparent through oscillatory features in the absorption spectrum^[6-8] that suggest the presence of nanoscale features of periodicity around 10–20 nm present in sub-volumes.^[6] We show^[7] that such nanoscale electronic effects can be controlled through partial replacement of the FA cation with Cs, and allow for photon emission, highlighting their potential usefulness to light-emitting devices and single-photon sources.^[7] However, we reveal that such QC features are clearly detrimental to photovoltaic operation.^[8] We explore three common solution-based film-fabrication methods for FAPbI_3 , and show that elimination of these QC absorption features yields increased power conversion efficiencies (PCEs) and short-circuit currents, suggesting that quantum confinement hinders charge extraction. A meta-analysis of literature reports, covering 244 articles and 825 photovoltaic devices incorporating FAPbI_3 films corroborates our findings, indicating that PCEs rarely exceed a 20% threshold when such absorption features are present. Accordingly, ensuring the absence of these absorption features should be the first assessment when designing fabrication approaches for high-efficiency FAPbI_3 solar cells.

Defects, Devices and Degradation of Metal Halide Perovskites: An Electrochemist's Perspective

Erin L. Ratcliff; University of Arizona, United States

Defects are considered to be one of the most prominent contributions to diminished power conversion efficiencies and long-term stability in printable metal halide perovskite materials and optoelectronic devices. Defects can arise from a combination of point defects, grain boundaries, charge transfer with Lewis acid/base sites at the contacts, and/or mobile redox-active halides. Thus every perovskite composition and contact choice can result in differences in defect distributions.

Defect states have most often been characterized using electrical, optical, and magnetic techniques; however, independently assessing donor and acceptor defect quantities and energetics using a direct experimental approach with few empirical assumptions can be challenging. Realization of high-performing and long-term stable devices requires a combination of method advancement for the quantification of defects and mitigation strategies.

This talk will discuss emerging electrochemistry-based measurement science approaches to quantify the distribution and energetics of donor and acceptor defects in a prototypical perovskite solar cell material (FA_{0.79}MA_{0.16}Cs_{0.05})Pb(I_{0.87}Br_{0.13})₃ (or Cs_{0.05}FA_{0.79}MA_{0.16}), with demonstrations of the methodology to other perovskite active materials. We utilize a solid-state electrolyte top contact to create “half-cells” of device-relevant material stacks under realistic electric fields. This allows us to spectroscopically assess onsets in valence and conduction bands under conditions of *operando*, as well as quantify near-band defects using redox probes. Connections to device performance, including modifications to the near-surface region of hole-transporting layers (i.e. NiOx), will be provided as well as preliminary results to understand degradation pathways using near-ambient pressure x-ray photoelectron spectroscopy and *operando* x-ray scattering. Collectively, this developed tool-suite provides a holistic approach to understand defects, device performance and stability in this exciting class of materials.

Progress in Perovskite Active Layers and Interfaces for Energy Capture and Utilization Edward H. Sargent^{1,2}; ¹Northwestern University, United States; ²University of Toronto, Canada

I will discuss recent advances in managing the quality and reliability of perovskite active layers, and interfaces, in recent years. I will include both 2D/3D strategies and also molecular adlayer approaches to producing reliable interfaces.

9:00 AM *EN05.01.02

Models of Disorder in Halide Perovskites Aron Walsh; Imperial College London, United Kingdom

The structural arrangement of metal halide perovskites varies in space and time. Beyond the conventional vibrations of atoms around their average positions, collective motion in the form of octahedral tilting and molecular librations/rotations introduces additional layers of complexity in the dynamic crystal structure. To complicate matters further, dilute point defects, such as charged vacancies and interstitials, exist in a diverse landscape of extended defects including dislocations, polytypes, and grain boundaries. There can also be chemical gradients due to mixing on the A, B or X crystallographic positions, e.g. as found in mixed formamidinium/methylammonium, tin/lead, and iodide/bromide compounds. I will discuss our latest understanding of these phenomena at the atomic scale drawing from our work on data-driven materials modelling [1,2,3] and linked to multi-modal experimental characterisation [4].

Optimization of Indium Oxide Interconnecting Layer for All Perovskite Tandem Solar Cells with Efficiency > 26% Gaurav Kapil^{1,2}, Yasuhiro Fujiwara¹, Qing Shen¹, Hiroshi Segawa² and Shuzi Hayase¹;

¹University of Electrocommunications, Japan, Japan; ²The University of Tokyo, Japan

All perovskite tandem solar cells (APTSCs) are now showing power conversion efficiencies (PCEs) more than the highest reported single-junction perovskite and silicon solar cells [1,2]. The rapid rise in the performance of APTSC can be ascribed to the improvement in the performances of both top (wide bandgap, WBG) and bottom (narrow bandgap, NBG) cells. Recently, the focus has been on the reduction of halide segregation and improvement of open circuit voltage (Voc) in WBG cells which led to an immense increase in Voc of APTSC to 2.2V [2,3]. We noticed that most of the recent reports on efficient APTSCs utilize SnOx (prepared by atomic layer deposition) coated with Au (1-2nm) as an interlayer. However, the optical loss due to the use of Au nanoparticles can't be ignored. Therefore, in this work, we focused on the preparation of indium oxide doped with zinc oxide (IZO) as an interconnecting layer in place of Au nanoparticles to reduce the optical loss and improvement of facile hole and electron recombination at the SnOx layer. It is explored that the physical properties of IZO can be tuned while its preparation which finally plays a crucial role in enhancing the Voc of the APTSC. The other advantages that come with the IZO are that electrical properties can be changed according to the hole transport layer (HTL) utilized. So far, PEDOT:PSS is the only hole transport layer that can be used for efficient APTSCs. Therefore, the use of IZO interconnect further gives flexibility in choosing other HTLs such as self-assembled monolayers. In conclusion, we obtained PCE of 26.39% for APTSC with a Voc of 1.94V, Jsc of 17.18 mA/cm², and FF of 0.79. APTSC employing Au nanoparticle interlayer showed an inferior PCE of 22.32% with a Voc of 1.84V, Jsc of 15.4 mA/cm², and FF of 0.79. Moreover, in this work, we will support the increase in device performance with the use of different IZO interconnect by evaluating the carrier mobility, diffusion length, charge transport time, and recombination time. Also, its role in charge transport between the top and bottom cells will be discussed.

Preserving Bond Ionicity under Illumination to Achieve Photostable Halide Perovskites Malgorzata Wierzbowska; Institute of High Pressure Physics Polish Academy of Sciences, Poland

Lead halide perovskites (LHPs) with the formula ABX₃ are very efficient materials for optoelectronic devices: solar cells, light-emitting diodes, lasers, photodetectors, γ -detectors, and field effect transistors. But they are very fragile and sensitive to humidity, temperature, and operating conditions such as voltage bias and light. The reason is their weakly ionic structure with twice lower atomic ionicities than those in oxides. Photostability is difficult to achieve in LHP, due to the nature of electronic states that originate mainly from the halide anions in the valence band and B cations in the conduction band; hence, the charge transfer lowers the ionicity at the B–X bond.

To date, the A cations used have been optically inactive and only served as one-electron donors for the

charge balanced BX₃ frame. We propose a mechanism of photoexcitation acting between two different A cations, namely SLi₃ and SH₃, while the inorganic frame remains unchanged under illumination preventing B–X bond breakage and halide migration. Demand for a specific crystal localization of the optical excitations is a new factor for achieving photostability, in addition to a control of the ionic radii, defects, morphology, and surface and interface stabilization.

We theoretically demonstrate that the absorption spectra of (SLi₃,SH₃)PbI₃ perovskite are optically efficient for the distributions of two types of A cations that form the planar structures. The excitations in such case take place over the interface. The optimal light polarization should be oriented with the electric vector perpendicular to the interface between the regions with two types of molecular cations, that means the beam direction oriented within the interface plane. The spectra were obtained by solving the Bethe-Salpeter equation. The results are published [1].

Heterointerface and Intragrain Microstructures of Perovskite Semiconductors Yuanyuan Alvin Zhou; Hong Kong Baptist University, China

Heterointerface and intragrain microstructures are prominent factors influencing the properties and performance of perovskite semiconductors, which remain *terra incognita*. In my talk, I will discuss our recent developments on the novel characterization and tailoring of these microstructures, which elevate our fundamental understanding of microscopic structure-property-performance relationship in perovskites. Specifically, I will demonstrate two examples of perovskite-substrate heterointerface designs, featuring an interlocking interfacial microstructure and a flattened grain-boundary groove structure, respectively. Such microstructural designs contribute to improved carrier injection, chemical stability, and more importantly, (opto-)mechanical reliability of resulting perovskite solar cells. Then, we will illustrate our findings on performance-limiting intragrain defects and their structural dynamics, enabled by our latest innovations in scanning transmission electron microscopy methodologies. Finally, I will provide the perspectives and current ΣLab (www.alvinzhou.com) efforts pushing the frontier of perovskite knowledge as well as the broad materials research *via* unravelling novel microstructure phenomena.

2:00 PM EN05.02.02

Local Charge Carrier Dynamics in Lead Halide Perovskites by Nano Surface Photovoltage

Spectroscopy Yenal Yalcinkaya¹, Pascal N. Rohrbeck¹, Lukas Schmidt-Mende² and Stefan A. Weber^{1,3};

¹Max Planck Institute for Polymer Research, Germany; ²University of Konstanz, Germany; ³University of Stuttgart, Germany

Understanding electron and ion dynamics is an important task for improving lead halide perovskites based

solar cells and related devices. Perovskite materials usually have a delicate nano- and micro structure that influences the device parameters. Here, macroscopic measurement techniques are not sufficient. This study investigates the spatial defect distribution in the vicinity of grain boundaries (GB). To this end, we introduce Nano surface photovoltage spectroscopy (Nano-SPV) via time-resolved Kelvin probe force microscopy (tr-KPFM) [1,2]. By measuring the SPV decay on perovskite samples with small, large, and passivated grains, areas of increased charge carrier recombination, ion migration, and defects were locally detected. Using Nano-SPV, we revealed local SPV overshoots in the vicinity of grain boundaries following an illumination pulse. Furthermore, we introduce a new KPFM-based method to map the local light ideality factor within the perovskite films. The ideality factor is correlated to the dominant charge recombination processes within the absorber layer. Our results clearly show an improved uniformity of SPV and SPV decay distribution within the perovskite films upon passivation. Furthermore, the perovskite films with large grains show better recombination properties based on SPV decay and ideality factor values.

2:15 PM EN05.02.03

R&D on Gateway Technologies for Perovskite Solar Cells Tao Xu; Northern Illinois University, United States

Various formulations have been developed to improve the stability of hybrid perovskite layer in perovskite solar cells (PSCs), while their mutual compatibility remains uncertain. Thus, it is important to focus future R&D on technologies that are both adaptable to all other formulations and also independently exhibit added enhancement in stability. In addition, >50% infrastructure investment of PSC production line will be on the expensive and energy-costly vacuum evaporation equipment. In this talk, based on the fundamental reaction kinetics, we will present a low-cost isotope technology that is adaptable to any existing PSC formula and also retards degradation reaction kinetics, thus to improve stability of PSCs as an add-on feature independently. We will also present a disruptive vacuum-free paint & brush coating technology based on basic band structure theory for back electrode deposition for n-i-p configured PSCs, which also circumvents the use of expensive gold as the back electrode. These novel methods are promising gateway technologies that either synergistically enhance the stability of PSCs or reshape the infrastructure of PSC production line in the forthcoming commercialization of PSCs.

3:00 PM *EN05.02.04

Accelerating The Transition from Lab to Fab via High Throughput Automated Synthesis and Characterization of Metal Halide Perovskites Jonghee Yang¹, Sheryl L. Sanchez¹, Benjamin Lawrie², Yipeng Tang¹, Bin Hu¹, Juanita Hidalgo³, Sergei V. Kalinin¹, Juan-Pablo Correa-Baena³ and Mahshid Ahmadi¹; ¹University of Tennessee, Knoxville, United States; ²Oak Ridge National Laboratory, United States; ³Georgia Institute of Technology, United States

Metal halide perovskites have garnered considerable attention in the field of optoelectronics due to their exceptional properties. However, so far little has been understood based on the fundamental principles for designing the functional perovskites, which is now crucially decelerating the lab-to-fab transformation and realization of the scalable manufacturing of these materials for optoelectronics. In this talk I will discuss the potential of machine learning-driven high throughput automated experiments to expedite the discovery of hybrid perovskites, optimize processing pathways, and enhance the understanding of formation kinetics [1-4]. Notably, the utilization of a high-throughput robotic system to accelerate the exploration of the ligand-assisted reprecipitation (LARP) method for synthesizing perovskite nanocrystals represents a significant contribution to the field [5]. The workflow demonstrated in this study serves as a powerful tool for constructing detailed chemical maps of perovskite nanocrystal synthesis, enabling tailored customization of their functionalities. Additionally, another study showcases how high throughput automated synthesis provides a comprehensive guide for designing optimal precursor stoichiometry to achieve functional quasi-2D perovskite phases in films capable of realizing high-performance optoelectronics [3,4]. I further introduce the concept of co navigation of theory and experiment spaces to accelerate discovery and design of hybrid perovskites. These studies exemplify how a high-throughput automated experimental workflow effectively expedites discoveries and processing optimizations in complex materials systems with multiple functionalities, facilitating their realization in scalable optoelectronic manufacturing processes.

Surface and Interface Passivation for Perovskite Devices Bin Chen; Northwestern University, United States

Perovskite photovoltaics have made remarkable progress in the last decade, with the best lab perovskite cell now achieving over 26% power conversion efficiency. The key to this rapid improvement lies in understanding and controlling the interfaces in perovskite solar cells. In this talk, I will focus on interface engineering in perovskite solar cells (e.g., energy alignment, doping, and carrier dynamics), including the construction of heterostructures of multi-dimensional perovskites. I will discuss surface passivation by synthesizing 2D perovskites atop 3D bulk perovskite. The precise control over the dimensionality of these quantum-confined 2D thin layers enables us to achieve efficient carrier transport across the interface while maintaining desirable trap passivation. I will also discuss field-effect passivation when the perovskite active layer is in contact with a carrier transport layer. Modulating the minority carrier

population at the perovskite/C60 interface is critical for reducing interfacial recombination. Lastly, I will explore how we combine chemical and field-effect passivation to achieve optimal passivation. Adjusting interface conditions will be even more important as we move towards multi-junction device architecture in pursuit of higher efficiency.

3:45 PM EN05.02.08

Machine Learning Assisted Development of Sn/Pb Free Perovskites Solar Cells Ankit Choudhary¹, Alex Mohan¹, Miah A. Sahriar², Abdul H. Rumman², Md. T. Islam³, Saquib Ahmed⁴ and Haralabos Efstathiadis¹; ¹SUNY Polytechnic Institute Albany, United States; ²Bangladesh University of Engineering and Technology, Bangladesh; ³SUNY – University at Buffalo, United States; ⁴SUNY – Buffalo State University, United States

This study focuses on Cs₃Bi₂I₉, a zero-dimensional perovskite absorber material with great potential for photovoltaic applications. We employed Machine Learning (ML) techniques to understand and optimize the performance of Cs₃Bi₂I₉ perovskite solar cells. A prepared sub-dataset comprising 26,457 experimentally developed perovskite solar cell device data was utilized for ML calculations. The cleaned dataset contained 29 features and four target variables, including open circuit voltage (Voc), short circuit current density (Jsc), fill factor (FF), and power conversion efficiency (PCE). Among the models, Random Forest Regressor showcased the best performance. Predicted values for Voc, Jsc, FF, and PCE were determined to be 0.562 V, 9.544 mA/cm², 0.508, and 5.356%, respectively.

We characterized the different layers of the device using techniques such as X-ray Photoelectron Spectroscopy, Ultraviolet-Visible Spectroscopy, Atomic Force Microscopy, and Ellipsometry to gain insights into the individual layers' properties. The absorber layer bandgap was found to be 1.9 eV, which indicates that Cs₃Bi₂I₉ exhibits favorable characteristics for indoor photovoltaic applications. The solution-processed spin-coated complete solar cells have the structure glass/FTO/c-TiO₂/Cs₃Bi₂I₉/CuSCN/Ag. Preliminary tests on the complete Cs₃Bi₂I₉ perovskite solar cell have shown the values for Voc, Jsc, FF, and PCE as 0.447 V, 29.08 mA/cm², 0.291, and 3.63%, respectively. These initial results indicate the potential of Cs₃Bi₂I₉ as a viable material for solar cell applications.

Reduced Melting Temperature of Lead-Free 2D Perovskite Semiconductor to 142 °C Akash Singh, Ethan Crace, Yi Xie and David B. Mitzi; Duke University, United States

Hybrid metal halide perovskite (MHP) semiconductors are currently revolutionizing the research realm of electronic and photonic materials, with an overwhelming number of studies conducted on their synthesis and device fabrication and with particular emphasis on deposition of device quality films. The dominant film deposition techniques involve solution processing and vapor deposition, which have their advantages, but may be harmful to humans and the environment. Melt processing as an alternative route has been demonstrated before; however, due to the high T_m (close to $T_d \sim 200$ °C, the degradation onset temperature), the approach tends to induce partial decomposition (loss of organic component and halides) in MHPs, which hinders their utility in certain applications. Furthermore, slight loss of organic components/halides creates defects that may significantly harm the optoelectronic properties of the MHP film, pointing to a need to develop MHPs with lower T_m . In this work, we therefore synthesized a lead-free 1-methylhexylammonium tin iodide (1-MeHa₂SnI₄) perovskite. Single crystal X-ray diffraction is

used to resolve the crystal structure of the resulting compound, confirming its crystallization in a two-dimensional Ruddlesden-Popper phase. Synthetic design rules toward obtaining a low T_m value are summarized and adopted to achieve an exceptionally low T_m of 142 °C. The hydrogen bonding, cation penetration, inter- and intra-octahedral distortions, and electronegativities (ionic sizes) of the synthesized perovskite and its corresponding lead counterpart (1-MeHa₂PbI₄) are studied to understand the reduced T_m along with the comparison of the existing pairs of meltable Sn and Pb MHPs with same organic cations. Additionally, we developed a protocol to assess the stability of the MHP melt by performing iterative calorimetric scans, monitoring changes in the T_m and melt crystallization temperature (T_c) through multiple heat-cool cycles. This analysis confirmed the stable nature of the 1-MeHa₂SnI₄ melt, leading to its facile melt deposition into films on flexible substrates with visible range optoelectronic properties. Our present work serves as a display of the strength of chemical compositional engineering of perovskite structures for tuning the thermal properties, resulting in exceptionally low T_m and facile melt-processing of MHPs. Reduction in T_m not only lowers the thermal budget of the deposition process but also renders robustness to the melt for the development of cost-effective flexible optoelectronic devices on plastic/polymer substrates.

SESSION EN05.03: Poster Session I: Fundamental Understanding of Halide Perovskites

Session Chairs: Marina Leite and Lina Quan

Anharmonic Electron-Phonon Coupling in Polymorphous Perovskites Marios Zacharias¹, George Volonakis², Feliciano Giustino³ and Jacky Even¹; ¹INSA Rennes, France; ²Universite de Rennes 1, ISCR, France; ³The University of Texas at Austin, United States

Ab initio simulations of halide perovskites typically assume that the potential energy felt by electrons is defined with the nuclei fixed at their crystallographic Wyckoff positions. This assumption misses the effect of local disorder (polymorphism) which affects profoundly the mechanical, optoelectronic, and light-absorbing properties of halide perovskites. In this talk, I will discuss the important role of *polymorphism* and *anharmonicity* in the electron-phonon coupling of halide perovskites [1]. In particular, I will demonstrate that (i) polymorphism is at the origin of overdamped and strongly coupled vibrational dynamics, (ii) anharmonic optical vibrations dominate thermal renormalization of their band gaps, and (iii) polymorphism is the key to understand the gradual variation of their band gaps around the phase transition temperatures. To address these points we develop a new very efficient methodology for anharmonic lattice dynamics, relying on the special displacement method (A-SDM) [2]. The A-SDM is a very simple tool that can be exploited by both condensed matter theorists and experimentalists, opening the way for systematic simulations of anharmonic phonons. Overall, our new theoretical advances [1,2] set up a new framework for interpreting the fundamental mechanisms driving the optoelectronic, transport, and photovoltaic properties of halide perovskites.

Interfacial Toughening with Self-Assembled Monolayers for Mechanical Reliability in Inverted Perovskite Solar Cells Zhenghong Dai and Nitin P. Padture; Brown University, United States

Metal halide perovskites (MHPs) have emerged as the most promising light-absorber materials in the photovoltaic community due to their near-ideal bandgaps and extraordinary optoelectronic properties. However, MHPs have extremely poor mechanical properties. They are inherently compliant, soft, and brittle. While significant progress has been made in improving the stability of MHPs, perovskite solar cells (PSCs) will also need to be mechanically reliable if they are to operate efficiently for decades. In this context, we study the mechanical integrity of PSCs by measuring their cohesion/adhesion energies (Gc) using double cantilever beam method. We will then report a novel approach to strategically enhance the interfacial adhesion and performance of p-i-n structure PSCs using carefully designed hole transporting self-assembled monolayers (SAMs), where we find that the perovskite solar cell stability is closely intertwined with its mechanical reliability. This work points to a new route for designing mechanically robust PSCs with long-term durability.

Triiodide Attacks The Organic Cation in Hybrid Lead Halide Perovskites: Mechanism and Suppression Junnan Hu, Zhaojian Xu, Tucker L. Murrey, Istvan Pelczar, Antoine Kahn, Jeffrey Schwartz and Barry P. Rand; Princeton University, United States

Molecular I_2 can be produced from iodide-based lead perovskites under thermal stress; triiodide, I_3^- , is formed from this I_2 and I^- . Triiodide attacks protic cation MA^+ - or FA^+ -based PbI_3^- perovskites as explicated through solution-based NMR studies: Triiodide has strong hydrogen-bonding affinity for MA^+ or FA^+ , which leads to their deprotonation and perovskite decomposition. Triiodide is a catalyst for this decomposition which can be obviated through perovskite surface treatment with thiol reducing agents. In contrast to methods using thiol incorporation into perovskite precursor solutions, no penetration of the thiol into the bulk perovskite is observed, yet its surface application stabilizes the perovskite against triiodide-mediated thermal stress. Thiol applied to the interface between $FAPbI_3$ and Spiro-OMeTAD (“Spiro”) prevents oxidized iodine species penetration into Spiro and thus preserves its hole transport efficacy. Surface-applied thiol affects the perovskite work function; it ameliorates hole injection into the Spiro overlayer, thus improving device performance. It helps to increase interfacial adhesion (“wetting”): Fewer voids are observed at the Spiro-perovskite interface if thiols are applied. Perovskite solar cells (PSCs) incorporating interfacial thiol treatment maintain over 80% of their initial PCE after 300 h of 85 °C thermal stress.

8:00 PM EN05.03.08

Highly Stable and Efficient Perovskite Solar Cells by Enhanced Interface Toughening via Iodine-Terminated Self-Assembled Monolayer Inseok Yang, Anush Ranka and Nitin P. Padture; Brown

University, United States

The mechanical reliability of lead halide perovskite solar cells is a key factor to determine device stability. We applied iodine-terminated self-assembled monolayers (I-SAM) on the mesoporous TiO₂ layer of the perovskite solar cells. We achieve a 40% increase of adhesion toughness at the interface between the electron transporting layer (ETL) and the perovskite layer to enhance mechanical reliability. I-SAM treatment on the mesoporous TiO₂ layer leads to enhanced photovoltaic performance including power conversion efficiency (PCE) and stability of the device. The device working stability with a projected T80 (time to 80% initial PCE retained) increasing from ~792 hours for the control device to ~6,670 hours for the I-SAM device for 0.1 cm² sized active area device and ~2,822 hours to 6,333 hours for 1.0 cm² sized active area device under 1-sun illumination. The champion power conversion efficiency (PCE) is 24.12% with 25.89 mA/cm², 1.131 V, and 82.35% of FF with a 0.1 cm² sized active area device. This device performance enhancement is derived from superior interface properties through the I-SAM layer on the mesoporous TiO₂ layer. The I-SAM layer contributes interfacial toughness between the TiO₂ layer and perovskite layer and this increased interfacial toughness property leads to performance enhancement.

8:00 PM EN05.03.12

Low Temperature Sintering of Polycrystalline Hybrid Organic-Inorganic Perovskites Michael C. Brennan^{1,2}, Christopher McCleese^{1,3}, Lauren Loftus^{1,3}, Douglas Krein^{1,3} and Tod Grusenmeyer¹; ¹Air Force Research Laboratory, United States; ²Azimuth Corporation, United States; ³General Dynamics Information Technology, United States

Hybrid organic-inorganic perovskites [HOIPs] (ABX₃; A=CH₃NH₃, CH(NH₂)₂, Cs; B=Pb, Sn; X=Cl, Br, Cl) embody intriguing optoelectronic properties (e.g. tunable bandgaps, high absorption coefficients, and large charge carrier mobilities). However, many target applications for these semiconducting materials (e.g., scintillators, lasers, and photodetectors) require large area, millimeter thick perovskite single crystals with high optically transparency. Unfortunately, single crystals grown by melt-based approaches are limited to all-inorganic perovskites due to organic cation volatility, and solution-based methods are inundated with scalability and reproducibility issues. Sintering HOIP powders into high relative density (>0.999) polycrystalline wafers under an applied uniaxial pressure is a promising route towards overcoming the current limitations of melt and solvothermal single crystal growth. We demonstrate low temperature (~20 °C) sintering methods under an applied uniaxial pressure to compress high purity HOIP powders into high density, polycrystalline wafers with optical transparency and charge transport properties akin to their ideal single crystal counterparts. Structural, optical, and electrical properties of HOIP wafers are benchmarked against single crystals analogues. Fully understanding the tradeoff between manufacturability of polycrystalline wafers versus the performance of single crystals could enable key advancements in perovskite technologies.

Exploring the Diversity of Two-Dimensional Perovskite Structures by a Comprehensive Database for Advancing Solar Cell Research and Development Ayman Maqsood and T. Jesper Jacobsson; Nankai University, China

An important property of hybrid perovskites is the possibility to reduce the dimensionality to provide wider band gaps and better stability. Of special interest is two-dimensional perovskites which have emerged as a promising alternative to their three-dimensional counterparts due to their unique structural

and optoelectronic properties. This project analyzes the recent advancements and key features of two-dimensional perovskite solar cells based on a comprehensive database of possible two-dimensional perovskite structures utilized in PV-devices that we have assembled. This database includes both experimentally reported structures and computationally designed ones and covers a wide range of compositions and variations, and provides a valuable resource for understanding and exploring the diverse range of two-dimensional perovskite materials employed in solar energy conversion. The database ontology outlines the criteria and parameters used to identify and classify two-dimensional perovskite structures, such as composition, layer thickness, and organic and inorganic components, and covers structures ranging from simple bilayers to more complex multilayer structures. In this talk, I will demonstrate how this resource can be used to provide insights into the structure-property relationships of 2D-perovskites, and how it can aid in the rational design of new 2D-perovskites with targeted properties suitable for specific device requirements.

8:00 PM EN05.03.15

Improving Photovoltaic Performance of CuSCN-Based Perovskite Solar Cells by Aging in Humid Air Atsushi Kogo and Takurou N. Murakami; National Institute of Advanced Industrial Science and Technology, Japan

Development of inexpensive and robust hole-transport material for organohalide perovskite solar cells (PSC) is one of the most important topics for industrial application. Copper thiocyanate (CuSCN) is an inorganic p-type material, which can be used as a robust hole-transport material of PSCs. However, the CuSCN-based PSCs tend to give poor power conversion efficiency (PCE) than conventional spiro-OMeTAD-based PSCs because of low conductivity and high charge carrier trap density of CuSCN. To improve hole extraction of CuSCN from perovskite materials, we investigated an effect of atmospheric parameters during the aging process of CuSCN layers.

CuSCN was formed by spin-coating a precursor solution on glass substrates and dried at 80 °C for 5 min. Then the substrates were aged in different humidity (RH 2%, 25%, 40%, 70%) overnight. To characterize crystallinity of CuSCN layers, we performed X-ray diffraction measurement. CuSCN layers aged in 70% RH exhibited larger crystal size (29.9 nm) than those aged in dry air (2% RH, 26.6 nm). Small grains were observed in CuSCN layers aged in 2% RH by atomic force microscope observation. However, the grains were disappeared, and flat morphology was observed in the layers aged at 70% RH. This indicates that crystal growth of CuSCN was promoted by humid moisture. We measured resistance of CuSCN layers by current voltage scan using indium tin oxide (ITO)/CuSCN/Au substrates. Owing to its improved crystallinity, CuSCN aged at 70% RH exhibited smaller resistance than those aged at lower humidity. We fabricated PSCs (ITO/SnO₂/perovskite/CuSCN/Au structure) and measured photovoltaic performance under 1 sun illumination. As the aging humidity increased, PCE was improved owing to improved fill factor. Further, solar cells aged at 70% RH gave larger open circuit voltage than those aged in lower RH. The dark current analysis revealed that the solar cells aged at 70% RH contains less trap density and less resistance than those aged in lower RH. We can conclude that improved CuSCN crystallinity increased conductivity and decreased trap density and enhanced photovoltaic performance of perovskite solar cells.

8:00 PM EN05.03.16

CsCl Induced Grain Size Control and Performance Enhancement of MA-Based Perovskites Film for High-Performance Memristive Devices Yen Shuo Chen¹, Ching Chang Lin² and Fu-Hsiang Ko¹;

¹National Yang Ming Chiao Tung University, Taiwan; ²The University of Tokyo, Japan

Recently, a new class of organic-inorganic hybridized perovskites (OIHPs) materials with various functionalities such as dielectric, semiconducting, and photosensitive properties have proven to be very promising for resistance switching (RS) memory applications. Due to the atmospheric instability of OIHPs materials, defects or pinholes can appear on the film surface during the manufacturing process. Some literature discusses the posttreatment process for improving defects. In this study, we purpose that the CsCl of the double-site repair mechanism not only passivates defects but also improves the electrical properties of the RS memory device due to the reduction of grain boundaries and grain size enlargement. The MAPbI₃ perovskite precursor was prepared by dissolving MAI and PbI₂ powder into the mixed solvent of GBL and DMSO. The CsCl solutions were prepared in methanol and ethanol; the concentrations were 0.5, 1 and 1.5 mg mL⁻¹, labeled as CsCl-0.5, CsCl-1 and CsCl-1.5, respectively. The untreated film is labeled as CsCl-0.

The pristine OIHPs films and the film with CsCl posttreatment both exhibit intense diffraction peaks at 13.9°, 20.2°, 21.4°, 28.5°, and 31.9°, corresponding to the (110), (200), (211), (220), and (310) MAPbI₃ tetragonal crystal planes. The XRD patterns result indicated that there is no significant peak shift. The UV-Vis absorption spectra showed a blue shift in the absorption edge after the addition of CsCl doping, indicating that some Cs substitution occurred on the OIHPs surface and most of MAPbI₃ was retained. The PL response spectra showed the same trend, with the highest intensity for the CsCl-1.5 film. It indicated a reduction of defects and pinholes in the film, which can be attributed to the higher concentration, resulting in more surface replacement effects. In addition, the average grain size of the OIHPs films was increased from ~339.2 nm (CsCs-0) to ~658.1 nm (CsCl-1.5) by raising the amount of CsCl doping. The MAPbI₃ films treated with CsCl exhibited signs of remodeling, resulting in grain size increase and grain boundary reduction. Control and moderate increases in grain size can affect the electrical characteristics of OIHPs memory devices. Thus, to achieve high-performance memory devices using OIHPs film, we realize the control of grain size in the film by CsCl facial treatment.

Herein, we reported the bipolar RS behavior of the organic-inorganic hybrid Cs_xMA_{1-x}PbI_{3-y}Cl_y perovskite memory device. The switching behavior of the OIHPs RS device in Al/PMMA/Cs_xMA_{1-x}PbI_{3-y}Cl_y/ITO configuration was studied under a direct current (DC) at ambient air conditions with high humidity between 50% and 70%. The top electrode (TE) Al is biased, and the bottom electrode (BE) ITO is grounded using a typical linear I-V sweep in the order 0V→-3V→0V→3V→0V at the bias voltage. To ensure the RS behavior and conductive filament were from the OIHPs layer, no significant switching behavior was observed for Al/PMMA/ITO. All the RS memory devices exhibited stable hysteresis I-V curves with bipolar resistive switching behavior. To prevent the RS memory device from being damaged during the measurement, a compliance current of 1 mA was applied. When an external voltage is swept from -3 to 0 V, the resistance transition from a high-resistance state (HRS) to a low-resistance state (LRS) was observed at 1.1 V, which means the set process occurs. The Al/PMMA/Cs_xMA_{1-x}PbI_{3-y}Cl_y/ITO device was maintained at LRS state when voltage was reversed from 3 to 0 V, corresponding to the reset process. The on/off current ratio of the CsCl-0 device reached about 10², 10³ for CsCl-0.5, 10³ for CsCl-1, and 10⁴ for the CsCl-1.5 device, respectively. Compared to untreated OIHPs devices, RSM devices with MAPbI₃ treated with CsCl-1.5 device are improved by two orders of magnitude. The results demonstrated the high-performance electronic applications of CsCl-induced OIHPs in resistive switching memories.

8:00 PM EN05.03.17

Introducing Ionic Liquid Dopant to Spiro-OMeTAD for Improving Thermal Stability in Perovskite Solar Cells Kohei Yamamoto and Takurou N. Murakami; National Institute of Advanced Industrial Science and Technology, Japan

Perovskite solar cells (PSCs) are attracting attention as next-generation solar cells because of their high-

power conversion efficiencies (PCEs) and lightweight. Lightweight PSCs can be installed on roofs with weight limitations, further increasing the potential for renewable energy. In practical out-door use, PSCs require measures for environmental stability such as heat and light. It is well known that there are issues regarding the thermal stability of PSCs. There are issues with thermal stability in the perovskite itself and in the components such as carrier transport layer in PSCs. Thermal stability of PSCs with conventional structure has present a challenge in doping materials of hole transport layer (HTL). In conventional PSCs, LiTFSI is widely used as a doping material for Spiro-OMeTAD of HTL. However, LiTFSI is known to change to Li_2O_3 or become Li^+ and diffuse inside PSCs. To improve the thermal stability of PSCs, it is important to avoid diffusion into the device by fixation Li^+ at HTL. We focused on the doping method of HTL in conventional PSCs for improving thermal stability. For immobilization of the dopant in the HTL, bulky organic cations were investigated introducing PSCs. Since TFSI is an effective doping for Spiro-OMeTAD, a combination of TFSI and organic cations were selected as dopants for spiro-OMeTAD. Our PSCs structure is $\text{FTO}/\text{SnO}_2/\text{Cs}_{0.05}\text{FA}_{0.95}\text{PbI}_3/\text{Spiro-OMeTAD}/\text{Au}$. N-Ethyl-N-(2-methoxyethyl)-N,N-dimethylammonium TFSI (EMe-TFSI) and LiTFSI were used as dopants for HTL and compared, respectively. Optimized PSCs have PCE of 18.1% with LiTFSI and 18.2% with EMe-TFSI. The solar cell performance with EMe-TFSI was found to be equivalent to LiTFSI, and it was found that EMe-TFSI can function as a dopant. We evaluated thermal stability of both PSCs at 85°C and 30% RH. The PSC with EMe-TFSI exhibited 50% of its initial properties after 300 hours at thermal stability test. On the other hand, the PSC with LiTFSI reduced to 10% of its initial characteristics in just 24 hours. These results suggest that the thermal stability of PSCs can be improved by using bulky organic ions rather than small and easy to diffuse ions such as Li.

8:00 PM EN05.03.18

Insights from the Additive Engineering Perovskite Database. Can We Design Functional Molecules More Intelligently? Chen Chen and T. Jesper Jacobsson; Institute of Photoelectronic Thin Film Devices and Technology, Key Laboratory of Photoelectronic Thin Film Devices and Technology of Tianjin, College of Electronic Information and Optical Engineering, Nankai University, China

Additive engineering has been widely used to improve the properties of perovskite solar cells. By carefully selecting the right additive, it is possible to for example improve film uniformity, morphology, and crystallinity, alter the electronic properties and improve stability. Specifically, some of additives are used to modulate grain size and orientation, passivate defects, shift the Fermi-level, enhance charge carrier extraction, suppress recombination and ion migration, increase carrier lifetimes, etc. A large number of molecular additives have been explored in the literature. The understanding of the underlying interaction mechanisms of additives and perovskite is, however, still limited, and positive results are often the result of a trial-and-error approach based on a few simplistic heuristic rules. For more efficient additive engineering we would need to go beyond this and develop more general principles for perovskite additive interactions based on their respective molecular and crystal structure. As a step towards addressing those challenges, and to enable more rational selection and design of functional additives for specific targeted purposes, we have started to establish a database of perovskite additives and their effects. With the help of this database, we aim to leverage machine learning for intelligent screening and identification of new functionalized molecular additives. In this talk, we will give a brief overview of the historic additive landscape and discuss what new insights applicable to additive engineering that have been achieved by analyzing the historical data.

8:00 PM EN05.03.19

Nano Structural Analysis of Various Metal Halide Perovskite Films for Solar Cells using

Synchrotron X-Ray Seungyeon Hong and Hyo Jung Kim; Pusan National University, Department of Organic Material Science and Engineering, Korea (the Republic of)

The metal halide perovskite materials were intensively researched for solar cells because of their outstanding photoelectronic properties. There are numerous methods to achieve high performance, high quality, and highly stable perovskite films, for example, formula combination, solution engineering, additive manufacturing, dimension control and etc. Most of those strategies pursue to obtain high-quality and well-aligned perovskite crystal structures. In this work, we adopt solvent and additive engineering and analyzed their effect on nano crystal structure of metal halide perovskite.

First, we obtained high quality perovskite grains in slow crystallization process by antisolvent and the ratio of DMSO in solution in the ambient air condition at RH 20-30%. The amount and state of the intermediate phase, which is consist of PbI_2 -MAI-DMSO, inside the as-deposited film were analyzed from GIWAXS analysis. The deposited perovskite layer with the pure intermediate with extremely slow crystallization showed highest absorption, few grain boundaries and suppressed defect recombination losses than fast crystallized perovskite phase. Furthermore, the water resistance of perovskite film was enhanced and as a result, the long-term stability was extremely increased.

And then, we employed the oleylamine(OAm) additive as defect the passivation and crystal cross-linker material. Generally, the defect the passivation and crystal cross-linker effect appeared simultaneously, and it is hard to separate the single effect of them. We could separately analyze the passivation and crystal cross-linker effect of OAm just by adopting a simple drying process during perovskite structure formation. Without the drying process, the OAm affected the orientation of the crystal structure from the surface to the bulk of the perovskite film and also exhibited the passivation effect. However, when the drying process was performed, the OAm only affected on the surface of the perovskite film. We could confirm this tendency from GIWAXS and XPS analysis.

8:00 PM EN05.03.20

Accelerating Perovskite Solar Cells Development: A Pathway to Accelerate Carbon Neutrality Targets and Reduce Renewable Energy Transition Costs Jie Liu and Xiao Shen; Bo-Zhi Digital Labs, China

The transition to renewable energy sources, including photovoltaics (PV) and wind power, is crucial for achieving carbon neutrality and addressing the challenges of climate change. To expedite the progress towards these goals, it is essential to explore technological advancements that can lower costs and reduce energy consumption and carbon emissions. Different PV technology pathways, including multi-crystalline silicon, mono-crystalline silicon, and perovskite solar cells, are evaluated using a life cycle assessment approach and learning rate analysis. By quantifying key metrics such as costs, energy consumption, carbon emissions, and material utilization, this research provides valuable insights into the comparative advantages and potential benefits of these technologies for global PV development. Utilizing data from papers, public reports, open-source databases and industry sources, this study presents a quantitative assessment of the potential impact of perovskite solar cell penetration from 2023 to 2050 under various scenarios defined by the International Energy Agency (IEA). The results underscore the importance of accelerating the development of perovskite solar cells, which have demonstrated significant potential for achieving higher cost reductions, energy savings, and greenhouse gas emissions avoidance compared to conventional silicon-based solar cells. These outcomes provide a robust foundation for policymakers, researchers, and industry professionals to prioritize and guide the accelerated development and deployment of perovskite solar cells within the global PV market. Furthermore, this study sets a precedent for future investigations into PV technology development and offers a pathway for sustainable

and cost-effective global energy transformation.

8:00 PM EN05.03.24

Strategies to Boost the Photocatalytic Activity in Halide Perovskite Nanocrystals Tae Hyung Kim and Young Hoon Kim; Hanyang University, Korea (the Republic of)

Colloidal halide perovskite nanocrystals (PNCs) are an ideal material for high photocatalytic activity, in addition to the tremendous attention already focused on optoelectronics such as light-emitting diodes and photovoltaics due to long charge carrier lifetime, narrow bandgap and facile wavelength tunability. Here, we report two strategies to improve photocatalytic activity based on colloidal CsPbBr₃ PNCs. First, we prepared CsPbBr₃ PNC/amorphous TiO₂ composites using hydrolysis of titanium butoxide in PNC dispersion under air ambient. High absorption coefficient and narrow bandgap of CsPbBr₃ can generate and transfer photo-excited electrons to the amorphous TiO₂, which performed 4.1 times higher photocatalytic CO₂ reduction efficiency (30.43 $\mu\text{mol g}^{-1} \text{h}^{-1}$) than pristine CsPbBr₃ PNCs under outdoor sunlight (7.44 $\mu\text{mol g}^{-1} \text{h}^{-1}$). Second, we doped Fe into CsPbBr₃ PNC via post-synthetic ion exchange method. Fe dopants induce dissociation of charge carriers while suppressing the recombination of them in the presence of external magnetic fields which prolong the lifetime of spin-polarized charge carriers. By application of both Fe dopants and external magnetic fields on the CsPbBr₃ PNCs, we achieved photocatalytic CO₂ reduction of 45.48 $\mu\text{mol g}^{-1} \text{h}^{-1}$ in visible region which is 1.48 times higher than that of pristine CsPbBr₃ PNCs. These results provide simple paths toward efficient photocatalytic reaction in metal halide perovskite nanocrystals for CO₂ reduction.

8:00 PM EN05.03.25

Effects of a site Cation on Perovskite Quantum Dot for Emission Wavelength and Photoluminescence Quantum Yield Ryota Sato¹, Yusaku Morikawa¹, Satoshi Asakura², Motofumi Kashiwagi³, Takayuki Chiba^{1,1} and Akito Masuhara^{1,1}; ¹Yamagata University, Japan; ²ISE Chemicals Corporation, Japan; ³ZEON Corporation, Japan

ABX₃ type (*A* site: Cs, Methylammonium (MA), Formamidinium (FA) etc., *B* site: Pb, and *X* site: halogen such as Cl, Br, I) perovskite quantum dot (PeQD) has attracted attention as a next generation material for the optoelectrical device such as light emitting diode (LED) due to its excellent optical properties. In general, it is known that the optical properties, in other words, the energy band gap of PeQD are composed of the hybrid orbital of the *B* and *X* site (*B-X* hybrid orbital). The state of the energy band gap directly depends on the PeQD optical properties such as the emission wavelength and photoluminescence quantum yield (PLQY). For instance, the emission wavelength of PeQD is controlled by inserting another *X* site materials (= *X'* site). In detail, the new hybrid orbital composed of the *B* site, *X* site, and *X'* site (*B-X/X'* hybrid orbital) was generated by inserting the *X'* site material, resulting in controlling the energy band gap. Therefore, controlling the emission wavelength in the entire visible range by only adjusting the halide components. On the other hand, surface defects of PeQD generate new trap levels that prevent the electron transition within the energy band gap, so excess *B* and *X* site materials are used to passivate the surface defects. As a result, it is possible to achieve a high PLQY. Based on these facts, the state of the energy band gap on PeQD was controlled by mainly using the *B* and *X* site materials composed of the energy band gap in the previous research.

In this work, we proposed the strategies for “Controlling the emission wavelength” and “Improving the PLQY” by using the *A* site mixture on PeQD. The *A* site does not directly affect the *B-X* hybrid orbital. On the other hand, we also found the indirect effects of the *A* site against the emission wavelength and PLQY of PeQD. About the emission wavelength, it was successfully achieved to control the emission

wavelength by inserting another *A* site material into the PeQD structure. In detail, the PeQD structure was distorted by using two type of the *A* site materials with different ionic radii. This distortion indirectly changed the distance between the *B* and *X* site. This distance is strongly related to the *B-X* hybrid orbital. Finally, successful control over the emission wavelength was accomplished through the indirect manipulation of the *B-X* hybridized orbital linked to the energy bandgap. From the results such as FT-IR, XRD, and TEM measurement, it was revealed that the PeQD structure is distorted. In addition, by effectively regulating the energy band gap, it was successfully precise controlled of the emission wavelength with a precision of 1 nm.

On the other hand, we successfully achieved to prepare PeQD with high PLQY over 80% by inserting the alkali metal on the surface of PeQD. In detail, by inserting the alkali metal with a smaller ionic radius than the *A* site material composed of PeQD on the *A* site position of the PeQD surface, it was successfully suppressed the detachment of the *X* site adjacent to alkali metals. This means the generation of the trap level in the energy band structure was suppressed. In fact, PL lifetime measurement supported the proof of decreasing the trap level. In addition, PLQY values of PeQD with alkali metal was improved about 2 - 3 times compared with untreated PeQD.

In summary, we proved the effect of the *A* site on the PeQD optical properties, notably, the emission wavelength and PLQY. By using this finding, it is possible to expand the application range not only to LED, but also to color conversion material, quantum dot laser, and so on.

8:00 PM EN05.03.28

Molecular Orientations and Hole-Collection Efficiency of Monolayer Materials for Hole-Transport Layer of Inverted Perovskite Solar Cells Aruto Akatsuka¹, Minh Anh Truong², Atushi Wakamiya², Gaurav Kapil³, Shuzi Hayase³ and Hiroyuki Yoshida^{1,4}; ¹Chiba University, Japan; ²Kyoto University, Japan; ³Electro-Communications University, Japan; ⁴Chiba University MCRC, Japan

For the hole collection layer of inverted structure perovskite solar cells, recently monolayers of carbazole derivatives [1] have been proposed to replace the polymer hole transport layer materials such as PTAA and PEDOT: PSS. The monolayers have the advantages of thin film, high transparency, and stability. Large orbital overlap and good interfacial energy alignment at the perovskite/hole collection layer interface are essential to obtain high hole transfer constants. To achieve the sizable orbital overlap, the π -conjugated backbone of the monolayer materials should be aligned face-on to the conductive metal oxide electrode (ITO). However, measuring the molecular orientation is usually difficult owing to the large surface roughness of ITO. For example, polarization-dependence of optical measurements such as ellipsometry gives averaged orientation.

In this study, we employ ultraviolet photoelectron spectroscopy (UPS) and metastable atom electron spectroscopy (MAES) to examine the molecular orientation of monolayers. In UPS, the photoelectron is generated by the excitation of UV light which can penetrate the sample. On the other hand, MAES uses metastable excited atoms (He*) as the excitation source, which only interact with the outermost molecular orbital of the sample material. For example, for a molecule whose π -conjugated backbone is aligned face-on to the ITO surface, only the π orbitals are observed in the MAES spectrum while both π and σ orbitals are detected by UPS. The molecular orientation can be evaluated by comparing the UPS and MAES spectra. We chose 2PACz and MeO-2PACz, which have one anchor group to bind to the ITO substrate, and 3PATAT-C3, which has three anchor groups.

The monolayers were prepared by spin-coating on ITO substrates, and the UPS and MAES spectra were measured. We used molecular orbital calculations (B3LYP/6-31G(d)) for the isolated molecules to assign features of UPS and MAES spectra. Comparing UPS and MAES spectra of 3PATAT-C3, the intensity of the σ orbital is weaker in MAES spectra than UPS spectra, whereas the π orbital is stronger in both.

Therefore, the π -conjugated backbone of 3PATAT-C3 is aligned face-on to the ITO surface. The results of 2PACz and MeO-2PACz show that the π -conjugated backbone is tilted in 2PACz and edge-on alignment to the ITO surface in MeO-2PACz. The results are consistent with the higher hole transfer rate constant in 2PACz than MeO-2PACz obtained by time-resolved surface photovoltage [3]. To further discuss the hole-collection efficiency, we will report the energy level alignments at the perovskite-monolayer-ITO interfaces.

Ultimate 2D Perovskite-FA DJ 2D Perovskites with Maximum Symmetry Jin Hou¹, Jared Fletcher², Hao Zhang¹, George Volonakis³, Claudine Katan³, Jacky Even³, Mercouri G. Kanatzidis² and Aditya D. Mohite¹; ¹Rice University, United States; ²Northwestern University, United States; ³Université de Rennes, France

Two-dimensional halide perovskites (2D-HaP) have emerged as a class of highly durable solution-processed organic-inorganic (hybrid) low-dimensional semiconductors. They exhibit a combination of properties derived from four classes of materials - quantum wells, atomically thin 2D materials, organic semiconductors, and three-dimensional (3D)-HaP perovskites. The general formula of 2D-HaP is $(A')_m(A)_{n-1}M_nX_{3n+1}$, where A' is a bulky organic cation, A is a small organic cation, M is a divalent metal, and X is a halide, with $m=2$ in Ruddlesden-Popper (RP) phases and $m=1$ in Dion-Jacobson (DJ) phases. The number n determines the thickness of the perovskite layer, which consists of alternate organics $(A')_m$ and hybrid $(A)_{n-1}M_nX_{3n+1}$ layers, making 2D-HaP a platform to engineer hybrid composites with attractive optoelectronic properties.

Currently, similar to 3D-HaP, most of the 2D-HaP takes Methylammonium (MA) as the A site cation. While the MA^+ cation has the most suitable effective radius of any monovalent cation (either organic or inorganic) for forming a stable perovskite structure in a strain-stress perspective, the chemical instability of MA had motivated the use of less suitably sized but more chemically stable cations, such as formamidinium (FA).¹ Different from 3D-HaP which already has some successful demonstrations using FA as A site cation,² FA based 2D-HaP remains underexplored, with only a few reports achieving an “ n ” equal to 1 or 2.³ We propose that the difficulty of synthesizing FA based 2D perovskite coming from the larger size of FA compared to MA, which will increase lattice mismatch between the organic parts and the inorganic parts in the 2D perovskites.⁴ Therefore, the key to synthesizing a multi-layer FA based 2D perovskite is to find the appropriate organic spacer which has a small lattice mismatch with the inorganic part.

Here, we demonstrate a synthesis of FA based 2D DJ perovskites crystals, from $n=1$ to $n=4$ after

screening a series of different organic spacers. This new series of 2D perovskites shows a surprisingly zero distortion along both in-plane and out-of-plane (Pb-I-Pb angle is equal to 180 degrees for both directions), which is never observed before in any multi-layer 2D perovskites. They are all tetragonal phase and with P4/mmm as the space group, which is the maximum symmetry a 2D perovskite can theoretically have.⁵ The interlayer distance (below 4 Å) of the FA DJ 2D perovskite is also one of the smallest among all reported 2D perovskite, and this could allow for better interlayer electronic coupling. As the consequence of zero distortion and short interlayer distance, this new 2D perovskite series exhibits systematically lower band gap, probably the smallest bandgap among all the 2D perovskite to our best knowledge. Preliminary stability test shows this new FA DJ maintained 75% of the perovskite phase under 1.2 suns plus 100% RH (relative humidity) over 2.5 hours.

8:00 PM EN05.04.03

On-Site Wettability-Induced Growth of Perovskite Nano-Structure Arrays Guannan Zhang, Zhao Sun, Chuwei Liang, Zhuofei Gan, Liyang Chen and Wendi Li; The University of Hong Kong, Hong Kong

Due to their unique properties including tuneable band gaps, superior carrier mobility, high color purity, high absorption and emission efficiency, halide perovskites have been widely used in various kinds of optoelectronic applications such as photodetectors, PeLED, laser, etc [1-2]. Specifically, low-dimensional perovskite nanostructures have attracted extensive attention due to their excellent optical, electrical, and stability characteristics, as compared to continuous film materials [3]. Ensuring the size uniformity and controllability of perovskite nanostructures is a prerequisite for their adoption in practical device applications. Diverse methods, such as inkjet printing, spin coating, vapor phase growth, blade coating, and slot-die coating, have been applied to fabricate low-dimensional perovskite nanostructures. However, these methods are usually achieved by utilizing nano-templates, which increases the complexity and cost of the fabricating process. Besides, ensuring uniform morphology and good crystallization is also very challenging to achieve high-performance perovskite nanostructures.

Herein, a template-free fabrication method to realize the controllable growth of perovskite nano-structure arrays including nanowires and nanodot arrays via the inducement of patterned wettability is demonstrated. Take nanowires as an example, figure 1 shows the schematics of perovskite nano-structure fabrication strategy. The hydrophilic-hydrophobic nanograting structure is constructed by interference lithography and trichloro(1H,1H,2H,2H-perfluorooctyl)silane (FDTS) treatment. Figure 2 shows the photoresist patterns prepared by interference lithography, including nanogratings and nanopillar arrays. Then, perovskite nanowires can be fabricated by high-throughput blade coating system consisting of a

blade, hot plate, and control system as well as other auxiliary equipment.

Furthermore, in order to avoid obtaining perovskite structures with discontinuous morphology and low crystallinity, we adjust blade coating parameters (i.e., blade gap, velocity, and temperature) and the solvent properties, particularly the viscosity. We found that when the blade speed is too fast, the liquid film is very discontinuous, while if the blade speed is too slow, the perovskite film is too thick so that the separate nanowire structure cannot form. The optimized coating speed is 160 $\mu\text{m/s}$, at which a continuous perovskite nanowire array with excellent morphology can be obtained. In addition to good morphology, crystallization plays a crucial role in the performance of subsequent perovskite devices. Substrate temperature is another key factor affecting the morphology and crystallization of perovskite nanowires. When the substrate temperature was higher, the deposition front was overly close to the meniscus edge, leading to the formation of the widened nanowires. At high temperature, the solvent can evaporate in a short time, and the grain grows rapidly, resulting in a larger grain size. On the other hand, when the substrate temperature was rather low, the liquid filament was found to easily dewet into segmented perovskite nanowires. And solvent evaporation rate and crystal growth rate are slower at low temperature, resulting in dendritic structure or small-sized grains.

By utilizing the optimized process parameters obtained, MAPbI_3 perovskite nanowire structure with uniform dimension and excellent crystallization can be obtained, as shown in Figure 3. In addition, this method can be used to prepare diverse perovskite nanowire arrays, such as CsPbBr_3 nanowires. Using the same approach, diverse types of perovskite nanodot arrays can also be generated, as shown in Figure 4. The strategy shows a facile method to fabricate perovskite nano-structure arrays, paving the way to low-cost, large-area, and rapid fabrication of high-performance perovskite optoelectronic devices.

Surface treatment of 3D perovskite materials with their layered counterparts has become the most utilised strategy against air- and moisture-induced degradation. Whilst layered materials confer great benefits to the longevity and long-term efficiency of the resulting device stack via passivation of defects and surface traps, numerous reports have previously demonstrated that these materials evolve under exposure to light and humidity, suggesting they are not fully stable. Therefore, it is crucial to study the behaviour of these materials in isolation and as part of a device stack. Herein, it is demonstrated via optical, PL, AFM, XRD, and TAS studies that these “stable” capping layers undergo numerous changes in conditions commonly found during perovskite fabrication, such as exposure to light, solvent, and moisture. A pinhole-mediated degradation mechanism is identified as the cause of the degradation of exfoliated flakes of PEA_2PbI_4 , an $n = 1$ material. This results in the loss of whole perovskite sheets, from a few monolayers to tens of nanometres of material. We discuss important steps to take to slow down their degradation. Additionally, we show high- n PEA-based perovskite capping layers on top of MAPI undergo uncontrolled rearrangements to form lower- n phases, which can severely impact band alignment within devices, or degrade completely. Crucially, they do not act as perfect barrier layers, with the underlying 3D perovskite also demonstrating signs of degradation.

Antisolvent Engineering for Microstructural Improvement of Lead Free Solar Absorber Material
Memoona Qammar, Bosen Zou and Jonathan Halpert; Hong Kong University of Science and Technology, Hong Kong

Lead free halide materials are seeking attention owing to their astonishing optoelectronic properties accompanied with better stability and less toxicity. Silver bismuth halides being ecofriendly and seen as potential candidates for photovoltaic applications but they are still struggling with power conversion. To address this issue here we have used antisolvent engineering to improve film morphology and tested the absorber material in an inverted solar cell for the first time with device architecture:

ITO/NiO/AgBiI₄/C₆₀/BCP/Ag. The efficiency was improved from 0.5% to 1.3% for the solar cell based on absorber layer fabricated via chloroform assisted antisolvent solvent spin casting method. The microstructural improvement was proven by a thorough analysis with SEM and AFM. This study has demonstrated that low boiling antisolvent can assist less polar antisolvent to improve the microstructure of the thin films which ultimately resulted in enhancement of PCE in AgBiI₄ inverted solar cell.

Understanding The Impact of Ions on Open Circuit Voltage in Perovskite Solar Cells Fraser J. Angus¹, Lucy J. Hart², Piers R. B. Barnes² and Pablo Docampo¹; ¹University of Glasgow, United Kingdom; ²Imperial College London, United Kingdom

Metal halide perovskites are a nascent class of materials that combine competitive power conversion efficiencies with low-cost materials and manufacturing processes for use in next-gen solar cells. These materials, uniquely amongst PV materials, are capable of conducting both ionic and electronic charge. However, the presence of mobile ions can lead to extraction losses and carrier accumulation, as a function of the applied bias history of the device which can lead to unreliable performance. However, mobile ions can also reduce recombination currents at the perovskite/transport layer interfaces, increasing open-circuit voltage (V_{oc}). Employing Stabilise-and-Pulse (SaP) measurements, we show that ion accumulation can increase V_{oc} by 0.1 V, which decreases as the flat-ion potential of the PSC becomes larger. We validate these results with drift-diffusion simulations and confirm that under poor energetic alignment conditions, ions can provide a significant boost to the device performance.

8:00 PM EN05.04.07

Exploring The Correlation Between The Built-In Potential of Perovskite Solar Cells and The Thickness of Passivating Layered Perovskites. Fraser J. Angus and Pablo Docampo; University of Glasgow, United Kingdom

Perovskite solar cells have shown significant improvement in recent years, with the power conversion efficiency exceeding 25%. The integration of layered perovskites into a perovskite heterojunction is a promising approach for further enhancing their performance and providing long-term device stability. However, the effects of increasing the thickness of the layered perovskite on device physics and the role of the built-in potential (V_{bi}) in charge extraction are not well understood. Herein, we discuss the intricate physics that come into play when the thickness of the layered perovskite is increased, resulting in a dynamic change in band bending and a consequent effect on the built-in potential. This work elucidates the mechanisms behind the well-known performance enhancement resulting not just from the layered perovskites' role in surface passivation, but also from their effect on the built-in potential.

8:00 PM EN05.04.09

Influence of Interface Configuration on Carrier Transport at 2D/3D Halide Perovskite Heterojunctions Young-Kwang Jung and Samuel D. Stranks; University of Cambridge, United Kingdom

Halide perovskite photovoltaics have shown significant advancements, with power conversion efficiencies (PCEs) increasing to commercially viable levels. However, device stability remains a significant hurdle for the success of the technology and requires further improvement. The introduction of Ruddlesden-Popper (RP) two-dimensional (2D) perovskite overlayers on top of three-dimensional (3D) perovskite active layers has emerged as a promising strategy for enhancing the stability of perovskite solar cells (PSCs) [1-2]. While many successful cases of efficient and stable PSC fabrication via the inclusion of 2D/3D heterojunctions have been reported [3-4], a fundamental understanding of the interaction between 2D and 3D perovskites at their interfaces remains elusive. Therefore, uncovering the relationship between the atomic configuration of the interface and the behavior of electrons at this interface is crucial.

In this work, we performed first-principles density-functional theory (DFT) calculations to explore how the atomic configurations of interfaces influence the properties of 2D/3D halide perovskite heterojunctions. We adopted $\text{PEA}_2\text{PbX}_4/\text{CsPbX}_3$ ($\text{X} = \text{Br}, \text{I}$) heterojunctions as model systems, optimizing their interface geometries and calculating electronic structures. Our results show that both the thermodynamic stability and band alignment of 2D/3D halide perovskite heterojunctions are highly dependent on the configurations of Cs/PEA cations at their interfaces.

8:00 PM EN05.04.10

The Role of Ligand Capping in Achieving High-Efficiency Perovskite Solar Cells and QD LEDs

Farzaneh Jahanbakhshi¹, Andres Felipe Castro Mendez², Shaun Gallagher³, Jessica Kline³, David S. Ginger³, Juan-Pablo Correa-Baena² and Andrew Rappe¹; ¹University of Pennsylvania, United States; ²Georgia Institute of Technology, United States; ³University of Washington, United States

Formamidinium lead iodide (FAPbI) has gained prominence in photovoltaic (PV) applications due to its notable thermal and chemical stability compared to methylammonium lead iodide (MAPI). However, a significant challenge arises from its inherent tendency to spontaneously transform from the cubic (alpha) phase to the non-perovskite yellow (delta) phase under ambient conditions, posing obstacles for practical utilization. We introduce a novel technique involving the evaporation deposition of FAPI onto the substrate that is functionalized with specific acid ligands. This method is designed to exert precise control over the preferential formation and growth of the alpha phase, thereby mitigating the unfavorable transformation to delta-FAPbI. Additionally, we investigate the impact of ligand capping on modulating photoluminescence intermittency in CsPbBr_3 Quantum Dots (QDs). Specifically, we compare the efficiency of CsPbBr_3 QDs capped with a zwitterionic ligand against the traditional approach employing oleic acid and oleylamine. Our findings demonstrate that tight-binding ligands hold promise for reducing blinking phenomena in perovskite QDs, particularly in single-particle and quantum light

experiments. These strategies are elucidated through rigorously analyzing the formation and surface chemistry of these systems at the Density Functional Theory (DFT) level.

8:00 PM EN05.04.11

Efficient and Stable Inverted Perovskite Solar Cell via Incorporation of Halogenated Polystyrene

Saikiran S. Khamgaonkar and Vivek Maheshwari; University of Waterloo, Canada

Rationale design and use of additives to enhance the stability of Metal halide perovskite (MHP) is a key challenge that needs to be addressed for their commercial adoption in photovoltaics. Although high efficiency has been achieved, long term operational stability under daily temperature variation remains an unsolved issue for their large-scale deployment. In this work we use halogenated polystyrene as an additive to improve the long term operational and thermal stability, as well as the efficiency of perovskite solar cells. The incorporation of optimized amount halogenated polystyrene (PS) namely PS-X ($X=F, Cl, Br$) into perovskite precursor solution along with its direct interaction with PbI_2 through Lewis acid base interaction leads to the formation of enlarged, cross-linked perovskite grains. Similarly, the hydrophobic and insulating nature of PS leads to reduced ion migration effects, lower dark and enhanced stability. As a result, halogenated PS (PS-X) p-i-n inverted solar cell showed enhanced efficiency and reduced hysteresis effect when compared to pristine perovskite. A major improvement was seen in the short circuit density (J_{sc}) and fill factor (FF) of the halogenated PS cells due to effective defect passivation caused by the addition of the polymer. In addition to the improvement in performance, halogenated PS cells showed enhanced thermal stability when compared to pristine perovskite cells, which is attributed to the properties and structure of the PS-X additive.

8:00 PM EN05.04.15

Structural Evolution and Octahedral-Coordination Control in $Cs_2Ag_{1-x}Pb_{2x}Bi_{1-x}Br_6$ Perovskite

Materials Yi-Ting Tsai, Wei-Lun Su and Mu-Huai Fang; Academia Sinica, Taiwan

Halide-based perovskite materials have garnered significant attention due to their diverse structures and various synthesis conditions. Serving as customizable optoelectronic materials, they play pivotal roles in electronic applications like light-emitting diodes, backlight systems, solar cells, photodetectors, etc. Nevertheless, their intricate structural adjustment mechanisms remain significant challenges for future utilization. In this study, we successfully synthesized a series of $Cs_2Ag_{1-x}Pb_{2x}Bi_{1-x}Br_6$ materials with a hetero-valent substitution strategy, forming solid solutions bridging $CsPbBr_3$ perovskite and $Cs_2AgBiBr_6$ double-perovskite materials. High-resolution synchrotron X-ray diffraction, coupled with Rietveld refinement, confirmed that samples possess the third phase between the $CsPbBr_3$ perovskite and $Cs_2AgBiBr_6$ double-perovskite end-members. Theoretical calculations, X-ray absorption spectra, Raman spectra, and photoluminescent spectra are conducted to realize the solid-solution process. This study provides valuable insights into the diverse structures by hetero-valent substitution strategy and contributes to precise analysis for subtle changes in crystal structures.

8:00 PM EN05.04.16

Chlorine Addition Effect on The Properties and Stability of Flexible Printed Hybrid Halide

Perovskite Solar Cells Crysa Stavarakis¹, Alexandros Zachariadis¹, Spyridon Kassavetis¹, Christos Kapnopoulou¹, Eirini Paraschoudi¹, Alexandros Paliagas¹, Volha Heben¹, Christoforos Gravalidis¹, Evangelos Mekeridis², Argiris Laskarakis¹ and Stergios Logothetidis^{1,2}; ¹Aristotle University of Thessaloniki, Greece; ²Organic Electronic Technologies P.C. (OET), Greece

Flexible printed perovskite solar cells based on Hybrid Organic–Inorganic Metal Halides have attracted significant attention due to the combination impressive power conversion efficiency and low-cost production and their impressive increase in power conversion efficiency. In this work we focus on the flexible printed perovskite solar cells and in the addition of Chlorine anion addition into $\text{CH}_3\text{NH}_3\text{PbI}_3$ perovskites effectively improves the crystallinity, stability and as a result the performance and durability of the of flexible printed perovskite solar cells (PSCs).

The flexible printed PSCs were fabricated in the inverted structure using one-step slot-die coating that involves the sequential printing of PEDOT:PSS/ $\text{CH}_3\text{NH}_3\text{PbI}_3$ /PCBM layers on top of flexible PET/IMI substrates, while the top electrode (silver, Ag) was grown by thermal evaporation in vacuum. The effect of PbCl_2 addition to perovskite precursor solution was primarily studied in terms of surface morphology and structure of the perovskite layer due to the variations of chlorine ratio in the precursor solution. X-Ray Diffraction showed the effect of chlorine addition on the crystal grain size and orientation, the surface topography characteristics were evaluated by Atomic Force Microscopy (AFM), while UV-Vis optical characterization and nIR-Vis-UV Spectroscopic Ellipsometry (SE) were used to study the optical properties and measure / control the thickness of each printed layer.

The printed hybrid halide perovskite layers were of high crystalline quality as the [(110), (220), (330)] diffraction peaks of $\text{CH}_3\text{NH}_3\text{PbI}_3$ XRD appeared in the XRD spectra, while the analysis of the AFM images showed that the perovskite crystals' size was enlarged by more than 150 nm and the RMS surface roughness increased up to 30 nm as the PbCl_2 addition to perovskite precursor solution increases.

Analysis of the SE spectra provided us with information on the printed perovskites thickness (> 400 nm), the quality and enables the study the effect PbCl_2 addition on the printed perovskite stability and degradation mechanisms through the changes in the PbI_2 absorbance peak in 4.64 eV. The stability studies are also supported by the nanoindentation testing, that provides information on the mechanical properties (elastic modulus, hardness and printed layers adhesion) of the individual layers and the device as well as the mechanical stability of the printed perovskite layers. Finally, we focus on the effect of the printed hybrid halide perovskite properties to the PSCs devices electrical characteristics and power conversion efficiency.

Thermomechanical Durability Study of Flexible Hybrid TCEs on PET made by Photonic Curing

Justin C. Bonner¹, Robert Piper¹, Bishal Bhandari¹, Matthew Davis² and Julia W. Hsu¹; ¹University of Texas at Dallas, United States; ²Energy Materials Corporation, United States

Solution-deposited transparent conducting electrodes (TCEs) can potentially reduce the cost of perovskite solar cell (PSC) manufacturing. However, high-temperature thermal annealing is still needed to convert solution-deposited metal oxide films and is not compatible with plastic substrates. Photonic curing is an alternative to thermal annealing; instead of heating directly, it uses a xenon flash lamp to pulse broadband light onto a sample for micro to millisecond durations. Light absorption, dependent on material optical constants, is converted to heat during a flash from the lamp; a thin absorbing layer is selectively heated during a light pulse while the nonabsorptive plastic layer does not heat up significantly. In our lab, we fabricate hybrid TCEs consisting of silver nanowires (AgNWs) and indium zinc oxide (IZO) on polyethylene terephthalate (PET) by blade coating and photonic curing. Because solution-deposited metal oxides have lower conductivity, adding AgNWs is crucial to achieve a low sheet resistance. The AgNW

layer determines the sheet resistance, transmittance, and energy needed from the flash lamp to convert the IZO, which decreases the roughness of our hybrid TCEs and prevents device shorting.

While the PET substrate does not heat up significantly during photonic curing, subsequent processing of device layers and operating conditions often require high temperatures or temperature cycling that can lead to oxide cracking. Oxide-based TCEs and PET substrates are known to have a coefficient of thermal expansion (CTE) mismatch because a metal oxide has a CTE ten times smaller than the CTE of the plastic substrate. When a TCE made with a plastic substrate and brittle metal oxide is heated to elevated temperatures, the CTE mismatch will induce cracks in the metal oxide film, leading to high resistance and open circuit devices. In this work, we study the thermomechanical durability, particularly the cracking failure in the IZO layer, of the AgNW + IZO TCEs on PET substrates. Thermomechanical durability is tested by heating the PET/TCE samples to 120°C for 10 minutes, a typical annealing temperature and time used for PSC fabrication. We investigate the cause(s) for IZO cracking including IZO thickness, relative humidity during coating, PET substrate thickness, thermal and mechanical properties, and surface treatment. We then devise processing conditions to alleviate the thermomechanical failures. TCEs that survive the thermomechanical durability test will be used to make PSCs and benchmarked to PSCs made on commercial flexible TCEs. The success in producing a robust TCE will facilitate roll-to-roll manufacturing of PSCs.

This work is supported by DOE SETO DE-EE0009518.

Enhanced Humidity Stability of 2D Perovskites using Sulfonium Cations Daniel Ratchford, Gloria Bazargan, Blake S. Simpkins, Jeff Owrutsky and Matthew D. Thum; Naval Research Laboratory, United States

Metal halide 2D perovskites, consisting of alternating layers of metal halide octahedra sheets and cations, have broad technological appeal because of their tunable mechanical, optical, and electrical properties. Compared to 3D perovskites, 2D perovskites offer a greater flexibility in the range of cations that can be incorporated into a stable crystal structure, which then offers the potential for a broader range of material properties. Here, we discuss our work on the synthesis and characterization of lead halide perovskites which contain fluorinated phenethylsulfonium (FPES) cations. We fabricate thin film perovskites which incorporate varying amounts of this new sulfur-containing cation mixed with conventional cations (phenethylammonium and methylammonium) and compare material optical properties and stability under humid conditions. We use visible absorption spectroscopy to measure the degradation of samples at 90% RH. We show that incorporating the FPES cation can dramatically slow down humidity induced degradation, while also reducing the charge carrier recombination lifetimes. This work highlights that sulfonium cations could play an important role in enhancing the environmental stability of lead halide perovskites.

8:00 PM EN05.04.19

Expanding the Interface Engineering for Efficient Perovskite X-Ray Detectors Thanh Hai Le and Wanyi Nie; Los Alamos National Laboratory, United States

Although perovskite material-based detectors exhibit remarkable optoelectronic performance, they face a significant challenge in terms of operational stability, which does not meet market demands. Several technological strategies have been suggested to tackle the instability problem attributed to halide ion

migration. While these methods have resulted in some progress, they have not yet yielded a solution ready for the market. Here, we present evidence that a zero-dimensional PEA_2ZnI_4 material can significantly enhance surface passivation in 2D perovskite single crystals and create stronger two-dimensional/zero-dimensional heterojunctions compared to their lead-based counterparts. The resulting 0D/2D configuration forms a unique and well-organized multi-dimensional interface, resulting in an impressive external quantum efficiency increase of up to 30%, surpassing the 8% improvement seen in 2D perovskite devices. Furthermore, our device maintains 100% initial efficiency even after undergoing 1000 on-off cycles and enduring over 70 hours of continuous illumination at $178.7 \mu\text{Gy/s}$ while under an applied voltage of 10V. Additionally, our unencapsulated device exhibits no loss in performance under normal measurement and storage conditions (temperature: 25°C , humidity: 20 to 60%) for up to 2 months. These findings significantly broaden the range of materials available for low-dimensional interface engineering and create an opportunity for the timely commercialization of perovskite x-ray detectors.

Enhancing The Bending Stability of Flexible Perovskite Solar Cells based on Stainless Steel Substrate through Interface Incorporation of Buffer Layer onto TiO_2 Kyunghwan Kim¹, Solhee Lee¹, Jae-Keun Hwang¹, Wonkyu Lee¹, Dowon Pyun¹, Jiyeon Nam¹, Seok-Hyun Jeong¹, Ji-Seong Hwang¹, Sujin Cho¹, Youngmin Kim², Hae-Seok Lee², Yoonmook Kang², Youngho Choe¹ and Donghwan Kim¹; ¹Korea University, Korea (the Republic of); ²KU-KIST Green School, Korea (the Republic of)

As the importance of renewable energy is increasingly emphasized, photovoltaic technology stands at the forefront of this energy transition. Building-integrated photovoltaics (BIPV) and vehicle-integrated photovoltaics (VIPV) are extending the application scope of traditional solar systems, exploring their potential in more diverse and complex environments. In response to these advancements, researchers continually delve into this domain, aiming for more efficient and sustainable energy solutions. The first-generation crystalline silicon solar cells have already demonstrated high efficiency and reliability in their performance. However, the wafer's inherent physical properties present limitations in flexibility and adaptability to diverse curvatures. In contrast, perovskite thin-film solar cells emerged to address these challenges, expanding applicability not only to traditional glass substrates but also to flexible substrates of various forms and materials. Specifically, when applied to intricate structures such as BIPV and VIPV, their utility and cost-effectiveness are anticipated to significantly increase. In this study, we investigated the fabrication process of these perovskite solar cells on stainless steel (SS) substrates, leveraging the substrate's mechanical robustness, thermal and moisture stability, and excellent corrosion resistance. To evaluate their suitability for BIPV and VIPV applications, bending tests were conducted under varying curvature conditions ranging from 3mm to 15mm. Damage to the Electron Transfer Layer (ETL) and the perovskite layer was observed in these tests, affirming their substantial impact on the solar cell's performance and stability. Consequently, to fortify damage during the bending process, the insertion of a buffer layer between these layers was proposed to enhance the bending stability and performance of perovskite solar cell.

SESSION EN05.05: Halide Perovskites Photovoltaics and Stability I

2D or Not 2D for High Efficient NIP Perovskite Solar Cells Giulia Grancini; University of Pavia, Italy

Three-dimensional (3D)/low-dimensional (LD) perovskite solar cells (PSCs) offer an effective strategy to overcome the trade-off between perovskite solar cells device performance and stability. Improving the device longevity, while concomitantly simultaneously enhancing increasing the solar cell open circuit voltage and fill factor of the solar cell is the current challenge. Despite being one of the most popular and effective way processing techniques, whether the presence of this surface LDP layer would be - or not- represents the winning crucial path for the future of this technology remains elusive. In particular, atomic layer combined surface and bulk passivation using surface modifiers such as organic dopants, casts the doubts on the effective need for of having an homogeneous LDP cover capping layer. In this talk, I will discuss the interfacial passivation with different cations such as M-PEAI, M-PEABr, and M-PEACl, showing the role of the passivation and how different halides affect the device performance of the devices. In addition, I will compare recent results obtained in the 3D/LDP configuration with the surface cation passivation strategy, which can still pushes produce the performances to values comparable to the LDP/3D bilayers. I will providing a comprehensive perspective on the benefits from of the two different strategies, but also presenting how LDP interfaces can play a role in alternative new configurations, such as tandem solar cells [1,2].

Acknowledgements I acknowledge the “HY-NANO” project that has received funding from the European Research Council (ERC) Starting Grant 2018 under the European Union’s Horizon 2020 research and innovation programme (Grant agreement No. 802862).

Hot Carriers in Metal Halide Perovskites: Cold Background Effect and the Hot Phonon Bottleneck

Tim Faber¹, Lado Filipovic² and Lambert Jan Anton Koster¹; ¹University of Groningen, Netherlands; ²TU Wien, Austria

The goal of third-generation PV is to go beyond the Shockley–Queisser limit, the theoretical limit of 33 % for a single junction solar cell. The hot carrier solar cell concept has been proposed to overcome this limit, by harvesting carriers before they have lost their surplus energy. Theoretically the prevented thermal losses could boost the efficiency up to 66%.

One promising type of materials for these purposes are perovskites. Next to having excellent PCE, being cheap and solution processable, some perovskites have shown very long cooling times, the key requirement for a hot carrier solar cell. We wish to shed light on why relaxation times are found to be so long in perovskites.

By using an Ensemble Monte Carlo (EMC) simulation we are able to simulate the trajectories of charge carriers and model their interactions with their environment. In the EMC random free flight times are generated and interrupted by scattering events with desired scattering mechanisms. It is this freedom of

choice which makes the EMC an excellent tool in order to investigate what exactly causes charge carriers in halide perovskites to cool.

In this contribution we first identify the roles of electron-phonon and electron-electron scattering in the thermalisation and cooling process. We show how these processes depend on several material parameters. We zoom in on how cooling times are impacted by the degree of background doping and show how an ensemble of background carriers can have a detrimental effect on the cooling time.

Secondly, we quantify the effect of a hot phonon bottleneck on the cooling time. The hot phonon bottleneck has been put forward as a prominent mechanism explaining the extended cooling times measured for perovskites. We show on what scale the hot phonon bottleneck could extend cooling times and how it depends on carrier concentration and phonon lifetime.

Our results give important insights in the hot carrier cooling dynamics of perovskites, and are highly relevant for the discussion on whether or not perovskites are suitable candidates for a hot carrier solar cell.

8:45 AM EN05.05.03

Unlocking the Potential of Single-Crystal Hybrid Perovskites: Pushing the Limits to Achieve Stable and Efficient X-Ray Detection Bekir Turedi^{1,2,3}, Kostiantyn Sakhatskyi^{1,2}, Gebhard J. Matt^{1,2}, Erfu Wu², Anastasiia Sakhatska^{1,2}, Vitalii Bartosh^{1,2}, Muhammad N. Lintangpradipto³, Rounak Naphade³, Ivan Shorubalko², Omar F. Mohammed³, Sergii Yakunin^{1,2}, Osman M. Bakr³ and Maksym V. Kovalenko^{1,2}; ¹ETH Zürich, Switzerland; ²Empa–Swiss Federal Laboratories for Materials Science and Technology, Switzerland; ³King Abdullah University of Science and Technology, Saudi Arabia

Recently, hybrid metal halide perovskites have emerged as promising candidates for X-ray detectors, attributed to their cost-effective, scalable, and robust solution growth, as well as their competency in detecting individual gamma-photons under high bias voltages. Yet, the rapid degradation of perovskites, being mixed electronic-ionic conductors, under high electric fields presents a significant obstacle to the advancement of perovskite-based X-ray detectors.

In response to this challenge, we devised an innovative strategy that harnesses the photovoltaic mode of operation at zero-voltage bias. This approach employs thick and uniform methylammonium lead iodide (MAPbI₃) single-crystal films, with thicknesses extending up to 300 µm, solution-grown directly onto hole-transporting electrodes via the space-confined inverse temperature crystallization (ITC) technique. Our results reveal that this approach engenders both near-optimal and long-term stable performance in perovskite X-ray detectors. We achieved an impressive detection efficiency of 88% and a noise equivalent dose of 90 pGy_{air} (below the dose of a single incident photon) with 18 keV X-rays, thereby enabling single-photon counting as well as low-dose and energy-resolved X-ray imaging. Furthermore, we fabricated array detectors that showcased high spatial resolution, reaching up to 11 lp mm⁻¹.. Our study evidences that hybrid perovskites are viable materials for developing cost-effective commercial detector arrays for X-ray imaging technologies. The operational stability of the device matches the intrinsic chemical shelf lifetime of MAPbI₃, registering at least one year in the investigated case. Furthermore, our results indicate that perovskite X-ray detectors can approach ideal detection performance and are amenable to medical diagnostic applications, where the radiation dose can be potentially minimized to its fundamentally lowest limit, as dictated by Poisson photon statistics. In conclusion, this research unveils a pioneering approach to constructing a near-ideal X-ray detector utilizing hybrid metal halide perovskites, overcoming the significant issue of rapid degradation under high

electric fields, thereby displaying promise for commercial application in medical diagnostics. By highlighting the direct growth of the single crystal on pixelated substrate, the study paves the way for the commercial implementation of perovskite-based array detectors. This development could bring about a new era in the field of medical imaging, with low-cost, low-dose, and high-resolution imaging becoming widely accessible.

Design Strategies for Efficient, Stable and Commercially Viable Inverted Perovskite Solar Cells Yi Hou^{1,2}; ¹National University of Singapore, Singapore; ²Solar Energy Research Institute of Singapore, Singapore

Inverted perovskite solar cells (PSCs) have immense potential as a standalone technology or as a complement to silicon in tandem configurations. Nonetheless, the primary barriers impeding the commercialization of state-of-the-art inverted PSCs are still the interface recombination losses and degradation. Through the development of novel interface materials and innovative device design concepts, we demonstrate the first instance of inverted structured perovskite solar cells surpassing conventional structured perovskite solar cells in terms of performance, specifically in an active area of 1 cm². These findings have been validated and certified by the NPVM, with the inverted PSCs achieving a certified steady-state efficiency of 24.8% for an area of 0.05 cm², and a record-breaking certified steady-state efficiency of 24.0% for an area of 1 cm². Furthermore, these inverted PSCs exhibit stable performance under maximum power point tracking. In this presentation, I will provide insights into the rationale behind inverted perovskite design, elucidate how thin-film-based perovskites approach the Shockley-Queisser limit, and unveil the potential of this technology in both single-junction and tandem devices.

9:45 AM EN05.05.06

Approaches to High-Efficiency III-V/Si and Perovskite/Si Tandem Solar Cells Masafumi Yamaguchi¹, Tatsuya Takamoto², Kyotaro Nakamura¹, Ryo Ozaki¹, Nobuaki Kojima¹ and Yoshio Ohshita¹; ¹Toyota Technological Institute, Japan; ²Sharp Corporation, Japan

PV-powered vehicle applications are very attractive for reducing CO₂ emission and creation of new market [1]. Development of high-efficiency (> 30%) and low-cost solar cell modules is very important. Although Toyota Prius and Nissan eNV 200 demonstration cars installed with Sharp's high-efficiency III-V 3-junction solar cell modules with an efficiency of more than 30% have demonstrated longer driving range of 26 km/day average compared to 16 km/day average for Sono Motors Sion installed with Si back contact solar cell modules with an efficiency of 21.5%, cost reduction of multi-junction (MJ) solar cells is necessary for PV-powered vehicle applications. Development of Si tandem solar cells [2] such as III-V/Si and perovskite/Si tandem solar cells is very promising for cost reduction.

This paper presents our results for III-V/Si 3-junction tandem solar cells and modules, and analytical results for efficiency potential of various Si tandem solar cells including perovskite/Si tandem solar cells. Previously, the authors have demonstrated 34.1% efficiency with 23 cm² area 4-terminal InGaP/GaAs/Si 3-junction solar cell by using Si heterojunction solar cell with an efficiency of 24.9% as a bottom cell.

Most recently, the authors have achieved a new record efficiency (33.7%) with 4-terminal InGaP/GaAs/Si 3-junction solar cell module with an area of 775 cm².

Si 3-junction tandem solar cell modules with an efficiency of more than 35% are shown to have driving distance potential of more than 30 km/day average and more than 50 km/day on a clear day. Toward 35% efficiency Si tandem solar cell modules, efficiency potential of various Si tandem solar cells was analyzed by using external radiative efficiency (ERE) [3,4]. The authors have defined bandgap energy E_g dependence of $\Delta V_{oc,rad}$ ($= E_g/q - V_{oc,rad}$) for radiative open-circuit voltage $V_{oc,rad}$ relative to E_g/q as $\Delta V_{oc,rad}$ [V] = 0.1708 + 0.0671 E_g [eV].

The efficiency of Si tandem solar cells in radiative limit was calculated by assuming ERE of 100%, optical loss of 2% and resistance loss of 2%. High efficiency of 43.2% and 47.9% is expected with 2-junction solar cell and 3-junction solar cells. Practically feasible efficiencies estimated by assuming ERE of 10%, optical loss of 2% and resistance loss of 2% are 40.8% for 2-junction Si tandem solar cells and 45.4% for 3-junction Si tandem solar cells. Because optimum bandgap energy combination [5] of Si tandem solar cells is 1.73 eV/Si (1.11 eV) and 2.01 eV/1.50 eV/Si (1.11 eV), optimization of bandgap energy for perovskite/Si tandem solar cells is necessary. Because 3-junction tandem solar cells have higher potential efficiency by 4-5% compared to 2-junction tandem solar cells, development of high-efficiency perovskite based 3-junction solar cells is suggested to be very attractive. Several losses such as non-radiative recombination, optical and resistance losses in Si tandem solar cells are discussed in this paper.

Engineering Ligand Reactivity Enables High-Temperature Operation of Stable Perovskite Solar Cells So Min Park^{1,2}, Mingyang Wei³, Jian Xu², Kenneth R. Graham⁴, Michael Graetzel³ and Edward Sargent^{1,2}; ¹Northwestern University, United States; ²University of Toronto, Canada; ³EPFL, Switzerland; ⁴University of Kentucky, United States

Perovskite solar cells consisting of interfacial two-dimensional/three-dimensional heterostructures that incorporate ammonium ligand intercalation have enabled rapid progress toward the goal of uniting performance with stability. However, as the field continues to seek ever-higher durability, additional tools that avoid progressive ligand intercalation are needed to minimize degradation at high temperatures. We use ammonium ligands that are nonreactive with the bulk of perovskites and investigate libraries varying ligand molecular structure systematically. We find that fluorinated aniliniums offer interfacial passivation and simultaneously minimize reactivity with perovskites. Using this approach, we report a certified quasi-steady-state power-conversion efficiency of 24.09% for inverted-structure PSCs. In an encapsulated device operating at 85 degrees Celsius and 50% relative humidity, we document a 1560-hour T85 at maximum power point under 1-sun illumination.

10:45 AM *EN05.05.09

Melting and Glass Formation in Hybrid Metal Halide Perovskites David B. Mitzi; Duke University, United States

Crystalline metal halide perovskites have generated intense recent interest, due to outstanding and versatile semiconducting character and associated prospective device applications. So-called two-dimensional (2D) perovskites offer the widest range of tunability within this family, due in part to the essentially unlimited range of prospective organic cations that can be employed. While most work targeting tunability in these systems has focused on optoelectronic properties, another interesting research direction relates to thermal properties—e.g., particularly as they relate to melting and ordering. Ability to melt hybrid perovskites provides an alternative solvent-free approach for film deposition, as well as offering pathways for controlling grain nucleation/growth. While hybrid perovskites are often susceptible to decomposition at temperatures below the prospective melting transitions, over the years we and others have shown that, through tailoring metal/halogen and molecular interactions within the hybrid, the melting temperature can be reduced over a >100 °C range for Ge-, Sn- and Pb-based 2D perovskites (e.g., see refs.¹⁻³) thereby enabling the formation of relatively stable hybrid melts. Most of these melts crystallize rapidly upon cooling; however, appropriate selection of organic cation component can favor a glassy state during cooling.^{3,4} Demonstration of a reversible transition between the glass and crystalline states, each with distinct physical properties, opens new opportunities for application, and points to a new direction of fundamental study related to understanding and broadening the range of local structure, crystallization kinetics, and properties exhibited by the hybrid glass state.

Degradation Mechanisms in Triple-Cation Perovskite and Protection by a 2D Capping Layer Isaac Metcalf and Wenbin Li; Rice University, United States

We have used in-situ Wide-Angle X-Ray Scattering to investigate the degradation mechanism of unencapsulated mixed-cation, mixed-anion ($\text{Cs}_{0.05}\text{MA}_{0.16}\text{FA}_{0.79}\text{Pb}(\text{I}_{0.83}\text{Br}_{0.17})$) halide perovskite films under various external stimuli (light/humidity/temperature), with and without a capping layer of 2D perovskite. Under combined light and humidity, the perovskite film segregates into nonperovskite phases of FAPbI_3 , CsPbI_3 , and $\text{MAPbI}_3 \bullet \text{H}_2\text{O}$. This process appears to consume PbI_2 , which itself is a degradation product that appears before phase segregation. Temperature accelerates this degradation process but the mechanism is the same for temperatures below 100°C. Under dark humid conditions we see no formation of nonperovskite phases and PbI_2 persists as the only degradation product, suggesting that light activates the phase segregation. Moreover, no degradation was seen in samples exposed to light and humid N_2 , suggesting that the degradation process is also oxygen-catalyzed. We further performed degradation tests on 2D Ruddlesden-Popper perovskites with a butylammonium (BA) A'-site cation. Under humid conditions these 2D perovskites degrade into BA and MA hydrate phases. When the humidity is reduced the 2D partially recovers, forming the same or lower n-value films. With capping by

BA-based 2D perovskite, the degradation of mixed-cation, mixed-anion 3D under light and humidity is suppressed but the same degradation products form. Under combined light and humidity the 2D and 2D hydrate diffraction signals disappear over time but 2D continues to have a protective effect on the 3D, suggesting that it intercalates into the 3D layer.

11:30 AM EN05.05.11

Defect Passivation and Gradual Energy Band Modulation for Efficient and Stable Perovskite Solar Cells Soo-Kwan Kim¹, Jinseck Kim², Bumjoon J. Kim² and Jongmin Choi¹; ¹Department of Energy Science and Engineering, Daegu Gyeongbuk Institute of Science and Technology (DGIST), Korea (the Republic of); ²Department of Chemical and Biomolecular Engineering, Korea Advanced Institute of Science and Technology (KAIST), Korea (the Republic of)

Passivation engineering is crucial for achieving high power conversion efficiency (PCE) and long-term stability in perovskite solar cells (PSCs). A promising strategy involves introducing passivation polymers to the grain boundaries (GBs) of perovskite film, where defects are densely formed during the film growth. These defects trigger non-radiative recombination, negatively impacting the performance of PSCs. Additionally, they serve as pathways for oxygen, humidity, and lithium ions, further degrading the perovskite active layer. As such, defect restoration is necessary for stability and humidity resistance. The principle of Lewis adduct formation offers a simple and effective method for passivation. The primary component of perovskite defects, the uncoordinated lead ion (Pb^{2+}), is known to be a Lewis acid. The polymer's Lewis base can neutralize these Lewis acids, forming Lewis adducts. Consequently, the polymer can physically cover and neutralize defects, leading to high photovoltaic factors and long-term stability.

However, traditional polymer-based approaches for GB passivation can face limitations, such as increased series resistance and insufficient passivation coverage. To date, no solution has simultaneously addressed these issues. High polymer concentration can cover the entire perovskite surface, leading to high series resistance. In contrast, a lower concentration mitigates series resistance yet results in uneven passivation coverage. The GBs are locally exposed at the interface, leading to open-circuit voltage loss (V_{oc}) through non-radiative recombination.

In this study, we introduce a novel multifunctional polymer to passivate perovskite solar cells, addressing the aforementioned limitations. Our polymer was successfully introduced into both the perovskite film and the hole transport layer (HTL), facilitating comprehensive passivation of defect sites within the active perovskite layer. Moreover, this strategy offered several benefits for perovskite devices. Firstly, there was a significant reduction in the band offset between the perovskite active layer and the hole transport layer (HTL). Secondly, our polymer was found to mitigate lithium-ion diffusion from the HTL to the perovskite, substantially reducing hysteresis and enhancing the stability of PSCs. Lastly, the integration of our passivation strategies resulted in the suppression of pinhole formation at the HTL and reduced the surface energy difference between the perovskite films and the HTL interface. This set of improvements suppressed void formation between interfaces, thus enhancing charge extraction and reducing charge recombination losses.

Consequently, the PSCs integrated with our polymer exhibited a remarkable increase in power conversion efficiency (PCE), reaching up to 24.0%, compared to the control devices (21.0%). Furthermore, our integrated PSCs retained 92% of their initial PCE after 2000 h of storage under ambient conditions. Under damp-heat conditions (85 °C and 85% relative humidity), the cell preserved 80% of their initial PCE after 432 hours.

Additive Engineering for Thermally Stable Perovskites Xiwen Gong; University of Michigan, United States

Organic-inorganic perovskites offer exceptional optoelectronic properties but suffer from poor thermal stability, hampering their practical application in photovoltaics. I will discuss a systematic investigation of the impact of the molecular structure of base additives on the thermal stability of perovskite. By synthesizing additives with controllable coordination numbers, molecular weights, and steric hindrance, we systematically study the impact of these molecular properties on the morphological, optoelectronic properties, and thermal stability of perovskite films. This study provides rational molecular design strategies for additive engineering in perovskites, enabling efficient defect passivation and enhanced thermal stability.

2:15 PM EN05.06.03

Low-Dimensional Perovskite Materials for Efficient and Stable Light-Emitting Diodes Wallace C. Choy; University of Hong Kong, China

Low-dimensional halide perovskite emitters with the advantages of quantum confinement effects have emerged as a novel class of revolutionary semiconductors with high color purity, wide color gamut, low cost, and a simple solution process for vivid natural color yet cost-effective displays. However, perovskite materials commonly exhibit environmental instability due to humidity, light, and/or elevated temperature significantly hindering their applications in light-emitting diodes (LEDs) where reported lifetimes are commonly in the order of minutes. In this talk, we will discuss some of our recent work on perovskite LEDs. Regarding quasi-2D perovskites, limited attention has been paid to rational design to balance the carrier confinement and transfer in quasi-2D perovskites, which is essential to achieve high-performance PeLEDs. By using blue PeLEDs as an example, we will enhance the hole injection for better balance carrier and improve the efficiency [1], we also modulate the n-phase distribution [2,3] and optimize the carrier transfer and confinement to improve the performances of PeLEDs [4]. For perovskite nanocrystals (NCs), we will introduce new ligands to synthesize red color perovskite (CsPbI₃) NCs. The ligand can significantly stabilize the CsPbI₃ NCs without any crystalline deformation on the NC crystal structure. Additionally, these chemically crosslinked PMAs also significantly reduce Pb_{Cs} deep defects. Moreover, CsPbI₃ NCs exhibit increasing exciton binding energy and reduced longitudinal-optical (LO) phonon energy [5,6]. Recently, by designing the multifunctional-group ligands for ion migration suppression and carrier transportation enhancement, we further improved the efficiency and stability of the pure red and pure green perovskite LEDs meeting the standard of Rec. 2100 for promoting their display applications. Optical Mater., DOI:10.1002/adom.202300912.

2:30 PM *EN05.06.04

Scalable Interfaces Passivation for Perovskite Solar Cells David S. Ginger; University of Washington, United States

Halide perovskite semiconductors are being explored for applications including solar photovoltaics (PV), light emitting diodes (LEDs), radiation detectors, and even sources of quantum light. While perovskite semiconductors are often described as remarkably defect tolerant, they are not defect free. As these materials race towards commercialization, it is important to understand how different processing methods lead to semiconductor films with different levels of efficiency and stability. In this talk I will discuss defects and heterogeneity, and our ability to control them at perovskite interfaces from the molecular to macroscopic scale. We show how processing additives can undergo unexpected chemical reactions that alter the growth processes in perovskite films, leading to improved uniformity with processing over large areas, and how interfacial layers can improve overall photovoltaic performance, as well as stability under reversed bias conditions.

3:30 PM *EN05.06.05

Making High-Efficiency Halide-Perovskite Solar Photovoltaics More Durable: Challenges and Opportunities Nitin P. Padture; Brown University, United States

The unproven durability of perovskite photovoltaics (PVs) is likely to pose a significant technical hurdle in the path towards the widespread deployment of this burgeoning thin-film PV technology. The overall durability of perovskite PVs, which includes operational stability, is directly affected by the mechanical reliability of metal-halide perovskite materials, cells, and modules, but this issue has been largely overlooked. Thus, there is a sense of urgency for addressing the mechanical reliability issue comprehensively, and help perovskite PVs reach their full potential. This presents many challenges, but it also offers vast research opportunities for making meaningful progress towards more durable perovskite PVs. Here I will highlight the important challenges and opportunities, together with best practices, pertaining to the three key interrelated elements that determine the mechanical reliability of perovskite PVs: (i) driving stresses, (ii) mechanical properties, and (iii) mechanical failure. I will also present examples of approaches to mitigate failure and extend the durability of perovskite PVs.

4:00 PM EN05.06.06

Efficient All-Perovskite Tandems Enabled by Surface Anchoring of Bifunctional Long-Chain Amphiphilic Ligands Aidan Maxwell, Hao Chen and Edward H. Sargent; University of Toronto, Canada

Perovskite solar cells (PSCs) in the stability-enhancing pin structure are limited by nonradiative recombination at the materials interface with the electron transport layer (ETL). This recombination is particularly acute in narrow-bandgap (~ 1.2 eV) mixed Pb-Sn PSCs, a crucial active layer in emergent all-perovskite tandem solar cells: these suffer higher V_{OC} deficits than do their Pb-based counterparts due to Sn-related surface oxidation and consequent detrimental p-doping. Our photoluminescence quantum yield studies herein indicated that state-of-the-art ethane-1,2-diammonium (EDA) passivation only partially alleviates harmful perovskite/ETL quasi fermi level splitting losses. We pursued physical separation at the defect-rich perovskite:ETL interface to reduce non-radiative losses: our target was to unite chemical surface coordination of Sn sites with physical interlayer separation, an approach we implemented by introducing amphiphilic long-chain carboxylic acid ligands at the perovskite surface. Treatment with oleic acid (OA), a long-chain carboxylic acid, led to carrier dynamics and surface chemistry indicative of

reduced carrier recombination at the perovskite/ETL interface, and evidence of coordination with surface Sn^{2+} . The addition of OA reduces the V_{OC} deficit to 0.34 V, resulting in a 0.89 V V_{OC} and PCE of 23.0% (22.4% stabilized) for 1.23 eV Pb-Sn PSCs. Incorporating the OA-treated Pb-Sn layer into a monolithic all-perovskite tandem, we report 27.3% PCE (26.4% certified) having a record V_{OC} of 2.21 V.

4:15 PM EN05.06.07

Unraveling Perovskite Metal Shunting in Reverse Bias: Insights for Enhanced Module Design Isaac Gould, Daniel Morales and Michael McGehee; CU Boulder, United States

In a photovoltaic module under partial shading conditions, shaded subcells may experience reverse bias. For perovskite solar cells reverse bias often rapidly leads to degradation. One of the most common forms of degradation is shunting which is linked to metal migration. Our findings suggest that the metallic anodic interface's oxidation leads to the formation of mobile metallic cations. These metal ions migrate across the device under the reverse bias field, and electroplate on the opposite electrode, forming metal filament type shunts. Time-of-flight secondary ion mass spectroscopy confirms the infiltration of metal into the perovskite layer during reverse bias operation. Relating the shunt resistance to the radius of the shunt leads to a calculation of 10-35 nm. High current density through these nanosized filaments generates significant localized heating, causing substantial damage to the adjacent perovskite material. To mitigate this issue, we advocate for using ion barriers, like atomic layer deposited tin oxide, between the perovskite layer and the metal electrode. Notably, cells with the NIP orientation do not exhibit this shunting phenomenon, suggesting that halide-induced oxidation of the metallic electrode occurs exclusively when it serves as the anodic electrode during reverse bias operation.

The understanding of metal migration and shunting mechanisms in perovskite solar cells is invaluable for improving solar module design and optimization. Once shunting is stopped reverse bias breakdowns can range from -3V to -15V. High breakdown opens the possibility of bypass diode implementation, although resistance losses from the transparent conducting oxides must be managed. With a low voltage breakdown (-3V), self-bypassing is possible, as the resultant temperature increase is a modest 5°C, assuming uniform heating. This can still be problematic as reverse bias breakdown can lead to redox of halide species and other electrochemical degradations to proceed. The trade-offs in perovskite solar module design necessitate crucial decisions that can affect the module's efficiency, cost, and reliability. A thorough understanding of perovskite chemistry, the implications of shunting, and the role of different interlayers in the module is essential to guide these decisions towards optimal solar module design and performance.

Investigation of The Influence of The Voids Formed During The Operation of The Device on The Thermal and Light Stability of Perovskite Solar Cells Mengru Wang; University of North Carolina at Chapel Hill, United States

The formation of voids in the perovskite films close to the embedded bottom interface has been reported to form during film deposition and limit the efficiency and stability of perovskite solar cells. Here we studied the voids formed during the long-term operation or thermal stress for a typical perovskite made by solution process, even if the initial perovskite films are already optimized to avoid voids during film deposition. These voids preferred to assemble along grain boundaries at the bottom interface. Detailed studies show that the voids originated from the shrinking of perovskites caused by the leaving of residual dimethyl sulfoxide (DMSO) and the conversion of the amorphous phase to the crystalline phase as a

result of solid-state ion diffusion. Surprisingly, we found the formation of these voids did not notably impact the solar cell thermal stability. After decreasing the amorphous region in perovskites by thermal annealing, the light stability of perovskite solar cells was actually improved despite of the creation of voids by thermal annealing. The annealed devices maintained 90% of their initial efficiencies after annealing and light soaking for 1900 hours at open circuit conditions under one-sun light at 50 °C. The positive iodide interstitial density in the perovskite films was actually reduced during post-annealing despite the generation of three-dimensional voids, which further confirms that removing the amorphous region is an effective method to enhance the operational stability of perovskite solar cells.

Bandgap Bowing in Inorganic Lead-free Perovskite-Inspired Materials Fang Sheng, Eunice Aissi, Alexander E. Siemenn, Basita Das, Hamide Kavak and Tonio Buonassisi; Massachusetts Institute of Technology, United States

The recent success of lead-halide perovskites has inspired the search for similar materials, with potential advantages of greater stability and absence of lead. Some of these materials form alloy series that exhibit a property known as “bandgap bowing”, whereby a mixed alloy AB has a lower bandgap than either phase-pure A or B, for example $\text{Cs}_3(\text{Bi}_{1-x}\text{Sb}_x)_2(\text{I}_{1-x}\text{Br}_x)_9$ reported in Ref. [1].

Bandgap bowing can be expensive and challenging to predict by first-principles simulations, motivating the application of high-throughput methods to experimentally synthesize alloy series and quickly measure them. As a benchmark, we consider spin coating and UV-Vis, which requires approximately 15 minutes per sample for synthesis and annealing, and 30 minutes for characterization.

In this work, we employ a high-throughput workflow that combines direct multi-material printing of alloy series with an automated computer-vision-based bandgap extraction, to experimentally screen for bandgap bowing in a broader materials space of ABX_3 and $\text{A}_3\text{B}_2\text{X}_9$ alloys. The high-throughput synthesis is conducted by our direct multi-material printer, Archerfish, which has the capability to print and anneal 1000 unique alloy materials in 15 minutes. Bandgaps for each of the 1000 alloys are measured using a hyperspectral camera operating in reflectance mode, in 2 minutes. Finally, bandgaps are autonomously extracted using an algorithm in 30 minutes, with potential to accelerate using more powerful computation. We report bandgap bowing effects in $\text{Cs}_3(\text{Bi}_x\text{Sb}_{1-x})_2\text{I}_9$ and compare with density functional theory calculations. We then screen broader range of elements including Ge, Ga, and Sn on B sites and Cl^- , Br^- on X sites.

Effect of Grain Boundaries on the Mechanical Properties of Organic-Inorganic Halide Perovskite Polycrystalline Thin Films and Bulk Crystals Madhuja Layek, Meaghan Doyle, Anush Ranka, Zhenghong Dai, Inseok Yang and Nitin P. Padture; Brown University, United States

The past several years have observed a growing interest in hybrid organic-inorganic perovskites (HOIPs) owing to their remarkable application potential in optoelectronics, especially photovoltaics. In order to manufacture efficient and reliable perovskite solar cells (PSCs) that can operate satisfactorily for decades, it is critical to study the mechanical properties of MHPs that are inherently compliant, soft, and brittle. Thus, we have employed multi-beam optical stress sensor (MOSS) curvature measurement and X-ray diffraction (XRD) techniques to estimate Young's modulus of polycrystalline methylammonium lead iodide (MAPbI₃) thin film. Furthermore, we synthesized and sintered HOIP powders into bulk crystals to understand the effect of grain size on Young's modulus and other relevant mechanical properties of HOIPs. We aim to provide an in-depth understanding of the mechanical properties of HOIPs to effectively use them in PSCs.

Understanding the Effect of Post-Growth Vacuum Annealing on 2D Hybrid Organic-Inorganic Perovskite Thin Films Manosi Roy¹, Jose Castaneda², Sharonda LeBlanc² and Adrienne D. Stiff-Roberts¹; ¹Duke University, United States; ²North Carolina State University, United States

The rapid advancements in power conversion efficiency (PCE) of perovskite active regions, achieving a remarkable 26% in 2023, have positioned them as leading contenders in the development of high-efficiency solar cells. However, the issue of moisture instability in three-dimensional (3D) perovskites poses a significant hurdle for the commercialization of perovskite solar cells.¹ To address this challenge, the use of more environmentally stable, two-dimensional (2D) hybrid organic-inorganic perovskites (HOIPs) as a passivating layer for the 3D perovskite active region shows promise in improving stability.² One of the key obstacles in this context is the lack of desired alignment or orientation of the 2D sheets comprising organic and inorganic layers. Traditional solution-based processing methods tend to align these sheets parallel to the substrate, limiting charge transport in the vertical direction. While resonant infrared matrix-assisted pulsed laser evaporation (RIR-MAPLE) yields a random orientation of crystallites and offers a partial remedy to the problem, the ultimate goal is to deliberately promote vertical orientation of the crystallites.^{3,4} Therefore, it is crucial to better understand the RIR-MAPLE synthesis process to influence the orientation of the films, and one possible approach is to conduct post-growth vacuum annealing.¹ Accordingly, phenethylammonium lead halide 2D HOIPs will be grown for comparison using RIR-MAPLE at 50-degree celsius without and with a post-growth vacuum annealing step at three distinct temperatures – 60, 90, and 110-degree celsius. The films will be characterized using a full suite of standard techniques, including X-ray diffraction (XRD) to confirm crystal structure and conduct crystallite size analysis (using the Williamson-Hall method), Stokes shifts (derived from photoluminescence (PL) and UV-Vis spectroscopy), and scanning electron microscopy (SEM) and atomic force microscopy (AFM) to determine surface morphology. In addition, the full-width-half-maximum values for XRD peaks corresponding to different orientations of crystallites will be used to quantify changes in vertical orientation.⁴ Overall, this investigation will shed light on the potential of employing post-growth vacuum annealing to promote vertical orientation of crystallites in 2D HOIP thin films deposited using the RIR-MAPLE, paving the way for future explorations in this area.

Dimethylammonium-Incorporated Mixed Halide Perovskite Nanocrystals for Stabilized Red Emission Shaoni Kar^{1,2}, Bernard Wenger² and Henry Snaith¹; ¹University of Oxford, United Kingdom; ²Helio Display Materials Ltd., United Kingdom

In addition to their stellar performance in photovoltaics, metal halide perovskites have seen a meteoric emergence in several other optoelectronic applications of which light emission is of special significance. Perovskites have been used in light emitting diodes (LEDs), lasing and displays (as colour-converting phosphors) to achieve record efficiencies with immense potential to compete with the commercial standards of III-V and organic LED (OLED) systems within a relatively short time. With high exciton binding energies affording enhanced quantum confinement of carriers, low-dimensional perovskites are especially useful for realizing colour-pure, highly efficient emission. Among such systems, all-inorganic perovskite nanocrystals are attractive candidates owing to easy bandgap tunability through compositional engineering, narrow emission peaks and high photoluminescence quantum yields.

Cesium lead halides of the form CsPbX_3 are the most commonly demonstrated workhorse systems in this category with halide tuning determining the emission range. Cesium lead iodide (CsPbI_3) nanocrystals have been shown to be promising but their device application is still inhibited by their inherent ambient instability. With facile conversion of the metastable black perovskite γ -phase into the yellow δ -phase at room temperature, this material has hardly been effective under sustained optical or electrical excitation. In addition, this composition shows emission outside the visible range (around near-IR wavelengths) which severely limits their usage in displays and other common applications. With addition of bromine (Br), $\text{CsPbI}_x\text{Br}_{3-x}$ nanocrystals are formed with ideal bandgaps for application in visible range LEDs and displays with emission wavelengths lying within the Rec 2020 colour gamut. Furthermore, in contrast to the pure-iodide compositions that require high temperature-based (hot injection) processes to form the perovskite phase, mixed-halide nanocrystals afford facile synthesis through ligand assisted reprecipitation (LARP) in ambient conditions due to the possibility of crystallization at much lower temperatures. However, these materials are still plagued by phase separation under optical or electrical excitations of intensities typical in a working device.

In this work, we try to alloy the A-site of the pure-red emitting CsPbI_2Br with dimethylammonium (DMA) to improve its phase stability under excitation while retaining high photoluminescence quantum yields. DMA, among other organic cations, has recently been shown to alloy successfully with Cs in 3D perovskite thin films and lend it stability under operational conditions. However, with lower-dimensional nanocrystals, the nucleation and growth kinetics are radically different and further intricacy is introduced with the remnant (unwashed) ligands that are unavoidable in the synthesis process. To our knowledge, this is the first study of DMA-alloying through facile LARP synthesis techniques. We propose a novel synthetic route at room temperature and then study the crystal structure and morphology as a function of different DMA contents through an interplay of crystallographic and optical data. We report higher

ambient stability even under intense optical excitation. Finally, we employ these materials as the emitter layer in LEDs and find significant improvement in LED performances with notably improved air-stability in the DMA-incorporated variant.

8:00 PM EN05.07.09

Deterministic Solution-Processed Fabrication of Halide Perovskite Heterostructures Faiz Mandani, Siraj Sidhik, Altaf Pasha, Andrew J. Torma and Aditya D. Mohite; Rice University, United States

Heterostructures play a crucial role in the semiconductor industry as they offer unique optoelectronic properties. However, the conventional methods used for fabricating heterostructures involve specialized and costly processes such as chemical vapor deposition, epitaxial growth, or e-beam deposition. Halide perovskites have emerged as a promising material for various optoelectronic applications due to their tunable bandgap, high carrier mobility, and solution processability. In recent years, considerable efforts have been made to develop perovskite heterostructures using vapor phase techniques¹. These techniques aim to enhance photogeneration, fine-tune band alignments, and passivate the underlying semiconductor. In our previous work, we introduced a solution processed technique for depositing selective (Ruddlesden-Popper) two-dimensional perovskite on top of three-dimensional perovskite². We achieved this by leveraging solvent properties such as dielectric constant and Guttman number.

However, the development of a universal solution processed approach for fabricating multilayer perovskite heterostructures has remained a challenge. To address this, we conducted detailed perovskite-solvent interaction studies to gain a deeper understanding of perovskite solvation dynamics. In this study, we present a solvation-based approach to synthesize perovskite seed solutions, enabling the fabrication of 2D/3D, 3D/2D, and even 3D/3D heterostructures. This approach allows us to create an arbitrary number of layers with any perovskite phase while maintaining high optoelectronic quality and scalability. To demonstrate the universality of our approach, we successfully created formamidinium lead iodide (FAPbI₃)/Dion-Jacobson 2D (3D/2D) perovskite and methylammonium lead iodide (MAPbI₃)/MAPbI₃ (3D/3D) heterostructures. We validated the quality and characteristics of these heterostructures through optoelectronic and cross-sectional analyses. The introduction of this universal approach marks a significant milestone in solution processed heterostructures, extending its applicability beyond perovskites to the broader field of semiconductors. This advancement opens up new possibilities for the synthesis of high-quality, scalable heterostructures, revolutionizing the semiconductor industry.

Light-Induced Expansion Kinetics of Lead Halide Perovskite Crystals Measured via Laser Interferometry Christopher Petroff, Kuan-Ting Liu, Emily E. Hiralal, Lara A. Estroff and John A. Marohn; Cornell University, United States

Light-induced changes to lead halide perovskite (LHP) crystals can provide key information about their electrical properties and degradation mechanisms. It is shown in the literature that LHP crystals exhibit light induced expansion, so called "photostriction" [1]. Generally, it is concluded that these—mainly atomic force microscopy (AFM) derived—data are the result of the photoinduced production and diffusion of electrons. We assert that the several second expansion onset and decay shown in the literature and in our data, is inconsistent with the sub-microsecond timescale of electronic diffusion. We instead

propose that this expansion is due to the light-induced creation of ionic vacancies [2–4]. The formation of ionic vacancies should exhibit an activated temperature dependence. We are developing a series of variable temperature, laser interferometric measurements of LHP crystals to study these expansion kinetics. Laser interferometry is ideal for this kinetics study, as it offers better temporal resolution than the AFM data in the literature; AFM is limited by the time constants of the phase-locked loop whereas laser interferometry is only limited by the bandwidth of the photodetector.

Using laser interferometric measurements, we show non-thermal, light-induced expansion of methylammonium lead tribromide (MAPbBr_3) perovskite crystals, even when excited below band gap. The expansion displays two-rate kinetics and hysteresis with a rapid (10 s) expansion followed by continued slow (10s of seconds) expansion; upon returning to the dark, a rapid contraction is observed which does not reach baseline. We are working to explore this effect and its kinetics across various temperatures; illumination wavelengths; and perovskite crystal compositions, including the all inorganic cesium lead tribromide (CsPbBr_3) system.

Magnetic Resonance Spectroscopy as an Investigation Tool for The Structure of Ytterbium-Doped Cesium Lead Chloride Perovskites Thiago Rubio, Hannah Van Son, Seda Sarp, Iver J. Cleveland and Claudia E. Avalos; New York University, United States

In the search for methods to push the power conversion efficiency of photovoltaic (PV) devices beyond the Shockley-Queisser limit, doping halide perovskites with lanthanide ions, such as Yb^{3+} , has shown promising results. This is due to quantum cutting, the conversion of one high energy photon into two (or more) low-energy photons. Quantum cutting materials can then be utilized as a down-converting layer in PV cells, where the wavelength of the incoming photons can be shifted from the UV to the near IR region, and then be used by the photoactive layer for electricity generation [1].

Understanding the doping mechanism and the defect structure in these materials is essential in order for a more effective insertion of the dopant into the host crystal lattice and subsequent higher photoluminescence quantum yields (PLQY) to be obtained. The doping sites can be studied by means of the effects they produce in the other species in the host structure. Many times, the dopant species only produces local effects. Magnetic resonance spectroscopic techniques such as nuclear magnetic resonance (NMR) and electron paramagnetic resonance (EPR) can probe local environments and can provide information about doping that techniques that probe long-range order, i.e. X-ray diffraction, are not able to [2,3,4].

In this project, ytterbium-doped cesium lead chloride ($\text{Yb}^{3+}:\text{CsPbCl}_3$) perovskite powders were synthesized using dry ball-milling, a method that has been shown to yield high photoluminescence quantum yields due to the emission of Yb^{3+} in the near-infrared region [5]. Solid-state NMR was used to give an insight into how the local environments of the probed nuclei are affected by the insertion of Yb^{3+} to the crystal lattice, and to determine whether the insertion of Yb^{3+} into the crystal lattice was uniform. ^{133}Cs NMR data revealed that longitudinal relaxation times (T_1) for cesium nuclei decrease with increasing amounts of ytterbium added to the composition. Furthermore, the stretching parameter

obtained from a stretched exponential fit of the T_1 data collected showed that this decrease is due to a uniform distribution of paramagnetic centers in the structure. ^{207}Pb NMR data showed that the chemical environments of the detectable lead sites is not distorted due to the insertion of Yb^{3+} , this is evidenced by no change in the chemical shift anisotropy fit of the static NMR signal with increased doping. PLQYs above 135% were obtained for all samples.

Stable and Efficient Large Area 4T Si/perovskite Tandem Photovoltaics with Sputtered

Transparent Contact Ananta Paul, Abhijit Singha, Sakshi Koul, Vikas Sharma, Sudhanshu Mallick, K.R. Balasubramaniam and Dinesh Kabra; Indian Institute of Technology Bombay, India

With the boost in the thin film-based energy and optoelectronics devices' performance, there is an urgent need to improve and modify one of the essential components of such devices: transparent electrodes. In particular, we need to deposit high-conductive and transparent electrodes to fabricate the next-generation tandem structure while maintaining low sputtering damage. Si-perovskite tandem PV devices in the four-terminal (4T) configuration could solve the problems associated with the stability gap between the component perovskite and Si devices. We report the fabrication of NIR-transparent perovskite solar cells (PSCs) with the stable triple cation perovskite as the photo-absorber and subsequent integration with a Si solar cell in a 4T tandem device. The critical development of the sputtered top transparent conducting electrode (TCE) layer and oxide buffer layer at room temperature leads to reproducible, highly efficient NIR-transparent PSCs of both small area (0.175 cm^2) with PCE of 17.1% and large area (0.805 cm^2) with PCE of 16.0%. Electrically disparate, optically coupled 4T tandem devices of the optimized PSCs with commercial monocrystalline PERC Si solar cells exhibit greater than 26% PCE. In addition to enabling industry-compatible TCE-based low-cost Si/perovskite tandem photovoltaics, this study could also be the gateway for the potential use in niche applications like building integrated photovoltaics.

8:00 PM EN05.07.14

Photostability of Formamidinium-Based Mixed-Halide Perovskites Halyna Okrepka, Maksym

Zhukovskyi and Masaru Kuno; University of Notre Dame, United States

Light-induced anion photosegregation is a near-ubiquitous response of lead-based, mixed-halide perovskites to illumination. It is observed as unwanted, yet reversible, changes of the optical and electronic response of these materials when subjected to above-gap excitation and represents an impediment to proposed uses of mixed-halide perovskites in applications such as tandem solar cells. Photosegregation sensitivity depends on the nature of the A-cation (methylammonium (MA^+), formamidinium (FA^+) and Cs^+). For $\text{APb}(\text{I}_{1-x}\text{Br}_x)_3$ photostability rank order follows $\text{CsPb}(\text{I}_{1-x}\text{Br}_x)_3 > \text{FAPb}(\text{I}_{1-x}\text{Br}_x)_3 > \text{MAPb}(\text{I}_{1-x}\text{Br}_x)_3$. Qualitatively, this stems from well-known chemical and thermal instabilities of MA^+ as well as to the generally robust nature of all-inorganic Cs-based perovskites. Here, we assess the relative proclivity of formamidinium-based mixed-halide perovskites such as formamidinium/methylammonium $[(\text{FA},\text{MA})\text{Pb}(\text{I}_{1-x}\text{Br}_x)_3]$, formamidinium/cesium $[(\text{FA},\text{Cs})\text{Pb}(\text{I}_{1-x}\text{Br}_x)_3]$, and formamidinium/methylammonium/cesium $[(\text{FA},\text{MA},\text{Cs})\text{Pb}(\text{I}_{1-x}\text{Br}_x)_3]$ iodide/bromide perovskites to photosegregate under illumination. Goals of the study are to establish their photosegregation propensity and, where possible, compare observations to a recently developed model for light-induced, mixed-halide photosegregation. The model currently explains numerous features of the phenomenon, including the existence of excitation intensity (I_{exc}) thresholds, I_{exc} -dependent photosegregation rates/rate constants, and temperature insensitive, as well as carrier diffusion length-dependent terminal halide stoichiometries.

8:00 PM EN05.07.15

Overcoming Evaluation Challenges of Perovskite Solar Cells with a Multi-Channel Maximum Power Point Tracking (MPPT) Integrated PV Power Analyzing System P.V.V. Jayaweera¹, S. Maeshima¹, Satoshi Uchida², Shoji Kaneko¹ and Hiroshi Segawa²; ¹SPD Laboratory, Inc., Japan; ²RCAST, The University of Tokyo, Japan

The rapid research and development of perovskite solar cell (PSC) for practical applications are driven by both global warming concerns and industrial demands. Due to the distinctive characteristics exhibited by PSC, such as hysteresis, establishing a universally standardized and rational evaluation process becomes challenging. In this study, we present an equipment system designed to address this challenge. Hysteresis in I-V measurements, caused by capacitance components in stacked PSC, can lead to overestimation or underestimation of the performance. PSC exhibiting hysteresis in the I-V curve manifests two distinct maximum power points in the forward and reverse I-V curves, which depend on the scan speed, starting point, and direction of the scan. By implementing Maximum Power Point Tracking (MPPT), the genuine maximum output power of PSC can be promptly determined. Our newly developed device enables simultaneous I-V tracing and MPPT for up to six solar cells, facilitating research and development. The system continuously plots the light intensity and temperature data alongside the maximum power point, allowing each sample to handle up to 10 V and 1 A capacity. With six independently programmable electronic loads integrated into the analyzer, the MPPT algorithm individually maintained each sample at its maximum power point, ensuring efficient power generation. This multi-channel MPPT-integrated PV power analysis system offers a comprehensive solution to the evaluation challenges faced in PSC research and development. It enables accurate and efficient assessment of PSC performance, contributing to the advancement of practical applications and standardization of evaluation methods.

High Performance Inorganic CsPbI_2Br Perovskite Solar Cells via Crystallization Management Soo Woong Jeon, Min Ju Jeong and Jun Hong Noh; Korea University, Korea (the Republic of)

Inorganic CsPbI_2Br perovskite has a substantial potential for triple-junction tandem solar cells as a top

subcell, however it exhibits relative instability in the air compared with organic-inorganic perovskites as well as significantly lower efficiency than the theoretical efficiency limit. To further enhance the air-stability and efficiency of CsPbI₂Br-based perovskite solar cells (PSCs), it is vitally crucial to improve the crystallinity and passivate the defects within films that accelerate the phase transformation to the photo-inactive phase in the air. Here, it is reported that crystallization management via incorporating sodium formate (NaFo) in a CsPbI₂Br perovskite solution effectively leads to enlarged grain size and the reduced trap density. The Na⁺ cation and HOOC⁻ anion produce a synergistic effect for engineering the defects by acting as cation and pseudo-halide anion passivators, respectively. As a result, the NaFo-incorporating device shows an improved power conversion efficiency (PCE) of over 17% and a fill factor (FF) of 84.5%. To the best of our knowledge, this progressive FF value is the highest value among CsPbI₂Br-based PSCs reported thus far. In addition, the NaFo-incorporated device shows improved air stability compared to the control device, retaining over 95% of its initial PCE for 1000 hours under 10% relative humidity at room temperature without any encapsulation.

8:00 PM EN05.07.18

Efficient and Stable Perovskite Quantum Dot Solar Cells via Incorporation of Multifunctional 3D Star-Shaped Organic Semiconductors Seyeong Lim, Dae Hwan Lee and Taiho Park; Pohang University of Science and Technology, Korea (the Republic of)

CsPbI₃ perovskite quantum dots (PQDs) exhibit superior optical and optoelectronic characteristics, such as tunable bandgap, high photoluminescence quantum yield, and high absorption coefficient. Owing to these advantages, the CsPbI₃ PQDs have been considered as promising and effective photovoltaic absorber. Since PQDs have been stabilized with long-chain ligands, the ligand exchange using short ligands is indispensable to enhance the electronic coupling within PQD solids and then realize high-efficiency solar cells. However, the inefficient ligand exchange can form trap states on the PQD's surface, leading to low device performance and stability. Herein, we demonstrate that a newly designed and synthesized three-dimensional (3D) star-shaped semiconductor (Star-TrCN) can be chemically bound with PQDs through theoretical modelling and experimental validation. The hybrid films of Star-TrCN and PQDs show reduced surface trap states and improved cubic-phase stability. As a result, the Star-PQD hybrid devices not only achieve improved device stability over 1000 h at 20–30% relative humidity, but also increase power conversion efficiency up to 16.0% by establishing a cascading energy band structure.

8:00 PM EN05.07.19

The Deposition of CH₃NH₃PbI₃ Thin Film using Close Space Sublimation for Large Scale Perovskite Solar Cells Youngmin Kim, Wonkyu Lee, Youngho Choe, Donghwan Kim, Yoonmook Kang and Hae-Seok Lee; Korea University, Korea (the Republic of)

Abstract

To achieve large-scale perovskite solar cells and to deposit on a textured silicon wafer to apply silicon-perovskite tandem solar cell, it is crucial to implement the fabrication process for pin-hole-free thin film with optimal crystalline morphology and full coverage. In this work, we used a close space sublimation deposition to grow a high quality CH₃NH₃PbI₃ thin film in a different temperature. Reducing the process temperature is highly advantageous in fabricating perovskite films since perovskite materials exhibit significant degradation and adverse effects on crystal structure when exposed to high temperature. Therefore, the process temperature was conducted at the minimum temperature at which the MAI powder was sublimated. And The thickness of PbI₂ precursor determines the thickness of perovskite film. The PbI₂ precursor was adjusted using the sputtering method, and we controlled the thickness of PbI₂ by the

sputtering time. The results indicate that high quality perovskite films with variable thickness can be obtained by the close space sublimation process demonstrated here. Although $\text{CH}_3\text{NH}_3\text{PbI}_3$ was selected for this study, this close space sublimation method demonstrated can be easily applied to other hybrid perovskites.

Defect Passivation for Highly Efficient Perovskite/Silicon Tandem Solar Cells So Jeong Park, Deok Ki Cho, Geonpyo Hong and Jin Young Kim; Seoul National University, Korea (the Republic of)

Halide perovskites are promising photovoltaic materials, the power conversion efficiency (PCE) of the single junction solar cell has been improved to 26.0%, which is approaching the Shockley-Queisser limit. Perovskite/silicon tandem solar cells are attractive candidates to overcome the theoretical limit efficiency. Controlling the perovskites with a bandgap of ~ 1.7 electron volts is indispensable to enhance the photovoltaic performance. In this study, we developed high-performing perovskite top cells with a thiocyanate (SCN^-) based additive and attained a PCE of 21.01% without hysteresis. The additive strategy led to improved crystallinity, enlarged grain size, and reduced defect density. Non-radiative recombination responsible for open-circuit voltage decreased from the enhancement of perovskite film quality. By regulating the window layer thickness consisting of fullerene and indium tin oxide, an efficient semi-transparent cell was produced to minimize the short-circuit current density reduction caused by optical loss. The efficiency over 28% of a monolithic two-terminal perovskite/silicon tandem solar cell was achieved.

High Reproducible Fabrication of Perovskite Solar Cells using an Automated Perovskite Film Coating System Naoto Eguchi, Kohei Yamamoto and Takuro N. Murakami; The National Institute of Advanced Industrial Science and Technology, Japan

Perovskite solar cells are expected to be the next generation of solar cells due to their favorable characteristics such as high conversion efficiency, light construction, and flexibility. However, there are considerable variations in perovskite solar cell's performances even though the solar cells are fabricated under the same conditions. Consequently, when evaluating new materials or new processes, it is necessary to fabricate many devices for comparing them with considering the large variations. This can be related to both cost increasing and time consuming for R&D.

One of the reasons for the variability in the performance of perovskite solar cells is the sensitivity of crystal growth in the perovskite layer to environmental factors such as temperature, humidity, and solvent evaporation rate. It is well known that these environmental factors influence the morphology of the film, making it important to control the atmosphere during deposition processes.¹⁻³ In addition, the widely used anti-solvent method for fabricating high-efficiency perovskite solar cells can cause significant changes in the film morphology and the solar cell performances based on the factors such as the drop volume, timing, and drop rate of the poor solvent. As a result, even when perovskite solar cells are fabricated under consistent conditions, their performances are still variable. In particular, the manual dropping of the poor solvent during the spin-coating of the perovskite precursor solution by human hands induces slight variations in the drop timing or drop speed, which leads to variations in the solar cell performances.

In this study, the low reproducibility, which is one of the challenges for perovskite solar cells, was improved by automating the dropping process of poor solvents and substrate transfer during the coating of perovskite layer. To remove human involvement in the perovskite layer coating process, an automated coating system was developed by integrating a robotic arm with a spin coater, an automatic solution drop system and a hot plate. This system enabled the transfer of glass substrates, the dropping of poor solvents during spin coating, and the heating of substrates on the hot plate. Using this automated coating system, we evaluated the performance variations of perovskite solar cells and compared them to those fabricated manually. The results showed that the perovskite solar cells fabricated using the automated coating system had reduced standard deviation of photoelectric conversion efficiency from 0.61 to 0.40 compared to those fabricated by hand. This system is expected to enable more objective evaluation of new materials and new processes, leading to reduced development time and costs.

Enhanced Perovskite Solar Cells Performance Through Surface Engineering Investigation of a Zn-Complex Based Hole-Transporting Materials Chaochin Su¹, Wen-ren Li², Yogesh Tingare¹ and Hsu Ya-Chun¹; ¹Taipei Tech, Taiwan; ²National Central University, Taiwan

Interface Engineering plays a critical role in the performance of perovskite solar cells (PSCs). High-quality perovskite films with suitable hole transport properties of the hole-transporting materials HTMs are critical factors in obtaining high-performing PSCs. Small inorganic molecule HTMs have attracted considerable interest in PSCs because of their structural flexibility, operational durability, and good hole mobilities, but they suffer unsatisfied cell efficiency. In this work, a ligand **BT28** and its zinc-based coordination complex **BTZ30** were designed and synthesized as hybrid organic-inorganic structured HTMs for PSCs applications. Both HTMs exhibit similar optical and electrochemical properties. The mixed-halide perovskites can be grown uniformly with large crystalline grains on top of both HTMs. However, it is discovered that the BTZ30-based solar cell exhibited a higher power conversion efficiency close to 20%. This can be due to the higher hole mobility of **BTZ30** than that of BT28. The high hole mobility of **BTZ30** is attributed to low trap-assisted recombination and efficient charge extraction efficiency, indicating a good perovskite/HTM interface. The PSC fabricated with the metal-containing HTM **BTZ30** shows the best power conversion efficiency (PCE) of 19.50%, which is higher than the PCE of 18.01% from the PSC fabricated with its ligand and non-metal HTM **BT28**.

Thermal and Electrical Properties of ZnO-PCBM Composite Layer for p-i-n Perovskite Solar Cells Seongtak Kim, Dong-woon Han and Chan Bin Mo; Korea Institute of Industrial Technology, Korea (the Republic of)

Expectations for commercialization of perovskite solar cells are increasing with the recent announcement of 25.8% efficiency. However, the stability of perovskite solar cells is still lower than that of silicon solar cells, which is an obstacle to commercialization. Solar cells driven in the field not only emit most of their energy as heat, but are also exposed to high temperatures of 80°C or more during operation, so thermal stability is very important. When the heat of the solar cell increases, not only the power conversion efficiency decreases, but also the stability of the perovskite(PVSK) materials becomes weak. In particular, since the p-i-n thin-film perovskite solar cells almost use an organic materials manufactured by a low-temperature process or a solution process, the thermal conductivity is very low. In general, phenyl-C61-butyric acid methyl ester(PCBM) is mainly used as electron transfer layer(ETL) of p-i-n structure, but its thermal conductivity is only 0.07W/mK preventing heat transfer inside the perovskite from escaping to the outside. In this study, the PCBM-ZnO composite layer was applied to improve the heat dissipation performance of the solar cell. The heat dissipation performance and electrical properties were investigated according to the amount of ZnO added between PCBM and perovskite layer. The addition of ZnO improved the thermal conductivity of ETL and improved the thermal stability of the PVSK layer. When the ZnO content was too high, ZnO was accumulated at the interface between PVSK and PCBM, reducing the solar cell efficiency. Therefore, it was confirmed that the ZnO content of 0.1 wt% was the optimal composition in this study. In conclusion, the improvement effect of the solar cell due to the application of the PCBM-ZnO composite layer was confirmed.

8:00 PM EN05.07.24

The Big Bang of Halide Perovskites: The Starting Point of Crystallisation Ana Palacios Saura^{1,2}, Joachim Breternitz³, Armin Hoell¹ and Susan Schorr^{1,2}; ¹Helmholtz-Zentrum Berlin für Materialien und Energie, Germany; ²Freie Universität Berlin, Germany; ³FH Münster, Germany

Halide perovskites (HPs) are extremely popular amongst the scientific community, not only for their astonishing increase in power conversion efficiency up to 26% [1], but also for using low-cost solution-based processing methods.

Some of the distinctive properties of HPs are the decrease in solubility with increasing temperature[2], and the bandgap tunability via anion and cation substitution[3]. With this study we aim to elucidate the role of the A-cation in the crystallisation process as well as how the precursors are arranged prior to crystallisation. For this reason, we investigated the precursor solution of different HPs (RbPbI₃, KPbI₃ and NaPbI₃) using small angle X-ray scattering (SAXS) as well as the precursor solution of MAPbI₃ at increasing temperature (from room temperature up to 120°C). The binary precursors (e.g. RbI and PbI₂ to synthesise RbPbI₃) were dissolved in common solvents to synthesise HPs such as γ -butyrolactone (GBL), dimethylformamide (DMF) and mixtures thereof.

SAXS is a non-destructive technique based on the scattering length difference between the scattering objects in a solution. Applying SAXS, the size and shape of nanoscale particles (scattering objects) can be investigated, as well as their adjacent distance and interactions with each other.[4,5] We performed SAXS experiments at BESSYII, at the PTB's four-crystal monochromator beamline[6] using the ASAXS endstation.[7]

The SAXS pattern of all the measured samples show a peak in the scattered intensity at q-values between 2.5 and 3.3 nm⁻¹. The presence of such peak is a clear indication of the existence of interacting scattering objects in solution. The position of the peak correlates with the distance between adjacent scattering objects (d_{exp}). In a previous study[8], we developed a core-shell model with [PbX₆] (X = I, Br) octahedra surrounded by randomly oriented solvent molecules to explain d_{exp} in HPs with a molecular A-cation (MA⁺, FA⁺), showing that the size of the agglomerates changes with the composition of HPs precursors

and with the solvent, but not with the A-cation. However, when alkali metals are used as A-cation, we can demonstrate that d_{exp} not only depends on the solvent but also on the A-cation. This is explained by the smaller ionic radius of alkali metals compared to the molecular cations [9,10] therefore the charge density is higher. For this reason, we extended the previous model to take this phenomenon into account. Based on this information, the extended core-shell model assumes that the A-cation and the solvent molecules compete to surround the $[PbI_6]$ octahedra. In this A-cation core-shell model, the core is composed of $[PbI_6]$ octahedra, which can be arranged as a single octahedron or a corner-sharing octahedra. The $[PbI_6]$ octahedra of adjacent scattering objects are surrounded by a solvent shell with randomly oriented molecules or by an A-cation shell. The SAXS data analysis (using SASfit[11]) shows higher polydispersity as the previous model, which indicates an increase in the heterogeneity of the solution, this is in agreement with the proposed extended model.

We will discuss the influences of the A-cation and solvent on the core as well as the solvent shell of the scattering objects since they have the potential to influence the crystallization process of the HP and therefore the performance of a device produced from solution processing.

Semi-Transparent Perovskite Solar Cells: Unveiling The Trade-Off Between Transparency and Efficiency Nageh K. Allam; American University in Cairo, Egypt

Semi-transparent perovskite solar cells (Pero-SCs) are realized by tuning the band gap of the perovskite to resolve the trade-off between the transparency and efficiency of the photo-absorber. We synthesized wide-bandgap $MAPbI_3-xBr_x$ perovskite, and the transparency and efficiency of the corresponding semi-transparent Pero-SCs were investigated systematically by varying the I : Br ratio and thickness of the perovskite film. Increasing Br content widened the bandgap of perovskite (i.e., blue shift of the absorption edge), and led to an increase in the average visible transmittance (AVT). This strategy allowed for high AVTs, and concomitantly achieved high power conversion efficiencies. Meanwhile, increasing the Br content could facilitate formation of perovskite films with large grains that were highly crystallized. Compared with the narrow-bandgap perovskite, the wide-bandgap perovskite showed advantages for obtaining semi-transparent Pero-SCs with thick perovskite films (>200 nm) and high (20%) transparency.

Crosslinkable Siloxane Induced Direct Patterning of Highly Stable Halide Perovskite Nanocrystals Sang Woo Bae¹, Jin Min Park¹, Junho Jang², Hyukmin Kwon¹, Byeong-Soo Bae², Do Hwan Kim¹ and Young Hoon Kim¹; ¹Hanyang University, Korea (the Republic of); ²Korea Advanced Institute of Science and Technology, Korea (the Republic of)

High resolution patterning of color conversion layers (CCLs) is essential for the demonstration of color converting light-emitting diodes (LEDs). Conventional color converting materials such as organic phosphor and inorganic quantum dot (QD) so far suffer from low color purity and high materials cost. Metal halide perovskite nanocrystals (PNCs) have been regarded as a promising color converting material in CCLs due to their high absorption coefficient, spectrally narrow light, easy color tuning, low materials cost, and high photoluminescence quantum efficiency (PLQE). However, the instability of PNCs in thermal treatment and in polar solvents limits its high resolution patterning through consequent photolithography process and its long-term stability in various condition. To enable low-cost direct patterning without using a high polarity photoresist and improve the stability of patterned PNCs, we here introduce the direct optical patterning of crosslinkable siloxane resin/PNC composite. Multicolored patterning of PNCs in micrometers was demonstrated by siloxane resin pinning (SRP) process which mitigate the high viscosity and concomitant shrinkage problem in the siloxane/PNC composites. The patterned PNCs showed stable photoluminescence quantum efficiency (PLQE) in harsh liquid environments (e.g., in water, acid, or base solutions, and in various polar solvents), which provide the breakthrough into high density PNC-based micro-LED.

8:00 PM EN05.07.28

Tailoring the Molecular Structure of Dopant-Free Polymeric Hole Transport Materials for Improved Charge Extraction in Perovskite Quantum Dot Solar Cells Dae Hwan Lee, Seyeong Lim and Taiho Park; Pohang University of Science and Technology, Korea (the Republic of)

We have developed three dopant-free hole transport materials (HTMs) as an alternative to the commonly used doped Spiro-OMeTAD in perovskite quantum dot solar cells (PQD-SCs). The dominant HTM, Spiro-OMeTAD, requires the use of doping systems to enhance charge mobility. However, these dopants can lead to the degradation of PQD-SCs, making the development of efficient dopant-free HTMs crucial for commercialization. In our study, we designed three types of dopant-free HTMs: Asy-PDTS, Asy-PSDTS, and Asy-PSeDTS. To improve their electrical properties, we incorporated a chalcogenide-based fluorinated benzothiadiazole rigid segment acceptor unit. This rigid segment acted as an effective charge hopping channel, compensating for the impaired electrical properties through side chain engineering. Through a conformation-locking approach utilizing chalcogenide-fluorine noncovalent interactions, we achieved favorable planar structures with face-to-face stacking of the rigid segments. Among the optimized devices, the one utilizing Asy-PSeDTS exhibited remarkable performance. It achieved a power conversion efficiency (PCE) of 15.2%, the highest reported PCE among dopant-free HTM-based PQD-SCs. Additionally, this device maintained 80% of its initial PCE even after 40 days, demonstrating superior stability compared to other dopant-free HTM-based PQD-SCs.

8:00 PM EN05.07.30

Anion-Dependent Piezoelectric Power Generation in Lattice-Strained Hybrid Halide MAPbX₃ (X = I, Br, and Cl) Thin Films Da Bin Kim^{1,2}, Kyeong Su Jo¹, Kwan Sik Park¹, Ju Han¹ and Yong Soo Cho¹; ¹Yonsei University, Korea (the Republic of); ²University of Toronto, Canada

The compositional dependence of piezoelectricity in halide perovskite materials has rarely been reported based on experimental results. To the best of our knowledge, for the first time, we demonstrate experimental evidence of the dependence of piezoelectricity and electromechanical energy harvesting performance on the anions in a hybrid halide thin-film system of MAPbX₃ (X = I, Br, and Cl). As expected from their crystal structures, i.e., tetragonal MAPbI₃, cubic MAPbBr₃, and cubic MAPbCl₃, the highest piezoelectricity was observed in MAPbI₃, which electromechanically harvested the largest amount

of energy owing to its ferroelectricity possessing permanent dipoles based on PbI_6 octahedra. Interestingly, cubic MAPbBr_3 and MAPbCl_3 also delivered considerable piezoelectric energy harvesting performance, unlike other cubic oxide-based perovskites, as they are associated with organic MA^+ ions in soft phonon modes, which can induce lattice distortion under a mechanical stimulus. The origin of the piezoelectricity even with the cubic halides is discussed as being related to the tolerance factor and bond strength, with experimental support for the estimated effective piezoelectric coefficient and grain boundary potential. Such experimental results on piezoelectricity and energy harvesting for MAPbBr_3 and MAPbCl_3 have not been reported thus far. In addition to exploring the anion-dependent piezoelectricity in flexible MAPbX_3 halide thin films, we attempted to enhance their electromechanical power-generating capability by incorporating vertical tensile lattice strain (for extra lattice extension between electrodes) and by applying an optimal poling field (for vertical domain orientation). Introducing out-of-plane tensile strain and poling effectively improved the harvesting performance of all three halide thin films, with their performance increasing in the order $\text{MAPbCl}_3 < \text{MAPbBr}_3 < \text{MAPbI}_3$, as anticipated from their piezoelectricity. Notably, the output voltage and current demonstrated herein of 23.1 V and 1,703 nA for the ~486 nm-thick MAPbI_3 thin film are the highest values reported for any thin-film-based perovskite halide harvesters to date.

8:00 PM EN05.07.31

Fabrication of Electrospun Nanofiber Yarns Decorated with Organic-Inorganic Double Halide Perovskite for Wearable Piezoelectric Applications Seongcheol Ahn, Yujang Cho and Il-Doo Kim; Korea Advanced Institute of Science and Technology, Korea (the Republic of)

Research efforts are actively focused on capturing energy from renewable sources due to concerns about environmental pollution and resource shortages. Among the various methods, the piezoelectric nanogenerator (PENG) stands out as it harvests energy from the deformation of a crystalline material using the piezoelectric effect. This technique shows promise in converting mechanical energy into electrical energy in an eco-friendly manner. The piezoelectric organic-inorganic hybrid nanocomposite is able to utilize the advantages of high piezoelectricity of piezoelectric ceramics, dielectric properties, and flexibility of polymers. The organic-inorganic hybrid piezoelectric material-based PENG is fabricated by the composite of halide double perovskite (HDP) and PVDF piezoelectric materials. After mixing the HDP in the polymer matrix, an organic-inorganic hybrid nanocomposite yarn was fabricated with enhanced efficiency characteristics of HDP while maintaining the flexibility and processability of the polymer. Also, the nanofiber (NF) yarn platform, composed of ultrahigh-density polymeric NFs electrospun by two spinnerets with opposite applied bias, has attained great attention as a suitable flexible substrate featuring a large specific surface area and high porosity. The 1D-type PENG using organic-inorganic nanocomposite is flexible and can be applied to wearable devices, electronic devices, etc.

8:00 PM EN05.07.32

Thermal Co-Evaporation of Lower-Dimensional Metal Halide Perovskites Kunal Datta and Juan-Pablo Correa-Baena; Georgia Institute of Technology, United States

Lower-dimensional perovskite structures have advanced the field of perovskite-based optoelectronics through their bandgap tunability, high defect tolerance and low ion mobilities, either used as active layers or at charge-transport interfaces. However, solution-based processing of such materials typically yields poor structural selectivity due to the interactions between precursor ions and the solvent. This results in the formation of phase gradients across the thickness of thin films that develop bandgap and energetic barriers, thereby impeding charge-carrier transport and optoelectronic performance.

This work describes thermal co-evaporation methods for the deposition of high quality lower-dimensional Ruddlesden-Popper perovskites as a route to develop structurally homogeneous thin films for optoelectronic devices such as photovoltaics, light emission and light detection. The dimensionality (n -value) of the structures, and thereby the optical bandgap, is controlled accurately through precursor deposition rates. The work assesses the role of deposition conditions, substrate functionalization and post-deposition treatment in determining crystallographic structure and phase purity. As a result, in addition to being commercially scalable, conformal and demonstrating precise thickness control, the elimination of the precursor-solvent interaction in thermal co-evaporation depositions ensures an accurate and consistent precursor stoichiometry leading to phase homogenization and improved charge-carrier transport.

8:00 PM EN05.07.34

Mixed Ruddlesden-Popper and Dion-Jacobson Phase Perovskites for Stable and Efficient Blue Perovskite LEDs Pui Kei Ko; The Hong Kong University of Science and Technology, Hong Kong

Producing efficient blue and deep blue perovskite LEDs (PeLEDs) still represents a significant challenge in optoelectronics. Blue PeLEDs still have problems relating to color, luminance, and structural and electrical stability so new materials are needed to achieve better performance. Recent reports suggest using low n states ($n = 1, 2, 3$) to achieve blue electroluminescence in quasi-2D Ruddlesden-Popper (RP) perovskite films. However, there are fewer reports on the other quasi-2D structure, Dion-Jacobson (DJ) perovskites, despite their highly desirable optical properties, due to the difficulty in achieving charge injection. To resolve this issue, here we have mixed DJ phase precursors, propane-1,3-diammonium (PDA) bromide into RP phase perovskites and fabricated low-dimensional PeLEDs. It was found that these specific precursors aid in suppressing both the low n ($n = 1$) and high n ($n \geq 4$) quasi-2D RP phases and is an effective strategy in blue-shifting sky-blue RP perovskites into the sub-470 nm region. With optimization of the PDA concentration and device layers, we achieved an EQE of 1.5% at 469 nm and stable electroluminescence (EL) for the first deep blue PeLED to be reported using DJ perovskites.

8:00 PM EN05.07.35

Highly Stable Tin Iodide Perovskites Synthesized in Ambient Aqueous Phase using Alkali Iodides and Ascorbic Acid Koji Yokoyama, Shun Yokoyama and Hideyuki Takahashi; Tohoku University, Japan

Tin iodide perovskites (ASnI_3) are emerging as photoactive layers in photovoltaics due to their excellent optical and electronic properties. However, their preparation typically requires an inert environment and anhydrous organic solvents due to their vulnerability to oxygen and moisture. These conditions have resulted in complex and environmentally unfriendly processes. Previous studies have reported the aqueous-phase synthesis of ASnI_3 using hydroiodic acid (HI) as a solubilizer and hypophosphorous acid (H_3PO_2) as a reductant. Nevertheless, HI is highly unstable and cannot be used in ambient air, and both HI and H_3PO_2 are hazardous chemicals. Consequently, there is a high demand for more stable solubilizers and safer reductants to enable a facile and green synthesis of ASnI_3 in an ambient aqueous phase. In this study, we present the ambient aqueous-phase synthesis of ASnI_3 perovskites using alkali iodides and ascorbic acid (AA).

Aqueous solutions containing 6.0 mol L⁻¹ of HI, lithium iodide (LiI), or sodium iodide (NaI) as solubilizers and 1.0 mol L⁻¹ of H_3PO_2 or AA as reductants were prepared. Subsequently, 0.5 mol L⁻¹ of tin iodide was dissolved in these solutions to prepare tin precursor aqueous solutions. The valence states and complex structures of tin species in these precursor aqueous solutions were characterized via electrospray

ionization time-of-flight mass spectrometry (ESI-TOFMS). 0.5 mol L⁻¹ of organic cation iodides was added to the precursor aqueous solutions, and the resulting precipitated samples were collected by suction filtration. Structural, compositional, and optical characterizations were carried out for the samples immediately after synthesis and after exposure to ambient air using X-ray diffractometry (XRD), X-ray photoelectron spectroscopy (XPS), and optical absorption/photoluminescence measurements.

The tin precursor aqueous solutions containing HI turned muddy and degraded rapidly, even though they contained reductants, whereas those containing LiI or NaI remained completely transparent and stable even in ambient air. Tin species formed complexes with the reductant molecules in the solutions containing reductants. ESI-TOFMS analysis revealed that the reducing and chelating abilities of AA efficiently stabilized the Sn²⁺ valence states. The resulting samples were determined to be pure-phase ASnI₃ perovskites. Interestingly, XRD, XPS, and optical measurements clearly indicated that ASnI₃ perovskites synthesized using NaI and AA exhibited excellent stability after exposure to ambient air. Detailed analyses suggested that Na⁺ ions and a trace amount of AA molecules present on the sample surface passivate the surface defects and stabilize the ASnI₃ phases.

In conclusion, we successfully prepared highly stable tin precursor aqueous solutions even in ambient air, using stable alkali iodides and safe AA. Highly stable ASnI₃ perovskites were synthesized from the solutions containing NaI and AA. These findings pave the way for the green fabrication of highly efficient and long-life perovskite photovoltaics.

8:00 PM EN05.07.36

Highly Efficient and Stable Perovskite Photocathode for Hydrogen Generation in Acidic and Basic Conditions Saikiran S. Khamgaonkar and Vivek Maheshwari; University of Waterloo, Canada

In the pursuit of sustainable energy solutions, the direct conversion of solar energy into fuels, such as hydrogen, through photoelectrochemical systems (PEC), holds immense promise. Organo lead halide perovskites with their excellent optoelectronic properties and their reported record photovoltaic efficiencies are therefore being researched for integration in PEC. Particularly, their integration as photocathodes for the hydrogen evolution reaction (HER) is gaining attraction due to their impressive HER photocurrent density ($\sim -20 \text{ mA.cm}^{-2}$) and high onset potential ($\sim 1 \text{ V}$). However similar to photovoltaics, the limited stability of perovskites in PEC devices is a critical challenge. This is further amplified due to immersion in an aqueous medium which is required for the operation of the PEC devices for HER. Previous research work have primarily focused on enhancing the extrinsic stability of the perovskite layer through the implementation of moisture-resistant encapsulant layers like Ni, Field metal, conductive carbon paste, metal oxide, or Ti foil. However, little attention has been paid to addressing both the extrinsic and intrinsic stability of the perovskite film, which is crucial for prolonged device operation. Intrinsic stability, crucially linked to ion migration effects leading to perovskite degradation, complements extrinsic stability, which is governed by the degradation of the perovskite structure due to decomposition with water (in the case of PEC). Moreover, selecting a catalyst capable of exhibiting exceptional stability and performance in extreme pH conditions poses a further challenge. While the kinetics of HER are facile in acidic conditions, alkaline environments present a hurdle due to the sluggish water dissociation step. Therefore, there is need for a single catalyst that can exhibit excellent HER performance and stability in extreme pH conditions In this work, we have fabricated a highly efficient and stable perovskite-based photocathode which displays excellent HER performance with enhanced stability. To enhance both performance and internal stability, a polymer additive has been introduced into the perovskite thin film. The use of the polymer greatly improves the solar cell efficiency, the polymer-perovskite cells have an efficiency of $\sim 15.3 \%$, while the pristine perovskite cells show an efficiency of $\sim 12 \%$. Additionally, we have synthesized a bimetallic catalyst comprising Au, Pt, and Ni, characterized by

low overpotential and Tafel slope values for HER in highly acidic and basic conditions. The polymer-conjugated photocathode with the bimetallic catalyst layer exhibits excellent HER performance both in acid and basic electrolyte and shows high photocurrent density ($\sim 20 \text{ mA.cm}^{-2}$), high onset potential ($\sim 0.95 \text{ V}$), and a half-cell solar to hydrogen conversion efficiency (HC-STH) of 10.11 %. More impressively, the photocathode exhibits an unprecedented stability, with T_{80} (time for 80% degradation) values of approximately 70 hrs. (H_2SO_4) and 78 hrs. (KOH), retaining over 50 % of its initial photocurrent after 120 hrs. of operation. These stability values are the highest reported among various perovskite-based photocathodes.

SESSION EN05.09: Halide Perovskites for Energy Applications

Functionalized MXenes for Stable Halide Perovskite Solar Cells Monica Lira-Cantu; Nanostructured Materials for Photovoltaic Energy, Spain

Perovskite solar cells (PSCs) with an accredited power conversion efficiency (PCE) above 25% demonstrate a great potential towards commercialization. Currently, PSCs are largely susceptible to poor stability and durability issues which restricts their utility in practical applications. Shallow and deep defects in perovskites are a major contribution to the stability loss and this loss can be minimized by passivating the defects through surface functionalization. Materials functionalization and modification has been employed as an strategy to improve the stability of PSCs by controlling the surface properties by bringing novel chemical, electronic and optical properties. Two-dimensional (2D) materials are excellent candidates for potential applications including photovoltaics owing to their high conductivity, hydrophilicity, flexibility, and surface modifications. In this work, we apply the 2D Ti_3C_2 MXene in a normal PSC configuration of the type: FTO / c- TiO_2 / m- TiO_2 / halide perovskite (HP) / MXene / Spiro-OMeTAD / Au. We used the quadruple halide perovskite (HP) $\text{Rb}_{0.05}\text{Cs}_{0.05}\text{MA}_{0.15}\text{FA}_{0.75}\text{Pb}_{1.75}(\text{I}_{0.95}\text{Br}_{0.05})_3$ as the absorber, and the MXene ($\text{Ti}_3\text{C}_2\text{-T}_x$) at the interface of HP and the hole transport layer (HTL) to fabricate HP/MXene heterojunctions. We employed the organic ligand 3-Phosphonopropionic acid (H_3pp) to functionalize the bulk of the MXene and the bulk of the HP. The functionalization of only the MXene transport layer resulted in PSC with 19.89 % efficiency, the functionalization of both, the MXene and the Halide Perovskite layers, resulted in champion PSCs with 21.95% PCE. Both indoor stability studies under ISOS-L protocol (continuous MPP tracking under N_2 atmosphere for 1000 h) and outdoor stability analyses under the ISOS-O protocol (MPP tracking, encapsulated devices) demonstrated the superior stability of PSCs when the 2D MXene interface is employed, especially under high humidity (60-85%) conditions where the PSCs showed excellent recovery after a low light irradiation and rainy day. The best results were observed for the PSC with the functionalization of both the MXene layer and the HP absorber layer. The ISOS-L protocol study revealed almost 100% retaining of the PSC device. Outdoor testing under ISOS-O protocol for > 600 h holding devices at open circuit voltage revealed a T_{80} of 600 h, while the control devices showed T_{80} at about 250 h. Thermal admittance spectroscopy (TAS) revealed that the functionalization of the halide perovskite results in shallow defect passivation, when the functionalization takes place at the MXene interface, TAS analyses revealed the reduction of both deep

and shallow trap state densities. This report provides pioneering study of additive engineering for adaptable bulk passivation and interface passivation through MXene nanosheets.

Diamine-Templated Crystal Growth of Perovskite Films for Record p-i-n Perovskite Solar Cells

Hao Chen^{1,2}, Junke Wang¹, Bin Chen² and Edward Sargent^{1,2}; ¹University of Toronto, Canada;

²Northwestern University, United States

Energy loss of perovskite/ETL interface is the limiting factor for pin perovskite solar cells, various methods are explored to address this issue, for example, post-treatment with organic salts are normally used to get more n-type surface, so as to gain good energy alignment between perovskite and ETL. Here, by using a diamine molecule in the bottom surface to template the crystal growth of perovskite film, we get highly oriented perovskite films with more n-type characters, after combining with the 2D passivation, the energy loss was reduced effectively, based on this, we get above 26% PCE for pin perovskite solar cells in the lab, and 25.75% PCE from fast scan and 24.9 % QSS PCE (Certified in Nrel), which are the record efficiencies for pin PSCs, and 1 cm² devices also shows 23.8 % PCE, except for the record PCE, the devices also show great operational stability, after 1000 illumination, the device shows no degradation.

Current Understanding of Phase Transformations in Lead Halide Perovskites Juan-Pablo Correa-Baena; Georgia Institute of Technology, United States

Halide perovskites have shown great promise for applications that span from solar cells to lasers and radiation detectors. However, these materials suffer from rapid phase transformations upon exposure to external stimuli. Therefore, it is essential to unravel the mechanisms that lead to these phase transformations in order to design materials that can withstand different environmental conditions. Thus far, there is little understanding of how chemistries influence phase transformations in lead halide perovskite when these are exposed to external stimuli. In this presentation, I will discuss the role of chemistry on phase transformations of lead halide perovskites through in-situ synchrotron-based techniques. The importance of these phase transformations on the optoelectronic properties of the halide perovskite materials will also be discussed.

From PL-Inactive to PL-Active: Synthesis and Properties of Novel PL-Active 2D Lead-Free Double Perovskites Chunyang Chi and Andrew B. Wong; National University of Singapore, Singapore

In this work, novel two-dimensional lead-free double perovskites ((R)₄M_aM_bM_cX₈, a+b+c=2) were synthesized to achieve novel compositional and dimensional tunability. Herein, PL-inactive (PA)₄AgInBr₈ was alloyed with Mn²⁺ with the goal of forming PL active materials.

Bandgap and PL emission tunability were explored through halogen substitution (chlorine and iodine). An enhanced PL emission was observed for mixed halogen phases. Three emission pathways are investigated including band edge emission, emission stemming from self-trapped excitons, and the unique energy transfer process of alloyed Mn²⁺ ions, which will be discussed.

4:00 PM EN05.09.06

Quantification of Strain and Its Impact on the Phase Stabilization of All-Inorganic Cesium Lead Iodide Perovskite

Han K. Le¹, Chung-Kuan Lin¹, Jianbo Jin¹, Ye Zhang¹, Zhenni Lin¹, Arturas Vaillionis^{2,3}, Nobumichi Tamura⁴ and Peidong Yang¹; ¹University of California, Berkeley, United States; ²Stanford University, United States; ³Kaunas University of Technology, Lithuania; ⁴Advanced Light Source, United States

Halide perovskites have emerged as a compelling class of materials and garnered significant interest for its impressive performance in photovoltaic technologies, with power conversion efficiencies (PCEs) of perovskite solar cells (PSCs) increasing from 3.8% to a certified 25.2% and rivaling commercial silicon solar cells in recent years. A type of all-inorganic perovskite, cesium lead iodide (CsPbI₃) draws special attention owing to its suitable bandgap for photovoltaics (~1.73 eV) and its superior thermal tolerance as compared to the organic-inorganic hybrid counterparts. Despite these advantages, a main obstacle to realizing the commercial applications of these materials lies in the long-term phase instability and interconversion between different CsPbI₃ polymorphs. The high-temperature (high-T) perovskite γ -phase of CsPbI₃ readily undergoes phase transition at ambient conditions to a low-temperature (low-T) non-perovskite δ -phase with a poorer optoelectronic performance, thus hindering commercialization of these materials in photovoltaics. Here, we present the epitaxial growth of CsPbI₃ nanoplates on muscovite mica single crystal substrates, and demonstrate that the high-T phase stability of these nanoplates is enhanced by a strained interface. Strain is measured as a function of nanoplate thickness on a single particle level through spatially resolved structural and optical characterizations, and found to increase with decreasing thickness. From quantitatively tracking the CsPbI₃ phase transition for thin (<400 nm) and thick (>400 nm) nanoplates using *in situ* photoluminescence optical microscopy, we observe a larger fraction of thin nanoplates still maintaining their high-T phase after one month as compared to the thick counterparts. The enhanced phase stabilization of the strained high-T nanoplates is most likely owing to the strain-induced energy destabilization for the low-T phase relative to the high-T phase. The strain is suggested to originate from several factors, including lattice mismatch, thermal expansion coefficient mismatch, and ionic and van der Waals forces that contribute to the strong substrate-lattice interaction. These findings establish a fundamental understanding of the impact of lattice strain on perovskite phase stabilization, thereby driving advancements in the rational design of long-term, stable optoelectronic devices.

Unraveling The Magnetic Interactions in Halide Double Perovskites: A High-Throughput Study

Utkarsh Singh¹, Johan Klarbring¹, Igor A. Abrikosov¹ and Sergey I. Simak^{1,2}; ¹Linköping University, Sweden; ²Uppsala University, Sweden

In recent years, lead-free halide double perovskites (LFHDPs) have attracted attention for their significant chemical versatility [1] and potential as multifunctional materials [2]. The exploration of their magnetic properties however, has remained relatively uncharted [3, 4]. Our study elucidates the mechanism of magnetic exchange interactions in halide double perovskites (HDPs), revealing a general propensity towards antiferromagnetic ordering with low Néel temperatures (< 50 K), while highlighting exceptions that are predicted to exhibit ferromagnetic behaviour and relatively high Curie temperatures.

Employing a high-throughput approach, we identified ferromagnetic compounds in Cs₂HgCrCl₆ (~ 450 K), Cs₂AgNiCl₆ (~ 190 K), and Cs₂AuNiCl₆ (~ 240 K) as noteworthy candidates, with the latter two exhibiting potential for robust half-metallicity due to a large gap in the insulating channel.

To comprehend the observed magnetic properties in HDPs, we leverage the Magnetic force theorem [5] and calculate energy-resolved and orbital-resolved magnetic exchange interactions. Contextualizing these resolved magnetic interactions within the nature and strength of bonding interactions using Density of States (DOS) and Crystal Orbital Hamilton Population (COHP) [6] analysis, the reasons for observed disparities in magnetic strength are unveiled. The comparison of these findings with well known oxide double-perovskites exhibiting high Curie temperatures [7, 8] enriches our understanding of magnetism in HDPs, and underscores the intricate mechanisms at play.

This nuanced understanding enables a more informed approach towards the design of HDPs with tailored magnetic properties. By providing insights into the magnetic behaviors of HDPs that aim to guide potential design strategies, this research could represent a step towards a deeper understanding of HDPs and encourage further exploration in this dynamic field.

What is in Your Perovskite Precursors? Improving Reproducibility and Stability of Perovskite

Films via Purification of Precursors Connor Dolan, Sean P. Dunfield, Emma Yakel, Shiwei Liu, Jack R. Palmer and David P. Fenning; University of California, San Diego, United States

While much effort has been given to reducing or passivating intrinsic defects both in the bulk and at interfaces of perovskite devices, relatively few efforts have been made toward understanding and mitigating the presence of extrinsic impurities. Despite this, even small concentrations of extrinsic impurities have been shown to play a role in altering film formation and seeding the nucleation of macroscale degradation under operational stressors. Further, minute changes in precursor stoichiometry and impurity profiles even in different bottles of precursor from the same supplier have been shown to be a significant barrier to reproducibility in perovskite solar cell fabrication.

In this work, we demonstrate Solvent Orthogonality Nucleation Induced Crystallization (SONIC) purification for removing extrinsic defects present in commercially available precursors commonly used to fabricate high efficiency perovskite solar cells. SONIC purification uses the slow diffusion of an antisolvent into a perovskite precursor solution to induce supersaturation, enabling controllable growth of high quality perovskite single crystals. Using a combination of inductively coupled plasma mass spectrometry and proton nuclear magnetic resonance, we demonstrate that there are significant impurities present in even the highest purity commercially available precursors and that SONIC purification is more effective at removing impurities than strategies commonly employed in the literature. We demonstrate that SONIC purification is effective for both high purity (99.99% trace metals basis) and low purity (99% trace metals basis) from different suppliers. This enables increased reliability in processing of perovskite precursors toward consistent impurity profiles to mitigate batch-to-batch and supplier-to-supplier variability. Finally, we show that perovskite thin films made from purified precursors demonstrate improved performance and stability over films made from as-received precursors. SONIC purification provides a method for removing extrinsic defects present in commercially available precursors, enabling improved stability and reproducibility in perovskite fabrication.

Interstitial Defect Relaxation DFT Study of Lead Halide Perovskites Kumar P. Miskin and Paulette Clancy; Johns Hopkins University, United States

Perovskite solar cells have garnered a lot of attention in the last decade. The efficiency obtained for solar cells using metal halide perovskites (MHP) have exceeded 22%. A major reason for this is the high carrier lifetimes in these materials [1]. These high efficiencies have been obtained despite relatively high defect densities as compared to those in Silicon solar cells, giving rise to an appreciation of high defect-tolerance in MHPs. Polycrystalline films made using metal halide perovskites can exhibit high defect densities of ($10^{15} - 10^{16}$ per cm^{-3}), with minimal effect on efficiency. However, the origin of this tolerance is still a matter of active research. Halide defects (vacancies and interstitials) are some of the most common defects in perovskites. This is due to low defect formation energy in these systems. DFT studies exist to quantify the formation energies of halide defects [2]. Our work will study the relaxation of these

interstitials back to their lattice site using DFT (Quantum Espresso). The recombination pathway as well as the activation energy for this relaxation will help us better understand how these defects affect the recombination time for photogenerated carriers. The pathway to relaxation can be estimated using Nudged Elastic Band calculations (NEB).

Water-Assisted Morphology and Crystal Engineering of Hybrid Organic-Inorganic Halide Perovskite: Implications for Optoelectronic Properties Andre Luiz M. Freitas and Jose A. Souza; UFABC, Brazil

The versatile application of hybrid organic-inorganic halide perovskites relies heavily on their crystal organization, which gives rise to distinct electronic structures. By manipulating the dimensionality and incorporating quantum confinement effects within the layered building blocks composed of n layers of $[\text{MX}_6]^{4-}$ octahedra, the optoelectronic properties of lead halide perovskites can be further modulated. In this study, we present a water-assisted approach for the formation of microwires and 2D layered morphologies, achieved through a dissociation-recrystallization process using MAPbBr_3 microcubes. Along with a systematic alteration of the bandgap energy, our investigation uncovers variations in trap- and exciton-assisted recombination lifetimes, attributed to changes in exciton binding energy and structural confinement. Notably, the control of water and organic molecules within the precursor ionic solution plays a pivotal role, inducing or inhibiting growth and confining charge transport in specific directions, resulting in modified optical properties and exciton dynamics. This work sheds light on the significance of water-assisted methodologies and structural manipulation in hybrid organic-inorganic halide perovskites, providing a pathway towards advanced control and optimization of their optoelectronic characteristics.

Self-Leveling Inks for Engineering Large Area Uniformity in High-Performance Flexography-Printed Perovskite Solar Cells Julia Huddy and William J. Scheideler; Dartmouth College, United

States

Solution processing of metal halide perovskites can offer opportunities for efficient roll-based manufacturing of emerging flexible optoelectronic devices such as lightweight photovoltaics and light emitting diodes (LEDs). However, current techniques for perovskite deposition are limited by damaging subtractive scribing steps and lack wide processing windows that offer high uniformity. This work presents a class of self-leveling perovskite inks with specifically engineered viscosity, Marangoni coefficients, and drying rates to ensure ultra-uniformity. We show rapid open-air fabrication of double cation perovskite solar cells (PSCs) using high-speed (60 m/min) flexography, printing films over 500 cm² in < 1s with high photoluminescent uniformity (RMS variation < 4 %). Integrating inline N₂ drying, we achieve highly uniform patterns with < 25 μm features and single-micron line edge roughness, ideal for solar module and perovskite LED integration. XRD and SEM reveal the impact of the ink design and anion composition on perovskite crystallization while 2D scanning photoluminescence (PL) resolves a correlation between ink leveling dynamics and optoelectronic quality. This allows us to optimize the self-leveling inks for mitigating Saffman-Taylor instabilities inherent in contact-based ink transfer, leading to enhanced uniformity, higher photovoltaic performance, and improved operational stability. Our flexography printed n-i-p planar PSCs achieve a photovoltaic conversion efficiency > 20 %, the highest reported for PSCs fabricated by roll-based methods. Collectively, these results illustrate how self-leveling inks can broaden process windows for perovskite device manufacturing by healing coating defects rather than freezing non-uniformities that otherwise lead to stability weakpoints.

8:00 PM EN05.10.06

Towards Highly Efficient Fully Evaporated Perovskite/Si Tandem Solar Cells [Sofia Chozas Barrientos](#)^{1,2}, Lidon Gil-Escrig^{1,2}, Federico Ventosinos^{1,2}, Manuel Piot^{1,2} and Henk J. Bolink^{1,2}; ¹Instituto de Ciencia Molecular (ICMol), Spain; ²Universitat de València, Spain

Thanks to its abundance on Earth, its suitable bandgap, and its non-toxicity, silicon dominates over 90% of the photovoltaic market. However, the efficiency of single-junction silicon cells is approaching its theoretical limit of 29%, with a current experimental record of 26.8%. In the quest for overcoming this limit and for reducing the cost of electricity, perovskite/silicon tandem cells have become the most promising contenders.

Pyramid texturing is a standard process in the fabrication of the best performing silicon technologies since it is known to enhance light trapping in the infrared and to reduce primary reflection due to double-bounce effects. However, most of the perovskite-on-Si work has been reported on flattened silicon substrates due to the incompatibility of the textured surfaces with the standard solution-processing of the top perovskite absorbers.

Here, we present the conformal vacuum deposition of wide bandgap perovskites atop fully textured silicon heterojunction cells. We have optimized vacuum deposition processes for different wide bandgap perovskite compositions, mainly FACsPbIBr and MAPbIBr. Their bandgaps range between 1.65 and 1.70 eV, making them ideal candidates as top cells in perovskite/Si tandems. As evidenced from cross-sectional SEM images, our co-evaporation processes enable a conformal coverage of the pyramidal surface of the silicon substrates avoiding shorts between the subcells. This leads to Voc values of above 1.8 V, which correspond well to the sum of the Voc of the perovskite top cell and the silicon bottom cell. Moreover, the use of QCM sensors for monitoring the sublimation of the top cell enables fine tuning of the absorber thickness. This allows to achieve current matching between the subcells as we have been

able to demonstrate through EQE measurements. The J-V curves show FFs above 70% and no detectable hysteresis. All in all, we will show our latest results on perovskite/Si tandems employing textured Si and fully sublimed top cells.

8:00 PM EN05.10.07

The Outstanding Role of Dielectricity in Hybrid Solar Cell Absorbers Doru C. Lupascu, Young U. Jin, Andrei Karabanov, Lars L. Schaberg and Niels Benson; University of Duisburg-Essen, Germany

The perovskite crystal structure has been hosting a multitude of functionalities discovered over the last seventy years spanning from magnetism, ferroelectricity to supraconductivity. The most recent developments have brought forward hybrid halide perovskites containing a halide ion and small organic molecules as constituents of the crystal structure. The forerunner material is methylammonium lead iodide. One of the most remarkable properties of these emergent materials is their high charge carrier mobility and an outstanding robustness of the electronic properties towards lattice defects. In this presentation the role of dielectric effects will be discussed covering a very broad frequency range. Paraelectric effects will be contrasted to the role of apparent ferroelectricity, charge disorder and the potential misinterpretation of a number of experiments in this context. The hyperpolaron is shown as the charge carrier type peculiar for the hybrid perovskites.

8:00 PM EN05.10.09

Controlling The Crystallization of Pure Bromide Quasi-2-Dimensional Perovskite Crystals for High Efficiency Pure-Blue Light-Emitting Diodes Seoyeon Park¹, Joonyun Kim², Gui M. Kim¹, Doh C. Lee¹, Soohyeong Lee³, Byeong-Gwan Cho³ and Byungha Shin¹; ¹Korea Advanced Institute of Science and Technology, Korea (the Republic of); ²Samsung Advanced Institute of Technology, Korea (the Republic of); ³Korea Research Institute of Standards and Science, Korea (the Republic of)

Metal halide perovskites have emerged as promising candidates for next-generation display applications due to their remarkable color purity and tunable bandgaps by adjusting the composition of halide anions. Mixed halide perovskites allow for facile bandgap tunability through composition control, but they have limitations in terms of emission spectral stability due to halide segregation occurring during device operation. An alternative approach to widen the bandgap involves constructing a quasi-2-dimensional structure using a single halide anion, leveraging the confinement effect. However, this approach often results in multi-bandgap phases, leading to a red-shifted emission due to energy funneling toward a phase with a bandgap lower than the target. Here, we synthesized $(\text{PBA})_2\text{Cs}_{n-1}\text{Pb}_n\text{Br}_{3n+1}$ quasi-2D perovskite crystals where 'n' indicates the number of PbBr_6 octahedral sheets in each repeating unit. To achieve pure-blue emission within the range of 460-470 nm, the target wavelength by the ITU-R Recommendation BT.2020 (Rec. 2020), the industry standard for 4K and 8K ultra-high definition television standard, we manipulated the crystallization process of the quasi-2D perovskite prepared by solution process. The manipulation involved controlling the distribution of different 'n' (i.e., different bandgap) phases, with a specific focus on ensuring the dominance of the phase with the smallest bandgap, which is also the target emission bandgap. We attained pure-blue photoluminescence (PL) at 461 nm with a relatively narrow full-width at half maximum (FWHM) of 25 nm through a two-step crystallization control process. Initially, we performed a coarse adjustment of the PL wavelength by changing the solute concentration and solvent polarity, as these factors heavily influence the diffusion of cations, a crucial determinant for the value of 'n'. Subsequently, we further enhanced the PL quantum yield (PLQY) from 31% to 51% through fine-tuning in the second-step crystallization process, which involved the incorporation of trioctylphosphine oxide (TOPO) as an additive during the antisolvent treatment. The

antisolvent treatment with TOPO slightly slowed down the diffusion of precursors, resulting in halide-vacancy passivation and well-ordered crystals and leading to faster carrier transfer between phases. Based on these strategies, we successfully fabricated pure-blue light-emitting diodes (LEDs), which exhibited a relatively low turn-on voltage of 3V and an external quantum efficiency of 2.5% at an emission peak of 465 nm with a FWHM of 29 nm.

8:00 PM EN05.10.10

Compositional Engineering of Single-Crystal Perovskite for Highly Efficient Photovoltaics You Jin Ahn¹, Jin Young Kim¹ and Ik Jae Park²; ¹Seoul National University, Korea (the Republic of); ²Sookmyung Women's University, Korea (the Republic of)

Organic-inorganic lead halide perovskite materials have received great attention for promising optoelectric devices. To achieve high performance solar cells, defect control in perovskite materials is very crucial. Single-crystal perovskite-based solar cell exhibits excellent carrier diffusion length and light absorption due to significantly reduced bulk defects. In here, we discuss compositional engineering of single-crystal perovskite films for highly efficient perovskite solar cells. Single crystal perovskite films were grown by space-limited inverse temperature crystallization (ITC) method. Due to different solubility of perovskite precursor solute, γ -butyrolactone (GBL) and *N,N*-dimethylformamide (DMF) solvent ratio should be precisely controlled for compositional engineering. We investigated the effect of mixture solvent on growing single crystal perovskites. X-ray diffraction patterns confirmed that composition of perovskite can be controlled by the composition of perovskite precursor solution. We successfully synthesize wide-bandgap perovskite films and confirmed using UV-vis-NIR analysis. Single-crystal films over 4 mm were grown on ITO/PTAA substrates, and we fabricated single-crystal perovskite-based solar cells. The device shows high external quantum efficiency due to the micrometer-size film thickness. The best performing devices exhibited power conversion efficiency of over 20%.

8:00 PM EN05.10.11

Atomistic Origin of Transparent Absorption Spectra of Halide Perovskites Young Won Woo^{1,2}, Savyasanchi Aggarwal³, Seán R. Kavanagh^{3,2}, Alex M. Ganose² and Aron Walsh²; ¹Yonsei University, Korea (the Republic of); ²Imperial College London, United Kingdom; ³University College London, United Kingdom

Differential spectroscopy has emerged as a valuable characterisation tool in materials science. Transient absorption spectroscopy (TAS) involves probing changes in optical absorption following laser excitation. While TAS spectra provide information about carrier recombination kinetics, interpreting individual features remains challenging. In this talk, we present a novel procedure to calculate TAS spectra for crystals using first-principles density functional theory calculations. Our approach simulates changes in band-to-band transitions within the electronic band structure, encompassing ground-state bleaching and photo-induced absorption processes.

This methodology is particularly relevant to the investigation of halide perovskite materials, where TAS can provide insights into their unique optical properties and charge carrier dynamics. Applications will be given to a range of inorganic and hybrid perovskite compositions. Our procedures are implemented in the PyTASER code, an open-source package that facilitates the implementation of our simulation approach to help accelerate materials characterisation and bridge the gap between modelling and measurements for researchers working on halide perovskites.

8:00 PM EN05.10.13

Exploring a Novel Family of Conjugated Polymers for High Efficiency and Thermally Stable Perovskite Solar Cells Sanggyun Kim, Sina Sabury, Carlo Andrea Riccardo Perini, John R. Reynolds and Juan-Pablo Correa-Baena; Georgia Institute of Technology, United States

Long-term stability remains to be one of the critical challenges for organic-inorganic hybrid perovskite solar cells (PSCs). One of the most important limiting factors toward achieving long-term stability has been attributed to the hole transport layer (HTL), originating from interfacial degradation between perovskite and HTL, thermal/moisture induced degradation, and ionic migration. In this work, we examine novel conjugated polymer (CP)-based HTLs that are resistant to high temperatures in PSCs. CPs offer efficient hole extraction/transport properties, easy processing, and low-production cost. We highlight differences in optoelectronic properties, crystallinity, and stability of the CPs with respect to its different chemical structures using measurements including UV-VIS, UPS, DSC, GIWAXS, and XPS. These new polymers are further incorporated into devices to analyze its photovoltaic performance and stability at elevated temperature under illumination over 200 hours.

8:00 PM EN05.10.14

Charge Transfer Doping of Ruddlesden–Popper Metal–Halide Perovskites via Bulk Incorporation of Organic Molecular Dopants Kyeong-Yoon Baek^{1,2}, Jonghoon Lee¹, Jeongjae Lee¹, Heebeom Ahn¹, Yongjin Kim¹, Keehoon Kang¹ and Takhee Lee¹; ¹Seoul National University, Korea (the Republic of); ²Harvard University, United States

Ruddlesden–Popper metal–halide perovskites have recently attracted much attention as next-generation semiconducting materials due to their outstanding opto-electrical properties. However, these low dimensional materials critically suffer from relatively poor electrical conductivity, which is challenging to tune with traditional method of bulk atomistic doping. While doping with molecular dopants, a family of versatile dopants for molecular design has been suggested as a solution to this problem.[1,2] Nonetheless, the action of these dopants was typically restricted to perovskite surfaces, therefore significantly reducing their doping potential. In this study, we report successful bulk inclusion of ‘magic blue’, a molecular dopant, into two-dimensional (2D) Ruddlesden–Popper perovskites.[3] Our doping strategy of immersing the perovskite film in dopant solution increased the electrical current up to ~60 times while maintaining clean film surface. We provide a full mechanistic picture of such immersion doping, in which the solvent molecule facilitates bulk diffusion of dopant molecule inside the organic spacer layer, based on the optimum solvent processing. The immersion doping method developed in this work which enables bulk molecular doping in metal–halide perovskites in general will provide a strategic doping methodology for controlling electrical properties of low dimensional metal–halide perovskites for electronic and optoelectronic devices.

Additive Engineering in 2-Methoxyethanol Based Perovskite Film Formation for Perovskite Solar Cells Sung Hun Lee and Hyo Jung Kim; Pusan National University, Korea (the Republic of)

Perovskite solar cells (PSCs) have attracted significant attention because of their unique characteristics such as low-cost fabrication through solution processes and excellent photoelectric properties. Solution-processed perovskite films using polar aprotic solvent such as dimethyl sulfoxide (DMSO) generally required auxiliary process like anti-solvent drop. However, the anti-solvent dripping process has strict process window to form a uniform film such as dripping duration, volume, and pressure of the anti-solvent.

Recently, solvent engineering using 2-methoxyethanol (2MOE), which has selective solubility that dissolves methylammonium iodide (MAI) but not PbI_2 alone, have been studied for perovskite film formation for an anti-solvent free process. Although perovskite phase film could be obtained on the 2MOE solvent system without the anti-solvent process, the film generally has many pinholes leading to low power conversion efficiency (PCE) in PSCs. This problem is caused by low coordination with the precursor and high volatility of 2MOE.

To overcome this issue, we applied several additives, which affect to the kinetics of crystallization, in the 2MOE-based anti-solvent free process. First, we used various co-solvents, such as dimethyl sulfoxide (DMSO) and N-methyl-2-pyrrolidone (NMP), that can induce intermediate phases in which highly coordinated system with the precursors and solvents (MAI- PbI_2 -DMSO and MAI- PbI_2 -NMP). The formation of intermediate phases retards crystal growth of perovskite and leads to high crystallinity of the perovskite. Through this, we found that NMP is a suitable additive for pinhole free perovskite film. We obtained an efficiency of 20.39% with the maximum efficiency for the device based on the $\text{MAPbI}_{3-x}\text{Cl}_x$ film fabricated with a 2MOE-based solution containing NMP.

Second, we compared film formation by adding alkyl amines with different chain lengths in 2MOE single solvent system. Through this, we found that the uniform and dense film could be obtained by adding small molecule of oleyamine (OAm) having long 18-carbon chain without anti-solvent dripping. In that study, we measured real-time grazing incidence wide angle X-ray scattering (GIWAXS) in spin cast process to study how the added alkylamine affected to film quality. We found that the longer alkyl chain of alkyl amines induced the faster nucleation and fast crystal growth of perovskite in film formation. We fabricated inverted PCSs using the high-quality film containing OAm as a light absorption layer and obtained PCE of 21.01%.

Metal Microgrid Embedded Transparent Electrode for Enlarge Perovskite Solar Cells Hyungwoo Kim and Kwanyong Seo; Ulsan National Institute of Science and Technology, Korea (the Republic of)

Organic-inorganic hybrid perovskite (OIHP) solar cells have attracted much attention as next-generation energy devices. In the fabrication of OIHP solar modules, the unit cells are designed by considering the charge carrier loss in the collection process through transparent electrodes. However, in the modularization process of OIHP solar cells, the optical dead area increases, resulting in the degradation of the overall module efficiency. To mitigate the efficiency loss, it is crucial to enlarge the size of the unit cells. However, as the unit cell size increases, the power loss due to the inherent electrical resistance of transparent electrodes also becomes more critical, leading to a decrease in the fill factor (FF) of OIHP solar cells and modules. For example, when the voltage and current density at the maximum power point of the OIHP solar cell is 1.0 V and 23.5 mA/cm^2 , respectively, the power loss will become the same as the overall photo-generated power when the carriers need to move over 3.5 cm to be collected through the ITO layer which has a sheet resistance of 10 ohm/sq. Therefore, the lower sheet resistance of transparent electrodes would be essential to realize the larger-sized OIHP solar cells. Here, we report a hybrid transparent electrode in which a metal microgrid is embedded into the glass substrate, and ITO covers the substrate. The hybrid electrodes exhibit excellent sheet resistance of lower than 1 ohm/sq and comparable

optical transmittance (~82%, @300-800 nm) to that of ITO/glass substrate (~83%, @300-800 nm). When utilizing the developed hybrid electrode, the OIHP single solar cell with a size of 12.25 cm² shows an open-circuit voltage of 1.04 V, a short-circuit current density of 20.1 mA/cm², FF of 65.8%, and an overall efficiency of 13.8%. In particular, the FF of the OIHP solar cell based on the hybrid electrode is 2.01 times higher than that of the OIHP single solar cells based on an ITO/glass substrate (32.7%), confirming that charge carriers are collected efficiently. Our work suggests enormous potential for significant performance improvement of large-scale OIHP solar cells.

Solvent-Annealing Assisted 3D Printing of High-Performance, Freestanding Perovskite Nanolasers
Shiqi Hu and Ji Tae Kim; The University of Hong Kong, Hong Kong

Inorganic metal halide perovskites are emerging as promising optoelectronic materials due to their strong, tunable, and high-color-purity photo- and electroluminescence, and solution processability¹⁻³. Recently, extensive research has been made to utilize perovskite nanowires as lasers due to their structural benefits such as ultra-compact sizes, highly localized coherent output, and efficient waveguiding^{4,5}. The current fabrication of perovskite nanowires relies on electron beam lithography, photolithography, chemical vapor deposition, solution-phase synthesis, and nanoimprinting. That is to say, these processes are energy- and labor-intensive, which is in stark contrast with the industrial low-cost requirements. Furthermore, technological challenges associated with individual tailoring of nanowire geometries remain unresolved, making it difficult to manipulate stimulated emission characteristics at the single nanowire level. A new method that can fabricate perovskite nanowires with programmed shape, dimension, and placement is in great demand for addressing the abovementioned issue.

Here, we demonstrate an electrohydrodynamic (EHD) 3D printing of perovskite nanowires for high-performance bespoke lasers. The printed perovskite nanowire presents a two-photon pumped Fabry–Pérot (FP) mode lasing. By adjusting the height of a freestanding nanowire at will, we are able to select the lasing mode and also control the lasing threshold and mode spacing ($\Delta\lambda$). On this basis, we successfully demonstrated the 3D printed nanowires arrays for multi-level anti-counterfeiting security labels by storing information in the cavity-height-dependent features such as the lasing threshold and mode spacing ($\Delta\lambda$), which are unclonable. More importantly, solvent annealing was exploited to increase the grain size and crystallinity by promoting recrystallization in the printed nanowire. As a result, the lasing threshold was drastically improved from 25 $\mu\text{J}/\text{cm}^2$ to 3 $\mu\text{J}/\text{cm}^2$, which is the leading record for CsPbBr₃ FP lasers. It is also worth mentioning that the advanced features of our technique such as maskless operation and low-cost production with high stability make it an effective platform to bring the proof-of-concept demonstration into practical commercial application. Likewise, these outcomes not only give us inspiration for the function-oriented design of the nanolaser-based devices but also facilitate the development of high-performance perovskite-based photonic anti-counterfeiting applications. Last but not least, our method could provide an excellent platform to construct scalable, on-demand laser-based photonic devices.

Conjugated Polyelectrolytes as Additives for Inverted Perovskite Solar Cell Jung Min Ha¹, Jong Hyun Park², Young Wook Noh², Myoung Hoon Song² and Han Young Woo¹; ¹Korea University, Korea (the Republic of); ²Ulsan National Institute of Science and Technology, Korea (the Republic of)

Defects in perovskite solar cells (PSCs) significantly hinder their efficiency and stability. To tackle this challenge, our study explores the potential of two distinct π -conjugated polyelectrolytes (CPEs), MPS2-TEA and PCPDTBT2-TMA, as additives in PSCs. Unlike previous approaches where CPEs primarily served as interlayers or charge transporters, our focus is on their direct impact within the perovskite layer for defect passivation. Through thorough analysis, we observe that MPS2-TEA exhibits superior defect passivation compared to PCPDTBT2-TMA. This difference is attributed to the highly conductive nature of MPS2-TEA, enabling efficient mitigation of defects within the perovskite layer. In contrast, PCPDTBT2-TMA's self-doping effect, along with its negative sulfonate groups stabilizing polarons, reduces its effectiveness in defect passivation. The integration of MPS2-TEA into PSCs results in remarkable outcomes. The inverted perovskite solar cell with MPS2-TEA achieved notable power conversion efficiencies (PCEs) of 22.7% retaining over 87.3% of their initial PCE after 960 hours of continuous 1-sun illumination and maintaining 89% of PCE after 850 hours at 85°C in a nitrogen glovebox without encapsulation.

8:00 PM EN05.10.21

Nanostructure Strategies for Improved Perovskite Solar Cells Antonio Garcia-Martin; Instituto de Micro y Nanotecnología, CSIC, Spain

Organic-inorganic hybrid perovskite solar cells have attracted much attention due to their high power conversion efficiency (>23%) and low-cost fabrication. Directions to further improve these solar cells include strategies to enhance their stability and their efficiency by modifying either the perovskite absorber layer or the electron/hole transport layer. For example, the transparent electron transport layer (ETL) can be an important tuning knob influencing the charge extraction, [1] light harvesting, [2] and stability [3] in these solar cells, or the use of up-conversion nanoparticles to get better performance in the near IR part of the visible spectrum. [4] Here we present two strategies based on nanostructuration, first a fundamental study of upconversion fluorescence enhancement effects near Au nanodisks by scanning near-field optical microscopy and second the effects of a nanocolumnar TiO₂ layer on the performance and the stability of Cs_{0.05}(FA_{0.83}MA_{0.17})_{0.95}Pb(I_{0.83}Br_{0.17})₃ perovskite solar cells. For the first case, the enhancement and localization of light near the metallic structures are directly visualized by using a single Er/Yb-codoped fluorescent nanocrystal glued at the end of a sharp scanning tip. [5] For the second we find that, compared to devices with planar TiO₂ ETLs, the TiO₂ nanocolumns can significantly enhance the power conversion efficiency of the perovskite solar cells by 17 % and prolong their shelf life. By analyzing the optical properties, solar cells characteristics, as well as transport/recombination properties by impedance spectroscopy, we observed light-trapping and reduced carrier recombination in solar cells associated with the use of TiO₂ nanocolumn arrays. [6]

Beginner's Guide to Visual Analysis of Perovskite Solar Cell Current-Voltage Characteristics

Albert These^{1,2}, Christoph J. Brabec¹ and Vincent Le Corre¹; ¹Institute Materials for Electronics and Energy Technology, Germany; ²Friedrich-Alexander-Universität Erlangen-Nürnberg (FAU), Germany

The current-voltage characteristic (JV) is a critical tool for understanding the behavior of solar cells. In this presentation, I will provide an overview of the critical aspects of JV analysis and introduce a user-friendly flowchart that facilitates the swift identification of the most probable limiting process in perovskite solar cells, based mainly on the outcomes of light-intensity-dependent JV measurements. The flowchart was developed through extensive drift-diffusion simulations and a rigorous literature review, with a specific focus on perovskite solar cells (it is also applicable for organic solar cells with minor adjustments). Hereby, each loss mechanism is supported by a drift-diffusion simulation showing the exact influence on the main JV parameters, namely short-circuit current, open-circuit voltage, and fill factor. The flowchart also suggests an additional experiment besides JV characteristics to get a more accurate and definitive prediction of the main losses. It is therefore a valuable starting point for the analysis of experimental data and provides guidance to quantify the main loss processes of perovskite solar cells.

8:00 PM EN05.10.24

Thick and Efficient Perovskite Solar Cells Enabled by Fast Co-Evaporation Manuel Piot, Javier Sebastien, Nathan Rodkey, Kassio P. Zanoni, Michele Sessolo and Henk J. Bolink; Institut de Ciència Molecular (ICMol), Spain

Conformal deposition of perovskite on textured silicon for perovskite/silicon tandem solar cells remains challenging using the widely-used solution spin-coating route. In contrast, perovskite thermal evaporation allows highly-controlled thin film deposition, ensuring conformality on large areas, regardless on the surface texture. To take advantage of the full photocurrent generating capabilities of the perovskite front cell, rather thick films are required. Currently, most perovskites are sublimed in a single approach by co-sublimation of the precursors. This deposition technique is usually done under high vacuum and the deposition rates of each precursor are monitored using quartz crystal microbalances (QCMs). However, due to the slow deposition rates ($< 1 \text{ Å/s}$) it is challenging to deposit sufficiently thick perovskite films that are required for highly efficient perovskite/silicon tandem devices.

Herein, we explore the co-evaporation of $\text{CH}_3\text{NH}_3\text{PbI}_3$ (MAPI) perovskite using faster deposition rates ($> 2 \text{ Å/s}$), by simultaneously subliming $\text{CH}_3\text{NH}_3\text{I}$ and PbI_2 . These rates are deduced by scaling up linearly the initial speed by a factor of up to 8 times, leading to quick and reproducible evaporation processes. Moving to faster deposition speeds, a change in crystallite orientation is observed by XRD and GIWAXS, showing a preferential growth along the (202) family of planes, as opposed to the (110) orientation. Thanks to these faster deposition speeds, 1 μm -thick MAPI films can be deposited in a short amount of time. This allows a noticeable J_{sc} gain in planar glass based single junction solar cells ($\sim 0.8 \text{ mA}$), due to an enhanced absorption of the infrared light, as revealed by EQE. On the other hand, the FF drops to

lower values, possibly due to a diffusion length problem.

8:00 PM EN05.10.25

Potential of Close-Space Sublimation for Scalability of Perovskite Solar Cells Nathan Rodkey, Inma Gomar Fernández, Federico Ventosinos, Cristina Roldan-Carmona and Henk J. Bolink; Universitat de València, Spain

Vacuum techniques for perovskite photovoltaics (PV) are promising in their potential for scalability but are rarely studied with techniques that are readily adaptable for industry. Co-sublimation is one such technique, whose potential as a dry, additive technique for highly uniform and large-area depositions makes it attractive as an industrial candidate for perovskites. However, low-deposition rates, and its dependence on high-vacuum and in-situ rate monitoring make integration on large scales difficult to imagine. Furthermore, the organic sources used (e.g. FAI and MAI) tend to be unstable, decomposing over time. This is severe enough that the organic sources are not reused, instead discarded after each evaporation. In this work, we study the use of close-space sublimation (CSS) for making perovskite solar cells, a technique that has already seen wide-spread use in industry, including in PV and benefits from high material-transfer and low working pressures. We show that organic sources of FAI used in these systems can be cycled multiple times (>30 depositions) and estimate they can be continuously sublimated for months before needing replacement. We show the conversion of inorganic perovskite precursor layers in a 2-step process using CSS for the organic, FAI source. We show that a rough vacuum process (10 mbar) can be used for the sequential conversion of evaporated $\text{PbI}_2/\text{PbCl}_2/\text{CsI}$ thin-films. The $\text{FA}_{0.9}\text{Cs}_{0.1}\text{PbI}_3\text{:Cl}$ perovskites converted in this work have a bandgap at 810 nm (1.53 eV), with large grains (>400 nm). Devices were then thermally stressed at 85 °C and exhibited a stable photoconversion efficiency (PCE) for >650 hours. This thermal stressing was found to be necessary for high -performing devices, who experienced an increase in average PCE from 12.2 – 17.5% after 1 week annealing. We report a champion cell of 18.7% PCE. To explain this drastic increase in PCE, we collect the JV characteristics of the devices at varying light intensities (dark, 0.1, 0.5, and 1 sun) and use drift-diffusion simulations to explain the transformation. These drift-diffusion simulations are powered by SIMSalabim, and by fitting multiple JV curves at different light intensities, we are able to ensure a unique fit of the data. In this way, a reduction in trap density of 5 orders of magnitude was observed after 1 week of thermal stressing.

8:00 PM EN05.10.26

Double Punch for Suppressing Phase Segregation: Interface Engineering with Synergistic Passivation and Efficient Hole Extraction Zhaojie Zhang¹, Julia Martin², Ronald L. Grimm² and Dhandapani Venkataraman¹; ¹University of Massachusetts--Amherst, United States; ²Worcester Polytechnic Institute, United States

In p-i-n perovskite solar cells (PSCs), the buried hole transport layer (HTL)/perovskite interface plays a vital role in dictating the performance and stability of the full photovoltaic device. However, the impact of HTLs on vertical phase segregation remains unknown. This work systematically explores the impact of electronic and chemical properties of HTLs on vertical halide segregation of mixed-halide perovskite materials. Here, we demonstrate that $\text{PTAA}/\text{Cu}_x\text{Br}_{1-x}$ bilayer HTL significantly suppresses light-induced vertical phase segregation of $\text{MAPb}(\text{I}_{0.7}\text{Br}_{0.3})_3$. We used grazing-incidence X-ray diffraction (GI-XRD) to capture the depth-resolved composition change of $\text{MAPb}(\text{I}_{0.7}\text{Br}_{0.3})_3$ at the interface and bulk with different HTLs under illumination. Electronic properties including hole density, hole mobility, and energy levels of $\text{Cu}_x\text{Br}_{1-x}$ were systematically characterized to reveal the impact of HTL on phase segregation. By

manipulating the illumination and electronic properties of HTL, we illustrate the interplay between illumination direction, interfacial defects, charge carrier extraction, and vertical phase segregation. Our findings demonstrate that the PTAA/CuI_xBr_{1-x} bilayer, with its synergistic passivation and efficient hole extraction ability, stabilizes the interface and bulk of the mixed halide perovskite layer, preventing phase segregation and possible amorphization. This work highlights that synergetic passivation and efficient hole extraction pack a more powerful punch for suppressing the vertical phase segregation in mixed-halide perovskite.

8:00 PM EN05.10.27

Interstitial Defect Thermodynamics Drive Phase Separation in Lead Halide Perovskites Ross Kerner¹, John L. Lyons², Kai Zhu¹ and Joseph J. Berry^{1,3,3}; ¹National Renewable Energy Laboratory, United States; ²U.S. Naval Research Laboratory, United States; ³University of Colorado Boulder, United States

Lead halide perovskites show unrivaled performance and versatility in optoelectronic devices; however, the issues of photo- and electrochemical stability and halide phase segregation remain a challenge to take full advantage of halide perovskites. Here, we describe our proposed model to explain how homogeneously mixed iodide (I):bromide (Br) perovskite alloys (e.g. MAPbBr_xI_{1-x}) phase separate into I-rich and Br-rich regions under bias or illumination. The model predicts iodine +1 interstitials play a critical, intrinsic role giving rise to unequal fluxes of halide species – the origin of voltage- or photo-induced compositional instabilities. We briefly review our recent experimental results testing the model and discuss in detail our recent density functional theory (DFT) computations comparing the relative formation enthalpies of I_i⁺ versus Br_i⁺ interstitial defects in different halide compositions. We find that I_i⁺ defects are energetically favorable by 0.1-0.4 eV over Br_i⁺ under most conditions, and also show that I_i⁺ is further stabilized when surrounded by iodide first- and second-nearest neighbors. In other words, I_i⁺ will be most stable and favorably migrate towards iodide-rich regions making them more iodide-rich. Thus, we confirm our model's core assumption and elucidate a major fundamental, thermodynamic driving force for halide phase separation following oxidation and creation of I_i⁺ defects. Overall, this body of work brings a level of clarity to interstitial defect chemistry and physics in halide perovskites, advancing our understanding a step closer to that of more conventional semiconductors.

8:00 PM EN05.10.29

Enhancing Interfacial Properties via Ionic Exchange for the Highly Efficient Sn-Pb Mixed Perovskite Based Solar Cells Sangheon Lee, Changyong Kim, Hyemin Lee, Seok Beom Kang, Joo woong Yoon, Sang Won Lee and Dong Hoe Kim; Korea University, Korea (the Republic of)

Sn-Pb mixed perovskite is considered as an ideal light absorber not only for single-junction solar cells, but also for bottom cells of multi-junction solar cells due to its narrow-band gap feature. The p-orbital hybridization of Sn²⁺ and Pb²⁺ causes an upward shift of the valence band maximum (VBM) and conduction band minimum (CBM) in addition to the bandgap reduction. This results in the highest occupied molecular orbital level of poly[3,4-ethylenedioxythiophene]:poly[styrene sulfonate] (PEDOT:PSS) having an ideal band alignment with the VBM of Sn-Pb mixed perovskite. Therefore, the PEDOT:PSS is the most widely used hole transport layer (HTL) in p-i-n structured Sn-Pb mixed perovskite solar cells (PSCs).

However, PEDOT:PSS showed several critical drawbacks that affected the device performance such as their acidic condition, inferior molecular structure, and nonideal absorption property. Among them, the

inappropriate molecular structure composed of hydrophilic PEDOT molecule and hydrophobic PSS molecule does not form a uniform and ideal micro structured surface when it has been coated. Therefore, it has been induced undesirable interface like voids between PEDOT:PSS and perovskite. Various studies have been conducted to obtain better interfacial properties with respect to the perovskite precursor, like adding additives. However, the origin of the undesirable interface was due to the structural limit of the PEDOT:PSS molecule. Therefore, fundamental research is needed to address these issues from the perspective of the PEDOT:PSS surface.

This study introduces an effective ionic exchange for PEDOT:PSS surface modification to drastically enhance the interfacial properties between PEDOT:PSS and perovskite. The surface modified PEDOT:PSS by ionic exchange brought the conformal interfacial contact and enhanced charge extraction confirmed via time-resolved photoluminescence (TRPL) analysis. As a result, we achieved more than 20% efficiency of p-i-n structured Sn-Pb mixed PSCs. The mechanism of ionic exchange also had been elucidated through various surface analysis and density functional theory (DFT) calculations. In addition, we confirmed that this ionic exchange was also effective for tandem devices. In conclusion, we fabricated all-perovskite tandem solar cells with an approaching 24% efficiency through this ionic exchange

8:00 PM EN05.10.30

Efficient Perovskite Solar Cells with Improved Carrier Transport via Composition-Graded Titanium Oxynitride Electron Transport Layer Yonghoon Jung; Seoul National University, Korea (the Republic of)

State-of-the-art perovskite solar cells (PSCs) have achieved power conversion efficiencies (PCEs) exceeding 25% by enhancing the charge transport layers to facilitate efficient carrier transport while minimizing non-radiative recombination. The effective transport of charge carriers through the perovskite and the charge transport layers can improve the fill factor and open-circuit voltage. An ideal electron transport layer (ETL) should possess complete and conformal coverage, as well as optimal band alignment that facilitates efficient extraction of electrons. Additionally, the minimal defect density in charge transport layers is essential to prevent detrimental interface recombination. While TiO_2 has been widely used as an ETL, it exhibits limitations as an ideal ETL due to an energy level mismatch and relatively poor electrical characteristics. Specifically, the conduction band minimum (CBM) of TiO_2 is slightly higher than that of MAPbI_3 , leading to a significant energy barrier for electron extraction. Additionally, the relatively low conductivity and mobility of TiO_2 hinder efficient charge transfer. To address the limitations of TiO_2 , metal doping such as Nb, Al, and Li has been employed to modify its electronic band structures and improve its electrical properties.

In this study, nitrogen is incorporated into TiO_2 using the pulsed laser deposition (PLD) method to form titanium oxynitride (TiO_xN_y), resulting in enhanced electron transport characteristics including minimal defect density. Controlled substrate temperature and oxygen partial pressure during the deposition facilitated the achievement of optimal thin-film characteristics, including high transparency typical of TiO_2 semiconductors and high conductivity typical of nitrogen-rich TiN. Furthermore, TiO_xN_y thin films with graded atomic ratio nitrogen to oxygen (N/O) are achieved by sequentially changing the oxygen partial pressure during the process. The graded TiO_xN_y thin film exhibits characteristics that enable the achievement of superior functionality as an ETL compared to TiO_xN_y thin films without grading. By increasing the oxygen partial pressure during the deposition process, the CBM was raised, leading to a reduced energy offset with the mesoporous TiO_x layer directly above it. Furthermore, TiO_xN_y fabricated in a multilayer structure can provide a continuous variation of energy levels within the ETL, optimizing the electron pathway and improving charge transport, ultimately enhancing charge extraction capabilities.

This alignment facilitates the selective transfer of electrons to the respective electrodes while inhibiting hole transport. The accurate composition control of TiO_xN_y films is characterized using such as atomic force microscopy, X-ray photoelectron spectroscopy, ultraviolet photoelectron spectroscopy, and Hall measurement to uncover the mechanism behind the enhanced properties. The conformally deposited films with high crystallinity and tailored optoelectrical properties exhibit effective suppression of interfacial recombination as an ETL, resulting in solar cell devices and resulting in high PCEs.

8:00 PM EN05.10.31

Tunable Anode Work-Function by Self-Assembled Monolayers for High-Performance Pure Blue Light-Emitting Diodes Low Driving Voltage Hyo Jae Lee, Jung Jae Do and Jae Woong Jung; Kyung Hee University, Korea (the Republic of)

Organometallic trihalide perovskites have garnered significant attention for their potential in light-emitting diode applications, thanks to their unique characteristics including excellent color purity, color tunability, and ease of solution processing through scalable printing technology. Presently, perovskite emitters have achieved comparable electroluminescence and quantum efficiency to organic and quantum-dot display technologies in green and red-emitting perovskite light-emitting diodes (PeLEDs). However, blue-emitting PeLEDs still face challenges in terms of electroluminescence, operational stability, and efficiency, primarily due to the relatively wide bandgap of the perovskite emitters ($E_g > 2.5$ eV), which thus requires high driving bias for device operation. In this study, we propose a straightforward interfacial engineering approach to reduce the driving voltage of pure-blue PeLEDs by employing self-assembled monolayer (SAM) molecules on the indium tin oxide (ITO) electrode. The SAM layer facilitates the control of the electronic structure of the ITO surface by modulating its work function, thereby improving hole extraction properties at the lower internal interface. Furthermore, the functionalized SAM molecules interact with the under-coordinated perovskite lattices, providing interfacial interaction with the perovskite layers and facilitating radiative carrier recombination at lower driving bias. These desirable characteristics of SAM molecules enable enhancements in the electroluminescence and quantum efficiency of pure blue emission while requiring lower driving voltage. Moreover, the superior properties of the perovskite film, coupled with the reduced driving voltage, contribute to an extended operational stability of blue electroluminescence in PeLEDs. Consequently, this strategy demonstrates the remarkable potential of achieving high-performance PeLEDs with blue light emission, which is highly attractive for full-color perovskite display technologies.

8:00 PM EN05.10.32

Bandgap Optimization by Cu Doping of Ag-In Halide Double Perovskites for Photovoltaic Applications Shunnosuke Ikegaya, Koji Yokoyama, Shun Yokoyama and Hideyuki Takahashi; Tohoku University, Japan

Lead iodide perovskites (APbI_3 , where A represents organic cations) have been used as photoactive layers in perovskite photovoltaics due to their excellent optical and electronic properties. However, the toxicity of Pb and the ambient instability caused by the degradation of organic cations and iodide anions have hindered their widespread use. Metal halide double perovskites ($\text{A}_2\text{B}^{\text{I}}\text{B}^{\text{III}}\text{X}_6$, where B^{I} , B^{III} , and X represent monovalent and trivalent metal cations, and halide anions, respectively) have been theoretically proposed as Pb-free halide perovskites. Theoretical calculations predict that $\text{Rb}_2\text{CuInCl}_6$ double perovskites have a direct and optimal bandgap of 1.36 eV, whereas they cannot be synthesized directly due to their low thermodynamic stability. Instead, we focused on $\text{Cs}_2\text{AgInCl}_6$ double perovskites, which can be synthesized directly and exhibit superior ambient stability; however, they have a large bandgap

(>3.0 eV), making them unsuitable for photoactive layers. Recent studies have reported that Cu^{2+} doping reduces the bandgap of $\text{Cs}_2\text{AgInCl}_6$ from 3.0 to 2.2 eV. Furthermore, it was demonstrated that $\text{Cu}^+/\text{Cu}^{2+}/\text{In}^{3+}$ -based layered perovskites exhibited better optical properties than perovskites composed of Cu^+ or Cu^{2+} alone. In this study, we present the synthesis of Ag-In double perovskites with an optimal bandgap as photoactive layers through $\text{Cu}^{+/2+}$ doping.

All of the following processes were performed at 75°C in ambient air. Ag-In precursor aqueous solutions (denoted as S1) were prepared by dissolving AgCl and $\text{InCl}_3 \cdot 4\text{H}_2\text{O}$ in concentrated HCl. Precursor aqueous solutions containing only Cu^{2+} (denoted as S2) were prepared by dissolving $\text{CuCl}_2 \cdot 2\text{H}_2\text{O}$ in concentrated HCl. Precursor aqueous solutions containing only Cu^+ (denoted as S3) were prepared by dissolving CuCl with reductants in concentrated HCl. Precursor aqueous solutions containing Cu^+ and Cu^{2+} simultaneously (denoted as S4) were prepared by dissolving CuCl and/or $\text{CuCl}_2 \cdot 2\text{H}_2\text{O}$ with reductants in concentrated HCl. Ultraviolet-visible (UV-Vis) absorption spectra of the S2-S4 solutions were measured to evaluate the valence states and complex structures of Cu species in these solutions. The solid samples precipitated by adding CsCl into the S1 solutions, the S1/S2 mixtures, the S1/S3 mixtures, or the S1/S4 mixtures were collected and washed. The composition, structure, and bandgap of the resulting samples were evaluated by inductively coupled plasma-mass spectrometry (ICP-MS), X-ray diffraction (XRD), and optical absorption measurements.

The S2, S3, and S4 solutions turned yellow, colorless, and dark, respectively. The UV-Vis spectra of these solutions indicated that the S2 and S3 contained only $[\text{Cu}^{\text{II}}\text{Cl}_4]^{2-}$ and $[\text{Cu}^{\text{I}}\text{Cl}_4]^{3-}$ complexes, respectively, whereas the S4 contained mixed-valence $\text{Cu}^{+/2+}$ species. The resulting samples from the S1 solutions were completely white in color. XRD analysis confirmed the presence of the $\text{Cs}_2\text{AgInCl}_6$ phase in these samples. In contrast, the resulting samples from the S1/S2 and the S1/S3 mixtures were yellow and pale yellow, respectively. These samples had a smaller bandgap compared to $\text{Cs}_2\text{AgInCl}_6$. Trace amounts of Cu were detected via ICP-MS, indicating that Cu doping of the $\text{Cs}_2\text{AgInCl}_6$ can reduce the bandgap. Interestingly, the resulting samples from the S1/S4 mixtures exhibited darker colors than the samples doped with Cu^+ or Cu^{2+} alone, suggesting that simultaneous $\text{Cu}^{+/2+}$ co-doping leads to emergent optical properties in these samples.

8:00 PM EN05.10.33

Electrical Field-Assisted Direct Ink Deposition of Methylammonium Lead Iodide Layer for Fabricating Large-Scale Inverted Perovskite Solar Cell Banashree Gogoi, [Carson Gockley](#), Sushmitha Venu, Yizhen Zhu, Raveena Phadnis, Xiangjia Li, William T. Petuskey and Terry L. Alford; Arizona State University, United States

A high-performing perovskite solar cell (PSC) requires an outstanding perovskite layer in excellent contact with high-performing charge transfer layers. Commercial development of simple and scalable deposition techniques will need to focus on processes that yield smooth films of uniform composition, microstructure and composition. Ideally, it is desired that the same technique be used sequentially for all of the layers. Several techniques aspire to this goal including one-step chemical solution processes using spin coating and ceramic processing approaches such as doctor-blading, slot-die coating, inkjet printing, and spray coating. As an alternative, we report on the electric field-assisted direct ink deposition (EF-DID) fabrication process for rapid printing of large-area perovskite nanofilms.

Our prior work successfully demonstrated the utility of EF-DID in fabricating PEDOT:PSS hole transport layers. Now we demonstrate its application for depositing perovskite films. Essentially, this technique forms a stable electrospray condition that yields a uniform, large grain-sized perovskite film deposits. Concurrent heat treatment thermally converts the perovskite precursor solution in orthorhombic methylammonium lead iodide ($\text{CH}_3\text{NH}_3\text{PbI}_3$). Post-deposition, solvent vapor annealing (SVA) refines the

films to improve their surface smoothness and to greatly reduce pinhole defects. With very little experimental effort, a ten-fold improvement in the power conversion efficiency (from 1 to 10%) was achieved, suggesting that even greater efficiency can be anticipated in the future.

Enhancing the Performance of the MAPbI₃ Perovskite Solar Cells Synthesized in an Ambient Environment via Modification of the SnO₂ Electron Transport Layer Biplav Dahal; Florida International University, United States

The tin oxide (SnO₂) electron transport layer (ETL) plays a vital role in the photo-conversion efficiency (PCE) and stability of organic-inorganic perovskite solar cells (PSCs). However, SnO₂ ETL-induced defects such as hydroxyl groups, oxygen vacancies, exposed Sn atoms, and dangling bonds hinder device performance. In this study, rubidium chloride (RbCl) has been used to modify the SnO₂ ETL. MAPbI₃ perovskite film formed on the RbCl-modified SnO₂ ETL exhibits improved crystallinity with enlarged grain size and reduced grain boundaries, and enhanced optical absorption. The Hall-effect measurements indicate the improved carrier mobility and the dark J-V curve shows the increment of electrical conductivity for the RbCl-modified SnO₂ ETL. X-ray photoelectron spectroscopy (XPS) results demonstrate the surface defects passivation of the perovskite layer by modifying the SnO₂ ETL. A champion PCE of 19.35% has been achieved for the RbCl-modified SnO₂ ETL-based devices with improved stability, while the control devices with unmodified SnO₂ ETL show a PCE of 17.18%.

SESSION EN05.11: Poster Session V: Structure Property Relationships in Halide Perovskites

Session Chairs: Marina Leite and Xiaotong Li

Effects of Light and Electricity on Mechanical Properties of Metal Halide Perovskite Single Crystals Meaghan Doyle, Madhuja Layek, Anush Ranka, Zhenghong Dai and Nitin P. Padture; Brown University, United States

Metal halide perovskites (MHPs) have emerged as promising light absorber materials for their use in perovskite solar cells (PSCs). Although significant progress has been made in enhancing the efficiency and operational stability of PSCs, their mechanical reliability needs to be improved if they are to operate efficiently for many years. However, the mechanical properties of MHPs have not been fully explored. This is especially important because MHPs possess poor mechanical properties — they are compliant, soft, and brittle. To that end, we have used nanoindentation and micro-indentation to study the plastic deformation, elastic deformation, and fracture properties of MHP single crystals of various compositions. We also investigated the effects of creep as well as light and electricity on the mechanical properties of MHP single crystals. These parameters impact the mechanical properties of other similar semiconductors, and in MHPs such effects could translate to important implications for PSCs. Through this we aim to provide a more comprehensive understanding of mechanical properties of MHPs, which are relevant for understanding and enhancing the mechanical reliability of PSCs.

8:00 PM EN05.11.04

Design and Characterization of Low-Dimensional Perovskites with Multiple-Ring Aromatic

Cations Andrei Mitrofanov^{1,2}, Yonder Berencén³, Elaheh Sadrollahi², Khrystyna Rymsha¹, Regine Boldt¹, David Bodeshiem², Hendrik Weiske⁴, Fabian Paulus², Quinn Besford¹, Agnieszka Kuc³ and Brigitte Voit^{1,2}; ¹Leibniz Institute of Polymer Research, Germany; ²Technische Universität Dresden, Germany; ³Helmholtz-Zentrum Dresden-Rossendorf, Germany; ⁴Universität Leipzig, Germany

Metal halide perovskites have become promising next-generation semiconducting materials for many applications due to their prominent optoelectronic properties and ease of manufacturing. These materials are widely tailorable in composition, which allows the incorporation of various organic cations. Tuning the structure of the organic molecules can cause remarkable changes in the structural arrangement of halide perovskites resulting in the formation of two-dimensional (2D) layers, one-dimensional (1D) chains, or isolated zero-dimensional (0D) clusters and, as a consequence, the modification of the optoelectronic properties of the perovskite system.

In recent works devoted to the low-dimensional metal halide perovskites, significant attention has been paid to the molecular engineering of the functionalized cations. This allows the design of a variety of new organic-inorganic hybrid materials, in which semiconducting organic and inorganic layers are assembled at the molecular scale. High structural distortion of the resulted low-dimensional perovskite structures induces electron-phonon coupling and enhances the self-trapped excitons (STEs) processes, resulting in an enhanced broadband emission [1,2]. In addition, it has been demonstrated that perovskites grown in a form of atomically thin sheets possess unique features compared to their bulk counterparts [3]. For example, hybrid perovskite sheets exhibit an unusual structural relaxation, which leads to a band gap shift. Consequently, the controllable synthesis of ultrathin perovskite sheets has gained a great research interest for implementation in high-performance optoelectronic devices.

In this work, we fabricated several low-dimensional hybrid organic-inorganic metal halides, based on multiple-ring aromatic ammonium cations and lead iodide with a strong focus on structural and optoelectronic investigation. Examination of the influence of organic cations on the structural properties reveals that the number and position of amino groups at the aromatic ring affect the dimensionality of the perovskite, resulting in 2D and 1D corner- and face-sharing structures with different optical behaviors. Highly distorted 1D perovskites show broadband emissions originating from STEs. Theoretical results reveal, that the organic cations in the 1D compounds strongly contribute to the band structure resulting in strong orbitals hybridization. Using a facile and fast template-assisted crystallization method we have synthesized metal halide perovskite few-layer free-standing nanosheets with micron size containing the naphthalene diammonium-based linker. Varying the synthetic conditions, we can modulate the thickness and lateral sizes of the nanosheets, making them promising candidates for optoelectronic applications.

Maximizing Photoluminescence Quantum Efficiency of Stacked Halide Layer for Highly Efficient Perovskite Solar Cells Min Ju Jeong and Jun Hong Noh; Koera University, Korea (the Republic of)

To further approach the theoretical limit of perovskite solar cells (PSCs), it is crucial to analyze and interpret the external photoluminescence quantum efficiency (PLQE) of a light-absorbing halide layer stacked with charge transporting layers (CTLs) rather than solely as a halide layer. Here, we propose the

next phase research direction for reaching radiative limit of PCE by maximizing PLQE of the stacked halide layer. We demonstrated that controlling the bottom charge transporting layer (CTL)/perovskite interface is a main factor to maximize PLQE in full device stack. On combining interface and bulk engineering, the FTO/bottom CTL/halide structure and full device stack exhibited an enhanced external photoluminescence quantum efficiency (PLQE) of 40.67% and 15.57%, respectively. As a result, the device combined with the interface and bulk engineering showed a certified quasi-steady-state (QSS) efficiency of 25.06%. The certified open-circuit voltage (V_{oc}) of 1.18 V is 94.93% of the radiative limit V_{oc} of 1.243 V, the highest value among certified QSS V_{oc} of PSCs. This research approach provides a promising direction for reaching the theoretical limit of PSCs by maximizing PLQE.

8:00 PM EN05.11.06

Origin of Excitonic Absorption in Multi-Grain CsPbBr₃ Perovskite Nanocrystals for Photodiode Applications Atif Suhail¹ and Monojit Bag²; ¹IIT Roorkee, India; ²Indian institute of Technology Roorkee, India

Inorganic halide perovskite nanocrystals exhibit some extraordinary properties compared to their parent materials due to the finite size effect. However, the exciton dynamics in these nanocrystals are not well understood due to the wide variation of structural properties. In this study, we have synthesized single-grain and multi-grain nanocrystals of CsPbBr₃ and analyzed the excitonic absorption and photoluminescence by correlating them with their structural properties. There exist two types of excitonic absorption; low energy localized excitons having binding energy from 64 to 156 meV and near band-edge excitons having binding energy from 18 to 23 meV. Small-size single-grain nanocrystals have a relatively higher bandgap of 2.576 eV due to increased micro-strain compared to multi-facet polyhedral with multi-grain nanocrystals. The broadening of the near band-edge excitonic absorption peak is possibly due to the presence of different sizes, shapes, and nature of the grain boundaries which also modulate the photoluminescence decay lifetime. The overall steady-state photoluminescence is higher in single-grain nanocrystals compared to multi-grain nanocrystals due to the localization of excitons. Therefore, these single-grain nanocrystals can be used for efficient light emission in perovskite photodiodes while multi-grain nanocrystals could be better suited for photodetector application.

Keywords: Halide perovskites; Nanocrystals; Excitonic absorption; Grain boundaries; Photoluminescence lifetime.

8:00 PM EN05.11.07

Effect of Hole Transport Layer on Energy Loss of Perovskite Solar Cell Heunjeong Lee, Tran H. Nhan, Dongchan Lee and Shinuk Cho; University of Ulsan, Korea (the Republic of)

The performance of perovskite solar cells (PVSCs) is most affected by the crystallinity of perovskite. Among several conditions, the interfacial properties between the charge transfer layer and the perovskite active layer, where the perovskite crystalline structure begins, are also one of the factors that have a great influence. Thus, various studies have been performed the ways to modify HTL to improve the device performance in the p-i-n structure. As the crystallinity including grain size of perovskite layers is influenced by the HTLs, the various charge dynamics will be also changed. Until now, however, there is little research related to energy loss analysis about the perovskite layer depending on HTLs. In this study, the difference in V_{oc} between PEDOT:PSS and NiO_x was explained through energy loss analysis. Despite the energy levels of PEDOT:PSS and NiO_x are similar to -5.0 eV and -5.1 eV, respectively, significant V_{oc} difference is observed between PEDOT:PSS based PVSCs (0.933 V) and NiO_x based PVSCs (1.088 V).

Our energy loss analysis clearly indicated that this V_{oc} difference originated by non-radiative recombination. It is known that the non-radiative recombination in PVSCs is generally occurred by traps in the perovskite film, which is generated by grain boundary and defects of perovskite film. The perovskite film on NiO_x showed a larger grain size and improved crystallinity compared to the perovskite film on PEDOT:PSS. Therefore, we concluded that the increased V_{oc} in PVSCs using NiO_x HTL was due to the decrease in non-radiative recombination induced by the improved morphology.

8:00 PM EN05.11.08

Effects of Precursor Purity and Post-Synthesis Treatments on Mechanochemical Mn^{2+} and Rb^{1+} Co-Doped CsPbCl_3 Perovskite Powder

Ivy K. Jones¹, Uwe Hommerich¹, Kesete Ghebreyessus¹, Vadivel Jagasivamani¹, Demetris Geddis¹, Kabir Al Amin¹, S. B. Trivedi², Amanda L Tiano³ and Seth Fraden³;

¹Hampton University, United States; ²Brimrose Corporation of America, United States; ³Brandeis University, United States

Inorganic halide perovskites (HPs) exhibit optimum optoelectronic material characteristics such as wider band gaps, enhanced atmospheric stability, and improved photoluminescence quantum yield, as well as demonstrated balanced and higher carrier mobility in comparison to hybrid organic-inorganic HPs. The synthesis of perovskite material often involves the utilization of toxic and large quantities of hazardous complex solution-based techniques which are not eco-friendly. Alternately, crystal growth methods require highly purified precursors that have negative ecological impacts on the environment, leading to increased pollutants within the atmosphere, and accompanied by high-energy consumption deemed an unsustainable practice. Mechano-chemical synthesis is considered a green chemistry method that significantly can reduce the use of complex and time-consuming reactions, energetic-enabled conditions, expensive precursor sources, hazardous reagents, catalysts, additives, surfactants, and overall waste. In this study we report fluorometric characterization results of mechano-chemical synthesis of manganese (Mn^{2+}) and rubidium (Rb^{1+}) co-doped CsPbCl_3 halide perovskite powder thermal calcination treatment and post-synthesis ligand-mediated techniques. The grinding process is considered a non-homogeneous synthesis approach which may result in residual unconsumed precursor present in the sample leading to surface defects during post-synthetic treatments. Dry and wet high-energy ball-milling experiments used different (low = 2N-99%, med = 3N-99.9%, and high = 5N-99.999%) purity precursors: CsCl (5N), PbCl_2 (5N & 2N), RbCl (5N) and the (non-anhydrous) hydrated dopant source: $\text{MnCl}_2 \cdot 4\text{H}_2\text{O}$ (3N). Synthesized theoretically ~ 4.5 wt % Mn^{2+} and ~ 11 wt% Rb^{1+} co-doped CsPbCl_3 HPs were characterized by X-ray diffraction, scanning electron microscopy, transmission electron microscopy, and steady-state & time-resolved spectroscopic studies. The HPs powder suspension and supernatant (colloidal) exhibited a broad band Mn^{2+} emission band at room temperature with average peak wavelengths of ~ 600 nm and ~ 598 nm, respectively. Room-temperature (RT) lifetime transients of the HPs raw powders were 0.50 – 1.17 ms, powder suspension ranged from 1.65 – 1.71 ms and colloidal solution demonstrated the longest transients ranging from 1.72 – 1.75 ms, comparable to previously reported RT lifetimes for Mn^{2+} doped CsPbCl_3 nanoparticles and bulk crystals at 1.10 ms and 0.70 ms, respectively.

Organic-Inorganic Gas Sensor Based on a Perovskite Nanocrystal-Conductive Polymer Hybrid

Duho Jang, Ming Hong and Yeong Don Park; Incheon National University, Korea (the Republic of)

We present a novel approach for fabricating organic-inorganic hybrid gas sensors by blending perovskite nanocrystals with a conductive polymer matrix. Organic semiconductors (OSCs) hold considerable potential as sensing materials for printed organic gas sensors. However, they face challenges in terms of

limited sensitivity and poor stability under ambient conditions, which hinder their development compared to inorganic-based gas sensors. To overcome these limitations, we have incorporated functional nanomaterials into the organic semiconductors. In this study, we introduce a perovskite-structured material, specifically CsPbBr_3 , into the conductive polymer matrix, resulting in a significant enhancement of the gas-sensing performance of the sensors while retaining their high responsivity and response rates. Moreover, we have employed a zwitterionic polymer surface modification with a hydration treatment to further improve the adsorption of target gas molecules on the perovskite surface. Our results demonstrate that the amide group of the encapsulation polymer exhibits a strong affinity towards NO_2 gas molecules, and this affinity is enhanced upon hydration of the polymer. Additionally, the presence of perovskite materials within the semiconducting polymer layer acts as a protective barrier, effectively shielding the polymer thin film against oxidation during extended storage under ambient conditions, owing to the perovskite crystals' ability to adsorb oxidizing molecules. This approach addresses the limitations of OSCs, resulting in improved gas-sensing performance, enhanced responsivity, and increased stability, thus paving the way for practical applications in gas sensing and detection.

8:00 PM EN05.11.10

Synergetic Effect of Aluminium Oxide and Organic Halide Salts on Surface Passivation and Stability Enhancement of Perovskite Solar Cells Eunyoung Choi^{1,2,3}, Jin-Won Lee⁴, Jae Sung Yun^{5,3} and Helen H. Park^{4,6}; ¹Diamond Light Source, United Kingdom; ²University of Cambridge, United Kingdom; ³University of New South Wales, Australia; ⁴Korea Research Institute of Chemical Technology (KRICT), Korea (the Republic of); ⁵University of Surrey, United Kingdom; ⁶University of Science and Technology (UST), Korea (the Republic of)

Although long-chain organic halide salts have been effectively used in three-dimensional (3D) perovskite-based solar cells for surface passivation, it has been reported that unexpected halide defects could be formed from the organic halide salts and the solvents used for dissolving the organic halide salts, which results in degradation of the devices. In this work, aluminium oxide (AlO_x) via atomic layer deposition (ALD) was introduced onto octylammonium iodide (OAI) on the perovskite layer to suppress the generation of undesired defects while still obtaining the benefits of organic halide salts. The devices incorporating AlO_x on OAI-treated perovskites (OAI/ AlO_x) show enhancement in both device performance and photostability compared to devices with only OAI surface passivation. Diffusion of aluminium from AlO_x into the perovskite is observed from surface characterization. Photo-generated carrier transport in both the surface and bulk of the perovskite absorber is investigated by wavelength-dependent surface photovoltage microscopy, and grazing-incidence-wide-angle X-ray scattering was utilized to investigate the crystallinity changes of the perovskite under prolonged illumination. The effects of the inorganic oxide layer on the stability and performance of organic halide salt-treated devices will be addressed, and the mechanisms involved in the enhanced performance and stability will also be discussed.

8:00 PM EN05.11.11

Off-Stoichiometric Perovskite Photodetectors for Direct Time-Of-Flight Distance Measurements Lorenzo J. Ferraresi^{1,2}, Sergey Tsarev^{2,1}, Sebastian Sabisch^{2,1}, Frank Krumeich², Vladyslav Hnapovskiy^{2,1}, Gebhard J. Matt², Sergii Yakunin^{2,1}, Ivan Shorubalko¹ and Maksym V. Kovalenko^{2,1}; ¹Empa—Swiss Federal Laboratories for Materials Science and Technology, Switzerland; ²ETH Zürich, Switzerland

Hybrid organic-inorganic metal halide perovskites have recently emerged as a promising alternative to conventional semiconductors for their use in optoelectronic devices such as vertical photodiodes, offering a tuneable band gap and near-unity quantum efficiencies. They can be deposited with facile and diverse

methods. The latest feat focused on reducing their defect density to minimise the noise and improve charge collection efficiencies. Yet the response times are limited by the devices' capacitance and, intrinsically, by the lifetime and transit time of the charge carriers. The capacitance limitation can be addressed only to a limited extent via the reduction of the active area of the photodiode, increasing in the meantime the fabrication complexity for comparable signal amplitudes. Alternative strategies focused on the intrinsic properties of semiconductors - such as exploiting the photo-Dember effect or engineering the defect-limited carrier lifetimes - elevated photodetectors to the femtosecond regime, and have yet to be considered for perovskite devices.

In this study, we explored controlled photocurrent quenching through the introduction of selective recombination sites, to obtain fast, one-mm² perovskite photodiodes with response times beyond their capacitance limitations. By choosing suitable charge transport layers, and by offsetting the perovskite precursor stoichiometry, the density of interfacial recombination sites can be controllably increased, as highlighted through an in-depth study of photocurrent transients under picosecond laser pulses. The device photo-response is tuned to observe an isolated sharp signal with ns decay and a 3-dB drop at 15 MHz, enabling the resolution of distances in the cm-range using direct time-of-flight measurements. These results are a major leap towards the development of wavelength-selective, cost-effective, and fast perovskite photodetectors with improved photo-response for Light Detection and Ranging (LiDAR) applications. LIDAR sensors are of paramount importance in highly automated processes and for self-driving cars.

8:00 PM EN05.11.12

Lead Halide Perovskites and Its Applications in Whispering Gallery Mode Micro-Lasing Subitan Laskar and C Sudakar; Indian Institute of Technology Madras, India

Ultrahigh luminescence quantum yield (~100%), low non-radiative recombination rates, and tunable spectral emissions from the ultraviolet to the visible range can be achieved through lead halide perovskites (LHP) (APbX₃; A= Rb⁺, Cs⁺, and X= Br⁻, I⁻); hence they are promising candidates for optoelectronics and photonics applications. However, a lack of atmospheric stability impedes their effective use as photovoltaic absorbers. Highly emissive perovskite quantum dots (PQDs) are being investigated to develop solar cells, efficient lasers, LEDs, etc. Here, we report the bandgap tunability and stability of APbX₃ PQDs synthesized through the hot-injection method. Structural characterization through X-ray diffraction (XRD) reveals highly phase pure cubic polymorph of PQDs. The A-site ions have a significant impact on the photophysical and chemical properties. Cs⁺ cations are substituted with Rb⁺ at the A site, and anionic X sites are substituted either with Br⁻ or I⁻ or a combination of halide ions in these PQDs to study the changes in structure and optical properties. With increasing Rb⁺ concentration, the bandgap of Cs_{1-x}Rb_xPbX₃ is shown to vary between 1.7 eV to 3.2 eV, as evident from the blueshift observed in the photoluminescence peak. Bandgap is also shown to be tunable by alloying I⁻ with Br⁻ in CsPbX₃ and Cs_{0.5}Rb_{0.5}PbX₃. The latter is found to be more stable than the former when stored in laboratory conditions. A detailed analysis will be presented on the effect of cationic and anionic substitution on the absorbance and emission spectra of PQDs. These quantum dots are further used for whispering gallery mode (WGM) lasing from PQDs coated on TiO₂ spherical microcavities. The photoluminescence emission from a CsPbI₃-QDs gain medium strongly couples with a TiO₂ microspherical resonating optical cavity. Spontaneous emission in these microcavities switches to a stimulated emission above a distinct threshold point of 708.7 W/cm². Quality factor as high as Q~1195 for WGM micro-lasing is demonstrated at room temperature. CsPbI₃-QDs/TiO₂ microcavities are found to be photostable even after continuous laser excitation for 75 minutes. [1] The CsPbI₃-QDs/TiO₂ microspheres are promising as WGM-based tunable microlasers. Results on WGM micro-lasing using

Updated as of October 28, 2024

Cs_{0.5}Rb_{0.5}PbX₃ will be presented.

Rigorous Optical Dispersion Data Analysis of Single Crystal MAPbBr₃ for Optimized Perovskite Solar Cell Active Layer Absorption Christopher McCleese^{1,2}, Michael C. Brennan^{1,3}, Lirong Sun^{1,3}, Nina Hong⁴, Nathan Episcopo⁵, C.V. Ramana⁵, Tod Grusenmeyer¹ and Peter Stevenson¹; ¹Air Force Research Laboratory, United States; ²General Dynamics Information Technology, United States; ³Azimuth Corporation, United States; ⁴J.A. Woollam Company, Inc., United States; ⁵The University of Texas at El Paso, United States

Lead halide perovskites have garnered significant attention for optoelectronic applications including photovoltaics, light-emitting diode, photodetector, and laser technologies. However, material quality and stability issues lead to a wide range of reported values for the electrical and optical properties which may complicate device design and optimization strategies for commercialization. Critical to the development of perovskite solar cells (PSC) are the optical properties (refractive index, n , and extinction coefficient, k), which describe the way perovskites interact with light and subsequently function as a photovoltaic material. Optimizing perovskite active layer absorption necessitates solar cell optical coating design iterations using material optical constants derived from rigorous optical dispersion data analysis. The refractive index and extinction coefficient for MAPbX₃ have been observed to significantly vary in the literature depending on the processing methodologies. If such optical dispersion variation is ignored in practice at the design stage, PSCs can exhibit parasitic device absorption by non-perovskite (non-active) layers resulting in variable optical transmission, reflectance, or haze-like characteristics within solar radiation bands of interest (300-2500 nm). To our knowledge, no comprehensive experimental optical dispersion data analysis to derive the optical constants of MAPbX₃ has been performed to include notable anomalous optical dispersion characteristics including the band edge transition (bandgap ~539 nm) and methylammonium spectral overtones below the band edge (observed within 1050-2050 nm). As such, the optical property determination of exemplary MAPbX₃ has been largely under approximated and, consequently, evokes optical property uncertainty with respect to prior reports. Proper fundamental derivation of MAPbX₃ optical constants is critical toward the development of high-performance electronic and optoelectronic perovskite devices. Here, we present a rigorous optical dispersion data analysis of single crystal MAPbBr₃ via variable angle spectroscopic ellipsometry appended with transmission intensity spectra to provide a robust derivation of the optical constants for normal and anomalous optical dispersion regimes. Using derived optical constants for our single crystal MAPbBr₃, exemplary modeled solar cell optical device designs are optimized for perovskite layer absorption and we compare our derived optical properties to illustrative MAPbBr₃ literature values reported to-date.

8:00 PM EN05.11.16

The Quest for the Missing Link – From Lead Complexes to Perovskite Formation Kai O. Brinkmann¹, Timo Maschwitz¹, Lena Merten², Feray Ünlü³, Andreas Kotthaus¹, Cedric Kreusel¹, Manuel Theisen¹, Henrik Weidner¹, Jaffres Anael Morgane⁴, Alexander Hinderhofer², Christian Wolff⁴, Stefan F. Kirsch¹, Sanjay Mathur⁵, Frank Schreiber² and Thomas Riedl¹; ¹Bergische Universität Wuppertal, Germany; ²University of Tübingen, Germany; ³Helmholtz-Zentrum Berlin für Materialien und Energie, Germany; ⁴École Polytechnique Fédérale de Lausanne, Switzerland; ⁵University of Cologne, Germany

Perovskite solar cells currently enter a stage, where market introduction is within reach. For serious upscaling, control over the quality of the perovskite material is most critical. To this end, the community currently relies heavily on laboratory experience, engineering, and fine-tuning approaches. A key challenge is the controlled growth of perovskite crystallites while processing thin films. Several strategies are currently in use, such as like anti-solvent or additive engineering. While the impact of these strategies is well-evidenced in the resulting layers, the underlying mechanisms that govern the crystallization process are still subject to a vigorous debate. A frequently cited theory is that the nuclei for the perovskite crystallization evolve from intermediate $\text{Pb}^{2+}\text{-MA}^+\text{-I}^-$ -solvate clusters. [1] A dominant role of solvate clusters implies a strong impact of complexing and coordination in the precursor solution on the crystallization process. Reports of the colloidal structures and Lewis-base-acid interactions in the perovskite precursor ink seemingly support this theory. [2] As of yet, however, insights that unambiguously link the complex formation in the precursor inks to the perovskite formation are lacking. We present a holistic approach in which we study the entire course of perovskite formation. We begin with a study of lead complexation in the precursor stage (using NMR and electrical conductivity measurements in the solution) and proceed with in-situ GIWAXS investigations during thin film deposition and along the way to thin film formation (bare layers and solar cells). We systematically study the impact of common solvents like DMF, DMSO and NMP. As an exemplary additive, to study the influence of Lewis-base additives, we chose thiourea, which is a strong sulphur donor and an effective crystallization mediator. With ^{207}Pb NMR and conductivity studies, we found a strong and systematic impact of the choice of solvents on the formation of lead complexes in the precursor solution, as well as indications, that may imply the presence of 3D corner sharing structures already in the precursor ink. Importantly, the differences in lead complexation depending on the solvent apparently diminish with increasing the concentration of the precursor ink; the final grain sizes remained largely unaffected by even strong variations found in the diluted precursors. On the other hand, the addition of thiourea did not affect the nature of lead complexes in the precursor solution. By in-situ GIWAXS, we are finally able to identify the annealing step as the decisive stage, where the presence of the additive affects the formation of perovskite grains and their crystallographic orientation. We could further substantiate our interpretation by FTIR studies. As such, for the first time, we provide a convincing link between precursor chemistry and final thin film formation.

All-Solution-Processed Fabrication of Intrinsically Flexible Multicolor Perovskite Light-Emitting Diodes and Photodetectors on Diverse Substrates (Elastomer, Paper, Textiles, etc.) Junyi Zhao and Chuan Wang; Washington University in St. Louis, United States

Owing to the unique properties such as tunable bandgap and strong optical absorption, perovskite holds great potential for optoelectronic device applications. Although significant progress has been made to explore high-performance light-emitting diodes (LEDs) and photodetectors (PDs) using perovskite, existing fabrication techniques based on the rigid substrate are unable to meet the growing demand from large-area flexible displays. In this work, we report all-solution-processed perovskite LEDs (PeLEDs) and photodetectors (PePDs) fabricated on various unconventional substrates commonly found in our daily life, including paper, textiles, plastics, rubber, metal, and even three-dimensional surfaces using a

versatile and low-cost direct writing approach. Compared to conventional spin-coating and vacuum-evaporation processes, the direct writing approach enables mask-free patterning and allows even untrained individuals to “draw” a batch of high-performance LEDs/PDs in a time-efficient and energy-saving manner. A significant challenge when implementing optoelectronic devices on paper and textiles is the rough surface morphology of yarn and fiber networks, which can lead to nonuniform film thickness and leakage current. To address this issue, we have demonstrated that blending ionic polymer poly(ethylene oxide) (PEO) with poly(3,4-ethylenedioxythiophene) polystyrene sulfonate (PEDOT:PSS) not only enhances the conductivity and flexibility of the polymer conductors, but also achieve local self-planarization. For the emissive layer, we have successfully achieved multicolor LEDs covering the entire visible spectrum on both paper and textile substrates by substituting halide elements in the perovskite material (MAPbX_3) and formulating inks with varying halide compositions. Meanwhile, the brightness and efficiency of LEDs could be further boosted by introducing the butylammonium (BA) group to reduce the perovskite structure dimensionality to form 2D Ruddlesden–Popper perovskite (RPP) structures. Furthermore, we have conducted systematic investigations on perovskite-polymer composites and demonstrated that the morphology and optoelectronic properties of the perovskite photoactive layer can be tuned by incorporating different polymer additives. Specifically, PEO allows for precise and smoother perovskite film deposition by tuning ink rheology and viscosity, while polystyrene (PS) increases the density and uniformity of crystal arrangement, resulting in improved LED brightness and reduced current leakage. Poly(methyl methacrylate) (PMMA) helps reduce grain defects and boundaries, benefiting carrier diffusion in photodetectors. The PeLEDs written on paper substrates exhibited a brightness as high as $15,225 \text{ cd m}^{-2}$, a current efficiency of 6.65 cd/A , and a turn-on voltage of 2.4 V . Owing to the extraordinary flexibility of each functional layer, the written LEDs on the paper substrate could be bent to a 1 mm extreme curvature radius for over 5000 cycles without decay in performance. In summary, the written perovskite optoelectronic devices are ideally suited for low-cost and large-area emerging application scenarios such as deformable displays, wearable E-Textiles, E-Papers, and E-packaging.

Enhancing Efficiency of Quasi-2D PeLEDs Through Anti-Solvent Treatment-Induced Phases Modulation Lyuchao Zhuang, Qi Wei, Chuanzhao Li and Shu Ping Lau; The Hong Kong Polytechnic University, Hong Kong

Quasi-2D perovskite has drawn considerable attention for application in perovskite light-emitting diodes (PeLEDs) due to their higher exciton binding energy and moisture resistance. However, the inhomogeneous distribution of phases formed in spin-coated quasi-2D perovskite films inevitably leads to energy transfer loss, limiting the emission performance. Here, we systematically investigated the phases modulation behavior for a series of anti-solvent with different polarity -namely, the toluene (TO), diethyl ether (DE), chlorobenzene (CB), anisole (AN), ethyl acetate (EA). Due to the strong hydrogen bonding interaction between EA and organic spacer cations, it will hinder the organic and $[\text{PbBr}_6]^{4-}$ combination. The crystallization rate of intermedia phases slows, resulting in a large proportion of high-n phases formation subsequently. As a result, an efficient energy cascade is ensured with a narrow distribution centered around the desired phases. Leveraging these insights, we achieved PeLEDs with improved external quantum efficiency (EQE) of 4.21%, 7.11%, and 8.77%, corresponding to $\sim 490 \text{ nm}$, $\sim 497 \text{ nm}$, and $\sim 503 \text{ nm}$ emissions, respectively. Furthermore, the anti-solvent treatment strategy provides a guide to regulate the phase distribution for eliminating energy transfer loss to fabricate efficient quasi-2D PeLEDs.

8:00 PM EN05.11.19

Ionization of Hole Transport Materials as a Method for Improving the Photovoltaic Performance of Inverted Perovskite Solar Cells Wen-ren Li¹, Yogesh Tingare², Chaochin Su², Dibyajyoti G Hosh³, Hsinhan Tsai⁴, Wanyi Nie⁴, Chien-Hsiang Lin¹, Sheng-Chin Chou², Ning-Wei Lai² and Xin-Rui Lew¹;
¹National Central University, Taiwan; ²National Taipei University of Technology, Taiwan; ³Indian Institute of Technology Delhi, India; ⁴Los Alamos National Laboratory, United States

Increasing energy demands and concerns over global warming have led to a focus on the development of solar energy technologies. Perovskite solar cells (PSCs) have emerged as one of the most promising photovoltaics and are being investigated extensively. In inverted PSCs, hole transport materials (HTMs) assist directional charge transfer and electron blocking and also play an critical role in forming large-grained perovskites which enhance cell performance. In this work, we demonstrate a strategy for increasing the power conversion efficiency (PCE) of the device by ionizing HTMs, which introduces hydrophilicity into the HTM, improved interfacial properties, and excellent surface topographies. A comparative study of different ionizing counter anions showed that ionization also affects the absorption and emission properties, energy levels, and hole mobility of HTMs. Perovskite morphology significantly impacts PSC performance, and the anion groups like sulfoxide, SCN⁻, and iodide contribute effectively to the film formation and defect passivation of perovskites. Ionic dopant-free HTM with iodide entity was found to efficiently passivate the dominant surface halogen vacancy due to its smaller size, lowering the density of charge-trapping defect states and achieving a hysteresis-free power conversion efficiency of 20.46%, which was 1.71% higher than that of the non-ionic HTM. Detailed research and analysis using atomistic modeling were also investigated, providing valuable insights into the correlation between anion size and perovskite passivation and efficiency. Durability is an important aspect in PSCs and can be assisted by a suitable HTM. As result, the devices based on HTM with iodide and non-ionic HTM retained 97% and 89%, respectively, of their original PCE for 500 hours, but the device fabricated with PEDOT: PSS retained about 81% of its PCE for the same time. This study provides a technologically relevant solar cell demonstration with a mechanistic understanding of the interfacial material design. Studying other charged molecules with varying properties and sizes as counterions to develop high-performing PSCs will also be reported in the meeting.

8:00 PM EN05.11.20

Comparative Study of Shelling CsPbBr₃ Quantum Dots with CdS and TiO₂ Noah J. Pitcher, Bryce Baird-Taylor, Daniel Muscato, Isak Hurtic and Yiliang (Yancy) Luan; Binghamton University, The State University of New York, United States

Halide perovskites (HP) have been attractive in the development of optoelectronics due to their many favorable properties, such as high efficiency and adjustable band gap. However, HP are unstable when exposed to an ambient atmosphere, including varying moisture, light, and heat, which limits their applications. Furthermore, HP quantum dots (QDs) have enhanced properties and improved stability compared to perovskite thin films because of the quantum effect. However, better stability is still desired for the introduction of HPQDs into optoelectronics. Shelling engineering is a powerful method that can boost the stability of nanomaterials. Nevertheless, it is still challenging to effectively shell HPQDs due to the harsh conditions required by the process. In this report, we will present the shelling of CsPbBr₃ QDs with titanium dioxide (TiO₂) and cadmium sulfide (CdS), respectively. The two shelling methods will be demonstrated in parallel with each of the protocols, structures, and properties of the products. Our results indicate that the shelling with CdS was successfully achieved, while the QDs collapsed during the shelling with TiO₂. Additionally, the photoluminescence of our HPQDs is dependent on the amount of CdS introduced during shelling. This research does not only demonstrate successful shelling of HPQDs

with CdS, but also yields constructive insights for the shelling engineering of nanomaterials.

8:00 PM EN05.11.21

Performance of Flexible MAPbI₃ Solar Cells Made on Different Transparent Conducting

Electrodes with Different Hole Transport Layers Bishal Bhandari, Robert Piper, Justin C. Bonner and Julia W. Hsu; The University of Texas at Dallas, United States

Perovskite solar cells (PSCs) have gained interest as a viable technology in recent years because of their low fabrication cost, solution processability, and high-power conversion efficiency. Commercializing perovskite solar cells requires high-throughput and low-cost manufacturing, e.g., solution-based roll-to-roll (R2R) process for making flexible PSCs. Transparent conducting electrodes (TCEs) are critical for flexible PSCs to achieve high efficiency. In our laboratory, flexible hybrid TCEs are made on polyethylene terephthalate (PET) with R2R flexographically printed Ag metal lines by blade coating silver nanowires (AgNWs) and planarized with indium zinc oxide (IZO) on top, and then the entire stack is photonic cured. With this process, we achieve TCEs with transmittance averaged between 400 and 700 nm wavelengths (T_{avg}) = 81 ± 0.4 %, sheet resistance (R_{sh}) = 11 ± 0.5 Ω/sq , and root-mean-square surface roughness (σ_{rms}) = 4.3 ± 0.4 nm. Flexible PSCs were fabricated on the hybrid TCEs and compared to devices made on commercially available PET/TCEs. We also investigated the J-V characteristics of these flexible PSCs using different hole transport layer materials. TCEs with comparable electrical, optical, and morphological properties displayed varied J-V performance with different hole transport layers. These results are surprising because, normally, other than transmittance and sheet resistance, TCEs are not considered to have a great effect on solar cell performance. We perform additional studies to probe the factors that influence the J-V characteristics of these flexible PSCs, such as contact resistance losses and interfacial properties between the TCE and the charge transport layers. The size of devices is also varied to study upscaling behavior. We aim to understand the charge extraction and recombination process and gain insights into the underlying mechanism affecting the performance and efficiency of flexible PSCs.

Effects of Van der Waals Interactions on Excitonic Properties of Lead Halide Perovskite

Photovoltaic Materials Amir A. Farajian; Wright State University, United States

Excitons dissociation and diffusion are among the key properties that determine the efficiency of light harvesting in photovoltaic materials. As representatives of a promising category of novel photovoltaics, lead halide perovskites include both bonding and non-bonding interactions. In order to assess, and engineer, excitonic properties of these materials, theoretical calculations can complement experimental results to determine the effects of van der Waals interactions. The focus of this work is to utilize density functional theory simulations that explicitly incorporate van der Waals interactions to estimate excitonic properties. The results reveal how van der Waals interactions affect key excitonic characteristics, e.g., binding energies and effective masses, and help determine strategies for constituent selection towards improving light-harvesting efficiency.

SESSION EN05.12: Structure Property Relationships in Halide Perovskites I

Update on The Synthesis and Surface Chemistry of Highly Luminescent Lead Halide Perovskite Nanocrystals Maksym V. Kovalenko^{1,2}; ¹ETH Zurich, Switzerland; ²Empa–Swiss Federal Laboratories for Materials Science and Technology, Switzerland

Colloidal lead halide perovskite (LHP) nanocrystals (NCs), with bright and spectrally narrow photoluminescence (PL) tunable over the entire visible spectral range, are of immense interest as classical and quantum light sources. Severe challenges LHP NCs form by sub-second fast and hence hard-to-control ionic metathesis reactions, which severely limits the access to size-uniform and shape-regular NCs in the sub-10 nm range. We show that a synthesis path comprising an intricate equilibrium between the precursor (TOPO-PbBr₂ complex) and the [PbBr₃⁻] solute for the NC nucleation may circumvent this challenge [1,2]. This results in a scalable, room-temperature synthesis of monodisperse and isolable CsPbBr₃ NCs, size-tunable in the 3-13 nm range. The kinetics of both nucleation and therefrom temporally separated growth are drastically slowed, resulting in total reaction times of up to 30 minutes. The methodology is then extended to FAPbBr₃ (FA = formamidinium) and MAPbBr₃ (MA = methylammonium), allowing for thorough experimental comparison and modeling of their physical properties under intermediate quantum confinement. In particular, NCs of all these compositions exhibit up to four excitonic transitions in their linear absorption spectra, and we demonstrate that the size-dependent confinement energy for all transitions is independent of the A-site cation. We then show that this synthesis – relying on the labile ligand capping with TOPO-phosphinic acid mixture – makes for a convenient platform for the subsequent surface functionalization with diverse capping ligands [3]. Robust surface functionalization of highly ionic surfaces, as is the case of LHP NCs, has remained a formidable challenge due to the inherently non-covalent weak surface bonding. Leveraging the vast and facile molecular engineering of phospholipids, we present their efficacy as surface-capping ligands for LHP NCs. Molecular dynamics simulations and solid-state NMR confirm that the surface affinity of these zwitterionic molecules is primarily governed by the geometric fitness of their anionic and cationic moieties. Judicious selection of the ligands yielded colloiddally robust FAPbBr₃ and MAPbBr₃ NCs and enabled colloids in a variety of solvents, from n-hexane to alcohols. We will discuss the atomistic details of the ligand surface binding, ranging from conventional alkylammonium ligands [4] to diverse zwitterionic moieties. In particular, we show that solution and solid-state NMR readily captures the surface binding motifs and the impact of the ligands on the surface structure of CsPbX₃ NCs [5]. We also present non-hydrolytic coating of perovskites with amorphous metal oxides [6] and exploration of other semiconductive perovskite NCs within the AMX₃ perovskite family.

High-Performance Perovskite Solar Cells Incorporated with Conjugated Organic Molecules Lening Shen, Tao Zhu and Xiong Gong; The University of Akron, United States

In the past years, perovskite solar cells (PSCs) as alternative cost-effective solar technology have drawn great concentrations in both academic and industrial sectors. High power conversion efficiency (PCEs) has been reported from the PSCs based on three-dimensional (3D) perovskites, but 3D perovskites are sensitive to moisture and air. Moreover, unbalanced charge transport within perovskites restricts further boost PCEs of PSCs. In this presentation, we reported efficient and stable PSCs based on either the perovskite: polymer bulk heterojunction composites or ternary perovskite-organic composites. Systemically studies demonstrated that an extended spectral absorption, enhanced and balanced charge transport, improved film morphology, enlarged crystallinity, and suppressed ion immigration movement were observed from the above two different systems compared to those based on the 3D perovskites. As a result, PSCs with over 23 % PCEs, dramatically enhanced stability, and suppressed photocurrent hysteresis were demonstrated. These results indicated that our studies provided a facile and promising way to realize high-performance PSCs, where perovskites are incorporated with conjugated organic molecules.

Achieving Metal Doping of Strongly Confined Perovskite Nanocrystals under Ambient Conditions Zachary VanOrman, Mateo C. Wuttig and Sascha Feldmann; Harvard University, United States

Halide perovskite (HP) nanocrystals (NC) hold great promise for optoelectronic applications due to their high photoluminescence (PL) quantum yields and energetic tunability *via* composition and size.¹ Further, doping M^{2+} metal cations into the HP lattice can enhance the radiative rate of the NC emission, and, in the case of manganese, it can simultaneously introduce an additional decay pathway in the form of long-lived Mn d-d orange PL.^{2,3} However, so far, M^{2+} -doped $CsPbCl_3$ NC synthesis relies on hot injection, making it challenging to achieve strongly confined NCs.⁴ Recently, a novel synthesis method has been reported for HP NCs using complexation agents, resulting in the capability of synthesizing strongly confined HP NCs.⁵

Using the complexation agent synthetic approach, we now show that facile M^{2+} doping of $CsPbX_3$ NCs for various dopants (Mn, Ni, Zn) can be achieved, without the necessity of inert synthesis conditions or high temperatures.⁶ This gives access to a highly controlled size-dependence series for doped NCs, especially in the strongly confined regime (down to ~ 3.5 nm) which was previously inaccessible for doped perovskite NCs. We demonstrate that doping Mn and other divalent transition metals can vary the optical properties in vastly different and opposing ways, depending on the degree of quantum confinement and doping concentration. The presented work therefore not only outlines a new and improved synthetic approach for doped HP NCs but also elucidates the impact of metal doping on the resulting optical properties under confinement.

Enabling Robust Chemical State Analysis of Sn-Based Perovskites via Auger Parameter Analysis in XPS Alexander Wieczorek and Sebastian Siol; Empa - Swiss Federal Laboratories for Materials Science and Technology, Switzerland

Sn-based perovskites exhibit compelling properties such as reduced toxicity and lowered band gaps over those purely based on Pb. As a result, they are of increasing interest for photovoltaic applications in single-junction and all-perovskite tandem applications.^[1]

For high performances, control of the oxidation state and interfacial chemistry is paramount, which can be determined using X-Ray photoelectron spectroscopy (XPS). However, the minor chemistry related shifts of the Sn core level emission complicate the analysis, especially for semiconducting materials. Here, surface band-bending as well as differences in the work function can be particularly pronounced

In this presentation, we demonstrate that studies based on the modified Auger parameter α' provide a robust method to resolve different chemical states in Sn-based perovskites. Using a set of reference samples, we identified a high sensitivity to the halide, resulting in a shift of up to $\Delta\alpha' = 2$ eV between ASnI₃ and ASnBr₃-type polycrystalline perovskite thin-films.^[2] Observed dependencies of α' on the Sn oxidation state and local chemistry provide a framework that enables reliable tracking of degradation as well as X-site composition for Sn-based perovskites and related compounds. More recently, we successfully applied this framework on Sn-based perovskite nanocrystals to ensure the absence of Sn(IV) impurities upon optimized synthesis procedures.^[3]

The higher robustness and sensitivity of such studies not only enables more in-depth surface analysis of Sn-based perovskites than previously performed, but also increases reproducibility across laboratories. Due to the facile data analysis, this method is ideal for high-throughput studies that are increasingly being adopted in the development of new semiconducting materials.^[4]

Advancements in Pulsed Laser Deposition of Hybrid Halide Perovskites [Monica Morales-Masis](#);
University of Twente, Netherlands

In this presentation, we present recent progress in utilising Pulsed Laser Deposition (PLD) as a vacuum-based single-source deposition method for a wide range of hybrid and organic halide perovskites. We address the specific challenges associated with hybrid film growth, such as incompatible volatility and solubility, by employing laser ablation of a solid target containing dry perovskite precursors. The quality of the thin films can be tuned by controlling parameters like laser fluence, target composition, and process pressure.

The first part of the presentation focuses on the development of $\text{MA}_x\text{FA}_{1-x}\text{PbI}_3$ and $\text{Cs}_x\text{FA}_{1-x}\text{PbI}_3$ absorbers with tunable MA/FA ratios, as determined by XPS, NMR, and microstructure analysis. We demonstrate P-i-n solar cell devices incorporating PLD $\text{MA}_x\text{FA}_{1-x}\text{PbI}_3$ absorbers with power conversion efficiencies exceeding 17%.

The second part of the presentation highlights the epitaxial formation of PLD-grown MAPI_3 and CsPbI_3 on lattice-matched substrates. PLD enables precise control over film thickness and deposition rate, which facilitates the investigation of polymorph stabilization, and the impact of strain on the optoelectronic properties of perovskite materials.

By combining controlled growth through PLD with insights into structural-property relationships, we can pave the way for designing a new generation of complex, stable, and non-toxic hybrid perovskite films.

A 0-D Barrier Layer Increases Stability in Mixed Sn-Pb and All-Perovskite Tandem Cells

[Chongwen Li](#)^{1,2}, Lei Chen³, Fangyuan Jiang⁴, Zhaoning Song³, Bin Chen¹, Xiaoming Wang³, Esma Ugur⁵, Adam Balvan¹, Xuefei Wu⁶, Zachary Fink⁶, Carlo Andrea Riccardo Perini⁷, Juan-Pablo Correa-Baena⁷, Zheng-Hong Lu², Thomas Russell⁶, Stefaan De Wolf⁵, Mercouri G. Kanatzidis¹, David S. Ginger⁴, Yanfa Yan³ and Edward Sargent¹; ¹Northwestern University, United States; ²University of Toronto, Canada; ³The University of Toledo, United States; ⁴University of Washington, United States; ⁵King Abdullah University of Science and Technology, Saudi Arabia; ⁶Lawrence Berkeley National Laboratory, United States; ⁷Georgia Institute of Technology, United States

Perovskite tandem solar cells promise performance beyond the detailed balance limit of single-junction solar cells; however, non-radiative recombination and its progressive worsening with time, especially in the mixed Sn–Pb low-bandgap layer, currently limit performance and stability. We find that mixed Sn–Pb perovskite thin films exhibit a compositional gradient, with an excess of Sn on the surface – and we show this gradient exacerbates oxidation and increases the the rate of recombination. We develop a materials processing strategy wherein diamines preferentially chelate Sn atoms, removing them from the film

surface and achieving a more balanced Sn:Pb stoichiometry, making film surface resistive to Sn oxidation. This process forms electrically-resistive low-dimensional barrier layers, passivating defects and reducing interface recombination. Further regulating the dimensionality of the barrier layer to 0-D using 1,2-diaminopropane results in more uniform distribution and passivation. Tandems achieve a power conversion efficiency of 28.8%. Encapsulated tandems retain 90% of initial efficiency following 1000 hours operating at the maximum power point under simulated one-sun illumination in air without cooling.

10:30 AM EN05.12.07

Interlayer Ordered Mixed-Spacer 2D Halide Perovskites Xiaotong Li¹, Hao Dong², George Volonakis³, Constantinos C. Stoumpos⁴, Jacky Even³, Claudine Katan³, Peijun Guo² and Mercouri G. Kanatzidis¹; ¹Northwestern University, United States; ²Yale University, United States; ³University of Rennes, France; ⁴University of Grete, Greece

Two-dimensional (2D) halide perovskites exhibit extraordinary stability and structural tunability because they can incorporate different organic cations as spacers. Their structures can be divided into the Ruddlesden-Popper (RP) and Dion-Jacobson (DJ) phases depending on the spacers. When different spacers are mixed into one perovskite structure, they are usually disordered and occupy the same interlayer space. In this work, we demonstrate that when cyclic 1,2,4-triazolium (Tz) is used as a spacer and combined with another linear spacer such as propylammonium (PA) or butylammonium (BA), the interlayer ordered mixed-spacer 2D perovskites can form. The Tz and PA (BA) spacers occupy separate interlayer spaces and show two different interlayer distances. The octahedra next to the Tz spacers resemble the stacking of the DJ phase while those adjacent to the PA (BA) layers exhibit the stacking of the RP phase. The bandgaps of (PA)(Tz)PbBr₄ and (BA)(Tz)PbBr₄ are in between the parent $n = 1$ compounds ((PA)₂PbBr₄ or (BA)₂PbBr₄, and (Tz)₂PbBr₄). DFT calculations suggest that the band structures of (PA)(Tz)PbBr₄ and (BA)(Tz)PbBr₄ combine features from parent compounds yet differ from a simple superposition. This way, we are able to combine the properties of different spacers (cyclic and linear, aromatic and aliphatic) in one structure. This work expands the structure types in 2D perovskites and suggests many possible combinations of spacer cations for all kinds of optoelectronic applications.

All-Inorganic Quantum Dot in Perovskite PbS-CsPbBr₃ for High Energy Radiation Scintillation Grayson C. Johnson, Haritha Rajeev, Sammy Fieser, Seung-Hun Lee and Joshua Choi; University of Virginia, United States

Efficient and stable scintillators are crucial for medical imaging, high energy physics, security, and other fields. However, current scintillators are typically produced as single crystals in energy intensive, high-cost processes. Recently, inorganic-organic quantum-dot-in-lead halide perovskites compatible with scalable, low-cost, and large area manufacturing have been synthesized to address these shortcomings. Still, organic components result in lower stability of 3D lead halide perovskites compared to their all-inorganic counterparts. Here, we synthesize all-inorganic PbS quantum dot in CsPbBr₃ perovskites at the gram scale and demonstrate their utility as an ionizing radiation scintillator. Emissions under X-ray excitation span from 1400 nm to 1000 nm depending on the PbS quantum dot size. This material retains luminescent activity after exposure to ambient conditions at least 3 times longer than the PbS quantum dots in hybrid methylammonium lead bromide perovskites. Finally, this material was successfully pressed into bulk, polycrystalline pellets that may be used as individual pixels for high energy radiation detection

devices.

11:00 AM *EN05.12.09

Defects Activity in Metal Halide Perovskites Annamaria Petrozza; Istituto Italiano di Tecnologia, Italy

Bandgap tuning is a crucial characteristic of metal-halide perovskites, with benchmark lead-iodide compounds having a bandgap of 1.6 eV. To increase the bandgap up to 2.0 eV a straightforward strategy is to partially substitute iodine with bromine in so-called mixed-halide lead perovskites. Such compounds are prone, however, to defect-induced halide segregation resulting in bandgap instabilities, which limits their application in tandem solar cells and a variety of optoelectronic devices. The optimization of the perovskite composition and surface passivating agents can effectively slow down, but not completely stop, such light-induced instabilities. Here I will show how we identify the defect and the relative intra-gap electronic state/charge carrier dynamics that triggers the material transformation and bandgap shift. It allows us to engineer the perovskite band edge energetics by engineering the chemical composition of the perovskite crystalline unit to radically deactivate the photo-activity of such electronic states and stabilize the perovskite bandgap over the entire spectral range above 1.6 eV. Overall, I will show how the photo-instability of lead based single and mixed halide perovskites, which can be seen as photo-degradation and bandgap photo-destabilization, has the same root. Then, I will conclude my lecture showing how, by halides alloying, we can achieve photo-stable bandgaps in a broad spectral range from NIR to 2 eV, in tin-based perovskites. Here, the defect chemistry modulates the electronic property of the semiconductor switching from a highly p-doped to an intrinsic one

11:30 AM EN05.12.10

Structural and Photophysical Consequences of the Interplay Between Cations in 2D Ruddlesden-Popper Metal Halide Perovskites Willa Mihalyi-Koch¹, Giulia Folpini², Daniele Cortecchia², Kyana M. Sanders¹, Annamaria Petrozza² and Song Jin¹; ¹University of Wisconsin–Madison, United States; ²Istituto Italiano di Tecnologia, Italy

2D hybrid lead halide perovskites have been widely studied for optoelectronic and photovoltaic applications. Given the toxicity of lead, there is renewed interest in lead-free 2D halide perovskites including those based on Sn²⁺ and Ge²⁺. Changing the B-site metal cation can have structural consequences due to different ionic radii and lone pair activity. Here, we report a series of 2D Ruddlesden-Popper metal iodide perovskites based on a new spacer cation, 4-bromo-2-fluorobenzylammonium that contain different B-site [Pb, Sn, Ge] and A-site cations [Cs, methylammonium (MA), and formamidinium (FA)]. Comparing across 8 crystal structures, we investigate the structural changes that result from varying the cations and the dimensionality of the perovskite (*i.e.*, $n = 1, n = 2$, vs. 3D). Strong lone pair effects and reduced B-site radii lead to distinct changes in the octahedral tilting and spacer cation packing in the Ge-based perovskites, while the Sn and Pb-based perovskites are structurally analogous. Although the Ge perovskites exhibit weak, broad photoluminescence (PL), the PL emission from the Sn and Pb perovskites containing the 4Br2FBZ spacer cation appears bright and color-pure at room temperature. However, through temperature-dependent photoluminescence and lifetime measurements, we reveal that the photophysical behaviors of the Sn and Pb 2D perovskites are different despite their structural similarities. Understanding the interplay of cation effects and the impact on the optoelectronic properties is important for informed materials design of lead-free 2D perovskites.

11:45 AM EN05.12.11

Controlling Phase Transitions in 2D Perovskites with Organic Cation Alloying Rand Kingsford and Connor G. Bischak; The University of Utah, United States

Ruddlesden-Popper (RP) two-dimensional perovskites are quantum well materials with alternating layers of organic cations and inorganic octahedral layers. These materials have numerous applications due to their optoelectronic properties, including light-emitting diodes and photodetectors. RP perovskites also undergo structural phase transitions at relatively low temperatures, in which the organic layers undergo an ordered-to-disordered transition. Here, we present a synthetic strategy to tune the structural phase transition temperature of RP perovskites by alloying hexylammonium (HA) and pentylammonium (PA) cations. We also explore the connection between this phase transition and changes in the emissive properties of RP perovskites. Surprisingly, we find that HA_2PbI_4 and PA_2PbI_4 exhibit different changes in emissive properties upon undergoing the phase transition: the photoluminescence spectrum of HA_2PbI_4 decreases in intensity and blueshifts and the photoluminescence spectrum of PA_2PbI_4 exhibits an increase in intensity and redshifts. We attribute these changes in the photoluminescence spectra of HA_2PbI_4 and PA_2PbI_4 to changes in the degree of octahedral distortion. Last, we leverage changes in the photoluminescence of HA_2PbI_4 and PA_2PbI_4 to directly observe phase transition dynamics with photoluminescence microscopy. Our study represents an important step towards understanding couplings between structural dynamics and changes in optical properties in RP perovskites.

SESSION EN05.13: Structure Property Relationships in Halide Perovskites II

1:30 PM *EN05.13.01

From 2D to 3D Metal Halide Perovskites Nanostructures Loredana Protesescu; University of Groningen, Netherlands

Metal halides perovskites with nanoscale geometries have revolutionized the field of solution-processed photovoltaics and light-emitting devices due to their strong absorption and exceptional photoluminescence properties combined with a remarkable tolerance to structural defects. However, the further development of these materials to practical commercialization is hindered by their toxic components like lead and their inherent structural lability. Moreover, we still have little understanding of their crystallographic structures, chemical and physical interactions, and surface chemistry at a fundamental level.

The chemical design of metal halide perovskites proved to be the key to addressing those issues. Our recent findings confirm that a direct transition of the synthetic approach at nanoscale from Pb to Sn halide perovskites is not feasible. For Sn-based perovskites nanostructures, the structural dynamics between 3D cuboids and 2D Ruddlesden-Popper nanosheets colloids are highly dependent on the synthetic strategy. The presence of both species has a direct impact on the optoelectronic properties. Moreover, heterostructures containing halide perovskites nanocrystals are the next step towards obtaining accessible materials for industry. With the help of polymers or metal-organic frameworks, we can access air stable materials or ultra-small quantum dots.

2:00 PM EN05.13.02

Nearly Perfect Perovskites: Disorder and Anharmonicity in APbBr₃ (A = MA⁺, FA⁺, Cs⁺) Nicholas J. Weadock¹, Cameron MacKeen², Kiley Mayford², Xixi Qin³, Julian Vigil⁴, Yevgeny Rakita⁵, Hemamala Karunadasa⁴, Volker Blum³, Michael F. Toney¹ and Frank Bridges²; ¹University of Colorado at Boulder, United States; ²University of California, Santa Cruz, United States; ³Duke University, United States; ⁴Stanford University, United States; ⁵Ben-Gurion University of the Negev, Israel

Lead halide perovskite (LHP) semiconductors remain at the forefront of materials for high-performance optoelectronic devices. A defining characteristic of LHPs is the low point defect formation energy, yielding point defect concentrations as high as 10¹⁵ cm⁻³ [1]. This high defect concentration, combined with ionic bonding and a soft lattice [2], suggests a high degree of both static and thermally induced disorder in LHPs.

Here, we use extended X-ray absorption fine structure (EXAFS) and single-crystal X-ray diffraction (XRD) measurements to characterize disorder in the nearest neighbor Pb-Br bond for MAPbBr₃, FAPbBr₃, and CsPbBr₃. Surprisingly, the static disorder for all compositions is negligible, with low temperature disorder dominated by zero-point-motion. The disorder becomes significant as the temperature is increased, with subtle changes in bond character observed for MAPbBr₃ and FAPbBr₃. The high degree of thermal disorder manifests as an asymmetric Pb-Br pair distribution function (PDF), observable even at low temperatures of 150 K. Several origins of this asymmetry have been proposed, including single-site anharmonic potentials [3,4] and Pb split-sites [5,6]. We compare several asymmetric models to the experimental PDFs obtained from EXAFS and demonstrate that the asymmetry arises from an anharmonic interatomic potential.

Our results improve the understanding of point defects and intrinsic doping in LHPs: although the defects are charged, a lack of static disorder from coulombic interactions confirms the near complete ionization of these defects at room temperature. Finally, we will discuss the possibility of implementing these “nearly perfect” crystals for low temperature applications in quantum computing.

NJW, XQ, VB, and MFT gratefully acknowledge full support from the Center for Hybrid Organic Inorganic Semiconductors for Energy (CHOISE), an Energy Frontier Research Center funded by the Office of Basic Energy Sciences, Office of Science within the U.S. Department of Energy through contract number DE-AC36-08G028308.

Thermotropic Liquid Crystals Enable Efficient and Stable Perovskite Solar Cells and Modules Yi

Yang, Cheng Liu, Bin Chen, Mercouri G. Kanatzidis and Edward Sargent; Northwestern University, United States

Perovskite solar cells (PSCs) have seen impressive progress in performance and stability, yet maintaining power conversion efficiencies (PCEs) when scaling areas remains a challenge. Here we find that the additives used to passivate large-area perovskite films often co-crystallize near-simultaneously with perovskites or tend to aggregate at the surface/interface, which contributes to defects and to spatial inhomogeneity. We therefore introduce a thermotropic liquid crystal (TLC) additive with heightened diffusion ability at the perovskite annealing temperature to enable uniform, low-defects, and stable large-area perovskite films. We document as a result small-area PSCs achieving a PCE of 25.6% and modules having a certified PCE of 21.6% at an aperture area of 31 cm². These retain performance under the damp-heat test (ISOS-D-3, 85% relative humidity, 85°C) with T₈₆ of 1200 hours, and show high resistance to reverse bias with (ISOS-V-1, negative V_{mpp}) and without bypass diodes.

Direct Observation of Contact Reaction Induced Ion Migration and Its Effect on Non-Ideal Charge Transport in Lead Triiodide Perovskite Field-Effect Transistors Youcheng Zhang and Henning Sirringhaus; University of Cambridge, United Kingdom

The migration of ionic defects and electrochemical reactions with metal electrodes remains one of the most important research challenges for organometal halide perovskite optoelectronic devices. There is still a lack of understanding of how the formation of mobile ionic defects impact charge carrier transport and operational device stability, particularly in perovskite field-effect transistors, that tend to exhibit anomalous device characteristics. Here, we investigate the evolution of the n-type FET in CsFAMAPbI₃ during repeated measurement cycles as a function of different metal source-drain contacts and precursor stoichiometry. The channel current increases for high work function metals and decreases for low work function metals when multiple cycles of transfer characteristics are measured. The cycling behaviour is also sensitive to the precursor stoichiometry. These metal/stoichiometry-dependent device non-idealities are correlated with the quenching of photoluminescence near the positively biased electrode. Based on elemental analysis using electron microscopy our observations can be understood by an n-type doping effect of metallic ions that are created by an electrochemical interaction at the metal-semiconductor interface and migrate into the channel.

Our findings improve our understanding of ion migration, contact reactions and the origin of non-idealities in lead triiodide perovskite FETs.[1] These findings shed light on how bias-induced migration of extrinsic metallic ions impacts charge transport at a device level, revealing the widespread nature of this phenomenon when perovskite is in direct contact with metals. Our work underscores the crucial role of careful metal selection and precise composition control for the successful design of durable and reliable perovskite-based optoelectronic devices.

Supramolecular Assembly of Halide Perovskite Building Blocks Cheng Zhu^{1,2} and Peidong Yang^{1,2}; ¹UC Berkeley, United States; ²Lawrence Berkeley National Laboratory, United States

Metal halide ionic octahedron, $[MX_6]^{n-}$ ($M = Pb^{2+}, Sb^{3+}, Te^{4+}$, etc., $X = Cl^-, Br^-, I^-$), is the fundamental building block and functional unit of halide perovskites. The properties of the extended solids are dictated by the way how these octahedra are assembled, connected, and interact with the surrounding atomic environment. Hence, the ability to manipulate and control the assembly of the octahedral building blocks is paramount for constructing new perovskite materials. Here, we propose a systematic supramolecular strategy as a new method for the assembly of a family of $[MX_6]^{n-}$ into an extended network. Crown ethers are used to bind with various alkali metal cations to form supramolecular cations, two of which can sandwich one halide octahedron to form a structurally and optoelectronically tunable dumbbell structural unit. The dumbbell building blocks can be further assembled into extended crystals with diverse packing geometries and symmetries. Starting from the prototypical example of $(18C6@Cs)_2TeCl_6$ crystal structure, we can explore the synthetic space along: (1) varying the size of the crown ether (18C6 and 21C7), (2) changing the octahedra center cation (8 different metal cations), (3) tuning the halide anion (Cl^- , Br^- , and I^-), (4) modifying the alkali metal cation coupled with the crown ether, and (5) introducing 1D and 2D electronic dimensionality by connecting the octahedra. With all these synthetic possibilities, this supramolecular assembly route introduces a new general strategy for designing halide perovskite structures with tailorable optoelectronic properties. For example, the supramolecular-assembled crystals have strong photoluminescence (PL) with a highly tunable emission color. $(18C6@Cs)_2ZrCl_6$ has a very bright blue emission, and the PL quantum yield is 12.57%. Furthermore, by varying the alkali metal cation from K^+ to Rb^+ to Cs^+ , the PL spectra continue to redshift. We expect that the assembly approach of the supramolecular building blocks could bring a new general method for halide perovskite materials discovery, and we could further appreciate the structural and functional versatility of halide perovskites.

3:30 PM EN05.13.07

Direct Experimental Evidence for Defect Tolerance in Pb-Halide Perovskites, at Last David Cahen^{1,2}, Naga P. Jasti^{2,1}, Sigalit Aharon¹, Yishay Feldman¹ and Igal Levine³; ¹Weizmann Institute, Israel; ²Bar-Ilan University, Israel; ³HZB, Germany

While *defect tolerance* (DT) lacks direct *experimental* evidence, it is widely used as the basis for the exceptional optoelectronic properties of Halide Perovskites, HaPs, and their devices. It became a “fact” in the field, also when the initial theoretical model and computational support for it, was challenged. DT in semiconductors implies tolerance to *structural defects* without the *electrical and optical effects* (e.g., traps), associated with such defects. As such it also directly impacts what we view as the stability of such materials.

We present the first DIRECT experimental evidence for DT in Pb-HaPs by comparing the structural quality of 2D, 2D-3D, and 3D Pb-iodide perovskite single crystals with their optoelectronic characteristics using high-sensitivity methods. Importantly, we get information from the materials’ bulk, because we sample *at least* ~0.1 to several μm , from the sample’s surface. Therefore, we assess the intrinsic bulk (and not only surface-) properties of HaPs. The results point to DT in 3D, to a lesser extent in 2D-3D, but not in the crystals. We ascribe such dimension-dependent DT to the higher number of (near)neighboring species, available to compensate for structural defect effects in the 3D than in the 2D crystals. Our experimental results and their interpretation can now guide the search for, and design of other materials with DT.

3:45 PM EN05.13.08

Temperature-Dependent Reversal of Phase Segregation in Mixed-Halide Perovskites Adam D. Wright^{1,2,3}; ¹University of Oxford, United Kingdom; ²University of Warwick, United Kingdom;

³Princeton University, United States

Tandem solar cells with metal halide perovskite top cells have achieved power conversion efficiencies better than single-junction silicon solar cells. However, the success of these devices is constrained by the phenomenon of halide segregation, which afflicts the mixed iodide-bromide compositions used to achieve the necessary wide bandgaps. When exposed to above-bandgap illumination, these mixed-halide perovskites de-mix into iodide-rich and bromide-rich regions. This phase segregation is deleterious to the performance of mixed-halide perovskites in tandem cell applications, but none of the multiplicity of proposed models have been able to fully explain all reported observations of light-induced halide segregation.

In this study¹, I report on the influence of temperature and light intensity on light-induced halide segregation in $\text{MAPb}(\text{Br}_{0.4}\text{I}_{0.6})_3$ by measuring changes in the photoluminescence spectra across an exceptionally wide parameter space. I reveal a reversal in the temperature trend in halide segregation rate, which speeds up as temperature is increased from 125 K to ≈ 290 K, but slows down again with further increases in temperature. I attribute this reversal to the trade-off between the temperature activation of segregation, e.g. through enhanced ionic migration, and its inhibition by entropic factors. I further show that while halide remixing indeed occurs at highly elevated light intensities, and becomes more pronounced at higher temperatures, this effect is only transient, reversing on its own over the time scale of minutes under continued illumination. I utilize our findings to elucidate the validity of the most commonly examined models describing the origins of halide segregation, and discuss their relevance to applications of mixed-halide perovskites in tandem and concentrator solar cells.

Bimolecularly-Passivated Interface Enables Efficient and Stable Inverted Perovskite Solar Cells

Cheng Liu, Bin Chen, Mercouri G. Kanatzidis and Edward Sargent; Northwestern University, Afghanistan

Compared to the n-i-p structure, inverted (p-i-n) perovskite solar cells (PSCs) promise increased operating stability; however, to date, these photovoltaic cells suffer lower power conversion efficiencies (PCEs), the result of nonradiative recombination losses, particularly at the perovskite/ C_{60} interface. Here we hypothesize that implementing the two functions is highly needed at the interface – 1) passivation of surface defects; and 2) the reflecting of minority carriers away from the interface and back into the bulk. We incorporate one molecule to passivate surface defects and suppress recombination via chemical interactions with perovskite. The other molecule was employed to repel minority carriers and reduce contact-induced interface recombination, achieved through field-effect passivation. The approach leads to a 5-fold increase in carrier lifetime and a 3-fold reduction in photoluminescence quantum yield (PLQY) loss, enabling the first certified quasi-steady-state PCE over 25% for inverted PSCs with stable operation at 65°C for over 2,000 hours in ambient air. We produce monolithic all-perovskite tandem solar cells with 28.1% PCE.

4:15 PM EN05.13.11

Architecture Optimization Improves Reverse Bias Stability in p-i-n Structured Perovskite Solar

Cells Fangyuan Jiang¹, Yangwei Shi¹, Tanka R. Rana¹, Daniel Morales², Isaac Gould², Declan P. McCarthy², Joel Smith³, Greyson Christoforo³, Muammer Y. Yaman¹, Faiz Mandani⁴, Hannah Contreras¹, Stephen Barlow², Aditya D. Mohite⁴, Henry Snaith³, Seth R. Marder², J. Devin MacKenzie¹, Michael McGehee² and David S. Ginger¹; ¹University of Washington, United States; ²University of Colorado Boulder, United States; ³University of Oxford, United Kingdom; ⁴Rice University, United States

As perovskite photovoltaics make strides towards commercialization, reverse bias instability has been considered a serious challenge. We systematically investigate methods to improve reverse bias behaviors of p-i-n structured perovskite solar cells, including passivating halide vacancies, changing the electron transporting layer, and systematically varying the hole transporting layers and metal electrodes. Our results suggest that having a robust polymer hole transporting layer and an electrochemically stable electrode are important for preventing reverse bias breakdown of p-i-n perovskite solar cells. This result is surprising since much of the current effort and understanding has focused on the perovskite/electron transport layer/metal electrode interface. Nevertheless, with appropriate hole transporting layers, and optimized top electrode, we demonstrate breakdown voltages exceeding -15 V, comparable to that of silicon photovoltaics. Furthermore, our optimized solar cells demonstrate completely recoverable device performance even after being stressed at high reverse bias for many hours (i.e., at -7 V for 9 hours both in the dark and under partial shading). Following these observations, we propose a self-consistent model which highlights the role of electrochemical reaction pairs that has not been appreciated previously.

SESSION EN05.14: Halide Perovskites for Light Emission

8:00 AM EN05.14.01

Bioinspired Liquid Encapsulation Platform for Protection of Optoelectronic Devices Haichao Wu, Zachary A. Goodwin, Baptiste Lemaire, Yanhao Yu, Nicola Molinari, Boris Kozinsky and Joanna Aizenberg; Harvard University, United States

The next-generation semiconductors and devices, such as halide perovskites and flexible electronics, are extremely sensitive to water, thus demanding highly effective protection that not only seals out water in all forms (vapor, droplet, and ice), but simultaneously provides mechanical flexibility, durability, transparency, and self-cleaning. Although various solid-state encapsulation methods have been developed, no strategy is available that can fully meet all the above requirements. Here, we report a bioinspired liquid-based encapsulation strategy that offers protection from water without sacrificing the operational properties of the encapsulated materials. Using halide perovskite as a model system, we show that damage to the perovskite from exposure to water is drastically reduced when it is coated by a polymer matrix with infused hydrophobic oil. With a combination of experimental and simulation studies, we elucidated the fundamental transport mechanisms of ultralow water transmission rate that stem from the ability of the infused liquid to fill-in and reduce defects in the coating layer, thus eliminating the low-energy diffusion pathways, and to cause water molecules to diffuse as clusters, which act together as an excellent water permeation barrier. Importantly, the presence of the liquid, as the central component in this encapsulation method provides a unique possibility of reversing the water transport direction;

therefore, the lifetime of enclosed water-sensitive materials could be significantly extended via replenishing the hydrophobic oils regularly. We show that the liquid encapsulation platform presented here has high potential in providing not only water protection of the functional device but also flexibility, optical transparency, and self-healing of the coating layer, which are critical for a variety of applications, such as in perovskite solar cells and bioelectronics.

Towards Efficient and Stable Perovskite Light Emitting Diodes Daniel Congreve¹, Sebastian Fernandez¹, Manchen Hu¹, Mahesh Gangishetty², Shaocong Hou², Qimin Quan², William Michaels¹, Pournima Narayanan¹, Natalia Murrietta¹, Aryn Gallegos¹, Ghada Ahmed¹, Junrui Lyu¹, Qi Zhou¹, Balreen Saini¹ and Tracy Schloemer¹; ¹Stanford University, United States; ²Rowland Institute at Harvard, United States

Perovskite LEDs are an exploding field, with high performance red and green devices demonstrated by many groups. However, two key challenges towards commercialization remain: poor performance at higher energies, and poor overall stability (particularly at those higher energies). Here, we demonstrate investigations into both issues. First, we identify two crucial issues holding blue materials back: the low internal photoluminescence yield and the LED device structure itself. By rectifying these issues, we were able to build LEDs that were 60x brighter than control, and, when combined with red and green downconverters, white light emitting LEDs. We further demonstrate how careful control over fabrication conditions allows for more uniform thin films, creating violet LEDs with 5x the efficiency over control devices. Finally, we study the interplay between efficiency and stability in green LEDs, showing that while an additive material can increase efficiency, it also leads to a stability decrease, highlighting the need for global evaluation of these changes to the device composition.

8:45 AM EN05.14.03

Designing Metal Halides for Fast Neutron Imaging Scintillators: Lessons from Perovskite Nanocrystals and Ionic Liquids Kyle M. McCall; University of Texas at Dallas, United States

The lead halide perovskites have captivated the research community due to their exceptional optoelectronic properties that enable high performance as solar cells and light emitters. In particular, perovskite nanocrystals (NCs) have demonstrated their potential as next-generation light emitters, with applications ranging from QLED displays to X-ray scintillators. Recent work on metal halides for fast (high-energy, >1 MeV) neutron detection has shown that they have the potential to deliver low-cost, efficient scintillators for this application, with the advantages of high spatial resolution, low gamma-ray sensitivity, and negligible afterglow on the timescale of seconds. However, there are several challenges to overcome before these materials can displace the commercial polypropylene screens (embedded with microscale ZnS:Cu phosphors).

This presentation will summarize three studies in this field, which have each contributed design rules that will enable a more complete understanding of how to design metal halides for this application. A first comparison of perovskite nanocrystals with a variety of other halide and chalcogenide NCs showed that FAPbBr₃ NCs offered the highest light yield, while CsPbBrCl₂:Mn²⁺ NCs offered the highest spatial resolution. Composition and thickness-dependent measurements highlighted the need to 1) enhance concentration and 2) reduce self-absorption for all NC systems. Subsequently, we sought to further test these design rules by 1) exploring the use of metal halide ionic liquids for maximal concentration, and 2) separately pursuing the optimized synthesis and doping in CsPb(Br_xCl_{1-x})₃:Mn²⁺ NCs to improve concentration and eliminate reabsorption.

These follow-up studies showcased the importance of these design principles for improved fast neutron scintillation, as the latter system demonstrated the capacity for concentrations above 100 mg/mL while essentially eliminating self-absorption, while the former system yielded significantly higher spatial resolution and competitive light yields. This presentation will synthesize this series of results into a succinct summary of the needs of this lesser-known application, providing the fundamental background to engage with the burgeoning field of fast neutron imaging and design the perovskite materials that can deliver the next generation of fast neutron scintillators.

9:00 AM EN05.14.04

Efficient and Stable Perovskite Light Emitting Diodes by using Stabilized Interface Tianjun Liu, Samuel D. Stranks, Neil Greenham and Richard H. Friend; University of Cambridge, United Kingdom

Metal halide perovskites have shown great optoelectronic properties for light emitting diodes (LEDs), such as high photoluminescence quantum yields (PLQYs), tunable bandgap, narrow emission linewidths and high charge-carrier mobility. Owing to the development of the strategy of defect passivation and controllable growth of grains, the external quantum efficiencies (EQEs) of perovskite light emitting diodes (PeLEDs) have achieved more than 25%. Furthermore, critical interface engineering has also been developed for fabricating PeLEDs with long operational stability, making a key step toward practical applications and future commercialization. We report an efficient PeLED with EQE > 24% in near infrared emission range by using organic additives. Owing to the stabilized interface, the achieved devices present long term operational stability with T50 above 800 hours at current density of 20 mA/cm².
<quillbot-extension-portal></quillbot-extension-portal>

9:15 AM EN05.14.05

Continuous-Wave Amplified Spontaneous Emission and High-Current-Density Operation from a Transparent Perovskite LED Architecture Karim Elkhoully^{1,2}, Iakov Goldberg^{1,2}, Xin Zhang^{1,2,3}, Nirav Annavarapu^{1,2}, Weiming Qiu¹, Cedric Rolin¹, Jan Genoe^{1,2}, Robert Gehlhaar¹ and Paul Heremans^{1,2}; ¹Imec, Belgium; ²KU Leuven, Belgium; ³Fudan University, China

Metal halide perovskites are excellent candidates for the gain material in thin film laser diodes. They exhibit high optical gain, low amplified spontaneous emission (ASE) thresholds, and a wide emission wavelength tunability. These attributes have facilitated notable advancements such as optically-pumped pulsed and continuous-wave (CW) lasing from a large library of optical cavities, operating under both room-temperature and cryogenic conditions. The successful development of perovskite laser diodes and their prospective heterogeneous integration into photonic circuits would pave the way for a multitude of applications in domains such as sensing, ranging, data communication, and miniaturized displays.

However, achieving a current-injection perovskite laser, a promising yet complex feat, remains elusive due to the inherent complexity of the optoelectronic design challenges. Firstly, there is the necessity for high internal quantum efficiency (IQE) at extreme current densities ranging from hundreds to thousands of A/cm². This demands effective strategies for mitigating Joule heating, a problem magnified by perovskites' inherent low thermal conductivity and diminished stability at such high current densities. Secondly, the device stack must be optimized in terms of its optical design to maximize the net modal gain. This imposes stringent criteria on the thickness and conductivity of the layers comprising the device stack. In particular, the key challenge stems from the presence of conductive metal electrodes in the vicinity of a gain layer. It's essential, on the one hand, that electrodes inject kA/cm² current densities into the device. On the other hand, these highly conductive layers contribute to substantial free-carrier optical

absorption, thereby increasing ASE threshold and current density necessary for ASE/lasing. In the last step toward a laser, a high quality-factor optical cavity has to be integrated into the perovskite LED (PeLED) without compromising the device performance and reliability.

In this work, we embed a perovskite waveguide stack, optimized for high-current density operation, into a scaled (50 μm in diameter) transparent LED architecture with reduced optical losses. We reliably operate this miniaturized PeLED in a sub- μs pulsed mode above 3 kA/cm^2 without irreversible degradation. At these current densities, the device delivers EQEs above 1% at 77 K. Moreover, we achieve low ASE thresholds ($< 10 \mu\text{J/cm}^2$) from this fully contacted electrical structure at 77 K using 3-ns optical pumping. This PeLED allows us to achieve several crucial milestones towards injection lasing: 1) ASE enhancement at synchronized photo-electrical co-excitation; 2) optically-pumped CW ASE when excited with 1- μs -long optical pulses; 3) electroluminescence brightness levels close to half of the brightness produced by CW optical pumping at ASE threshold. These milestones set us within reach of realizing a perovskite-based thin-film laser diode. Finally, we will also discuss novel concepts of integrating a fully functional PeLED with optical cavities for future thin-film perovskite laser diodes.

9:30 AM EN05.14.06

On the Photolysis of Mixed Halide Perovskite Nanocrystals Michael C. Brennan^{1,2} and Tod Grusenmeyer¹; ¹Air Force Research Lab, United States; ²Azimuth Corporation, United States

Colloidal mixed halide perovskite nanocrystals (NCs) irreversibly degrade when exposed to ultraviolet—visible irradiation. Here, mixed halide perovskite NC photolysis is tracked via mass spectrometry, electron microscopy, and photoluminescence. The data shows continuous wave ultraviolet—visible irradiation causes the heavier halides within the alloy to sublime. This ultimately transforms $\text{CsPb}(\text{I}_{1-x}\text{Br}_x)_3$ and $\text{CsPb}(\text{Cl}_{1-x}\text{Br}_x)_3$ ($x \approx 0.50$) NCs into CsPbBr_3 and CsPbCl_3 NCs, respectively. Time-resolved mass spectrometry demonstrates real-time desorption of volatile halide species (e.g. $\text{I}_{2(g)}/\text{HI}_{(g)}$) during irradiation. Energy-dispersive X-ray spectroscopy confirms near complete expulsion of I from $\text{CsPb}(\text{I}_{1-x}\text{Br}_x)_3$ and Br⁻ from $\text{CsPb}(\text{Cl}_{1-x}\text{Br}_x)_3$ NCs. Electron diffraction and cathodoluminescence establish lattice contractions and emission blueshifts consistent with formation of single halide perovskites from parent mixed halide alloys. Finally, increasing photolysis rates at higher temperatures follow an Arrhenius relationship with an effective activation energy of $\sim 62 \text{ kJ mol}^{-1}$ for $\text{CsPb}(\text{I}_{1-x}\text{Br}_x)_3$ NCs ($x \approx 0.50$). Altogether, this work provides important insight into the photolysis of colloidal perovskite NC alloys.

Implementing QD-In-Host Structure for High Efficiency in Deep-Blue Perovskite LEDs Kyung Yeon Jang¹, Seung-Je Woo¹, Hyeree Kim¹ and Tae-Woo Lee^{1,1,2}; ¹Seoul National University, Korea (the Republic of); ²SN Display Co., Ltd., Korea (the Republic of)

Metal halide perovskite light-emitting diodes (PeLEDs) have received substantial interest due to their exceptional color purity, satisfying the Rec. 2020 color gamut standard, and impressive efficiency in pure-green and pure-red perovskite nanoparticle LEDs. However, the challenge lies in achieving high efficiency in the deep-blue region, an area hitherto under-explored. This study focuses on using CsPbBr_3 quantum dots (QDs) as the light-emitting layer in PeLEDs. We identify two obstacles that need to be

overcome: the difficulty in ligand post-treatment and the spectrum red-shift in the film state. Here, we propose an alternative ligand enriched with a chemical passivation process, effectively amplifying the photoluminescence quantum yield (PLQY) of deep-blue QDs from 15% to nearly 90%. Furthermore, to address the spectrum red-shift induced by energy transfer or electronic coupling, we introduce a QD-in-host structure to physically separate the QDs in the film state. A reduction in the concentration of QDs in the film yielded a blue-shift of approximately 7 nm in the emission spectrum. By incorporating these strategies, we achieved a maximum external quantum efficiency of 6.2% at a peak wavelength of 462 nm. The findings of this study provide crucial strategies for deep-blue QD PeLEDs, which hold potential for broad applicability across diverse PeLED types.

10:15 AM EN05.14.10

Ultra-Stable Dual-Color Emitting Lead-Free Double Perovskite Cs_2SnI_6 with a Wide Emission Span Fuqian Yang; University of Kentucky, United States

We have developed a green-route approach to prepare lead-free double perovskite Cs_2SnI_6 powder and nanocrystals, using an environmentally friendly aqueous solution. The sonication of the Cs_2SnI_6 powder in hexane under ambient conditions leads to the formation of Cs_2SnI_6 nanocrystals. The Cs_2SnI_6 powder and nanocrystals exhibit band gaps of 1.3 and 2.8 eV, respectively. There is a difference of 1.5 eV in the band gaps. The Cs_2SnI_6 nanocrystals with good long-term structural and optical stabilities have a PLQY of ~7% and a PL peak wavelength of 440 nm over a span of 50 days. The dual-color emission of the perovskite Cs_2SnI_6 is likely due to the dependence of dielectric constant on crystal size instead of the effect of quantum confinement. This work is supported by the NSF through the grant CMMI-1854554 and CBET- 2018411.

Dimensionality and Tunability in The Tin Halide Perovskite Colloidal Nanostructures Kushagra Gahlot and Loredana Protesescu; University of Groningen, Netherlands

The chemistry of tin-halide perovskites remain under-developed when compared to their lead counterparts in bulk as well as in nano owing to their inability to provide a stable Sn(II) oxidation state to maintain pristine crystal structure phase in ambient conditions. Hence, a simple reciprocation of the synthetic conditions from Pb-halide perovskites doesn't suffice. In this work, I will discuss the physical and chemical parameters which can help us to achieve a stable, tunable and monodisperse CsSnX_3 perovskite nanocrystals with defined optical features.¹ Pertaining to the formation energies of these perovskite nanostructures, the studies on the interplay of the 2D Ruddlesden-Popper ($\text{L}_2\text{Cs}_{n-1}\text{Sn}_n\text{X}_{3n+1}$) crystal phases and 3D CsSnX_3 nanocrystals were performed with respect to ligand combinations (ammonium, carboxylate, phosphinate), metal precursor ratios and temperature when SnX_2 salt is used as a precursor in order to understand the nucleation mechanism of nanocrystal formation. Moreover, the successful transformation of a purified 2D Ruddlesden-Popper (L_2SnX_4) phase to form 3D CsSnX_3 nanocrystals via a hot-injection approach and their ability to undergo post-synthetic anion exchange processes at room temperature using benzoyl halides will be discussed in details. X-ray diffraction and scattering studies conjoined with optical spectroscopy and electron microscopy helps us in acquiring the useful insights in directing the chemistry of Sn-halide perovskites at nanoscale. This research work showcases the insistent necessity for the development of mechanistic understanding to design efficient synthetic routes in order to achieve high-quality tin-halide perovskite nanocrystals.

Nanostructure Modification on Thermally Evaporated Perovskite Films Toward Large-Area Light-Emitting Diodes Chan-Yul Park¹, Jung-Min Heo¹, Joo Sung Kim^{2,3}, Eojin Yoon¹ and Tae-Woo Lee^{1,1,2};
¹Seoul National University, Korea (the Republic of); ²SN Display Co. Ltd, Korea (the Republic of); ³Soft Foundry, Seoul National University, Korea (the Republic of)

In the contemporary era of digital society, there is a rising demand for vibrant color displays applicable in wearable electronics, indoor lighting, and expansive display systems. Metal halide perovskites have emerged as a highly promising material due to their advantages such as cost-effectiveness, excellent color purity with narrow full width at half maximum (FWHM, ~20nm), and the ease of color tuning by altering halide components. Nonetheless, despite the high-efficiency perovskite light-emitting diodes (PeLEDs) with external quantum efficiency (EQE) of over 20% was achieved through facile spin-coating methods, it couldn't be applied to the fabrication of large-area devices due to the low uniformity of the film. To overcome these limitations, a thermal evaporation method utilizing all-inorganic 3D CsPbBr₃ powders as precursor was developed. However, their use as emitters showed poor emission efficiency arising from critical drawbacks such as large crystal size, low exciton binding energy, and high defect concentration. In this study, we introduced a new thermal evaporation method by co-evaporating 3D CsPbBr₃ and bulky ammonium cation (benzylammonium bromide, BzABr) to achieve quasi-two-dimensional (quasi-2D) perovskites with energy funneling and strong charge confinement. The existence of quasi-2D perovskites with efficient charge funneling and quantum confinement was confirmed by optical analysis. The grain size was also reduced from 80 to 50 nm, which could induce additional spatial charge confinement for efficient radiative recombination. Compared to the pristine 3D CsPbBr₃ film, the quasi-2D perovskite film showed tenfold-increased photoluminescence (PL) intensity. PeLEDs based on the thermally-evaporated quasi-2D perovskite thin films showed a maximum current efficiency of 3.6 cd/A and a maximum luminance of 1700 cd/m², showing an considerable improvement than that of Compared to PeLEDs based on thermally-evaporated 3D CsPbBr₃ without light emission due to the low luminous efficiency and high leakage current, PeLEDs based on the thermally-evaporated quasi-2D perovskite thin films showed a maximum current efficiency of 3.6 cd/A and a maximum luminance of 1700 cd/m², showing the great possibility of efficient PeLEDs based on thermal evaporation method. . This work represents a significant advancement towards the commercialization of metal halide perovskites for future vivid color displays by successfully addressing a critical challenge in the fabrication of large-area perovskite-based display devices.

10:35 AM EN05.15.02

Color-Stable Mixed-Halide Blue Perovskite Light-Emitting Diodes Seong Eui Chang¹, Joo Sung Kim^{2,3} and Tae-Woo Lee^{1,1,2}; ¹Seoul National University, Korea (the Republic of); ²SN Display Co. Ltd., Korea (the Republic of); ³Soft Foundry, Seoul National University, Korea (the Republic of)

Metal halide perovskites have emerged as a highly promising candidate for the advancement of next-generation light-emitting materials owing to their exceptional optoelectronic properties, including superior color purity, high photoluminescence quantum efficiency, and facile tunability of their bandgap through facile compositional control. As a consequence of these advantages, efficient perovskite light-emitting diodes (PeLEDs) with external quantum efficiency (EQE) surpassing 20% have been successfully demonstrated. However, the realization of efficient and stable blue-emitting PeLEDs, which are crucial for achieving vivid emission across the entire color gamut, has proved to be a formidable challenge, primarily due to the spectral instability exhibited by mixed-halide composites employed for blue emission. In this investigation, we present the successful realization of color-stable mixed-halide blue PeLEDs achieved through the implementation of core/shell perovskite nanograins with mitigated halide segregation. By employing shell materials that effectively bind at the grain boundaries, we effectively suppress the electric-field-induced segregation of halide ions, resulting in stable and narrow emission spectra during the operational lifetime of the devices. Our study thus presents a promising strategy for the realization of stable mixed-halide perovskite materials with complete suppression of halide segregation, thereby facilitating the development of bandgap-tunable perovskite optoelectronic devices.

10:40 AM EN05.15.03

Carbon Nanoflake Based Materials for Charge Transport Layers of Perovskite Solar Cells: Insight from Atomistic Modeling into Nanosizing and Functionalizations Suitable for Electron and Hole Transport Ruicheng Li, Keisuke Kameda, Sergei Manzhos and Manabu Ihara; Tokyo Institute of Technology, Japan

A key bottleneck on the way to practical deployment of perovskite solar cells (PSC) are charge transport materials. Charge transport layers are needed to achieve high performance with PSCs, but hole transporting materials (HTM) and electron transporting materials (ETM) used in high-performance lab-scale PSCs are relatively high-cost. Another key bottleneck, low cell stability, is related to the issue of charge transport layers, as high-performance HTMs typically require the use of dopants that are detrimental to cell stability.

Recently, the use of carbon-based materials for both HTM and ETM has been gaining attention, in particular due to the possibility of synthesizing such materials from biomass or plastic wastes. This promises combining large-scale, low cost production with environmental remediation. Much of such research is empirical, without detailed insight into electronic properties of the synthesized materials. Such insight is needed to understand the possibility of forming correct band alignment and to ensure adequate charge transfer properties and for rational design of carbon-based HTMs and ETMs.

Carbon nanoflakes are one promising type of carbon based materials. Their size and functionalization/doping can be controlled, albeit imperfectly. We perform ab initio and semiempirical calculations to understand what sizes, shapes, and functionalizations can allow carbon nanoflakes to achieve band alignment and charge transport properties suitable for their use as either HTM or ETM. We include the effects of solid packing in the calculations and show that they substantially affect electronic properties. We show, in particular, that nanoflake sizes required for HTM capability should be as small as 1.5 nm, which is much smaller than nanoparticle sizes typically used in the literature. We also show that different functionalizations can make the same nanoflakes work as either ETM or HTM, and can also be used to control charge transport properties. Conversely, our results indicate that tight control of the presence of functional groups is required during synthesis to preserve HTM or ETM capability of such materials.

10:45 AM EN05.15.07

Theoretical Insights into Cs_2MSbX_6 ($\text{M} = \text{Cu, Ag, Na, K, Rb, Cs}$ and $\text{X} = \text{Cl, Br}$) Halide Double-Perovskite Materials for Optoelectronic Applications Priya Johari and [Surajit Adhikari](#); Shiv Nadar University, India

Lead-halide perovskites APbX_3 ($\text{A} = \text{Cs, CH}_3\text{NH}_3$ and $\text{X} = \text{Cl, Br}$) have attracted broad interest in photovoltaic applications over the past decade due to their suitable bandgap and high optical absorption ability [1]. But lead-induced toxicity and materials instability has sparked interest in alternative materials with properties like APbX_3 perovskites. Recently, lead-free inorganic double halide perovskites $\text{Cs}_2\text{M(I)M(III)X}_6$ have been proposed as promising nontoxic materials with enhanced chemical stability for optoelectronic applications [2]. However, not much has been explored in the context of their mechanical, transport, and excitonic properties, which play a crucial role in defining an efficient and flexible optoelectronic device. We have, therefore, systematically conducted a series of state-of-the-art first-principles density functional theory, hybrid density functional theory, and many-body perturbation theory (namely GW and BSE) calculations to investigate the mechanical, transport, and excitonic properties of Cs_2MSbX_6 ($\text{M} = \text{Cu, Ag, Na, K, Rb, and Cs}$; $\text{X} = \text{Cl, Br}$) along with their structural, electronic, and optical properties. Our results indicate that all the systems maintain the standard cubic lattice and show high phase stability against decomposition (decomposition enthalpy > 20 meV/atom). Band structure calculations (HSE06 and G_0W_0 @PBE) reflect that the compounds have a wide range of tunable bandgaps (1.2 eV - 5.2 eV), and the bandgap decreases on going from Cl to Br. BSE calculations reveal that these materials have excellent absorption capabilities from visible to ultraviolet light region. Investigation of transport properties and excitonic parameters elucidates that most of the Cs_2MSbX_6 materials exhibit small charge carrier effective masses (higher mobility) and low to moderate exciton binding energy as well as longer to shorter exciton lifetime, which make them suitable for a solar cell application. Further, on calculating the mechanical properties these compounds are found to exhibit low elastic moduli that decrease from $\text{Cs}_2\text{MSbCl}_6$ to $\text{Cs}_2\text{MSbBr}_6$. Furthermore, except $\text{Cs}_2\text{CuSbBr}_6$, these compounds are predicted to be ductile in nature with a noticeable elastic anisotropy, revealing these materials to exhibit good flexibility. Further, on considering the mixed halide double perovskites $\text{Cs}_2\text{MSbBr}_{6-x}\text{Cl}_x$ ($x = 0-6$, $\text{M}=\text{Ag}$) it is found that the optoelectronic properties can be widely tuned, and thus, such materials may a suitable component for the future generation of optoelectronic devices. Overall, our study predicts Cs_2MSbX_6 to be a stable double perovskite with a wide range of tunable optoelectronic properties, and promising transport and excitonic properties, providing a helpful guide to developing next-generation photovoltaics and flexible optoelectronics.

Highly-Sensitive X-Ray Detectors Based on Single-Crystal Mixed-Halide Perovskite $\text{CsPbBr}_{3-x}(\text{Cl, I})_x$ [Rong Wu](#) and Fangze Liu; Beijing Institute of Technology, China

Lead halide perovskites are emerging materials for a variety of optoelectronic applications, for example,

photovoltaics, light-emitting diodes, photodetectors, lasers and photocatalysts. During the past few years, they have been extensively studied for radiation detection, especially for X-ray detectors due to their high absorption cross section, high carrier mobility lifetime product, tunable direct bandgap and low-cost synthesis. Perovskite X-ray detectors have shown higher sensitivity as well as lower detection limit compared with conventional Se and CdZnTe detectors. Despite the rapid advances in perovskite X-ray detectors, their performance is significantly hindered by the intrinsic limitations of perovskites, including low stability, low resistivity and high ion migration. Compared with hybrid organic-inorganic perovskites, all-inorganic CsPbBr₃ has attracted a lot of interests mainly for its high thermal stability. Various solution growth methods have been proved as effective routes to achieve large-size CsPbBr₃ single crystals. However, achieving stable perovskite X-ray detectors with suppressed ion migration and low dark current remains a challenge.

Here, we synthesized mixed-halide perovskite CsPbBr_{3-x}(Cl, I)_x single crystals with x ranging between 0 and 0.3. The structure and composition of single crystals are verified using XRD, EDS, UV-vis absorption and photoluminescence. The single crystal X-ray detectors show high sensitivity exceeding $3 \times 10^4 \mu\text{C Gy}_{\text{air}} \text{cm}^{-2}$ and low detection limit below 50 nGy s^{-1} for 90 keV X-ray under 500 V cm^{-1} electric field. By constructing detectors with high and low work function contacts, we find that the dark current mainly originates from the hole current, and therefore using low work function contact can effectively suppress the dark current, achieving a low current density of $\sim 40 \text{ nA cm}^{-2}$ under 500 V cm^{-1} electric field, which is lower than 1/100 of the dark current density using high work function contacts. The halide doping and contact engineering prove that the mixed-halide perovskites are promising materials for high-performance X-ray detectors.

10:55 AM EN05.15.09

Exploring Self-Assembled Hole Transport Materials in p-i-n Perovskite Solar Cells Minsik Shin¹, Dongmin Yoon², Hongyi Huang³, Yifan Yin⁴ and Miriam Rafailovich⁴; ¹Seoul International School, Korea (the Republic of); ²North London Collegiate School Jeju, Korea (the Republic of); ³Shenzhen Middle School, China; ⁴Stony Brook University, The State University of New York, United States

Renewable energy plays a crucial role in combating climate change, and one of the primary focuses is improving the efficiency and production of solar cells. Over the past decade, perovskite solar cells (PSCs) have garnered significant attention due to the extraordinary evolution of the power conversion efficiency (PCE): perovskites are a class of materials with unique crystal structures, represented by the chemical formula ABX₃. Here, A denotes monovalent organic cations like methylamine (MA⁺), formamide (FA⁺), or cesium, while B refers to metal cations such as lead and tin. Finally, X represents halide anions. The inverted structure PSCs, also known as p-i-n PSCs offer several advantages, including lower production costs and enhanced stability compared to the conventional n-i-p PSCs. However, the inverted PSCs face the challenge of lower device efficiencies. In this study, we focus on two distinct materials for the Hole Transport Layer (HTL): PTAA and MeO-2PACz. Our primary goals involve investigating the fabrication process to create an optimal substrate for subsequent perovskite layer deposition and evaluating the efficiency of MeO-2PACz as a Hole Transport Material in inverted p-i-n perovskite solar cells. By exploring these aspects, we aim to contribute to the ongoing efforts to enhance the performance of PSCs. Fabricating the solar cell, the HTL was first deposited onto the ITO glass through spin-casting. Two solutions were used: 1 mM MeO-2PACz in ethanol and 2 mg/ml PTAA in chlorobenzene. The spin-casting was done at 4000 rpm for 30 s, followed by annealing at 100°C for 10 minutes. Next, a 1.2M MAPbI₃ precursor solution in a mixed solvent of DMF/DMSO (v:v=9:1) was spin-casted on the glass at 4000 rpm for 30 s. 150 μL of toluene was dripped onto the surface 10 s after the beginning of spinning, the as-casted film was annealed at 100°C for 10 min. The subsequent steps involved spin coating a 20

mg/ml solution of PCBM at 1500 rpm for 30 s, followed by spin coating a 0.5 mg/ml BCP at 4000 rpm for 30 s. Finally, Ag electrodes (100 nm) were deposited using physical vapor deposition (PVD). In terms of measurements, the surface roughness of Meo-2PACz and PTAA coated substrates was investigated using Atomic Force Microscopy (AFM). Both films exhibited relatively small surface roughness. Fourier Transform Infrared Spectroscopy showed peak shifts of the phosphate functional group due to its reaction with the glass substrate. Contact Angle measurements demonstrated that Meo-2PACz exhibits higher hydrophilicity, which enhances nucleation and crystal growth. X-ray Diffraction (XRD) analysis revealed that both perovskites coated onto Meo-2PACz or PTAA substrate show a similar crystallinity. Scanning Electron Microscopy (SEM) revealed that the perovskite prepared from the Meo-2PACz-coated substrate had a larger average grain size. Furthermore, PV Performance testing confirmed Meo-2PACz's superiority as a Hole Transport Material, achieving a higher PCE of 17.7% compared to PTAA's 16.3% PCE in the fabricated inverted p-i-n device.

Photovoltaic Performance Analysis of Organic and Inorganic Hole Transport Layer for Cu-Ag-Bi-I Based Perovskite Solar Cell Md Arif Ul Islam, Shinya Kato and Tetsuo Soga; Nagoya Institute of Technology, Japan

In this study, the environmental friendliness of Cu₆AgBiI₁₀ (CABI), a cheap and non-toxic material, has received the most attention for the investigation. Recently, the inorganic Cu-Ag-Bi-I base compounds have shown great potential for solar, optoelectronic, and other applications. Their outstanding stability, high absorption coefficients, and ability to transport charged carriers are all factors that make them attractive. In this study, we investigated the performance of organic and inorganic Hole Transport Layers (HTL) on Cu-Ag-Bi-I based solar cells, conducted experimental and simulation analyses to improve their efficiency, and explored new approaches for optimizing solar cell devices. The method used was a single-step spin coating using hot-casting droplets poured onto pre-heated substrates. To anneal films, two-step annealing was used. In the first step, the films were annealed in the glove box at 75°C for 3 minutes before being annealed at 150°C for 6 minutes in the second step on the hot plate. The films were characterized using XRD, UV and SEM to identify the structural, optical, and surface morphological behavior and properties of these materials and device simulations for optimizing their photovoltaic performances. In addition, P3HT, PEDOT:PSS, Spiro-MeOTAD, NiOx, CuSCN, and CuO were used as layers for hole transport to identify the most suitable HTL layer for the FTO/(c+mp)TiO₂/CABI structure using the SCAPS-1D solar cell device simulation tool. This study demonstrates that inorganic HTLs are more crucial than organic HTLs in terms of the efficiency and performance of solar cells. In the six structures of devices, the best-optimized device design, FTO/(c+mp) TiO₂/CABI/CuO/Au was found with an efficiency of 2.08%. The effects of absorber layer thicknesses of absorber and ETL layers, rate of generation, recombination, capacitance voltages, current density voltage, and the characteristics of quantum effectiveness are investigated. The SCAPS-1D results were compared with similar experimental results of the photovoltaic devices. The research revealed that HTLs are a key factor in the efficiency of CABI solar cells. The research reveals that HTLs are key to CABI solar cell efficiency.

Surface Reconstruction of Inorganic Perovskite by The Nanosecond Laser Pulse Hyong Joon Lee,

Seok Yeong Hong, Jin Kyoung Park, Jin Hyuck Heo and Sang Hyuk Im; Korea University, Korea (the Republic of)

While the organic-inorganic hybrid metal halide perovskite has recently achieved remarkable performance in photovoltaics, all-inorganic perovskite ($\text{CsPbI}_{3-x}\text{Br}_x$, $X = 0\sim3$) has been proposed as a stable alternative to their organic counterparts. The all-inorganic perovskite demonstrates robust thermal- and photo-stability owing to relatively high thermal decomposition temperature and high ion migration activation energy. Moreover, their suitable energy bandgap (>1.65 eV) offers wide opportunities for applications such as single-junction photovoltaics, tandem solar cells, and indoor photovoltaics. However, inorganic perovskite suffers from rapid crystallization during the film fabrication process, resulting in morphological and surface electronic inhomogeneities. Such inhomogeneities act as charge recombination centers and deter efficient charge extraction, leading to poor reproducibility and performance.

In this study, we implement a nanosecond pulsed laser as an effective tool to reconstruct the surface of inorganic perovskite films. The pulsed lasers are powerful instruments that provide rapid, accurate, and precise processes and are readily accessible as they are already widely adopted in industries. With careful control of the pulse energy, we were able to homogenize the surface potential of inorganic perovskite. In addition, we thoroughly characterize the impacts on the various perspectives including crystallinity, morphology, chemical features, optoelectronic properties, and device performance of the inorganic perovskite film. We believe our study on the inorganic perovskite-laser pulse interaction offers an insightful approach for optimizing inorganic perovskite solar cells and potentially any other applications involving pulsed laser processes.

11:10 AM EN05.15.11

Crosslink Polymer Strategy to Minimize Voltage Loss in Wide-Bandgap Perovskites for All-Perovskite Tandem Solar Cells Xin Zheng; Huazhong University of Science & Technology, China

In recent years, the photoelectric conversion efficiency (PCE) of perovskite solar cells (PSCs) has exceeded 25%. However, according to Shockley-Queisser's limitations, the maximum theoretical efficiency of a single-junction solar cell is about 33%. The room for efficiency improvement of single-junction perovskite solar cells is very limited. Therefore, the development of tandem solar cells is an important way to break the limit and further improve the efficiency of PSCs. The theoretical limit efficiency of double-junction tandem solar cells (TSCs) can reach 46%, which is much higher than that of single-junction solar cells. In practice, The efficiency of all-perovskite tandem solar cells (28%) has surpassed that of single-junction perovskite solar cells (26%). Wide-bandgap (WBG) mixed-halide perovskites show promise of realizing efficient tandem solar cells but at present suffer from large open-circuit voltage loss because of excess lead iodide and light-induced halide phase segregation.

Here, a crosslink polymer strategy with high crosslinking degree and high density of functional groups is reported for finely regulating the crystal growth of $\text{FA}_{0.8}\text{Cs}_{0.2}\text{Pb}(\text{I}_{0.6}\text{Br}_{0.4})_3$, thereby obtaining high-performance PSCs. The pentaerythritol tetraacrylate (PTA) is introduced to form hydrogen bonds and strong Pb–O bonds with perovskite precursors, realizing the complete elimination of excess lead iodide. Besides, this uniformly distributed PTA crosslink polymer system passivates the defects and inhibits the photo-induced halide segregation effectively. The prepared PSCs with a band gap of 1.77 eV yield an impressive open-circuit voltage (V_{OC}) of 1.36 V, corresponding to a record low V_{OC} -deficit of 0.41 V and an efficiency of 19.58%. With these WBG perovskite subcells, we report 27.3% monolithic all-perovskite TSCs shows an outstanding combination of a high V_{OC} of 2.15 V and a FF of 81.4% with improved operational stability.

11:15 AM EN05.07.25

Heterostructure Solar Cells Fabricated via Sequential Spin and Transfer Printing Technique Anjali Thakran^{1,2}, Mario Hofmann¹ and Chih Wei Chu²; ¹National Taiwan University, Taiwan; ²Academia Sinica, Taiwan

Among the top contenders in photovoltaic materials, mixed halide organic/inorganic perovskite solar cells (PSCs) have attracted the market with strong potential of their facile processing methods, low temperature processability and cost-effectiveness over Si based solar cells (1/3 of the cost). The inherent properties of perovskites such as ambipolar nature, widely tuneable bandgap, low exciton binding energy, high mobility and long carrier lifetime have been extensively explored in electronic applications. However, the single junction solar cells based perovskites limited by their Shockley and Queisser limit and heterostructure/multi-junction device are limited with their complex stacked device architectures. Herein, we have demonstrated a successful approach of sequential spin and transfer printing technique to fabricate NBG perovskite over WBG perovskite to form a heterostructure. With as-adopted transfer printed technique on pre-fabricated spin coated layer, we are successfully able to fabricate two-solution processable layers on top of each other without any harmful dissolution. In results, we have obtained enhanced performance of stacked device compared to their single-junction counterpart. With our morphology studied, we have observed full coverage of surface, better crystal quality and less pin-holes film formation in heterostructure. Apart from it, the well-designed band alignment between top and bottom layer leads the effective transport of carriers through the device, therefore improved performance. Togetherness, with optimum parameters of film thickness, the obtained external quantum efficiency shown stronger intensity and enhanced spectral response. The single WBG layer are able to cover wavelength range around ~ 700 nm and with printed top layer onto it, the spectral enhanced till ~ 950 nm. Additionally, we can tune spectral response through composition variation in top and bottom layers. The purposed strategy can be implemented to stacked architecture including application including photodetector, sensors, transistor and LEDs.

Development of High-Performance Sn Based Halide Perovskite Transistors Yong-Young Noh; Pohang University of Science and Technology, Korea (the Republic of)

Developing high-mobility p-type semiconductors that can be grown using cost-effective scalable methods at low temperatures, has remained challenging in the electronics community for the integration of complementary electronics with the well-developed n-type metal oxide counterparts. Tin (Sn²⁺) halide perovskites emerge as promising p-type candidates but suffer from low crystallisation controllability and high film defect density, which result in uncompetitive device performance. In this talk, I would like to introduce a general overview and recent progress of our group of p-type Sn-based metal halide perovskites for the application of field-effect transistors (FETs). In the first part of the talk, I will mainly address inorganic perovskite thin-film transistors with exceptional performance using high-crystallinity and uniform cesium-tin-triiodide-based semiconducting layers with moderate hole concentrations and superior Hall mobilities, which are enabled by the judicious engineering of film composition and crystallization. The optimized devices exhibit high field-effect hole mobilities of over 50 cm² V⁻¹ s⁻¹, large current modulation greater than 10⁸, and high operational stability and reproducibility [1]. In the second part of the talk, I will introduce A-site cation engineering method to achieve high-performance pure-Sn perovskite thin-film transistors (TFTs). We explore triple A-cations of caesium-formamidinium-phenethylammonium to create high-quality cascaded Sn perovskite channel films, especially with low-defect phase-pure perovskite/dielectric interface. As such, the optimized TFTs show record hole

Updated as of October 28, 2024

mobilities of over $70 \text{ cm}^2 \text{ V}^{-1} \text{ s}^{-1}$ and on/off current ratios of over 10^8 , comparable to the commercial low-temperature polysilicon technique level. The p-channel perovskite TFTs also show high processability and compatibility with the n-type metal oxides, enabling the integration of high-gain complementary inverters and rail-to-rail logic gates.

Water-Based and Defect-Free 2D Material Inks for Printed Electronics Cinzia Casiraghi; University of Manchester, United Kingdom

Solution processing of 2D materials allows simple and low-cost techniques, such as ink-jet printing, to be used for fabrication of heterostructure-based devices of arbitrary complexity [1]. Our group has developed highly concentrated, defect-free, printable and water-based 2D crystal formulations, enabling fabrication of large area arrays of photosensors on plastic [2], printed capacitors [3], transistors [3,4], and memristors on both rigid and flexible substrates [5]. Furthermore, we have demonstrated simple and scalable fabrication of graphene-silicon rectifying devices with ON/OFF ratio higher than three orders of magnitude and a remarkable photovoltaic effect, whose fabrication is compatible with back-end-of-line fabrication processes [6]. Finally, inkjet printing can be easily combined with 2D materials produced by

chemical vapour deposition, allowing simple and quick fabrication of complex circuits on paper, such as high-gain inverters, logic gates, and current mirrors [7].

11:00 AM *EN06.01.02

Excitons in Two-Dimensional Metal Halides Maria Antonietta Loi; University of Groningen, Netherlands

Metal halide perovskites are under the spotlight for optoelectronic applications due to their remarkable photophysical properties. 3D compounds of this family have been used to demonstrate highly efficient solar cells, light emitting diodes, and x-ray detectors. Very recently, 2D and quasi-2D Ruddlesden–Popper phases, have also been explored for optoelectronic devices.

Layered perovskites afford specific advantages over other inorganic 2D materials such as transition metal dichalcogenides. As they are easily grown by both solution methods and vapor transport methods at low temperature, and they display a tuneable direct bandgap. In my presentation I will discuss the excitonic properties, of Ruddlesden–Popper phases based on Pb and on Sn, concluding on the metal influence on their physical properties. I will further underline the prospective for these materials in new optoelectronic devices.

Exploring the Potential of 1T-TiS₂ Electrode Materials for Supercapacitors Ali D. Ucar, Sumeyye Kandur, Mete Batuhan Durukan and Husnu E. Unalan; Middle East Technical University, Turkey

The distinctive characteristics of two-dimensional materials have attracted considerable interest for their prospective applications, especially in the field of energy storage. The relatively well studied transition metal dichalcogenides (TMDs), such as molybdenum disulfide (MoS₂) and tungsten disulfide (WS₂), have been shown to have electronic, chemical, and optical properties that can be tailored through fabrication methods. Relatively less studied and the lightest member of the TMD family, titanium disulfide (TiS₂) is a promising material for supercapacitor electrodes. In this work, electrically conductive bare 1T-TiS₂ nanosheets were fabricated and utilized as electrodes for supercapacitors. For this purpose, self-standing and flexible TiS₂ films were fabricated through vacuum filtration. Bare TiS₂ films showed poor cyclic stability in aqueous electrolytes. Therefore, a simple dopamine treatment was developed to enhance the enhance oxidation stability of the TiS₂ films. The resulting 1T-TiS₂ film based symmetric supercapacitor devices showed a specific capacitance and capacity retention of 10 F/g (at a scan rate of 100 mV/s) and 90% after 5000 cycles in 2M Li₂SO₄/0.1 M thiourea electrolyte, respectively.

The Influence of Cation Structure on Ionization Energies in 2D Organic Metal Halide Perovskites and Best Practices for Defining Ionization Energies Harindi R. Atapattu, Syed Joy, Henry Pruett, Kevin Pedersen and Kenneth R. Graham; University of Kentucky, United States

The ionization energy (IE) and electron affinity (EA), which are equated with the valence band maximum

and conduction band minimum, respectively, are important material parameters for semiconductor device design and understanding device physics. Thereby, determining relationships between organic metal halide perovskite (HP) structure and the IE and EA is critical for development and selection of HPs for targeted device integration. Currently, it is not well understood how structural changes to the HP shift the IE and EA, and furthermore, assigning the IE and EA in organic metal halide perovskites (HPs) is not straightforward. In three-dimensional (3D) HPs, the IE and EA are typically assigned based on Gaussian fits to the lowest energy feature; whereas, in two-dimensional (2D) HPs the IE and EA are commonly assigned based on linear fits to the leading edge of the signal onset. In this work we use a combination of techniques, including ultraviolet photoemission spectroscopy (UPS), electrochemistry, and photoluminescence (PL) quenching measurements to determine the most appropriate method to assign the ionization energy. In the case of PL quenching, a series of hole accepting materials with varying IEs are deposited on top of the HPs, and based on quenching of the HP PL as a function of IE of the hole accepting material we are able to determine the range in which the HP IE lies for both Ruddlesden-Popper (RP) and Dion-Jacobson (DJ) phase HPs. We further investigate how the structure of the A*-site organic cation impacts the IE in both RP and DJ Pb- and Sn-based HPs. In RP phase HPs containing phenethylammonium (PEA) derivatives as the A*-site cation, we find that appending an electronegative substituent at the 4-position of the phenyl group results in an increase in the IE relative to PEA, whereas when an electronegative substituent is attached at the 2-position the IE decreases relative to PEA. Overall, changing the position of the substituent in 2D HPs can result in a 1.0 eV change in the IE, which highlights the wide tunability of frontier energy levels provided by minor variations to the A*-site cation structure.

2D Carbides and Nitrides (MXenes) for Energy Storage—Use in Passive and Active Components

Yury Gogotsi; Drexel University, United States

Nanomaterials, particularly, two-dimensional (2D) materials, are among promising candidates to address some of the ongoing challenges in manufacturing batteries and supercapacitors and enable devices with superior performance metrics and a lower cost.^{1,2} Two-dimensional metal carbides and nitrides (MXenes) are a very large yet quickly growing family of 2D materials with the formula of $M_{n+1}X_nT_x$ where M is an early transition metal, X is carbon or nitrogen, and T_x refers to the surface terminations. Molecular dynamics and *ab initio* simulations, along with experiments, show that the electronic, optical, and, most importantly, electrochemical properties of MXenes distinguish them from other widely studied 2D materials. Chemical and electrochemical insertion of ions and molecules between the MXene layers allows modification of their properties, as well as electrochemical charge storage and harvesting, which use both, double-layer and redox mechanisms. The high electronic conductivity ($\sim 20,000 \text{ S cm}^{-1}$), redox-active surfaces, cation intercalation in 2D slits between MXene layers, and rich chemistry of these materials with more than 50 different compositions reported, have enabled their use as charge storage hosts and building blocks of passive cell components in various types of energy storage devices.³

Freestanding, binder-free films of $\text{Ti}_3\text{C}_2\text{T}_x$ are capable of ultra-high-rate pseudocapacitive charge storage in protic electrolytes delivering $\sim 400 \text{ F g}^{-1}$ (1500 F/cm^{-3}) at rates of up to 100 V s^{-1} and volumetric energy and power densities several times higher than conventional carbon-based capacitive electrodes. MXenes can intercalate a variety of monovalent and multivalent cations from aqueous or non-aqueous electrolytes and, therefore, can be used as electrodes for emerging new battery chemistries. Their mechanical robustness and high conductivity expand their use as current collectors, conductive additives in electrodes and also building blocks for conformal coatings to avoid dendrite growth in metal batteries. Yet, unlike most other 2D materials, the synthesis and processing of MXenes is scalable and cost-effective, and they can be processed in large batches from aqueous solution into powders, dispersions, and films. The combination of these properties and scalable synthesis, not only renders MXenes as interesting materials for academic research and development studies but also as practical materials of choice for future charge storage applications.

Understanding Complex Layered Halide Perovskites: Double Perovskites and Mosaic Perovskites

Bridget Connor¹, Alexander Su¹, Jiayi Li¹, Feng Ke², Yu Lin², Linn Leppert³ and Hemamala Karunadasa^{1,2}; ¹Stanford University, United States; ²SLAC National Accelerator Laboratory, United States; ³University of Twente, Netherlands

Layered halide perovskites offer a flexible platform for tuning optoelectronic properties through changes in composition. One of the most intriguing aspects of 2D halide double perovskites is the change in bandgap symmetry with dimension, observed for certain compositions. For example, the indirect gap of $\text{Cs}_2\text{AgBiX}_6$ converts to a direct gap at the $n = 1$ (monolayer) 2D perovskite, whereas the direct gap of $\text{Cs}_2\text{AgTlX}_6$ transitions to an indirect gap at the $n = 1$ limit. I will present a molecular orbital analysis that explains this transition and allows us to predict which double perovskite compositions will feature such a change in band dispersion pattern upon dimensional reduction. I will also present our recent studies on further increasing the accessible electronic structures of 2D perovskites by incorporating three stoichiometric octahedral metals. We refer to this family as “mosaic perovskites” due to the numerous local packing arrangements of the three different metal-halide octahedra that nevertheless maintain a fixed metal ratio. Notably, mosaic perovskites allow for Cu(I/II) mixed valence and sets the stage for many more mixed-valence metal combinations to be incorporated into halide perovskites.

2:30 PM EN06.02.03

Enhanced Air Stability in 2D Tin Halide Perovskites Enabled by Rational Spacer Cation Design

Christopher T. Triggs, R. Dominic Ross, Willa Mihalyi-Koch, Catherine Clewett, Kyana M. Sanders, Ilia A. Guzei and Song Jin; University of Wisconsin--Madison, United States

Two-dimensional (2D) tin halide perovskites are lead-free semiconductors promising for photovoltaic, optoelectronic, and spintronic devices. However, their inherent instability to air and humidity relative to their toxic lead counterparts makes them more difficult to study and employ in applications. In this work, we report two new 2D tin perovskite crystal structures and systematically compare them among a series

of Ruddlesden-Popper (RP) and Dion-Jacobson (DJ) tin iodide perovskites to elucidate the spacer cation structural motifs that enable better air stability, as well as the underlying mechanism of how they protect the inorganic sublattice from degradation. Using solid-state NMR, we find 2D tin perovskites decompose into ligand salts and SnO_2 upon exposure to ambient air, which are localized at the crystal surfaces and produced at varying rates depending on the spacer cation. Direct comparisons between the studied phases demonstrate substantially enhanced air stability compared to the benchmark $(\text{PEA})_2\text{SnI}_4$ (PEA = phenethylammonium) phase by use of halogenated aromatic spacer cations in RP perovskites or bulky ringed spacer cations in DJ perovskites. Interestingly, X-ray photoelectron spectroscopy depth profiling, complemented by synchrotron X-ray absorption spectroscopy, revealed that the long term bulk stability of 2D tin perovskites is not solely due to surface-level protection by the hydrophobic spacer cations as generally believed, but also due to effective subsurface protection from strong interlayer interactions that prevent penetration of air and water underneath the surface of the crystal. This study informs how we can rationally design 2D tin perovskites for enhanced air stability to enable further property studies and eventual applications in stable, high performance devices.

2D Materials for the Electrocatalytic Conversion of CO_2 and Water Depollution Damien Voiry;
University of Montpellier, France

Mitigating climate change and securing water resources are two of the major challenges of the century^{1,2}. In this context, membranes and electrocatalysis process are promising avenues to reduce the energy footprint, while mitigating carbon dioxide emissions. Our research aims to evaluate the potential of low dimensional materials for membrane and electrocatalytic applications.

Due to their atomic thickness and confined interlayer spacing, nanolaminate membranes made of re-stacked 2D nanosheets could theoretically enable improved separation performance. We developed a novel strategy to control the interlayer spacing and improve the separation performance of nanolaminate membranes using covalent functionalization of exfoliated nanosheets. The functionalized MoS_2 membranes demonstrated remarkable performance for water purification and desalination, while they have enabled to discriminate the role of the surface and stacking disorder on the nanofluidic behavior of water in the laminates³.

We also investigated the influence of surface chemistry on the electrocatalytic behavior of low dimensional materials. In particular, we have developed a new strategy to enhance the conversion of CO_2 to hydrocarbon molecules with two or more carbon atoms (C_{2+}) via molecular doping of a metal catalyst⁴. Specifically, we have identified electrophilic functional groups that can direct electrochemical reactions to produce C_{2+} species such as ethanol and ethylene and improve reaction rates at the catalyst surface. In my presentation, I will review our recent findings on understanding electrocatalytic and nanofluidic phenomena that take place on the surface of low dimensional materials.

Two-Dimensional Organic-Perovskite Hybrid Materials and Heterostructures Letian Dou; Purdue University, United States

Epitaxial heterostructures based on oxide perovskites and III–V, II–VI and transition metal dichalcogenide semiconductors form the foundation of modern electronics and optoelectronics. Halide perovskites—an emerging family of tunable semiconductors with desirable properties—are attractive for applications such as solution-processed solar cells, light-emitting diodes, detectors and lasers. Their inherently soft crystal lattice allows greater tolerance to lattice mismatch, making them promising for heterostructure formation and semiconductor integration. Atomically sharp epitaxial interfaces are necessary to improve performance and for device miniaturization. However, epitaxial growth of atomically sharp heterostructures of halide perovskites has not yet been achieved, owing to their high intrinsic ion mobility and their poor chemical stability. Therefore, understanding the origins of this instability and identifying effective approaches to suppress ion diffusion are of great importance. In this talk I will present an effective strategy to substantially inhibit in-plane ion diffusion in two-dimensional halide perovskites by incorporating rigid π -conjugated organic ligands. Highly stable and tunable lateral and vertical epitaxial heterostructures, multiheterostructures and superlattices will be demonstrated. Furthermore, using these 2D heterostructures as a new platform, I will present our recent efforts in 1) quantitatively understanding the anion inter-diffusions and migrations, and 2) controlling and manipulating exciton transport and light-emission in halide perovskites.

4:15 PM EN06.02.06

Unveiling Electronic and Excitonic Properties of 2D Ruddlesden-Popper Perovskites Based on Bifunctional Ligands Xinjue Zhong¹, Xiaojuan Ni², Alan B. Kaplan¹, Xiaoming Zhao¹, Marko Ivancevic¹, Melissa L. Ball¹, Zhaojian Xu¹, Hong Li², Barry P. Rand^{1,1}, Yueh-Lin Loo^{1,1}, Jean-Luc Brédas² and Antoine Kahn¹; ¹Princeton University, United States; ²The University of Arizona, United States

Two-dimensional (2D) Ruddlesden-Popper halide perovskites exhibit remarkable tunability of optoelectronic properties and good environmental stability achieved through the selection of organic cations. The incorporation of bifunctional ligands featuring non-ammonium terminus and functional groups capable of forming extra bonding motifs within the organic bilayer provides an effective strategy to engineer perovskite structures and introduce additional functionalities.

Here, we explore a series of $n = 1$ 2D perovskites incorporating organic ligands with diverse functional groups (-CN, -OH, -COOH, -Ph, and -CH₃), each exhibiting distinct bonding characteristics and dielectric properties, and report on the impact of these bifunctional ligands on the electronic and excitonic properties of these 2D perovskites.^[1]

We perform ultraviolet and inverse photoemission spectroscopies (UPS/IPES) to determine the energy positions of the valence band maximum and conduction band minimum, and the electronic, or single-particle, gap of these 2D perovskites. We observe a strong correlation between the electronic gaps of the -CN, -COOH, -Ph, and -CH₃-based perovskites and the in-plane Pb-I-Pb bond angle, aligning with earlier findings regarding the relationship between optical gaps and the in-plane Pb-I-Pb bond angle.^[2]

Interestingly, the gap of the -OH-based perovskite deviates significantly from this trend. We conduct density functional theory calculations and tight-binding model analysis to further elucidate this structure-property relationship. We attribute the “-OH” anomaly to band dispersion along the out-of-plane

direction, caused primarily by interlayer electronic coupling present in (OH-EA)₂PbI₄. By subtracting optical gap from single-particle gap, we estimate the exciton binding energy (E_b) in these 2D layers, which ranges from 420 meV for (CH₃-PA)₂PbI₄ to 130 meV for (OH-EA)₂PbI₄. This large variation is attributed to specific structural aspects, such as in-plane Pb-I-Pb bond angle, interlayer spacing, and the dielectric constant of the bifunctional ligands.

Our results provide deeper insights into the complex impact of organic ligands on the electronic and excitonic properties of 2D perovskites, in particular the substantial role of strong interlayer electronic coupling. These findings contribute to a better understanding of the structure-property relationship in such materials, facilitating the design and optimization of perovskite-based devices for various applications.

Valence Alternation in Quasi-One-Dimensional Antimony Selenide Xinwei Wang¹, Seán R. Kavanagh^{1,2} and Aron Walsh^{1,3}; ¹Imperial College London, United Kingdom; ²University College London, United Kingdom; ³Ewha Womans University, Korea (the Republic of)

Antimony selenide (Sb₂Se₃) has emerged as an earth-abundant and environmental-friendly alternative among thin-film photovoltaic light absorbers due to its promising optoelectronic properties. A distinguishing feature of Sb₂Se₃ is its anisotropic crystal structure, which is composed of quasi-one-dimensional (1D) [Sb₄Se₆]_n ribbons. However, the current record conversion efficiency of Sb₂Se₃ (~10%)^[1] is far from optimal. It has been reported that orientation control of Sb₂Se₃ films is important to achieve high device performance^[2], but the underlying physics remains unclear.

In this talk, I will present our most recent work^[3-5] investigating reasons that affect the conversion efficiency in Sb₂Se₃ based on first-principles calculations. I will first introduce the anisotropy in bulk Sb₂Se₃ structure and the resulting impacts on structural, electronic and optical properties. Then I will present results on the unusual defect physics. Multi-electron negative-*U* transitions between defect charge states can be understood from valence alternation enabled by large local structural rearrangements. Finally, I will discuss potential strategies to optimize the performance of Sb₂Se₃-based photovoltaics.

Patterning Edge-Like Defects and Tuning Defect Propagation on the Basal Plane of Ultra-Large MoS₂ Monolayers Toward Hydrogen Evolution Reaction Bianca R. Florindo¹, Leonardo H. Hasimoto^{1,2}, Nicolli S. de Freitas¹, Graziâni Candiottto³, Erika N. Lima⁴, Cláudia de Lourenço¹, Carlos Ospina¹, Jefferson Bettini¹, Edson R. Leite¹, Renato S. Lima¹, Rodrigo B. Capaz¹ and Murilo Santhiago^{1,2}; ¹Brazilian Nanotechnology National Laboratory, Brazil; ²UFABC, Brazil; ³UFRJ, Brazil; ⁴UFR, Brazil

The catalytic sites of MoS₂ monolayers towards hydrogen evolution are well known to be vacancies and

edge-like defects. However, it is still very challenging to control the position, size, and propagation of defects on the basal plane of MoS₂ monolayers by most of defect-engineering routes. In this work, the fabrication of arrays of etched windows on ultra-large supported [1] and free-standing MoS₂ monolayers using focused ion beam (FIB) is reported for the first time. By tuning the Ga⁺ ion dose it is possible to confine defects near the etched edges or propagate them over ultra-large areas on the basal plane. The electrocatalytic activity of the arrays toward hydrogen evolution reaction (HER) was measured by fabricating microelectrodes using a new method that preserves the catalytic sites. We demonstrate that the overpotential can be decreased up to 290 mV by assessing electrochemical activity only at the basal plane. HRTEM images obtained on FIB patterned freestanding MoS₂ monolayers reveal the presence of amorphous regions and X-ray photoelectron spectroscopy indicate excess of sulfur in these regions. Density-functional theory calculations provide identification of catalytic defect sites. Our results demonstrate a new rational control of amorphous-crystalline surface boundaries and future insight for defect optimization in MoS₂ monolayers.

Highly Stable Perovskite Solar Cells Coated with Solar Transparent and Thermally Emissive Mesoporous Nanoparticles Heesuk Jung^{1,2}, Sung Yoon Min³, Byungsoo Kang¹, Yongseok Yoo⁴, Jinhun Jang⁵, Yeoun-Woo Jang⁴, Hyojeong Choi⁶, Hyeong Won Lee⁶, Swarup Biswas⁶, Yongju Lee⁶, Mansoo Choi⁴, Phillip Lee¹, Min Seok Jang³, Hyeok Kim⁶ and Shu Yang²; ¹Korea Institute of Science and Technology, Korea (the Republic of); ²University of Pennsylvania, United States; ³Korea Advanced Institute of Science and Technology, Korea (the Republic of); ⁴Seoul National University, Korea (the Republic of); ⁵Frontier Energy Solution, Korea (the Republic of); ⁶University of Seoul, Korea (the Republic of)

Continuous heat generation in perovskite solar cells (PSCs) due to repeated exposure to solar light is detrimental to the device lifetime. Existing active cooling strategies often require extra energy input. Meanwhile, most passive radiative cooling materials are not solar transparent or require complex fabrication processes. Here, we design, synthesize, and assemble mesoporous silica nanoparticles in multi-layered stacks to create a graded refractive index (GRI) coating for PSCs. The coating offers not only high transparency in the visible wavelength but also high emissivity in the mid-infrared regions. When applied to PSCs that are placed outdoors for 20 days, 81.2±9.50% of the initial photo conversion efficiency (PCE) is maintained, whereas PCE of the pristine PSCs decreases significantly to 8.44±6.84%. The calculated cooling power of the GRI coated PSCs is 28.9% more than that of the pristine PSCs. Our study sheds light on efficient cooling materials that will assist broader adoption of PSCs.

Ramifications of B Site Cation Variation in Some Piezoelectric Organic-Inorganic Hybrid

Halometallates Michael Wells¹, Jacob L. Hempel¹, Santosh Adhikari², Y.T. Cheng^{1,1}, Sean Parkin¹, Christopher Sutton² and Aron J. Huckaba¹; ¹University of Kentucky, United States; ²University of South Carolina, United States

The need for alternative energy sources is rising align with increased utilization of dwindling fossil fuels. One way to help meet the ever-increasing demand is to develop materials and devices that turn wasteforces like vibrations into electricity through the piezoelectric effect. Ceramics such as Lead zirconium titanate(PZT) and Barium titanate (BTO) and polymers like poly (vinylidene difluoride) (PVDF) have been the goldstandard materials, but recently organic-inorganic hybrid metalates (OIHMs) have come to the forefront of thefield, due to high piezoelectric moduli and voltage constants. OIHMs have a basic structure of ABX,are simple to synthesize and process with solution methods, and can be deposited on a variety of substrates.Here we report efforts to probe the effects of the B-site cation identity on chlorometallate structures in piezoelectric materials with chiral and achiral A site cations. Screening many transition metal and main group heavy element B-site cations andsingle or dicationic chiral ammonium cations led to the formation of single-crystalline piezoelectric OIHMs.Piezoresponse force microscopy (PFM) was used to measure local piezoelectric response values of the OIHMs, and other material properties were correlated with material structure.

8:00 PM EN06.03.04

Tailoring Reduced Graphene Oxide Layer onto Microstructured Surface for Enhanced Boiling Heat Transfer Maroosol Yun, Dong Il Shim, Juyeong Nam and Hyung Hee Cho; Yonsei University, Korea (the Republic of)

As cooling capacity demands for systems of high heat flux, such as nuclear fusion reactor, integrated chip cooling, continuously grows, boiling heat transfer which utilizes latent heat accompanied by phase change could be an advantageous thermal management method with smaller superheat of system. Two major factor, critical heat flux (CHF) and heat transfer coefficient (HTC), which indicates the maximum cooling capacity of nucleate boiling and heat transfer efficiency, respectively, can be employed for determining boiling heat transfer performance. CHF and HTC can be enhanced by promoting bubble nucleation and supplying working fluid to the heated surface to fully utilize the latent heat of vaporization. Nanoparticle coating with graphene related particles on heated surface could promote bubble nucleation as it generates smaller bubbles compared to the plain surface, by offering nucleation sites (micro-sized cavities) in the coating. However, hydrophobic coating layer could block liquid paths, which leads to immature critical heat flux by rejecting working fluid supply. To ensure liquid paths with hydrophobic particle coating, hydrophilic liquid paths should be secured. In this study, we propose tailored coating of reduced graphene oxide (rGO) particle on the micropillar array and plain surfaces. The rGO-coated surfaces were prepared by stepwise methods of deep reactive ion etching (DRIE) and nanofluid boiling with 0.0005 wt% rGO solution. Micropillars are made to be 10 μm in height, 4 μm in diameter, and 20 μm in pitch, respectively, and nanofluid boiling step was controlled for surface tailoring. First, surfaces were coated by nanofluid boiling with increasing heat fluxes immediately before CHF, which results in completely coated micropillar and thick porous coating on plain surface. Then, we run nanofluid boiling at 60 W/cm^2 heat flux for overnight, which is equivalent to the full coating procedure to make thin floating layer on the micropillar. Experimental surfaces of Plain, fully coated micropillar, lightly coated recorded 89 W/cm^2 , 201 W/cm^2 , and 238 W/cm^2 in CHF and 20.4 $\text{kW}/\text{m}^2\text{K}$, 45.9 $\text{kW}/\text{m}^2\text{K}$, and 90.98 $\text{kW}/\text{m}^2\text{K}$ in maximum heat transfer coefficient, respectively. CHF and HTC records confirm that surface with floating rGO layer demonstrates superior heat transfer performance to the fully coated micropillar surface. The notable

improvement on CHF and HTC in the tailored rGO surfaces indicates ensuring liquid path beneath the hydrophobic rGO layer by tailoring deposition condition could improve nanoparticle-coated surfaces heat transfer performance, allowing 160% increased HTC compared to the plain surfaces. This study will be helpful for enhanced boiling heat transfer on cooling systems for high heat flux devices like heat exchangers and fusion reactors.

8:00 PM EN06.03.05

Weak-Localization Phenomena as a Tool for Quantification of Defects in MXenes and 2D Metallic Nanolayers Barbara Pacakova^{1,2}, Anupma Thakur², Nithin Chandran Balachandran Sajitha², Karel Vyborny³, Annabelle Harding² and Babak Anasori²; ¹Norwegian University of Science and Technology, Norway; ²IUPUI, United States; ³Institute of Physics, CAS, Czechia

Weak localization¹ (WL) is a quantum phenomenon, where at cryotemperatures, electrons in the metal move around a closed loops and return to their initial point of origin rather than proceeding forward in the lattice, which increases resistivity of metal with decreasing temperature. Typically, metals with defects exhibit transition from normal metallic conductivity to WL regime at low temperatures. In this study, we introduced defects in MXene flakes, such as vacancy clusters and flake boundaries and measured the temperature and field dependence of the resistivity in 2D metallic MXene films. We observed the transition temperature to WL state increases with increasing the amount of defects in MXene flakes. Properties of the 2D nanosheets were also studied by complementary experiments such as XRD, AFM and SEM. Our results indicated that measurements of the temperature and field dependencies of resistivity, can be used as a sufficient and superior technique to understand the amount of defects in the MXenes and 2D metal nanosheets in general, by determining coherence length of electrons at low temperatures in the WL regime. We thus present how the overall quality of 2D flakes in MXene films can be determined by investigating their transport properties. This technique gives a broader picture of MXene defects compared to more localized defect characterization techniques such as transmission electron microscopy.

Graphene Aligned 2D Charge Transport Network for the Thick Electrode for Lithium-Ion Batteries via the Spark Plasma Sintering Process Bo Nie and Hongtao Sun; Penn State University, United States

Developing electrochemical energy storage that can achieve high areal, volumetric, and gravimetric performance simultaneously presents a significant challenge from both a fundamental and technological standpoint. Increasing the thickness and density of electrodes to enhance areal and volumetric performance while maintaining high gravimetric performance is a straightforward yet problematic approach. The insufficient charge transports in these electrodes, which have high mass loading and density, can severely degrade energy storage performance.

In this study, we address this challenge by developing a graphene-based network that is automatically aligned within thick electrodes, fabricated through energy-efficient spark plasma sintering. The electrodes exhibit a high electrode density (2.0-2.3 g cm⁻³) and high mass loading (70-100 mg cm⁻²). Leveraging the exceptional properties of vertically aligned graphene-based networks, anisotropic pore channels, and intrinsic properties of two-dimensional (2D) graphene (e.g., superior thermal and electrical conductivity

as well as the large surface area), efficient charge transport is enabled throughout the entire electrode thickness. Furthermore, by incorporating a small amount of carbon nanotubes to improve electrode integrity, the hybrid carbon network and characteristic alignment structure of the sintered lithium iron phosphate (LiFePO_4) electrodes perform high areal (8.6 mAh cm^{-2}), volumetric capacity (246 mAh cm^{-3}), uncompromised gravimetric performance (164 mAh g^{-1}) at normal current ($<2 \text{ mA cm}^{-2}$), and stable cycling with a capacity retention of 84% after 200 cycles under a current density of 4.5 mA cm^{-2} . The automatic alignment of the graphene-based network through the spark plasma sintering process provides a promising approach for designing efficient charge transport pathways in high-energy-density batteries. The insights gained from this graphene alignment strategy can be applied to various other electrode materials in energy storage systems, such as batteries, fuel cells, and supercapacitors. Furthermore, our future research will focus on extending this approach to solid-state systems by incorporating an ionic conducting phase.

8:00 PM EN06.03.08

Biexciton-Induced Hyper-Raman Scattering in Two-Dimensional Halide Perovskite $(\text{C}_6\text{H}_5\text{C}_2\text{H}_4\text{NH}_3)_2\text{PbI}_4$ under Resonant Two-Photon Excitation Seung Han Shin and Joon Ik Jang; Sogang University, Korea (the Republic of)

$(\text{C}_6\text{H}_5\text{C}_2\text{H}_4\text{NH}_3)_2\text{PbI}_4$ is a prototype two-dimensional (2D) halide perovskite, exhibiting various excitonic phases due to strong quantum and dielectric confinements, thereby ideal for investigating fundamental exciton physics. Being four-body quasiparticles in a semiconductor, biexcitons are typically generated via inelastic Coulomb binding of two excitons under strong pulsed excitation. However, they can be efficiently generated by resonant two-photon exciton utilizing the effect of giant oscillator strength. Here, the biexciton level of $(\text{C}_6\text{H}_5\text{C}_2\text{H}_4\text{NH}_3)_2\text{PbI}_4$ is precisely determined to be 4660.8 meV by resonant two-photon excitation, which is also confirmed by considering the mechanism for the biexciton photoluminescence (PL) process. The corresponding two-photon absorption coefficient turns out to be extremely large ($\beta = 2.0 \times 10^5 \text{ cm/MW}$) due to the giant oscillator strength for the transition. Intriguingly, upon increasing the excitation intensity, a new sharp peak emerges near the high-energy onset of the biexciton PL line, corresponding to the $k = 0$ state. This peak shifts by $\Delta 2\omega$ when the excitation photon energy is varied by $\Delta\omega$ near the two-photon resonance. We show that this strong signal arises from two-photon hyper Raman scattering into the exciton level, where the biexciton state only serves as a virtual intermediate state. This Raman peak is highly suppressed under co-circular polarized excitation, which is also consistent with the two-photon selection rules for the angular momentum of the biexciton. Moreover, the threshold for stimulation in the Raman process is determined to be 80 MW/cm^2 at 10 K , which gradually increases with temperature. Our findings highlight highly nonlinear optical properties of this important material and its potential for biexciton-based photonic applications.

Keywords: 2D halide perovskites, biexcitons, hyper Raman scattering, giant two-photon absorption, stimulated Raman scattering

Pathways to Successful Deployment of Perovskite Solar Cell Technology: A Data-Driven Approach on Research Trends Through Bibliometrics Jun-Seok Yeo¹, Jihong Kim¹ and Seung-Hoon Lee²;

¹Korea Institute of S&T Evaluation and Planning, Korea (the Republic of); ²Kongju National University, Korea (the Republic of)

Achieving the goal of global carbon neutrality by 2050 will require faster technology innovation and deployment across a range of sectors including power generation, transportation, industrial processes, and more. In particular, an energy transition based on renewable energy is a prerequisite for the new-zero emission of other sectors. Among the next-generation power sources, photovoltaic (PV) has been considered as a viable technology for the energy transition. Especially, hybrid organic-inorganic perovskite solar cells (PeSCs) have been intensively researched due to their high performance, light weight, affordability, and wide range of applications. In this study, we systematically examined the research trends and the cooperation networks by bibliometric methods, focusing on the social acceptance of the technology. A total of 8,607 documents published from 2019 to 2021 were investigated. First, we determined the commercialization factors by considering the LCOE and environmental impact; cost, efficiency, stability, scaling-up, and public acceptability. All publications were categorized by publication years and the commercialization factors. In addition, a variety of bibliometric methods were used: (1) statistical analyses, (2) topic modeling based on publication abstracts, and (3) social network analysis of institution-level co-authorships. These strategic analyses will provide different aspects of the scientific findings and facilitate further discussion on PeSC research directions.

Determining Bandgap Energy of Arbitrary Low-Dimensional Structures from Simulated Absorbance Philip M. Chamberlin and Kofi Adu; The Pennsylvania State University, United States

Low-dimensional structures are critical in developing the next generation of energy harvesting devices, such as photovoltaics. The bandgap energy of a material is critical in determining the wavelength range that can be absorbed by a given material and is influenced by quantum confinement effects. We propose a flexible program made in MATLAB that can analyze absorbance data of arbitrary low-dimensional structures to determine the bandgap energy using the Tauc plot and sigmoid-Boltzmann methods. We analyzed absorbance data generated using a COMSOL Multiphysics simulation of absorbance of exotic nanostructures. This program can be extended to all configurations, from zero dimensional structures to bulk materials.

Investigation Resistive Switching Mechanism of 2D Inorganic Halide Perovskite CsPb₂Br₅ Microsheet Based Memristor Uijin Jung, Zhaozhong Tan, Wonjun Heo, Sangmin Kim and Jinsub Park; Hanyang University, Korea (the Republic of)

Resistive switching (RS) devices based on inorganic metal halide perovskites (IMHPs) are currently under extensive investigation as prospective materials for next-generation memory due to their inherent hysteric behavior, simple manufacturing process, and improved environmental stability. However, the RS operations of polycrystalline IMHPs based devices are generally governed by migrations of ions and defects along to grain-boundaries (GBs) with low activation energies, which hinder the emergence of RS behavior coming from the IMHPs material itself. In addition, GBs in the IMHPs layer greatly increase the leakage current in the high-resistance state (HRS), degrading the RS characteristics, especially the narrowing of the on/off resistance window. Herein, we fabricated RS devices using GBs-free single crystal CsPb₂Br₅ microsheet and analyzed their RS characteristics. Through high-resolution transmittance electron microscope (HRTEM) and selected area diffraction (SAED) pattern and Raman analysis, we

confirmed that the synthesized microsheet was pure single crystal CsPb_2Br_5 without any other impurities. The vertical-type device was fabricated by depositing the top and bottom electrodes (T and BE) on the CsPb_2Br_5 (001) and (00-1) plane. In terms of effects of TE materials, RS did not occur when the inert electrode was used as the TE, unlike previous reports, but, the RS devices with active metal TE showed bipolar non-volatile RS characteristics, and exhibited an on/off resistance ratio ($\sim 10^8$) with low operating voltage ($\sim 0.32\text{V}$). In addition, a reset voltage-driven multi-level operation was also shown, and each state had a large on/off resistance window up to $\sim 10^2$. On the other hand, a planar-type device in which both electrodes are formed on the (001) plane of CsPb_2Br_5 microsheet was also fabricated, and the RS characteristics were investigated. Unlike the vertical-type device, the device with inert metal electrode exhibited volatile RS characteristics, while the device with an active metal electrode showed non-volatile RS characteristics with a short retention time. Through nudged elastic band (NEB) calculations, we know that the bromine vacancy defects which mainly present inside CsPb_2Br_5 crystal prefer movement in the (001) plane rather than the [001] direction corresponding with the measured RS characteristics of the device based on the inert metal electrode. Moreover, the presence of Ag elements in CsPb_2Br_5 in the LRS was confirmed through auger electron spectroscopy (AES) depth-profile analysis, which suggests that active metal ion migration and redox reaction are the main causes of RS in vertical-type CsPb_2Br_5 based memristor. This study can provide insight into the influence of the used active electrode as well as internal defects in the material in the HPs based RS device.

Colloidal Synthesis of Quaternary Chalcogenide Nanocrystals [Irina Gushchina](#)^{1,2}, Stefano Toso², Masaru Kuno¹ and Liberato Manna²; ¹University of Notre Dame, United States; ²Istituto Italiano di Tecnologia, Italy

Thanks to their optoelectronic properties, good stability, and abundance of elements involved, chalcogenides of IV and V group metals are considered promising candidates for future electrical and optical applications.¹⁻² However, their limited processability in bulk form, which requires maintaining high-temperature conditions for long times, represents a challenge for their implementation in functional devices. This has recently stimulated the exploration of alternative synthetic routes based on colloidal chemistry for obtaining the same materials in milder conditions, resulting in the successful preparation of lead- and bismuth- based ternary chalcogenides.³⁻⁵ However, these materials are all indirect-gap semiconductors, which limits their applicability to light harvesting and thermoelectric devices. Nevertheless, direct-gap materials are within reach if we start considering quaternary chalcogenides, with general formula $\text{M}_a\text{M}'_b\text{E}_c\text{X}_d$ (M and M' = metals; E = S, Se, Te; X = Cl, Br, I).⁶ In this study, we explore the colloidal synthesis of quaternary sulfide nanocrystals containing Pb, Bi, and Sb. Through the choice of precursor concentrations, metals feed ratios and reaction temperatures, this highly tunable synthetic approach offers control over the composition, morphology and ultimately properties of the reaction product. Our investigations confirm the direct gap of these materials, which can be tuned in the visible spectrum by alloying different metals and halides in the structure. This, combined with the remarkable stability of these materials, offers a first step towards real-world applications in optoelectronic devices.

Elastic Crystalline Silicon Solar Mini-Module Based on All-Back-Contact Structure Jeonghwan Park and Kwanyong Seo; Ulsan National Institute of Science and Technology, Korea (the Republic of)

Flexible and foldable solar cells have attracted numerous interests because they can provide continuous power on uneven surfaces of wearable applications. Crystalline silicon (c-Si) solar cells currently account for more than 95% of the total solar cell market share due to the abundance of Si and stability and high efficiency of the c-Si solar cells. However, c-Si solar cells are difficult to bend and stretch because they tend to become brittle when external forces are applied. Therefore, c-Si solar cells need to be installed on mechanically flat surfaces due to their rigid nature. In this work, we have demonstrated an elastic c-Si solar mini modules through the novel design of an all-back-contact configuration and the introduction of PDMS-based elastic interconnecting electrodes. The elastic c-Si solar module exhibited a module efficiency of 15.0% and a high voltage output of 4.87 V, with a size of 12 cm². Additionally, the elastic solar module demonstrated stable photovoltaic properties by maintaining less than a 4% reduction in initial efficiency under both folding and stretching conditions (up to a strain of 40%). We expect that this module can overcome the existing limitations of solar module installation and seamlessly integrate with flexible or wearable electronics, providing a continuous power source.

Molecular Insight into Charge Storage Mechanism in 2D Conjugated Covalent Organic Frameworks Zhengnan Tian, Vinayak S. Kale, Osama Shekhah, Mohamed Eddaoudi and Husam N. Alshareef; KAUST, Saudi Arabia

2D conjugated covalent organic frameworks (COFs) are currently attracting significant interest as host materials in electrochemical energy storage. They show some intriguing properties, such as designable conductivity, tunable layer distance, and flexible stacking form. However, there has been a lack of deep understanding of the charge storage mechanism related to conjugation degree, stacking model, and pore accessibility. Therefore, by topochemical molecular design, we synthesized two different aromatized imine-based 2D conjugated COFs. According to the detailed electrochemical analysis, in situ measurements, and theoretical simulation, we have discovered a charge storage mechanism that shows that ion diffusion kinetics, which is controlled by the stacking model of the COF, play a more important role than electron migration kinetics, which are controlled by the degree of conjugation, in the charge storage process. We believe this new understanding can be leveraged to design and develop more suitable 2D conjugated COFs for electrochemical energy storage.

MXene Sandwiched with Micro Polymer Fibers for Supercapacitor Energy Storage Zuwan Wen, Youngseok Kim, Jaeil Park, Minhu Huang and Myung-Han Yoon; Gwangju Institute of Science and

Technology, Korea (the Republic of)

MXene ($\text{Ti}_3\text{C}_2\text{Tx}$), is considered as a promising electrode material for supercapacitors due to its metallic conductivity, large specific surface area and fast surface redox reaction capability. However, MXene flakes are inclined to stack together, resulting in severe loss of electrochemically active sites that restricts the electrochemical energy storage capability. Herein, we demonstrated a simple and effective strategy to fabricate MXene/PEDOT:PSS micro fibers sandwich structure films via alternative filtering MXene and PEDOT:PSS fiber dispersions with different mass ratio. The conductive crystallized PEDOT:PSS fiber self-fused into porous fibillar networks not only acted as conductive bridge facilitating electron transport, but also played a role as pillar between MXene nanosheets to expose more electrochemical active surfaces and shorten electrolyte ion pathways. As a result, the as-prepared composite film delivered a capacitance higher than 300 F/g with good rate performance in 1M H_2SO_4 electrolyte, which is better than the compact packed pristine MXene film. Furthermore, the PEDOT:PSS fiber networks improved composite film flexibility enables it bend and fold to arbitrary shapes without apparent electrical/electrochemical damage. This work reveals the importance of MXene based electrode architecture on electrochemical performance and guide on designing hierarchical composites materials for energy storage, catalysis, and flexible electronics applications.

Keywords: $\text{Ti}_3\text{C}_2\text{Tx}$ MXene, PEDOT:PSS fibers, Flexible composite electrode, Supercapacitor

Redox based Chemical Organometallization: A Novel Strategy for Phase Engineering in Transition Metal Dichalcogenides Juhwan Lim, Ebin Sebastian, Pratyush Ghosh, Jiho Han, Christoph Schnedermann and Akshay Rao; University of Cambridge, United Kingdom

Phase engineering in transition metal dichalcogenides offers the ability to tune electric and optical properties, leading to enhance performance in electrical, optoelectronics and energy applications. Among the various available methods (i.e. chemical, electrochemical, optical, and mechanical approaches), chemical lithiation using pyrophoric n-butyllithium has been most widely used for inducing crystallographic phase transformation, from the semiconducting octahedral (2H) to the metallic trigonal prismatic (1T) phase in group 6-TMDs. Here, the donation of electron as well as gliding and adsorption of lithium ion play pivotal roles in driving the phase transition.

In this study, we demonstrate a novel facile and safe method to synthesize organometallic agents, which are then utilized for lithiating and sodiating 2H- MoS_2 and 2H- WS_2 to phase engineer 1T- Li_xMoS_2 , 1T- Na_xMoS_2 , and 1T- Na_xWS_2 . Our approach is based on the correlation between the chemical redox potential and electrochemical potential, which were determined with in-situ optical reflectance measurements. In electrochemical measurements, MoS_2 exhibits discrete electrochemical potentials for a phase transition (PT) and further decomposition (amorphization, D) at both electrochemical lithiation (PT : 1.13 V, D: 0.55 V versus Li/Li^+), and electrochemical sodiation (PT : 0.9 V, D: 0.8 V versus Na/Na^+) processes. Therefore, we employed a reduced species of anthracene (redox potential around 0.9 V versus Li/Li^+) to align the chemical redox potential with that of MoS_2 . Remarkably, the use of anthracene facilitates a rapid and safe approach for both lithiation and sodiation, which yields high-quality metallic 1T- MoS_2 .

We have extended this approach to reliably synthesize metallic 1T- WS_2 . WS_2 displays distinct electrical potential values for phase transition and subsequent decomposition only when interacting with sodium (PT: 1.1 V, D: 0.55 V versus Na/Na^+), while both potentials are nearly indistinguishably close with lithium. Thus, by employing an anthracene-sodium system, we are able to produce 1T- Na_xWS_2 .

Furthermore, we demonstrate that this process can be complemented by above-gap light, which accelerates the reaction by up to 1000 times. We carefully examined each TMD flakes with different phase, by monitoring the change of A-exciton photoluminescence, the emergence of Raman J peaks, and shifts of Raman peaks.

Taken together, our study reveals a novel method to synthesize organometalization agents, for advanced, safe phase engineering of 2D materials by creating cation intercalation structures, which can be further accelerated by integration of above-gap light illumination.

Fabrication and Characterization of Nanoscale Multilayered Thin-Film Thermoelectric Materials and Devices Fabian Sanchez¹, Elton Mawire¹, Eric Smith¹, Kim Kisslinger² and Zhigang Xiao¹;

¹Alabama A&M University, United States; ²Brookhaven National Laboratory, United States

In this study, we report the growth of nanoscale multilayered thermoelectric thin films and fabrication and characterization of integrated thermoelectric devices for the application of high-efficiency energy conversion and solid-state cooling. Nano multilayered Bi₂Te₃/Sb₂Te₃, Sb/Sb₂Te₃ and Te/Bi₂Te₃ thermoelectric thin film materials were grown on various substrates using the e-beam evaporation. The multilayered thin films were prepared with 100 to 300 layers, where each layer is about 3 to 5 nm thick. The effect of substrates on the growth of films such as the crystalline structures in the films was studied. Integrated thermoelectric devices with a high density of thermoelectric elements were fabricated with the nanoscale multilayered thin films using the clean room-based microfabrication techniques such as UV lithography. Plasma-enhanced atomic layer deposition (PE-ALD) was used to grow zirconium dioxide (ZrO₂) as the insulation layer in the device fabrication. X-ray diffraction and high-resolution tunneling electron micrograph (HRTEM) were used to analyze the nanoscale multilayered thin films. The fabricated device was cooled in liquid nitrogen or annealed at 150 °C for 30 min, respectively. HRTEM was used to analyze the cross-section of the nanoscale multilayered thin films for the three cases: as-grown, after being cooled in the liquid nitrogen, and after being annealed. The thermoelectric characteristics of the fabricated devices were measured and compared for the three cases of as fabricated, after being cooled, and after being annealed, respectively, showing that the integrated thermoelectric device had the highest efficiency of thermal-to-electrical energy conversion after being cooled in the liquid nitrogen. The fabricated nanoscale multilayered thin-film thermoelectric materials and devices could be used for the application of high-efficiency energy conversion and solid-state cooling.

Carrier Type Switching in Bismuth Telluride through *In-Situ* Organic Molecule Coating Jun Beom Park¹, Wei Wu², Jason Y. Wu², Rijan Karkee^{1,3}, Theresa M. Kucinski¹, Karen Bustillo⁴, Matt Schneider^{1,1}, David A. Strubbe³, Colin Ophus⁴ and Michael T. Pettes¹; ¹Los Alamos National Laboratory, United States; ²University of Connecticut, United States; ³University of California, United States; ⁴Lawrence Berkeley National Laboratory, United States

Thermoelectric materials have gained significant attention for their ability to efficiently convert waste heat into electricity. Among these materials, Bi₂Te₃ stands out as a near-room temperature thermoelectric

material due to its exceptional properties, such as high electrical conductivity and relatively low thermal conductivity. Furthermore, low-dimensional Bi_2Te_3 nanostructures has also shown promise in enhancing thermoelectric properties, but it faces challenges, such as chalcogen vacancies and surface oxidation. To address these challenges, various methods have been proposed, including oxygen plasma treatment, superacid treatment, and atomic layer deposition (ALD) of Al_2O_3 to prevent surface oxidation. Simultaneously, several approaches have been explored to enhance thermoelectric properties of nanostructures through employing external dopant layer, such as tetrafluoro-tetracyanoquinodimethane ($\text{F}_4\text{-TCNQ}$). Here, we demonstrated the successful synthesis of $\text{Bi}_2\text{Te}_3/\text{F}_4\text{-TCNQ}$ layered nanostructures through catalyst-free chemical vapor deposition (CVD). Even after a month of exposure to air, TEM analysis revealed an oxidation-free interface, confirming the efficacy of the coating as an oxygen diffusion barrier. In addition to this, the majority carrier type of the nanostructures switched from *n*-type to *p*-type and their Seebeck coefficient increased over an order-magnitude. It confirms that this in-situ organic layer coating not only provides an oxidation-protecting layer, but also act as a hole-injecting layer that can lead to a significant improve of thermoelectric characteristics. Finally, the $\text{F}_4\text{-TCNQ}$ -coated Bi_2Te_3 exhibited an order-of-magnitude higher thermoelectric figure of merit (zT) that peaks at a minimum of 10–20 times improvement 250 K.

SESSION EN06.04: 2D Materials for Energy Conversion and Energy Storage I

WITHDRAWN EN06.04.01 Exfoliated Hafnium-Based Nanosheets as Catalysts for Oxygen Evolution in Acid Manish Chhowalla; University of Cambridge, United Kingdom

The zero pH condition of proton exchange membrane (PEM) water electrolyzers means that only a few metal oxide catalysts involving rare and expensive metals are sufficiently stable for the oxidation reaction. Therefore, earth-abundant acid-stable oxygen evolution reaction (OER) catalysts are required for sustainable water splitting. We report electrochemically exfoliated nanosheets from HfS_2 as stable and high-performance OER catalysts in pH 0 media. The oxidation during synthesis and composition of mixed amorphous and crystalline regions ($\text{a/c-HfS}_x\text{O}_y$) render this material sufficiently conductive to allow electrocatalytic activity while remaining stable in the acidic environment. $\text{a/c-HfS}_x\text{O}_y$ catalysts exhibit among the highest reported mass activity of $\sim 103,000$ A/g at an overpotential of 0.5 V versus RHE and excellent stability. Efficient PEM water electrolyzers are demonstrated using low-dimensional noble-metal-free catalysts.

8:30 AM *EN06.04.02

Advancing Design and Discovery of 2D and Quasi-2D Perovskites via Combinatorial Synthesis and Characterization Jonghee Yang¹, Foadian Elham¹, Benjamin Lawrie², Juanita Hidalgo³, Sergei V. Kalinin¹, Juan-Pablo Correa-Baena³ and Mahshid Ahmadi¹; ¹University of Tennessee, Knoxville, United States; ²Oak Ridge National Laboratory, United States; ³Georgia Institute of Technology, United States

The emergence of 2D and quasi-2D perovskites has opened exciting possibilities for next-generation

optoelectronic devices. These materials exhibit unique electronic, optical, and transport properties, making them promising candidates for a wide range of applications including solar cells, light emitting diodes and radiation sensors. However, their complex structural and compositional nature presents significant challenges in the design and exploration of these materials.

In this talk, I will discuss the use of high-throughput combinatorial synthesis and characterization techniques for the design, discovery, and exploration of 2D and quasi-2D hybrid perovskites [1,2]. By leveraging the power of automation, we can rapidly synthesize a diverse library of 2D and quasi-2D hybrid perovskite compositions and systematically investigate the effects of different synthesis parameters on the layer thickness and properties of these materials, facilitating the discovery of novel structures with enhanced performance.

Furthermore, high-throughput characterization techniques including photoluminescence and Grazing-Incidence Wide-Angle X-ray Scattering (GIWAXS) [3] allow for rapid and comprehensive analysis of the synthesized materials. This multidimensional high-throughput characterization approach helps us understand the influence of synthesis parameters and composition on layer thickness, multi-phase formation and crystal structure on the optoelectronic properties of 2D and quasi-2D perovskites, paving the way for targeted design strategies.

I will showcase recent advances in this field, including the discovery of new perovskite phases, general phase distributions in the quasi-2D hybrid perovskites compositional space, offering a comprehensive guide for designing phase-controlled systems [4].

Correlation Between Electronic Properties and Surface Reactions of Doped and Undoped MoS₂

Films for Hydrogen Production Carmela Aruta¹, Paolo Barone¹, Pasquale Orgiani¹, Piero Torelli¹, Luca Braglia¹, Elisa Riedo², Nan Yang³ and Zhiwei Nie³; ¹National Research Council, Italy; ²New York University, United States; ³ShanghaiTech University, China

MoS₂ is gaining more and more importance in the field of energy applications. In particular, it is well known that MoS₂ has interesting hydrogen evolution reaction (HER) properties for electrochemical water splitting. H 1s - S 3p orbital overlap can be modified by doping MoS₂ with transition metal ions in order to tune H adsorption and thus HER activity. Among these, Co and Mn have shown great potential. To address these issues, we used a multipurpose pulsed-laser deposition (PLD) facility directly connected to the distribution chamber of the synchrotron beamline to produce and characterize MoS₂ films grown on different substrates, with different thickness and doped with Co and Mn. The in-situ transfer technology allowed measurements by surface sensitive X-ray photoemission (XPS) and X-ray absorption (XAS)

techniques avoiding any surface contamination that may affect the sample properties. We observed that the MoS₂ interacts with the substrate at the interface which affects the electronic properties. In-operando XAS characterizations were performed with different gas environment on undoped and doped MoS₂ films in a reaction cell. The results demonstrate that the electronic structure is modified by reduction or oxidation atmospheres and are correlated with the electrocatalytic performance for HER, investigated by polarization curves. The measurements show a very high stability after many cycles and a decrease of the overpotential for hydrogen evolution in doped samples. Our study allows to understand the chemical environment, atomic response and changes in the electronic state during the absorption and desorption processes.

9:30 AM EN06.04.04

Two Dimensional Ferroelectric-Based Catalysts for Enhanced CO₂ Reduction Joshua Young and Mo Li; New Jersey Institute of Technology, United States

The electrochemical CO₂ reduction reaction (CO₂RR), which can turn CO₂ into C1 and C2 products, has been proposed as a route to both combat global warming and produce value-added fuels; however, a lack of efficient catalysts is limiting its implementation. Recently, single atom and dual atom catalysts (SACs and DACs, respectively), have been shown to enhance the CO₂RR but still suffer from scaling relationships limits. In this work, we show that 2D ferroelectric (2DFE) materials, which display a spontaneous electric polarization in a single monolayer that is switchable by an applied electric field, can be used to overcome limiting scaling relationships and break the Sabatier principle, leading to enhanced CO₂RR propensity. We first show that the predicted 2DFE MXene Y₂CO₂ with an O vacancy can preferentially adsorb CO₂ or CO. We then investigated the reduction CO₂ to various C1 products (e.g., methanol, formic acid, etc.) and find that switching the direction of the polarization changes the shape of the reaction pathway. Second, we investigated the CO₂RR on SAC and DAC-doped graphene interfaces with the 2DFE In₂Se₃. In this case, the reduction of CO₂ to CO is greatly enhanced compared to the free standing doped graphene layer regardless of the SAC/DAC coordination environment. In both systems, the asymmetry in the surface electron density allows for the tuning of surface adsorption and intermediate stability, as well as activation of alternative pathways. By combining the catalytic properties of 2D-support SACs and DACs with the switchable polarization of 2DFEs, such heterostructures can exhibit higher efficiency and selectivity for CO₂RR than existing catalysts and provides a unique route to overcome these issues.

9:45 AM EN06.04.05

New Lamellar Materials as Anode Electrodes for Alkali Metal Ion Batteries Vincent Seznec^{1,2,3}, Xi Chen^{1,2,3} and Laure Monconduit^{4,3}; ¹Laboratoire de Reactivite et Chimie des Solides, France; ²University of Picardie Jules Verne, France; ³Réseau sur le Stockage Electrochimique de l'Energie RS2E, France; ⁴Institut Charles Gerhardt, France

Recent studies have shown that two-dimensional (2D) materials, such as siloxene and germanane, as electrode in alkali metal ion batteries can lead to excellent performance. The improved electrochemical behavior of these 2D active materials could be due to the limited volume change during charge and discharge, based on an intercalation rather than an alloying mechanism. In addition, if Si is effective in reducing costs due to its low price and abundant resource reserves, its conductivity is low, while Ge can provide higher electronic conductivity than Si, but is more expensive. In this respect, in order to integrate their cheapness and excellent conductivity, we propose a series of layered materials (named siliganes, *i.e.*, Si_{1-x}Ge_x, 0.1 < x < 0.9), which consist of 2D Si-Ge composites. Through a simple method, the Ca²⁺

cations were completely removed from the precursor $\text{Ca}(\text{Si}_{1-x}\text{Ge}_x)_2$, and the lamellar siliganes were obtained. The layered materials were tested in Na- and K- ion batteries. Based on the better electrochemical performance, we identified siligane_ $\text{Si}_{0.1}\text{Ge}_{0.9}$ as the best candidate. At a current density of 0.05 A g^{-1} , its reversible capacities of the Na ion and K ion cells were 276 mAh g^{-1} and 132 mAh g^{-1} after 50 cycles, respectively.

10:30 AM *EN06.04.06

Layer-By-Layer Assembly of 2-Dimensional MXene Nanosheets with Polyelectrolyte Energy Storage Applications Junyeong Yun¹, Michel W. Barsoum², Micah Green¹, Miladin Radovic¹ and Jodie Lutkenhaus¹; ¹Texas A&M University, United States; ²Drexel University, United States

A broad family of two-dimensional ceramic nanosheets referred to as MXenes have caught the world's attention because of their wide compositional diversity and tailorability to different engineering applications including energy storage. One challenge is to translate these applications into a thin-film platform. This presentation will discuss the water-based solution-assembly of two-dimensional MXene nanosheets with polyelectrolyte using the layer-by-layer assembly technique. This approach produces conformal MXene-based coatings on a variety of surfaces including hydrophobic poly(dimethylsiloxane), glass, thread and fiber, and silicon. The result is a conformal coating consisting of a brick-and-mortar-type architecture with tunable layer thicknesses. We take advantage of the MXene-polymer morphology for electrochemical energy storage in wire shaped capacitors consisting of reduced graphene and MXene or capacitor thin films of polyaniline with MXene. Last, the energy storage mechanisms for $\text{Ti}_3\text{C}_2\text{T}_x$ MXene multilayer (ML) sheets is proved using electrochemical impedance spectroscopy (EIS) and cyclic voltammetry coupled with in situ gravimetric electrochemical quartz crystal microbalance with dissipation (EQCM-D) measurements in various electrolytes. EIS frequency-dependent mass changes associated with the transfer of hydrated cations are revealed. This study demonstrates that although cations are primarily responsible for the energy storage mechanisms in $\text{Ti}_3\text{C}_2\text{T}_x$ MLs, the anion and the time scale of observation can have a strong effect.

Application of 2D Transition Metal Sulfides in Energy Storage Hongli Zhu; Northeastern University, United States

The emergence of metallic phase two-dimensional molybdenum disulfide (MoS_2) introduces a new class of materials boasting superior electrical conductivity and catalytic activity. This presentation aims to provide a comprehensive review of the atomic structures and electrochemistry of metallic MoS_2 , an essential element in an array of established and burgeoning technological applications, with detailed studies of our lab in hydrogen evolution reaction, lithium ion and sodium ion batteries, supercapacitor, and all solid state Li sulfur batteries.

For example, recently, in our lab, a highly conductive carbon fiber decorated with hybrid 1T/2H MoS_2 nanosheets is designed. The high chemical and electrochemical compatibility among MoS_2 and sulfide solid state electrolyte can greatly improve the stability of the cathode and therefore maintain pristine interfaces. The uniform distribution of electrical conductive metallic 1T MoS_2 on carbon fiber benefits the electron transfer between carbon and sulfur. Meanwhile, the layered structure of MoS_2 can be intercalated by a large amount of Li ions facilitating ionic and electronic conductivity. In consequence, the charge transfer and reaction kinetics are greatly enhanced, and the decomposition of SSEs is

Updated as of October 28, 2024

successfully relieved. As a result, the all solid state lithium sulfur delivers an ultrahigh initial discharge and charge capacity of 1456 and 1470 mAh g⁻¹ at 0.05 C individually with ultrahigh coulombic efficiency and maintains high capacity retention of 78% after 220 cycles. The batteries also obtain a remarkable rate performance of 1069 mAh g⁻¹ at 1 C.

This talk will span the exploration of the atomic and band structures of metallic MoS₂, its electrical and optical properties, fabrication methodologies, and prominent emergent applications in the realm of electrochemical energy storage and conversion. A central feature of the talk will be the intricate relationship between the atomic structure, properties, and performance of metallic MoS₂, emphasizing the critical importance of understanding these fundamentals for emerging energy applications.

11:30 AM EN06.04.08

Layered Vanadium Disulfide Electrodes for Printed Zinc Ion Batteries Stefano Tagliaferri, Nagaraju Goli, Evan Fisher, Maria S. Sokolikova and Cecilia Mattevi; Imperial College London, United Kingdom

Aqueous Zinc Ion Batteries (ZIBs) are receiving growing attention as beyond-lithium power sources for wearable electronics and sensors, owing to their high theoretical capacity, environmental friendliness, and low cost. However, Zn²⁺ ions have a high charge density, almost double the charge density of Li⁺, which is detrimental for the intercalation kinetic and the structural stability of the battery electrodes.

Layered transition metal dichalcogenides (TMDs) have ideal features for high-performing energy storage devices, including high surface area and large two-dimensional diffusion channels inside their structure. The adjacent layers in the TMD structure are connected by weak van der Waals interactions, resulting in a large interlayer spacing which enables rapid ion diffusion kinetic and promotes the reversible insertion and extraction of multivalent ions. Among TMDs, vanadium disulfide is a promising cathode material for ZIBs, owing to its large interlayer spacing (~ 5.76 Å) and metallic character. Despite these beneficial features, vanadium disulfide has mainly been investigated in coin-cell batteries, which are difficult to directly integrate in wearable electronics.

Here, we demonstrate the combination of an easily-scalable hydrothermal synthesis with a room-temperature 3D Printing process to fabricate vanadium disulfide electrodes with customized geometry. The hydrothermal vanadium disulfide was mixed with a polymeric binder and conductive additives to obtain a stable ink with optimal printability. The architecture of the VS₂ electrodes was rationally tailored *via* the printing process to facilitate the electrolyte penetration and promote fast charge transfer. Finally, the printed vanadium disulfide electrodes were coupled with zinc anodes to assemble aqueous zinc-ion batteries. The full cells were tested in a water-in-salt electrolyte, which improved the stability of the vanadium disulfide electrode, extending the achievable potential window and energy density.

SESSION EN06.05: Low-Dimensional Perovskites—Optoelectronics and Theory

2D Layered Halides Perovskites Optoelectronic Properties Manipulation by Crystalline Orientation Rational Control Giulia Grancini; University of Pavia, Italy

In recent years, the interest in low-dimensional perovskite (LDP or 2D perovskite) materials has flourished. This is due to their beneficial effects in perovskite-based photovoltaics, enabling devices with record power conversion efficiencies and prolonged stability. These materials are mainly utilized as surface modifiers, enabling 3D/2D heterostructures, acting as passivating agent. However, the research on the implementation of LDPs as self-standing absorbing material is limited, especially for LDPs with low dimensionalities ($n=1,2,3$). The main challenges are related to their optoelectronic properties, such as reduced carriers' diffusion length and high exciton binding energies, that limit their performances. Nevertheless, LDPs still represent a valid candidate for applications where wide bandgap (>2 eV) materials are required. Indeed, LDPs circumvent the problem of halide segregation typical of 3D perovskite for such band gaps, guaranteeing prolonged stabilities of the device. Here, we present a powerful strategy to optimise LDP optoelectronic properties by finely controlling the crystallization of the material in a preferential direction. Our approach consists in orienting the inorganic sheet of the LDP material in the same direction of the charge extraction of the photovoltaic device, in order to maximize the transport of carriers and their collection at the electrodes. The preferential crystalline orientation of the LDP has been studied by advanced X-Ray Diffraction techniques, high resolution TEM imaging and directional dependent conductivity analysis, confirming the validity and the potential of the solution. The rational control over the crystal growth direction has allowed to fabricate a 2.1 eV LDP-based solar cell with power conversion efficiency about 10%, as well as semi-transparent devices with a high degree of transparency (Average Visible Transmittance $>30\%$). The chemical composition of the LDP and its improved intrinsic stability guaranteed much prolonged stability with respect to the state of the art devices with such high band gap. These results pave the way to the implementation of LDP for wide bandgap photovoltaic applications, such as semi-transparent and multi-junction tandem devices.

Synergy of 3D and 2D Halide Perovskites for Durable & Efficient Photovoltaics Aditya D. Mohite;
Rice University, United States

Three-dimensional (3D) organic-inorganic lead halide perovskites have emerged in the past few years as a promising material for low-cost, high-efficiency optoelectronic devices. Spurred by this recent interest, several subclasses of halide perovskites such as two-dimensional (2D) halide perovskites have begun to play a significant role in advancing the fundamental understanding of structural, chemical, and physical properties of halide perovskites, which are technologically relevant. While the chemistry of these 2D materials is similar to that of the 3D halide perovskites, their layered structure with a hybrid organic-inorganic interface induces new emergent properties that can significantly or sometimes subtly be important. Synergistic properties can be realized in systems that combine different materials exhibiting different dimensionalities by exploiting their intrinsic compatibility. In many cases, the weaknesses of each material can be alleviated in hetero architectures. For example, 3D-2D can demonstrate novel behavior that neither material would be capable of separately. Here I will describe how the structural differences between 3D halide perovskites and 2D halide perovskites give rise to their disparate materials properties, discusses strategies for realizing mixed-dimensional systems of various architectures through solution-processing techniques, and presents a comprehensive outlook at the use of 3D-2D systems in solar cells. Finally, we investigate applications of 3D-2D systems beyond photovoltaics, and offer our perspective on mixed-dimensional perovskite systems as semiconductor

materials

with unrivaled tunability, efficiency and technologically relevant durability.

2:30 PM EN06.05.03

Optical Control of Polarization in 2D Hybrid Molecular Crystals Lina Quan and Yixuan Dou;
Virginia Tech, United States

Spontaneous polarization is a key in developing advanced functional materials for a broad range of applications such as memory device, piezoelectric sensors, radio frequency/microwave devices, and many other systems. To manipulate structural polarization in organic-inorganic hybrid system, external stress and electric fields can induce the switching of ferroelectric polarization domains. When it comes to the electric field control, the limitation is anticipated involving the requirements for circuits and complicated device fabrication. In this presentation, I will talk about the observation of optically induced switchable polarization in 2D hybrid molecular crystal. By employing a number of advanced characterization tools, such as X-ray diffraction scattering measurement under the photo-excitation, we were able to probe and study the excited state structural dynamics from 2D hybrid molecular crystal with a clear observation of reversible lattice expansion and contraction in various time-scales.

Disentangling The Relationship between Cation and Perovskite Structures Marcin Giza¹, Justas Deveikis², James Lloyd-Hughes², Rebecca L. Milot² and Pablo Docampo¹; ¹University of Glasgow, United Kingdom; ²University of Warwick, United Kingdom

Layered perovskites utilising bulky organic cations have recently emerged as promising candidates for tackling the issues faced by conventional perovskite materials, such as their degradation in ambient conditions. Combining the benefits of good stability with desirable properties like efficient charge extraction relies on a precise understanding of the perovskite energetics, careful control of band alignment and optimised layer quality. In order to make further progress and guide future synthetic efforts, the relationship between the structure and optoelectronic properties of these films needs to be fully disentangled. Here, the interlayer spacing and the distortion of the crystal dictate the majority of the optoelectronic properties of the material. Typically, this is explained by a tunnelling mechanism, where the barrier width determines the likelihood of the process, and therefore the charge transport properties. In addition, the relative positions of the energy bands also influence this parameter, determined by the degree of distortion in the lattice. In these systems, the organic cations determine the structure, affecting every key property of the material at the same time, making disentangling these effects difficult. As such, an effort must be made to methodically investigate the structure-property relations of layered perovskite materials. Here, the crystal structures of a family of closely related cations are used to link how elements of the molecular structure impact the spacing and symmetry of the resulting perovskite layer. The optoelectronics of the resulting materials are also studied, to draw links between the perovskite structure and their optical bandgap, thus identifying key parameters which need to be target in order to effectively tailor future perovskite materials.

3:30 PM *EN06.05.05

Structural and Optoelectronic Properties of 2D Multilayered Perovskites Jacky Even¹, Mikael Kepenekian², George Volonakis², Pedesseau Laurent¹, Simon Thébaud¹, Marios Zacharias¹, Wei Li³,

Mercouri G. Kanatzidis⁴, Aditya D. Mohite⁵ and Claudine Katan²; ¹INSA Rennes, France; ²Université de Rennes, France; ³Nankai University, China; ⁴Northwestern University, United States; ⁵Rice University, United States

2D multilayered perovskites share similarities with 3D perovskites including direct electronic band gaps, strong spin-orbit coupling, sizeable optical absorptions, small effective masses, Rashba-like effects [1]. Interestingly, they exhibit other attractive features related to tunable quantum and dielectric confinements, strong lattice anisotropy, more complex combinations of atomic orbitals and lattice dynamics, extensive chemical engineering possibilities. This will be illustrated by recent combined experimental and theoretical studies on excitons, formation of edge states, hot carrier effects and carrier localization [3-6]. More, combined in 2D/3D bilayer structures using new versatile growth methods, excellent solar cell device stability can be achieved [7]. Band alignment calculations nicely explain the difference of performances for ni-p or p-i-n devices [8]. The lattice mismatch concept can provide guidance for the choice of the proper 2D/3D combination [1,2].

Structural, Electronic, Electron-Phonon and Chiral Properties of Layered Organic-Inorganic Perovskites from First Principles Volker Blum; Duke University, United States

Layered organic-inorganic perovskites and related halides offer broad tunability of their electronic, optical and spin properties by tailoring their organic and inorganic components. This talk focuses on first-principles structure and electronic structure predictions from large-scale spin-orbit coupled hybrid density

functional theory. We show that quantum-well like energy level alignment can be predicted faithfully, i.e., in agreement with the experimentally observed optical response, at this level of theory. In a particular example, we further show how close alignment of the valence bands of the organic and inorganic components can be exploited to induce laser-controlled, coherent charge oscillations between the spatially separate organic and inorganic components. We next explore chiral systems, i.e., perovskites that either incorporate a chiral organic component or those that spontaneously break their symmetry, showing that a simple structural parameter can account for predicted relativistic splitting of the conduction bands, as well as for the associated chiroptical response. Based on the same rationale, we then explore perovskite nanostructures, i.e., quantum dot arrays and platelets with chiral organic functionalization, which also show significant spin-dependent optical responses. Finally, a key prerequisite for practical semiconductor applications of any material is dopability. For the paradigmatic layered halide perovskite phenethylammonium lead iodide, we explain experimentally observed, weak n-doping by Bi incorporation and weak p-doping by Sn incorporation through the interaction of either substituent with intrinsic defects in the material. This work would not be possible without numerous collaborators, including experimental colleagues around the world and the very large group of contributors to the FHI-aims code, used in this work, as well as the open-source Electronic Structure Infrastructure ELSI and the CECAM Electronic Structure Library (ESL). Funding from the National Science Foundation under awards number 1729297 and 1450280 is gratefully acknowledged. Work on doping and chiral systems was primarily supported as part of the Center for Hybrid Organic Inorganic Semiconductors for Energy (CHOISE), an Energy Frontier Research Center funded by the Office of Basic Energy Sciences, Office of Science within the U.S. Department of Energy.

Modelling Orientational Disorder and Phase Transitions in Hybrid Piezoelectric Materials from First Principles Kasper Tolborg and Aron Walsh; Imperial College London, United Kingdom

Piezoelectric materials interconvert electrical and mechanical energy and find applications in diverse areas as sensors, actuators, and high precision motors. However, current state-of-the-art Pb-based piezoelectric ceramics pose significant environmental issues and preclude design of biocompatible devices. In recent years, solution processable, flexible and potential biocompatible hybrid organic-inorganic piezoelectric materials rivaling the performance of lead-based ceramics have been discovered [1,2].

The most promising candidates are based on low-dimensional inorganic frameworks with perovskite inspired structures, and they feature order-disorder phase transitions close to room temperature. Above these phase transitions, disordered, centrosymmetric phases appear, destroying their piezoelectric performance. Furthermore, conventional computational methods fail to predict the large piezoelectric response of this materials category [3]. Thus, modelling of this materials class must include entropic effects to phase stability [4], and nanoscale effects for response properties.

Here, we present the development of coarse-grained model Hamiltonians for the correlated disorder of dipolar organic cations in the archetypical 1D hybrid hexagonal perovskite, $\text{TMC}(\text{M}=\text{Cd})\text{Cl}_3$ (TMC=trimethylchloromethyl ammonia) from first principles [5]. Coupled with Monte Carlo simulations, we predict and rationalise its order-disorder phase transition, showing that vibrational entropic contributions are key for quantitative agreement with the experimental phase transition temperature. This highlights the importance of vibrational entropy in describing phase stability for a materials class seemingly driven by configurational entropy.

Based on an observed easy stabilisation of anisotropic, two-dimensional disorder in the system, we calculate defect formation energies of isolated and extended orientational defects, which are shown to be easily formed at ambient conditions. Switching of these defects is suggested to be the origin the strong, unconventional piezoelectric response [5].

SESSION EN06.06: Low-Dimensional Perovskites—Synthesis and Photovoltaic Application

Session Chairs: Shubhanshu Agarwal and Aron Huckaba

Wednesday Morning, November 29, 2023

Hynes, Level 3, Room 306

8:30 AM EN06.06.01

Solution Processed Cs₂PbI₂X₂ for Interface Passivation in CsPbI₂Br Solar Cells Gaukhar Nigmatova, Zhuldyz Yelzhanova, Gulzhan Bizhanova, Hryhorii Parkhomenko, meruyert Tilegen, Damir Aidarkhanov, Vladimir Pavlenko, Chang Keun Lim, Askhat N. Jumabekov, Tri Pham, Mannix Balanay and Annie Ng; Nazarbayev University, Kazakhstan

Hybrid halide perovskites have shown promise as absorber materials for third-generation solar cells. However, improving the stability of perovskite solar cells (PSCs) remains a key challenge for commercialization. All-inorganic Cs-based perovskites have recently gained attention for their enhanced thermal stability compared to organic-cation perovskites. This work focuses on CsPbI₂Br absorbers with a 1.9 eV bandgap. We demonstrate an effective surface modification technique by forming 2D Cs-based perovskite nanostructures via solution processing on CsPbI₂Br thin films. The 2D Cs₂PbI₂X₂ layer passivates defects at the CsPbI₂Br surface, leading to improved photovoltaic efficiency and device lifetime. Controlling the nanomorphology of the 2D perovskite layer is critical for optimized passivation. Our experiment conditions show the evolution of Cs₂PbI₂X₂ growth on 3D perovskite thin films. This work demonstrates the approaches for tuning the morphology of Cs₂PbI₂X₂ through solution-processing parameters. Understanding the crystallization dynamics of the 2D Cs₂PbI₂X₂ nanostructures will also provide insights into developing other scalable solution processing techniques for large-scale manufacturing. Overall, this work shows that interfacial engineering of CsPbI₂Br PSCs via incorporation of solution-processed Cs₂PbI₂X₂ enables improvement of photovoltaic performance, motivating further study of 2D perovskite crystallization and nanostructure control for advancing all-inorganic PSC technologies.

8:45 AM EN06.06.02

Exploring the Structural Origin of Self-Trapped Exciton Emission in Cs₇Cd₃Br₁₃ Andrew Gruber, Kulatheepan Thanabalasingam and Kyle M. McCall; University of Texas at Dallas, United States

Low-dimensional metal halides with self-trapped exciton emission are a burgeoning materials class with important applications in solid-state lighting, X-ray scintillation, and luminescent solar concentrators. These materials exhibit effective and intrinsic self-trapping, with dual excited state origins arising from either Jahn-Teller distortion or ns^2 lone pair dynamics. The intrinsic nature of this emission makes it ideal for testing structure-property relationships, as altering the composition, coordination, or dimensionality directly impacts the resulting excited state and thereby the resultant optical properties.

One such material is $\text{Cs}_7\text{Cd}_3\text{Br}_{13}$, which adopts a complex mixed 1D-0D structure with isolated $[\text{CdBr}_4]^{2-}$ tetrahedra and corner-connected 1D chains of $[\text{CdBr}_4\text{Br}_{2/2}]^{3-}$ octahedra. This compound has demonstrated orange STE emission at room temperature (PLQY above 9%), derived from the Jahn-Teller related distortion of the excited state, but it is unclear whether this emission is derived from the octahedral or tetrahedral cadmium halide subunits. We hypothesize that the straight octahedral chain is the emissive subunit in this system, as this coordination is unknown amongst inorganic cadmium halides. This work aims to elucidate the structural origin of STE emission in this compound using a combination of chemical substitution and temperature-dependent photoluminescence (PL) studies (PL emission, PL excitation, and time-resolved PL). Zn^{2+} has been chosen as an isoelectronic dopant that will exclusively occupy the tetrahedral site, providing a structural knob that can tune this emission as a function of temperature if the tetrahedral unit is involved in the excited state, thereby revealing whether this tetrahedral unit is responsible for the room-temperature emission. The upper limit of this doping will also be explored up to 66.7%, as Zn^{2+} may be able to fully substitute the CdBr_4 tetrahedral units, resulting in the theoretical compound $\text{Cs}_7\text{Zn}_2\text{CdBr}_{13}$. This work will illuminate the effective emissive subunit in $\text{Cs}_7\text{Cd}_3\text{Br}_{13}$ and add to the growing body of knowledge on transition metal halides with Jahn-Teller-active excited states.

9:00 AM DISCUSSION TIME

9:15 AM EN06.06.04

New Paths for Low-Dimensional Lead-Free Perovskites: From Traditional Wet Chemistry to *In Situ* Synthesis Rafael Abargues; Universidad de Valencia, Spain

Metal Halide Perovskites (MHP) have attracted significant research interest due to their unique properties and potential applications in photovoltaics, optoelectronics, and catalysis. Due to the huge concerns about lead toxicity in traditional metal halide perovskite, Lead-free perovskites have gained significant attention in recent years as alternative materials that can offer similar or better performance. Sn has been extensively investigated as an alternative to Pb in perovskite materials because they have a similar crystal structure as Pb-based MHP and can exhibit desirable optoelectronic properties, including high absorption coefficients and long carrier lifetimes. However, Sn perovskites also face challenges that must be addressed for widespread implementation. One of the major issues is their lower stability compared to lead perovskites, especially when exposed to moisture or elevated temperatures due to the prone of Sn(II) to oxidize to Sn(IV). Tin perovskites tend to undergo phase transitions and degrade more easily, decreasing device performance over time.

Researchers are actively working on improving the stability and performance of tin perovskites through various synthetic strategies. These include compositional engineering, dimensionality, interface modifications, encapsulation techniques, and device architecture optimization. Among them, low-dimensional perovskite structures, particularly layered structures, often exhibit improved stability compared to their bulk counterparts. The reduced dimensionality can mitigate ion migration and phase instability issues, leading to enhanced device performance and longevity. In low-dimensional materials, the confinement of charge carriers can lead to quantum confinement effects. These effects result in unique electronic properties, such as increased exciton binding energy and efficient charge transport. This can be

advantageous for achieving high-efficiency solar cells and other optoelectronic devices.

Our research group has conducted investigations into the synthesis of low-dimensional Sn halide perovskites from micro and nanocrystals using different chemical routes, from traditional wet chemistry to in situ synthesis. We explore the versatility of the hot-injection approach for the dimensionality control of tin (II) halide perovskites microcrystals using 2-thiophene ethylene amine (TEA) as a bulky cation. TEA-Sn molar ratio plays an essential role in the formation and stabilization of 0D Sn-based MHP with excellent photoluminescence quantum yields (PLQY > 70%). Moreover, we report on a novel approach for the in-situ synthesis of 2D and 0D TEA₂SnX₄ nanocrystals embedded in a nanocomposite with excellent stability. This technique is low-cost and low-energy demanding, allowing modifications to precursor solutions for compatibility with commercial printing techniques, ultimately contributing to the success of MHP. The in-situ synthesis approach also offers a low-carbon footprint synthetic route, making it more sustainable than traditional wet chemistry. We demonstrated how adjusting crystal growth from macro to nanoscale, using innovative synthetic routes¹ and surface treatments, can alter optoelectrical response through fundamental changes in surface and bulk structure and composition.

Application of Low Dimensional Materials in Solar Cells Yanfa Yan; The University of Toledo, United States

Low dimensional materials are gaining attentions in fabrication of efficient and stable thin-film solar cells. They are either used as absorbers or interfacial layers. In this talk, I will present two representative cases. For the case of absorber, I will present our work on fabrication of efficient thin film solar cells based on Antimony chalcogenides (Sb₂Ch₃). I will introduce the method developed to grow highly oriented films to promote extraction of photo-generated carriers. In the case of interfacial layer, I will present our work on utilizing layered perovskites to passivate and stabilize three-dimensional perovskite solar cells.

10:30 AM EN06.06.07

Methylammonium and Bromine Free Phase-Pure Dion Jacobson 2D Lead Halide Perovskites for High Efficiency and Durable Wide Bandgap Solar Cells Ayush Agrawal, Jin Hou, Faiz Mandani and Aditya D. Mohite; Rice University, United States

In the last decade, three-dimensional (3D) metal halide perovskite solar cells have displayed tremendous progress in photoconversion efficiencies. The tunable bandgaps enable mixed halide perovskite compositions to be used as the wide bandgap (WB) sub-cell in Si-perovskite and all perovskite tandems. However, halide segregation and ion migration of I-Br mixed halide systems under photo-illumination create bandgap instability that limits the long-term durability of these wideband gap subcells. 2D halide perovskites, on the other hand, have demonstrated better durability against moisture and photo illumination due to their large organic cations but still lag in efficiency due to >2eV band gaps and charge

extraction barriers. Furthermore, the methylammonium (MA^+) cation used in quasi-2D ($n=2$) perovskites is hygroscopic and can still limit the stability of the perovskite. Here, we synthesize formamidinium (FA^+) based 2D Dion Jacobson (DJ) perovskite solar cells with diammonium organic spacer cation. Optical absorption on FA 2D DJ reveals a band gap of 1.7-1.8 eV for $n=3$ perovskites, ideally suited for building bottom cells for perovskite-perovskite and Si-perovskite tandems. Films fabricated using the phase-selective memory seeds¹ process preserved the phase purity of the $n=3$ 2D perovskite. FA 2D DJ perovskites demonstrate commercially viable durability against temperature, moisture, and maximum power point (MPP) tracking. These properties make FA 2D DJ perovskites promising candidates for wide bandgap subcells in perovskite-perovskite tandem.

10:45 AM EN06.06.08

Band-Like Transport and Charge Carrier Dynamics in BiOI Films Snigdha Lal¹, Marcello Righetto¹, Aleksander Ulatowski¹, Silvia G. Motti^{1,2}, Zhuotong Sun³, Judith L. Driscoll³, Robert Hoyer¹ and Laura Herz¹; ¹University of Oxford, United Kingdom; ²University of Southampton, United Kingdom; ³University of Cambridge, United Kingdom

Following the emergence of lead halide perovskites (LHPs) as materials for efficient solar cells, research has progressed to explore stable, abundant and non-toxic alternatives. However, the performance of such lead-free perovskite-inspired materials (PIMs) still lags significantly behind that of their LHP counterparts. For bismuth-based PIMs, one significant reason is a frequently observed ultrafast charge-carrier localization (or self-trapping), which imposes a fundamental limit on long-range mobility. BiOI is a widely studied 2D layered material which has recently been explored as a Pb-free PIM for photovoltaic applications. A wide bandgap material, it is highly suitable for tandem applications. However, despite reported defect tolerance and strong band-edge absorption, the power conversion efficiencies for BiOI-based devices has remained stunted with record efficiencies reaching barely 2%. An extensive photophysical study is needed to elucidate the performance limiting factors for BiOI along with highlighting the true intrinsic potential of the material as a photovoltaic absorber.

Here, we report the charge-carrier dynamics of BiOI and show that unlike many other Bi-based compositions such as $\text{Cs}_2\text{AgBiBr}_6$ and Ag-Bi iodides, BiOI shows sustained band-like transport with respectable mobilities. Crucially our investigation reveals an absence of self-trapping despite the presence of strong electron phonon coupling and lower dimensionality. Using optical pump terahertz probe (OPTP) spectroscopy, time resolved microwave conductivity (TRMC) spectroscopy and time resolved photoluminescence (TRPL) spectroscopy, we unravel the early and long-time charge-carrier dynamics in BiOI and show that the material performance is limited by the presence of multi-phonon emission mediated non-radiative channels in the material. Using temperature-dependent OPTP transient, we quantify the bimolecular recombination constant and show that the material has low rates of band-to-band recombination likely originating from an indirect bandgap. Taken together with a slightly higher-lying direct bandgap, such low levels of intrinsic band-to-band recombination set high upper limits of achievable charge-carrier lifetime. Altogether, this contribution highlights the promise of BiOI solar cells.

Thermoelectric Properties in Phase-Transition-Induced Thermal Hysteresis for Refrigeration Mona Zebarjadi; University of Virginia, United States

The phase transition from crystal to crystal or crystal to amorphous is accompanied by electron and phonon dispersion changes and hence sharp modifications of electronic and phononic transport properties versus temperature. In particular, the strong variations of the Seebeck coefficient and the heat capacity with temperature can be used for the design of heat management devices. Sharp changes in the Seebeck coefficient result in significant Thomson coefficients ($\tau = TdS/dT$, T is temperature). The Thomson effect induces heat release or absorption under the simultaneous application of a charge current and a temperature gradient in conductors, with applications in refrigeration. Thomson modules are not currently used. Their efficiency is barely studied as most materials show a minor Thomson coefficient much smaller than the Seebeck. Recently, Uchida's group reported a giant Thomson coefficient for FeRh alloys as a result of a phase transition. In this talk, I will present our results of phase transition-induced thermal hysteresis in FeRh alloys and 1T'-Td phase transition in type II Weyl semimetallic layered materials MoTe_2 and $\text{Mo}_{1-x}\text{W}_x\text{Te}_2$. In the latter case, we show consistency between the Seebeck hysteresis and direct measurements of the crystallographic angle using temperature-dependent X-ray diffraction. I will discuss how the Thomson coefficient is related to other materials' properties and can be used for refrigeration.

Two-Dimensional Li_xMoS_2 /Graphene Heterostructures for Li-S Batteries Zhuangnan Li and Manish Chhowalla; University of Cambridge, United Kingdom

Abstract

Lithium-sulfur (Li-S) batteries based on redox chemistry can store more energy than conventional insertion-type lithium-ion technologies^{1,2}. Our previous discoveries have shown that compact electrodes assembled from monolayered nanosheets of lithiated metallic 1T phase molybdenum disulfide (Li_xMoS_2) are electrically and ionically conductive, lyophilic and catalytically active³⁻⁶. In this presentation, I will describe a sulfur host design of two-dimensional (2D) Li_xMoS_2 /graphene heterostructure for Li-S batteries. The construction of heterointerfaces results in charge transfer from graphene to Li_xMoS_2 , which yields enhanced catalytic activity and promotes redox kinetics for sulfur conversion. The accumulation of greater charge in the Li_xMoS_2 layer of heterostructures also reduces its Lewis acidity compared to that of bare Li_xMoS_2 . The resultant ampere-hour-scale Li-S pouch cells deliver energy density of exceeding 400 Wh kg^{-1} . This work demonstrates an universal strategy of using 2D heterostructures to tune the electrode properties for realising practical energy storage.

Enhanced Photoelectrochemical Water Splitting with Doped Transition Metal Dichalcogenide Nanofilms Cansu Ilhan^{1,1,2}, Ievgen Nedrygailov^{1,1}, Ross Smith², Jun Lin¹, Chris Kent^{1,3}, Ian Povey^{1,1}, Colm O'Dwyer^{1,1}, Salvatore A. Lombardo⁴, Giuseppe Nicotra⁴, Paul Hurley^{1,1,1}, Mick Morris^{1,2}, Dara Fitzpatrick³, Justin Holmes^{1,1} and Scott Monaghan^{1,1,1}; ¹University College Cork, Ireland; ²Trinity College Dublin, Ireland; ³BARDS, Ireland; ⁴CNR-IMM, Italy

Photoelectrochemical water splitting to produce hydrogen fuel from solar energy conversion has been a hot topic for at least the past few decades. Nevertheless, Solar-to-Hydrogen efficiency levels have been severely limited due to many factors, including light absorption, charge separation and transport, surface chemical reaction rate [1]. Novel and emerging materials that may just address key bottlenecks are some of the transition metal dichalcogenides (TMDCs) due to their tuneable band gap and an ability to be doped n-type or p-type [2]. In recent times, nanometer thickness control, uniformity and large area growth of continuous films have been demonstrated by rapid deposition methods in manufacturing-compatible processes [3]. However, little is known about the effect of different impurity concentrations incorporated into TMDCs, particularly on the semiconductor transport properties; the structural, chemical, and physical stability; and their photoelectrochemical properties. In this work, we focus on the enhanced water splitting capability as photoanodes/photocathodes and tandem diode cells when combined with novel doped transition metal dichalcogenide (TMD) materials in an acidic aqueous medium. We use thermally assisted conversion (TAC) processes to form n-type and p-type TMDCs by converting transition metals to sulphide-based TMDCs with different impurity concentrations. The photoelectrochemical responses were assessed by standard potential sweep methods and electrochemical impedance spectroscopy. To determine transport properties, TMDCs were studied with 4-point resistivity measurements and AC Hall-effect measurements. Structural, chemical, optical and physical properties were characterized using Raman spectroscopy, X-Ray diffraction, UV-Vis spectroscopy, and atomic force microscopy. The performance of the cells was assessed within a purposely built PEC setup. The integrated light source was a G2V Pico Var Solar Simulator with 32 LEDs, providing an AM 1.5G 1.0 simulated Sun equal to a total irradiance of 87.2 mW cm⁻² with a spectral range of 361 nm to 1556 nm. We show that the doped TMD nanofilms acting as photoelectrodes provide a significant enhancement of PEC water splitting response when compared to the underlying silicon photoelectrodes without the nanofilms. We analyze the correlation between the increased activity with and without the nanofilms, the influence of their doping density and doping type on the mechanisms and compare the different cell geometries. Finally, we assess a selection of TMDCs using photoelectrochemical methods to understand their potential contribution to solar energy conversion and hydrogen fuel generation. [1] Eds. John A. Two-Dimensional Graphene and MXene for Flexible and Stretchable Displays Tae-Woo Lee^{1,2};

¹Seoul National University, Korea (the Republic of); ²SN display Co. Ltd., Korea (the Republic of)

Two-dimensional materials, such as graphene and MXenes, offer promising alternatives to brittle indium tin oxide (ITO) for flexible and wearable displays. However, their practical application has been impeded by the high electron and hole injection barriers at the electrode/organic interfaces. To overcome this challenge, post-fabrication treatments were employed to modify the work function of 2D electrodes. Electron-withdrawing or electron-donating polymeric overcoating allowed for precise control of charge transfer doping, resulting in improved electroluminescent efficiency with reduced injection barriers. These surface modifications not only enhanced the environmental stability of the 2D electrodes in ambient air but also maintained their electrical properties. Furthermore, to address charge injection issues at stretchable electrode interfaces, a graphene layer can be introduced atop a silver nanowire percolation network, forming a two-dimensional stretchable contact electrode. This approach achieves remarkable current efficiencies among all intrinsically stretchable light-emitting diodes. These advancements in 2D materials establish a solid foundation for the practical implementation of 2D conductive materials in flexible and stretchable displays.

4:00 PM EN06.07.06

Transitioning toward more sustainable materials and manufacturing methods will be critical to continue supporting the rapidly expanding market for lithium-ion batteries. Meanwhile, energy storage applications are demanding higher power and energy densities than ever before, with aggressive performance targets like fast charging and greatly extended operating ranges and durations. Due to its high operating voltage and cobalt-free chemistry, the spinel-type $\text{LiNi}_{0.5}\text{Mn}_{1.5}\text{O}_4$ (LNMO) cathode material has attracted great interest as one of the few next-generation candidates capable of addressing this combination of challenges. However, severe capacity degradation and poor interphase stability have thus far impeded the practical application of LNMO. In this study, by leveraging a dry electrode coating process, we demonstrate LNMO electrodes with stable full cell operation (up to 68% after 1000 cycles) and ultra-high loading (up to 9.5 mA h cm^{-2} in half cells). This excellent cycling stability is ascribed to a stable cathode-electrolyte interphase, a highly distributed and interconnected electronic percolation network, and robust mechanical properties. High-quality images collected using plasma focused ion beam scanning electron microscopy (PFIB-SEM) provide additional insight into this behavior, with a complementary 2-D model illustrating how the electronic percolation network in the dry-coated electrodes more efficiently supports homogeneous electrochemical reaction pathways. These results strongly motivate that LNMO with a high voltage cobalt-free cathode chemistry combined with an energy-efficient dry electrode coating process

Updated as of October 28, 2024

opens up the possibility for sustainable electrode manufacturing using cost-effective and high-energy-density cathode materials.

SESSION EN06.08: 2D Materials for Energy Conversion and Energy Storage III

Solution-Processed Transition Metal Dichalcogenide 2D Nanoflakes for Photoelectrochemical Energy Conversion Kevin Sivula and Rebekah Wells; Ecole Polytechnique Federale Lausanne, Switzerland

Given their established robustness and favorable optoelectronic properties, the layered semiconducting transition metal dichalcogenides (TMDs, e.g. MoS₂ and WSe₂) are attractive for optoelectronic applications including photoelectrochemical solar fuel production.[1] Recent advances in the liquid-phase exfoliation (LPE) of semiconducting TMDs into mono- or few-layered 2D nanoflake dispersions and their processing by inexpensive roll-to-roll techniques suggests that large-area TMD-based devices can be fabricated in a scalable manner and at low cost.[2] However, the high concentration of defects in these materials act as recombination sites for photogenerated carriers and limit their performance. In this presentation the challenges with charge transport, separation, recombination, and interfacial transfer in LPE TMD nanoflake thin film devices will be discussed with respect to the 2D flake size and defect passivation/charge extraction treatments.[3] Our results give insight into the roles of both edge and internal defects and suggest routes for improvement. In addition to suitable defect mitigation techniques [4], we show that the exfoliation conditions play an important role on the performance of 2D TMD nanoflake films. Indeed, a powder-based electrochemical intercalation technique [5] can produce internal quantum efficiency for photon harvesting up to 90%. Moreover, for solar-driven H₂ production, we show that WSe₂ nanoflake thin films achieve absorbed-photon-to-current efficiency over 50% and photocurrent densities for solar water reduction at 4 mA cm⁻² under standard testing conditions.[4] These results suggest that roll-to-roll processed 2D TMDs are promising for economical solar-to-hydrogen conversion with a photoelectrochemical tandem cell.

Energy Level Engineering, Co-doping and Extended Conjugation in Heptazine Frameworks: Towards Efficient Solar Energy Conversion using Carbon Nitride-Based Heterojunctions Kazi M. Alam, John Garcia, Narendra Chaulagain, Navneet Kumar and Karthik Shankar; University of Alberta, Canada

Carbon nitride (C_xN_y) is a layered crystalline polymeric organic semiconductor consisting of nanosheets of sp^2 -hybridized triazine heterocycles. C_xN_y aggregates can either be large (3D crystals or sub-micron sized nanosheets) or small (truncated nanosheets or small spherical nanoparticles resembling quantum dots). The conjugated nanosheets allow for relatively fast charge transport, a high active surface area and the customizability of surface reaction sites. Consequently, carbon nitrides have shown remarkable performance as electrocatalysts, photocatalysts, optoelectronic sensors and carrier transport layers for a range of applications including, but not limited to - water splitting, CO_2 reduction, photovoltaics, photodetectors, water treatment and fuel cells. Carbon nitride combines the aforementioned advantages with scalable synthesis compatible with the use of agricultural wastes as precursors and an elemental constitution made of earth abundant elements. Insofar as the electronic applications of C_xN_y are concerned, further enhancements in the performance of based optoelectronic devices require the following conditions to be met: (i) Narrowing of the electronic bandgap (ii) Increase in carrier mobility (iii) Availability of high quality interfaces for exciton dissociation and charge transfer and (iv) Achievement of high photoluminescence and/or electroluminescence quantum yields. These technical challenges are interconnected and not entirely independent of each other. Herein we present a sequence of materials synthesis, device fabrication and compositional doping strategies to address these challenges and achieve the desired enhancements. We show that incorporation of graphene-like sp^2 carbon regions within C_xN_y nanosheets through the formation of carbon-rich carbon nitride extends π -conjugation and improves carrier transport. A secondary positive effect of such carbon-rich regions in C_xN_y is the reduction in intra-sheet and inter-sheet hydrogen bonding, which is widely believed to be a source of non-radiative recombination in C_xN_y . Doping and co-doping C_xN_y by highly polarizable main group elements such as S, P, Se, etc enriches the electron density in the nanosheets and increases the dielectric constant of carbon nitride, which in turn increases carrier mobility and reduces the exciton binding energy. We found that main group element-doped carbon-rich carbon nitrides exhibit narrow bandgaps as low as 1.5 eV and generate photocurrent densities as large as 5 mA/cm² for photoelectrochemical water splitting under AM1.5G one sun illumination. Finally, we tackled the issue of heterojunction formation through operando matrix-assisted solid-state condensation polymerization and electrophoretic anodization. The device testing data has been backed up by extensive characterization using XANES, SSNMR, HRXPS and HRTEM.

9:15 AM EN06.08.04

Low Dimensional Composite Materials as Binder-Free Anode for Energy Storage Applications

Kavin Arunasalam, Kevin Synnatschke, Meiying Liang and Valeria Nicolosi; Trinity College Dublin, Ireland

The prolonged use of non-renewable energy such as fossil fuel and coal is having a deteriorating impact on our environment leading to severe climate changes. Hence, there is a dire need to explore new methods for energy generation and storage which are environmentally friendly, cost-effective and sustainable. Sodium-ion batteries have been attracting great interest as an alternative to lithium-ion batteries due to their material abundance, lower cost, and sustainability. However, a high-performance viable anode for the sodium-ion battery has yet to be discovered because of the difference in its molecular size and intercalation mechanism to the comparatively smaller lithium ions.

This issue has garnered global research interest in the quest to develop anodes with expanded interlayer spacing capable of accommodating sodium ions. This area of study has emerged as a promising field within material science, particularly in the realm of 2D materials research. 2D materials are known for their unique structure and electronic properties such as hardness, tuneable band gap by variation of the

number of layers and their high surface area. These properties make them intriguing candidates for applications in batteries and electrocatalysis. Black phosphorus, a well-studied 2D class material, has previously been reported to show very high theoretical capacity for both sodium and lithium-ion battery systems but suffers from low cycling stability due to chemical and structural instability.^[1] To overcome this problem, we decided to explore the prospect of a new 2D composite material made from nanosheets of black phosphorus (phosphorene) and MXene ($\text{Ti}_3\text{C}_2\text{T}_x$) to be potentially used as an anode in a sodium-ion battery. The MXene layers with terminating fluorine and oxygen functionals are expected to promote the growth of stable solid-electrolyte interfaces (SEI) which in turn is expected to further improve the overall coulombic efficiency of the battery.^{[2][3]}

Both nanomaterials were synthesized via liquid-phase exfoliation (LPE). Phosphorene is notorious for being oxidized easily. Hence, to protect the phosphorene, a novel layer-by-layer (LBL) vacuum filtration technique was implemented to obtain the electrode. The resulting electrodes were then assembled in a lithium-ion coin cell to study their cycling stability and rate capacity, given the similarity of the lithium and sodium ion intercalation mechanism in the anode. XPS, SEM, EDX, UV-Vis, XRD and AFM characterization were performed on the composite nanomaterial to study its morphology, as well as compositional and structural changes upon processing. It was found that the electrode material showed a high discharge capacity of 700 mAh/g at 0.2 C with 98% coulombic efficiency for 100 cycles which indicates a promising performance potential for sodium ion battery systems.

In conclusion, the layer-by-layer MXene-phosphorene composite structure effectively shields the phosphorene nanosheets from extensive oxidation in ambient conditions. This preservation of phosphorene enables a reversible reaction and ensures excellent cycling stability as an electrode material. Moreover, the inclusion of the MXene component acts as a conductive binder in this composite eliminating the need for traditional non-conductive binders like PVDF and CMC. This substitution reduces dead volume within the anode and enhances the material's specific capacity. Finally, the composite's large interlayer spacing highlights its potential application as an anode in sodium ion battery systems, emphasizing the need for continued exploration and research in this area.

Thermal Transport Characterization Method for 2D Layered Materials and Their Polymorphs **Sungjin Park**, Kyomin Kim and Woonchul Kim; Yonsei University, Korea (the Republic of)

Two-dimensional (2D) layered materials are known to possess different physical properties than bulk materials due to the weak van der Waals bonds between their layers. Graphene is a representative 2D material whose material properties is known to different from its bulk counter part [1]. The material properties of 2D materials can be further altered by changing the stacking sequence of the interlayers such as in MoS_2 where different stacking sequences lead to the 2H and 3R polymorphs [2]. NbSe_2 is a 2D layered material whose new polymorphic form (2H-3R) was discovered recently [3]. This work proposes a method to characterize the thermal transport properties of 2D layered materials by measuring the thermal conductivity of the different polymorphs of NbSe_2 using the in-house T-bridge method. Photolithography technique was utilized to fabricate the micro-scale T-bridge device and mechanical

exfoliation was used to obtain thin 2D layered NbSe₂ samples for their bulk material. The thermal conductivity of various thickness 2H-NbSe₂ and 2H-3R-NbSe₂ was measured, and results showed that the difference in stacking sequence of the 2D layered material can alter its thermal transport properties. The in-house T-bridge method can be further utilized to measure the thermal transport of various 2D layered materials and their polymorphs.

Photothermal Processing of Layered Materials under Controlled Pressure for Energy Storage Applications

Applications Najma Khatoon, Binod Subedi, Ahmad Majed, Julie Albert, Michael Naguib and Douglas B. Chrisey; Tulane University, United States

2D layered materials are promising candidates for synthesizing materials with customizable properties contributing from each layer. Enhanced electrical, mechanical, thermal and optical properties by tailoring the layers makes layered materials highly versatile and adaptable for various applications. MXenes are one such example of 2D layered materials class. Their high conductivity, excellent chemical stability, good mechanical properties, tunable surface chemistry, large specific area, and ability to integrate with other materials makes them an excellent customizable layered material. Titanium carbide (Ti₃C₂-T_x) MXene, where T_x are surface terminations, have high conductivity, and excellent Li-ion diffusion properties. Intercalation of ions/molecules in Ti₃C₂ layers is one route to enhance its electrochemical properties. Silicon-based nanomaterials are promising candidates for intercalation due to their higher theoretical specific capacity.

In this work, we intercalated PDMS (Polydimethylsiloxane) in Ti₃C₂ with initial d-spacing ~1 nm. Intercalation of PDMS resulted in increase of d-spacing from 1 nm to ~12 nm. The intercalated PDMS was converted into silica (SiO₂) by processing it through a unique process of photonic curing. Our results showed that after photonic curing the d-spacing changed from 12 nm to ~5 nm. The PulseForge parameters were 450 V bank voltage 7 pulses, and ~4 Jcm⁻² per pulse fluence. Furthermore, we cured the intercalated MXene under controlled pressure and in a different gas environment. Results showed a less oxidation rate of MXenes when cured under controlled pressure. The stability of reversible electrochemical reactions was observed in the cyclic voltammetry of MXene intercalated within cured PDMS, indicating the enduring nature of these reactions throughout repeated cycling. This study demonstrates the potential of photonic curing as a cost-effective and scalable method for synthesizing customizable layered materials with precise control over the nanostructure within the layers. The process offers an instantaneous and roll-to-roll compatible approach for large-scale synthesis.

Colloidal Quantum Dot Near-Infrared Light Emitting Diodes with High External Quantum Efficiency Maria Vasilopoulou; National Centre for Scientific Research Demokritos, Greece

Semiconductor colloidal quantum dots (CQDs) have become a prominent class of solution-processed

emitting nanocrystals owing to their potential to provide size- and composition- tunable luminescence of high colour purity. Importantly, their emission can be extended deep into the second biological near-infrared (NIR) window (1000-1700 nm, NIR-II) where related lighting technologies based on organic and perovskite semiconductors have so far failed to access. However, the application of NIR-II CQD light emitting diodes (LEDs) is still hindered by low efficiencies mainly attributed to low photoluminescence quantum yield (PLQY) and poor charge transport properties of pure CQDs films. Here, we report NIR-II CQD LEDs with unprecedented external quantum efficiency (EQE) of 16.98% and power conversion efficiency (PCE) of 11.28% at 1397 nm. This extraordinary performance stems from a combinatorial device engineering approach that allowed us to achieve high PLQY in CQDs-embedding films and charge balance close to unity in the CQD-emissive device. More specifically, we employed a binary emissive layer consisting of silica-encapsulated Ag_2S CQDs dispersed into a cesium-containing triple cation perovskite matrix that serves as an additional passivation medium and carrier supplier to the emitting CQDs. Furthermore, we applied successful engineering at the hole injection contact through inserting a thin porphyrin interlayer to balance the device current and enhance carrier radiative recombination. The remarkable efficiency of our devices surpasses the performance of any previously reported CQD NIR LED. Additionally, it represents a record efficiency for any solution-processed lighting source in the second NIR-II window and foreshadows CQD technologies that will transcend the lighting products already available in the market.

11:00 AM EN06.08.08

Edge Engineering of Two-Dimensional Transition Metal Dichalcogenides Guoxiang (Emma) Hu; Georgia Institute of Technology, United States

Two-dimensional (2D) transition metal dichalcogenides (TMDCs) have attracted tremendous interest as functional materials due to their exceptionally diverse and tunable properties, especially in their edges. In addition to the conventional armchair and zigzag edges common to hexagonal 2D materials, more complex edge reconstructions can be realized through careful control over the synthesis conditions. However, the whole family of synthesizable, reconstructed edges remains poorly studied. Here, we develop a computational approach integrating ensemble-generation, force-relaxation, and electronic-structure calculations to systematically and efficiently discover additional reconstructed edges and screen their functional properties. Using MoS_2 as a model system, we screened hundreds of edge-reconstruction to discover over 160 reconstructed edges to be more stable than the conventional ones. More excitingly, we discovered new synthesizable reconstructed edges with record thermodynamic stability, in addition to successfully reproducing recently synthesized edges. We also find our predicted reconstructed edges to have multi-functional properties—they show near optimal hydrogen evolution activity over the conventional edges, ideal for catalyzing hydrogen-evolution reaction (HER) and also exhibit half-metallicity with a broad variation in magnetic moments, making them uniquely suitable for nanospintronic applications. Our work reveals the existence of a wide family of synthesizable, reconstructed edges in 2D TMDCs and opens a new materials-by-design paradigm of ‘intrinsic’ edge engineering multifunctionality in 2D materials.

11:15 AM EN06.08.09

Promising Properties of 2D Layered Cobalt and Nickel Nitrides as Negative Electrodes for Li-Ion Batteries Jean-Pierre Pereira-Ramos¹, Yanlong Zhou^{1,2}, Nicolas Emery¹, Olivier Nguyen² and Rita Baddour-Hadjean¹; ¹ICMPE CNRS, France; ²Technocentre Renault, France

2D materials largely dominate the field of Li-ion batteries with the transition metal oxides LCO

(LiCoO₂), NMC LiNi_xMn_yCo_z) and NCA (LiNi_xCo_yAl_z) used as positive electrode materials and carbon graphite as negative electrode. However graphite suffers from a low rate capability and from a limited specific capacity. Intensive research has been made to find alternative anode materials such as the LiAl, Li_xSn, Li_xSi...alloys or transition metal oxides as conversion materials. But in all cases, huge volumetric changes occur upon discharge-charge reaction inducing a fast capacity decline. In spite of numerous studies, this important drawback has never been solved as yet.

We have decided to explore the group of lithiated transition metal nitrides as alternative negative electrode materials to overcome safety issues related to the use of graphite at high current. Some of these compounds were firstly investigated in the wide voltage window 1.4V-0V leading to high specific capacities but also to irreversible structure change with the irreversible oxidation of nitride anion framework. Hence poor electrochemical properties were achieved. Our key idea has been to rigorously control the upper cut-off voltage inside the stability domain of the nitride framework which is strongly dependent on the metal and metal content.

The present work reports the chemical synthesis and the structural characterization of lithium nitridocobaltates Li_{3-2x}CoxN and Li_{3-2x}NixN nitridonickelates with $0.1 \leq x \leq 0.6$. These 2D compounds with an hexagonal symmetry constitute unique examples of intercalation compounds based on the nitrogen framework in which lithium can be reversibly inserted and extracted due to numerous cationic vacancies. With a mean working voltage around 0.5V, these “zero strain” materials deliver high specific capacities in the range 200-320 mAh/g with a remarkable stability over at least 100 cycles. In addition to a complete investigation of their electrochemical features in the 1V-0.02V potential range, we have elucidated the electrochemical mechanism involving the Co and Ni redox species (I/II/III) in relation with the tiny structural changes revealed through operando XRD experiments. A detailed kinetic study of the charge-discharge process in the case of nickel-based compounds allows to give a complete picture of electrochemical performances of these 2D lithiated nitrides as negative electrode materials for Li-ion batteries.

SESSION EN06.09: Layered Perovskites and 2D Materials for Energy Conversion and Energy Storage

1:45 PM EN06.09.02

High Pressure Synthesis of Low Dimensional Pnictogen Chalco-Halides Based on

(Sb,Bi)(S,Se)(Br,I) for Emerging Energy Applications Ivan Caño Prades, Alejandro Navarro Güell, Edoardo Maggi, Cibrán López, Marcel Placidi, Lluís Soler Turu, Claudio Cazorla, Joaquim Puigdollers and Edgardo Saucedo; Universitat Politècnica de Catalunya, Spain

There is an increasing interest in the development of novel van der Waals materials with low dimensionality and with exotic properties, for emerging energy applications such as photocatalysis, photovoltaic and thermoelectric devices. Among them, pnictogen chalco-halides with low dimensional morphology (commonly quasi-one-dimensional nanocolumnar structures) are attracting a lot of attention due to the unusual combination of bandgaps suited for different energy applications, excellent stability, and possible high tolerance to defects. Despite these clear advantages, it is very complex to synthesize this type of materials containing one halogen and one chalcogen in the structure, even if there are clear

evidence that these materials can be synthesized at relatively low temperature (< 400 C). In this work, we will present first a detailed DFT modelling of the structure, stability and optical properties of pnictogen chalcogenides based on $(\text{Sb,Bi})(\text{S,Se})(\text{Br,I})$. Theoretical calculations confirm the high stability of all possible ternary compounds, with band structures and bandgaps very well suited for different energy applications. Then, we will present an innovative synthesis route for complex pnictogen chalcogenide compounds based on a sequential process, starting with the co-evaporation of chalcogen thin films, followed by a high-pressure reactive annealing (from 2 atm up to 20 atm) under halogen atmosphere. Using this innovative approach, the complete set of ternary van der Waals $(\text{Sb,Bi})(\text{S,Se})(\text{Br,I})$ chalcogenide semiconductors are synthesized, including: SbSBr, SbSI, BiSBr, BiSI, SbSeBr, SbSeI, BiSeBr, and BiSeI. It will be also demonstrated for the 8 compounds, that high purity phase can be synthesized through a thin film-to-nanocolumnar topological transformation. All the possible ternary compounds exhibit orthorhombic Pnma structure with quasi-one-dimensional nanocolumnar morphology; which thicknesses, heights, and densities can be tuned by changing the temperature and pressure during the synthesis process. The bandgap of the materials ranges from 1.25 eV for BiSeI up to 1.93 eV for SbSBr, covering a wide range of energy applications and correlating very well with the DFT calculations. A complete comparative analysis of the morphology, structure, optic, and electric properties of the 8 compounds will be presented. As examples, two possible applications of these $(\text{Sb,Bi})(\text{S,Se})(\text{Br,I})$ low dimensional structures will be proposed. In one hand, first solar cell prototypes will be shown, with very encouraging open circuit voltages around 600 mV, and conversion efficiencies exceeding 1% level in a very short period. In a second hand, some of these compounds were tested as visible light sensitized of TiO_2 photocatalytic activity for hydrogen production, demonstrating an impressive hydrogen evolution increase of up to 90% under white light illumination. Finally, a comparative analysis and possible future applications of these novel low dimensional materials will be presented, and a perspective for their future accelerated development will be proposed.

O, N-Enriched, Self-Activated, Holey Carbon Sheets for Low-Cost and High-Loading Zinc-Ion Supercapacitors Zhixiao Xu and Xiaolei Wang; University of Alberta, Canada

Low-cost and high-loading cathodes are crucial for the practical application of zinc ion supercapacitors but achieving high performance in high-loading electrodes has remained a challenge due to sluggish ion transport, increased resistance, and unstable structure. Guided by theoretical calculations, high-loading carbon cathodes based on holey activated carbon sheets (HACS) were fabricated from a carefully chosen molecule. By subjecting the molecule to a simple pyrolysis-leaching treatment, it can be converted into HACS with large surface area, hierarchical porous structure, and electroactive oxygen/nitrogen dopants. Remarkably, when combined with an aqueous binder, the optimized HACS-based high loading electrode (16.1 mg cm^{-2}) exhibits outstanding performance, delivering high-capacitance (454 F g^{-1} , capacity: 208 mAh g^{-1}) and fast-rate (1 A g^{-1}) capability even under lean electrolyte conditions ($6.2 \text{ } \mu\text{L mg}^{-1}$). This leads to maximal areal energy and power densities of 2.40 mWh cm^{-2} and 10.7 mW cm^{-2} , respectively. This outstanding performance can be attributed to fast ion transport enabled by through-plane pores of HACS, as well as abundant double-layer and redox-active surfaces from favorable heteroatom-doped porous nanosheets. With its cost-effectiveness, elemental abundance, and structural tunability, this molecular carbon strategy could serve as a platform for making self-activated carbon electrodes at the molecular level towards practical supercapacitors.

Enhancing Transport in Formamidineum Lead Iodide Quantum Dot Solar Cells by Substitution of

Octadecene Bruno Alessi¹, Davide Mariotti² and Vladimir Svrcek¹; ¹AIST: National Institute of Advanced Industrial Science and Technology, Japan; ²Ulster University, United Kingdom

Perovskite quantum dots (QDs) solar cells are recently becoming very popular as they currently hold the record power conversion efficiency (PCE) of over 16% with a light absorber film made of stacked perovskite QDs of mixed cation Formamidinium (FA)/Cesium lead (Pb) iodide (I).¹ The most common synthesis method (hot injection) is based on the injection at moderate temperatures (50 to 120 °C) of a cation-oleate compound into a saturated lead iodide solution in Octadecene (ODE) in the presence of Oleic Acid and Oleylamine.² This leads to the formation of thick colloids where particles are capped by long chain ligands. However, for application in solar cells these long insulating ligands need to be exchanged in favor of shorter ones, leading to higher interparticle hopping probabilities for photocarriers. FAPbI₃ QDs themselves have ideal bandgap (~1.5-1.6 eV) for the single junction design and longer photocarrier lifetimes, however a reliable and satisfactory ligand exchange protocol is lacking. To have an efficient ligand exchange recipe that does not compromise the structural integrity of the quantum dots, significant efforts have been made in a plethora of studies by addition of small molecules during the synthesis process, zwitterionic compounds or Pb- FA- and I- containing salts and amino acids during the QDs film formation, nonetheless there is still room for improvement.

In this study we explore a different approach to synthesize FAPbI₃ QDs by changing one of the main solvents used in the synthesis stage. Specifically, we replaced ODE with a shorter chain linear alpha olefin. Despite facing some experimental challenges, we successfully obtained high-quality films of FAPbI₃ QDs using this new method. Furthermore, we correlate the new synthesis method with ODE-based QDs in terms of the purification protocol, synthesis practice, optical properties, and their application in QDs solar cells. The results revealed superior photoluminescence properties for the QDs synthesized with the new solvent. QDs obtained in this way have a narrow photoluminescence emission peak at 1.61 eV and exhibit higher absolute quantum yields ranging from 70% to 80% and only a small blueshift ($\Delta\lambda=5$ nm) compared to the ODE-based QDs. Additionally, we compare the performance of the two systems in prototype solar cells, specifically by using layers of stacked QDs with equal thickness (100 nm). The prototype solar cells incorporating the QDs synthesized with the new solvent showed a PCE of 4.9% with 1.06 V open-circuit voltage (V_{OC}). In relation to an ODE-based solar cell of the same thickness it represents a two-fold increase in PCE, as well as consistently higher V_{OC} and short-circuit current density (J_{sc}). Furthermore, we investigate how the new solvent enhances the performance of FAPbI₃ QDs based solar cells without compromising the stability and optical properties of individual quantum dots.

Abstract presented on demand only - Influence of Doping Density on the Optoelectronic Properties of V-Doped WS₂ Monolayers John B. Asbury; Pennsylvania State University, United States

A critical step in the development of transition metal dichalcogenides (TMDs) as next generation electronic and photonic materials is to identify pathways to control their electronic properties using chemical doping methods. The controllable incorporation of dopant atoms into a TMD host lattice during growth requires the ability to predict dopant atom reactivity in comparison to the host lattice during the

nucleation, growth and annealing stages. Toward this end, we investigated the growth of V-doped WS₂ monolayers by Atmospheric Pressure Chemical Vapor Deposition and examined the spatial distribution of V atoms in WS₂ crystallites and their influence on the defects and optoelectronic properties of the monolayers using temperature-resolved time-dependent photoluminescence microscopy (μ PL). We observed that the V-doping density was higher in the centers of the crystallites where the initial nucleation process began. The V-doping density decreased as the growth continued, leading to non-uniform doping densities and a spatial gradient in the optical bandgaps of the WS₂ monolayers. Regions of the WS₂ monolayers with higher V atom density exhibited defect-related emission features at low temperatures in the μ PL measurements that were red-shifted by 0.2 eV relative to defect-related emission peaks in regions with lower V atom densities. Scanning transmission electron micrographs of the V-doped WS₂ monolayers indicated the presence of two or more neighboring V dopant atoms paired with sulfur vacancies (V-V-S_V) in the more heavily V-doped regions with the lower energy defect-related emission. Our findings suggest that dopant-defect interactions can influence the distribution of dopants and defects in TMD monolayers. Learning to control the doping density and predicting such dopant-defect interactions may provide a framework for understanding the chemical reactivity and growth conditions needed to utilize TMDS in next generation electronic and photonic materials applications.

First-Principles Study of N, P, Si, C-Functionalized Ti₂B as Potential Anode Materials for Metal-Ion-Batteries Shaiokh B. Abi and Ahmed Zubair; Bangladesh University of Engineering and Technology, Bangladesh

The design and development of the next-generation energy storage device are strongly tied to the exploration of alternate electrode materials for rechargeable metal-ion batteries to lithium. Recently, non-lithium-ion batteries, such as sodium-ion batteries, potassium-ion batteries, magnesium-ion batteries, calcium-ion batteries, and zinc-ion batteries, have thus received substantial interest from researchers. This work explored N, P, C, and Si-functionalized Ti₂B, a 2D nanomaterial, as anode materials for metal-ion batteries using first-principles calculations. Density functional theory (DFT) was the theoretical foundation for the first-principles computations performed here. The ion-electron interaction was described using the projected augmented wave (PAW) method, and the exchange-correlation functional was defined using the generalized gradient approximation (GGA) in the Perdew-Burke-Ernzerhof (PBE) functional. We created the unit cell of Ti₂B monolayer with a sufficient vacuum between layers, and it was optimized until the appropriate threshold of total energy and force were reached. We added N, P, C, and Si to the optimized Ti₂B monolayer at different sites creating Ti₂BN₂, Ti₂BP₂, Ti₂BC₂, and Ti₂BSi₂. We optimized these structures' geometry to determine the most stable configurations with minimum ground-state energy. Phonon dispersion calculations showed no negative frequencies implying their dynamic stability. From the band structure and density of states calculations, Ti₂BN₂ and Ti₂BP₂ had degenerate spin-up and spin-down bands, indicating that both are non-magnetic. However, there were spin-up and spin-down band splitting of Ti₂BSi₂ and Ti₂BC₂, revealing that they are magnetic. The total magnetization value of 0.13 and 0.26 μ B/cell was found for Ti₂BSi₂ and Ti₂BC₂, respectively. The structures had significant electronic states close to the fermi level according to the partial density of states referring to their good electrical conductivity. To investigate the viability of these structures as anode materials in metal-ion batteries (MIBs), we adsorbed sodium at three different sites- the top of a functional atom, the top of the first Ti atom, and the top of the second Ti atom of the structures. The most favorable adsorption site for sodium was on top of the first Ti atom. Therefore, we utilized this configuration for further investigation. The adsorption energies were -0.78 eV, -1.03 eV, -1.51 eV, and -1.82 eV for single sodium adsorption on (2 \times 2 \times 1) Ti₂BN₂, Ti₂BC₂, Ti₂BP₂, and Ti₂BSi₂ supercells,

respectively. Furthermore, the adsorption of the sodium atom layer was also performed. We added layers on both the top and bottom of the structures. The adsorption energies were negative, suggesting layer adsorption was favorable too. The adsorption energy values were -0.73, -0.95, -1.36, and -1.38 eV per atom for Ti_2BN_2 , Ti_2BC_2 , Ti_2BP_2 , and Ti_2BSi_2 , respectively. Bader charge density calculation and charge density difference plot showed the charge transfer between sodium and functionalized Ti_2B monolayers—the electron localization function of the structures agreed with these findings. Finally, we conducted diffusion calculations to explore the migration properties of metal ions over the structure. For diffusion, we selected two paths; path-1 started from the first Ti atom to the second Ti atom through to another Ti atom in the first position, and path-2 started from the first Ti atom to the boron atom through to another Ti atom in the first position. The energy barriers for path-1 and path-2 were 0.32 and 0.86 eV for Ti_2BN_2 and 2.51 and 0.82 eV for Ti_2BP_2 . The findings from our study confirmed N, P, C, and Si-functionalized Ti_2B as potential candidates for anode materials in rechargeable sodium-ion batteries.

High Capacity NH_4^+ Charge Storage in Covalent Organic Frameworks Zhengnan Tian, Vinayak S. Kale, Osama Shekhah, Mohamed Eddaoudi and Husam N. Alshareef; KAUST, Saudi Arabia

Ammonium ions (NH_4^+), as nonmetallic charge carriers, have spurred great research interest in the realm of aqueous batteries. Unfortunately, most inorganic host materials used in these batteries are still limited by the sluggish diffusion kinetics. Here, we report a unique hydrogen bond chemistry to employ covalent organic frameworks (COFs) for NH_4^+ ion storage, which achieves a high capacity of 220.4 mAh g^{-1} at a current density of 0.5 A g^{-1} . Combining the theoretical simulation and materials analysis, a universal reaction mechanism of nitrogen and oxygen bridged by hydrogen bonds is revealed. In addition, we explain the solvation behavior of NH_4^+ leading to a relationship between redox potential and de-solvation energy barrier. This work provides a new insight into NH_4^+ ion storage in host materials based on hydrogen bond chemistry. This mechanism can be leveraged to design and develop COFs for electrochemical energy storage.

Magnon Selection Rules in NM/TMDC/FM Trilayer Structures Chanho Park, Jae Won Choi, Yunho Kim, Min-Sung Kang, No-Won Park and Sangkwon Lee; Chung - Ang University, Korea (the Republic of)

The spin Seebeck effect, widely known as the spin-wave analogue of the Seebeck effect, is the crucial makeshift for detecting the spin current resulting from nonequilibrium magnetization, which transfers angular momentum to adjacent system via spin waves.¹ Throughout astonishing works in spintronics for more than a decades the field has suggested schematics with normal metal deposited on ferromagnetic substrate, such that one makes the magnetization out of the equilibrium state, generating quantum properties for magnetization distribution called magnons. The injection of magnons to the interface of the normal metal / ferromagnetic insulator metal (NM/FM) heterostructures is usually referred as injection of the spin current, since the magnons themselves contain spin-polarized quantities for each component.² The injected spin current is then converted into voltage signal, named as Inverse Spin Hall Effect (ISHE) voltage.

In this paper, we conducted SSE signal detecting experiments on basic well-known Pt/YIG ($\text{Y}_3\text{Fe}_5\text{O}_{12}$) structure and Pt/ML MoS_2 /YIG structure, where ML MoS_2 fits in the category of monolayer transitional metal dichalcogenide (ML TMDC) layers and checked their temperature dependence ranging from 190-300 K. We firstly assumed both samples obey 3D spin-to-charge conversion. We gave both samples

temperature gradient $dT = 1$ K out of plane, to observe maximum SSE voltage on both samples under same dT .

Results shows that the ISHE voltage of Pt/ML MoS₂/ YIG yields is much less Pt / YIG, about ~ 27 times lower than that of the Pt/YIG system at 190 – 300 K. This can be inferred as such that MoS₂ monolayer considerably blocks the injection of spin current.

On the other hand, we kept obtaining wavy signals in Pt/ML MoS₂/YIG structure even though magneto-resistance (MR) effects were excluded. This is assumed for different magnetic properties on MoS₂ layer which have already been reported. With competing diamagnetism in ML MoS₂ itself and ferromagnetism in MoS₂ induced from magnetic proximity effect from YIG substrate,³ significant portion of the magnons are blocked where they should not if they were in original Pt/YIG system. Finally, we theoretically calculated the temperature dependent ISHE voltages by combining a conventional Boltzmann transport equation with the magnon relaxation time model, and the results were consistent with the experimental results of both for Pt / YIG and Pt / ML MoS₂ / YIG structures. Our finding presents an important achievement in understanding and measuring the LSSE and provides a promising platform, with a high spin-mixing conductance and thermoelectric performance, for two-dimensional interlayered Pt / YIG systems.

Ultrathin Two-Dimensional Transition-Metal Alloy Nanofilm Stabilized Photoanodes for Efficient Solar Water Oxidation Fei Xiang, Ning Li, Arturo Burguete-Lopez, Zhao He, Maxim Elizarov and Andrea Fratalocchi; King Abdullah University of Science and Technology, Saudi Arabia

Harvesting solar energy for photoelectrochemical (PEC) hydrogen production has attracted significant research interest in contributing to the clean energy economy and sustainable development. Despite the progress achieved in photocathodes with an applied bias photon-to-current efficiency (ABPE) above 12%, the poor kinetics and chemical instability of photoanodes in the alkaline medium limit the efficiency and long-term operations of the entire PEC devices. The current state-of-the-art efficiency of the photoanode side is below 4%, and the corresponding operation time is around 30 hours. Although the additional protective layer coating, such as TiO₂ and SiO_x, prolongs the photoanode lifetime to around 200 hours, the ABPE efficiency greatly drops to below 1%. In this work, we engineer ultrathin two-dimensional nickel-iron (NiFe) alloy film as protective and catalytic layers on Si photoanodes, extending the device lifetime to above 250 hours without compromising the PEC performances. The optimized photoanodes exhibit a low onset potential of 1.06 V versus the reversible hydrogen electrode (RHE) at the photocurrent density of 10 mA cm⁻² and high saturated current density of around 39 mA cm⁻² under one sun illumination, reporting an applied bias photon-to-current efficiency (ABPE) of 4.24%. We employ aberration-corrected scanning transmission electron microscopy combined with electron energy loss spectroscopy (STEM-EELS) to visualize the atomic-level structural and chemical information at the crystalline/amorphous hybridized interfaces. We apply high-resolution X-ray photoelectron spectroscopy

to trace the chemical species changes in the NiFe alloy layer after the PEC reaction. Benefiting from the NiFe alloy coating strategy, the PEC photoanodes operate for over 250 hours with 90% retention of its initial current density during continuous working conditions under a large current density above 30 mA cm⁻². This work opens the pathway to the designing and implementing earth-abundant, highly efficient, and stable PEC devices with 2D transition-metal alloy film for green hydrogen production and can be extended to other solar-assisted catalytic fields, such as CO₂ reduction and ammonia synthesis.

Enhanced Thermoelectric Transport Characteristics of a Novel BiSbTe-WSe₂ Composite Film

Karan Giri, Yen-Ling Wang, Ling-Chun Chao, Chuan-Wen Wang, Hung-Shuo Chang, Wen-Chieh Hsieh and Chun-Hua Chen*; National Yang Ming Chiao Tung University, Taiwan

A novel technique is developed to combine a layered structure transition-metal dichalcogenide material, tungsten diselenide (WSe₂), recognized for its extremely low thermal conductivity, with another layered structure material, bismuth antimony telluride (BiSbTe), renowned for its exceptional performance in waste heat recovery applications. To enhance the thermoelectric properties even more, WSe₂ as a secondary target is encapsulated periodically in the primary target Bi_{1.5}Sb_{0.5}Te₃ using a pulse laser deposition technique. The WSe₂, for the first time, is co-ablated with the BiSbTe at four distinct deposition temperatures, resulting in hetero-nanocomposite thin films. The diffractogram of BiSbTe-WSe₂ composite thin film exhibits sharp peaks indicating strong crystallinity and evidence that the crystals are growing in a highly c-oriented manner. The electrical transport properties are significantly improved due to the optimized hole concentration, measured in the order of 10¹⁹ and 10²⁰. The electrical conductivity is significantly increased from 134 S cm⁻¹ for the sample grown at 573 K to 1200 S cm⁻¹ that grown at 723 K. The room temperature Seebeck coefficient is 250 μV K⁻¹ for the sample grown at 673 K and 360 μV K⁻¹ for that grown at 723 K. The overall outcome is a significant increase in the power factor which is computed as 12 to 156 μW cm⁻¹ K⁻² demonstrating outstanding room temperature thermoelectric performance. The observed values are rather adequate, demonstrating an excellent trade-off between them. In addition to electrical characteristics, the specimens have a low electronic thermal conductivity, k_e. The calculated room temperature k_e values are 0.10 W m⁻¹ K⁻¹ and 0.87 W m⁻¹ K⁻¹ for the samples grown at 573 K and 723 K, respectively. The enhanced thermoelectric transport characteristics of the periodically encapsulated WSe₂ in the BiSbTe matrix place it among the best thermoelectric materials with excellent performance for thermoelectric conversion such as solid-state refrigeration and power generation.

Flat-Optics Photon Harvesting in Large-Scale 2D Semiconductor Layers for Photoconversion

Applications Giulio Ferrando¹, Matteo Gardella¹, Giorgio Zambito¹, Pham Duy Long², Si Hieu Nguyen², Chi Le Ha², Thanh Tung Nguyen², Maria C. Giordano¹ and Francesco Buatier de Mogeot¹; ¹University of Genoa, Italy; ²Vietnam Academy of Science, Viet Nam

The development of clean light harvesting platforms and technologies is crucial in view of a new generation of photonic devices with impact in renewable energy conversion and environmental applications. For this purpose, nanophotonic methodologies hold great promise. Specifically, both plasmonics and flat optics approaches offer exciting opportunities to enhance light-matter interactions at the nanoscale, making them highly appealing for applications in photoconversion and sensing. In this context, we present innovative solutions for large-scale light trapping to maximize photon harvesting in ultra-thin semiconductor layers. Within them an emerging class of materials is represented by the Two-dimensional (2D) Transition Metal Dichalcogenides semiconductor (TMDs) layers that are characterized by exceptional optoelectronic properties tunable in the Visible and Near-Infrared spectrum [1]. Among them few-layer MoS₂ is notable for an electronic bandgap in the Visible range and a high optical absorption coefficient. Such intriguing optical response combined with high chemical reactivity qualifies this 2D semiconductor layer as a promising candidate in photoconversion and energy storage applications [2].

The first solution presented is based on large area plasmonic metasurfaces obtained by ion beam assisted self-organized process. Nanostructured templates that can be used to laterally confine arrays of plasmonic nanoantennas with tunable optical response [3].

The second solution is based on large area periodic nanograting templates, fabricated by Laser Interference Lithography, to reshape large-scale (cm²) two-dimensional MoS₂ semiconductor layers as an active optical element featuring a flat optics configuration that enhances the light coupling by arising of photonic anomalies [4,5].

Light harvesting performances of the proposed solutions were tested by photocatalytic and photoelectrochemical experiments. The plasmonic system is used in an Oxygen Evolution Reaction (OER) reaction with both the function of a transparent electrode and a co-catalyst coupled to an ultra-thin film of TiO₂. On the other hand the subwavelength reshaping of ultra-thin semiconductor layers results in enhanced methylene blue photobleaching [6].

These light harvesting platforms are thus promising in view of various large-scale applications such as waste water treatment, dye molecules sensing and energy storage.

Controlling The Hydrogen Evolution Activity by Tailoring The Outer Transition Metal Layers in Double Transition Metal MXenes Anupma Thakur, Nithin Chandran Balachandran Sajitha, Brian Wyatt and Babak Anasori; Indiana University- Purdue University Indianapolis, United States

Two-dimensional transition metal carbides, nitrides, or carbonitrides, known as MXenes, have shown great promise as active materials in catalytic applications such as the hydrogen evolution reaction. In double transition metal (DTM) MXenes two different transition metals occupy the metal sites which can enhance the tunability of MXenes electrocatalytic properties. The transition metal occupying the outer atomic layers controls the hydrogen evolution reaction (HER) performance based on their basal plane catalytic activity. We investigated out-of-plane ordered DTM MXenes, with inner layers of transition

metal (M'' : Ti) sandwiched by outer layers of different transition metals (M' : Mo, W, Cr) in a layered $M'_2M''C_2T_x$ MXenes. We investigated the role of exposed basal plane transition metals on the HER catalytic activity of these out-of-plane ordered DTM MXenes and compared their behavior to a mono-transition metal MXene, $Ti_3C_2T_x$. $W_2TiC_2T_x$ MXene shows the lowest HER overpotential of 147 mV at 10 mA/cm² under acidic conditions compared with $Mo_2TiC_2T_x$, $Cr_2TiC_2T_x$, and $Ti_3C_2T_x$ MXenes. The improved electrocatalytic performance of $W_2TiC_2T_x$ can be due to the presence of tungsten atoms in the outer M' layers. Additionally, $W_2TiC_2T_x$ MXene showed long-term stability of more than 24 hours. Our findings further demonstrate that MXenes are precious-metal-free 2D flakes with highly HER active basal planes and promising and tunable electrocatalysts for clean energy applications.

8:30 AM EN06.10.03

Computationally Guided Design of Single-Atom Catalysts Embedded on Reduced Graphitic

Carbon Nitride Monolayers Mukesh Jakhar and Veronica Barone; Central Michigan University, United States

The design of efficient single-atom catalysts (SAC) with optimal activity and selectivity for sustainable energy and environmental applications remains a challenge. Herein, first-principles calculations are performed to validate the feasibility of single TM atoms (3d, 4d, and 5d series) embedded in two different conformations of graphitic carbon nitride ($g-C_3N_4$) monolayers (planar and corrugated). We explore the effects of $g-C_3N_4$ monolayer nitrogen vacancies on the absorption of SAC considering three potential absorption scenarios, i.e. *on-vacancy*, *via-substitution*, and *on-center*, that correspond to different experimental conditions. Our results highlight the most stable configurations with the lowest formation energies and find that the absorption of single TM atoms *on-vacancy* and *on-center* sites are more favorable than *via-substitution*. Furthermore, in addition to thermodynamics stability, electrochemical stability is also investigated through the calculation of the dissolution potential of the SACs. Within the scenarios considered in this study, we find that Co, Fe, Rh, Ir, Pt, and Ni will produce the most robust SAC on reduced $g-C_3N_4$. Our findings provide guidance for the design and development of $g-C_3N_4$ sheets decorated with single TM atom catalysts for applications such as pollutant degradation, CO₂ reduction, N₂ fixation, selective oxidation, water splitting, and metal ion-based batteries.

Enhancing Sodium and Potassium-Ion Storage in 2D MoWSe₂ : Effect of Upper Voltage Cut-Off

Sonjoy Dey, Arijit Roy and Gurpreet Singh; Kansas State University, United States

The superior properties, such as large interlayer spacing and the ability to host large alkali-metal ions, of two-dimensional (2D) materials based on transition metal di-chalcogenides (TMDs) enable next-generation battery development beyond lithium-ion rechargeable batteries. In addition, compelling but rarely inspected TMD alloys provide additional opportunities to tailor bandgap and enhance thermodynamic stability. This study explores the sodium-ion (Na-ion) and potassium-ion (K-ion) storage behavior of cation-substituted molybdenum tungsten diselenide (MoWSe₂), a TMD alloy. This research also investigates upper potential suspension to overcome obstacles commonly associated with TMD materials, such as capacity fading at high current rates, prolonged cycling conditions, and voltage polarization during conversion reaction. The voltage cut-off was restricted to 1.5 V, 2.0 V, and 2.5 V to realize the material's Na⁺ and K⁺ ion storage behavior. Three-dimensional (3D) surface plots of differential capacity analysis up to prolonged cycles revealed the convenience of voltage suspension as a viable method for structural preservation. Moreover, the cells with higher potential cut-off values conveyed improved cycling stability, higher and stable coulombic efficiency for Na⁺ and K⁺ ion half-

Updated as of October 28, 2024

cells, and increased capacity retention for Na⁺ ion half-cells, respectively, with half-cells cycled at higher voltage ranges.

***Operando* Methods for Mechanistic Studies of Energy Systems** Hector D. Abruna and Rui Zeng;
Cornell University, United States

This presentation will deal with the use of *operando* methods for mechanistic studies energy systems with emphasis on fuel cells and battery materials and technologies. The presentation will begin with a brief

overview of the methods employed with emphasis on the use of X-ray based methods, transmission electron microscopy (TEM) under active potential control, confocal Raman spectroscopy and microscopy and DEMS (differential electrochemical mass spectrometry) coupled with SEIRAS (surface enhanced infra-red absorption spectroscopy). The utility of these methods will be illustrated by case studies focusing on non-precious metal electrocatalysts for the oxygen reduction reaction (ORR) in alkaline media, Li/S batteries the reduction of carbon dioxide and the oxidation of ethanol. The presentation will conclude with an assessment of future directions.

11:00 AM EN07.01.02

Tuneable Ethylene Production using the Electrochemical Oxidative Coupling of Methane (EOCM): Exploiting Oxygen Evolution to Create the Active Oxygen Species Filip Grajkowski, Subhash Chandra, Sanaz Koohfar, Dongha Kim, Georgios Dimitrakopoulos and Bilge Yildiz; Massachusetts Institute of Technology, United States

Ethylene (C_2H_4) is one of the most valuable compounds in the chemical industry as it is used as a building block for a wide range of applications. The current ethylene production pathway via the steam cracking of naphtha or ethane is highly endothermic, resulting in ethylene production being the second-biggest CO_2 -generating process in industry.¹ In 1982, Keller and Bhasin first reported on an alternative ethylene production method,² the oxidative coupling of methane (OCM). In this approach, CH_4 is oxidised on oxide catalyst surfaces by adsorbed O_2 -derived species to yield C_2H_6 and the desired C_2H_4 . Unfortunately, this thermochemical OCM approach suffers from significant “deep oxidation” where CH_4 is instead combusted to CO/CO_2 and H_2O : this arises as the products of oxidative coupling are more reactive than the parent CH_4 . In order to improve the C_2 selectivity and yield of OCM processes, recent works have focused on integrating OCM activity into typical solid oxide electrolyser systems.³ In this electrochemical OCM (EOCM) approach, O^{2-} ions from the cathode side are transported across the solid electrolyte to the anode where they oxidise CH_4 molecules to yield the desired C_2 (C_2H_4 and C_2H_6) products.

In this study, inspired by recent results using mixed ionic-electronic conductors for EOCM, we use $La_{0.3}Sr_{0.7}TiO_3$ as the anode material for EOCM. By using combined electrochemical and gas chromatographic analyses, we demonstrate that this titanate system can successfully yield the desired C_2 products and can respond to changes in the O^{2-} flux. We highlight that the C_2 selectivity of the reactor can be tuned using the applied potential: we show a tuneability in the C_2 selectivity with enhancements of $>3\times$ at higher currents relative to lower currents. These results are rationalized mechanistically with reference to the oxygen evolution reaction which occurs at the anode surface. We demonstrate that by controlling the delivery of oxygen to the anode, we gain the ability to selectively produce the active oxygen species necessary for selective CH_4 activation towards C_2 products. These findings furnish the ability to increase both the CH_4 conversion and the C_2 selectivity and have finally broken the inverse relationship between the CH_4 conversion and the C_2 selectivity which dominates the thermochemical OCM literature. Additional chemical and structural characterizations illustrate that the anode material is stable under the EOCM operational conditions with no noticeable phase decomposition, a notorious limitation of other EOCM anodes.³ The results presented herein can serve as a guide for the field on how to effectively choose the anode composition to enhance both the product selectivity and the overall performance of the combined reactor system.

Highly Stable Pentagonal 2D Palladium Diselenide Enables Rapid Electrosynthesis of Hydrogen Peroxide R. Dominic Ross, Gerardo J. Quintana Cintron, Kwanpyung Lee, Hongyuan Sheng, JR Schmidt and Song Jin; University of Wisconsin–Madison, United States

Electrosynthesis of hydrogen peroxide (H_2O_2) via the two-electron oxygen reduction reaction (2e^- ORR) is promising for various practical applications such as wastewater treatment. However, few electrocatalysts are active and selective for 2e^- ORR yet also resistant to catalyst leaching under realistic operating conditions. Here, a joint experimental and computational study reveals highly active and stable 2e^- ORR catalysis in neutral media over 2D layered PdSe_2 with a unique pentagonal layered structure type. Computations predict active and selective 2e^- ORR on the basal plane and edge of PdSe_2 , but with distinct kinetic behaviors. Electrochemical measurements of hydrothermally synthesized PdSe_2 nanoplates show higher 2e^- ORR activity than Pd_4Se and $\text{Pd}_{17}\text{Se}_{15}$, suggesting unique performance enabled by the PdSe_2 structure type. PdSe_2 on a gas diffusion electrode can rapidly accumulate H_2O_2 in a buffered neutral solution under high current density. Elemental analysis of the catalyst and electrolyte and synchrotron X-ray absorption spectroscopy confirm the chemical stability of PdSe_2 under these practical electrosynthesis conditions. This work establishes a new efficient 2e^- ORR catalyst with high intrinsic stability at practical current densities and opens catalyst designs utilizing the unique 2D pentagonal structure motif.

Activation Energies of Heterogeneous Electrocatalysis from First Principles Saerom Yu, Zachary Levell, Ruoyu Wang and Yuanyue Liu; The University of Texas at Austin, United States

Electrocatalysis at solid-water interface is central to many technologies addressing energy and environmental challenges. However, the reaction kinetics at atomic level is not well understood and difficult to simulate due to the complexity of the electrochemical interface. Here I will present an advanced model, which accurately and efficiently simulates the realistic electrochemical interface, particularly the reaction activation energies. I will also show the application of this model to understand the electrocatalysis of single metal atoms embedded in nitrogen doped graphene (M-N-C), such as: (1) the active site structure in Ni-N-C for CO_2 reduction; (2) the origin of high H_2O_2 selectivity of Co-N-C for 2e^- oxygen reduction; and (3) the kinetic mechanism of Fe-N-C for 4e^- oxygen reduction.

What Makes Lithium Unique for Nitrogen Reduction? Ifan E. Stephens; Imperial College London, United Kingdom

There is a burgeoning interest in the development of a green method of ammonia synthesis; ammonia, already critical for fertilisers in the agricultural industry, is also being touted as a possible future energy vector or carbon-free fuel. The current method of production - the Haber Bosch process - is environmentally damaging and energy intensive but to date no viable alternative has been demonstrated. An electrochemical method operating under ambient conditions would be particularly attractive, as it would enable ammonia to be produced on a decentralised basis on-site and on-demand.¹

Thus far, amongst solid electrodes, only lithium based electrodes in organic electrolytes can unequivocally reduce nitrogen to ammonia.^{2,3} Even so, at present, the lithium based system is far too inefficient for practical uses; moreover, it is highly unstable.

In the current contribution, we will explore the underlying reasons why lithium is unique in its ability to reduce nitrogen to ammonia.^{4,5} We use a combination of electrochemical experiments, cryo-microscopy, infrared spectroscopy, electrochemistry mass spectrometry, time-of-flight secondary ion mass spectrometry, X-ray photoelectron spectroscopy and density functional theory. By drawing from the adjacent fields of enzymatic nitrogen reduction and battery science, we will aim to build a holistic picture of the factors controlling nitrogen reduction. On the basis of our insight, we propose new avenues towards going beyond lithium in electrochemical nitrogen fixation.

Metal-Free Nanofibers with Tailored Electronic Structures for Highly Active and Selective Hydrogen Peroxide Electroproduction Fei Xiang¹, Xuhong Zhao², Jian Yang³, Ning Li¹, Xiaobin Niu² and Andrea Fratalocchi¹; ¹King Abdullah University of Science and Technology, Saudi Arabia; ²University of Electronic Science and Technology of China, China; ³Southwest Jiaotong University, China

Electrocatalytic hydrogen peroxide (H₂O₂) production via two-electron oxygen reduction reaction (2e-ORR) has attracted significant research interest as a promising alternative to the traditional energy-intensive traditional anthraquinone cycling process. However, designing low-cost, highly active, and selective electrocatalysts remains challenging due to the fierce competition from the four-electron reaction pathway. In this study, we engineer the electronic structure of electrospun nanofibers via fluorine and sulfur dual-doping to develop large-scale metal-free electrocatalysts for hydrogen peroxide

production. Experimental and theoretical computation results demonstrate the manipulated electronic structures of the carbon active sites after suitable fluorine and sulfur dual-doping, originating from intermolecular charge transfer and electron spin redistribution at the active sites. The optimized catalyst exhibits an onset potential of 0.814 V versus the reversible hydrogen electrode (RHE) in an alkaline medium and a selectivity of 99.1%, outperforming most of the previously reported carbon-based and metal-based counterparts. Density functional theory (DFT) results elucidate the manipulated free energy profiles and kinetic energy barriers in 2e⁻ ORR after fluorine and sulfur dual-doping, confirming the enhanced activity and selectivity in the 2e⁻ ORR pathway for hydrogen peroxide production. This fluorine and sulfur dual-doping strategy on carbon nanofibers from electrospinning provides the pathway to designing and implementing large-scale, low-cost, and highly efficient catalysts for hydrogen peroxide production. Moreover, this strategy also enjoys versatility in the materials for other catalytic fields, such as water splitting, CO₂ reduction, and ammonia production.

2:15 PM *EN07.02.03

Light-Driven Reduction of Carbon Dioxide with Hybrid Photoelectrodes Jillian Dempsey; University of North Carolina at Chapel Hill, United States

Integration of molecular catalysts that reduce CO₂ to CO with silicon photoelectrodes has been achieved through both covalent and non-covalent attachment methods. These hybrid photoelectrodes have been characterized by x-ray photoelectron spectroscopy, inductively-coupled plasma mass spectrometry, and attenuated total reflectance infrared spectroscopy. Cyclic voltammetry and bulk photoelectrolysis with product analysis are used to establish that these hybrid photoelectrodes are competent for light-driven fuel production with high Faradaic efficiencies.

A New Strategy for Improving Durability of Electrodes in Cell Reversal during Fuel Starvation Cycles of PEMFC with Reversal Tolerant Anode Chi-Yeong Ahn^{1,2}, So Yeon Lee^{1,2} and Hyungwon Shim¹; ¹Korea Research Institute of Ships & Ocean Engineering, Korea (the Republic of); ²University of Science and Technology, Korea (the Republic of)

Due to the strengthening of environmental regulations of international societies, the introduction of eco-friendly technologies is being rapidly carried out in the marine and shipping sectors. Among them, fuel cells (especially PEMFC) are in the limelight as a propulsion system for small and medium-sized coastal ships due to fast starting characteristics and low operating temperature. However, ships require higher output than passenger cars, which require an FC capacity of about 100 kW. In the case of such a large-capacity FC, hydrogen may not be evenly diffused to the electrode when starting or when an electric load rapidly increases due to stoichiometry control. In some parts (or all) of the electrode where hydrogen supply is insufficient, fuel starvation will proceed, and cell reversal may occur. This cell reversal

phenomenon causes severe degradation of the anode.

Degradation by cell reversal can be mitigated by adding a material with OER activity such as iridium oxide to the anode. This anode is called a reversal tolerant anode (RTA). In addition, several studies have been conducted on RTA under various conditions. However, we observed that when RTA was added in fuel starvation cycles, the anode was well protected but the cathode rather degraded. Therefore, in this study, we sought the cause of cathode degradation during fuel starvation cycles and conducted experiments to prevent it.

8:00 PM EN07.03.09

Pt-Ni-Ru Nanoframes with Superior Performance for Methanol Oxidation Reaction Eduardo Lezama, Kira Shulman, Yoor Cho and Yiliang (Yancy) Luan; Binghamton University, The State University of New York, United States

Direct Methanol Fuel Cells (DMFCs) offer a promising solution for energy conversion with relatively low carbon emissions. Nevertheless, the efficiency of the anode is hindered by the sluggish kinetics of the Methanol Oxidation Reaction (MOR), preventing the widespread commercialization of DMFCs. Despite being a successful commercialized catalyst, Platinum (Pt) has been demonstrated to be costly and inefficient. Pt-based alloys with open structures offer feasible alternatives that have the potential to improve MOR while also being economically viable. This study synthesized Pt-Ni-Ru nanoframes (NFs) via a galvanic replacement process, resulting in remarkable MOR activity attributed to the combined effect of alloying and large surface area from the NFs. The Pt-Ni-Ru NFs exhibited mass and specific activities 2.8 and 2.0 times higher, respectively, compared to the commercial Pt/C catalyst. The study demonstrates that Pt-Ni-Ru NFs serve as a superior catalyst for the anode reaction in DMFCs, emphasizing the potential of open nanostructures and alloying in the advancement of future catalysts.

Unravelling Hidden Parameters during Electrode Processing: The Role of Coherent Workflows in Electrocatalysis Doris Segets^{1,2}; ¹University of Duisburg-Essen, Germany; ²Center for Nanointegration Duisburg-Essen (CENIDE), Germany

Micron and nano-sized functional materials play a key role for future technologies that are currently developed in the field of energy conversion (electrolysers, fuel cells) and electrocatalysis. While new materials with outstanding properties are continuously developed, they rarely find their way into – urgently needed – large scale production and industrial applications [1]. One reason for this are hidden parameters that occur during ink formulation, coating (and decal transfer), cell assembly, and operation. We propose the development of coherent workflows that help us to identify reliable correlations. These should be developed for each electrocatalyst, bridging synthesis, electrode and gas diffusion electrode (GDE)/membrane electrode assembly (MEA) fabrication, and testing. All information, including “negative” results like crack formation, delamination, structural ageing and dissolution, must be reported until the relevant hidden parameters are deciphered, and the design chain is understood. Then, materials and electrodes derived from complementary processes and exhibiting subtle variations in composition and structure, can be evaluated against each other.

However, this implies to fill the “blackbox” between technical catalysts and electrochemical testing in flow cells, GDEs or MEAs, with quantitative data on powders, ink formulations and coating properties. In the past years, we developed a toolbox of methods that starts from key control characteristics for technical catalysts, i.e., ball-milled pentlandites for hydrogenation reactions, that thereon enable the in situ analysis of ink formulations and pastes during the dispersion process and at application concentration [2,3]. This is

followed by the assessment of the resulting coatings from large-area crack analysis down to the level of surface roughness and pore size characteristics [4]. Finally, this input is connected with performance and stability testing results to enable the comparison of different materials, the assessment of structure property relations, and ultimately to establish inline process control during electrode manufacturing. In this contribution, the developed methods will be summarized and related to their current limitations and prospects, in particular for unraveling hidden parameters during GDE assembly as well as in line process control.

Phase Engineering of Noble Metal-Based High-Entropy Alloy Nanocrystals Peng Han and Ye Chen; The Chinese University of Hong Kong, Hong Kong

High-entropy alloys (HEAs) possessing five or more elements exhibited unique physical and chemical characteristics. Delicate size/shape and composition control would significantly boost their performance toward various catalytic reactions. However, the phase-dependent properties of HEAs are rarely studied because controlling the crystal structure of HEAs with the same composition is extremely challenging. Herein, through facile wet chemistry and subsequent heat treatment, quinary and senary noble metal-based HEA nanocrystals with well-controlled phases, including hexagonal close-packed (*hcp*) and face-centered cubic (*fcc*) phases are successfully synthesized. The phase of noble metal-based HEA nanocrystals is tunable by altering the types of metal precursors and the temperature during heat treatment. The effect of the crystal structure on the catalytic performance of noble metal-based HEA nanocrystals is also investigated. This work opened a significant avenue in developing well-defined HEA nanocrystals with precise control over phases for heterogeneous catalysis.

Efficient Oxidation of Aqueous Persistent Organic Pollutants using Zwitterionic Hydrogel-Bound Iron(II) Ions as Heterogenous Fenton Catalysts Devashish Gokhale, Ian S. Chen and Patrick Doyle; Massachusetts Institute of Technology, United States

Persistent organic pollutants, such as xenoestrogens and PFAS, present a global challenge requiring immediate action. The Fenton oxidation reaction is an advanced oxidation process catalyzed by dissolved Fe(II) ions and their complexes, which converts hydrogen peroxide to hydroxyl radicals to degrade organic contaminants. Though the Fenton reaction is extremely promising for scalable water treatment, there are several limitations to its practical use, such as the difficulty in transporting and storing hydrogen peroxide. Further, though Fe(II) ions are called catalysts in Fenton processes, they are continuously oxidized to Fe(III) ions and are difficult to reuse or recover from water. Attempts to create a practical Fenton process have used electrochemical cells to produce hydrogen peroxide *in situ*, while replacing dissolved Fe(II) ions with heterogenous catalysts. Such catalysts typically encapsulate iron or iron oxide

nanoparticles in polymers or support them on traditional adsorbents but have so far been limited by slow reaction rates due to reduced surface area, the need to adjust pH with acids, unintended substrate/polymer degradation by the Fenton reaction, and the release or slow dissolution of nanoparticles. These catalysts are also incompatible with other improvements to the traditional Fenton reaction, such as UV light to accelerate the production of hydroxyl ions.

A practical Fenton process to eliminate POPs will require the development of (1) a heterogeneous catalyst that retains iron while (2) eliminating the need for acid addition, (3) is highly porous and has a large effective surface area to preserve efficacy, (4) is transparent to UV radiation and (5) resistant to degradation by UV light, hydrogen peroxide, and the iron itself, (6) preferably does not use nanoparticles which may pose a threat to the environment if they escape the catalyst over long periods of time, and (7) can be regenerated and reused in a facile manner. Here, we introduce an innovative heterogeneous Fenton catalyst based on a zwitterionic hydrogel material that effectively addresses these challenges. Containing individually complexed iron ions in a highly porous scaffold, the hydrogel catalyst has a large effective surface area and exhibits kinetics comparable to homogeneous Fenton degradation. The complexed ions can initiate Fenton degradation at neutral, and even alkaline pH, eliminating the need for acid additions. At the same time, the zwitterionic hydrogel scaffold is specifically selected to be resistant to Fenton oxidation and strongly bind to the iron ions, enabling repeatable long-term use. Using our catalytic hydrogels, we showcase the rapid and complete degradation of three structurally disparate contaminants of major concern, ethinyl estradiol (a xenoestrogen), 2,4-dichlorophenol (a model pesticide and chlorinated aromatic) and perfluorooctanoic acid (PFOA, a model for PFAS), over multiple cycles of use at environmentally relevant concentrations. Our zwitterionic hydrogel-based Fenton catalyst offers a promising solution for the efficient and scalable degradation of persistent organic pollutants in electrochemical water treatment processes and beyond.

8:00 PM EN07.03.05

Electrosynthesis of Hydrogen Peroxide and Electro-Fenton Application using Metal Chalcogenide Electrocatalysts Gerardo J. Quintana Cintron, R. Dominic Ross and Song Jin; University of Wisconsin–Madison, United States

Hydrogen peroxide (H_2O_2) is an environmentally friendly oxidant that has diverse applications in wastewater treatment, paper bleaching, and chemical disinfection. However, its traditional production is costly, unsafe, and not energy efficient. Electrochemical production of H_2O_2 using the two-electron oxygen reduction reaction (2e^- ORR) could enable decentralized production of H_2O_2 with just air and electricity. Furthermore, electrosynthesized H_2O_2 can be reacted with Fe^{2+} to produce hydroxyl radical ($\bullet\text{OH}$) via the electro-Fenton (EF), which can break down or convert organic compounds that are otherwise difficult to oxidize directly. Metal selenides such as CoSe_2 and NiSe_2 have previously been demonstrated as effective electrocatalysts for the 2e^- ORR and EF. Here we further explore a series of Fe-Se compounds toward practical EF. Metal and selenium leaching was systematically studied through inductively coupled plasma-optical emission spectroscopy (ICP-OES) to understand better how the Fe ion leaches (Fe ion concentration) and can “self-catalyze” the EF reaction. The electrosynthesis of H_2O_2 and the electrochemical removal of model contaminant Rhodamine B via the EF process was studied with or without added Fe^{2+} with various metal selenide catalysts in a conventional H-cell and a gas diffusion electrode (GDE) flow cell. This work also studies the production of H_2O_2 through the cathodic reduction of oxygen in acidic and neutral medium by comparing the results obtained using different metal chalcogenide catalysts on a GDE flow cell setup.

8:00 PM EN07.03.07

Low-Cost 3D Printable Flow Reactors for Electrochemistry Erin Heeschen, Elena DeLucia, Yilmaz A. Manav, Daisy Roberts, Benyamin Davaji and Magda H. Barecka; Northeastern University, United States

Transition to carbon neutrality requires the development of more sustainable pathways to synthesize the next generation of chemical building blocks. Electrochemistry is a promising pathway to achieve this goal, as it allows for using renewable energy to drive chemical transformations. While electroreduction of carbon dioxide (CO₂) and hydrogen evolution are attracting a significant research interest, there exist fundamental challenges in moving the research focus towards performing these reactions on scales relevant to industrial applications. To bridge this gap, we aim to facilitate the access of researchers to flow reactors, which allow characterizations of electrochemical transformations under the conditions closer to those deployed in the industry. Here we provide a 3D-printable flow cell design (manufacturing cost < \$5) which consists of several plates, offering a customizable alternative to commercially available flow reactors (cost > \$6,000). Proposed design and detailed build instructions allow a wide variety of chemical reactions in flow to be performed, including gas and liquid phase electroreduction, electroplating, and photoelectrochemical reactions, providing researchers with more flexibility and control over their experiments. By offering a low-cost reactor alternative, we reduce the barriers toward performing research on sustainable electrochemistry, supporting the global efforts necessary to realize the paradigm shift in chemical manufacturing.

8:00 PM EN07.03.08

Engineering the Electronic Structure of Aluminate Spinel Oxide using a High Entropy Approach Francisco Marques dos Santos Vieira, Ismaila Dabo, Raymond Schaak, Zhiqiang Mao and Rowan Katzbaer; The Pennsylvania State University, United States

Due to its high energy density, hydrogen fuel shows promise in the decarbonization of freight transport. However, there remain challenges in the synthesis of hydrogen fuel. Electrocatalytic water splitting holds the potential to sustainably produce hydrogen fuel provided suitable catalysts are identified. Here, we present the high entropy aluminate spinel oxide (Fe_{0.2}Co_{0.2}Ni_{0.2}Cu_{0.2}Zn_{0.2})Al₂O₄ (A⁵Al₂O₄) as catalyst for the oxygen evolution reaction (OER) in an alkaline electrolyte, and explore its electronic structure. In High entropy oxides (HEOs), numerous cations coexist in a single sublattice forming a solid solution throughout the crystalline solid. The sharing of a sublattice gives rise to unique, and even enhanced, properties including improved catalytic performance. Experimental measurements indicate A⁵Al₂O₄ has a bandgap far narrower than its parent phases. First principles calculations indicate that this narrowing of the bandgap is a consequence of the broadening of bands arising from the hybridization of the 3d states due to the variation of electronegativity across the 3d transition metal series. The observed narrowing of the bandgap in the high entropy spinel highlights a new method of engineering electronic structure using a high entropy approach to achieve desired material properties.

8:00 PM EN07.03.10

Structural and Electrocatalytic Properties of Pulsed Laser-Deposited Titanium Nitride/Titanium Oxynitride Thin Films Sheilah Cheron¹, Ikenna Chris-Okoro¹, Valentin Craciun^{2,3}, Mihai Maria^{3,4} and Dhananjay Kumar¹; ¹North Carolina Agricultural and Technical State University, United States; ²National Institute for Laser, Plasma, and Radiation Physics, Extreme Light Infrastructure for Nuclear Physics, Romania; ³University Politehnica of Bucharest, Romania; ⁴Horia Hulubei National Institute for Nuclear Physics and Engineering, Romania

Pulsed laser deposition (PLD) technique has been used to grow titanium nitride (TiN) and titanium oxynitride (TiNO) thin films on sapphire (Al_2O_3), titanium dioxide (TiO_2) and niobium doped titanium dioxide (Nb - TiO_2) single crystal substrates using high vacuum conditions. A pulsed Krypton Fluoride (KrF) excimer laser (Wavelength=248nm, pulse duration=30ns) has been used, with a laser repetition rate of 10 Hz, 6000 pulses, and a deposition temperature of 600° C. Structural properties of the films were investigated using X-ray Diffraction and Reflection (XRD, XRR) while X-ray Photoelectron Spectroscopy (XPS) and Rutherford backscattering spectrometry (RBS) was used for compositional investigations. XRD phi scans show the in-plane orientation of the deposited TiN film with respect to the substrate orientation; depending on the substrate orientation, films are either (111) or (200) oriented, thus offering different orientations for surface chemical reactions. The full-width half maximum (FWHM) value of plane (200) was 0.5754° for the film grown on undoped TiO_2 (110), while for those growing along the (111) plane was 0.1617° for the film on sapphire and 0.1457° for the film on Niobium-doped TiO_2 (100). Films deposited onto niobium-doped TiO_2 have shown the highest crystallinity, whereas those deposited onto undoped TiO_2 have shown poor crystallinity. The rocking curve results show that changing the substrate orientation can control the crystal quality of the grown TiN.

Simulation of the acquired XRR curves indicated mass densities from 5.2 to 5.4 g/cm³, very close to the TiN tabulated value, while the roughness was less than 1 nm indicating flat surfaces for chemical reactions. XPS analysis shows the initial film surface is oxidized, and the chemical formula indicates the existence of a composite made of TiO_2 +TiON+some TiN. After sputtering of the surface heavily oxidized layer is removed, and the chemical composition changes to TiN-TiON and some TiO_2 . For the films deposited under low vacuum, the atomic oxygen concentration was lower than 10%, a result also confirmed by Rutherford backscattering spectrometry. Such films also exhibited resistivities around 70 mΩ.cm, which is close to the best-reported values. TiON films are epitaxial, despite the relatively high oxygen concentration. By controlling the oxygen-to-nitrogen ratio by regulating the vacuum level during PLD, optical bandgaps of the composite films were controlled from 2.1 eV to 3.2 eV, and electrocatalytic overpotentials for oxygen evolution reaction potentials as low as 300 mV at 10mA/cm² was obtained. The Tafel slopes, indicative of a rate of increase of electrode potential with respect to current, for these films, are determined to be in the range of 80–60 mV/decade. These results further demonstrate the superiority of TiNO thin film as an electrocatalyst for water oxidation to generate fossil-free fuels. The improvement in the electrocatalytic behavior of the TiNO thin films is explained based on an adjustment in the valence band maximum edge and an enhancement in the number of electrochemically active sites. Both effects are realized by the substitution of N by O, forming a TiNO lattice that is isostructural with the rock-salt TiN lattice.

This work was primarily supported by a DOE EFRC on The Center for Electrochemical Dynamics And Reactions on Surfaces (CEDARS) via grant # DE-SC0023415. The authors (IK, VC, and DK) also acknowledge the support of the NSF PREM via grant # DMR-2122067 PREM.

Improved Alkaline Hydrogen Oxidation on Strained-Modulated Pt Overlayers on Ordered Intermetallic PtSb Cores Tianyao Gong¹, Hamdan Alghamdi¹, David Raciti² and Shoji Hall¹; ¹Johns Hopkins University, United States; ²National Institute of Standards and Technology, United States

Alkaline exchange membrane fuel cells (AEMFCs) have emerged as an inexpensive and robust renewable energy conversion device. However, the kinetics Hydrogen Oxidation Reaction (HOR) in alkaline

conditions (the anode reaction of AEMFCs) is $\sim 100\times$ slower in than in acidic electrolytes. Significant progress has been made developing improved catalyst materials for alkaline HOR, yet due to the complexity of alloy surfaces, it is difficult to determine the true source of such enhancement. To address this issue, here we report the use of Ordered Intermetallic Compounds (OICs) as a well-defined platform to produce strain modulated Pt overlayers. Two OICs phases of the Pt-Sb system, PtSb and PtSb₂, with different crystal structures were prepared. Electrochemical dealloying of the Pt-Sb alloys resulted in the formation of core shell Pt-Sb@Pt particles. By judicious choice of the OIC precursor material, we were able to produce PtSb@Pt and PtSb₂@Pt with compressive and tensile strain, respectively, relative to elemental Pt. It is worth noting that this approach cannot be accomplished with solid solution alloys (with an alloy core composed of the same two elements) since the d-spacing of the lattice follows Vegard's law. This enabled us to interrogate the role of how strain controls HOR performance without the possible influence of atoms with different identities on the surface of the Pt. PtSb@Pt exhibited a weaker HBE than Pt, enabling to achieve an exchange current density (j_0) 1.5x larger than benchmark Pt catalyst for alkaline HOR; whereas PtSb₂ exhibited tensile strain which increased the HBE, reducing the j_0 by 1.5x to Pt catalyst. Interestingly we found no correlation with the OH_{ads} coverage as estimated by CO stripping. Therefore, this work revealed that HBE is the dominant parameter for improving the kinetics of Pt sites for alkaline HOR.

8:00 PM EN07.03.13

Effect on Oxygen Reduction Reaction of Iron Catalyst Synthesized by Aniline Monomer-Mediated Technique Yeongeun Choi¹, SeungMin Lee¹, Jihyeok Song², Hyo Eun Bae² and Oh Joong Kwon¹;
¹Incheon National University, Korea (the Republic of); ²Seoul National University, Korea (the Republic of)

An anion exchange membrane fuel cell (AEMFC), which uses hydroxyl conductive membranes instead of proton conductive ones, is highlighted as a replacement for a proton exchange membrane fuel cell. AEMFC has the advantage of using abundant and inexpensive transition metals, such as iron, cobalt, and nickel for catalysts owing to mild reaction conditions. Among numerous non-platinum metal catalysts (NPMCs), M-N-C catalyst has been reported considerably and Fe-N-C catalyst, which co-doped nitrogen and Fe, was considered the promising M-N-C owing to their high atomic utilization and excellent electrocatalytic performance. For the Fe-N-C catalyst, it is important to expose the maximum number of active sites and distribute the Fe in the Fe-N-C catalyst uniformly on a carbon support. Therefore, many researchers have been exploring Fe-N-C catalyst, in which Fe exist as a single atom. The common method for synthesizing single atom Fe-N-C includes the random mixing and high-temperature pyrolysis process, which tends to cause the aggregation of metals and leads to the degradation of catalytic activity. Thus, the research for preventing the aggregation of metals is crucial for high electrocatalytic activity.

This study explores the possibility of applying M-N-C to AEMFC through the development of Fe single atom. We adopted the method of aniline-mediated metal reduction and high-temperature pyrolysis for synthesizing the Fe-N-C catalyst. The Fe single atom reported high performance and durability and possess the optimal Fe-N_x coordination structure by optimizing the synthesis condition. The optimization of the synthesis conditions for the Fe-N-C catalyst proceeds through the control of the amount of Fe precursor and aniline and the temperature of pyrolysis. Several characterizations such as Thermogravimetric analysis (TGA), X-ray diffraction (XRD), Inductively coupled plasma-mass spectrometry (ICP-MS), and Scanning transmission electron microscopy (STEM) were introduced to investigate the catalyst properties. The uniform distribution of the single atom on the carbon support was confirmed by STEM and XRD, and the Fe content was checked to be about 1wt.% using ICP-MS and

Updated as of October 28, 2024

TGA. Furthermore, electrochemical measurements were conducted to present the correlation between catalytic activity and structure. The catalyst, which possesses single atom active sites, showed high electrochemical performance and durability for oxygen reduction reaction and proposed the applicability for AEMFC. The study proved that the Fe single-atom catalyst was successfully synthesized by metal reduction and pyrolysis processes

Tailoring the Ensemble Geometry and Electronic Properties of Active Sites in Catalytic Nanomaterials Christina Li, Purdue University, United States

Supported metal atoms and nanoparticles are found ubiquitously as heterogeneous catalysts for a wide variety of industrial, organic, and energy catalytic processes. The electronic and steric environment at the nanomaterial surface has a huge impact on the reactivity and selectivity of catalytic transformations occurring at surface active sites, but these properties are difficult to independently control through conventional materials synthetic methods. In this work, we develop molecularly-precise surface functionalization strategies in order to precisely tune both the ensemble geometry and redox properties of active site metal atoms. These strategies include 1) the adsorption of inorganic ligands on colloidal nanoparticle surfaces in order to synthesize monolayer and sub-monolayer core-shell catalysts, 2) control of bimetallic surface ensemble geometry in alloy nanoparticles, and 3) tuning the metal-sulfur coordination environment of single atoms supported on metal chalcogenide nanosheets for electrochemical catalysis. All of these strategies develop new structural frameworks for modulating the surface active site environment in order to access more reactive and selective nanomaterial catalysts.

Composition, Structure and OER Behaviors of Highly Catalytic Manganese-Doped Bismuth Ruthenium Oxide (MBRO) for Alkaline Water Splitting Masatsugu Morimitsu, Sachi Matsuura, Hayato Suzuki and Chinami Iketani; Doshisha University, Japan

Water splitting using alkaline solutions is one of the most promising methods to produce green hydrogen and accounts for 61% of the world's hydrogen production capacity in 2020¹⁾. The anodic reaction, which is oxygen evolution reaction (OER), occurs through a 4-electron transfer in highly corrosive solutions. While currently nickel-based materials are used for the anode because of the chemical stability of their oxides and oxyhydroxides in alkaline media, the current density during electrolysis is limited due to the low catalytic activity of those materials and cannot be as high as PEM water splitting. Our group has recently developed bismuth ruthenate-based pyrochlore oxide as a new OER catalyst and has found some excellent properties on the polarization for and durability to OER in KOH solutions. In this paper, the composition, structure, and OER behaviors of manganese-doped bismuth ruthenium oxide (MBRO) are presented with the results by instrumental analyses and electrochemical measurements.

MBRO was prepared by calcination at 600 °C of the precursor deposited in the solution which had been obtained by adding NaOH solution into the metal salt solution containing bismuth nitrate and ruthenium chloride with manganese nitrate. The composition and structure of the oxide were analyzed by AAS, RBS, EDX, XRD, and XAFS and the surface morphology and particle size were measured by SEM. The electrochemical performance was evaluated by Titanium Disk Method (TDM), in which the oxide particles loaded on a titanium disk (4 mm in diam.) was mounted in the rotating-disk electrode of a conventional three-electrode cell. The cell was also equipped with a platinum plate counter electrode and an Hg/HgO reference electrode. The electrolyte was 0.1 mol/L KOH solution and all measurements were performed at room temperature.

The obtained MBRO showed a single phase of pyrochlore structure and ruthenium at the B site was partly substituted with manganese. The particle size ranged from 20 to 40 nm, which was small enough to load it on a titanium disk without any binders or ionomers. The results obtained by polarization measurements revealed that the onset potential of OER was 0.45 V vs. Hg/HgO, which is the overpotential of 0.16 V, and the Tafel slope was ca. 39 mV/dec, while the other materials reported in the literature²⁾ shows the overpotential higher than 200 mV and Tafel slope of 60 mV/dec or more. The above results suggest that MBRO is suitable for the anode material of alkaline water splitting to reduce the cell voltage at high current densities. In this work, MBRO-loaded graphite electrodes were prepared and examined for OER in 6 mol/L KOH solutions, of which the results will be also presented.

Tungsten-Induced *Operando* Transformations of the Perovskite $\text{Ba}_{0.5}\text{Sr}_{0.5}\text{Ni}_{1-x}\text{W}_x\text{O}_{3-\delta}$ Series during the Oxygen Evolution Reaction Natasha Hales, Emiliana Fabbri and Thomas Schmidt; Paul Scherrer Institute, Switzerland

Water electrolysis provides a means for long-term energy storage in the form of hydrogen gas, helping to offset seasonal variations in renewable energy production. Developing non-noble metal catalysts for the anodic oxygen evolution reaction (OER) is a key step in reducing the cost and increasing the energy efficiency and sustainability of this vital technology. Flame-spray synthesized perovskite oxides of the composition $\text{Ba}_{0.5}\text{Sr}_{0.5}\text{Ni}_{1-x}\text{W}_x\text{O}_{3-\delta}$ exhibit excellent OER activity in alkaline conditions. In particular, $\text{Ba}_{0.5}\text{Sr}_{0.5}\text{Ni}_{0.5}\text{W}_{0.5}\text{O}_{3-\delta}$, with a catalytic turn over frequency (TOF) five-times that of NiO, displays a competitive Tafel slope of 44.7 mV/dec. The perovskite structure, with its tunable ABO_3 formula, provides a unique opportunity to enhance the intrinsic activity of Ni sites with high-valence metal co-doping, and explore the relationship between structural properties and electrocatalytic activity.

B-site W doping strongly influences the oxidation state of surface Ni sites, as revealed by *ex-situ* soft X-ray absorption spectroscopy (XAS) at the Ni L-edge. A higher concentration of W^{4+} increases the $\text{Ni}^{2+}/\text{Ni}^{3+}$ ratio, enhancing the intrinsic activity of the Ni active sites. In addition, analysis of the O K-edge indicates a positive correlation between W content and oxygen vacancy concentration, activating $\text{Ba}_{0.5}\text{Sr}_{0.5}\text{Ni}_{0.5}\text{W}_{0.5}\text{O}_{3-\delta}$ for the lattice oxygen mechanism (LOM), whereby mobile oxygen atoms can move through vacant lattice sites to participate directly in OER catalysis.¹ This pathway is largely considered to be more efficient than the traditional adsorbate evolution mechanism (AEM), leading to enhanced

reaction kinetics and decreased OER overpotentials.¹

Akin to the the well-known surface reconstruction processes of NiO during alkaline OER ($\text{Ni}^{\text{II}}\text{O} \rightarrow \text{Ni}^{\text{II}}(\text{OH})_2 \rightarrow \text{Ni}^{\text{III}}\text{OOH}$), NiW perovskites experience complex, electrochemically-induced transformations under OER conditions.² Therefore, catalyst ‘pre-activation’ using cyclic voltammetry is essential to develop their high-performance final state *in-situ*. *Operando* hard XAS at the Ni K-edge and W L₃-edge revealed that NiW perovskites experience significant oxidation state changes at the catalytic Ni sites during cyclic voltammetry, with a strong overall trend of $\text{Ni}^{2+} \rightarrow \text{Ni}^{3+}$ oxidation. However, both the extent and rate of this oxidation are greatly influenced by the B-site W concentration. Furthermore, *operando* X-ray diffraction revealed significant surface reconstruction that facilitates a strong growth in electrochemically active surface area, but this process is also heavily dependent on the W content. It is evident that the ‘pre-activation’ of $\text{Ba}_{0.5}\text{Sr}_{0.5}\text{Ni}_{1-x}\text{W}_x\text{O}_{3-\delta}$ catalysts is a function of the Ni:W ratio; elucidating the ways in which high valence metal doping influences the catalyst activation mechanism will guide the development of future Ni-based OER catalysts, for which this process is intrinsically coupled with OER activity.

Discovery of High-Index Facet Nanocatalysts for Clean Energy Applications Bo Shen and Chad A. Mirkin; Northwestern University, United States

Nanoparticles with high-index facets are particularly attractive as electrocatalysts because such facets typically consist of a high density of low-coordinated atomic steps and kinks. However, the synthesis of high-index facet nanoparticles is very challenging, which prevents the wide application of such materials. Herein, we addressed this challenge by developing synthetic methods based on ligand-free, solid-state reactions. Combining synthetic techniques with high-throughput DFT simulations and machine learning, we have discovered a library of multimetallic high-index facet nanoparticles. Additionally, the size, composition, crystal structures, and phase structures of such materials can be further controlled by nanolithography, leading to a huge database of high-index facet catalysts, which can be used for a range of energy-related applications including electrooxidation of liquid fuels and CO₂ reduction.

Platinum Catalysts with Enhanced Activity and Durability Toward Oxygen Reduction Younan Xia; Georgia Institute of Technology, United States

In this talk, I will discuss a number of new strategies for augmenting the mass activity and durability of Pt-based catalysts toward the oxygen reduction reaction (ORR), which is key to the operation of proton-exchange membrane fuel cells (PEMFCs). Specifically, the strategies include the formation of intermetallic compounds, creation of twin boundaries on the surface, and introduction of chemical linkage between Pt surface and carbon support. When integrated together, these strategies can lead to the development of ORR catalysts with performance that meets the requirement set by DOE. For example, we were able to grow sub-2-nm Pt particles on a commercial carbon support *via* the galvanic reaction between a Pt(II) precursor and a uniform film of amorphous Se pre-deposited on the support. The residual Se could serve as a linker to strongly anchor the Pt nanoparticles to the carbon surface, leading to a catalytic system with extraordinary activity and durability toward ORR. Even after 20,000 cycles of

accelerated durability test, the sub-2-nm Pt particles were still dispersed well on the carbon support, maintaining a mass activity more than three times as high as the pristine value of a commercial Pt/C catalyst.

From Fundamental Studies to Applied Research: SrIrO₃ as Efficient Electrocatalysts for Proton Exchange Membrane Electrolyzer Zhenxing Feng; Oregon State University, United States

The search of efficient and stable electrocatalysts for oxygen evolution reaction (OER) in acidic electrolyte is the key to enable the commercialization of proton exchange membrane (PEM) electrolyzers and low hydrogen production price. However, there are few choices for such electrocatalysts due to the corrosive and oxidative conditions. As the discovery of SrIrO₃ as a new type of electrocatalysts in acidic OER, we have focused on the fundamental studies of mechanism that leads to its much better activity (~1000 times more) than the commercial standard, IrO₂. Using SrIrO₃ thin film epitaxially grown by molecular beam epitaxy (MBE) as the model system, we have studied the surface restructuring and Sr leaching in the reaction at the atomic scale. Later, using the learned knowledge, we design Ir less SrIrO₃-based catalysts in powder form that exhibit the same activity. We are currently extending our studies for this type of catalysts for general PEM electrolyzer applications.

11:00 AM EN07.04.07

Enhancing Hydrogen Evolution Reaction by Controlling Chemical States Through Electrochemical Reduction of Raney Nickel in Alkaline Water Electrolysis YoungHwa Yun^{1,2}, Changsoo Lee¹, Sechan Lee¹, MinJoong Kim¹, JongHyeok Park² and Hyunseok Cho¹; ¹Korea Institute of Energy Research, Korea (the Republic of); ²Yonsei University, Korea (the Republic of)

Porous electrocatalysts based on nickel (Ni) have found extensive application in alkaline water electrolysis for the hydrogen evolution reaction (HER). The selective leaching of aluminum (Al) from Ni-Al alloys is widely employed as a prominent approach to increase the surface area of porous Ni during fabrication, resulting in high surface area in Ni(OH)₂. However, the Ni(OH)₂ hampers the HER due to its weak hydrogen adsorption energy. To enhance the hydrogen adsorption energy, it is essential to control the chemical state of the Ni by incorporating metallic Ni, which exhibits strong hydrogen adsorption characteristics. In this study, we controlled the chemical states of Ni through plasma vapor deposition (PVD), heat treatment, chemical leaching, and electrochemical reduction. The phase evolution of the electrocatalysts during fabrication was confirmed using a range of characterization techniques, including X-ray diffraction (XRD), scanning electron microscopy (SEM), transmission electron microscopy (TEM), and energy-dispersive X-ray spectroscopy (EDS). We revealed that the heat-treated Ni-Al alloy, possessing a thick Ni₂Al₃ surface layer, underwent selective Al leaching, resulting in the formation of biphasic interfaces comprising Ni(OH)₂ at the grain and NiAl IMCs near the grain boundary of the outermost surface layer. X-ray photoelectron spectroscopy (XPS) analysis confirmed that the coupled oxidation of the NiAl IMCs facilitated the partial reduction of Ni(OH)₂ to Ni(OH)₂/Ni at the grains during electrochemical reduction. The electrocatalyst containing partially reduced Ni(OH)₂/Ni exhibited an overpotential of 54 mV at 10 mA/cm², and in single-cell operation, it demonstrated a cell voltage of 1.675 V at 0.4 A/cm² at 50 °C.

11:15 AM EN07.04.08

Catalyst-Support Interactions in Zr₂ON₂-Supported IrO_x Electrocatalysts for Enhanced Activity and Stability in the Acidic Oxygen Evolution Reaction. Changsoo Lee¹, Kihyun Shin², Youngtae Park¹, YoungHwa Yun¹, Gisu Doo¹, MinJoong Kim¹, Sechan Lee¹ and Hyunseok Cho¹; ¹Korea Institute of Energy Research, Korea (the Republic of); ²Hanbat National University, Korea (the Republic of)

Overcoming the challenge of developing highly active and durable Ir-based electrocatalysts for the acidic oxygen evolution reaction (OER) is difficult due to the corrosive conditions experienced during anodic processes. In this study, we present the utilization of IrO_x/Zr₂ON₂ electrocatalysts, which employ Zr₂ON₂ as a support material, to address the trade-off between activity and stability in the OER. Zr₂ON₂ was chosen for its exceptional electrical conductivity and chemical stability, as well as its ability to form strong interactions with the IrO_x catalysts. As a result, the IrO_x/Zr₂ON₂ electrocatalysts demonstrated remarkable OER performance, achieving an overpotential of 255 mV at 10 mA/cm² and a mass activity of 849 mA/mg_{Ir} at 1.55 V (versus the reversible hydrogen electrode). The activity of IrO_x/Zr₂ON₂ was sustained at 10 mA/cm² for 5 hours, while the unsupported IrO_x catalyst and IrO_x/ZrN underwent significant degradation. Through a combination of experimental X-ray analyses and theoretical interpretations, it was discovered that the reduced oxidation state of Ir and the extended Ir-O bond distance in IrO_x/Zr₂ON₂ effectively enhanced the activity and stability of IrO_x by modifying the reaction pathway from a conventional adsorbate evolution mechanism to a mechanism involving participation of lattice oxygen. These findings demonstrate that it is possible to significantly reduce the Ir content in OER catalysts through interface engineering without compromising their catalytic performance.

Designing Microenvironments for Selective CO₂ (Photo)Electroreduction Francesca M. Toma^{1,2}; ¹Helmholtz Zentrum Hereon, Germany; ²Lawrence Berkeley National Laboratory, United States

(Photo)electrochemical reduction of carbon dioxide is a process in which multiple proton-electron transfers are necessary to yield valuable carbon-based products. This process also offers an efficient strategy to reduce the presence of greenhouse gases in the atmosphere while concurrently producing valuable carbon-based products. However, most of the existing CO₂ reduction catalysts still exhibit reduced selectivity for CO₂ reduction products and high activity for the competing hydrogen evolution reaction.

To understand how to tune catalytic activity and selectivity, the identification of specific structure–reactivity relationships can inform catalyst development. We demonstrate that the confined reaction environment enables changes in reaction selectivity and can impart atypical catalytic behaviors. In this talk, we clarify the role of subsurface oxygen, water, and CO₂ on Cu and Ag based systems for CO₂ electroreduction. We show the development of a predictive framework to tune the selectivity of CO₂ reduction on Cu and Ag by examining a series of polymeric and molecular modifiers. We also demonstrate how considerations about the local reaction environment have relevance for photoelectrochemical systems. This understanding can reveal design principles that enable development of active and selective catalysts and provide further insights into the CO₂ reaction mechanism on existing catalyst such as copper and silver.

Atomic-Scale Insights into Electrocatalyst Structure and Function Shoji Hall; Johns Hopkins University, United States

The development of efficient renewable energy conversion and storage devices to curb climate change is one of the most important challenges of the 21st century. This can be addressed by using renewable electricity to manufacture chemical fuels and synthetic precursors, or by generating electricity with carbon-neutral fuel cell devices. However, electrocatalytic processes are hampered by low efficiencies and poor reaction selectivity because of a lack of rational methods available to create controllable catalyst materials with the preferred electrochemical activities. In this seminar Prof. Hall will discuss the use of ordered intermetallic compounds (OICs), which are alloys that display high electrocatalytic activities because their well-defined compositions and long-range atomic scale ordering enable predictable geometric and electronic interactions, in contrast to the more widely studied solid-solution type alloys. However, OIC materials are difficult to synthesize in nanomaterial form because conventional synthesis methods offer poor control over the composition, phase, and morphology. I will discuss our efforts on the synthesis, stability, and catalytic activity of OICs prepared by electrochemical methods at room temperature and atmospheric pressure. Our strategies include the use of electrochemically induced phase transformations which enables us to convert a base metal rich alloy to an OIC richer in nobler metal by removal of the base metal, and the direct production of OIC materials by electrochemical deposition. We will also discuss how we leverage the atomically precise configuration of atoms within OICs to reveal detailed insights into how a material's structure regulates its electrochemical properties. Developing new methods for preparing OIC compounds under ambient conditions is essential for designing catalysts for the next generation of renewable energy conversion devices.

Mitigating the Phosphate Anion Poisoning Effect on Oxygen Reduction Reaction (ORR) with a Hydrophobic Side Group Honghong Lin, Siwen Wang, Liang Wang, Gaohua Zhu, Ling Chen and Hongfei Jia; Toyota, United States

High-temperature polymer electrolyte fuel cells (HT-PEMFCs) have been developed for heavy duty applications, utilizing phosphoric acid (H_3PO_4) to overcome the proton conductivity limit of Nafion at elevated temperatures (120-220 °C). However, the adsorption of phosphoric acid onto the Pt catalyst hampers the oxygen reduction reaction (ORR) activity, necessitating a high Pt loading in HT-PEMFCs. Understanding the interaction between Pt and phosphate anions, as well as the anion adsorption effect on ORR, is crucial for activity improvement. In this study, we conducted a comprehensive theoretical and experimental investigation to gain insights into the effect of phosphate adsorption on ORR. While electrolyte adsorption inevitably obstructed active sites, our study revealed a weakened binding between Pt and key ORR intermediates, namely the OH_{ad} , in the presence of adsorbed anions. This weakened Pt- OH_{ad} binding had a beneficial effect on boosting the ORR kinetics. By appropriately modifying the side group structure of a substituted phosphonic acid ($\text{R-PO}(\text{OH})_2$), the activity loss caused by anion adsorption could be effectively compensated through enhanced ORR kinetics. Our findings highlight an alternative approach, alongside catalyst material modulation, to mitigate the adverse effects of electrolytes

in HT-PEMFCs. The tuning of catalyst interfacial structure using a hydrophobic surface modifier can also serve as a strategy to optimize ORR kinetics in both low-temperature (LT-) and HT-PEMFCs.

2:15 PM EN07.05.03

Probing the OER/ORR Mechanisms on MnO₂ using *Operando* TEY-STXM and Surface DFT Calculations Evan Z. Carlson^{1,2}, Xiao Zhao^{1,2}, Michal Bajdich³, Hendrik Ohldag², William C. Chueh¹ and Tyler Mefford¹; ¹Stanford University, United States; ²Lawrence Berkeley National Laboratory, United States; ³SLAC National Accelerator Laboratory, United States

Harnessing the unique bifunctional OER/ORR activity of manganese oxides in regenerative fuel cells could help reduce their material and capital requirements. However, using MnO₂ in reversible, single-catalyst oxygen electrodes requires a better understanding of the structural and chemical motifs responsible for its high electrocatalytic activity.

In this talk, I will discuss our investigation of the atomic-scale origins of Mn oxide's bifunctional OER/ORR activity using a hybrid experimental-computational approach. Our model system, α -K_xMnO₂, is among the highest-performing Mn oxide catalysts for both the OER and the ORR, with ORR activity rivaling that of Pt in basic electrolytes.^[1] The material's pH and cation-dependent activity is characterized via rotating ring disk electrochemistry (RRDE), and its voltage-dependent chemistry is probed via *operando* scanning transmission x-ray microscopy in bulk-sensitive transmission mode^[2] and surface-sensitive total electron yield mode (TEY-STXM). Surface DFT calculations further reveal the active sites and mechanisms for both the OER and ORR, as well as an unusual cation-dependency.

Conductive Dithiolene-Based Metal-Organic Frameworks for Electrocatalytic H₂ Production Smaranda C. Marinescu; University of Southern California, United States

Sustainable hydrogen evolution reaction (HER) from water has emerged as a promising pathway for the storage and conversion of solar energy in chemical bonds. Hydrogen is a valuable energy carrier that can be transformed into electricity using fuel cell technology or used in the production of industrially relevant chemicals such as ammonia and methanol. Heterogenization of molecular catalysts is an attractive strategy to combine the advantageous properties of homogeneous and heterogeneous catalysis. Metal-organic frameworks (MOFs) have emerged as a promising class of materials; however, their insulating nature has limited their applications in electronics and electrocatalysis. We have demonstrated the successful integration of metal dithiolene units into one and two-dimensional frameworks by using dinucleating and trinucleating thiolate-based ligand scaffolds. The developed metal dithiolene frameworks display high activity for the electrocatalytic HER in acidic aqueous media. The HER performance of the MOF-based electrocatalysts is investigated, to understand the charge transfer properties of the constructed MOF/electrode architecture. Density functional theory calculations were applied to understand the structure of the MOF and its mechanistic pathways for the HER. We expect the design principles discovered in these studies to have a profound impact towards the development of advanced materials and sustainable technologies.

3:30 PM EN07.05.06

Investigation of FeOOH for Mechanisms in Water-Splitting Reactions Alexandra M. Anderson and Wennie Wang; University of Texas at Austin, United States

Electrolysis is at the forefront of methods of producing hydrogen by separating water into oxygen and hydrogen gas. The oxygen evolution reaction (OER) is known for having slower kinetics due to multiple proton-electron coupled transfer steps being involved. Transition metal oxyhydroxides have been demonstrated to have low overpotentials while being composed of abundant and cheap elements and may be an important materials platform in scaled-up hydrogen production.¹ This project explores the relationships between structure and OER mechanisms in iron oxyhydroxides (FeOOH). Earth-abundant metals like Fe pose active catalytic sites and can be modeled in a FeOOH structure under alkaline conditions. Studies show that amorphous electrocatalysts exhibit greater catalytic activity compared to crystalline electrocatalysis, a trend which has often been attributed to amorphous electrocatalysts having a greater concentration of electrochemically accessible active sites.^{2,3} We hypothesize that the lack of long-range order in amorphous electrocatalysts may also introduce novel structural moieties not present in the crystalline form and play a role in enhanced electrocatalytic activity.

In order to begin testing this hypothesis, we study structure-property relationships between crystalline disorder and OER energetics using density functional theory (DFT) with a Hubbard U correction as implemented in Quantum ESPRESSO.⁴ We first discuss determining the Hubbard U correction value and constructing a representative adsorbate/surface structure using the crystalline structure. We manually manipulate the crystalline structure to imitate potential local structural distortions of the amorphous structure and compare computed overpotentials with the different structures and previously determined literature values. Finally, we present a rational model to understand the impact of structural distortion on electrocatalytic activity.

Multicomponent Alloy Nanoparticles as Efficient Oxygen Evolving Electrocatalysts Leanne Jones and Robert Weatherup; University of Oxford, United Kingdom

Designing efficient and cost-effective catalysts for electrochemical water splitting will be pivotal in the global effort towards net zero [1]. The two half reactions of water splitting; the hydrogen evolution reaction (HER, $2\text{H}^+ + 2\text{e}^- \rightarrow \text{H}_2$) and the oxygen evolution reaction (OER, $2\text{H}_2\text{O} \rightarrow \text{O}_2 + 4\text{H}^+ + 4\text{e}^-$), currently rely on Pt group metals such as Pt and Ru, and Ir and Ru oxides, when performed in acidic media. Overpotentials are still observed for these catalysts due to the sluggish kinetics of the reactions, with OER typically the rate limiting reaction [2]. It is therefore instructive to find alternative oxides to replace Ir and Ru. Nonprecious transition metal-based oxides may provide cheaper and more abundant OER catalysts. Unfortunately, these oxides are not stable in the acidic media, and therefore must be studied in alkaline media [3].

The activity of transition metal-based catalysts relates to their electronic structure, specifically the energy

difference between the valence d-band centre and the Fermi level (E_F) [4]. An increase in the energy difference usually results in a stronger interaction of the orbital and the adsorbate. The strength of this interaction in terms of catalytic activity is described by the Sabatier Principle. Therefore, tailoring the optimal energy of the d-band for the reaction of interest will allow for improved catalytic efficiency. Ni, Fe and Co based catalysts and their alloys have shown great promise as OER catalysts [5,6].

Multicomponent alloys (MCAs) exhibit improved corrosion resistance relative to the elemental constituents whilst still containing catalytically active elements such as Ni, Fe and Co. This synergistic relationship between the elements make MCAs promising as successful OER catalysts.

Here, size-selected nanoparticles are deposited via a state-of-the-art gas-phase synthesis. Using a quadrupole mass spectrometer placed in-line with the source, the size of the nanoparticles are well defined and controlled. Initial depositions of NiFeCoMoAl and NiFeCoMoCr have been successful, and characterised on an atomic scale using transmission electron microscopy (TEM). Hard and soft X-ray photoelectron spectroscopy (HAXPES and SXPS, respectively), measured at the i09 beamline at Diamond Light Source, gives depth resolved compositional information showing the presence of all elements as well as their possible arrangement within the nanoparticles. Meanwhile atom probe tomography (APT) measurements, made possible by simultaneous nanoparticle deposition and conventional magnetron sputtering, allow us to marry the information gathered using TEM and SXPS/HAXPES. The structural and chemical information thereby obtained is compared with electrochemical measurements of the intrinsic activities of different MCAs, revealing trends in valence band measurements from SXPS and activity. Unifying these complimentary techniques gives insight into the relationship between the atomic and electronic structure with electrochemical activities of MCA nanoparticles which will feed into future electrocatalytic design and will be a stepping stone in the wider effort of achieving net-zero emissions.

Simple Synthesis of Perovskite oxides/FeOOH with N-Doped Graphene Quantum Dots to Boost Electron Transfer Sang Heon Kim and Jeong Min Baik; Sungkyunkwan University, Korea (the Republic of)

Bifunctional electrocatalyst requires superior charge transfer and good electrochemical performance to produce overall and stable water splitting reaction. Perovskite oxides (ABO_3) have a good performance in oxygen evolution reaction but poor in hydrogen evolution reaction. Iron (oxy)hydroxides (FeOOH) show good electrochemical performance in hydrogen evolution reaction but have low conductivity. Herein, we successfully synthesized the LaSrCoO/N-GQD/FeOOH composites via impregnation method and high energy ball-milling, which exhibited an efficient OER and HER performance with a lower overpotential of 300mV and 420mV at 10mA cm^{-2} . Also, composites have a lower Tafel slope value of 51mV dec^{-1} compared with simple LaSrCoO@FeOOH composites. In the overall electrochemical water splitting system, the LaSrCoO/N-GQD/FeOOH showed excellent stability at 1 A cm^{-2} over 100 h in full cell voltage. These LaSrCoO/N-GQD/FeOOH composites will provide the development of designing other electrocatalysts and give new way in boosting electron transfer induced by intermediate electron bridge

Lattice Anion Redox in Perovskite Oxides under Oxygen Evolution Conditions Andrew Akbashev; Paul Scherrer Institute, Switzerland

Oxygen evolution reaction causes structural transformations and metal dissolution in most oxide electrocatalysts. In my talk, I will discuss how oxidative conditions cause intercalation of O^{2-} and can lead to the formation of oxidized oxygen inside the crystal lattice. Detection of anion oxidation is notoriously challenging and its unambiguous detection in electrocatalysts has been elusive so far. In our work, we used high-resolution resonant inelastic X-ray scattering (RIXS) to detect the oxidation state of oxygen in perovskites after OER, employing single-crystalline materials as model electrocatalysts. I will show that the emergence of oxidized oxygen depends on the transition metal and the amount of intercalation oxygen. In the end, I will discuss the possible relationship between lattice oxygen oxidation and the degradation of perovskite electrocatalysts during OER.

MOF Tessellation of Cation Defects-Rich 3D Bifunctional ORR/OER Electrocatalyst for Rechargeable Zinc-Air Batteries Gopalakrishnan Mohan and Soorathep Kheawhom; Chulalongkorn University, Thailand

A cost-effective bifunctional electrocatalyst for oxygen reduction reaction (ORR) and oxygen evolution reaction (OER) is essential for rechargeable zinc-air batteries (RZABs). Herein, we report porous nanorod-like NiFe@MOFs with tunable structures and multiple coordination modes showing fascinating architectures for the preparation of high-performance electrocatalysts. By tuning the structure and optimizing the Ni/Fe ratio, $Fe_2O_3/Ni_{0.6}Fe_{2.4}O_4@NC$ having a large surface area, porosity, and abundant cation vacancies, is successfully developed. It shows excellent activities for both ORR ($E_{1/2} = 0.856$ V) and OER ($\eta_{10} = 1.54$ V @ 10 mA cm $^{-2}$). By using density functional theory (DFT) calculations, ORR and OER mechanistic pathways are studied. Furthermore, RZAB using $Ni_{0.6}Fe_{2.4}O_4@NC$ catalyst demonstrates a high open circuit voltage (OCV) of 1.5 V, a peak power density of 187 mW cm $^{-2}$, and exceptional long-term cycling stability over 300 h (1800 cycles, 10 mA cm $^{-2}$). The flexible solid-state ZAB using $Ni_{0.6}Fe_{2.4}O_4@NC$ catalyst exhibits a power density of 66 mW cm $^{-2}$ and long-term durability over 43 h at 5 mA cm $^{-2}$. The proposed strategy allows for the rational design of cation defect-rich NiFe spinel structures attached to ultra-thin N-doped graphitic carbon sheets in order to enhance active site availability and facilitate mass and electron transport.

Evaluation of Activation Process for the Catalyst of Polymer Electrolyte Electrochemical Cell for Hydrogen Generation Itsuka Akita^{1,2}, Miyuki Nara², Kazuki Koike^{1,2}, Takayo Ogawa², Katsushi Fujii²,

Satoshi Wada² and Atsushi Ogura^{1,3}; ¹Meiji University, Japan; ²RIKEN RAP, Japan; ³MREL, Japan

Requirements for renewable energy are increasing to suppress global warming and to keep natural resources. Hydrogen by water electrolysis is useful as an energy storage way to realize the use of fluctuating renewable energy sources. Especially, polymer electrolyte electrochemical cell (PEEC) is attractive since it is a practical method for hydrogen production. The PEEC has a flexibility of scale adaptability for systems ranging from W- to kW-scale. The efficiency improvement of PEEC is an important issue to improve the energy system performance. To obtain the optimal performance of PEEC, activation is practically important, however, the mechanisms are still obscure. It is believed to bring the membrane and catalyst into specific conditions by activation.

In this study, we focused on the activation of PEEC with the cathode catalyst of Pt/C and the anode catalyst of IrOx. We investigated the activation processes by current density. The idea is based on the changes in the valency of iridium oxide. The oxygen evolution reaction (OER) is promoted by the valence change of iridium. Various valency change models have been proposed, but they were difficult to specify because the reaction takes place at the interface and is difficult to observe. Recently, the results of in-situ and ambient XPS, XAFS, and DFT simulations suggested that metastable iridium oxides with valences higher than tetravalent are the main contributors to OER [1]. It was also reported that the valency change of iridium oxides depends on the applied voltage.

In this study, the valency controls with the electron injection speed, that is, the current. The amounts of electrons were not the same, but the current was applied at the same time. That is, the activating currents (none, 0.1, 1.0, 10, 100 mA/cm², in this order) were applied for 1 hour to evaluate the activation. The evaluation method was the current value at 2.0 V when the voltage was swept with 10 mV/s from 1.45 V to 2.0 V and then a constant voltage of 2.0 V was applied for 5 minutes after the voltage change. After the measurement, sweeping from 2.0 V to 0.0 V with 1 mV/s and maintaining 0.0 V for 30 min was performed as deactivation process.

The voltage changes during the activation processes were different. The voltage reached 1.27 V and increased continuously even after 1 hr when the activating current was 0.1 mA/cm². The voltage reached 1.46 V before 1 hr passed and kept the values when the other activating currents were applied. The current density-increasing rates were also similar for all cases.

The turn-on current densities were the same for all activation processes at voltage sweeping. However, the current density slopes were different, and the current densities at 2.0 V applied were 0.573, 0.575, 0.602, 0.597, and 0.592 A/cm² when the activation currents were none, 0.1, 1.0, 10, and 100 mA/cm², respectively.

The current density changes during the voltage kept at 2.0 V were similar for all cases and the current density slightly decreased with time, except for no activation process which the current density increased at the beginning.

The valency change of IrOx was reported to occur at around 0.9, 1.3, and 1.5 V as valency from 3+ to 4 to 4+, respectively [1]. The results show the valency change at around 1.5 V is important to activate the IrOx. The activation current of 0.1 mA/cm² was not enough for activation from this. Since the current density at the 2.0 V application decreases with the activation current over 1.0 mA/cm², the amount of the activation charge and/or the activation speed may be also important for the activation process.

8:00 PM EN07.06.06

Structure-Activity Elucidation of Stainless Steel Waste Meshes as Efficient Oxygen Evolution Catalysts Nageh K. Allam; American University in Cairo, Egypt

Herein, the ability to convert waste stainless steel (SS) 316L meshes into highly efficient and durable oxygen evolution reaction (OER) catalysts is demonstrated. The process involves surface treatment of previously anodized SS meshes in different gaseous atmospheres. The activity of the resulted electrocatalysts varies as-anodized SS annealed in oxygen (ASS-O₂) > anodized SS annealed in hydrogen (ASS-H₂) > anodized SS annealed in air (ASS-Air). The ASS-O₂ showed an impressive low overpotential of 280 mV at the benchmark current density of 10 mA/cm², which is 120 mV less than that of the as-received SS (SS-AR), and a low Tafel slope of 63 mV dec⁻¹ in 1 M KOH. These findings have also been asserted by the estimated electrochemical active surface area, electrochemical impedance spectroscopy analysis, Mott–Schottky analysis, and the calculated turnover frequency, affirming the superiority of the ASS-O₂ electrocatalyst over the ASS-H₂ and ASS-Air counterparts. The high activity of the ASS-O₂ electrocatalyst can be ascribed to the surface composition that is rich in Fe³⁺ and Ni²⁺ as revealed by the X-ray photoelectron spectroscopy analysis. The simple method of anodization and thermal annealing in O₂ at moderate conditions (450 °C for 1 h) lead to the formation of a SS mesh-based OER electrocatalyst with activity exceeding that of the state-of-the-art IrO₂/RuO₂ and other complex modified SS catalysts. These results were also confirmed via density functional theory calculations, which unveiled the OER reaction mechanism and elucidated the d-band center in different SS samples with different oxygen content. The presence of oxygen moved the d-band center closer to the Fermi level in the case of ASS-O₂, explaining its superior activity.

8:00 PM EN07.06.09

RuO₂ Supported on the PdPb Multi-Frame for Enhanced Electrocatalytic Performance for Oxygen Evolution Reaction in Acidic Media Doyeop Kim and Kwangyeol Lee; Korea University, Korea (the Democratic People's Republic of)

Electrochemical water splitting offers a promising carbon-free method for hydrogen production, which can greatly reduce reliance on fossil fuels. However, one major challenge in enhancing the efficiency of this process depends on the sluggish kinetics of the oxygen evolution reaction (OER). Existing catalysts based on Ru nanoparticles show remarkable activity for acidic OER but are susceptible to dissolution in acidic conditions, limiting their stability. We have developed a novel approach to synthesizing RuO₂ catalysts supported by PdPb multi-frames to address this issue. This involved a seed-mediated growth method followed by thermal oxidation, stabilizing the Ru-based nanocatalyst. Through temperature control of thermal oxidation, it is possible to adjust the degree of doping of Pd into RuO₂, and the presence of Pd doped in RuO₂ prevents overoxidation, leading to exceptional catalytic activity and remarkable stability for the acidic OER. This study suggests an ideal synthesis method for efficiently introducing dopants into RuO₂-based catalysts while also providing a new understanding of catalyst development with improved performance in acidic conditions for the OER.

8:00 PM EN07.06.10

Block Copolymer Mediated Synthesis of TiO₂/RuO₂ Nanocomposite for Efficient Hydrogen and Oxygen Generation Binod R. K C and Bishnu Bastakoti; NC A&T State University, United States

Abstract: Ruthenium oxide (RuO₂) is one of the most effective electrocatalysts reported for oxygen evolution reaction (OER) but still has insufficient stability for practical water splitting. To solve this problem, herein we report the fabrication of TiO₂/RuO₂ nanocomposite by sol-gel method. An amphiphilic block copolymer, poly (styrene-polyvinyl pyridine-ethylene oxide) was used as structure directing and stabilizing agent. The strong interaction of polymer with metal precursors led to the formation of a heterointerface for synergetic effect and acts as a bridge for the electron transport which

can accelerate the water splitting reaction. Scanning electron microscopy, energy dispersive X-ray spectroscopy, transmission electron microscopy, and X-ray diffraction analysis of prepared $\text{TiO}_2/\text{RuO}_2$ sample revealed successful fabrication of $\text{TiO}_2/\text{RuO}_2$ nanocomposite. The electrochemical water splitting properties of prepared sample were measured by three electrode system in 0.1M KOH electrolyte which showed improved electrochemical properties of prepared sample.

This work was primarily supported by a DOE EFRC on The Center for Electrochemical Dynamics And Reactions on Surfaces (CEDARS) via grant # DE-SC0023415.

8:00 PM EN07.06.14

Synthesis of Two-Dimensional Tantalum Carbo-Selenide and their Electrochemical Performance for Hydrogen Production Elham Loni¹, Ahmad Majed¹, Chaochao Dun², Karammullah Eisawi¹, Anika Tabassum³ and Michael Naguib¹; ¹Tulane University, United States; ²Lawrence Berkeley National Laboratory, United States; ³University of the District of Columbia, United States

Two-dimensional transition metal carbo-chalcogenides (TMCCs) consist of early transition metal carbide core and chalcogen surface (e.g., S, Se, and/or Te). They are promising candidates for energy storage applications, such as ion batteries, supercapacitors, and water-splitting applications since they can have both properties of carbides and chalcogenides, such as electrical conductivity and catalytically active, respectively. In this work, we report on the synthesis of two-dimensional $\text{Ta}_2\text{Se}_2\text{C}$ (2D- $\text{Ta}_2\text{Se}_2\text{C}$) through the electrochemical intercalation to introduce lithium into multilayer (m- $\text{Ta}_2\text{Se}_2\text{C}$), followed by sonication in deionized water. The m- $\text{Ta}_2\text{Se}_2\text{C}$ material was obtained through a solid-state synthesis of $\text{Fe}_x\text{Ta}_2\text{Se}_2\text{C}$, followed by a chemical etching process. The electrocatalytic performance of 2D- $\text{Ta}_2\text{Se}_2\text{C}$ was found to be significantly superior to that of both multilayer $\text{Ta}_2\text{Se}_2\text{C}$ and 2D- TaSe_2 when utilized as an electrocatalyst for the hydrogen evolution reaction. Notably, 2D- $\text{Ta}_2\text{Se}_2\text{C}$ displayed an overpotential at 10 mA cm^{-2} of 260 mV, a Tafel slope of 91.4 mV.dec^{-1} , and an electrochemically active surface area of 780 $\text{cm}^2.\text{g}^{-1}$. These enhancements can be attributed to the extensive surface area of individual nanosheets, which maximizes the availability of catalytic sites, as well as the more open structure of $\text{Ta}_2\text{Se}_2\text{C}$ in contrast to TaSe_2 .

8:00 PM EN07.06.16

Investigating Synthesis Route Effect on the Electrochemical Performance of $\text{LiNi}_{0.6}\text{Co}_{0.2}\text{Mn}_{0.2}\text{O}_2$ Cathode Materials for Li-Ion Battery Mesfin A. Kebede¹, Emmanuel Mannzhi² and Rebecca Mhlongo²; ¹University of South Africa - Science Campus, South Africa; ²Sefako Makgatho Health Science University, South Africa

In this work Ni-rich $\text{LiNi}_{0.6}\text{Co}_{0.2}\text{Mn}_{0.2}\text{O}_2$ (NCM622) cathode materials were synthesized via combustion and solgel routes, to investigate the effect of synthesis route on the electrochemistry of the cathodes. The structural and electrochemical properties of the samples were confirmed by XRD, SEM, TEM and battery testing. The electrochemical properties of layered Ni-rich NMC622 cathode materials synthesized adopting these two synthesis routes were compared. The results confirm that the NMC622 cathode samples prepared by combustion synthesis route exhibited a better electrochemical performance than the samples synthesized by solgel method for the cycling stability and rate capability. The NCM622-Com delivered a first capacity of 206 mAh g^{-1} and retained 132 mAh g^{-1} after 100 cycles, whereas NCM622-Sol delivers only 141 mAh g^{-1} and retained 115 mAh g^{-1} after 100 cycles. Similarly, for the rate capability

the NMC622-Com performed higher for all the current rates.

In this work, we are presenting the comparison of the sol-gel and combustion synthesis routes on the electrochemical performance of Ni-rich $\text{LiNi}_{0.6}\text{Mn}_{0.2}\text{Co}_{0.2}\text{O}_2$ cathode materials. The detail structural, morphological, cyclic voltammetry, and galvanostatic charge/discharge capacity results will be discussed.

8:00 PM EN07.06.17

Understanding of Growth and Electrolytic Hydrogen Evolution of Directly Deposited 2D NiO

Electrodes via Alkali-free Chemical Synthesis Umesh T. Nakate¹, Jeongsik Choi², Dong-Won Kim^{1,1} and Sungjune Park³; ¹Hanyang University, Korea (the Republic of); ²Jeonbuk National University, Korea (the Republic of); ³Sungkyunkwan University, Korea (the Republic of)

Nanostructured metal oxides have been identified as potential candidates for electrochemical applications owing to their various properties such as high surface-to-volume ratio, number of active sites/ receptor functions, re-dox properties, thermal stability, semiconducting nature, structural properties, *etc.* The nano size (dimensions) has a significant impact on the physicochemical properties of metal oxide *via* its quantum effect. However, structural properties like growth, orientation, texture co-efficient, and defects also govern the performance of the material. The synthesis/preparation conditions primarily decide the nano size as well as the structural properties of the material. Hence, it is quite crucial to develop novel and unique synthesis routes to reveal the enhanced properties of the materials. Reducing the use of additional reactants and reagents/surfactants in synthesis could be advantageous in terms of synthesis cost reduction, unwanted impurities, crystal purity, repeatable output, growth simplicity, *etc.*

Herein, an alkali/buffer-free easy chemical hydrothermal route has been adopted to grow 2D NiO nanoplates electrodes. The synthesis parameters *viz* concentration and temperature could tune the thickness of the nanoplates leading to changes in structural and electrocatalytic properties. The electrochemical characteristics *viz* linear scan voltammetry (LSV), Tafel, Electrochemical impedance spectroscopy (EIS) Nyquist plot, cyclic voltammetry and chronopotentiometry, turnover frequency (ToF), Electrochemical surface area (ECSA), *etc* were investigated for prepared electrocatalyst electrodes. The electrocatalysts were characterized using XRD, FESEM, HR-TEM, EDS, mapping, XPS, *etc* standard tools. The different noble metal (Pd/Au/Ag/ Ru) decoration on the optimized 2D NiO electrodes was carried out *via* a wet impregnation technique and their electrolytic hydrogen evolution performance was studied. The Pd-decorated NiO electrodes were observed to have high hydrogen evolution performance. The different amounts of Pd decoration on NiO were performed and optimal Pd-NiO electrocatalyst was studied in detail. The optimal Pd-NiO electrodes exhibited a high HER activity with an overpotential of 90 mV, achieving a current density of 100 mA cm^{-2} and a Tafel slope of 52.05 mVdec^{-1} in 1 M KOH solution.

Further, the density functional theory (DFT) studies were carried out *via* first principle calculation to support the experimental results. The Pd/NiO exhibited a lower water dissociation energy barrier (0.35 eV) than NiO (0.46 eV), suggesting that the dissociation of H_2O easily occurs on the surface of the Pd/NiO catalyst. The formation of Pd/NiO heterojunction improves the HER activity. The change in Gibbs's free energy of Pd/NiO heterostructures is about -0.52 eV, which is lower than pristine NiO (-0.78 eV). The experimental and theoretical analyses are in good agreement.

The present synthesis technique and architecture of Pd decorated NiO nanoplates is a promising strategy and could be the potential candidate for fulfilling sustainable energy needs *via* high-performance hydrogen evolution reaction.

SESSION EN07.07: CO₂/NO_x Reductions I

Session Chairs: Maria Escudero-Escribano and Charles McCrory

Wednesday Morning, November 29, 2023

8:15 AM EN07.07.01

Insights into Interfacial Phenomena Driving Fast Carbon Isotopes Separation during CO₂

Electroreduction Magda H. Barecka¹, Mikhail Kovalev², Marsha Zakir Muhamad², Hangjuan Ren^{2,3}, Joel W. Ager^{4,5,6} and Alexei Lapkin²; ¹Northeastern University, United States; ²Cambridge Centre for Advanced Research and Education in Singapore, Singapore; ³University of Oxford, United Kingdom; ⁴Lawrence Berkeley National Laboratory, United States; ⁵University of California, Berkeley, United States; ⁶Berkeley Education Alliance for Research in Singapore, Singapore

Isotopes of carbon and kinetic effects related to the reactivity of carbon 12 vs carbon 13 have been widely explored to elucidate reaction mechanisms and metabolic pathways. We discovered that under the conditions of carbon dioxide (CO₂) electroreduction in gas-diffusion electrodes, the kinetic isotope effect is much higher than expected based on known carbon kinetic isotope effect during CO₂ absorption in oceans or photosynthetic conversion of CO₂ to reduced forms of carbon. Our experiments demonstrate that CO₂ electroreduction strongly favours the conversion of the dominant isotope of carbon (¹²C) and discriminates against the less abundant, stable carbon ¹³C isotope during all steps of the electrochemical process, and mostly at the triple phase interface created in gas-diffusion electrode based reactors. Using a natural abundance CO₂ feed, we experimentally demonstrate enriching of the ¹³C fraction to ~1.3% (+18%) in a single pass reactor, being an unprecedentedly fast isotope separation. This talk will provide insights into the interfacial phenomena, being a part of a complex isotope discrimination mechanism, which we anticipate to be applicable across a wide range of electrochemical systems.

8:30 AM EN07.07.02

Influence of the Gas Diffusion Layer on the Reaction Microenvironment of Electrochemical CO₂

Reduction Surani Bin Dolmanan¹, Annette Boehme^{2,2}, Ziting Fan³, Harry A. Atwater^{2,2} and Yanwei Lum^{1,3}; ¹Agency for Science, Technology and Research, Singapore; ²California Institute of Technology, United States; ³National University of Singapore, Singapore

Gas diffusion layers (GDL) have become a critical component in electrochemical CO₂ reduction (CO₂R) systems because they can enable high current densities needed for industrially relevant productivity. Besides this function, it is often assumed that the choice of catalyst and electrolyte play much more important roles than the GDL in influencing the observed product selectivity. Here, we show that tuning of the GDL pore size can be used to control the local microenvironment of the catalyst and hence, effect significant changes in catalytic outcomes. This concept is demonstrated using sputtered Ag films on hydrophobic PTFE substrates with 6 different pore sizes. Although Ag is known to be a predominantly CO generating catalyst, we find that smaller pore sizes favor the generation of formate up to a faradaic efficiency of 43%. Combined experimental and simulation results show that this is due to the influence of the pore size on CO₂ mass transport, which alters the local pH at the electrode, resulting in reaction pathway switching between CO and formate. Our results highlight the importance of the local microenvironment as an experimental knob that can be rationally tuned for controlling product selectivity: a key consideration in the design of CO₂R systems.

8:45 AM EN07.07.03

Boosting Selectivity Toward Formate Production using CuAl Nanowires by Altering the CO₂ Reduction Reaction Pathway Ibrahim M. Badawy and Nageh K. Allam; American University in Cairo, Egypt

Understanding the fundamentals behind an electrocatalyst's selectivity enables the ability to steer product formation. Herein, Cu nanowires were doped with Al (12%) for CO₂R. Al doping was found to enhance formate production by 16.9% over pure Cu nanowires. The DFT calculations ascribed the enhancement in the CO₂R performance to the change in the adsorption energy of the intermediates and thus the favourability of the reaction path involving the CO₂ adsorbing through its oxygen terminals. The COR experiments supported that conclusion when CuNW was discovered to produce higher Faradic Efficiency (FE) C₂H₄ than CuAlNW meaning that C-C dimerization is less supported on CuAl NW's surface.

9:00 AM EN07.07.04

Recovering Carbon Losses in CO₂ Electrolysis using a Solid Electrolyte Reactor Peng Zhu and Haotian Wang; Rice University, United States

The practical implementation of electrochemical CO₂ reduction technology is greatly challenged by notable CO₂ crossover to the anode side, where the crossed-over CO₂ is mixed with O₂, via interfacial carbonate formation in traditional CO₂ electrolyzers. Here we report a porous solid electrolyte reactor strategy to efficiently recover these carbon losses. By creating a permeable and ion-conducting sulfonated polymer electrolyte between cathode and anode as a buffer layer, the crossover carbonate can combine with protons generated from the anode to re-form CO₂ gas for reuse without mixing with anodic O₂. Using a silver nanowire catalyst for CO₂ reduction to CO, we demonstrated up to 90% recovery of the crossover CO₂ in an ultrahigh gas purity form (>99%), while delivering over 90% CO Faradaic efficiency under a 200 mA cm⁻² current. A high continuous CO₂ conversion efficiency of over 90% was achieved by recycling the recovered CO₂ to the CO₂ input stream.

9:15 AM EN07.07.05

Time Course of Product Selectivity by Ag Nanoparticle Modification on Metal Cathode Electrodes for Electrochemical CO₂ Reduction Kazuki Koike^{1,2}, Takeharu Murakami², Takayo Ogawa², Katsushi Fujii², Satoshi Wada² and Atsushi Ogura^{1,3}; ¹Meiji University, Japan; ²RIKEN RAP, Japan; ³MREL, Japan

Global warming is a major issue in modern society. The most significant cause of global warming is the increase in the concentration of carbon dioxide in the atmosphere. One of the technologies to reduce the concentration of carbon dioxide in the atmosphere is carbon dioxide reduction. Carbon dioxide reduction is a technology that uses electrical energy to electrochemically reduce carbon dioxide to formic acid, methane, ethylene, ethanol, and other substances. Current problems with electrochemical carbon dioxide reduction include the lack of product selection and the inability to operate for long periods of time. It is known that the selectivity of products varies with the material used for the CO₂-reduced cathode electrode and the cathode potential during the reaction. Especially for the electrode material, the metal type and crystal surface affect the products. The copper cathode has attracted much because of its high efficiency in generating ethylene, which is an industrially useful substance such as a raw material for plastics. However, the products have not yet been fully controlled. In addition, there is a problem in that the surface of copper changes after prolonged operation, making it decrease the ethylene reduction

efficiently.

It is known that CO is produced as an intermediate product in the reaction process of CO₂ to ethylene. Therefore, spray coating the Cu electrode with Ag, which reduces CO₂ to CO well, is expected to improve the CO₂ reduction capability. The Ag nanoparticles were sprayed on the Cu electrode surface using a spray coating machine to modify the electrodes in this report. The evaluations were performed with electrochemical cyclic voltammetry and chronopotentiometry. The reduced products were evaluated by gas chromatography. The surface condition of the electrode before and after the reaction was also evaluated.

It was found that the metal cathode electrode modified with Ag nanoparticles improved the CO₂ reduction ability to ethylene compared with the bare Cu metal electrode. It was also confirmed that the potential during the reaction was stabilized by modification with Ag nanoparticles. The surface evaluation results showed that the surface showed dispersed Ag nanoparticles on the metal surface, and it has the possibility of the improvement of CO₂ reduction.

9:30 AM *EN07.07.06

Reactive Separations using a Cobalt Macrocyclic Molecular Catalyst for Electrochemical Wastewater Refining of Nitrate to Ammonia William Tarpeh; Stanford University, United States

Enabling a sustainable food-energy-water nexus requires feeding a growing population while minimizing environmental impacts. Molecular catalysis of aqueous electrochemical nitrate reduction (NO₃RR) to ammonia can simultaneously reduce nitrogen pollution and electrify ammonia manufacturing. We focus on in this talk on Co(DIM), where DIM = 2,3-dimethyl-1,4,8,11-tetraazacyclotetradeca-1,3-diene, because it is the only water-soluble catalyst that has been reported to yield ammonia from NO₃RR with near full selectivity (> 95%). A dearth of experimental investigations prevents the rational design and implementation of NO₃RR molecular platforms such as Co(DIM). From an electroanalysis standpoint, kinetic benchmarking of Co(DIM)-mediated NO₃RR would contextualize the performance of Co(DIM) relative to state-of-the-art molecular electrocatalysts and quantitatively facilitate optimization goals for next-generation NO₃RR molecular catalysts. Molecular catalysts remain underutilized in electrochemical water treatment because they require separation of catalyst, wastewater, and product.

In this talk, we cover three main areas related to the development and characterization of Co(DIM). First, we describe its integration into electrochemical stripping as a reactive separation configuration that facilitates energy-efficient ammonia recovery. Second, we interrogate the stability of Co(DIM) in real wastewaters and describe electrocatalyst-in-a-box as a novel reactor design that enables catalyst reuse and continuous ammonia recovery. Finally, we elucidate the mechanism of Co(DIM) activation and catalysis to guide rational design of reactive separations, including catalyst immobilization. Together, these results will guide the rational design of molecular catalysts and reactive separations to valorize wastewater nitrate to ammonia and other products.

10:00 AM BREAK

10:30 AM *EN07.07.07

Compositional Control of Multidimensional Metal Sulfide Electrocatalysts to Drive CO₂ and CO Reduction to Alcohols Jesus M. Velazquez; University of California, Davis, United States

The dichotomy of increasing energy demands and carbon emissions is imperative in energy-related research efforts that demand the development of new materials capable of addressing these concerns. An

emerging technical avenue in this area is the conversion of vastly abundant renewable energy sources that can be harnessed and directed towards the synthesis of traditionally fossil fuel-based products from atmospheric feedstocks like CO₂. To this end, our work establishes structure—function relationships for materials within the versatile classes of MX₂ (M = Mo, W; X = S, Se) and Chevrel-Phase (CP) M_yMo₆X₈ (M = alkali, alkaline, transition or post-transition metal; y = 0-4; X = S, Se, Te) chalcogenides. The molybdenum sulfide structures from both families exhibit exceptional promise as CO₂R catalysts which can be accessed through synthesis techniques, such as hydrothermal or solid-state methods, that allow for control over the composition of these materials. Additionally, the use of membrane electrode assemblies (MEA) with molybdenum sulfide structures can maximize CO₂ interactions with the catalyst leading to improved efficiencies toward selective alcohol production. Furthermore, CP catalyst framework is selective towards the electrochemical reduction of CO₂ and CO to methanol (only major liquid-phase product) under applied potentials as mild as -0.4 V vs RHE. This reactivity toward the electrochemical reduction of CO₂ and CO to methanol is correlated with an increased population of chalcogen states, as confirmed via X-Ray Absorption Spectroscopy. Overall, this work seeks to unravel optimally reactive novel small-molecule reduction catalyst compositions.

11:00 AM EN07.07.08

Electrochemical Reduction of Carbon Dioxide: Investigating Tunable Porosity and Surface Morphology in PFPE Gas Diffusion Layers for Enhanced Ethylene Selectivity Eric A. Krall, Maxwell Goldman, Xiaoxing Xia, Andrew Wong and Sarah Baker; Lawrence Livermore National Laboratory, United States

The electrochemical reduction of carbon dioxide (CO₂) into higher-value materials has emerged as a promising avenue towards establishing a sustainable solar-fuel-based economy. Much work has been done in recent literature to improve selectivity towards C₂+ products, notably, copper has exhibited distinctive catalytic properties by yielding higher-order hydrocarbon products, predominantly methane, ethylene, and ethanol, with compelling efficiencies. Consequently, substantial research efforts have been dedicated to understanding the unique catalytic characteristics of copper and unraveling the underlying mechanism governing the formation of hydrocarbons. These mechanistic insights, coupled with the understanding of CO₂ reduction mechanisms on other metals and molecular complexes, serve as pivotal guidelines for designing future catalyst materials capable of efficiently and selectively converting CO₂ into valuable products. To overcome the inherent solubility limitations of gaseous CO₂, our electrochemical cell operates with CO₂ in the gas phase. Leveraging the enhanced transport properties and reduced diffusion length of gaseous CO₂ to the electrode surface, we employ a gas diffusion layer (GDL) made of a hydrophobic porous material, specifically PFPE (perfluoropolyether). This PFPE-based GDL facilitates the delivery of gas phase CO₂ to the electrocatalytic interface.

Our research centers on the controllable and tunable porosity and surface morphology of the PFPE material within the gas diffusion layer. By varying the outer morphology of the catalyst surface, we aim to selectively tune the GDL to yield higher-order reduction products, particularly focusing on enhancing the production of ethylene. Through comprehensive studies and characterization, we investigate the influence of PFPE material properties, including porosity and surface morphology, on CO₂ reduction and ethylene selectivity. By gaining insights into the correlation between the structural characteristics of the gas diffusion layer and the electrochemical performance, we aim to optimize the PFPE material design for efficient and selective CO₂ reduction, specifically targeting ethylene as the desired product.

This research sheds light on the crucial role of gas diffusion layers and their tailored characteristics in achieving desired electrochemical CO₂ reduction outcomes. The findings contribute to the development of advanced catalyst materials and pave the way for scalable and sustainable strategies in utilizing CO₂ as

a valuable feedstock for the production of high-value carbon products.

This work was performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344.

11:15 AM *EN07.07.10

Challenges and Opportunities in Transitioning Electrochemical Conversion of CO₂ and other Renewable Feedstocks to Deployable Technology Paul Kenis; University of Illinois, United States

Over the past decade or so, the electrochemical reduction of CO₂ has evolved from a barely studied topic to one of the most active research areas in the fields of electrochemistry and electrochemical engineering. The ongoing process of ‘the energy transition’, spurred by the need to drastically reduce global CO₂ emissions to achieve global sustainability, has driven the vigorous pursuit of different electrocatalysts, electrodes, and electrolyzer configurations that are able to reduce CO₂ -- an abundantly available, renewable feedstock -- to different value-added intermediates or products. These efforts go beyond ‘just’ CO₂ reduction. Electro-oxidation of for example renewable, bio-derived adducts for the manufacturing of chemicals that traditionally are derived from fossil fuels is also an active area of study. With many selective and efficient catalysts now available for these types of electro-oxidations and -reductions, attention has started to shift to topics such as catalyst stability, electrode durability, and electrolysis reactor design.

This presentation will provide insights into a number of practical aspects of turning advances in electrocatalyst and electrode design into scalable, durable processes. For example, CO₂ reduction is often unavoidably accompanied by carbonate formation. How can one suppress carbonate formation, or minimize the effects of carbonate formation on electrolysis performance? Can CO₂ electrolyzers operate on dilute CO₂ feeds, recognizing that CO₂ capture and its concentration, especially from the air, is highly energy intensive, regardless of what method is used? How realistic, technically and from a life-cycle perspective, are less energy-intense electrolytic co-conversion approaches where CO₂ is reduced on the anode in parallel with oxidation of a renewable substrate to a desired product on the anode (e.g. glycerol to lactic acid)? What are some of the typical byproduct waste streams available from biomass processing, e.g. ‘crude glycerol’ which also contains various amounts of NaOH, water, and methanol, and can one develop an electrolysis system and process that can tolerate the range in compositions? This presentation will explore some of these aforementioned challenges and opportunities based on our work as well as work by others in reactor engineering, process design, and techno-economic / life cycle analysis.

SESSION EN07.08: CO₂/NO_x Reductions II

1:30 PM *EN07.08.01

Electrocatalysis for Chemical Manufacturing of Ammonia and Environmental Remediation of Nitrate Marta Hatzell; Georgia Institute of Technology, United States

Of the four major energy-use sectors (transportation, residential, commercial, and industrial), the

industrial sector accounts for the largest amount of energy use (~33 EJ/year). This energy use results in nearly 1500 million metric tons of carbon dioxide emissions yearly^[1]. The large carbon footprint is due to most modern industrial processes' reliance on process heat which is often derived from coal, natural gas, and petroleum. With rising concerns related to global carbon emissions, there is a strong interest in displacing process heat with electricity. However, direct use of electricity for chemical manufacturing processes is challenging if not impossible. This has motivated a strong need to rethink and redesign many catalytic and separations-based processes to decarbonize the chemical manufacturing sector.

Within the chemical commodity industry, transforming thermocatalytic and thermal-based separation and catalysis processes with electrochemical-driven processes is one way to electrify and decarbonize the chemical industry. Thus, the primary aim of this talk is to detail how photochemical and electrochemical processes may aid in achieving this goal. I will aim to discuss the thermodynamic and kinetic challenges and opportunities which exist when transforming thermocatalytic systems into electrocatalytic or photocatalytic processes. I will then aim to discuss the specific growing opportunities related to electrocatalytic and photocatalytic ammonia production. Focus here will be placed on describing the opportunities in tuning molecular scale mechanisms and atomic scale materials design to enable ideal conversion.

2:00 PM EN07.08.02

Towards Controlling the Microenvironment in Electrochemical CO₂ Reduction Andrew B. Wong;
National University of Singapore, Singapore

The electrochemical CO₂ reduction reaction (CO₂RR) represents a critical approach toward the carbon-neutral generation of hydrocarbons. However, despite intense research efforts, the need remains to increase selectivity and activity for electrocatalysts for CO₂RR. Thus, there has been increasing interest in optimizing the microenvironment to boost the activity and selectivity of electrocatalytic sites for CO₂ conversion.

This presentation discusses several strategies that are being pursued in my research group to optimize the microenvironment for CO₂ conversion. These strategies include: (1) model systems to illustrate control of diffusion via engineering electrode structure at micro- and nano- length scales, (2) model systems to harness localization of tandem catalysts, (3) implementation of bioelectrochemical tandem systems for CO₂ conversion, (4) implementation of MOF/organic coatings to improve transport, and (5) implementation of high-temperature non-aqueous electrolytes.

Thus, this presentation surveys a wide range of ongoing research strategies to optimize the microenvironment toward more effective CO₂RR.

2:15 PM EN07.08.03

Enhancing Product Selectivity in CO₂ Reduction by Controlling Substrate Pore Size and Hydrophobicity in Gas Diffusion Electrodes Francesco Bernasconi^{1,2}, Alessandro Senocrate¹ and Corsin Battaglia^{1,2}; ¹Empa–Swiss Federal Laboratories for Materials Science and Technology, Switzerland; ²ETH Zürich, Switzerland

Electrochemical CO₂ reduction (CO₂RR) is a key technology to convert detrimental CO₂ emissions into sustainable fuels and chemicals, and close the carbon loop¹. To ensure the economic competitiveness of CO₂RR, electrocatalysts need to be highly active, selective towards a desired product and stable. High

activities can be achieved with gas diffusion electrodes (GDEs), circumventing mass transport limitations resulting from the low CO₂ solubility in water. However, product selectivity and stability still need to be improved before industrial implementation. In this work, we show that the GDE substrate pore size and hydrophobicity act as a powerful handle to tune selectivity and stability in both Ag and Cu GDEs^{2,3}. GDEs with large pore size and weak hydrophobicity readily lead to flooding of the catalyst by water and, in the Ag case, yield poor selectivity towards CO and a significant production of H₂. In contrast, GDEs with small pore size prevent flooding of the catalyst, thus yielding a greatly improved Faradaic efficiency towards CO (up to 95% at 100 mA/cm² in neutral electrolyte), minimal H₂ evolution, and remarkable long-term stability (97% of initial CO selectivity retained after > 40 h). In the Cu case, we observe a strong enhancement in C₂H₄ selectivity when employing GDE substrates with small pores and strong hydrophobicity (up to 50% Faradaic efficiency in neutral electrolyte at 200 mA/cm² for > 3 h). Both CO₂ and CO reduction reactions indicate transport limitations of reactants to the catalyst sites for all GDEs, however this limitation is less severe for GDEs with small pore sizes. We rationalize these findings with the presence of an electrolyte layer covering the electrocatalyst, forcing the electrocatalytic reaction to take place at double phase boundaries. Experiments with variable pressures show that only GDEs with small pores can sustain large overpressure of the liquid phase (> 1 bar), which enhances the resilience of the reaction towards unexpected pressure spikes that might occur during start-up and operation. Our results emphasize the importance of substrate microstructure on GDE product selectivity and stability during CO₂RR, and represent a new scalable strategy to improve GDE performance.

Advances in Electrified CO₂ Reduction to Chemicals and Fuels Edward H. Sargent^{1,2}; ¹Northwestern University, United States; ²University of Toronto, Canada

I will review recent advances, at the level both of catalysts and systems, in efficiently electrochemically reducing CO₂ and CO to chemicals (such as ethylene and propanol) and fuels (e.g. methane, ethanol). I will look at issues such as total voltage, single-pass utilization of the reagents, and overall energetic efficiency.

4:00 PM EN07.08.05

Electrochemical Growth and Restructuring of Cu Surfaces for Steering the Selectivity of Electrocatalytic CO₂Reduction Joseph S. DuChene; University of Massachusetts Amherst, United States

The electrocatalytic reduction of CO₂ into value-added chemicals is commonly performed with catalysts composed of Cu due to its propensity for producing C₂₊ products like ethylene and ethanol. While promising, the reaction is known to suffer from poor selectivity. Several studies have shown that the surface facets of Cu catalysts play an important role in dictating the distribution of CO₂ reduction products, yet the dynamic nature of Cu surfaces leads to significant surface reconstructions that alter the catalyst selectivity over the course of the reaction. The factors governing the evolution of Cu surfaces

during CO₂ reduction must be fully understood to enable control over these processes at the atomic level. Here, we discuss our efforts towards controlling the surface facets of Cu electrocatalysts via electrochemical treatments for steering the selectivity of electrocatalytic CO₂ reduction. Using both polycrystalline Cu foils and shape-controlled Cu or Cu₂O nanoparticles, we will show how the applied potential and chemical composition of the growth solution can be manipulated to tailor the surface facets of Cu electrocatalysts. Finally, we will present the results of electrocatalytic CO₂ reduction with these nanostructured Cu catalysts and highlight opportunities for using simple electrochemical techniques to tailor the surface facets of electrocatalysts at the nanoscale for the selective production of chemical fuels.

4:15 PM EN07.08.06

Electrocatalytic CO₂ Reduction using Heteroatom Doped Carbon Materials for Multi-Carbon Production Hyun-Tak Kim; Korea Research Institute of Chemical Technology, Korea (the Republic of)

Electrochemical reduction of CO₂ (CO₂R) to value-added chemicals and fuels presents a promising approach for mitigating the issues related to energy crisis and global warming. Different proton- and electron transfer steps and CO₂ reduction pathways are employed to convert CO₂ to C₁, C₂, or C₂₊ products. In addition, the production of liquid multicarbon alcohols is highly desired, because it possesses the potential to enable the synthesis of sustainable fuels that leverage high energy densities (21 MJ l⁻¹ ethanol, 27 MJ l⁻¹ propanol, and 34.2 MJ l⁻¹ gasoline) for long-range and heavy-freight transportation applications. However, owing to the limited selectivity and low activity of the currently available catalysts, the production of multicarbon alcohols via direct CO₂ electroreduction is not economically viable.

Here, we report a heteroatom doped carbon based electrocatalyst that exhibits a Faradaic efficiency greater than 70% for CO₂ reduction (CO₂R) and 90% of C₂₋₃ product selectivity. Density functional theory calculations suggest that CO₂ dual binding catalysts promote a C–C coupling between adsorbed CO intermediates and CO₂ for C₂₋₃ formation. This high efficiency and the corresponding mechanism are explained by theoretical calculations and spectroscopic analyses. With the results, we suggest a molecular design strategy for next-generation CO₂ reduction catalysts for a green ocean and atmosphere.

4:30 PM EN07.08.07

High-Rate CO₂ Conversion to Ethylene via Molecularly Enhanced Electrochemical CO₂ Reduction Taemin Lee¹, Jongyoun Kim¹, Hyun Dong Jung², Seoin Back², Youngu Lee¹ and Dae-Hyun Nam¹; ¹Daegu Gyeongbuk Institutes of Science and Technology, Korea (the Republic of); ²Sogang University, Korea (the Republic of)

Electrochemical conversion of CO₂ into value-added fuels and feedstocks is a promising route to realize sustainable energy cycle and carbon neutrality. Continued efforts to achieve effective electrochemical CO₂ reduction reaction (CO₂RR) have resulted in achieving high selectivity for multi-carbon (C₂₊) chemicals such as ethylene (C₂H₄) and ethanol (C₂H₅OH). To improve the productivity of C₂₊ chemicals, it is necessary to promote C-C coupling on the catalyst surface, as well as *CO formation by fast electron transfer even at high current density. However, even in the flow-type cell with a gas diffusion electrode, it still remains as a challenge due to the sluggish *CO formation on the catalyst surface.

In this work, we report the molecularly-enhanced CO₂ mass transport of Cu catalyst for high current density C₂H₄ production. We augmented ascorbic acid (AA) on Cu nanowires (CuNWs) using graphene quantum dots (GQDs) as a mediator to confine AA in heterogeneous electrocatalysts during CO₂RR. AA on CuNW surface enhanced the CO₂ conversion rate by promoting proton-coupled electron transfer (PCET) and providing strong hydrogen bonding site. The nanoconfinement effect and immobilization of

AA by GQDs enable redox reversibility and high current density CO₂RR. In the CO₂RR of pristine CuNWs, there is less carbon monoxide (CO) formation in the low potential, and this limits the potential range for stable C₂H₄ production. However, Cu NWs modified with nanoconfined AA by GQDs (cAA-CuNWs) exhibited outstanding C₂H₄ production rates with Faradaic efficiency (FE) of 60.7% and C₂H₄ partial current density of 539 mA/cm², which is about 2.9-fold higher performance compared to that of pristine CuNWs. *In-situ* Raman spectroscopy revealed that higher population of *CO is covering cAA-CuNW surface by Cu-CO rotation and stretch peak intensity. Also, appropriate ratio of atop bound CO and bridge bound CO has proven the efficient C-C coupling of cAA on CuNW. Grand-canonical density functional theory (GC-DFT) verified that multiple hydrogen bonding sites of AA can effectively control the electronic distributions of water molecules surrounding CO₂, thereby improving *CO formation on the Cu surface. This offers the potential for harnessing AA as a promoter to enhance CO₂ mass transport toward high rate CO₂ to value-added C₂₊ chemical conversion.

4:45 PM EN07.08.08

Thermodynamically Designed Cu-Sn Bimetallic Alloy Electrocatalysts for Electrochemical CO₂ Reduction Woosuck Kwon¹, Soohyun Go¹, Deokgi Hong², Young-Chang Joo² and Dae-Hyun Nam¹;

¹Daegu Gyeongbuk Institute of Science & Technology (DGIST), Korea (the Republic of); ²Seoul National University, Korea (the Republic of)

Electrochemical CO₂ reduction reaction (CO₂RR) has received great attention as a promising strategy for carbon neutrality and net zero emission. Copper (Cu) is the element which binds neither *CO strong nor weak and enables C-C coupling for multi-carbon product formation by inducing *CO dimerization. To enhance the CO₂RR selectivity of Cu, modulating the d-band center of the heterogeneous catalysts is essential to control the intermediate binding energy. Recently, Sn has been widely applied as a bimetallic Cu alloy element, which can suppress hydrogen evolution reaction (HER) and enables to tune CO₂RR reaction pathway. Although Cu-Sn bimetallic alloy can have various intermetallic compounds, current approaches of Cu-Sn bimetallic catalyst to control Cu:Sn ratio, arrangement of components, structure, and oxidation states resulted in the limited phase control and narrow range of product selectivity control accordingly.

In this work, we developed a thermodynamically designed Cu-Sn bimetallic alloy electrocatalysts which enable the efficient control of CO₂RR selectivity. In the alloy fabrication, escaping from the Cu:Sn ratio control approach, we focused on modulating Sn vapor pressure for the controllable formation of Cu-Sn intermetallic compounds. We applied carbon (C) matrix which enables to modulate the microenvironment of Cu which interact with Sn vapor pressure during Cu-Sn alloy fabrication. Starting from the thermochemical computation to discover the processing window, we fabricated Cu-Sn-C nanocomposite combined with Cu, Sn precursors, and polymers by electrospinning and calcination. By controlling the allocation of Cu and Sn sources in the core/shell structured nanofibers, we successfully fabricated Cu₄₁Sn₁₁, Cu₃Sn, and Cu₆Sn₅ respectively. As the local Sn vapor pressure increases, Sn-rich compounds formed accordingly and resulted the increased selectivity of formate (HCOO⁻). Interestingly, major CO₂RR product was shifted from formate to methane (CH₄) by controlling the stoichiometry of Cu-Sn alloy. Cu₄₁Sn₁₁ exhibited CH₄ faradaic efficiency (FE) over 40%. We believe that this approach can pave a way to design bimetallic alloy materials for efficient CO₂RR electrocatalysts.

Shape-Controlled Synthesis of 2H Au Nanomaterials for Highly Efficient Carbon Dioxide Reduction Reaction Gang Wang and Ye Chen; The Chinese University of Hong Kong, Hong Kong

Colloidal gold (Au) nanomaterials with fine controlled size and shape possess unique physicochemical properties and great potentials in various applications. However, most of the reported Au nanomaterials typically crystallize in the thermodynamically stable face-centered cubic (3C) phase, and there are still great challenges in synthesizing hexagonal close-packed (2H type) Au nanomaterials with high phase purity and controlled size and shape. Here, we report a one-pot colloidal synthesis of free-standing ultrasmall 2H Au nanosheets. A series of 2H Au nanomaterials with controlled shape are then synthesized using the 2H Au nanosheets as seeds. Moreover, the 2H Au nanomaterials exhibit superior electrocatalytic performance toward CO₂ reduction reaction than 3C Au nanoplates, possessing high Faradaic efficiency in a wide applied potential window. Our work provides an effective strategy to design and synthesize Au nanomaterials with unconventional crystal structure and demonstrates the potential of phase engineering in boosting catalytic performances of noble metal nanomaterials.

8:00 PM EN07.09.02

Synthesis of Ag-Sn Intermetallic Compounds via Mechanical Alloying as Selective Electrocatalysts for CO₂ Reduction Reaction Takeyuki Kamimura, Kazuyuki Iwase and Itaru Honma; Tohoku University, Japan

The electrochemical CO₂ reduction reactions (CO₂RR) have attracted attention as a method to convert CO₂ into value-added products using electricity derived from renewable energy sources[1]. In CO₂RR, various products such as carbon monoxide (CO) and formate (HCOO⁻) can be generated. Therefore, for CO₂RR catalysts, the higher selectivity for the desired products and suppression of the competing hydrogen evolution reaction (HER) is important.

Previous research has developed highly active and selective CO₂RR catalysts using various materials, such as polymers, organometallic complexes, and metal nanoparticles[2-4]. Among them, metal alloys catalysts are attracting attention as promising CO₂RR catalysts, as the catalytic activity and product selectivity can be tuned by choice of metal elements and their composition[5-7]. Intermetallic compounds, which have unique crystal structures and composition of metal elements compared to conventional metallic alloys, are expected to exhibit different reactivity and selectivity from conventional solid-solution alloy catalysts due to their unique atomic structures and electronic states. In this study, we synthesized intermetallic compounds composed of silver (Ag) and tin (Sn), which show high CO₂RR selectivity for producing CO and HCOO⁻, and investigated whether the CO₂RR activity and selectivity could be enhanced. Specifically, we employed mechanical alloying as a synthetic method since it has been gaining attention in recent years to synthesize various kinds of materials[8].

Intermetallic compounds of Ag and Sn (Ag-Sn) were synthesized by mechanical alloying using a planetary ball mill using Ag powder (particle diameter 50-80 nm) and Sn powder (particle diameter 60-80 nm) at the desired ratio (Ag: Sn = 3:1 ~ 7:1) as the starting materials. The CO₂RR activity was evaluated

by constant current measurements using gas diffusion electrodes as the working electrode and 1 M KHCO_3 as the electrolyte.

The powder x-ray diffraction (XRD) pattern showed that the sample at Ag: Sn = 7:1 can be attributed to the solid solution alloy of Ag and Sn, whereas the XRD pattern for Ag: Sn = 4:1 could be attributed to the ζ phase, which is an intermetallic compound phase. In both samples, no peaks of the unreacted precursor were observed, suggesting that the single phase of the Ag-Sn solid solution and the intermetallic compound phase was successfully synthesized. For the Ag: Sn = 4:1 sample, the concentration of Ag and Sn in the depth direction was analyzed by X-ray photoelectron spectroscopy (XPS) measurement. The results showed that the ratio of Sn on the surface was higher than the original Ag: Sn ratio (4:1). This result suggests that Sn atoms of the Ag: Sn = 4:1 sample are segregated on the surface. In contrast, the sample showed an intermetallic compound phase (ζ phase) as the bulk crystal structure. For CO_2RR activity at a constant current density (53.0 mA/cm^2), the synthesized Ag-Sn catalysts mainly produced HCOO^- . The faradaic efficiency of HCOO^- generation for Ag: Sn = 4:1 sample was 84 %. This value was larger than that of the Ag: Sn = 7:1 sample (78%). For comparison, we evaluated the CO_2RR activity of the pure Ag and Sn powders, which were used as precursors. They predominantly produced CO and HCOO^- with a respective faradaic efficiency of 89% and 62%. These findings imply that the formation of the ζ -phase, an intermetallic compound phase, may contribute to the generation of HCOO^- .

8:00 PM EN07.09.03

Development of Cost-Effective, Bespoke Tailored Ternary Nanoparticles as Catalysts for Lithium-Air Batteries Jong Seok Nam¹, Yujang Cho¹, Seongcheol Ahn¹, Min Soo Kim¹, Jaewan Ahn¹, HoJin Lee², Ji-Won Jung² and Il-Doo Kim¹; ¹Korea Advanced Institute of Science and Technology, Korea (the Republic of); ²University of Ulsan, Korea (the Republic of)

Lithium-air batteries, known for their exceptionally high theoretical energy density, have emerged as potential energy storage systems capable of replacing gasoline. However, their practical application is hindered by the challenging complete decomposition of insulating Li_2O_2 formed during the charge-discharge cycle. To overcome this, it is common to utilize precious metal catalysts such as iridium (Ir) and ruthenium (Ru), known for their high catalytic activity. Nevertheless, the scarcity and high cost of these precious metal catalysts pose significant barriers for commercial use. Hence, various research groups are striving to achieve high catalytic efficiency using non-precious metals. Metal oxides, in particular, have emerged as a versatile family of non-precious catalysts. They are favored for their intrinsic oxidation resistance, comparative stability, ease of synthesis and control, as well as the abundance of compositional and structural varieties.

In this study, we aim to explore the use of abundant, economically viable non-precious metals, specifically cobalt (Co), nickel (Ni), and iron (Fe), in lithium-air batteries. Our approach involves adjusting the composition ratios of these metals to assess their relative catalytic efficiencies. Our research

further includes: i) producing bespoke tailored ternary metal oxide nanoparticles from Co, Ni, and Fe using a rapid thermal process, ii) incorporating these nanoparticles onto a lightweight, porous, and highly conductive carbon nanofiber-based cathode for use in lithium-air batteries, and iii) assessing the potential for large-scale air battery production via surface optimization of carbon nanofibers integrated with these bespoke tailored ternary nanoparticles and the fabrication of pouch cells.

8:00 PM EN07.09.04

Regeneration of NiFe/LFNO for Solid Oxide Electrolysis Cell Application under Non-Ideal

Condition Musa O. Najimu¹, Matthew Hurlock², Tina Nenoff², Jonas Baltrusaitis³ and Kandis L. Abdul-Aziz¹; ¹University of California, Riverside, United States; ²Sandia National Laboratories, United States; ³Lehigh University, United States

The structural reversibility of smart exsolved nanoparticle catalysts offer the opportunity for SOEC application in reversible modes, however, structural reversibility in the presence of anthropogenic contaminant poisoning is important for nonideal SOEC conditions. In addition to redirecting the reaction pathways and lowering the selectivity, this contaminant poisoning can lower the overall conversion of the carbon feeds due to the preferential conversion of the contaminants. Sulfur removal in H₂S-poisoned perovskite materials as well as the restoration of the activity of the poisoned materials, is typically achieved by oxidative treatment at 800 °C. Here, the structural changes of SO_x-poisoned NiFe/LaFe_{0.9}Ni_{0.1}O₃ (LFNO) material were tracked for regenerability using cycling dry methane reforming (DRM) experiments to assess the intrinsic regenerability. While reduction of as-prepared LFNO facilitates the exsolution of NiFe with the formation of La₂O₃ and La(OH)₃, DRM causes partial reincorporation of the exsolved NiFe nanoparticle. The exsolved nanoparticle demonstrates structural recyclability as oxidation after DRM reincorporates the NiFe nanoparticle back into the LFNO perovskite, while subsequent reduction causes the re-exsolution of the NiFe alloy nanoparticle. In addition, the DRM activity after the regeneration closely matches the DRM activity of freshly reduced LFNO perovskite, further demonstrating the reversibility of the exsolved NiFe/LFNO. However, using the same regeneration condition, the deteriorated DRM activity of the NiFe/LFNO material exposed to SO_x at 600 °C is not restored, possibly demonstrating the prohibitory effect of SO_x exposure for regeneration. In addition to a direct comparison of the impact of the type of sulfur contaminant species on regeneration, the speciation of sulfur on the exsolved nanoparticle systems as well as the regeneration of this novel SOEC candidate will be discussed.

8:00 PM EN07.09.05

Bifunctional Catalytic Co₂VO₄ Nanoarray Grown on Carbon Nanofiber for Free-Standing

Lithium-Air Battery Cathode Mingyu Sagong, Jong Seok Nam, Seung Hyun Jeong and Il-Doo Kim; KAIST, Korea (the Republic of)

In recent research on cathode for LABs, systematic investigations have been conducted to develop rational catalysts with diverse morphologies. Studies have shown increased exposure to the high-activity surface leads to improved cycle life and cell performance. In particular, spinel cobalt oxide (Co₃O₄) draw attention due to Co²⁺/Co³⁺ bifunctional catalytic activity and electrochemical stability in electrocatalysis. Nevertheless, the efficacy of these applications was hindered due to the inherent constraints associated with their poor intrinsic electrical conductivity and comparatively low catalytic activity. To address these limitations, we have designed cobalt vanadium oxide uniformly decorated on the carbon nanofiber (Co₂VO₄@CNF) *via* hydrothermal synthesis as a free-standing cathode for LABs. By substituting vanadium for the octahedron site of Co₃O₄, vanadium atoms can offer an electron pathway and facilitate

high electrical conductivity. In addition, the substitution of vanadium improves oxygen reduction reaction (ORR) performance through proper electron configuration of Co^{2+} . The oxide catalyst grown on the CNF facilitates the maximization of active catalytic sites and stable formation/dissociation of Li_2O_2 , enabling greater capacity and longer cyclability. The findings indicate that the formation/dissociation process of Li_2O_2 is influenced by the presence of an appropriate catalyst and the surface chemistry. The air cathode structure composed of rational nanostructures and catalysts is expected to improve LAB performance in capacity and cyclability.

8:00 PM EN07.09.07

Boosting the Visible-Light-Driven Selective Toluene Oxidation via Synergistic Effect Between Nanoparticulate Pd/BiVO₄ Photocatalyst and a Cyclic Nitroxyl Redox Mediator Sayuri Okunaka¹ and Hiromasa Tokudome²; ¹Tokyo City University, Japan; ²TOTO Ltd., Japan

Selective oxidation of organic compounds using semiconductor photocatalysts has been focused on the viewpoint of sustainable synthesis processes. Especially, the selective oxidation of $\text{C}(\text{sp}^3)\text{-H}$ bonds in toluene, which is one of the C-H activation reaction, is an attractive reaction because the desired oxidation product, benzaldehyde, is extensively used as an indispensable intermediate in the synthesis of drugs, perfumes, and fine chemicals. Conventional synthesis of benzaldehyde involves TiO_2 -based photocatalysts, however, they have brought the drawback of absorbing only UV light and the low selectivity due to its large bandgap. Therefore, developing visible-light responsible photocatalyst system for efficient toluene oxidation has been strongly desired to construct an alternative way to realize sustainable organic synthesis.

Recently, we reported photo-oxidation of toluene to benzaldehyde over visible-light responsible Pd-loaded BiVO_4 (Pd/BiVO_4) photocatalyst. However, it remains challenging due to its low efficiency. In this work, we introduce a novel strategy to apply a cyclic nitroxide compound as an efficient redox mediator along with Pd/BiVO_4 for toluene oxidation. Addition of a cyclic nitroxide significantly improved the toluene oxidation activity on Pd/BiVO_4 photocatalyst under blue-to-green light irradiation. In particular, *N*-hydroxyphthalimide (NHPI) boosted the benzaldehyde production up to ca. 28 times compared to without NHPI. The optimized conditions realized a toluene conversion in high efficiency (apparent quantum yield = 10.8 and 5.4 % at 420 and 520 nm, respectively) and with excellent selectivity. The superior conversion yield was realized by the synergistic effect between the presence of NHPI and the use of nanoparticulate Pd/BiVO_4 with a relatively large surface area.

8:00 PM EN07.09.08

Tailoring Ag Electron-Donating Ability for Organohalide Reduction: A Bilayer Electrode Design Dwaipayan Chakraborty¹, Ali Abbaspourtamijani¹, Henry S. White², Matthew Neurock³ and Yue Qi¹; ¹Brown University, United States; ²The University of Utah, United States; ³University of Minnesota, United States

Electrochemical reduction of organohalides is a green and safe way for the reduction of environmental pollutants, synthesis of new organic molecules, and many other important applications. The presence of a catalytic electrode (i.e., electrocatalytic dehalogenation) can in many cases make the process more energetically efficient. Ag has been known to be very good catalysis for this purpose for a wide range of organohalides. In this work, we have particularly tried to put forward an electrode design strategy that can possibly be used to further increase the catalytic activity of pure Ag electrodes. We have shown how epitaxially depositing one to three layers of Ag on catalytically inert or less active support metal (defined as Ag/metal bilayer electrode) could increase the surface electron donating ability, thus increasing the

adsorption of organic halide and the catalytic activity. Many factors, such as molecular geometry, lattice mismatch, work function, and solvents, contribute to the adsorption of organic halide molecules over the bilayer electrode surface. To isolate and rank these factors, we studied three model organic halides, namely, haloethane, bromobenzene (BrBz), and benzyl bromide (BzBr) adsorption on Ag/metal (metal = Au, Bi, Pt, and Ti) bilayer electrodes in both vacuum and acetonitrile (ACN) solvent. The different metal support offers a range of lattice mismatches and work function differences with Ag. Our calculations show that the surface of Ag becomes more electron-donating and accessible to adsorption when forming a bilayer with Ti since Ti has a lower work function and almost zero lattice mismatch with Ag. We believe this study will increase the electron-donating ability of the Ag surface by choosing the right metal support which in turn can improve the catalytic activity of the working Ag electrode.

Hierarchical NiFe@NiFe Layered Double Hydroxides for Efficient Solar-Powered Water Oxidation
Deok Ki Cho, So Jeong Park, Geonpyo Hong and Jin Young Kim; Seoul National University, Korea (the Republic of)

The development of green hydrogen is crucial for achieving zero CO₂ emissions and sustainable energy production. Solar-powered electrocatalysis, also known as photovoltaic-electrolysis (PV-EC), is a promising technology that has the potential to efficiently convert solar energy into hydrogen with high efficiency and durability. However, the sluggish kinetics of the oxygen evolution reaction (OER) pose a significant challenge to efficient water splitting. To overcome this, there is a pressing need to develop cost-effective catalysts with high electrochemical activity and stability, as well as scalable synthetic processes for large-scale production. Layered double hydroxides (LDHs) based on transition metals have garnered considerable attention as promising candidates due to their abundant availability, porous morphologies, and adjustable compositions.

In this study, a hierarchical heterogeneous Ni²⁺Fe³⁺@Ni²⁺Fe²⁺ LDH was successfully synthesized using a sequential electrodeposition technique. The synthesis process involved the use of separate electrolytes containing iron precursors with different valence states (Fe²⁺ and Fe³⁺). By utilizing Fe²⁺ precursors, a well-defined nanosheet array of NiFe LDHs with high crystallinity, referred to as Ni²⁺Fe²⁺ LDH, was synthesized. On the other hand, employing Fe³⁺ precursors led to the formation of a thin layer of NiFe LDH with a relatively higher Ni content and lower crystallinity, denoted as Ni²⁺Fe³⁺ LDH. Different deposition behaviors depending on the oxidation state of the Fe precursor ions was attributed to their different solubility product constants (K_{sp}). The amorphous Ni²⁺Fe³⁺ LDH exhibited superior OER performance compared to its Fe²⁺-based counterpart. The heterogeneous hierarchical OER catalyst electrode was prepared by a simple two-step electrodeposition process using the Ni²⁺Fe²⁺ LDH nanosheet arrays with large surface area. As a result of the synergetic effect between the large dual advantages of large surface area of the Ni²⁺Fe²⁺ LDH nanosheet arrays and excellent OER activity of Ni²⁺Fe³⁺ LDH, the Ni²⁺Fe³⁺@Ni²⁺Fe²⁺ LDH exhibited outstanding OER activity with overpotentials of 218 and 265 mV required to achieve current densities of 10 and 100 mA cm⁻², respectively. Moreover, it demonstrated exceptional long-term stability, sustaining efficient performance for 30 hours even at a high current density of 500 mA cm⁻². In a water splitting system, the electrolyzer, using a Sn₄P₃/CoP₂ electrocatalyst as the cathode, only required a cell voltage of 1.55 V to achieve a current density of 10 mA cm⁻². Furthermore, the solar-powered overall water splitting system, comprising our electrolyzer and a perovskite/Si tandem solar cell, exhibited a high solar-to-hydrogen conversion efficiency of 15.3%.

Introduction of Carbon Shells on Copper(I) Oxide Nanocrystals Inducing Selective CO₂

Electroreduction to Methane Jong-Yeong Jung and Hyunjoon Song; KAIST, Korea (the Republic of)

Large-scale electrochemical CO₂ reduction reaction (CO₂RR) for methane production is crucial for achieving a carbon-neutral economy. However, practical methane production faces challenges from increased C–C coupling and the hydrogen evolution reaction. Here we introduced carbon shells on cuprous oxide nanocubes to preserve the copper oxidation states under reduction potential. As carbon shell thickness increased, methane production significantly improved. Optimizing the shell thickness to 50 nm resulted in a Faradaic efficiency of $50.2 \pm 3.9\%$ at a methane partial current density of -201 ± 16 mA cm⁻² in alkaline electrolytes. Operando X-ray absorption confirmed that the carbon shells prevent the reduction of Cu₂O nanocubes under the negative bias and stabilize Cu(I) species. In situ Raman studies observed a remarkable peak assigning Cu hydroxide species. The carbon shells seem to impede the transport of hydroxide ions, leading to a high local pH and stabilizing Cu hydroxide species. Density functional theory calculations confirmed the role of surface-adsorbed *OH molecules to suppress *CO dimerization and the Barder charge of Cu atoms during *OH adsorption which remained under +1. This work presents a simple strategy to control the major products of CO₂RR and reveals the role of hydroxyl groups on the Cu₂O surface.

Acceptor Doping of Bismuth Vanadate to Realize Photocathodes for Hydrogen Evolution: Joint Experimental and Computational Investigations Vrindaa Somjit¹, Daye Seo², Kyoung-Shin Choi² and Giulia Galli^{3,1}; ¹Argonne National Laboratory, United States; ²University of Wisconsin–Madison, United States; ³The University of Chicago, United States

Bismuth vanadate (BiVO₄) is a promising photoelectrode for water splitting due to its ease of synthesis, stability in aqueous conditions, and high electron-hole separation yield. Its favorable band edge alignment with the water oxidation potential has spurred extensive research into designing n-type BiVO₄ photoanodes for water oxidation [1]. However, relatively less attention has been given to the development of p-type BiVO₄ for water reduction to hydrogen gas. In this work, we show that calcium-doped BiVO₄ can serve as a photocathode that reduces water to hydrogen gas. Using density functional theory at the +U and hybrid levels, we report that Ca doping can shift the conduction band minimum (CBM) of BiVO₄ by 0.15 eV, moving it closer to the water reduction potential. This is consistent with experiments, which observe hydrogen evolution in Ca-doped BiVO₄ under illumination and a shift in the CBM towards vacuum. We show that changes to the electronic density of states and Bi-O bond lengths cause a sizeable shift in CBM. We also analyze compensation of the acceptor dopant by oxygen vacancies and hole polarons. Our work provides insight into the use of BiVO₄ as a photocathode, moving us towards the fabrication of p-n homojunctions based on BiVO₄ that could further increase charge separation efficiency, and development of electrodes for other important technological processes, like N₂ reduction to NH₃.

[1] Lee, D., Wang, W., Zhou, C., Tong, X., Liu, M., Galli, G., & Choi, K. S. (2021). The impact of surface composition on the interfacial energetics and photoelectrochemical properties of BiVO₄. *Nature Energy*, 6(3), 287-294.

Salt Template Based Synthesis of Bi Nanoparticles and Their Electrochemical CO₂RR Activity for Formic Acid Production Choi Sung Yeol and Jeong Min Baik; Sungkyunkwan University, Korea (the Republic of)

Fossil fuel combustion process has led to excess emission of carbon dioxide to air about 35 billion ton per year. It causes serious environmental crisis like global warming, acid rain, water pollution etc. Up to now, considerable strategies for reducing usage of fossil fuels are mostly focused on expanding renewable energy source (energy harvesting, green hydrogen, power generation from nature). But it is not sufficient for supplying increasing global energy demand[1] and for these reason, continuous CO₂ emission to atmosphere is inevitable. Carbon capture and utilization technology(CCUS) is rising as one of the most effective solution to these unavoidable combustion process. Among CCUS technology, Electroreduction of CO₂ to fuel (CO₂RR) which can be achieved from catalytic conversion at heterogeneous interface is promising technology because CO₂ can be transformed to other value-added multi carbon products. Formic acid, which is most high value-added products, can be synthesized through flow-cell set-up what can make CO₂ gas diffuses more easily to the catalytic active site. We coated Bismuth nanoparticle as active catalyst directly on Gas diffusion electrode by NaCl template method without adding any binder solution and checked the selectivity, efficiency of bismuth catalyst layer by analyzing final products using NMR, Gas chromatography spectroscopy method. The synthesized Bi NPs exhibits excellent selectivity to HCOOH(~90%) at -0.8V, and showed over than 30mA/cm² current density.

Machine Learning Assisted Computational Design of High Entropy Alloy Electrocatalysts for Selective Nitrate to Ammonia Conversion Boyang Li, Ying Fang and Guofeng Wang; University of Pittsburgh, United States

Human activities have influenced global nitrogen cycle and caused many energy and environmental issues. A possible solution is to directly reduce nitrate to ammonia electrochemically, which can synergistically mitigate environmental problems and provide economic benefits by generating fertilizer using renewable energy. In this study, we employed a machine learning assisted computational approach to find a high entropy alloy (HEA) catalyst toward highly selective and stable electrochemical nitrate reduction (ENR) for nitrate to ammonia conversion under acidic conditions. First, we explored the composition space of 10 active elements (i.e., Ru, Pt, Pd, Cu, Fe, Co, Ni, Rh, Ir, and Mo) with the atomic ratio of each element ranging from 5 to 50%, with a 5% step size. We launched a composition screening to ensure the solid solution phase based on atomic size mismatch, mixing enthalpy, and Gibbs free energy of mixing, and identified 24 types of element compositions to be stable under any composition. By using the literature-reported synergistic pairs for ENR to further prescreening, we identified Ru-Pd-Pt-Cu alloy as an appropriate candidate to disperse Ru atom and improve the performance of ENRT to ammonia. Furthermore, we used the DFT method to optimize the adsorption configurations of all possible ENR intermediates on RuPdPtCu (111) surface and used the elemental types on the first neighboring and second neighboring positions as input features to fit the calculated adsorption energies using a linear regression model. Our results show that nitrate reduction species are more favorable to be adsorbed on the Ru atom (i.e., first neighboring site) as compared to the Cu, Pt, and Pd atoms, suggesting that the nitrate reduction will predominantly occur on the site containing at least one Ru atom in RuPdPtCu (111)

surface. The limiting potential defined as the highest potential in which all free energy changes become downhill was predicted to be 0.17V for nitrate reduction reaction on RuPdPtCu(111) with the corresponding rate-determining step being the protonation of N to form NH. In comparison, the metallic Ru (0001) surface shows a lower limiting potential of -0.36 eV to promote nitrate reduction. This finding explains why the RuPdPtCu HEA catalyst exhibits a higher nitrate reduction activity than the unary Ru catalyst. Our predictions have been well validated by experimental measurement data.

Optimization Strategies of Photovoltaics-Powered Green Hydrogen Production Xuanjie Wang, Xinyue Liu and Lenan Zhang; Massachusetts Institute of Technology, United States

Green hydrogen production powered by photovoltaics provides a clean solution for energy conversion and storage. The key parameter of photovoltaic electrolysis (PV-EC) system is the solar-to-hydrogen (STH) efficiency. Previous studies have been mostly focused on improving the efficiency of each system individually using multi-junction PV materials, catalysts and electrolytes. However, the coupling between photovoltaic and electrochemical devices is still elusive to achieve high STH efficiency in a system level. In our study, the optimization strategies of PV-EC systems are demonstrated to approach thermodynamic limit (26.6%) for green hydrogen production. First, we list three design parameters for modeling, namely number of PV, number of EC and the area ratio between PV and EC. Then we model the crystalline silicon PV coupled with a real EC system. The STH efficiency varies under different PV and EC combinations. The STH efficiency map clearly defines three regions indicating the engineering space for PV-EC coupling, Tafel slope and area ratio. The optimization strategies presented in this study can lead to further advancements in coupled PV-EC systems with well-controlled performance for different conditions.

8:45 AM EN07.10.04

Ion Beam Analysis of MoNi₄-MoO₂ Catalyst Layer for Anion Exchange Membrane Electrolyzer Yamini Kumaran¹, Latika S. Chaudhary¹, Iulian Gherasoiu² and Haralabos Efstathiadis¹; ¹SUNY Poly CNSE, United States; ²SUNY Polytechnic Institute, United States

There has been an increased interest in Anion Exchange Membrane (AEM) electrolyzer technology enabling zero-gap configuration lately. This technology also allows non-noble metal-based materials to be used as catalyst layers in an alkaline environment. In this research, MoNi₄ supported by MoO₂ nanorods has proven to be a promising electrocatalyst for Hydrogen evolution reaction (HER) with a decreased overpotential of 40 mV at 10 mA/cm² with increased current density, and stability for almost 12 hours in half-cell configuration. However, it is important that the material be used as a catalyst layer in membrane electrode assembly to have the capacity to tolerate high steady-state potentials for extended periods of time in real operating systems. The aim of this study is to analyze the AEM electrode assembly with MoNi₄-MoO₂ as the cathode layer synthesized via hydrothermal synthesis for overall metal loading corresponding to the improved efficiency and catalyst dissolution arising due to the interaction between the catalyst layer and the ionomer membrane. The cathode catalyst synthesized was characterized by X-Ray diffraction, SEM and X-Ray photoelectron spectroscopy for structural, morphological and surface composition. Further, nuclear techniques like Rutherford Backscattering Spectroscopy (RBS) employed to provide information regarding the thickness and stoichiometry of the catalyst layer and metal dissolution in the ionomer membrane, and Nuclear Reaction Analysis (NRA) was utilized to study different defects in the ionomer membrane by high-resolution Hydrogen depth profiling after the operation. Overall, this work presents a better understanding of catalyst degradation effects on the

Updated as of October 28, 2024

ionomer membrane and vice versa responsible for the voltage and mass transport losses in AEM electrolyzers.

Metal Complex/Semiconductor Hybrid Photoelectrocatalysts and Photocatalysts for CO₂ Reduction
Akinobu Nakada^{1,2}; ¹Kyoto University, Japan; ²PRESTO/JST, Japan

Reductive conversion of CO₂ into energy-added molecules has been an important subject in various fields including materials chemistry, catalysis, electrochemistry, and photochemistry, from viewpoints of both decreasing CO₂ concentration and gaining energy and carbon resources. Among the various methods and schemes proposed, visible-light-driven CO₂ reduction in combination with water oxidation, one of the representative models of artificial photosynthesis, is an attractive solution because it enables abundant water and inexhaustible solar energy to be used to produce value-added chemicals. Molecular metal complexes and semiconductors are promising candidates for photocatalysts that can reduce CO₂ to CO, formate, formaldehyde, or other hydrocarbons. Although both molecular metal complexes and semiconductors have strengths and weaknesses, their weaknesses (low oxidation ability and low selectivity for reduction reactions) can be overcome via the construction of a suitable molecule/semiconductor hybrid material. However, facilitating electron transfer at the molecule/semiconductor junction while suppressing unfavorable back electron transfer events is challenging.

Here, our design principle for developing the hybrid photoelectrodes and photocatalysts will be reported, starting from introduction of selective electrocatalysis and photocatalysis of CO₂ reduction by a metal complex catalyst in aqueous solution. Subsequently, application of these metal-complex photocatalysts into a hybrid photoelectrode with semiconductor materials for photoelectrochemical CO₂ reduction will be presented. Simple hybrid photocatalysts directly connecting metal complexes and semiconductor particles, which facilitate photocatalytic CO₂ reduction via interfacial electron transfer without the aid of electrochemical techniques, will also be reported. Finally, we will report our recent approach for constructing hybrid photocatalysts with design-flexible conjugated polymers as a light absorber, a photoelectron transporter, and a suitable reaction center by site-selective modification of metal-complex catalysts.

10:00 AM *EN07.10.06

An Integrated View of Multi-Step (photo)Electrocatalytic Reactions Frances Houle; Lawrence Berkeley National Laboratory, United States

Our views of (photo)electrocatalytic reactions and how they are influenced by their environments are strongly shaped by atomic-level theoretical studies that examine reaction pathways to identify the most probable routes, and by macro-level observations of current densities, Tafel plots, and product distributions. Connecting these two very different pictures via multiscale stochastic kinetics simulations provides a way to examine factors that influence reactivity, and predict how systems can be designed for improved efficiency and selectivity. This talk will focus on the role of thermal steps and local fluctuations at the catalytic site level in influencing reactivity, and discuss how these characteristics are manifested in experimental studies.

Defect Engineering of WO₃ by Rapid Flame Reduction for Efficient Photoelectrochemical

Conversion of Methane into Liquid Oxygenates Ho Kun Woo¹, Ankit Gautam¹, Jaxiry S. Barroso-Martínez¹, Arthur P. Baddorf², Kai Zhou¹, Yoon Young Choi¹, Jiajun He¹, Alexander V. Mironenko¹, Joaquin Rodriguez-Lopez¹ and Lili Cai¹; ¹University of Illinois, United States; ²Oak Ridge National Laboratory, United States

Photoelectrochemical (PEC) conversion is a promising way to utilize methane (CH₄) as a chemical building block without harsh conditions. However, PEC CH₄ conversion to value-added chemicals remains challenging due to the thermodynamically favorable over-oxidation of CH₄ to CO₂. Here, we report WO₃ nanotubes (NTs) photoelectrocatalysts for PEC CH₄ conversion with high liquid product selectivity through defect engineering. By tuning the flame reduction treatment, the oxygen vacancies of WO₃ NTs were carefully controlled. The optimized reduced WO₃ NTs suppressed over-oxidation of CH₄ and showed high C₁ liquid selectivity of 69.4% and production rate of 0.174 μmol cm⁻² h⁻¹. Scanning electrochemical microscopy revealed that oxygen vacancies can restrain the production of hydroxyl radicals, the presence of which in excess could further oxidize C₁ intermediates to CO₂. In addition, optical characterization and computational studies elucidated that oxygen vacancies thermodynamically suppress over-oxidation. This work introduces a strategy to understand and control the selectivity of photoelectrocatalysts for direct CH₄ conversion to liquids.

***In-Situ* TEM Investigation on Redox Mechanisms of Transition Metal Oxides** Xiaozhi Liu, Yue Pan, Dan Zhou and Dong Su; Chinese Academy of Sciences, China

The physicochemical properties of transition metal oxides are determined by their phase structures, surface exposed atoms, morphology, and defects. Metal oxide catalysts usually undergo a series of activation and reaction processes in practical applications, which modulate their morphology and change their valence states and crystal phases. These structural variations alternate their properties significantly and have been believed to be a critical problem, e.g., in their catalytic applications. During reactions, metal oxides undergo either reduction or oxidation reactions depending on the ratio of reducing or oxidizing gases in the atmosphere. Although it is believed that *in situ* investigation of the reaction pathways is of importance to understand their intrinsic redox nature, as far as we know, the microstructural evolution during the redox of metal oxides is still not well understood. We have studied the dynamic reaction behaviors of iron oxides via *in situ* transmission electron microscopy (TEM) with a Climate system from DENSolutions. We have achieved atomic-scale resolution imaging to visualize the evolution of phase boundary and the competitive transitions between Fe₃O₄, FeO, and Fe in the nanoreactor. Thus we found the inhomogeneous reaction pathways which are strongly affected by the trace amount of oxygen or water vapor in catalytic reactions. Our results could provide new insights into the redox reaction mechanism of transition metal oxides, and help to understand the role of these oxides in catalytic reactions.

Controlling C(sp³)-H and C(sp³)-C(sp³) Transformations and Fuel Synthesis at Electrocatalytic Interfaces Marcel Schreier^{1,2}; ¹University of Wisconsin-Madison, United States; ²University of Wisconsin-Madison, United States

Producing fuels and chemicals using renewable electricity holds the promise to enable a circular economy based on sustainably produced carriers of electrical energy and sustainably produced chemicals. To date, the vast majority of electrocatalytic reactions are limited to the transformation of small inorganic molecules such as CO₂, H₂O, N₂, as well as the oxidation and reduction of alcohols. However, comprehensive electrification of the chemical industry will require electrocatalytic reactions that can promote the transformation of unactivated C(sp³)-H and C(sp³)-C(sp³) bonds, which are central to today's industry.

In this presentation, I will show how fundamental understanding of the interfacial processes occurring in electrocatalytic reactions can be exploited to expand the reaction scope of electrocatalysis to the transformation of complex substrates involving the controlled activation of C-H and C-C bonds. In a first step, I will show how this approach allows us to transform ethanol to ethylene oxide, an important plastic precursor. Subsequently, I will discuss methods to electrocatalytically transform inert alkanes such as methane, ethane, and butane at room temperature.

2:00 PM EN07.11.03

Photochemical Diodes for Simultaneous Bias-Free Glycerol Valorization and Hydrogen Evolution Jia-An Lin, Inwhan Roh and Peidong Yang; UC Berkeley, United States

Finding sustainable and renewable energy is currently one of the most urgent challenges facing society today. Artificial photosynthesis offers a route to using solar energy to produce fuels such as hydrogen, a fundamental component for building a carbonfree economy. One such approach to realizing artificial photosynthesis is presented through the photochemical diode. Conventional approaches targeted the optimization of the overall water splitting (OWS) reaction in which hydrogen and oxygen are produced. However, the sluggish kinetics of the oxygen evolution reaction (OER) and the high thermodynamic potential requirement of 1.23 V for the OWS limit the current performance of bias-free photoelectrochemical (PEC) systems. Here, we offer an alternative approach by replacing the OER with the glycerol oxidation reaction (GOR) for value-added chemicals using Si photoanode. By employing a low overpotential catalyst such as PtAu for GOR, which shows a low onset potential of 0.4 V vs RHE electrochemically, the voltage requirements to couple with hydrogen evolution reaction (HER) become substantially lowered compared to OWS. As a result, the PtAu/Si photoanode exhibits a low GOR onset potential of -0.05 V vs RHE and a photocurrent density of 10 mA/cm² at 0.5 V vs RHE. Coupled with a Si nanowire photocathode for the HER, the integrated system yields a high photocurrent density of 6 mA/cm² with no applied bias under 1 sun illumination and can run for over 4 days under diurnal illumination. The demonstration of the GOR-HER integrated system provides a framework for designing bias-free photoelectrochemical devices at appreciable currents and establishes a facile approach to artificial photosynthesis.

2:15 PM EN07.11.04

Molecular Additives Steer Selectivity of CO₂ Photoelectrochemical Reduction over Gold Nanoparticles on Gallium Nitride Aisulu Aitbekova, Nicholas Watkins, Jonas Peters, Theodor Agapie

and Harry A. Atwater; California Institute of Technology, United States

We demonstrate that functionalizing Au/p-GaN cathodic photoelectrochemical devices with molecular additives steers the selectivity for CO₂ reduction process toward reduced products of carbon dioxide and suppresses hydrogen generation via water splitting. The working hypothesis for this selectivity change is the suppressed proton transfer through hydrophobic molecular additive films, which results in the diminished hydrogen evolution reaction rates (Faradaic Efficiency to H₂ decreases from 90% to 18 %). Our work establishes a rigorous platform to elucidate structure-property relationships in photoelectrocatalysts and engineer active, stable, and selective materials for sustainable energy applications.

The wide bandgap semiconductor p-GaN exhibits stability under CO₂ photoelectrochemical conditions due to its nitrogen-rich surface. Additionally, its conduction band minimum is more negative than the CO₂ reduction potential. When combined with metals, such as gold nanoparticles, the semiconductor-metal interface forms a Schottky barrier. The downward bending of the conduction and valence bands drives electrons excited in p-GaN towards the metal-electrolyte interface, while the holes are transferred into the p-GaN bulk semiconductor.

Rising levels of greenhouse gases necessitate a reduction in the amounts of these harmful compounds in the atmosphere and a transition to sustainable production of fuels and chemicals. Photoelectrochemical CO₂ reduction (CO₂R) is an appealing solution to convert carbon dioxide into higher-value products. However, CO₂R in aqueous electrolytes suffers from poor selectivity due to the competitive hydrogen evolution reaction dominant in aqueous electrolytes. As noted above, our approach to overcome this challenge consists of (1) synthesis of metal/semiconductor structures with controlled properties and (2) functionalizing the metal/semiconductor surface with molecular additives.

2:30 PM BREAK

3:00 PM EN07.11.05

A Comprehensive Online Analytical System Coupled with Standardized Data Analysis for the Electrochemical Reduction of CO₂ Alessandro Senocrate^{1,2}, Peter Kraus¹, Francesco Bernasconi^{1,2} and Corsin Battaglia^{1,2}; ¹Empa–Swiss Federal Laboratories for Materials Science and Technology, Switzerland; ²ETH Zürich, Switzerland

The electrochemical reduction of CO₂ (CO₂RR) is a promising way to convert detrimental CO₂ emissions into sustainable fuels and chemicals, and thus to achieve a circular carbon economy.¹ Depending on catalyst type and reaction conditions, different gaseous and liquid products can be obtained from the CO₂RR, and their production rates vary with reaction time. It becomes thus imperative, for any catalytic performance analysis, to be able to assess the product distribution online during CO₂RR.^{2,3} However, while gaseous products are readily analyzed online by gas chromatography, liquid products are typically only assessed at the end of the reaction due to the lack of suitable automated liquid sampling and analysis methods. In addition, reaction parameters such as CO₂ mass flow rates, temperatures and pressures are seldom recorded, causing the loss of significant information on catalysts, electrodes, and electrolyzers behavior.

To overcome these issues, we assemble a comprehensive analytical system coupling online gas and liquid product analysis by gas and liquid chromatography leveraging a special automated liquid sampling valve with electrochemical protocols that assess CO₂RR performance, electrolyzer cell resistance and electrode

surface area. In addition, we record CO₂ mass flow rates, electrolyzer temperatures, as well as gas and liquid flow pressures.⁴ To rapidly and reproducibly handle the large and heterogeneous data volume obtained we implement a standardized data pipeline based on our own open-source software,⁵ which automatically parses the numerous different raw data files, composes a data set following FAIR practices,⁶ and post-processes and plots the data in a standardized way. We validate the analytical system by carrying out CO₂RR at 200 mA/cm² on Cu gas diffusion electrodes, following the changes in selectivity with reaction time for > 10 gaseous and liquid products, and recording mass flow rates, electrolyzer temperatures and pressures. The modular nature of our analytical system, combined with the standardized data pipeline, allows us to freely increase the number and type of sensors used with minimal impact on the data analysis time, as well as to multiplex our analysis to 8 parallel electrolyzer cells, paving the way for a much deeper and faster understanding of the function of CO₂RR catalysts, electrodes, and electrolyzers.

3:15 PM EN07.11.06

Computational Screening of Non-Copper Based Catalysts for Electrochemical CO₂ Reduction Reaction Samira Siahrostami; Simon Fraser University, Canada

Copper-based catalysts are currently being investigated as the most efficient catalysts for electrochemical CO₂ reduction reactions (CO₂RR) to valuable hydrocarbons such as methane, ethylene, and ethanol. Copper catalysts, on the other hand, are prone to restructuring and degradation, fueling the search for non-Cu catalyst families that enable C-C coupling. We use high-throughput DFT calculations to search a wide range of materials space and accelerate the discovery of more efficient catalyst materials beyond copper for CO₂RR, as well as scale-up the use of the catalysts in electrochemical reactors to enable meaningful conversion. In this talk, I will discuss the use of robust high-throughput DFT calculations to screen a massive library of non-conventional classes of materials such as perovskites, transition metal nitrides¹, and metal organic frameworks² as well as the insights we can gain from them.

Facile Sythesis of Novel Pt-Ni-Cu Nanoframes via Simple Galvanic Replacement for Methanol Oxidation Reaction Kevin Wilk, Yuhan Hu, Samantha Fuscus, Markus Higgins, Kira Shulman, Eduardo Lezama and Yiliang (Yancy) Luan; SUNY Binghamton, United States

Pt-based catalysts play a crucial role in various applications, such as catalytic converters, petroleum refinement, and chemical production. However, the widespread use of Pt-based catalysts is hindered by

their high cost. To address this issue, researchers have focused on combining Pt with non-precious metals to reduce Pt usage with intent to optimize electronic configurations for improved catalytic performance. Recently, there has been significant interest in nanoframes due to their unique open structure, which provides a large surface area and enhances catalytic performance compared to conventional solid nanoparticles. In this report, we present a facile preparation of novel Pt-Ni-Cu nanoframes from Pt-Ni nanocubes through a simple galvanic replacement process at high temperature. The resulting nanoframes retain the segregated Pt at the edges and diagonals of the Pt-Ni precursor while incorporating Cu into the alloy. The segregated Ni, except at the edges and diagonals, is selectively removed, resulting in a hollow structure through the Kirkendall Effect. The amount of Cu in the nanoframes can be controlled by adjusting the reaction time. The nanoframes were applied for methanol oxidation reaction (MOR), and the mass activity is proportional to the amount of Cu incorporated, which was adjusted by controlling the time on the synthesis of the nanoframes. These results not only highlight the exceptional potential of the Pt-Ni-Cu nanoframes as catalysts for MOR but also provide a promising solution to the cost-effectiveness challenge associated with Pt-based catalyst applications.

8:30 AM DISCUSSION TIME

8:45 AM EN07.12.03

Active-Site Imprinted M-N-C Electrocatalysts: Tailor-Made Synthesis and Tuned Activity Davide Menga¹, Tim-Patrick D. Feller² and Yang Shao-Horn¹; ¹Massachusetts Institute of Technology, United States; ²Bundesanstalt für Materialforschung und -prüfung, Germany

Due to the abundance and inexpensiveness of their constituent elements and their atomic dispersion, metal- and nitrogen- co-doped carbons (M-N-Cs) are currently the best alternative among noble-metal-free catalysts set to replace critical raw materials in several fundamentally important electrochemical reactions such as oxygen reduction reaction (ORR) and CO₂ reduction reaction (CO₂RR).

Due to the metastability of the active M-N₄ sites at the temperature of their pyrolytic formation, the final transition metal loading is currently limited and significant amounts of inorganic by-products are formed. Although synthesis protocols have been successfully optimized, multiple processing steps are required, making the preparation time-consuming.

In previous work, it has been showed that via an active-site imprinting strategy followed by a transmetalation reaction, Mg-N-C and Zn-N-C containing Mg-N₄ and Zn-N₄ sites respectively, can be transformed into ORR active Fe-N-C electrocatalysts, avoiding the formation of elemental iron, or iron carbide side phases. This synthetic method allows for high yields, controlled morphology and high metal loadings.

In this contribution, it will be presented how Zn-N₄ sites in tailor-made Zn-N-C materials are utilized as an active-site imprint for the preparation of the corresponding M-N-C catalysts with a high loading of atomically dispersed metal. The current state of this class of materials is discussed in terms of synthetic methods, activity and stability.

9:00 AM EN07.12.04

3D Printed Continuous Nanoporous Cu/CuOx Electrodes for Highly Efficient Hydrogen Evolution Reaction Anand P. Tiwari and William J. Scheideler; Dartmouth College, United States

The sluggish kinetics of electrocatalysts in alkaline media cause stability as well as low active site issues, restricting the conversion of renewable energy into hydrogen. Synergistic enhancements such as the formation of free-standing nanoporous heterostructures, homogeneous diffusion of active materials into

conductive supports, and atomic doping/defecting of active materials could promise to improve the kinetics and resolve key stability issues. Herein, we present scalable 3D-printing of continuous nanoporous Cu/CuO_x diffused carbon electrocatalysts for efficient alkaline hydrogen evolution reaction (HER) in which Cu/CuO_x acts as active sites, nanoporous carbon provides a higher conductive surface area to enhance HER kinetics, and periodic 3D lattice micro-structuring facilitates bubble evolution to improve stability. The resulting micro-architected porous electrodes deliver high electrocatalytic activity for HER, with an overpotential of 155 mV at a current density of 10 mA/cm² and a Tafel slope of 134 mV/dec, outperforming other 3D noble metal-free oxide materials. In addition, the as-fabricated catalysts also showed superior durability: up to 240 hours of continuous hydrogen evolution without any significant change in overpotential and current density, which is 10X better than reported 3D-printed catalysts. Our comparative analysis of multiple 3D lattice geometries indicates that our 3D-ordered nanoporous Cu/CuO_x electrocatalysts maximize performance by exposing more active sites and allowing faster discharge of H₂ gas bubbles through engineered microchannels. We will finally discuss how our micro-architected approach to transforming 3D-printed lattices can be applied to a variety of earth-abundant electrocatalysts based on transition metal/metal oxides for enhancing performance and stability of additional reactions including OER.

9:15 AM DISCUSSION TIME

9:30 AM EN07.12.06

Toward Scalable Nickel-Cobalt Based Anode Materials for Alkaline Electrolysis: Unveiling the Path from Micropowder Analysis to Electrochemical Performance Vineetha Vinayakumar^{1,2}, Adarsh Jain¹, Mohit Chatwani¹, Timo Wagner³, Christian Marcks⁴, Nicolas Wöhrle^{3,2}, Anna K. Mechler⁴ and Doris Segets^{1,2}; ¹Institute for Energy and Materials Processes–Particle Science and Technology (EMPI–PST), University of Duisburg–Essen (UDE), Germany; ²Center for Nanointegration Duisburg–Essen (CENIDE), University of Duisburg–Essen (UDE), Germany; ³Faculty of Physics, University of Duisburg–Essen (UDE), Germany; ⁴Electrochemical Reaction Engineering, RWTH Aachen University, Germany

The depletion of conventional energy resources has highlighted the need for sustainable alternatives, with hydrogen emerging as a promising option. However, the commercial-scale production of hydrogen remains a challenge (1). In this study, we focus on water electrolysis as an efficient method for energy conversion and storage, emphasizing the crucial role of electrocatalysis. Despite recent progress, establishing direct correlations between anode properties and performance in an industrial setting is crucial for the practical implementation of stable and highly efficient anodes for alkaline water electrolysis at pilot-scale systems. This requires linking the scale-up process with a comprehensive fundamental understanding, enabling successful scaling while maintaining optimal performance. To address these challenges, we evaluate the cycle of anode generation starting from the characterization of micropowders through catalyst inks to final electrodes. Our primary goal is to achieve efficient hydrogen production on a commercial scale. To accomplish this, our methodology utilizes complementary techniques to thoroughly analyze the physical and chemical properties of materials throughout the entire process chain. By adopting this comprehensive approach, we aim to gain a deep understanding of the materials involved and optimize their performance for the production of hydrogen on a large scale. To evaluate the interdependencies between different stages and to find out the determining steps during electrode manufacturing, we developed a framework in the sense of a coherent workflow starting with the characterization of commercially available Ni- and Co-based micro powders. Subsequently, ink formulations were optimized using analytical centrifugation (2) and Hansen parameter

calculations (3), followed by electrode layer fabrication using ultrasonic spray deposition of the ink on Ni plates. After optimizing each individual stage in the whole process chain, we also investigated the influence of post-treatments, specifically vacuum annealing, and surface plasma treatment, on the stability of electrodes against delamination. A framework based on atomic force microscopy was developed to precisely quantify micro features and analyze the surface characteristics of electrodes including large areas. Subsequently, the evaluated electrodes were subjected to functional testing as anodes in alkaline water electrolysis, revealing valuable correlations between the properties of the catalyst ink and coated electrodes with their electrochemical activity and stability. Consistent with the identified structural characteristics, our preliminary results demonstrate that plasma-treated Ni-Co-O electrodes exhibit reduced overpotentials and enhanced stability compared to both pristine and vacuum-annealed electrodes. This improvement can be attributed to the enhanced adhesion and favorable surface properties, including roughness, induced by the plasma treatment. This study contributes significantly to the evaluation of the system throughout its various stages, integrating valuable feedback from preceding steps to further optimize electrode performance. Notably, our approach proves particularly advantageous in facilitating the transition from laboratory-scale developments to scalable processing, bridging the critical gap for practical industrial applications.

Flow-Directing Electrodes with Multi-Scale Porosity for Controlling Transport and Reactions Max A. Saccone, Xi Chen, Philip R. Onffroy, William Tarpeh and Joseph M. DeSimone; Stanford University, United States

Systems that simultaneously optimize transport and reaction parameters are crucial for chemical process intensification. In this talk, we discuss recent progress towards additively manufactured electrode materials that control flow fields in electrochemical systems with forced convection, coined “flow-directing electrodes.” We show how 3D printed micro-scale architected structures formed from metal-coated polymers, pure metals/oxides, or pyrolytic carbon can tune flow properties and prevent fouling in electrochemical systems while simultaneously providing pathways for electron transfer. We additionally show how to create multiscale hierarchy through the incorporation of nano-scale porosity in these systems via ZnO nanorod templating to tune specific surface area and permeability. We demonstrate the utility of such flow-directing electrodes for applications ranging from electrochemical remediation of per- and poly-fluoroalkyl substances (PFAS) where a nano-porous layer could act as a size-exclusion membrane to design of electrodes for redox-flow batteries where transport of working ions and redox-active material is maximized but transport and crossover of other species such as electrolytes and mediators is minimized. Flow-directing electrodes represent a paradigm shift in electrochemical reactor design in which high resolution vat photopolymerization printing techniques are used to create co-designed structures with complex geometry using electrically conductive functional materials—all leading to the ability to explore a wide landscape of previously impossible device designs.

Suppression of Dopant Segregation and Improvement of Activity on a Perovskite Oxide Surface by Self-Formation of Ruddlesden-Popper Phase Sanaz Koohfar¹, Masoud Ghasemi², Tyler Hafen³, Georgios Dimitrakopoulos¹, Dongha Kim¹, S. Elangovan³, Jenna Pike³, Enrique Gomez² and Bilge Yildiz¹; ¹Massachusetts Institute of Technology, United States; ²The Pennsylvania State University, United States; ³OxEon Energy LLC, United States

Solid oxide fuel and electrolysis cells (SOFCs, SOECs) present a highly efficient platform for clean energy and chemicals conversion. However, degradation during operation challenges the commercialization and widespread feasibility of this technology. Segregation of dopants such as Sr and Ba to the surface is a main degradation mode that has been linked to the instability of the oxygen electrode surface. These segregated species form an insulating layer and leave behind a near-surface region that is depleted of the dopant. The segregated species on the surface suppress the oxygen reduction and evolution reactions. Improving the stability of surface chemistry and the resulting electrochemical activity on perovskite oxide oxygen electrodes is crucial for enabling efficient and durable SOFC/SOEC as a clean energy conversion platform. In this work, we take $\text{La}_{0.8}\text{Sr}_{0.2}\text{Co}_{0.8}\text{Fe}_{0.2}\text{O}_3$ (LSCF) as a state-of-the-art oxygen electrode, and we reveal that self-formation of Ruddlesden-Popper phase improves the surface chemistry, oxygen reduction kinetics, and electrochemical stability on it. We use X-ray photoelectron spectroscopy (XPS) and time of flight-secondary ion mass spectrometry (ToF-SIMS) to analyze surface and sub-surface chemistries. We reveal that the formation of Ruddlesden-Popper phase is accompanied by suppression of Sr dopant segregation. Moreover, our results show that B-site cations (Co and Fe) are depleted in the subsurface region. These findings reveal the structural elements that maintain an active and stable surface for oxygen reduction reaction on oxygen electrodes. Revealing this unique near-surface chemistry and phase formation is crucial in guiding the development of better surface chemistries for improving the oxygen electrode performance in SOFC/SOEC.

Covalent Anchoring of Macrocycles on Metallic Nanoparticles for Efficient Oxygen Reduction Reaction – A Joint Experimental and Theoretical Investigation Auguste Têtenoire, Arnaud Fihey, Corinne Lagrost and Mikael Kepenekian; University of Rennes, France

The activation of O_2 through electrochemical reduction (ORR, oxygen reduction reaction) has shown promising results as alternative energy conversion technologies that can produce added-value chemicals from simple and abundant feedstocks. However, despite extensive efforts to develop catalytic materials with high reactivity and high selectivity, one can currently observe the lack of demonstrative performance for viable industrial applications. The deliberate surface modification of catalyst has been recently recognized as a powerful approach to design efficient and durable electrocatalysts [1]. It then becomes essential to obtain a good control over the spatial distribution of the chemical functions over the nanoobject surfaces. Recently, excellent catalytic properties towards ORR have been obtained in alkaline media of gold [2], silver [3], and platinum [4] nanoparticles when modified through the reductive grafting of rigid macrocycle calix[4]arene-tetradiazonium salts [5]. However, many fundamental questions, with important operational implications, remain open about these calixarene-modified surfaces. In particular, the conformation of the calixarene on the surface, and the structural, thermodynamic and electronic description of the interface. In addition, the C-Au bond has been poorly investigated in comparison to the S-Au bond.

Here, using spectroscopic studies coupled with computational modeling performed with density functional based tight-binding (DFTB) approaches, we investigate the interaction between calix[4]arene macrocycles and gold and platinum nanoparticles. After exploring the nature of the bond between the macrocycle and the gold surface thanks to a good agreement between measured and calculated Raman spectra, we describe the effect of calix[4]arenes on nanoparticles electrocatalytic properties [6].

Unassisted Water-Splitting with Perovskite-Perovskite Tandem Photocathodes at 18% STH

Toward Commercially Relevant \$2/kg H₂ Austin Fehr^{1,2}, Chongwen Li³, Chase Sellers¹, Christian Conrad¹, Bin Chen³, Ayush Agrawal¹, Todd G. Deutsch⁴, Francesca M. Toma², Haotian Wang¹, Edward H. Sargent³, Michael Wong¹, Aditya D. Mohite¹ and Faiz Mandani; ¹Rice University, United States; ²Lawrence Berkeley National Laboratory, United States; ³University of Toronto, Canada; ⁴National Renewable Energy Laboratory, United States

Integrated photoelectrochemical devices have been proposed as a long-term, low-cost alternative to PV-electrolyzer systems for solar fuel production, but have historically lagged in performance metrics including efficiency, lifetime, and notably cost. We report technoeconomic analysis showing the critical role of photoabsorber and electrocatalyst cost in PEC devices, highlighting perovskite-perovskite tandems with low-PGM electrocatalyst loading as a platform capable of reaching \$2/kg H₂. We demonstrate a technoeconomically-informed approach to PEC system design using a perovskite-perovskite tandem device encapsulated by a conductive adhesive-barrier. Through optimization of reactor design, electrolyte composition, and catalyst content, we show that the cost of unassisted PEC water-splitting can be reduced without compromising on stability or efficiency, ultimately reaching 18% STH with 10 µg Pt/cm² HER catalyst loading and an Ir-free anode in acidic media. These findings show that device cost can be decreased without compromising, or even with improvement, on performance parameters in PECs.

1:45 PM EN07.13.02

Phase-Controlled Growth of Cobalt Oxide using Atomic Layer Deposition for Photoelectrochemical

Water Splitting Swapnil Nalawade¹, Moha F. Hossen¹, Valentin Craciun², Dhananjay Kumar¹ and Shyam Aravamudhan¹; ¹North Carolina A&T University, United States; ²National Institution for Laser, Plasma and Radiation Physics, Romania

Conformal cobalt oxide thin films, grown using an atomic layer deposition (ALD) method, have been found to possess remarkable photocatalytic capabilities assisted for solar-driven water oxidation. The present study has focused on establishing a structural property relationship to accomplish superior photoelectrochemical properties. During the ALD, bis (N-t-butyl-N'-ethylpropanamidate) cobalt (II) was used as a precursor with water vapor as a co-reactant. The ALD films, grown in the temperature range of 150 – 300⁰ C, were characterized using x-ray diffraction (XRD), x-ray photoelectron spectroscopy (XPS), atomic force microscopy (AFM), and Raman spectroscopy. XRD and Raman spectroscopic analysis has indicated that cobalt oxide film has a phase change from rock-salt (CoO) to cubic spinel (Co₃O₄) structure around a temperature of 300⁰ C. AFM has confirmed the flat deposition of cobalt oxide with RMS roughness less than 1 nm. The characterization techniques employed in this study have provided valuable insights into the structural and electrochemical properties of Co₃O₄. We have found that the overpotential for the solar-driven oxygen evolution reaction during water splitting is nearly 40% lower for the cubic spinel structure than for the rock salt structure.

This work was supported by a DOE EFRC at North Carolina A&T State University on the Center for Electrochemical Dynamics And Reactions on Surfaces (CEDARS) via grant #DE-SC0023415.

2:00 PM EN07.13.03

Electrosynthesis of Ethylene Oxide from CO₂ and Water Only Wan Ru Leow¹ and Edward Sargent²; ¹Agency for Science, Technology and Research (A*STAR), Singapore; ²University of Toronto, Canada

Ethylene oxide (EO) is among the world's most abundantly produced commodity chemicals due to its importance in the plastics industry, notably for manufacturing polyesters and polyethylene terephthalates (PET). The electrochemical production of EO from carbon dioxide (CO₂), water, and renewable electricity, can enable the consumption of 2 tons of CO₂ per ton of EO produced, in contrast to the emission of ~2 tons of CO₂ per ton of EO produced in existing thermochemical routes. This is achieved through an extended heterogeneous:homogeneous interface, using chloride as a redox mediator in conjunction with barium oxide-modified iridium oxide (BaO_x/IrO₂) catalysts.^{[1] [2]} The catalysts enabled EO FE of 85-91% and a selectivity of 98% in a current density range from 100 to 1500 mA/cm². When integrated into flow battery-analogue electrolyzer with an O₂/H₂O redox couple, we achieve record low energy input of 5.3 MJ/kg of EO, comparable to that of (emissions-intensive) existing industrial processes.

2:15 PM EN07.13.04

Tandem Electrosynthesis of Acetate on a Silver-Copper Oxide Catalyst Roham Dorakhan¹, Byoungsoon Lee¹, Ivan Grigioni², David Sinton¹ and Edward H. Sargent¹; ¹University of Toronto, Canada; ²Università degli Studi di Milano, Italy

Acetic acid is an important chemical feedstock with wide applications in pharmaceuticals, food and

clothing. The electrocatalytic synthesis of acetic acid from CO₂ offers a low-carbon alternative to traditional synthetic routes. The direct electroreduction CO₂ suffers from a substantial CO₂ crossover energy penalty, and recent CO₂ crossover mitigation strategies having significant energy penalties themselves.

In this work, we demonstrate a two-step approach, where CO₂ is initially converted to CO using a solid-oxide electrolyzer, followed by a CO electroreduction system that electrochemically converts CO to acetic acid. Solid-oxide electrolyzers do not suffer from the CO₂ crossover issue, and have been shown to operate in an industrial setting. The bottleneck in this synthetic approach is hence identified to be the CO electroreduction system. Current CO-to-acetate catalysts do not operate at the desired performance metrics, with selectivity ranges of 20 – 48%. Moreover, the system should produce acetic acid a sufficiently high concentration to minimize separation costs.

Here we report a catalyst design strategy in which off-target intermediates (such as ethylene and ethanol) in the reduction of CO to acetate are destabilized. A porous Cu₂O nanoparticle structure is first synthesized, and galvanic replacement of Ag at various loadings produced a alloy surface with near-atomic level dispersion. On the Ag–Cu₂O catalyst with optimized loading, the destabilization of off-target intermediates leads to an acetate Faradaic efficiency of 70% at 200 mAcm⁻². The destabilization is investigated by a combination of *operando* Surface Enhanced Raman Spectroscopy (SERS) and theoretical modeling using Density Functional Theory (DFT). The destabilization is shown to affect all pathways of C₂ hydrocarbons, however ethylene and ethanol pathway are rendered energetically inaccessible, while the acetate pathway remains open. Moreover, we demonstrate 18 hours of stable operation of the catalyst in a membrane electrode assembly; the system produced 5 wt% acetate at 100 mAcm⁻² and a full-cell energy efficiency of 25%, a twofold improvement on the highest energy-efficient electrosynthesis in prior reports.

Cu Surface Chemistry in Acid Media:Vibrational Spectroscopy, Mass Spectrometry and ECSTM Measurements David Raciti, Angela R. Hight Walker and Thomas Moffat; NIST, United States

Copper electrodeposition is a central process in the metallization of microelectronics and more recently has found use as an important electrocatalyst in the conversion of CO₂ to hydrocarbons. Gaining mechanistic insight into the reactivity of Cu surfaces requires *in situ* and better still *in operando* measurements. Herein the utility of the combination of vibrational spectroscopy (SEIRAS, SHINERS), electrochemical mass spectrometry (EC-MS) and scanning tunneling microscopy (ECSTM) to examine the competitive and co-adsorption interactions between potential dependent halide adsorption, molecular adsorption, underpotential metal deposition and hydride formation on low index Cu single crystals surface will be detailed. Further still, the opportunity to study the impact of such interactions on metal deposition reactions will also be explored.

Urea Oxidation Reaction on Ni-Based Electrocatalysts: Combating with Oxygen Evolution

Reaction. Jiseon Kim and Kangwoo Cho; Pohang University of Science and Technology, Korea (the Republic of)

Along with the societal pursuit of sustainable carbon neutrality, electrochemical urea oxidation reaction (UOR) has been an overarching subject to substitute oxygen evolution reaction (OER), primarily owing to lower thermodynamic requirement (0.37 V) for molecular hydrogen generation. The UOR not only enhances the energy conversion efficiency from renewable energy into molecular hydrogen, but also reduces carbon and nitrogen pollution loadings of urea-rich wastewater. Nickel-based catalysts are up-to-date the most widely investigated materials as the UOR electro-catalyst. However, the UOR overpotential is in-fact predominantly consumed for formation of Ni^{3+} (the most common active site), and the gap between the onsets of UOR and OER is only < 300 mV. Moreover, competitions between UOR and OER has been noted to explain a current collapse near the OER onset. This presentation introduces our recent findings on Ni-based UOR electro-catalysts that were prepared by i) potentiostatic dealloying of commercial NiFe alloys under variable pH, and ii) one-pot thermochemical treatment of NiFe alloy foam in oxalic acid to create a self-supporting O-NFF. Regarding the former electrocatalysts, this study revealed that current inflections near the OER onset in the presence of urea could be associated with $Ni^{3+/4+}$ redox peaks. The peak location and intensity, in relation with the OER activity during repetitive cyclic voltammetry unraveled the roles of Fe on OER, under dynamic dissolution and precipitation of Fe to/from the electrolyte. Therefore, accelerated UOR kinetics on Ni^{3+} would be the key consideration to avoid interferences from OER. To this end, Cutting-edge figure-of-merits for UOR were noted for O-NFF including 500 mA cm^{-2} of current density at 1.47 V RHE and exceptionally low Tafel slope of 12.1 mV dec^{-1} (in 1 M KOH with 0.33 M urea). The oxalate ligands withdraw electrons from Ni-motif and provide H-bonding sites for energetically favorable binding of Ni with urea-O. Incorporation of Fe escalate the inductive charge accumulation on oxalate-O and strengthen the H-bonding to accelerate the C-N cleavage of $*CO(NH)_2$. The findings of this study could be further utilized within wastewater electrolysis cell for water-energy nexus.

Accelerated Oxygen Chemisorption and ORR Activity on Cerium-Doped $LaFeO_3$ Perovskite Oxide

Myungju Kim¹, Kanghee Jo¹, Yongnam Kim² and Heesoo Lee¹; ¹Pusan National University, Korea (the

Republic of); ²Korea Testing Laboratory, Korea (the Republic of)

LaFeO₃-based perovskite oxides, which have both electronic conductivity and ionic conductivity, have been actively studied in energy conversion and storage fields including solid oxide fuel cells and metal-air batteries. Recently, doping elements with various valence states have been focused to enhance the electrochemical properties of LaFeO₃. Cerium forms a defect-rich structure since cerium has multivalence of Ce³⁺/Ce⁴⁺. These formed defects play a crucial role in catalytic activity by accelerating the adsorption of oxygen on the surface. Therefore, it is crucial to examine the effect of cerium doping on the electrochemical properties of LaFeO₃, specifically considering the influence of the defect structure. This study investigated the effect of cerium doping on the polarization resistance of LaFeO₃ perovskite oxide (LCFO_x, x = 1, 3, 5, 7) and analyzed the underlying mechanism in terms of the defect structure. The X-ray diffraction (XRD) patterns of the crystal structure revealed that doping cerium with ranging from 0 to 5 mol% resulted in the formation of a single perovskite phase with an orthorhombic structure of *Pnma* space group. The Rietveld refinement analysis further demonstrated that cerium led to a decrease in the octahedral tilting and an increase in the Fe-O-Fe bonding angle, respectively. The formation of oxygen vacancies was observed through the electron paramagnetic resonance (EPR) spectrum and O 1s core-level spectrum. The La 3d and Fe 2p core-level spectra indicated that cerium doping did not affect the valence state of La ions, while it caused a reduction in the Fe³⁺. Additionally, the O K-edge X-ray absorption spectrum (XAS) showed the hybridization between Fe 3d and O 2p orbitals upon cerium doping. The O₂-temperature programmed desorption (O₂-TPD) profile confirmed an increase in the concentration of surface-active oxygen species with cerium doping. The area-specific resistance (ASR) gradually decreased from 11.36 Ωcm² (LFO) to 4.65 Ωcm² (LCFO5) as the amount of cerium doping increased. Notably, the polarization resistance in the low-frequency range (R₂) exhibited a significant reduction of approximately 68%, indicating enhanced ORR activity attributed to accelerated oxygen adsorption. The ORR reaction steps were analyzed alongside electrochemical impedance spectroscopy (EIS) data using the distribution of relaxation times (DRT) technique.

9:15 PM EN07.14.03

Electrochemical Energy Harvesting from Phototrophic Biofilms Seeded with Wild-Type and Functionally Coated Phototrophs Mohd Golam Abdul Quadir¹, Melania Reggente², Charlotte Roullier², Ardemis Boghossian², Massimo Trotta³ and Fabian Fischer¹; ¹University of Applied Sciences and Arts of Western Switzerland, Switzerland; ²École Polytechnique Fédérale de Lausanne, Switzerland; ³Institute for Physical-Chemical Processes-CNR, Italy

Oxygenic phototrophs have been reported to produce electrical current in a photoresponsive manner when interfaced with electrodes [1]. It has been experimentally demonstrated that the origin of this electron flux emanating from the cellular structures is a water splitting reaction at the oxygen-evolving complex of the Photosystem II [2]. However, this mechanism of electron conduction across the cell wall of oxygenic phototrophs is not deciphered with certainty. Additionally, the oxygenic microenvironment of these organisms further reduces the photocurrent output. The scientific community aims to exploit this low-magnitude electrical output for clean energy harvesting. To this end, phototrophs like *Rhodobacter capsulatus* [3] and *Synechocystis* PCC6803 (**unpublished data**) have been imparted with functional coatings for enhanced charge extraction from cells that increased the current output with anodically biased electrodes.

This study aims to investigate the electrochemical performance of biofilms initiated with wild-type and functionally coated cells. We optimize these biofilms for long-term viability that can be integrated into an electrochemical device for sustainable energy harvesting in a cost-effective manner. Additionally, we also

study the influence of gradually increasing biochemical complexity of the extracellular biofilm matrix that ensues in response to various environmental and electrochemical stimuli over time. The biofilm matrix is a dynamic and biochemically active entity that helps the microorganisms to survive harsh environmental conditions [4]. In the context of low electrogenic performance of phototrophs, its role in electron conduction is also not well investigated. We deal with this aspect from both biochemical and material science perspectives [5]. Preliminary results indicate an influence of various biological, abiotic, and interfacial phenomena on electrochemical results.

Electrochemical Chloride-Mediated Marine Carbon Dioxide Removal Seoni Kim, Michael Nitzsche, Simon Rufer, Kripa Varanasi and T. Alan Hatton; MIT, United States

Negative Emissions Technologies (NETs) are crucial to avert catastrophic disruption of global climate patterns caused by the continuing atmospheric accumulation of CO₂ due to industrial emissions. The recent surge of interest in NETs in which CO₂ (currently at an atmospheric concentration of ~420 ppm) is removed from the ambient environment itself, by, e.g., direct air capture (DAC), has not yet been matched by a similar drive to reduce CO₂ in oceans, where increasing acidification has led to destruction of coral reefs, and reduced carbonate ion concentrations harm shellfish and other marine life. The total CO₂ accumulation rates by oceans rivals that in the atmosphere, and thus effective means for CO₂ removal could augment the other NETs to reduce the environmental burden imposed by this greenhouse gas. The concentrations in water (on a volumetric basis) are much higher at 100 mg/L than that in the ambient air (0.77 mg/L), and thus smaller volumes will need to be treated than in DAC, which could provide a processing advantage.

In current approaches for the removal of CO₂ from oceanwaters bipolar membrane catalysis water splitting coupled with electrodialysis is used to modulate the pH and thereby release the CO₂ as a gas (low pH) or carbonate salt (high pH). We have proposed an alternative approach to marine carbon dioxide removal (mCDR) that does not require expensive membranes or addition of chemicals, is easy to deploy, and does not lead to formation of byproducts or secondary streams. In this approach, the pH is regulated through a chloride-mediated reaction with electrodes in asymmetric electrochemical cells through which the seawater flows. In the acidification cell the DIC speciation shifts from bicarbonate and carbonate to CO₂ which can then be removed in a membrane contactor. The now-decarbonized water is introduced to a second electrochemical cell where the reverse reaction is promoted, the electrodes are regenerated, and the pH increases before the water is discharged back to the ocean. The CO₂ removal approach has perceived advantages in that it does not require expensive membranes or addition of chemicals, is easy to deploy, and does not lead to formation of byproducts or secondary streams.

We will discuss the overall electrochemical swing process, which can be enhanced through flexible electrode configurations to reduce transport and electrical resistances while enabling treatment of large quantities of water. Novel methods for the recovery of molecular CO₂ without the need for high vacuum desorption, and of calcium carbonate precipitates without fouling of the electrodes, will be highlighted.

9:15 AM *EN08.01.02

Bipolar Membranes for Electrochemical CO₂ Capture Chengxiang Xiang^{1,2}; ¹California Institute of Technology, United States; ²Captura Corporation, United States

Electrochemical CO₂ capture, conversion and storage can play a significant role in reducing atmospheric CO₂ concentration in the coming decades. Bipolar membranes that facilitate water dissociation reaction at the interface can be implemented in electrolysis, electrodialysis and other electrochemical devices for carbon capture, conversion, and long duration energy storage. In this talk, I will share recent developments

Updated as of October 28, 2024

in the synthesis, characterization, and electrochemical performances of catalyzed, asymmetric bipolar membranes for highly efficient acid and base generation both at Caltech and in Captura. I will talk about multiphysics modeling and simulation of BPMs for in-depth understanding of water dissociation mechanism as well as electroosmotic water transport at various current densities. Finally, I will discuss electrodialysis stacks development and deployment of Direct Ocean Capture (DOC) pilot systems for electrochemical CO₂ capture at a near-ocean site.

9:45 AM EN08.01.03

Elucidating the Effect of Solvent on Electrochemical Reduction of CO₂ using a Data Driven Approach Matthew Bliss, Aniket Kapote, Kuldeepsinh Raj and Nav Nidhi Rajput; Stony Brook University, The State University of New York, United States

The electrochemical reduction of carbon dioxide (CO₂) has great potential to alleviate important environmental problems: the elevated presence of CO₂ in the atmosphere and the need for fossil fuel-based production of fuels and commodity chemicals. However, the application of electrochemistry to CO₂ reduction is hindered by low selectivity, activity and stability¹. In aqueous media, the competing hydrogen evolution reaction (HER) and low solubility of CO₂ remain unresolved problems for selectivity; the use of nonaqueous solutions presents a possible path to mitigate these problems^{2,3}. However, the current aprotic solvents are limited by their high viscosity, large overpotential due to absence of protons, and instability of reaction key intermediates. To overcome these challenges, we investigate the effect of the solvent's chemical class on properties relevant to the CO₂ reduction reaction such as CO₂ solubility, electrochemical stability, and transport properties using high-throughput multi-scale simulations. High-throughput density functional theory (DFT) calculations and classical molecular dynamics (CMD) simulations are performed to build large databases of electronic, thermodynamic, structural and dynamical properties using the computational infrastructures developed by our lab, coined **MISPR** (Materials Informatics for Structure-Property Relationships - <https://github.com/molmd/mispr>) and **MDPropTools** (<https://github.com/molmd/mdproptools>)⁴. In this work, we uncover important correlations between molecular features of solvents and bulk ensemble properties of electrolytes for CO₂ electroreduction.

Molecular Design of Redox-Active Materials for Selective Electrochemical Separations Xiao Su;
University of Illinois Urbana-Champaign, United States

Achieving molecular selectivity is a critical challenge for deploying electrochemical separations for resource recovery, chemical and biochemical manufacturing, and environmental remediation. Leveraging redox-electron transfer can be a powerful pathway for accelerating separation kinetics, enhancing adsorption uptake, and controlling voltage for lower energy consumption. Here we discuss the molecular design of electroactive materials for two major directions in electrochemical separations: redox-mediated electrosorption and redox-mediated electrodialysis.

First, we discuss the development of redox-active materials for the selective binding of dilute ions from multicomponent mixtures. We highlight the bottom-up design of redox-copolymers, and synthetic modifications for enhancing affinity and reversibility. We demonstrate their capability for the capture and remediation of perfluoroalkyl substances (PFAS) through combinatorial monomer design, as well as strategies for coupling separation and reaction for the reactive separation of nitrate to ammonium. We unravel structure-function relationship between the redox-polymers and target species, such as the control of surface charge and hydrophobicity for the capture of both short and long-chain PFAS.

Next, we discuss new materials design strategies for advancing redox-electrodialysis, including translating concepts from redox-flow batteries to improve membrane and redox-electrolyte selection. We substitute costly ion-exchange membranes with affordable nanofiltration membranes and soluble redox-copolymers, which significantly reduce energy consumption and the cost of desalination, while enhancing membrane stability. Our work establishes rational design principles of redox-materials, tailoring their properties for selective electrochemical separations.

Engineering Porous Carbon Electrodes for Selective Boron Removal via Electrosorption Weiye Pan¹, Sohum Patel¹, Eungjin Ahn², Arpita Iddya¹, Debashis Roy², Jovan Kamcev² and Menachem Elimelech¹; ¹Yale University, United States; ²University of Michigan–Ann Arbor, United States

Boron (B) is ubiquitous in seawater in the form of boric acid (H_3BO_3 , $\text{pK}_a = 9.24$) at low concentrations (4-6 mg/L). While boron is an essential micronutrient, excessive intake can be highly toxic to humans and many crops. Therefore, effective removal of boron during seawater desalination is crucial. Reverse osmosis (RO) membranes alone are insufficient for reducing the levels of uncharged boric acid to acceptable levels for human consumption and agricultural use. Consequently, additional high-pH RO passes are necessary, leading to an increase in overall energy consumption of ~10-15%. Furthermore, this non-selective removal process also eliminates other beneficial minerals, necessitating subsequent remineralization. An alternative method for boron removal would benefit from reduced energy consumption, lower capital costs, and the elimination of chemical dosing requirements.

Boron is well known to react with 1,3 diols to form characteristic borate-ester complexes. Selectivity for boron over other species is enhanced by the presence of two or more hydroxyl groups in the *cis* position (*vis*-diols); hence, numerous sorbents which incorporate *vis*-diol moieties have been developed. Nevertheless, the hydrophobic nature of the polymeric backbone hampers efficient boron transport, leading to slow kinetics and the need for large bed volumes, which are costly. The polymeric structure repeated swelling and shrinking during regeneration cycles accelerate capacity decline, shortening the resin lifespan. Regeneration requires substantial amounts of strong acids or bases, increasing financial and environmental burdens.

Electrosorption has emerged as a highly promising process for water deionization. It exhibits exceptional efficiency when applied to low salinity waters and for removing small quantities of salts. Consequently,

utilizing electrosorption for boron removal, particularly from first-pass seawater RO permeate, could potentially be a promising application of this technology. We have recently developed a novel bipolar membrane (BPM) assisted electrosorption process for boron removal. With an applied voltage (< 1.2 V), BPM-facilitated water dissociation occurs with the anion-exchange layer (AEL) facing the anode, thus producing a high pH on the anode side, as is required for boron electrosorption. By further enhancing the selectivity of boron over competing anions (e.g., Cl^-), we can significantly reduce the specific energy consumption of the process (~ 2.5 kWh g-B $^{-1}$). This advancement would also enable direct application of the technology, unlocking its full potential.

Herein, we developed novel porous carbon electrodes that can selectively remove boron over competing anions during the BPM-assisted electrosorption process. We employed two fabrication methods for these porous carbon electrodes. In the first method, we deposited a functionalized polymeric thin film [e.g., poly(vinyl alcohol) and polydopamine] on porous carbon electrodes that could selectively allow borate anions to pass through over other competing anions in the presence of an electric field and accumulate in the electric double layer of the electrode micropores. In the second method, boron selective functional groups (e.g., N-methyl-D-glucamine) were directly appended to the micropore wall of the porous carbon electrode via chemical modification techniques, thereby eliminating the mass transfer limiting polymer layer between the carbon pore wall and the aqueous solution containing boron. To evaluate the boron removal capabilities of these electrodes, we conducted experiments using a custom-built BPM-assisted electrosorption cell with a solution mimicking first-pass seawater RO permeate (i.e., 5 mM NaCl and 1 mM B). The B/Cl selectivity of various electrodes was also calculated to compare their performance. Furthermore, detailed characterizations and molecular dynamic simulations were performed to gain deeper insights into the underlying mechanisms.

Perfect Monovalent Cation Selectivity with Capacitive Deionization [Ankita Mathur](#)¹, Sally Nijem², Rana Uwayid¹, Zohar Sahray¹, Amit N. Shocron¹, Charles Diesendruck² and Matthew Suss^{1,2,2};

¹Technion- Israel Institute of Technology, Israel; ²Technion–Israel Institute of Technology, Israel

Irrigation is a huge consumer of freshwater, typically $> 50\%$ of the total water usage for most countries. When treating water for irrigation use, selective removal of monovalent sodium ions is a particular challenge, but necessary for cost-effective irrigation and resource recovery. Presence of excessive sodium ions in water may lead to low crop yield, decreased soil permeability and water infiltration rate, but other ions such as calcium should not be removed. Capacitive deionization (CDI) is an emerging electrochemical technology promising towards highly selective removal of ions from water via electrosorption¹. Ion selectivity can be tuned by modifying the electrode pore structure and surface chemistry, in addition to cell parameters affecting electrosorption dynamics^{2,3}.

Here we show that utilizing judicious functionalization of microporous activated carbon cloth (ACC) electrodes can provide for exceptional selectivity towards removal of Na^+ from feedwater. We show that a charging CDI cell can remove ~ 130 $\mu\text{mol Na}^+$ per gram carbon, with zero Ca^{2+} electrosorption, from a feed of 2 mM CaCl_2 and 17 mM NaCl, with low energy consumption of 0.36 kWh/m³. We further describe the mechanism enabling such breakthrough selectivity results, which are based on the discovery of induced electric charge in asymmetric CDI cells. This study paves the way for more tunable selectivity and wider range of separations with CDI, and is especially promising for single-step treatment of water for use in irrigation.

Electrochemical Separation and Purification of Tungsten and Cobalt for High-Value Metals

Recovery from Cemented Tungsten Carbides Shao-Chi Lo, Tzu Ming Cheng and Chih-huang Lai; National Tsing Hua University, Taiwan

Cemented tungsten carbide (WC-Co), which consists of high-value metals such as tungsten (W) and cobalt (Co), is one of the important hard materials for cutting tools in industrial applications. The recovery and production of these valuable elements have drawn much attention due to the increased demand in the end-user industries such as mining, automotive, electronics, and even aerospace. Although the recycling methodology of WC-Co scraps has been developed for decades, energy consumption and wastewater discharge in the whole process remain a big concern for conventional approaches. Previously in the beginning of the year, our group demonstrated an energy-efficient approach called rapid breakdown anodization (RBA) for the first time to separate W and Co, and then convert WC-Co into high-purity hydrated tungsten oxide ($\text{WO}_3\cdot\text{H}_2\text{O}$) and Co metal in one-step electrochemical process. By using RBA with WC-Co as a sacrificial electrode in acidic aqueous solution, effective cobalt leaching was achieved without encountering anodic passivation issue during the electro-dissolution. However, elements such as nickel (Ni), iron (Fe), and chromium (Cr) remained in the cobalt-rich (Co-rich) solution and became major impurities in recovered Co metal owing to large overpotential during RBA. To fulfill the electrochemical separation and purification of tungsten and cobalt for high-value metals recovery, it is critical to explore selective adsorption materials and membranes for Co-rich solution purification. Here, we present the preliminary results on the selective removal of impurities such as Fe, Ni, and Cr from Co-rich solution by using alumina powder so that Co metal purity could be further enhanced after RBA. Eventually, an effective and environmentally-friendly pathway for WC-Co recycling is proposed with a significantly simplified process compared to traditional hydrometallurgical methods.

SESSION EN08.02: Electrochemical Separations II

1:30 PM *EN08.02.01

Towards Accelerated Design of Selective Membranes: Integrating Theory, Characterization and Simulations Ryan S. Kingsbury; Princeton University, United States

Precise separation materials capable of selectively permeating a single ion from an electrolyte have the potential to significantly enhance the performance of numerous electrochemical technologies, including processes for resource extraction, industrial waste recycling, and water purification. For example,

materials that can selectively remove lithium from geothermal brine would contribute to stabilizing supply chains for clean energy technology.

Polymer membranes are a proven technology capable of other types of ion separations, but engineering them for precise selectivity is extremely challenging because differences in solute size or charge, which have historically guided membrane development, are often absent in ion-ion separations. As such, the next generation of membranes must go beyond size and charge to exploit differences in solute chemistry.

New approaches to membrane research are critical for efficiently meeting this need. Characterization methods and transport models must evolve to more explicitly connect to the molecular scale interactions of interest, and more emphasis must be placed on understanding 1) which membrane design strategies are most likely to be effective for a given separation problem and 2) how improved material performance would translate into process performance.

This talk will first present membrane performance data compiled from more than 40 studies across 8 different applications to identify strengths and weaknesses of current materials. Next, I will describe a theoretical framework called Barrier Network Analysis that quantitatively relates conventional membrane characterization data (such as conductivity and partition coefficients) to activation energy barriers associated with partitioning and diffusion of individual species. This kinetics-first approach connects experimental observations more directly to the molecular-scale energetic landscape and yields information that is more naturally comparable to the outputs of molecular simulations, which are another important tool for understanding chemical interactions between solutes and membrane materials.

Finally, I will present results from a study of alkali chloride separation by a water-stable polymer of intrinsic microspore (AquaPIM) membrane and a commercial cation exchange membrane. Using Barrier Network Analysis, we demonstrated that crossing the solution-membrane interface (i.e., partitioning) has a higher activation energy barrier than diffusion through the polymer for both membranes. This insight contrasts with historical assumptions in the popular Solution-Diffusion model and suggests that selective membrane design should, at least in some cases, prioritize selective interfaces rather than engineering the polymer itself.

I will close by discussing other implications of these findings for membrane design, and suggest ways that Barrier Network Analysis (and related approaches) can be used to guide future research.

2:00 PM EN08.02.02

Ratchet Based Ion Pumps for Selective Ion Separation [Alon Herman](#)¹, Dafna Meltser¹, Eden Grossman¹, Karen Shushan¹, Joel W. Ager², Shane Ardo² and Gideon Segev¹; ¹Tel Aviv University, Israel; ²University of California, Irvine, United States

Even though highly selective ion pumps are found in the membrane of every living cell, artificial ion selective separation is a longstanding unmet challenge in science and engineering. The development of a membrane-based ion separation technology can drive a dramatic progress in a wide range of applications such as: water treatment, extraction of lithium from seawater, solar fuels and more. In this contribution, we report the experimental demonstration of ion pumps based on an electronic flashing ratchet mechanism.

Electronic flashing ratchets are devices that utilize a temporal modulation of a spatially asymmetric electric field to drive steady state current. Like peristaltic pumps, where the pump mechanism is not in

direct contact with the pumped fluid, electronic ratchets induce a net current with no direct charge transport between the power source and the pumped charge carriers. Thus, electronic ratchets can be used to pump ions in steady state with no electrochemical reactions between the power source and the pumped ions resulting in an 'all-electric' ion pump.

Ratchet-based ion pumps (RBIPs) were fabricated by coating the two surfaces of nano-porous alumina wafers with gold, thus forming nano-porous capacitor-like devices. The electric field within the nano-pores is modulated by oscillating the capacitor voltage. Thus, when immersed in a solution, ions within the pores experience a modulating electric field resulting in ratchet-based ion pumping. The RBIPs performance was studied for various input signals, geometries, and solutions. RBIPs were shown to drive ionic current densities of several $\mu\text{A}/\text{cm}^2$ even when opposed by an electrostatic force. A significant ratchet action was observed with input signal amplitudes as low as 0.1V thus demonstrating that RBIPs can drive an ionic current with no associated redox reactions.

An important hallmark of ratchets is the ability to invert the direction of particle flow with a change in the input signal frequency. The stopping frequency, which is the frequency at which the particle flux changes its direction, is determined by the potential distribution and particles transport properties. As a result, for a given ratchet, there can be a frequency at which particles with the same charge, but different diffusion coefficients, are transported in opposite directions. This concept, that was never applied to ion separations, can enable the extraction of ions with extremely low relative concentrations if their diffusion coefficient is even slightly different from the main ions in the solution. We show by simulation, that for the prevalent ions in water, ions with a relative diffusion coefficient difference as small as 1% can be driven to opposite directions with a velocity difference as high as 1.2 mm/s. Since the direction of ion transport is determined by the input signal frequency, the sorting properties can be tuned in real time providing a simple fit-to-purpose solution for a variety of ion separations applications.

2:15 PM EN08.02.03

Isotope Separation by Centrifuging an Electrolytic Solution Yuan Yang; Columbia University, United States

Enriched isotopes are critical to wide applications, such as nuclear reactors (e.g., ^6Li , D), radiology (^{18}O), and fundamenal sciences (e.g., tracer and synthesizing superheavy elements). Current methods, such as gas centrifuge, requires hazardous precursors and have limited applicability. Here we developed a general method of separating isotopes by centrifuging a liquid (e.g., salt solution), which is governed by electrochemical transport equations in electrolytes. This technique can be applied to the majority of elements and does not require gasification of isotopes. We have demonstrated high separation factors of 1.046-1.067 per unit neutron difference (e.g., 1.434 in $^{40}\text{Ca}/^{48}\text{Ca}$, 1.134 in $^{16}\text{O}/^{18}\text{O}$), which are better than or comparable to various conventional methods. Modeling was established to understand the process, which is in good agreement with experimental results. The scalability of the technique has also been demonstrated by performing a three-stage enrichment of ^{48}Ca .

Salinity Gradient Energy Harvesting using MXenes Husam N. Alshareef¹, Seunghyun Hong² and Jehad K. El-Demellawi¹; ¹King Abdullah University of Science and Technology, Saudi Arabia; ²Khalifa

University, United Arab Emirates

2D MXene can be constructed into membranes or electrodes for ionic or molecular separation due to their intriguing features such as hydrophilicity, abundant surface terminal groups, and structural and chemical tunability. The high aspect ratio of MXene nanosheets provides nanochannels as diffusion paths for solute transport. The introduction of pores and modification of the interplanar spacing between neighboring sheets can also contribute to the formation of fluidic nanochannels. By tailoring the interlayer spacing of 2D MXene assemblies, it is possible to establish well-defined transport channels that enable size-selective sieving for specific ions or molecules. In addition to the interlayer distance, the lateral dimension (sheet size) of MXene nanosheets can be modified by adjusting synthesis conditions. Through geometric control over the constituent MXene sheets, the extended fluidic paths across the stack membranes provide the selective transport of solutes, which serves as the basis for the selectivity within layered membranes. The fluidic channel length in layered membranes can also be introducing controllable pores within the MXene sheets, which can enhance ionic diffusion kinetics. The ionic transport can further be enhanced by tuning the membrane thickness and using external stimuli that can enhance ionic transport within MXenes.

These fundamental features of ionic and molecular transport in MXenes can be the basis of many types of devices including sensors, iontronic devices, ionic separation, heavy metal ion extraction, capacitive deionization, and energy harvesting and storage. In this talk, I will discuss leveraging these basic concepts to develop MXene energy harvesters based on salinity gradients, thermal gradients, and ultrasound power absorption.

4:00 PM EN08.02.05

Monovalent Selective Cation-Exchange Membranes for Electrodialysis Pretreatment of Brackish Water Reverse Osmosis Brielle Januszewski, Hanqing Fan and Menachem Elimelech; Yale University, United States

Brackish water reverse osmosis (BWRO) can supplement dwindling freshwater resources because of its inland availability and energy efficient treatment compared to seawater. However, water recovery is limited to 50-85% by mineral scaling from primarily divalent cation-based scalants, such as Ca^{2+} and Mg^{2+} , leaving significant quantities of water unusable and in need of costly disposal. Thus, removing scale-forming divalent ions before RO is the key to increasing water recovery, but current approaches, such as solvent extraction or adding scale inhibitors, are thermally or chemically intensive, creating a need for an effective, additive-free scale-controlling strategy. Electrodialysis (ED) could be a thermal and chemical input free brackish water pre-treatment that can remove scale forming ions before the RO step by separating incoming brackish water, using valent selective cation exchange membranes (vsCEMs), into streams that are rich with monovalent or divalent cations. This valent selective ED could be used in a coupled ED-RO hybrid system to achieve high water recovery (>90%) and would be tunable for use with a variety of BW feeds, thus mitigating scaling, improving zero liquid discharge (ZLD) management, reducing the total levelized cost of treatment and process downtime, and extending the overall system lifespan. Here, we focus on monovalent selective CEMs (msCEMs) which enable monovalent cation transport and reject divalent cations. There are a few commercially available msCEMs but they suffer from low monovalent-divalent selectivity. Previous work to improve msCEMs revolves around charge-based exclusion, which is typically achieved by including a thin coating of oppositely charged functional groups (having the same charge as the counter-ions) on the membrane surface, which more strongly repels divalent ions. However, a systematic study of the fabrication and operating conditions and their effect on membrane performance has not yet been performed, preventing them from further improvement.

Here, we use a commercial CEM and two polyelectrolytes of opposite charge, poly(allylamine hydrochloride) (PAH) and poly(styrene sulfonate) (PSS), to deposit a thin selective layer using layer-by-layer assembly, whose facile fabrication and tunability allows for a cohesive study of structure-property-performance relationships within the same framework. Our results using a (PAH/PSS)_{2.5} deposition on a commercial support show that we can make consistent, defect-free membranes with average Na⁺/Mg²⁺ selectivities of ~25, showing a noticeable increase over the support layer's 0.5 Na⁺/Mg²⁺ selectivity. Moreover, we show that the limiting current of these membranes is highly dependent on the ionic strength of the diluate and concentrate solutions, regardless of the ionic species present, with limiting current increasing with solution ionic strength. We show that our membranes are significantly monovalent cation-selective, while systematically revealing the relationships between the separation performance and operating conditions including applied current density, diluate and concentrate solution composition, and thin film composition. This work would advance the fundamental understanding of ion transport in ion exchange membranes and offer critical guidance for applying valent-selective ion exchange membranes in water and wastewater treatment.

4:30 PM EN08.02.07

Ex-Situ Characterization of Carbon Slurries for the Flow-Electrode Capacitive Desalination Yousif Alkhulaifi¹, Benjamin Alessio¹, Tomek Jaroslowski¹, Qi Jiang¹, Swetha Chandrasekaran², Alexandra Overland², Maira Cerón², Steven Hawks² and Juan G. Santiago¹; ¹Stanford University, United States; ²Lawrence Livermore National Laboratory, United States

Seawater desalination has great potential to meet the increasing global demand for freshwater. We are studying and developing a relatively new technology for desalination termed flow-electrode capacitive deionization (FCDI). FCDI cell design represents a significant development over standard capacitive deionization (CDI) cell by achieving continuous operation and the ability to process high salinity streams. These systems replace porous carbon-based solid electrodes with conductive carbon particles suspended in a continuously circulated electrolyte. We will present a study of the properties and chemistry of various carbon-based slurries. Particle type, size, shape, mass loading, and surface chemistry all play an important role in FCDI cells. Also important is the coupling among transport, charge exchange, and solution chemistry. We have developed an ex-situ experimental setup to quantify the charge transfer ability of carbon slurries, including carbon black and activated carbon. This ex-situ system enables convenient measurement of charge transport as a function of slurry properties and mixing. Our preliminary results suggest that the transport features, particle type, size, shape, and chemistry play a significant role in the charge transfer ability of the slurry.

Reinforced Composite Proton Exchange Membranes Through Polytetrafluoroethylene Surface

Modification Yeon Su Lee, Hyunjun Kim, Seonghyeon Yang, Yeji Kim and Sung-Kon Kim; Jeonbuk National University, Korea (the Republic of)

As the problems of environmental pollution and resource depletion become serious, fuel cells using hydrogen, an infinite resource that occupies most of the universe and does not emit pollution, are emerging as an alternative to solve these problems. Among fuel cell types, Polymer Electrolyte Membrane Fuel Cell (PEMFC) is attracting attention for its advantages such as high efficiency and high energy density, but it is difficult to commercialize it due to high price of fuel cell manufacturing materials. Nafion composed of a single polymer of perfluorosulfonic acid is currently the most widely used and considered a major reason for increasing the price of Membrane electrode assembly (MEA), which is a key component of a fuel cell that produces electrical energy through an electrochemical reaction. Therefore, the reinforced composite membrane is getting attention in that it can reduce the amount of ionomer impregnation and improve ionic conductivity through thinning based on the excellent mechanical properties of the support polymer. In this study, a reinforced composite membrane is produced by a surface modification of porous polytetrafluoroethylene (PTFE) through plasma-assisted silane treatment, followed by Nafion impregnation. The surface modification of PTFE is adjusted by time on plasma and silane treatments. The optimum conditions are observed at 1 min of 10 W, 100 kHz, Ar plasma and 0.5 vol% silane treatment at room temperature for 1 min. After surface modification, the surface of PTFE becomes hydrophilic with a contact angle of 65~75 °. The tensile strength and elongation at break of PTFE/Nafion were much higher than those of commercial homogeneous Nafion membranes. This PTFE/Nafion composite membrane has a tensile strength of 16 N mm⁻¹ and an elongation at break of 221 %. It also shows an ionic conductivity of 0.12 S cm⁻¹, similar to commercial homogeneous Nafion membranes.

8:00 PM EN08.03.02

Investigation of the Moisture Effects on Printed Nitrate-Selective Potentiometric Sensors for Direct Soil Monitoring Kuan-Yu Chen¹ and Joseph Andrews^{1,2}; ¹University of Wisconsin-Madison, United States; ²University of Wisconsin-Madison, United States

As the demand for sustainable and efficient agriculture grows, there is an increasing need for reliable and cost-effective methods to monitor soil nutrient levels. Printed nitrate-selective potentiometric sensors have emerged as promising tools for in situ soil monitoring, offering real-time and continuous measurements of nitrate concentrations. However, the performance and longevity of these sensors can be influenced by environmental factors, particularly moisture content in the soil. This work presents the effects of soil moisture level on the functionality and accuracy of printed nitrate-selective potentiometric sensors, with the goal of enhancing their performance and reliability for soil nutrient monitoring applications.

Building upon our prior research, we successfully manufactured inkjet printed potentiometric sensors that are specifically tailored for the detection of the nitrate in soil. The printed sensors contain two electrodes, the reference (RE) and ion-selective electrode (ISE). The ISE is covered by a drop-casted nitrate-selective membrane, which only allows the ion of interest in soil, nitrate in this work, interacting with electrode. This interaction generates a measurable potential difference across the RE and ISE, which can be correlated to the nitrate concentration in the soil.

To measure nitrate contents in moist soil environments, a porous hydrophilic polyvinylidene fluoride (PVDF) film is introduced into the potentiometric sensor. The PVDF shields the electrodes from charged soil particles, while allowing the passage of water. This feature ensures effective operation and provides protection from the soil environments, enabling direct sensing of nitrate in a medium that is similar to in

aqueous solutions. The printed potentiometric sensors exhibit sensitivities ranging from sensitivities 45 - 50 mV/dec. To evaluate the performance of the printed potentiometric sensors under realistic conditions, the sensors are tested in two common crop field soil texture classes: sandy soil and silt loam soil. These soil types were chosen to represent practical scenarios encountered in agricultural settings. A range of nitrate concentrations, representative of typical agricultural scenarios, are applied to the sensors, and the response of the sensors is recorded under different moisture conditions.

This study will provide valuable insights into the impact of moisture on the performance of printed sensors and contribute to the development of robust and moisture-tolerant sensor designs for accurate soil nutrient monitoring in agricultural systems. By understanding the impact of moisture on sensor performance and developing moisture-tolerant designs, this research contributes to the development of robust and reliable real-time sensing systems for precision agriculture. This research holds significant potential to advance the field of precision agriculture, enabling farmers to optimize fertilizer management practices, reduce environmental impacts, and optimize crop yields in a sustainable manner.

8:00 PM EN08.03.03

Interlocking Bipolar Membranes for Efficient Electrochemical Separations

Hyeon-Bee Song and Moon-Sung Kang; Sangmyung University, Korea (the Republic of)

A bipolar membrane (BPM) is a special type of ion-exchange membrane in which an anion-exchange layer (AEL) and a cation-exchange layer (CEL) are combined. Water molecules can be easily dissociated at the interface of the BPM by the strong electric field generated when a reverse bias voltage is applied through the membrane. The generated proton and hydroxide ions move out through the CEL and AEL, respectively, to produce acid and base solutions. Meanwhile, under a forward bias condition, protons and hydroxide ions move to the bipolar interface and neutralized again. Neutralization energy is generated according to the concentration of proton and hydroxide ions which move through the BPM and can be expressed as a junction potential (JP) value. When a BPM having an ideal JP is applied to an electro-membrane process, high separation and energy efficiencies can be obtained. In addition, the BPMs should have a highly adhesive bipolar junction for the long-term operation of electro-membrane processes. In this work, a novel BPM with an ideal JP and a highly adhesive bipolar junction property was developed and applied to several electrochemical separation processes such as acid-base flow battery and direct seawater electrolysis. The specially designed BPM was fabricated with poly(phenylene oxide) (PPO) based ionomers. In addition, an iron-based catalyst and a reinforcing material were introduced for excellent water-splitting performance and interfacial durability between the two ion-exchange layers, respectively. The prepared BPM not only had excellent interfacial adhesiveness and mechanical properties but also exhibited high water-splitting efficiency of 98% or more. The electrochemical separation processes employing the prepared BPM exhibited excellent performances comparable with those of commercial BPMs. This work was supported by the National Research Foundation of Korea (NRF) grants funded by the Korean government (MEST) (NRF-2022M3C1A3081178 & NRF-2022M3H4A4097521).

Enhancing Ion Conductivity and Robustness in Gel Polymer Electrolytes with a Semi-Interpenetrating Polymer Network Structure Seonghyeon Yang, Yeon Su Lee and Sung-Kon Kim; Jeonbuk National University, Korea (the Republic of)

In this study, we describe the synthesis of gel polymer electrolytes (GPEs) by casting a solution consisting of poly(ethylene glycol) methyl ether methacrylate (PEGMA) and trimethylolpropane ethoxylate triacrylate (ETPTA) combined with poly(vinylidene fluoride-co-hexafluoropropylene) (PVDF-HFP). The solution is subjected to thermal radical polymerization using different molar ratios. The resulting GPEs exhibit a semi-interpenetrating polymer network structure, as confirmed by morphological, structural, and electrochemical characterization. Among the various compositions investigated, the GPE with a molar ratio of PEGMA:ETPTA at 98:2, in the presence of 40 wt.% PVDF-HFP (relative to the total amount of PEGMA and ETPTA), demonstrates exceptional properties. It shows high ionic conductivity ($1.46 \times 10^{-3} \text{ S cm}^{-1}$) and excellent tensile strength (6.28 MPa at an elongation at break of 156%). Moreover, the GPE exhibits electrochemical stability up to 4.7 V (vs. Li/Li+). Based on these electrochemical performance results, the synthesized GPEs show great potential as polymer electrolyte membranes in the field of energy storage.

8:00 PM EN08.03.06

Development of Layered Oxides for Electrochemically Driven Li Extraction from Dilute Li Sources
Grant Hill and Chong Liu; University of Chicago, United States

Due to the rising demand of Li-ion battery powered vehicles, the lithium supply chain is projected to experience strain in the coming decades. This strain can be mitigated by developing new Li extraction methods that can access unconventional Li sources such as seawater. Electrochemical Li extraction has demonstrated high selectivity and recovery rates from dilute Li sources; the insertion host material selection plays a key role in the overall performance. However, few materials have been explored nor have materials been tailored for Li extraction from these multi-cation solutions. With this in mind, we have explored the role of particle size and morphology of layered cobalt oxide on Li extraction from mixed Li and Na solutions. We have found that large particles form a core-shell structured $(\text{NaLi})_{1-x}\text{CoO}_2$ by non-Faradaic ion exchange using parent LiCoO_2 with Na ions. Using electrochemical intercalation, this material successfully extracted Li from 1:20,000 Li to Na aqueous solution to 7.6:1 Li: Na, which is a Li selectivity of 1.5×10^5 over Na. Decreasing the particle size, parent $\text{Na}_{1-x}\text{CoO}_2$ was used to extract dilute Li from an organic solution and maintain high selectivity for multiple Li extraction sequences. After significant structural changes from the first Li extraction, high Li recovery performance can be maintained over multiple extraction sequences. Additionally, we also report C-rate dependence during the intercalation recovery step, indicating the importance of method development for optimizing material performance. This work highlights the importance of understanding the phase separation behavior of Li and Na in layered transition metal oxides for improved Li recovery capacity and lifetime.

8:00 PM EN08.03.07

Tailoring Vertically Aligned Multi-Layer Graphene Arrays for Selective Recognition of Dopamine Neurotransmitter: An Amperometric Approach Abdulrahman Al-hagri and Selva Palanisamy; Khalifa University, United Arab Emirates

The development of sensitive dopamine (DA) sensors has significantly contributed to our understanding of dopamine-related disorders and has enabled advancements in medical diagnostics and neuroscience research. Therefore, In the present work, a novel electrochemical sensing platform was developed using vertically aligned multi-layer graphene arrays (VA-MGA) for the selective detection of dopamine (DA). The preparation of high-quality VA-GA was achieved using the plasma-enhanced chemical vapor deposition method, eliminating the need for an additional catalyst. The formation of VA-MGA was confirmed using various physiochemical techniques such as transmission electron microscopy and Raman

spectroscopy. The modified electrode, made of VA-MGA, was utilized for the electrochemical detection of DA using cyclic voltammetry and amperometry i-t methods. The electrochemical oxidation response and sensitivity of DA at the VA-MGA electrode was found to be 10 and 3 times higher than that observed with an unmodified and commercially available multilayer graphene modified electrodes. The VA-MGA sensor exhibited excellent analytical parameters for DA detection, including a wide linear range of 10 nM to 180 μ M and a low detection limit of 2 nM. The sensor also demonstrated remarkable sensitivity, storage stability, and selectivity for DA detection, which makes it highly suitable for accurate detection of DA in medical diagnostics and neuroscience research. Furthermore, the practical application of the VA-MGA sensor for DA detection was demonstrated in various real samples.

SESSION EN08.04: Electrochemical Separations III

8:30 AM *EN08.04.01

Highly Selective Electrochemical Separations of Metals Martin Z. Bazant; Massachusetts Institute of Technology, United States

The selective separation of metals from aqueous solutions is a critical challenge for many problems in energy, health and sustainability. This talk will describe two classes of highly selective separation methods for metal ions, based on differences in either electrokinetic or electrochemical properties. The first involves the propagation of deionization shock waves through charged porous media. Shock electro dialysis can separate trace amounts of toxic lead from drinking water or radionuclides from nuclear wastewater with minimal energy consumption. Shock ion extraction integrates ion-exchange resins to amplify the separation of multivalent metal ions, such as cobalt, zinc, mercury, nickel and manganese. Further control of these separations is afforded by pH swings, which allow heavy metal cations to be separated by selectively forming oxyanions, as illustrated by chemical-free continuous separation of vanadium, molybdenum, tungsten, cobalt and nickel. The second method involves selective electrosorption of metal cations in capacitive electrodes. Functionalized nanoporous carbon electrodes can separate multivalent from monovalent cations with applications to transition metal recovery in Li-ion battery recycling. Intercalation electrodes can provide extreme chemical selectivity for lithium with applications to extraction from lithium brines and battery recycling leachates, eliminating the need for harsh reagents in traditional hydrometallurgical processes.

9:00 AM EN08.04.02

Polymeric Porous Electrodes for Electrochemically Mediated Carbon Dioxide Capture Youhong (Nancy) Guo and T. Alan Hatton; Massachusetts Institute of Technology, United States

Carbon capture is a promising technology to mitigate emissions and achieve net carbon neutrality. Electro-swing reactive adsorption using redox-active species is emerging as a versatile platform for a sustainable decarbonization approach. However, the pricy electrode with limited gas diffusion has become one of the major factors hindering its practicality. Herein, we developed thick hydrogel coated-polymeric electrodes with high porosity that can effectively enhance the diffusion of carbon dioxide

without the assistance of gas diffusion conduct. Such porous electrode also enables more interactive sites for redox-active polymers, leading to a ~ 90% quinone utilization efficiency at saturation. We also achieved continuous carbon capture-release operations with excellent capacity, stability, and Faradaic efficiency. Armed with lightweight and low-cost, as-developed electrodes present a vast potential to advance the future implementation of electrochemical carbon separation technologies.

9:15 AM EN08.04.03

Electrochemically-Mediated Enantioselective Interaction with Redox Metallopolymers Through Varied Chirality Jemin Jeon¹, Ching-Yu Chen¹, Fábio Z. Galetto^{1,2}, Johannes Elbert¹, Yuri G. Kappenberg¹ and Xiao Su¹; ¹University of Illinois Urbana-Champaign, United States; ²Universidade Federal de Santa Catarina, Brazil

Chirality plays a critical role in various industrial domains, such as molecular recognition, asymmetric catalysis and chiral purification¹. Thus, constructing and leveraging precise chiral structures for enantioselective interaction has been a research hotspot in many scientific fields. In this research, we successively synthesized two types of chiral metallopolymers containing point chirality and planar chirality, respectively. Their chiral properties were characterized with circular dichroism and 2D nuclear magnetic resonance spectroscopy, followed by an investigation in their enantioselectivity with deprotonated amino acids and pharmaceutical carboxylates in electrical chemical systems. The point chiral polymers synthesized with Ugi's amine -inspired chiral monomers exhibits higher enantioselectivity compared with its chiral building block. 2D Nuclear Overhauser Effect Spectroscopy indicates the intramolecular interaction between the ferrocene moiety and alkyl backbone, and we infer that it is the emerging supramolecular chirality in the metallopolymer that resulted in enhanced selectivity². The planar chiral polymers incorporated an additional functional group on the ferrocene, generating the stereogenic plane. Improved recognition was also observed in comparison with their monomer precursors, and the affinities toward analyte enantiomers were flipped when tested over their four enantiomeric and diastereomeric stereoisomers, respectively. Further investigations on solvent polarity, supporting electrolyte and pH effect revealed that the enantioselective interaction between the chiral polymer and analyte is influenced by the competition between π - π interaction, hydrogen bonding and steric effect. Our results demonstrate the potential of adopting chiral redox-metallopolymers in electrochemically mediated platforms for enantioselective sensing and separation.

Counterion Effects on Moisture Swing Direct Air Capture Applications Kelsey B. Hatzell; Vanderbilt University, United States

Direct air capture (DAC) is essential for achieving reversing the growth in greenhouse gas emission. Conventional sorbent materials require a regeneration approach which is energy intensive. Here, we evaluate a novel moisture-swing direct air capture approach which utilizes water vapor as a means to

regenerate absorbent materials. We specifically examine five anions (carbonate, phosphate, sulfide, acetate, and borate) and study how they interact impact CO₂ absorption capacity and kinetics. We discovered that the local short-range order in micropores determines the amount of hydroxide formation in the moisture-controlled reversible hydrolysis/neutralization reaction to affect CO₂ capture capacity. Among five anions, carbonate, phosphate, and borate exhibited greater ability to generate hydroxide and thus have higher capture capacity. A thorough understanding of the role anions impact moisture-swing DAC application can enable materials design strategies for advanced climate materials.

10:30 AM *EN08.04.05

Electrochemically-Driven Solution-Phase CO₂ Capture Michael J. Aziz; Harvard John A. Paulson School of Engineering and Applied Sciences, United States

We investigate the mechanisms of and demonstrate the efficacy of CO₂ capture/release systems based on several thermodynamic cycles undertaken by aqueous solutions. Low-energy electrochemically-driven methods of making acid and base enable CO₂ capture by reaction with hydroxide and release upon acidification. Reactions among the various species of dissolved inorganic carbon (DIC) leading to CO₂ absorption and outgassing are caused by, respectively, diluting and concentrating the alkalinity in a solution. Redox-active organic molecules can reversibly bind CO₂ directly in one redox state and release it in the other. The same molecules can swing the pH by undergoing proton-coupled electron transfer, thereby enabling CO₂ capture by hydroxide.

11:00 AM EN08.04.06

Electrochemical Carbon Capture using Organic Dye Compound: System Design and Optimization in a Symmetric Cyclic Flow Hyowon Seo, Michael Nitzsche, Michael Massen-Hane and T. Alan Hatton; MIT, United States

Electrochemical carbon capture systems are designed to effectively reduce atmospheric levels of carbon dioxide (CO₂) by capturing this greenhouse gas from industrial flue gas or directly from the air, thereby contributing to the mitigation of climate change. The electrochemical carbon capture system utilizes an organic dye compound, known as neutral red/leuco-neutral red (NR/NRH₂), has been demonstrated for CO₂ capture from 15% CO₂ and ambient air. Through the application of electrochemical potentials, the pH of aqueous electrolytes is modulated to enable efficient separation of CO₂ from dilute sources. In order to assess the effectiveness of this system, an initial continuous flow system was constructed, which successfully demonstrated CO₂ separation capabilities using a mixture of 15% CO₂ and ambient air.

To enhance the stability of the system using NR/NRH₂ redox couple, a cyclic flow configuration was subsequently constructed to investigate the performance of CO₂ capture under different operating conditions. These conditions include variations in current densities, liquid flow rates, feed gas composition, electrode materials, and system operation methods. The electrochemical process within the cyclic flow system was analyzed by examining the current and voltage responses under diverse electrochemical conditions. The integrated electrochemical system, operating under optimized conditions, underwent testing for carbon capture within the cyclic flow setup.

The demonstrated electrochemical carbon capture system design and optimization results will encourage future research into optimizing the electrochemical separation unit for long-term and stable operations in large-scale applications.

11:15 AM EN08.04.07

Continuous Carbon Capture via Oxygen/Water Electrolysis in a Solid Electrolyte Reactor Peng Zhu¹, Haotian Wang¹ and T. Alan Hatton²; ¹Rice University, United States; ²Massachusetts Institute of Technology, United States

Electrochemical carbon capture technologies, with renewable electricity as the energy input, are promising for carbon management but still suffer from low capture rates, oxygen sensitivity, or system complexity. Here we demonstrate a continuous electrochemical carbon capture design by coupling oxygen/water (O₂/H₂O) redox couple with a modular solid electrolyte reactor. By performing oxygen reduction (ORR) and oxygen evolution reaction (OER) redox electrolysis, our device can efficiently absorb dilute carbon dioxide (CO₂) molecules at the high-alkaline cathode/membrane interface to form carbonate ions, followed by a neutralization process through the proton flux from the anode to continuously output a high purity (> 99%) CO₂ stream from the middle solid electrolyte layer. No chemical inputs were needed, nor side products generated during the whole carbon absorption/release process. High carbon capture rates (440 mA cm⁻², 0.137 mmol_{CO2} min⁻¹ cm⁻² or 86.7 kg_{CO2} day⁻¹ m⁻²), high Faradaic efficiencies (> 90% based on carbonate), high carbon removal efficiency (> 98%) in simulated flue gas, and low energy consumptions (starting from ~ 150 kJ/mol_{CO2}) were demonstrated in our carbon capture solid electrolyte reactor, suggesting its promising practical applications.

SESSION EN08.05: Electrochemical Separations IV

Lithium-Selective Adsorbents and Membranes for Electrochemical Wastewater Refining William Tarpeh; Stanford University, United States

With global lithium supplies projected to fall short of demand between 2023 and 2027, there is great motivation to develop new technologies capable of lithium recovery from alternative sources such as battery waste, produced water, and geothermal brines. In these sources, the co-existence of other impurities at much higher concentrations than lithium (e.g., >60,000 ppm Na⁺ versus 50-1000 ppm Li⁺ in brines) presents a challenge for high-purity lithium extraction. Selective electrodialysis is a candidate for lithium recovery that aligns with recent resource extraction priorities including developing electrified separation processes, although it requires the development of ion-selective membranes. To inform the design of such membranes, we first studied fundamental ion transport and selectivity mechanisms in commercially available membranes. We then synthesized a library of novel ligand-functionalized membranes (including acrylic acid and vinylpyridine ligands) to study the impact of additional ion-specific coordinative interactions on lithium selectivity in the selective electrodialysis process. Finally, we integrated selective ion exchange resins into electrodialysis to accomplish in situ electrochemical regeneration that helps concentrate lithium from dilute sources and recovery high-purity lithium in electrochemical ion exchange reactors.

2:00 PM EN08.05.02

Augmenting the Interfacial Electrostatic Potential with Donnan-Enhanced Nanofiltration for Lithium Extraction from Salt-Lakes Lucy A. Kanas, Trent Lee, Zi Hao Foo and John H. Lienhard; Massachusetts Institute of Technology, United States

The exponential growth in the demand for lithium in the renewable energy and electric vehicle industries necessitates significant improvement in the efficiency of lithium production from primary sources. While lithium is abundant in salt lakes within South America and Asia, existing extraction methods based on brine evaporation are relatively costly and suffer protracted production cycles. By avoiding brine evaporation altogether, membrane processes such as nanofiltration can selectively concentrate monovalent ions, optimizing the extraction process directly from salt lakes while eliminating the environmental impacts of evaporation ponds.

The selectivity of conventional nanofiltration membranes can be attributed to their cross-linked polyamide active layer. The polyamide layer is typically fabricated by a condensation reaction between trimesoyl chloride and piperazine, along the interface of a polysulfone support layer and the organic monomer mixture. As a result of the charged moieties in the polyamide, the electrostatic potentials that form along the solution-membrane interface inhibit ions of the same charge from partitioning into the membrane, a phenomenon known as Donnan exclusion. However, the high concentration of the residual carboxyl moieties of the polyamide layer imparts a negative volumetric charge density to the active layer and attenuates the rejection of multivalent cations by Donnan exclusion.

To impart monovalent cation selectivity, emerging variants of nanofiltration employ a positively charged surface layer on the membrane that displays high water permeability and a positive volumetric charge density. Here, a Donnan-enhanced nanofiltration membrane employing a polyethyleneimine (PEI) surface layer is fabricated through a condensation reaction between perfluorosulfonic acid and the amine moieties in the polyamide layer, to attain enhanced $\text{Li}^+/\text{Mg}^{2+}$ selectivity. In this study, we present empirical evidence for the success of this method, based on experiments with high-salinity multi-cation brines that represent those encountered in salt-lake lithium extraction. Our conclusions are derived from 1000 original concentration measurements spanning three feed salinities and three pH levels.

The water permeability of the Donnan-enhanced NF membrane decreases from 17.2 % on average from the added hydraulic resistance. Our streaming potential measurements indicate that the zeta potential of the NF membrane increases from -17.2 mV to 19.8 mV with the addition of the PEI surface layer. Our experiments with binary cation solutions (i.e., Li^+ , Mg^{2+}) reveal that the $\text{Li}^+/\text{Mg}^{2+}$ separation factor increases from 39.1 with the unmodified membrane to 129.2 with the Donnan-enhanced membrane. Using multicomponent salt-lake brines from Salar de Atacama, Chile, the recorded $\text{Li}^+/\text{Mg}^{2+}$ separation factors are 13.2, 18.1, and 87.3, for solution pH of 7, 4 and 2, respectively. In a single pass, the Donnan-enhanced NF membranes register an Mg^{2+} rejection of 96.8 % while raising the concentration of Li^+ by 17.7 %. The enhanced $\text{Li}^+/\text{Mg}^{2+}$ selectivity at low solution pH arises from the protonation of the residual carboxyl moieties in acidic conditions ($\text{pK}_a \sim 4$). Lastly, we conduct a module-scale assessment of the process's membrane area requirement and energy efficiency.

Electrochemical Lithium Recovery: Investigating Electrode Behavior and Enhancing System Durability Seoni Kim; Ewha Womans University, Korea (the Republic of)

The demand for lithium has been rapidly increasing due to the widespread use of secondary batteries.

Currently, lithium production primarily relies on the time-consuming process of evaporation and precipitation from brine lakes. This method is limited to specific water sources with low ion concentrations, and environmental concerns have emerged surrounding its use.

However, the development of electrochemical lithium recovery systems, inspired by the principles of lithium-ion batteries, holds promise for alleviating these concerns. By utilizing cathodes, such as LiMn_2O_4 and LiFePO_4 , which possess suitable channel sizes for selective Li^+ insertion, these systems can selectively recover lithium from various source waters with a wide range of Li^+ concentrations. However, a lack of understanding regarding the physicochemical behaviors of the Li^+ -selective electrode under realistic operational conditions has been a hindrance. Furthermore, the stability and cost of the counter electrodes in this system present significant obstacles that impede its practical implementation.

This talk aims to delve into the physicochemical behavior of the Li^+ -selective electrode during the electrochemical lithium recovery process at various Li^+ concentrations in the source water and the operation rate. Through the characterization of the electrodes using X-ray techniques, it was suggested that increasing the density research aims to tackle the increasing demand for lithium by advancing electrochemical lithium recovery systems. It will focus on investigating the behaviors of the Li^+ -selective electrode during realistic operational conditions and propose strategies for enhancing the efficiency and durability of electrode designs.

In addition, this talk will explore the Faradaic and non-Faradaic capture of anions by modifying the silver-based electrode and utilizing a high-surface-area carbonaceous material, respectively. It was found that the system showed high stability by using those electrode materials. Moreover, a system that enables simultaneous lithium recovery and decomposition of organic pollutants will be introduced. This extends the applicability of the electrode to industrial wastewater, highlighting the versatility of the electrochemical system.

Electrified Mineralization of Nutrients from Real Municipal Wastewater and the Energy Implications Thereof Damilola A Daramola; Northeastern University, United States

Phosphorus and nitrogen are two of the three major nutrients required for plant and animal life and sustaining global population growth requires an anthropogenic impact on the natural cycles of these nutrients i.e., increased phosphorus mining and nitrogen fixation to sustain the per capita consumption of P and N availability, respectively.¹ However, this anthropogenic activity has also led decreased environmental sustainability: higher accumulation of N and P in water bodies due to nutrient runoff and leaching as well as higher greenhouse gas emissions from nutrient fixation, mining and transportation. Furthermore, the process energetics for solid P and N delivery are 4.0 and 5.7 GJ/t, respectively,¹ while the embodied energetics for P and N delivery are 10.4 and 55.5 GJ/t, respectively,² illustrating the key drivers for the associated GHG emissions.

An alternative, yet sustainable, anthropogenic approach is the recovery and re-use of these nutrients from waste via an electrical driving force.^{3,4} Although a chemical approach to recovery enhances the circular economy of nutrient use, an electrical approach using renewable electrons extends from materials conservation to significant process decarbonization. This electrified approach will be discussed in this invited talk, based on the combined efforts of researchers at Ohio University and Northeastern University.

This presentation will describe an electrochemically-driven phosphorus and nitrogen recovery system using real wastewater from a municipal treatment plant as the substrate. Initial analyses consisted of 1-year of sampling from 3 different recycle streams at two different wastewater facilities: 4 million gallons per day and 100 million gallons per day throughput. Multivariate screening analyses of stream, design and operational variables on recovery efficiency and energy consumption from synthetic wastewater were conducted. These screening analyses were subsequently used to evaluate recovery efficiency and energetics with real wastewater as the treated substrate.

Ammonium Recovery from Manure Wastewater and Simultaneous Electrosynthesis using Ammonium-Ion Selective Redox Material Rui Wang¹, Kai Yang¹, Cindy Wong², Horacio Aguirre-Villegas¹, Rebecca Larson¹, Fikile Brushett², Mohan Qin¹ and Song Jin¹; ¹University of Wisconsin–Madison, United States; ²Massachusetts Institute of Technology, United States

The greenhouse gas emissions and water contamination generated by livestock manure motivates the development of new approaches to reduce their environmental impacts and improve sustainability. Effective approaches to recover nutrients, especially ammonia, from manure wastewater to produce fertilizer are needed. Here we develop a new electrochemical strategy to achieve simultaneous ammonium (NH_4^+) ion recovery and electrochemical synthesis using potassium nickel hexacyanoferrate (K_2NiHCF) as the ammonium ion-selective redox material to mediate the process. The K_2NiHCF electrode spontaneously uptakes NH_4^+ (and K^+) from manure wastewater with a nutrient (NH_4^+ and K^+) selectivity of ~100% and oxidizes the organic matter. Subsequently, NH_4^+ -rich fertilizers are released electrochemically together with the electrosynthesis of value-added chemicals, such as H_2 as a green fuel or H_2O_2 as a disinfectant, without expensive ion-exchange membranes. The integrated process shows an estimated net profit for common cow dairy farms and could potentially reduce NH_3 emissions. These results provide a new conceptual strategy for distributed electrochemical resource recovery and on-demand electrochemical manufacturing that can improve agricultural sustainability and also open new opportunities for selective metal ion recovery towards zero liquid discharge water treatment and purification.

3:45 PM EN08.05.06

Separating Reactants in Membraneless Redox Flow Batteries: Leveraging Fluid Mechanics Sofia Kuperman¹, Ran Swisa¹, Robert Gloukhovski¹, Prakash Rewatkar¹, Mohamed Asarthen¹, Anna Zigelman¹, Matthew Suss^{1,2,3} and Amir Gat¹; ¹Technion - Israel Institute of Technology, Israel;

²Technion–Israel Institute of Technology, Israel; ³Technion – Israel Institute of Technology, Israel

Redox flow batteries are considered a highly promising electrochemical technology for grid-scale renewable energy storage. However, their commercialization has been hindered by high capital cost and balance of plant complexity. Single-flow batteries are an emerging subclass employing a membraneless cell design and simplified flow systems. Recently, single-flow zinc-bromine batteries leveraging novel multiphase electrolyte emulsions have been demonstrated. Such electrolytes are a mixture of a bromine-poor aqueous phase and bromine-rich polybromide phase, where in the latter phase the bromine is largely electrochemically inactive. However, separating the zinc and bromine reactants in the absence of a membrane is a challenging problem requiring deep understanding of multiscale flow phenomena and its coupling to battery performance.

In this work, we will briefly present our novel 2D analytical flow model describing the multiscale flow phenomena within such flow batteries. The model captures the concentration field of the polybromide phase, including sedimentation as this phase is denser. The model was validated with numerical simulations and experimental data. We will focus on how the predicted fluid mechanics phenomena support effective separation between the reactants, and how the model explains several counter-intuitive battery observations, such as decreasing electrolyte conductivity for decreasing flowrate. The model also points towards future battery optimizations for systems employing multiphase flow electrolytes, and thus is a key aspect towards unlocking their potential for low-cost renewable energy storage.

4:00 PM EN08.05.07

High-Performance Nanoparticle-Modified Membrane for Nonaqueous Redox Flow Batteries Daniel J. San Roman and Philip Cox; Mainstream Engineering Corporation, United States

For the effective implementation of environmentally friendly large scale renewable energy, low-cost grid-capable storage solutions must be implemented to accommodate the effective capture and load leveling of the typically periodic and variable production levels. One solution of particular interest is redox flow batteries (RFBs), which provide a high number of deep cycles and the ability to store large amounts of electrical energy cheaply and efficiently. However, aqueous RFBs typically suffer from low energy density, limited electrolyte stability, and capacity decay during cycling. Alternatively, switching RFBs to nonaqueous solvents and charge carrying redox complexes provides higher operating voltages allowing for higher energy density cells. However, to successfully implement these non-aqueous RFBs (NARFB) there remains the need to improve the durability of the cell membranes and reduce their susceptibility to crossover of active redox species.

To this end, Mainstream Engineering successfully demonstrated the preparation of a stable nanoparticle composite protective film that effectively reduces redox molecule crossover (> 90 % reduction compared to the non-reinforced anion exchange membrane [AEM]) with no effect on the key membrane ionic conductivity and shows promise as a high-performance membrane for NARFBs. Mainstream Engineering's approach to optimizing the AEM for NARFBs builds on our previous work developing scalable selective ion exchange membranes and membrane coatings of a fuel cell, batteries, and highly selective liquid and gas separation applications. For this work, we screened various potential AEMs for their chemical and mechanical stability in non-aqueous solutions as well as demonstrating a wide electrochemical stability window. After down selecting an AEM base membrane with excellent chemical stability, we formulated a nanoparticle/ionic binder coating to allow the deposition of a thin-film protective coating and the formation of a composite membrane on the AEM base membrane. We

examined both screen printing and knife coating approaches to provide a robust, uniform, and repeatable method of coating the slurry compositions to provide a stable, uniform thin-film coating. The surface characteristics of our composite films were evaluated with optical and scanning electron microscopy, to determine the base porosity and the coating uniformity. These composite membranes were demonstrated to be both chemically and mechanically stable in the non-aqueous solvents. The ionic conductivity and iron tris(2,2'-bipyridine) (FeBpy) permeability of the films were benchmarked against commercially available AEMs. We have further optimized our composite membranes for decreased FeBpy permeability and performed half- and full- cell testing of our membranes, both under stationary and flowing electrolyte conditions. The performance of the protective film was further optimized via surface charge modifications of the nanoparticles to allow a 75% reduction in the ionic resistance of the nanoparticle modified membranes, lowering the cell voltage drop and improving the power density. Our materials show increased performance, by lowering the redox molecule crossover without increasing the membrane thickness or overall ionic resistance. Mainstream Engineering's novel composite AEMs provide a promising approach to solving outstanding membrane performance issues with current NARFB chemistries, providing a commercially viable path forward for high-energy density non-aqueous RFB storage technologies.

4:15 PM EN08.05.08

Membrane-Enabled Direct Extraction of Critical Metals Michael Baird^{1,2} and Brett A. Helms²;
¹University of California, Berkeley, United States; ²Lawrence Berkeley National Laboratory, United States

Water treatment devices designed to extract critical elements from wastewater and natural brines rely on polymer membranes that exhibit selective permeability towards dissolved ions. However, the underlying design principles that govern selectivity between ions of similar size and charge (e.g. Li^+/Na^+) remain unclear because of natural tradeoffs in the solubility and diffusivity of dissolved species within a membrane. Given that these properties arise from the solvation environments made available to permeating ions, we proposed a membrane platform wherein specific coordination modes are enforced in at sub-nanometer length scales with rigid polymer backbones and pendant groups with unique geometries. To this end, a library of systematically tuned microporous polymers have been synthesized and evaluated for ion uptake, ionic conductivity, and salt permeability. Our results lend insights to an energy landscape model of ion transport across membranes, where the pendant is shown to influence the energetics of partitioning at the water-membrane interface, as well as hopping between adjacent solvation cages within the membrane.

Electrically-Modified Anion Exchange Membranes for Alkaline Membrane Water Electrolysis
Hanieh Bazyar and Athanasios Papageorgiou; TU Delft, Netherlands

Hydrogen has received much attention as a green energy alternative to replace fossil fuels in our effort to meet the requirements of global climate change. However, most of it is currently produced from fossil fuels through methane reforming, producing large amounts of carbon dioxide. Anion exchange membrane water electrolyzers (AEMWE) constitute a promising new technology to produce high-purity green hydrogen through water electrolysis, that use less expensive non-platinum based electrocatalysts than proton exchange membrane electrolyzers and low-cost polymer membranes. AEMWEs require membranes with high ion exchange capacity to achieve high hydroxide conductivity. However, this may lead to significantly low mechanical stability due to the increased water uptake and swelling ratio. Thus, the fabrication of AEMs with both high conductivity and mechanical stability is still a challenge [1].

In this study, novel membranes, based on poly(aryl quaternary ammonium), are fabricated through electrically-assisted solvent casting method. During the casting, DC and AC electric fields are applied on the polymer solution. The morphological and structural properties of the membranes are characterized by NMR and IR. The ion exchange capacity is measured through ion chromatography and the hydroxide conductivity is assessed via linear sweep voltammetry. The overall resistance of the cell and the durability of the membrane are investigated through electrochemical impedance spectroscopy and chronoamperometry, respectively.

We study how the application of an electric field improves the conductivity of the membrane by aligning the cationic groups of the polymer into ion channels, facilitating the movement of hydroxides. Results provide a comparison of the physicochemical and electrical properties of the membranes cast with and without the presence of various electric fields.

Nitrate Reduction Enhancements using Electrified Membrane Filtration Lea Winter¹, Yingzheng Fan¹, Xiaoxiong Wang^{1,2} and Claire Butler¹; ¹Yale University, United States; ²Tsinghua University, China

The release of nitrate to the environment from wastewater effluent and agricultural runoff contributes to groundwater contamination, harmful algal blooms, and disruption of biogeochemical nitrogen flows. Nitrate conversion via electrochemical reduction can eliminate the production of concentrated waste streams while avoiding the addition of reductant or hole scavenger chemicals. However, major challenges for nitrate removal from water via electrochemical conversion involve reducing the use of expensive precious metal electrocatalysts while also improving the reaction activity and selectivity, stability, and mass transport of nitrate to electrocatalyst active sites. The use of electrochemical membranes (EMs) as multifunctional porous flow-through electrodes could potentially address these challenges based on improved mass transport and altered kinetics under flow conditions within membrane pores.

We fabricated conductive membranes using polymers combined with carbon nanotubes. The EMs showed significantly higher nitrate removal efficiency during electrified filtration compared to flow-by mode. The small pore sizes in the membrane reduced the diffusional boundary layer by several orders of magnitude with respect to flow-by mode, overcoming diffusional mass transport limitations. During electro-filtration, the nitrate conversion activity was easily controlled by tuning the permeate flow rate, regardless of applied potential. These enhancements and tunability demonstrate key advantages of employing

membranes with pore sizes of $< 1 \mu\text{m}$ as flow-through electrodes compared to conventional 2D electrodes and 3D electrodes with larger pore sizes. Additionally, the EMs demonstrated nitrate removal to below EPA drinking water limits in synthetic surface water with product selectivity to N_2 of over 80% and without showing loss of stability over a period of 10 h. The mechanically-flexible membranes provide an advanced electrochemical water treatment architecture involving inexpensive materials and green synthesis methods.

9:30 AM EN08.06.03

Electrolyte Composition Effects on Bipolar Membrane Polarization and Transport for

Electrochemical Separations Thomas Y. George¹, Paige Brimley², Wilson Smith² and Michael J. Aziz¹;

¹Harvard University, United States; ²University of Colorado, Boulder, United States

Bipolar membranes (BPM), consisting of an anion exchange polymer membrane layer, a cation exchange polymer membrane layer, and a catalytic interfacial layer in between, enable electrochemical cells with strong gradients of pH between adjacent chambers. Bipolar membrane electrodialysis (BPMED) is a prominent example of an electrochemical separation process relying on this unique type of membrane material. In bipolar membrane electrodialysis, the BPM operates in “reverse bias,” dissociating water into hydronium and hydroxide at the interfacial layer, generating acidic and alkaline streams, while a third electrolyte chamber is essentially desalinated as it provides a source of counterions (*e.g.* K^+ and Cl^-) for the acid and base streams. Recently, this process has seen increased attention for applications in resource recovery and for removing anthropogenic carbon dioxide from the environment. Unlike the traditional application of BPMED, to generate pure acid and base as chemical products, the emerging applications involve the BPM contacting electrolytes that include supporting salt or environmental impurities, which can have significant effects on the polarization behavior of the membrane as well as its transport selectivity of protons/hydronium and hydroxide over their counterions and other salts in the electrolyte.

In this work, we systematically investigate the effects of ion size, charge, and concentration on salt crossover in a widely-used commercial BPM (Fumasep FBM) by combining polarization experiments in a four-electrode setup with a 1D continuum model of water dissociation and multi-ion transport. We find that salt crossover dominates at low current density, before the stronger electric field at larger applied potential drives water dissociation to dominate. Further, we investigate how the total ion concentration and ratio of supporting salt to acid and base concentration influence the overpotential across the membrane and the contributions of salt crossover to total current.

Both high overpotentials associated with water dissociation at high currents and the unwanted salt crossover at lower currents provide significant hurdles for the deployment of BPMs in electrochemical technology. This work emphasizes the importance of electrolyte effects on these phenomena, and may provide guidance both for designing new materials and for choosing electrolytes and operating conditions in electrochemical cells.

Impedance Analysis of Anion Exchange Membrane Electrolysis Athanasios Papageorgiou and Hanieh

Bazyar; TU Delft, Netherlands

Anion exchange membrane (AEM) electrolysis is a promising solution for low-cost hydrogen production from renewable energy sources on a large scale. However, the efficiency of AEM electrolysis is currently lower than that of traditional technologies, such as proton exchange membrane electrolysis. This

deficiency in performance can be attributed to certain integral components of the membrane electrode assembly and the reaction kinetics. The measurement of these limitations involves assessing the ohmic and charge transfer resistances.

In this study, we aim to investigate and quantify the impact of various parameters such as voltage, temperature, flow rate, electrolyte concentration, and catalyst on the ohmic and charge transfer resistances using electrochemical impedance spectroscopy. The membrane electrode assemblies are fabricated using commercially available membranes, assessing the effect of different membranes on the performance of the electrolyser. In addition, the effect of DC and AC fields on the H₂ production is investigated, while the production of H₂ is quantified and compared to that calculated through the current output.

Controlling Protein Ad-and Desorption by an Electrical Switch on Polymer-Coated Carbon Electrodes Kieke de Boer and Karin Schroen; Wageningen University, Netherlands

Capacitive Deionization (CDI) has been widely researched and applied to remove salt ions from brackish water in an energy-efficient way. During operation, two charged electrodes electrostatically attract ions, which are released again to the bulk solution once the potential is removed, resulting in a brine and freshwater solution. Carbon is generally used as electrode material, because of its high specific surface area and electrical conductivity. Building upon this principle, our research focuses on the separation of whey protein isolate (WPI) using a similar setup. We have successfully achieved reversible adsorption of up to 10 mg of protein per gram of electrode material on polyelectrolyte-covered carbon electrodes. To achieve this, positively and negatively charged polyelectrolytes are attached to the working and counter electrode, respectively, to create a surface charge in the absence of an electric field. The created surface charge enables spontaneous adsorption on the working electrode by electrostatic attraction with the negatively charged protein. Protein desorption is initiated by an electric field of -1.2 V, which neutralizes the positive chemical charges of the polyelectrolyte-covered working electrode through negative electronic charges. The negatively charged polyelectrolyte on the counter electrode prevents re-adsorption during this desorption phase. This set-up, with a spontaneous adsorption step, can be referred to as inverted capacitive deionization (iCDI). Adsorption is controlled by diffusion while desorption is mainly migration-driven due to the applied electric field, causing desorption to occur faster than adsorption.

Interestingly, salt adsorption and desorption occur in phases opposite to those of protein adsorption and desorption. This unique behaviour allows for simultaneous concentration and desalination of the protein solution. Furthermore, we have successfully enriched β -lactoglobulin during the active desorption phase, which represents a significant step towards a separation system with high capacity and selectivity. Looking ahead, we envision the potential of implementing stimuli-responsive polymers in the porous carbon structure to improve both the selectivity and reversibility of these electrically-driven separation systems. Stimuli-responsive polymers exhibit unique properties, such as the ability to reversibly alter their charge, conformation, and/or wettability in response to an external stimulus (e.g., an electric field). This capability provides greater control over the charge distribution and surface properties of the electrodes, and consequently allows tuning of the interaction forces with the proteins. Our research highlights that a comprehensive understanding of the surface properties and the underlying interaction forces is essential in selecting an appropriate responsive polymer coating for proteins or other target molecules.

The ultimate objective is to combine stimuli-responsive polymers with porous carbon structure, exploiting their respective strengths, to develop a separation system characterized by a high adsorption capacity, reversibility, and selectivity. While the focus of the current system is on the food industry, its potential applications extend to other industries, including biotechnology, wastewater treatment and the biomedical industry.

Ion-Conductive Properties of Polymeric Ionic Liquid-Coated Core-Shell Nanoparticles for Anhydrous Proton Exchange Membrane Keisuke Tabata, Tsutomu Makino and Akito Masuhara; Yamagata University, Japan

Polymer electrolyte fuel cells (PEFC) have attracted attention as next-generation energy sources for vehicles and distributed power sources. The operating environment of PEFC is expected to expand from the current low-temperature range ($< 90^{\circ}\text{C}$ and high-humidified environment) to the high-temperature range ($> 100^{\circ}\text{C}$ and low-humidified environment). Especially, the high-temperature range operating PEFC are classified as HT-PEFC. However, conventional perfluorosulfonic acid electrolytes, such as Nafion, are unsuitable for HT-PEFC because the proton-conduction mechanism is dependent on hydrogen bonding between water molecules. Thus, there is an urgent need to develop proton exchange membranes suitable for HT-PEFC that conduct protons in high-temperature and low-humidity environments. In a previous study, it was discovered that high proton conductivity can be achieved by constructing nanosized proton-conductive channels and using ionic liquids as proton-conducting materials. However, a facile method for fabricating proton exchange membranes with no anisotropy in the direction of proton conduction has not yet been developed.

In this paper, we have proposed a procedure for constructing isotropic three-dimensional (3D) controlled ion-conductive channels employing polymeric ionic liquid (PIL)-coated core-shell nanoparticles. A PIL is an ion-conducting material containing an ionic liquid with a repeating polymer structure. In this system, we employed SiO_2 (silica) nanoparticles as the core nanoparticles and poly(1-vinylimidazole)/bis(trifluoromethanesulfonyl)imide (P1VIm/TFSI) as the PIL. The PIL-coated nanoparticles were then assembled, resulting in the 3D ion-conductive channels have been constructed by the contact of the PIL layers on the surface of the nanoparticles between adjacent particles. The PIL-coated nanoparticles were prepared using a unique precipitation polymerization technique applying precipitation polymerization.

The progress of the PIL coating onto the surface of the silica nanoparticles was determined using SEM-EDS mapping analysis. We have observed sulfur and fluorine elements originating from TFSI anion from the same position as silicon elements derived from silica nanoparticles, indicating that the PIL was successfully coated onto the surface of silica nanoparticles. The ionic conductivity of the PIL-coated nanoparticles was measured in a pelletized state prepared by simply pressing the nanoparticles. The pelletized PIL-coated nanoparticles exhibited ionic conductivity even under high-temperature and anhydrous conditions, with a maximum conductivity of approximately $10^{-4} \text{ S cm}^{-1}$ (160°C). Subsequently, to evaluate the construction of 3D ion-conductive channels, we have measured the anisotropy of the ionic conductivity of the pellets. Notably, there was no anisotropy in the ionic conductivity, and both vertical and horizontal directions achieved similar ionic conductivities. Furthermore, the ion-conduction mechanism was clarified by using variable-temperature ^1H solid-state MAS NMR spectroscopy. The imidazole N-H resonances in the PIL structure were observed at 9–12 ppm assigned to “mobile” protons which is contributing to the proton conduction. As this phenomenon was not observed with the PIL homopolymer, we have concluded that the coating of PIL onto the surface of the silica nanoparticles and the accumulation of PIL-coated nanoparticles increased the number of mobile protons.

In conclusion, we have achieved the facile construction of 3D ion-conductive channels by the accumulation of PIL-coated core-shell nanoparticles. Moreover, the ion-conduction mechanism was discussed using solid-state NMR spectroscopy, and the fabricated PIL-coated nanoparticles contained mobile protons. Thus, the PIL-coated core-shell nanoparticles and their assembly process are effective for developing a proton exchange membrane for HT-PEFC.

11:15 AM EN08.06.08

Promoting the Selective Intercalation of Lithium in the Olivine FePO_4 Host Gangbin Yan and Chong Liu; University of Chicago, United States

The lithium supply challenge predominantly stems from the limitations of existing mining techniques in accessing lithium sources with intricate chemistry and low concentrations. Electrochemical intercalation presents an avenue for extracting lithium from diluted water sources. However, during the extraction process, the co-intercalation of lithium and its primary competitor, sodium ions, occurs. The comprehensive understanding of how host materials respond to this co-intercalation process remains an ongoing pursuit. Moreover, despite the well-acknowledged potential for lithium extraction, the reported selectivity for lithium can exhibit considerable disparity. This discrepancy in selectivity, as observed with olivine-type FePO_4 , can span nearly three orders of magnitude, potentially arising from the diverse particle forms adopted (e.g., sizes, morphology, dominant facets, etc.).

In this talk, using one-dimensional (1D) olivine iron phosphate (FePO_4) as a model host, I will first introduce the co-intercalation behavior of lithium and sodium ions and the control of lithium selectivity through intercalation kinetic manipulations. By combining computational and experimental investigations, we noticed that lithium- and sodium-rich phases tend to separate in the host. Exploiting this mechanism, I will discuss how the sodium-ion intercalation energy barrier can be increased using partially filled 1D lithium channels, generated via non-equilibrium solid-solution lithium seeding or remnant lithium in the solid solution phases. Furthermore, the lithium selectivity enhancement during co-intercalation shows a strong correlation with the fractions of solid-solution phases with high lithium content (i.e., Li_xFePO_4 with $0.5 \leq x < 1$). Finally, I will delve into the impact of different structural forms of the host material. Specifically, I will discuss how these structural variations can influence particle kinetics and chemo-mechanical responses during Li/Na intercalation, ultimately affecting the preference for lithium.

Recycling and Upcycling of Spent Battery Materials via Molten-Salt Technologies Tao Wang¹, Huimin Luo¹ and Sheng Dai^{1,2}; ¹Oak Ridge National Laboratory, United States; ²University of Tennessee, United States

The recycling and upcycling of end-of-life lithium-ion batteries (LIBs) has become an urgent and challenging issue with the surging use of LIBs, in which recovering high-value cathodes not only relieves the pressure on the raw material supply chain but also minimizes negative environmental impact. Beyond direct recycling of spent cathodes to their pristine states, the direct upcycling of spent cathodes to the next-generation cathodes is of great significance to maximize the value of spent materials and to sustain the fast development of LIBs. A novel molten-salt system was developed to directly upcycle spent NMC 111 to Ni-rich NMCs by simultaneously realizing the addition of Ni and the relithiation of Li in spent NMC 111. Our prior and present research activities through molten-salt techniques in this area will be summarized in this presentation. Quantitative, fundamental understanding of the mechanisms of solvent tunability, the factors limiting control over solvent flux properties, the forces driving chemical reactions, and modes of controlling redox reactions will be discussed.

11:00 AM *EN09.01.02

Lithium-Ion Battery Recycling: Options, Environmental Impacts and Economics Rebecca Ciez; Purdue University, United States

Demand for transportation and electricity grid energy storage will require gigawatt hours of lithium-ion batteries to power these systems. Recycling battery materials can assist in meeting the material demands for these systems and for reducing environmental impacts. This talk will discuss the economic and environmental costs associated with producing and recycling lithium-ion batteries using different recycling pathways. Process-based cost models provide context for the costs of manufacturing battery materials from new materials, and the potential for profitability from recycling. Finally, this talk will discuss the state of battery recycling given recent advances in the industrial policy to support the development of local battery material supply chains.

11:30 AM EN09.01.03

Towards Sustainable Polymer Solid-State Batteries: A Mechanical-Hydrometallurgical Case Study Kirstin Schneider^{1,2}, Marco Ahuis^{3,2}, Peter Michalowski^{3,2}, Daniel Goldmann^{1,2}, Arno Kwade^{3,2} and Bengi Yagmurlu^{1,2}; ¹Technische Universität Clausthal, Germany; ²Battery LabFactory Braunschweig, Germany;

³TU Braunschweig, Germany

Lithium-ion batteries have become indispensable in various sectors for electrochemical energy storage. The rising demand for enhanced battery performance triggers the development of new technologies, such as solid-state batteries (SSBs). Featuring a solid electrolyte instead of a liquid one, SSBs hold great promise for next-generation energy storage. To promote battery circularity throughout the entire life cycle, it is essential to develop recycling concepts for next-generation SSBs even before their market introduction. However, literature currently lacks comprehensive studies on SSB recycling. Among the options for solid electrolytes, polymers stand out due to their potential for scalable production. With the use of new materials in polymer SSBs, there is an immediate need to assess their recyclability. This study aims to explore mechanical-hydrometallurgical recycling routes for polymer SSBs, aiming to develop a holistic recycling concept. For this investigation, polymer SSB pouch cells, consisting of a polyethylene oxide/lithium bis(trifluoromethanesulfonyl)imide (LiTFSI) solid electrolyte, a lithium iron phosphate (LFP) cathode composite, and a Li metal anode, were utilized. In the mechanical processing phase, we extensively explored the shredding properties of polymer SSB cells, with special attention to the critical safety considerations arising from the presence of Li metal. Based on the intrinsic properties of the materials used in polymer SSBs, an optimum shredding process has been identified to prepare the shredded material for subsequent hydrometallurgical processing. Ensuring the homogeneity of the crushed material and employing gentle disintegration techniques are crucial to avoid cross-contamination during further stages. Subsequently, in the hydrometallurgical processing step, we examined different leaching strategies for the shredded cells to extract valuable metals into the solution. Ultimately, we evaluated various precipitation strategies for impurity removal and Li recovery. The obtained results provide valuable insights into the development of efficient recycling processes for SSBs. This forward-looking approach contributes to the establishment of a robust recycling industry that anticipates the evolving material flows of future battery technologies.

SESSION EN09.02: Lithium-Ion Battery Recycling and Reuse II

Selective Electrodeposition for Lithium-Ion Battery Recycling—Tuning Interfacial Chemistry for Selective Cobalt and Nickel Recovery Xiao Su and Kwiyoung Kim; University of Illinois Urbana-Champaign, United States

The recovery of transition metals from battery recycling streams is a critical challenge for materials circularity in the future, especially with the growing demand on battery-related critical elements. Electrochemical separation approaches have been gaining traction as a modular and electrified platform for ion-selective recovery. However, key transition metals in batteries such as cobalt and nickel often possess close reduction potentials in aqueous media, thus impeding selective recovery by electrodeposition. Here, we overcome this challenge by combining electrolyte design with interfacial control, to enhance the selectivity between cobalt and nickel. First, through highly concentrated chloride

solutions, we can discriminate between the two metals by charge, and through the application of charged polyelectrolytes, we can further enhance separation factor during electrodeposition. We implement this strategy for the recovery of cobalt, nickel, and manganese from commercially-sourced lithium ion batteries, and demonstrate the recovery of high purity transition metals. Finally, we discuss parallel directions in developing continuous electrochemical approaches for the selective recovery of lithium. Overall, we believe that electrochemical separations can play an important role in enabling sustainable and energy-efficient battery recycling technologies.

2:00 PM *EN09.02.02

Li Recovery from Brines using Recyclable Intercalation-Based Redox Membranes Beniamin Zahiri¹, John Cook², Heng Yang², Badri Shyam², Paul Braun¹, Rodrigo Rodriguez² and Yunkyu Choi¹;

¹University of Illinois at Urbana-Champaign, United States; ²Xerion Advanced Battery Corp, United States

The accelerated push towards renewable energy is leading to an exponential consumption of battery materials. Today, the United States net import reliance on battery materials varies widely from 25 to 80% (USGS Reports). If nothing is done, this import reliance is only expected to grow as electric vehicle and energy grid storage demands surge. Therefore, securing novel, domestic sources of critical lithium-ion battery components is of paramount importance and necessary to shield the U.S. from future global trade volatility and unforeseeable supply chain disruptions. The United States currently sources all its domestically produced lithium from one mine in Nevada where lithium carbonate is produced from evaporation ponds. Geothermal brines have been identified as a domestic lithium source candidate with the capacity to fulfill the entire Li consumption needs of the U.S., but this resource is currently unexploited. Isolating a pure Li product from these hot brines poses a major challenge due to their corrosivity, elevated temperatures, high levels of dissolved solids, and numerous cationic species. To address this challenge, we use a novel redox membrane concept for Direct Lithium Extraction (DLE). Our team's proprietary molten salt platform is capable of manufacturing fully dense layered, spinel, and olivine transition metal oxide battery cathode materials. We demonstrate that dense cathode materials could function as membranes between the input (lithium brine source) and output (enriched lithium product) streams while permitting Li-flux via an electrochemically driven redox reaction. Unlike traditional membranes, which utilize concentration gradients to drive ion migration between solutions, an electrochemical driving force is envisioned to selectively mobilize lithium cations through a dense, electroplated transition metal oxide membrane. Extracted lithium will be directly converted to a highly valuable LiOH product. Transition metal oxides are ideal candidates for lithium brine extraction due to their capability to selectively uptake lithium ions, high degree of chemical stability at elevated temperatures, and high corrosion resistance. We show that such intercalation based membranes are highly selective for lithium ions over other competing ions such as sodium as well as multivalent cations including calcium and magnesium. Selectivity factors of over 100 has been achieved in our benchtop testing. Continuous operation of this novel redox membrane concept in a flow cell format will also be presented. Combined electrochemical and characterization data confirm the applicability of such concept in several lithium brine streams from geothermal to salar brine compositions. Summary of techno-economics of Li extraction using these membranes, that are recyclable, will also be presented.

2:30 PM EN09.02.03

Alternative Process Chain via Selective Leaching, Flotation and Smelting for LIB Recycling Monika Keutmann, Daniel Dotto Munchen and Bernd Friedrich; IME RWTH Aachen, Germany

The increasing demand for batteries, particularly in the electric vehicle and renewable energy sectors, necessitates sustainable and efficient methods for battery recycling. This work presents a comprehensive proof of concept for a battery recycling process chain that employs selective leaching with an organic acid, flotation, and smelting to recover valuable metals. This process aims to extract lithium, graphite, cobalt-nickel alloy, and manganese from spent batteries.

Selective leaching with an organic acid was utilized as the initial step to extract lithium from black mass. This method ensures the targeted recovery of lithium without compromising the quality of other valuable components. The leaching process generated a lithium-rich solution, which underwent subsequent purification steps to obtain a high-purity lithium salt.

The flotation technique was employed to recover graphite, a critical component used in battery anodes. By selectively floating graphite particles, the process achieved efficient separation from other materials, enhancing the purity and recovery rate of graphite.

Following flotation, the remaining battery black mass was subjected to pyrometallurgy to recover cobalt, nickel, and manganese. Pyrometallurgy involves high-temperature processing, enabling the formation of a cobalt-nickel alloy, that can be further treated to produce precursor material for battery production.

Manganese, on the other hand, was found in the slag produced during pyrometallurgical treatment.

The developed process chain for battery recycling offers multiple advantages. Firstly, selective leaching ensures the recovery of lithium, a crucial metal for modern batteries, with high purity and minimal waste generation. Secondly, flotation enables efficient graphite recovery, addressing the increasing demand for this material. Lastly, smelting yields a valuable cobalt-nickel alloy and manganese is found in the produced slag, potentially opening up possibilities for further recovery.

The proof of concept presented in this work demonstrates the feasibility of the proposed recycling process chain for batteries. By integrating selective leaching, flotation, and pyrometallurgical treatment, this approach provides a comprehensive solution for recovering key battery materials. The successful extraction of lithium, graphite, cobalt-nickel alloy, and identification of manganese in the slag highlights the potential for resource sustainability and circularity in the battery industry.

2:45 PM EN09.02.04

Exploring Limits of Scale: Hydrothermal Relithiation for Direct Recycling Maura Appleberry and Zheng Chen; University of California, San Diego, United States

Direct recycling is a promising alternative for low-cost and more environmentally friendly disposal of lithium-ion batteries. Hydrothermal relithiation is a method of direct recycling that uses an aqueous lithium hydroxide solution to infuse lithium back into cathode black mass at high temperatures and pressures. Despite recent attention and study, the limits of scaling the hydrothermal process are not understood. Our work has built on previous advancements of optimizing hydrothermal parameters, and demonstrated that the amount of aqueous solution can be significantly limited to still recover spent cathode materials. Through a study of lithium diffusivity at various states of delithiation, it is shown that minimal excess lithium is necessary to relithiate various lithium nickel cobalt manganese oxide (NCM) cathode materials. The improved solution-to-black-mass ratio maintains high cycling performance, fully restoring to pristine electrochemical capacity, thus paving the way for at-scale rejuvenation.

3:00 PM BREAK

3:30 PM EN09.02.06

Exfoliation of LiCoO₂ into Nanosheets for Cobalt-Ion Extraction and Cathode Recycling Hsin Juei Wang and Candace K. Chan; Arizona State University, United States

In recent years, methods for recycling Li-ion battery cathode materials such as lithium cobalt oxide (LiCoO_2 , LCO) have attracted more and more attention. Since the cobalt in LCO is a limited resource, developing better ways to extract and recycle cobalt from the cathode materials becomes a critical issue. Traditional methods include pyrometallurgy and hydrometallurgy, which involve high temperatures and reaction of spent LCO with acid, respectively. Here, a new approach investigates cobalt extraction from nanosheets of LCO based on the rationale that cobalt extraction is more facile from high surface area LCO nanosheets compared to bulk LCO particles. To obtain LCO nanosheets, two exfoliation methods are used: 1) an oxidation-reduction assisted method, and 2) proton-exchange assisted method. Both approaches are aided by the intercalation of bulky ammonium cations into the interlayer space of the LCO structure, which facilitates exfoliation of LCO to form nanosheet suspensions in water upon sonication. The last step is to mix the nanosheet suspensions with cation solutions with the goal of achieving ion exchange and extraction of cobalt. The process is dependent on the pH of the solution and the choice of cation used to exchange for cobalt. This process is also demonstrated for other Co-containing cathodes such as LiNiMnCoO_2 (NMC) and LiNiCoAlO_2 (NCA). The effectiveness of cobalt extraction and ion-exchange are characterized using Raman and X-ray photoelectron spectroscopy, electron microscopy, and inductively coupled plasma spectroscopic analysis. Further research will focus on different kinds of ion exchange and the reassembly of nanosheet backs into functional cathode materials.

3:45 PM EN09.02.07

From Lab Scale to Upscale Lithium Recovery Through Neutral Leaching of Black Mass Daniel Dotto Munchen and Bernd Friedrich; IME - RWTH Aachen, Germany

In the next ten years, it is expected that the electric vehicles market will grow at least 20 % each year. Therefore, the manufacturing and usage of batteries, mostly of Lithium ion batteries, will rise. To avoid shortages in supply, the recycling of end-of-life batteries is the key for a complete circular economy. However, the recovery of lithium from the active material—so called black mass (BM)—lacks in a consolidated recycling route, especially concerning industrial scale. In hydrometallurgical treatment, water leaching with CO_2 injection was developed to recover Li in an early stage based on solubility, which is an easy and low cost operation. With that in mind, this work aims on upscaling neutral leaching of BM from lab scale in terms of Li recovery efficiency. Firstly, lab scale trials were performed in a 1.5 L reactor, CO_2 bubbling of 6 L/min, 60 min of leaching time, constant stirring rate of 350 rpm, and particle size $< 63 \mu\text{m}$. The parameters that varied were temperature (20 °C and 80 °C) and solid/liquid ratio (10 g/L and 70 g/L). Based on these results, the upscaling leaching was performed in a 100 L reactor, but with an intermediate solid/liquid ratio of 30 g/L. The lab scale Li recovery efficiency achieved up to 80 % in the conditions of 10 g/L and 80 °C, however at 10 g/L and 20 °C the recovery efficiency was only 3 % lower. The compounds that are expected to be formed are Li_2CO_3 as well as LiHCO_3 , which are soluble in water under such conditions. In contract, when 70 g/L was tested, the results in both temperatures showed Li recovery efficiency of only around 50 % because the solubility limit is reached. In addition, in all scenarios, less than 1 mg/L of other metals was found in solution. Maintaining lower consumption of energy by using 20 °C in the upscale and a slight higher S/L ratio of 30 g/L to better simulate industrial conditions, the Li recovery efficiency showed nearly 65 %, which clearly indicates that S/L ratio is the key factor. In summary, an early stage Li recovery with water and CO_2 injection in upscale presents low cost and has potential to be further enhanced. The Li_2CO_3 in solution can be precipitated through evaporation with low grade of impurities, which is beneficial for the refinement of the raw material for new batteries. Moreover, the filter cake after leaching contains Ni, Co, Mn, and Al. which can be further treated in hydrometallurgy, or even pyrometallurgically as an alloy.

4:00 PM EN09.02.08

Direct LiOH Production from Battery Cathode Leachate with Nanofiltration and Bipolar Membrane Electrodialysis Trent Lee, Lucy A. Kanas, Zi Hao Foo and John H. Lienhard; Massachusetts Institute of Technology, United States

With a growing global interest in environmental protection, the importance of lithium-ion batteries (LIBs) is rapidly increasing. As a result of their quick charging, longevity, and high power density, LIBs are the leading choice in powering portable devices like smartphones, laptops, and electric vehicles.

Unfortunately, domestic supplies of lithium, cobalt and manganese are limited, and current extraction methods are energy-intensive and generate large volumes of chemical waste. Lithium can be secured from primary sources, such as solid ore mining—an environmentally harmful process—or from brine evaporation, which is a very time intensive procedure.

The supply of lithium, cobalt, and manganese can also be augmented through secondary sources, namely by recycling spent cathodes from LIBs. Battery recycling is the process by which valuable metals are recovered from spent LIBs to manufacture pristine LIBs. Lithium, cobalt, and manganese make up the cathode layer of the majority of LIBs. The prominent cathode chemical composition includes: LiCoO_2 (LCO), LiMn_2O_4 (LMO), and $\text{LiNi}_{0.33}\text{Mn}_{0.33}\text{Co}_{0.33}\text{O}_2$ (NMC). Inorganic acid leaching—the process of soaking used batteries in inorganic acids like sulfuric acid and hydrochloric acid—is a highly effective method of recovering lithium, cobalt, and manganese from the spent cathodes. In this process, a highly concentrated acid leachate that comprises Li^+ , Mn^{2+} and Co^{2+} is produced, and electrochemical reactions are commonly leveraged to reduce the metal ions into their respective solid forms.

In this work, we investigate membrane processes for direct LiOH production from battery cathode leachates. First, the battery leachate is pressurized and passed into a Donnan-enhanced nanofiltration process. Conventional polyamide nanofiltration (NF) membranes possess negative volumetric charge densities as a result of the high concentration of carboxyl moieties, leading to poor monovalent selectivity for cations. To enhance cation separations from battery leachates, a highly crosslinked layer of polyethyleneimine (PEI) is covalently bonded with the polyamide substrate through a condensation reaction between the perfluorosulfonic acid and amine moieties. The composite NF membrane acquires a positive zeta potential and exhibits passive selectivity for monovalent cations from the enhanced Donnan exclusion effect. Our preliminary results indicate that the Mn^{2+} and Co^{2+} rejections increase from 65% to 99%, between the experiments involving the pristine and composite NF membranes. Conversely, the Li^+ rejection only increased incrementally from 5% to 13%, and the Li product stream has purity rating of at least 98%.

Second, the Li-rich permeate stream from NF is used as the input to a bipolar membrane electrodialysis (BMED) process. In BMED, a bipolar ion exchange membrane facilitates water dissociation, while the inherent cation and anion exchange membranes inhibit co-ion transport. As a consequence, BMED produces a basic LiOH, an acidic HCl and a desalinated stream. Here, we leverage high current densities to promote efficient water dissociation, enabling highly concentrated (1M or greater) HCl and LiOH streams to be produced from the NF permeate. The HCl can be recycled for acid leaching of battery cathodes, reducing acid consumption and chemical waste generation while promoting a closed atom economy. The concentrated LiOH can be used as a feedstock for direct battery manufacturing.

4:15 PM EN09.02.09

Investigating the Greenhouse Gas Emissions of the Global Lithium Supply Chain for Batteries Siddharth Shukla, Matthew Riddle and Jarod Kelly; Argonne National Laboratory, United States

The global demand for battery materials like lithium is increasing due to increased demand for battery-electric vehicles. Lithium is economically extracted from brine and spodumene ore resources, while clay resources are also gaining interest. These resources are diffusely spread across the globe. The greenhouse gas emissions of extracting lithium from these sources vary considerably due to the required processing energy and material inputs to the systems, along with the needs associated with the desired final products, namely lithium carbonate and lithium hydroxide. Also, different extraction and processing stages may occur in different countries leading to variability in grid electricity emissions and additional transportation emissions. Therefore, an accurate representation of the total greenhouse gas emissions from the global lithium supply chain is difficult to estimate. To fill this gap, the current work uses a novel framework to calculate the emissions from each step of the global lithium supply chain, accounting for the variability in lithium sourcing, additional material requirements, and processing locations. Further, the change in emissions due to possible supply disruptions is also investigated utilizing agent-based modeling of supply-demand flows. Overall, the results from this work can help identify carbon-intensive pathways in the global lithium supply chain and highlight pathways that lead to reduced emissions.

SESSION EN09.03: Poster Session: Lithium-Ion Battery Recycling and Reuse

Session Chairs: Kelsey Hatzell and Marta Hatzell

Monday Afternoon, November 27, 2023

Hynes, Level 1, Hall A

8:00 PM EN09.03.01

Electrochemical Properties of Recycled Battery Materials Jian Peng¹, Neeraj Sharma¹ and Stefanie Maslek²; ¹UNSW, Australia; ²Mint Innovation, New Zealand

Owing to its high energy density and long cycle life, Lithium-ion batteries (LIBs) have been world-widely used for portable devices and electric vehicles in the past decade.¹ Typically, a LIB consists of cathode, anode, electrolyte, separator and sealing components. The graphite and LiCoO₂ (LCO) have been regarded as dominant materials for anode and cathode in commercial LIBs respectively, due to their cycling stability and relatively high energy density. The graphite anode is able to deliver a relatively high reversible capacity of approximately 370 mAh/g, while LCO exhibits a moderate capacity of about 140 mAh/g under the cutoff voltage of 4.2V.²

However, all batteries have a finite lifespan. According to the report, the waste of spent portable LIBs will reach 180,000 tons/annum by 2023, but less than 1% Li-containing waste can be well recycled globally.³ This imbalance of battery waste and recycling/reused battery materials leads to plenty of research on how to effectively recycle transition metals (*e.g.*, Fe, Co, Ni, and Mn) and graphite from spent electrodes. In our study, we systematically investigated the electrochemical properties of recycled graphite powder as well as the LCO synthesized by recycled Co precursors. The capacity of recycled graphite can achieve 350.1 mAh/g at the current of 20 mA/g and capacity retention of 75.5% after 100 cycles. On the other hand, LCO powders synthesized by different Co precursors exhibit various electrochemical performance. The LCO synthesized by recycled CoCO₃ presents a capacity of 132.6 mAh/g at the first cycle but delivers the similar capacity after 100 cycles compared to that of commercial LCO powder. However, the LCO synthesized by recycled Co(OH)₂ only shows the capacity of about 120 mAh/g at the initial cycle.

In order to improve the electrochemical properties of recycled graphite, we have employed ball milling for 3h and 30h respectively to modify its particle size and surface morphology. Both Raman and scanning electron microscope (SEM) patterns indicates that ball milling successfully minimizes the number of defects in graphite particles, while surface area of particles enlarges with ball mill time. After 3h ball mill, these structural changes of graphite noticeably elevated the discharge capacity by 27% at the first cycle and 18.4% retention after 100 cycles. Whereas, regarding to 30h ball milled graphite a serious reaction between graphite and glass fibre separator was observed by SEM after 100 cycles, leading to a rapid capacity fading. It is unexpected that high surface area of graphite may cause the decomposition of glass fibre separator during cycling, which possibly induces safety issues of batteries. The electrochemical properties of ball milled graphite in full cells also implies that ball milling leads to unstable solid electrolyte interphase (SEI) on the graphite surface. Applying commercial LCO as the cathode, ball milled graphite presents a significant capacity fading with cycle number, with capacity decreases of 8.2% and 24.8% after 20 cycles for 3h ball milled and 30h ball milled graphite, respectively.

This work evaluated the electrochemical performance of recycled graphite and LCO synthesized by recycled Co precursors. The effect of ball mill on the electrochemical performance of recycled graphite has also been measured.

Design of a Hydrometallurgical Recycling Process for Polymer Solid-State Batteries using the Example of LFP Cathode Composite Kirstin Schneider, Daniel Goldmann and Bengi Yagmurlu; Technische Universität Clausthal, Germany

New battery technologies are constantly under research to meet the ever-increasing demands of electromobility imposed on lithium-ion batteries (LIBs). Solid-state batteries (SSBs) are emerging as one of the promising next-generation battery technologies, offering higher energy density and improved safety compared to conventional LIBs. Naturally, SSBs have distinct differences than conventional liquid electrolyte LIBs, and therefore, it is crucial to design, adapt and uncover possible recycling routes since the development of SSBs is accelerating. This study investigates the hydrometallurgical recycling of LFP (lithium iron phosphate) in a polyethylene oxide (PEO) composite structure used in the cathode of polymer SSBs.

In this case study, we present a comprehensive analysis on the leaching of LFP cathode composite using sulfuric acid followed by an exploration of possible Fe and Li recovery routes. An important aspect of this investigation is to assess the impact of the PEO matrix on the hydrometallurgical process. To achieve this, a comprehensive characterization of the sample was conducted, including the determination of the particle size distribution, chemical composition, and molecular weight of the virgin polymer. Various process parameters are investigated in detail for the optimization of the recycling process.

The study findings showed that LFP was leached even with under stoichiometric addition of sulfuric acid at 25 °C within a short duration of 60 minutes. Notably, the water-soluble PEO predominantly influenced

the storage stability of the leach solution. Moreover, strategies for iron removal and lithium recovery are also tested and proposed for a comprehensive design of the recycling process. The outcome of this case study offers valuable insights into the hydrometallurgical processing of LFP composites, particularly in the context of the recycling processes for next-generation SSBs. By understanding the leaching mechanism and the impact of the PEO matrix on the hydrometallurgical process, recycling processes can be strategically adapted to future material flows, thereby contributing to the advancement of the circular economy of batteries.

Analysis of R&D Investment and Performance Evaluation for Government-Funded R&D Programs in the Field of Lithium-Ion Batteries Dongyoung Kim, Sein Kwon, Junhwan Lee, Sangwoo Lim and Yeojin Jeong; Korea Institute of S&T Evaluation and Planning, Korea (the Republic of)

This study aims to overview the current status of government-funded R&D programs in the field of lithium-ion batteries, analyze the evaluation indicators, suggest future directions for designing new research programs, and provide a guide for selecting indicators to study the feasibility and performance of the programs.

As of 2022, there are seven government R&D programs in the field of lithium-ion batteries, organized by the Ministry of Trade, Industry, and Energy. These programs, of which budget amount to 26.815 billion KRW (20.5 million USD), include studies on improving the performance of lithium-based rechargeable batteries, to enhance the reliability of rechargeable batteries through evaluation infrastructure, developing ESS technology using battery packs used in electric vehicles/ESS, and developing a battery-sharing platform for electric vehicles (EVs).

The performance evaluation indicators for the outcomes of these programs include indicators related to battery performance, patent, paper, revenue, technology standardization proposals, equipment establishment and operation rates, and conducting user satisfaction surveys.

Although the programs for analysis were selected based on specific criteria, the ratio for the field of rechargeable batteries seems to be relatively low compared to the Korean government's R&D budget of 29.8 trillion KRW (20.5 million USD). Basic research projects for battery material development were excluded, and further discussions are needed on the overall support scale and the direction of support in the field of lithium-ion batteries, both in terms of government support R&D and private sector R&D.

Additionally, to improve the performance of R&D in the field of lithium-ion batteries, it is necessary to discuss the exploration of various evaluation indicators and data accumulation for performance evaluation, aiming to enhance R&D performances in the field of lithium-ion batteries.

8:00 PM EN09.03.04

Graphene Oxide (GO) as Chemical Anchor of Polysulfides for Li-S Batteries Balram Tripathi^{1,2}, Claudia Zuluaga Gomez¹, Ivan Castillo¹, Sunny Choudhary¹, Mohan Bhattarai¹, Rajesh Katiyar¹, Gerardo Morell¹ and Ram Katiyar¹; ¹University of Puerto Rico, United States; ²S S Jain Subodh PG College Jaipur, India

Lithium-sulfur (Li-S) battery is one of the most promising candidate for the next-generation rechargeable cell. In order to control the shuttle effect of dissolution lithium polysulfides (LIPSs), the chemical interactions between sulfur host and LIPSs on the performance of Li-S batteries has recently been highlighted. Herein, a facile strategy is proposed, which produces graphene oxide (GO) as an anchor to restrain LIPSs in Li-S batteries via chemical confinement by strong bonding interaction between GO and Li₂S₆. X-ray diffraction (XRD), Raman analysis & Scanning electron microscopy (SEM) of prepared

composite material was done to study structural and morphological properties. Electrochemical performance of GO-S composite cathodes using LiTFSI electrolyte was studied by galvanostatic charge-discharge at various c-rates as well as via cyclic voltammetry & EIS measurements. The detailed results of the study will be discussed during the presentation of meeting.

8:00 PM EN09.03.05

Efficient Separation of Cathode Materials in Direct Recycling of Spent Lithium Ion Batteries

Kwang Bum Kim and Hunseok Choi; Yonsei University, Korea (the Republic of)

There is a growing demand of lithium ion batteries in consumer electronics, electric vehicles, and energy storage systems, which would eventually generate a huge number of spent lithium ion batteries. Spent lithium ion batteries should not be treated as waste but be considered as a valuable resource rich in critical materials such as Co, Ni, Li and Cu. Recently, direct recycling process is being actively investigated to retrieve high value cathode materials which retains the original structure and morphology without chemical decomposition to metallic elements or metal ions. A major challenge for direct recycling is to efficiently separate cathode materials from aluminum foil because of the high adhesive bonding strength and chemical stability of polyvinylidene difluoride (PVDF) binder used in the production of lithium-ion batteries. In this regard, environmentally sustainable delamination process needs to be developed to efficiently recover cathode materials from cathodes. However, current procedures reportedly used toxic organic solvents to separate the active cathode materials from the aluminum foil. In this study, we report on the direct recycling of NCM cathode materials from spent lithium ion batteries, important delamination parameters and materials properties of delaminated NCM. More details will be discussed at the meeting.

8:00 PM EN09.03.07

Recycling and Upcycling Graphite Anode Materials Yi Peng, Margaret Wu, Jared Liao, Tyler

McGivern-Jimenez, Zhiqian Wang and Lance Yang; Princeton NuEnergy, United States

Lithium-ion batteries (LIBs) have emerged as the battery of choice for rapidly growing markets in electric vehicles (EVs) and energy storage devices. Thus, there is an enormous interest in the development of new technologies for recycling and recovery of valuable materials from secondary resources, such as those from used LIBs. Finding ways to decrease the cost of recycling could thus significantly reduce the life cycle cost of LIBs, avoid material shortages, lessen the environmental impact of new material production, and provide low-cost active materials for new LIB manufacturing. In recent years, the recycling of spent LIBs has mainly been focused on the recycling of the cathode, while recycling of the graphite anode has only received limited attention due to its low value and complex recycling process. However, with the recent shortage of resources and the increase in production costs, recycling of graphite anode from spent batteries can no longer be ignored. There are several challenges associated with recovering spent graphite anodes – mainly, there are a variety of metal impurities in addition to surface solid electrolyte interface (SEI) and interior impurities which need to be removed. Conventional recycling methods are unable to solve this issue, especially in the purification process. Most current recycling systems use pyrometallurgical and/or hydrometallurgical methods, which necessitate multi-unit operation, high energy consumption, and high cost. Direct recycling, on the other hand, is a promising solution for overcoming the hurdles involved with recovering spent graphite anodes.

Princeton NuEnergy (PNE) has successfully developed a novel low-temperature plasma process to enable purification and direct repair of graphite anode materials from spent LIBs. We also demonstrated a simple but effective approach to upgrade the spent graphite to produce graphite-silicon composite with improved

energy density. Spent graphite is an ideal choice for low-cost production of high-performance silicon-graphite composites because treated spent graphite presents a porous structure which can be well combined with silicon and effectively relieve volume expansion. The recycled graphite and upcycled graphite-silicon composite anode materials outperform the commercially available equivalent. The direct recycling/upcycling of graphite anode materials will increase the commercial viability of LIBs and reduce battery cost, thus accelerating the electrification of transportation and large-scale energy storage for renewable energy in the near future. In this presentation, the materials characterization and electrochemical performance of recycled/upcycled anode materials will be discussed.

8:00 PM EN09.03.08

Direct Recycling of NCM Cathode Materials from Spent EV Batteries Jared Liao¹, Christopher Brooks², Lyndon Huang¹, Zhiqian Wang¹ and Lance Yang¹; ¹Princeton NuEnergy, United States; ²Honda Research Institute USA, Inc., United States

Lithium-ion batteries (LIBs) have emerged as the battery of choice for rapidly growing markets in electric vehicles (EVs) and grid electricity storage. This spurs a great demand for lithium, cobalt, and nickel that could outstrip the supply of virgin materials. Thus, there is an enormous interest in the development of new technologies for recycling and recovery of valuable materials from secondary resources, especially those from used LIBs. Compared to conventional high temperature pyrometallurgical or strong acid hydrometallurgical methods, the direct recycling of LIBs shows great promise. Direct recycling regenerates the cathode materials without destroying the underlying compounds, while significantly reducing energy and chemical consumption.

Our low-temperature plasma-assisted separation (LPASTM) process has major reductions of adverse environmental impacts from mining/brine extractions of virgin metals, raw material transportation, and energy consumption. Direct regeneration of cathode materials using this technology is far less costly and disruptive than virgin production. Cathode materials account for over 50% of typical LIB material value. As a result, recycling cathode materials is especially important for reducing battery costs. PNE's technology has proven versatile – capable of recycling and regeneration of a variety of cathode materials. In this presentation, we will present one typical case to demonstrate the successful regeneration of NCM cathode materials from spent EV batteries via our LPAS based direct recycling process.

8:00 PM EN09.03.09

Recycling of Solid-State Batteries - Influence of Different Solid Electrolytes on Mechanical Recycling Behaviour Marco Ahuis^{1,2}, Peter Michalowski^{1,2} and Arno Kwade^{1,2}; ¹TU Braunschweig, Germany; ²Battery LabFactory Braunschweig, Germany

The growing use of lithium-ion batteries (LIBs) is leading to an increasing demand for raw materials, which may lead to raw material shortages and rising material costs in the future. In this context, solid-state batteries (SSBs) are promising next-generation batteries in which the liquid electrolyte of conventional LIBs is replaced by a solid-state electrolyte, offering advantages such as increased lifetime, energy density, and safety. To successfully establish the different SSB systems (e.g. polymer, sulfide, oxide and halide) in the market, material cycles need to be identified and closed to achieve lifecycle sustainability.

In this context, recycling and reuse of materials are essential elements of a climate-neutral and resilient energy system. Compared to the recycling of conventional LIBs, no drying or thermal step is required to recover the liquid electrolyte as it has been replaced by a solid electrolyte. However, the different SSB systems have different characteristics in terms of comminution and classification behaviour, so different

process chains need to be developed taking into account the technological, safety, economic, and environmental properties of the materials used. [1]

This study examines the influence of the different solid electrolyte systems on mechanical recycling, specifically focusing on the comminution and classification behaviour. The comminution of **polymer SSBs** produces a foil fraction that cannot be further separated and requires additional processing. One possibility is solvent-based processing to separate the cathode active material. **Oxide SSBs**, due to the intrinsic properties of the solid electrolyte, are well suited to mechanical separation, allowing for subsequent hydrometallurgical processing, regardless of the active material used. High yields of oxide material can be achieved here, especially after thermal pretreatment. Due to the formation of hydrogen sulfide upon contact with water, **sulfide SSBs** require a process route to stabilise or inactivate the electrolyte before mechanical treatment. Initial studies with sulfur-based materials show that they can be recovered (up to 75 wt.-% yield) in a dry atmosphere and fed directly back into the production process. In order to evaluate each process, basic characterisation of the materials or intermediate and final products was carried out using various analytical methods such as TGA, ICP-OES and SEM-EDX. The results of this work will indicate possible process routes for the recycling of solid-state batteries, paving the way for the development of efficient recycling processes even before SSB technology is ramped up. This establishes the foundation for creating closed, robust material cycles towards a CO₂-neutral energy system.

8:00 PM EN09.03.11

Optimization of the Discharge Process of Spent Li-Ion Batteries from Electric Vehicles for Direct Recycling Hyunseok Lee; Korea Battery Industry Association, Korea (the Republic of)

Since introducing electric vehicles 10 years ago, the disposal of spent LIBs generated from EVs has rapidly increased. The two main approaches for processing spent LIBs for EVs are reuse and recycling. Many studies have shown that the battery healthcare system can effectively estimate the spent batteries state of health for reuse. However, the spent LIBs must ultimately be recycled at the end of the reuse. Since the rare metals in spent LIBs are precious because they have limited reserves, researchers are investigating a systematic and safe recycling system. So far, three types of recycling methods for spent LIBs have been considered—pyrometallurgy process, hydrometallurgy process, and direct recycling. The pyrometallurgy process is widely used for the commercial recovery of cobalt. However, it has the disadvantages of high carbon emissions and difficulty in recovering Li. The hydrometallurgy process would be an alternative since it can recover more Li and Mn than the pyrometallurgy process. However, the hydrometallurgy process generates large amounts of wastewater and contaminated acid fumes, which can severely pollute the environment. Thus, research on direct recycling is recently gaining attention. Discharging spent LIBs is an essential process for direct recycling for the spent LIBs. By immersing the LIBs in the ionically conducting salt water to form the short circuit, the electrochemical discharge of LIBs in a conducting solution is introduced. Li et al. analyzed the chemical components of wastewater from the salt-water discharge process. Owing to salt-water discharge, they detected “high” levels of aluminum and iron and “moderate” levels of cobalt, lithium, copper, calcium, and manganese. In addition, considerable amounts of zinc, barium, and vanadium were also detected. The high concentrations of P were also observed, indicating that the corrosion of the metal collectors and sealing compartments causes the

leakage of a certain amount of the electrolyte (i.e., LiPF₆). Thus, a suitable discharge technology must be developed because the damage to LIB by salt-water discharge causes additional costs and steps in the recycling process.

In this study, we recovered spent LIBs used in two EVs and observed the state of the modules and cells through electrical discharge. Additionally, we performed a comparative experiment with the salt-water discharge of pouch-type LIBs because pouch-type LIBs are primarily used in EVs. After the discharge of the spent LIBs to various voltages, the crystal structures of the cathode and anode were analyzed. We examined problems caused by over-discharge based on the state of health and determined the appropriate discharge voltage. Swelling due to over-discharge became more rapid as SoH decreased. Cell volume expansion caused by swelling increases the internal pressure of the cell packaged in the module, leading to a risk of explosion. Therefore, it is essential to discharge pouch cells to an appropriate voltage that can prevent the pouch swelling of LIBs. The results of this study indicate the proper voltage for electrical discharge, which is adjudged applicable for environmentally friendly recycling processes.

As a spent LIB with a state-of-health of 66.8% was over-discharged, swelling significantly increased. Even after being discharged to 0 V, the voltage could recover to 2.689 V. We analyzed the discharged spent LIBs through X-ray diffraction, scanning electron microscopy, and electrochemical impedance spectroscopy, and confirmed the appropriate voltage for the discharge process is estimated to be 2.5 V. The proposed electrical discharge process will be suitable for the direct recycling of spent LIBs in the form of pouch cells.

8:00 PM EN09.03.13

Crosslinked Zwitterionic Amphiphilic Copolymeric Membranes for Ion Separations Ashleigh B. Herrera and Ayse Asatekin; Tufts University, United States

Lithium has become crucial for addressing the energy needs of the future. Current methods of lithium extraction are laborious, expensive, and environmentally damaging. Membrane technology offers an energy-efficient, simplistic, and scalable method for extracting lithium from aqueous sources. There has been recent progress showing the potential of membranes for recovering valuable mineral resources such as lithium and precious metals from wastewater, but many current membranes do not adequately address the selectivity, reliability, and fouling resistance these separations require. Recent work in our group has shown that thin film composite membranes with cross-linked zwitterionic amphiphilic copolymeric (x-ZACs) selective layers exhibit excellent fouling resistance coupled with exceptional ion selectivity. This ion selectivity is both size and charged based, separating like-charged ions such as chloride and fluoride. These x-ZACs readily self-assemble to form a network of nanochannels lined by the zwitterionic group. These channels are ~1 nm in size where the size is related to the degree of crosslinking. Previous work has suggested the ion selectivity is associated with selective interactions between the zwitterions lining the x-ZAC channels and the ions passing through. This effect appears to also be influenced by the confinement of the ions into the ~1 nm self-assembled nanochannels. However, to date, only one x-ZAC chemistry has been studied for ion separations. Current work expands on these findings to synthesize x-ZAC membranes that focus on other zwitterionic repeat units. The goal is to create membranes with cation-cation selectivity to use in various separations including lithium recovery from brines and lithium-ion battery waste solutions and selective extraction of valuable metal ions from wastewater and mine drainage. To accomplish this, we have synthesized x-ZAC membranes with different zwitterionic chemistries and analyzed the selectivity between cations. Preliminary studies have shown some selectivity between La⁺ and Na⁺ salts for a specific zwitterion chemistry. This work suggests that similarly sized and charged ions can be separated with pressure-driven membranes utilizing well-selected x-ZAC chemistries and crosslink densities, enabling more energy-efficient recovery of metal resources,

especially lithium.

8:00 PM EN09.03.14

Simplified Solvent Extraction Process for High-Purity Ni/Co Mixed Solution for Lithium-Ion Batteries Gogwon Choe¹, Young-Jin Lim¹, Younghyun Kim¹, Go-Gi Lee² and Yong-Tae Kim¹;

¹POSTECH, Korea (the Republic of); ²RIST, Korea (the Republic of)

The demands for Ni-based raw materials increase as Ni–Co–Mn ternary cathode materials become the main axis of the battery industry. Conventional hydrometallurgical process to produce raw materials from Ni ore for battery application is as follows: (i) leaching of metal ions by acid, (ii) solvent extraction process to extract target metals, and (iii) crystallization process to produce final single-metal compound as powder products. The conventional solvent extraction process is a three-circuit process comprising impurity removal, Co extraction, and Ni extraction circuits. Unlike conventional process, in this work, we suggest a simplified two-circuit process to simultaneously extract Ni and Co to produce Ni/Co mixed solution for cathode material precursor production which can also be applied to hydrometallurgical battery recycling process. Accordingly, the efficiency of site utilization can be maximized by reducing the investment cost for the manufacturing process and downsizing mixer-settler facilities. Further, ecofriendly effects such as reducing the consumption of titrants and cutting down the process costs and wastewater discharge can be realized.

8:00 PM EN09.03.15

Analysis of The Supply Chain Structure, Competitiveness and Risk in The Field of Lithium-Ion Batteries and Future Directions of The Government's Strategic R&D Policy Sein Kwon and

Dongyoung Kim; Korea Institute of S&T Evaluation and Planning, Korea (the Republic of)

The main purpose of this study is to analyze the supply chain structure, competitiveness, and risk factors in the lithium-ion battery sector, and to provide future directions for the government's R&D policy response to internal and external strategic environmental changes.

Traditionally, Raw material procurement in the lithium-ion battery supply chain is influential as the four core materials account for 75% of the cost. Recently, the importance of the recycling process has become more prominent due to the rapid growth of the market and the rise in raw material prices with black swans factors in the global supply chain. In the supply sector, three East Asian countries such as Korea, Japan, and China are leading the market. In particular, China's market dominance is overwhelming in the raw material mining and procurement sector. Meanwhile, due to the U.S.-China supply chain conflict, China is expected to promote internalization of the supply chain based on technological competitiveness and strategic assetization of key minerals. Therefore, the global supply chain structure also implies the possibility of uncertain change.

According to the results of the supply chain competitiveness analysis of 6 major countries, Korea has a relative competitive edge in design and cell manufacturing. Particularly, manufacturing companies are forming the mainstay of the industry by actively participating in R&D, and since many firms in the material and equipment sectors are participating in the supply chain network, the completeness of the domestic supply chain is robust. In contrast, It has low competitiveness in the demand and procurement process. Notably, there is a very high dependence on certain countries for raw material supply and demand. The material sector's dependence on China is 63.7%, with some of the LCO, PP/PE, and NCM accounting for 100% of the dependence.

In 2022, there are 7 government R&D programs led by the Ministry of Trade, Industry and Energy related to lithium-ion batteries, accounting for 0.09% of the total budget of 29.8 trillion KRW (20.5 million

USD) for the Korean government's R&D programs. Most R&D programs focus on investing infrastructure of large-scale facility and equipment, and improving performance and developing innovative manufacturing technologies. Furthermore, The government has selected secondary batteries as the 12 major national strategic technologies and is focusing on developing safety-enhancing technologies for the four core materials through a five-year short-term strategy.

Even though Korea has a competitive edge in the design and manufacturing sector, it is necessary to diversify its supply chain to cope with the dependence on raw materials procurement concentrated in certain countries. In this regard, specific strategies for eco-friendly supply chain processes such as building strategic recycling hubs are required. In addition, the recycling-related R&D budget and programs are very insufficient, so it is necessary to plan new R&D programs and projects and promote investment in this field. In particular, financial support for initial investment in waste battery reuse and recycling demonstration projects, a standard system for safety and performance verification, and a professional training policy should be prepared to enhance technological competitiveness.

SESSION EN09.04: Lithium-Ion Battery Recycling and Reuse III

Session Chairs: Zheng Chen, John Cook and Beniamin Zahiri

Tuesday Morning, November 28, 2023

Hynes, Level 1, Room 108

8:45 AM EN09.04.00

Rationally Designed Nanomaterials for Highly Efficient and Robust Electrochemical Lithium Recovery Jin Soo Kang; Seoul National University, Korea (the Republic of)

Lithium-ion batteries (LIBs), which have changed our everyday lives by enabling the use of mobile devices, are now impacting the fields of transportation and large-scale energy storage. LIBs in these applications are needed in a few orders of magnitude larger than in the mobile electronics, and the demand for lithium in the global market is increasing dramatically. For this reason, there have been significant efforts to develop methods for separation and extraction of lithium from various sources, including LIB wastes, in order to diversify and secure the supply of lithium resources. One example is electrochemical lithium recovery process developed around a decade ago. By using spinel- or olivine-structured LIB cathode materials, lithium ion could be extracted with a high selectivity. In addition, chloride-capturing electrode with fast kinetics led to successful constitution and operation of the electrochemical system. Meanwhile, there have been rooms for further understanding on the behaviors of the electrode materials under the recovery conditions, which is often challenging as there are species other than lithium being present in large amounts while the lithium concentration could be very low. Herein, our recent works on comprehensive analysis of electrode materials for lithium recovery will be introduced, and based on the obtained understandings, the rationally designed electrode materials with high efficiency and durability will be presented. Simple but intuitive strategies in designing lithium-selective oxide and chloride-capturing organic/inorganic composite led to substantial improvements in the utilization rate of the active components and long-term stability of the electrochemical system.

9:00 AM EN09.04.01

Achieving Low-Temperature Hydrothermal Relithiation by Redox Mediation for Direct Recycling of Spent Lithium-Ion Battery Cathodes Xiaolu Yu and Zheng Chen; University of California, San

Diego, United States

Lithium-ion battery (LIB) recycling is an urgent need to address the massive generation of spent LIBs from portable devices and electrical vehicles. However, the large-scale recycling is hampered by economic and safety issues associated with today's recycling processes. Here, we demonstrate a safe and energy efficient direct regeneration process based on low-temperature hydrothermal relithiation (LTHR) at low pressure for spent $\text{LiNi}_x\text{Co}_y\text{Mn}_z\text{O}_2$ ($0 < x, y, z < 1$, $x + y + z = 1$, or NCM) cathode materials. A low concentration of low-cost redox mediator is employed to improve the relithiation kinetics of spent NCM materials, enabling full relithiation temperature to be reduced from 220 degree Celsius to 100 degree Celsius or below. Correspondingly, the pressure incurred in the relithiation process can be reduced from ~25 bar to 1 bar, offering significantly improved operation safety. Specifically, three NCM materials, including chemically delithiated NCM111, cycled (degraded) NCM111, and cycled NCM622, were successfully regenerated with complete recovery of composition, crystal structure, and electrochemical performance, achieving the same effectiveness as that achieved at high temperature process. Meanwhile, the total energy consumption of spent cell recycling and the greenhouse gas emission is also reduced. This work provides a facile and scalable way to more sustainable LIB recycling with high economic return, high operation safety and low cost.

9:15 AM EN09.04.02

End-Of-Life Lithium-Ion Batteries—Recycling and Upcycling of Cathode Materials Rosie Madge^{1,2}, Abbey Jarvis^{1,2}, Laura L. Driscoll³, Paul A. Anderson^{1,2} and Peter Slater^{1,2}; ¹University of Birmingham, United Kingdom; ²Faraday Institution, United Kingdom; ³UKBIC, United Kingdom

Worldwide there has been an increase in the use of electric vehicles which has led to a consequent increase in the number of end-of-life lithium-ion batteries (LIBs) that need to be recycled. Recycling is commonly performed using pyrometallurgical and/or hydrometallurgical processes. These methods focus on the recovery of high value metals, such as Ni and Co, from the batteries. Alternative methods are therefore required to ensure that the entire battery is recycled and that the critical materials contained within the batteries are utilized in a meaningful way.

This work investigates recycling cathode material from an end-of-life Gen 1 Nissan Leaf (2011 model, 40,000 miles) which contains a mixture of LiMn_2O_4 (LMO) and $\text{LiNi}_{0.8}\text{Co}_{0.15}\text{Al}_{0.05}\text{O}_2$ (NCA). LMO is combined with NCA to provide good thermal stability along with high capacity and long lifetime.^{1,2} The use of such a blended cathode mixture increases the complexity of recycling as there are more components within the cathode that must be considered during recycling processes. A method has been developed which can selectively leach LMO from the cathode material using organic acids.³ The separated LMO and NCA can then be regenerated and reused in new LIBs.

However, LMO is no longer favoured commercially, therefore this work investigates upcycling it into higher value materials. LMO has been upcycled to form a range of cathode materials, such as $\text{LiMn}_{1.5}\text{Ni}_{0.5}\text{O}_4$ (LMNO) and $\text{Li}_4\text{Mn}_2\text{O}_5$, a cation disordered rocksalt. These upcycled cathodes have been shown to have a comparable electrochemical performance to cathodes synthesised using pristine starting materials. This therefore demonstrates that end-of-life cathode materials can be upcycled to form new higher value cathode materials.

Recycling Valuable Metals from All Species of Spent Lithium-Ion Batteries using Non-Organic Solvents System Tzu Ming Cheng, Zheng Yu Chen and Chih-huang Lai; National Tsing Hua University, Taiwan

Lithium-ion batteries have become the mainstream energy storage material in various industries due to their high energy density, high operating voltage, wide temperature range, and long lifespan. In recent years, the electric vehicle industry has flourished in an effort to reduce environmental pollution. Lithium-ion batteries, with their aforementioned advantages, have replaced traditional nickel-hydrogen batteries as the dominant power source for electric vehicles. This surge in demand for lithium-ion batteries is expected to generate a significant amount of waste batteries. Improper handling of these discarded batteries can pose serious risks to the environment and human health. Moreover, lithium batteries contain valuable metals such as lithium, cobalt, nickel, and manganese, which are vital and strategic resources. Developing suitable technologies to recycle and reuse these waste lithium-ion batteries can not only reduce environmental pollution but also enhance control over critical valuable metal resources, particularly since these metals are not domestically available and currently rely on imports. Mastering recycling techniques offers the opportunity to treat a large quantity of waste batteries as a valuable mineral deposit through urban mining. Therefore, lithium-ion battery recycling is poised to become a highly promising and profitable industry.

With the objectives of low cost, continuous operation, and scalability, we have developed an efficient, non-organic solvent recycling process for all species of lithium-ion batteries. Initially, we simulated the recycling scenario using simulated materials. The target elements including iron, phosphorus, and lithium, can be easily separated using pH control and therefore precipitants. However, the separation of nickel, cobalt, and manganese, which are closely positioned in the periodic table with similar physical and chemical properties, presents challenges in non-organic solvents system. To overcome this, we identified two aqueous phase precipitants, KMnO_4 and NaClO , combining with pH control, successfully separate these three elements without mutual interference. Ultimately, this method achieves high purity of recovered materials of all elements, with individual product purities reaching 98.72 wt% for iron phosphate, 92.97 wt% for manganese oxide, 98.06 wt% for cobalt oxide, 95.86 wt% for nickel hydroxide, and 96.76 wt% for lithium carbonate. This proposed process also provides high recovery yields which recovery yield reaching above 99% for valuable elements. To ensure the applicability of this technique to the industry, the real industrial black powder from a battery recycling plant was also applied for this research. Under the same process, we collected all the recycling products of above 90 wt% purity and the recovery yields reaching above 96% for valuable elements. Compared to existing lithium battery recycling technologies, this process offers a broader range of target products and provides an efficient recycling process with mass production potential.

10:15 AM *EN09.04.05

Lithium-Ion Battery Recycling Facts and Opportunities Ilias Belharouak, Yaocai Bai and Lu Yu; Oak Ridge National Laboratory, United States

The growing demand is generating a huge number of spent lithium-ion batteries, thereby urging the development of cost-effective and environmentally sustainable recycling technologies to manage

electrode scraps and end-of-life batteries. Lithium-ion battery recycling of end-of-life batteries is still in its infancy, with many fundamental and technological hurdles to overcome. The recycling rate of waste LIBs is projected to be much behind the rapid growth of the LIB market because of the complexity of the technology and its use cases. Several recycling strategies, including the pyrometallurgical process, hydrometallurgical process, and direct recycling approach, are being adopted on the market and are under further development by researchers. Here, we provide an overview of the current state of battery recycling by outlining and evaluating the incentives, key issues, and recycling strategies. A direct recycling strategy, which is developed in the US. Advanced Battery Recycling Consortium (ReCell) will be highlighted through a discussion of its benefits, processes, and challenges. Direct cathode regeneration seeks to recover the functional cathode particles without decomposition into substituent metals or salts along with other components such as graphite and current collectors. Perspectives on this important field's future energy and environmental science will also be discussed.

Selective Extraction and Upcycling of LiMn_2O_4 from used First Generation Lithium-Ion Battery Cathodes to Produce Mn-Based Conversion Anodes with Fascinating Electrochemical Properties
Beatrice Browning; University of Birmingham, United Kingdom

A multitude of cathode chemistries have been explored and utilised since the commercialisation of the Li-ion battery (LiB) in the 90s - including transition metal oxide chemistries (such as LiCoO_2 , LiFePO_4 , and LiMn_2O_4) and mixed transition metal oxide materials (such as NMC, $\text{Ni}_a\text{Mn}_b\text{Co}_c\text{O}_2$, and NCA, $\text{Ni}_a\text{Mn}_b\text{Al}_c\text{O}_2$). As electric vehicle adoption is rapidly increasing worldwide, the chemistry of Li-ion batteries used are heavily dictated by consumer demand. Customers expect fast-charging batteries with respectable range, factors which are dictated by the intrinsic electrode chemistry. High specific capacity cathodes that are thermally stable are preferable to consumers, as these features give rise to extended vehicle range and charging speeds. Current cathodes which meet these criteria are predominantly Ni-rich mixed TMO materials (such as NMC and NCA) and LiFePO_4 .

As LiB technology has advanced over the years, initial cathode chemistries have become outdated with each generation of electric vehicle as companies race to ensure consumer demands are met. LiMn_2O_4 (LMO) is an example of a electrode material that was initially seen in electric vehicle batteries, often in conjunction with a layered Ni-rich phase. As subsequent generation vehicles have been released and their performance and energy densities have been enhanced to meet consumer demand, the LMO material has been phased out as the Ni-rich layered materials with high energy density have been prioritised.

When LiBs reach end-of-life the versatility of LiB cathode scrap pool (between manufacturers and between generations of EVs for the same manufacturer) has proven to be challenging for battery recyclers. Selective extraction of materials is imperative to ensure recycling and upcycling of cathode material is feasible from such an assorted cathode scrap pool. Once selectively extracted, cathode material can be recycled in a closed-loop fashion to regenerate battery grade products. When extracting lesser used and redundant cathode chemistries from preliminary cell structures, it is vital that the maximum value of each product is obtained prior to extraction. Upcycling involves extracting and repurposing material to increase its value, and LMO is a key example of a lesser used material can be upcycled to form a variety of Mn-rich conversion anode materials with interesting properties.

Graphite is the main anode material used in LiBs, however graphite reserves are not infinite, nor are they evenly distributed globally - meaning reliance on other countries is great for this anode material and will only increase as reserves are depleted. There is no question that alternative anode materials are necessary to avoid the likelihood of bottlenecks in graphite supply. Through selective extraction and interconversion of LMO, an array of Mn-rich conversion anodes with fascinating electrochemical properties can be produced. Not only can Mn be extracted from redundant LMO cathode material, but Mn-reserves are cheap, non-toxic and abundant, and it is of great interest to explore these conversion anode materials and their characteristics.

Key electrochemical characteristics that are of great interest within this study include the anode capacities being several times greater than their theoretical capacities, and the increase in capacity that arises during cell cycling. The origin of the phenomena observed have been explored using an array of characterisation techniques, including in-situ Synchrotron X-ray diffraction and Pair-distribution function (PDF) analysis, Raman spectroscopy, galvanostatic cycling, cyclic voltammetry, Inductively Coupled Plasma-Optical Emission Spectroscopy and scanning and transmission electron microscopy, to name a few.

11:00 AM EN09.04.07

Resynthesized Electrode Materials from Chemically and Biologically Recycled Li-Ion Batteries

Witold Uhrynowski¹, Magdalena Winkowska-Struzik¹, Maciej Boczar¹, Michal Struzik², Zbigniew Rogulski¹, Andrzej Czerwinski¹ and Dominika A. Buchberger¹; ¹University of Warsaw, Poland; ²Warsaw University of Technology, Poland

Recently, a dynamic increase of interest in the possibilities of recycling and reuse of materials from lithium-ion batteries was observed. Along with the ever-increasing number of Li-ion cells powering new electric and electronic devices, the management of waste batteries and materials contained within them has become a more and more urgent problem to be solved. Due to the growing environmental awareness more stringent legislative means to control the matter are introduced. This includes the latest European Union directive on batteries which states that no less than 35% of Li and 90% of cobalt, nickel and manganese will need to be recovered from waste Li-ion cells. Based on those regulations, the new batteries produced after 2030 will need to contain, for example, at least 6% of recycled lithium. Although large-scale, proper processing of waste batteries is still an economical challenge, the changing global supply and demand dynamics, geopolitical events, technological advancements, and the aforementioned environmental regulations force stakeholders in the battery market to consider battery recycling not only necessary, but also potentially financially viable and sustainable practice.

The battery recycling process should be characterized by high efficiency and the lowest possible impact on the environment, and as such, needs to be optimized for every type of electrode material. For the purposes of this study lithiated nickel-manganese-cobalt oxide 6:2:2 (NMC622) material was chosen, due to its high energy and power density, relatively high resistance to subsequent cell charge/discharge cycles, as well as favorable economic and environmental parameters associated with decreased cobalt content. The electrode material, synthesized from supplier grade new substrates was subsequently recycled in a series of steps, including hydrometallurgical recovery of lithium, and transition metal ions recovery as (hydr)oxides. The leachates were further processed chemically and biologically, by means of selected bacterial consortia, to increase the yield of recycled materials and to lower the concentration of dissolved ions. The use of biological processes in the recycling of waste electrode material reduces the costs of the process, especially at low concentrations – where the load of the leachate is too low for effective and economic chemical recovery, but still too great for safe discharge of the effluents to ground waters. With

Updated as of October 28, 2024

the use of microorganisms, nearly complete removal of nickel, cobalt and manganese ions from the leachates can be obtained, and the resultant technical-grade waters may be reused in the cycle. Effective lithium recovery, however, still remains a challenge.

The obtained recovered lithium and transition metals were further used to resynthesize electrode materials. Crystallographic measurements were performed proving the structure and purity of the obtained recycled materials. The resynthesized NMC622 electrode material with 0 to 100% of recycled materials content were structurally and electrochemically investigated and compared with the "original" material. It was shown that the electrode materials made of recycled materials may perform in a comparable manner with the "original" materials. However, their endurance and stability in charge/discharge cycles is greatly affected by the purity of the recycled substrates.

Recovery of metals from waste batteries is important for economic and ecological reasons. The presented results indicate that optimization of the recycling process, though challenging, is promising, and the resynthesized materials may be a good additive or even an alternative for commercial ones.

A Promising Solid-State Synthesis of $\text{LiMn}_{1-y}\text{Fe}_y\text{PO}_4$ Cathode for Lithium-Ion Batteries Jinli Liu^{1,2};

¹Nanjing University of Science and Technology, China; ²Tsinghua University, China

$\text{LiMn}_{1-y}\text{Fe}_y\text{PO}_4$ (LMFP) is a significant and cost-effective cathode material for Li-ion batteries, with a higher working voltage than LiFePO_4 (LFP) and improved safety features compared to layered oxide cathodes. However, its commercial application faces challenges due to a need for a synthesis process to overcome the low Li-ion diffusion kinetics and complex phase transitions. Herein, we propose a solid-state synthesis process using LFP and nano $\text{LiMn}_{0.7}\text{Fe}_{0.3}\text{PO}_4$ (MF73). The larger LFP acts as a structural framework fused with nano-MF73, preserving the morphology and high performance of LFP. Our results demonstrate that the solid-state reaction occurs quickly, even at a low sintering temperature of 500 °C, and completes at 700 °C. However, contrary to our expectations, the larger LFP particles disappeared and fused into the nano-MF73 particles, revealing that Fe ions diffuse more easily than Mn ions in the olivine framework. This discovery provides valuable insights into understanding ion diffusion in LMFP. Notably, the obtained LMFP can still deliver an initial capacity of 142.3 mAh g⁻¹, and the phase separation during the electrochemical process is significantly suppressed, resulting in good cycling stability (91.2% capacity retention after 300 cycles). Our findings offer a promising approach for synthesizing LMFP with improved performance and stability.

10:45 AM *EN09.05.03

Solvent-Based Sequential Separation Processes for Direct Recycling of Lithium-Ion Batteries

Yaocai Bai, Lu Yu and Ilias Belharouak; Oak Ridge National Laboratory, United States

The recycling of end-of-life lithium-ion batteries and the direct reintegration of the reclaimed materials into the battery supply chain are increasingly recognized as pivotal steps toward fostering a sustainable battery ecosystem. In a typical recycling process, the spent cells are discharged and shredded, followed by electrolyte recovery and component separation to remove/reclaim components like plastics, pouch material, and steel casing. As a result, a feedstock of anode and cathode on their current collectors is generated. This feedstock contains the most valuable components in a lithium-ion cell, including black mass (e.g., active cathode materials and graphite), Cu foils, and Al foils. To reclaim active electrode materials with high purity for direct regeneration, separation of electrode materials from their current collector as well as of anodes from cathodes is necessary. Current techniques require a complex set of separation processes to produce clean streams of material, resulting in lower recovery rates and higher costs. In this talk, solvent-based separation processes will be discussed to sequentially separate both anode/cathode and electrode/current collectors to recover cathode films, Al foils, anode films, and Cu foils. By circumventing a complex set of separation processes, the sequential separation method alone could fulfill the goal of reclaiming higher-purity materials, making recycling more profitable. The designed solution does not damage the active cathode materials nor corrode the metal foils. In addition, this process enables low-temperature separation in a cost-effective solution, reducing energy consumption and processing costs. The discussion will shed light on how environmentally sustainable and cost-effective sequential separation processes pave the way for direct recycling.

Liquid-Phase Electron Microscopy for Probing Electrocatalytic Material Interfaces Vaso Tileli; EPFL, Switzerland

The oxygen evolution half-reaction (OER) is responsible for the limited efficiency of water splitting devices for storing clean energy. A holistic understanding of the fundamental processes taking place during operation of catalysts in solution can be gained by using advanced operando techniques that can complement characterization pre and post operation. In particular, electrochemical liquid-phase transmission electron microscopy (TEM) can provide morphological, structural, and chemical information for these catalysts.

As an example, I will focus on OER oxide-based catalysts studied using liquid-phase TEM to investigate the solid-liquid interface in an alkaline solution [1]. The potential-dependent variation of the local contrast was associated to the modification of the alkaline liquid electrolyte and its wettability at the Co-oxide surfaces. At low applied potential, the hydrophobic character of the oxides was found to reduce due to electrowetting induced by OH^- accumulation at the interface. A distinct transition towards hydrophilicity was probed at the potential associated with the redox $\text{Co}^{2+}/\text{Co}^{3+}$ reaction, which alters the interfacial capacitance. This leads to a relatively stable wetting character at intermediate potentials prior to the OER region where the oxide surfaces catalyse the adsorbed hydroxide ions at the solid-liquid interface to form molecular oxygen. Further operando measurements using electron energy loss spectroscopy (EELS) provided direct evidence of the evolution of molecular oxygen. Finally, similar experiments on IrO_2 particles reveal the possibility of facet-dependent production detections using EELS [2].

Overall, advanced electron diagnostics and characterization applied to electrocatalyst structures can provide valuable insights into solid/liquid/gas interfaces and can guide development of efficient devices.

Fundamental Understanding of Electrode-Electrolyte Interface in Hydrogen Evolution Reaction (HER) Kinetics Aamir H. Shah and Xiangfeng Duan; University of California, Los Angeles, United States

The hydrogen evolution reaction (HER) is one of the most fundamental and critical reactions in renewable energy conversion. The recent advancement in various platinum (Pt) nanocatalyst designs has led to greatly improved HER activity. Identification of the exact active sites and understanding the structure-activity relationship are critical for rational catalyst design but remain elusive due to the lack of

methods robustly resolving the role of different surface sites. Moreover, it is well recognized that the HER kinetics are drastically slower in alkaline media compared to acidic media, but the descriptors of the HER kinetics are still elusive. Specifically, in the presence of alkali metal cations and hydroxyl anions, the electrode–electrolyte (platinum–water) interface in an alkaline electrolyte is far more complex than that in an acidic electrolyte. The effects of different alkali metal cations (AM^+) and pH on these reactions are poorly understood due to a lack of suitable experimental methods. We are combining surface electrical transport spectroscopy (ETS) with other electrochemistry techniques and computational studies to probe and understand the fundamental role of different AM^+ and pH on the reaction kinetics of HER. Our study provides fundamental insights into how and why AM^+ and pH influence HER in alkaline media. We expect that this research will provide the molecular-level understanding that will shed new insights into electrolyte engineering as an alternative pathway to control electrochemical reaction kinetics.

11:15 AM EN10.01.03

Modeling Electrochemical Reaction Rates at Fluid-Solid Interfaces Rachel C. Kurchin; Carnegie Mellon University, United States

A detailed understanding of electrochemical reaction rates at interfaces between liquid electrolytes and a variety of solid electrodes is crucial in the engineering of next-generation electrochemical devices. In addition, it is becoming increasingly important to understand this behavior at higher overpotentials (where deviations from standard approaches such as Butler-Volmer are more likely) for applications such as fast charging of EV batteries. In this talk, I will introduce an extension to Marcus-Hush-Chidsey kinetics that explicitly accounts for the density of states of the electrode, and introduce several applications of it in a variety of systems, including twisted graphene structures.

Uncovering the Electrochemically Active Surfaces in Polycrystalline NMC Battery Cathode Particles Jinhong Min, Riley Hargrave and Yiyang Li; University of Michigan, United States

In battery electrodes, it is widely believed that the electrochemically active surface area equals the surface area of the particles. Based on this assumption, it has been generally believed that smaller particles have faster reaction and diffusion times than larger ones. In this study, we develop a new high-throughput, single-particle electrochemistry platform to test this belief for polycrystalline NMC battery particles. Surprisingly, we observed that the smaller particles have no shorter reaction and diffusion times than larger ones. To explain this unexpected relationship, we propose that electrolyte penetrates the grain boundaries of the secondary particle into the bulk. For this reason, the electrochemically active surface is not the area of the secondary particles, as typically believed, but the area of the primary particles. This work has substantial implications in accurate modeling and control of battery materials.

1:45 PM EN10.02.03

Electrode/Electrolyte Interface Control for Multivalent-Ion Batteries with High Stability and Reversibility Chang Li¹, Rishabh D. Guha², Abhinandan Shyamsuder¹, Zhuo Yu¹, Kristin A. Persson³ and Linda Nazar¹; ¹University of Waterloo, Canada; ²Lawrence Berkley National Laboratory, United States; ³University of California – Berkeley, United States

Rechargeable multivalent-ion batteries (RMBs) are attractive as a “beyond lithium-ion battery” because of their multi-electron transfer and high abundance (eg. Zn^{2+} and Mg^{2+}), which principally provides higher volumetric capacity and better affordability. The development of highly reversible and stable RMBs is correlated to the multivalent feature of these ions, which poses great challenges to the design of functional electrode/electrolyte interfaces.

This presentation will include discussion of key obstacles for these interfaces, followed by tailored strategies to foster good performance. The main topics will cover two different approaches to stabilize the electrode/electrolyte interface by preventing interfacial side reactions in nonaqueous magnesium batteries with an operating potential of over 3.5 V. This includes **a)** a low-cost inorganic surface membrane that protects against the decomposition of an organoborate-based electrolyte to yield an ultra-stable Mg anode for high-power magnesium batteries; **b)** eliminating passivation on the Mg anode by tailoring commercially available electrolytes to achieve over 2500-hour Mg plating/stripping at 2 mA cm^{-2} and 2 mAh cm^{-2} . Brief highlights of interfacial optimization in aqueous zinc batteries will be also presented. Characterization of these designed and highly functional interfaces using depth-profiling high-resolution XPS, TEM and cryogenic-EM will be described.

2:00 PM EN10.02.04

Lithium Metal Anode Enabled by a Robust and Stable Artificial Surface Layer Ridwan A. Ahmed, Ju-Myung Kim, Ji-Guang Zhang and Wu Xu; Pacific Northwest National Laboratory, United States

Lithium (Li) metal batteries have higher energy density than the state-of-the-art Li-ion batteries and the potential utilization in transportation devices. However, their practical application is still hindered by poor performance in terms of cycling stability and safety, especially at high current densities. This is due to a number of reasons among which are reactions between the Li metal and the liquid electrolyte, and formation of dendrites. In this study, we develop a robust and stable artificial solid electrolyte interface (aSEI), which consists of a surface treated (S_T) PEO – $\text{Li}_{6.4}\text{Ga}_{0.2}\text{La}_3\text{Zr}_2\text{O}_{12}$ composite polymer layer (CPL) on Li metal anode. The aSEI developed in this study is characterized by a good combination of electrochemical and mechanical properties. Benefitting from these characteristics, $\text{S}_\text{T}\text{CPL@Li||NMC811}$ cells with 4.7 mAh cm^{-2} cathode loading exhibit improved electrochemical cycling stability compared with the bare Li||NMC811 cells at high current densities of ~ 1.6 and $\sim 2.4 \text{ mA cm}^{-2}$. A capacity retention of $\sim 90\%$ is obtained for $\text{S}_\text{T}\text{CPL@Li||NMC811}$ at $\sim 1.6 \text{ mA cm}^{-2}$ after 200 cycles compared with 60% for bare Li||NMC811. In addition, $\text{S}_\text{T}\text{CPL@Li||NMC811}$ demonstrates higher charge rate capacities at charge current densities compared with bare Li||NMC811. These findings suggest that $\text{S}_\text{T}\text{CPL}$ is promising for high current density Li metal batteries.

2:15 PM EN10.02.05

Elucidating the Role of Prelithiation in Si-Based Anodes for Interface Stabilization Shuang Bai and Y. Shirley Meng; University of California, San Diego, United States

Prelithiation as a facile and effective method to compensate the lithium inventory loss in the initial cycle has progressed considerably both on anode and cathode sides. However, much less research has been devoted to the prelithiation effect on the interface stabilization for long-term cycling of Si-based anodes.

An in-depth quantitative analysis of the interface that forms during the prelithiation of SiO_x is presented here and the results are compared with prelithiation of Si anodes. Local structure probe combined with detailed electrochemical analysis reveals that a characteristic mosaic interface is formed on both prelithiated SiO_x and Si anodes. This mosaic interface containing multiple lithium silicates phases, is fundamentally different from the solid electrolyte interface (SEI) formed without prelithiation. The ideal conductivity and mechanical properties of lithium silicates enable improved cycling stability of both prelithiated anodes. With a higher ratio of lithium silicates due to the oxygen participation, prelithiated SiO_{1.3} anode improves the initial coulombic efficiency to 94% in full cell and delivers good cycling retention (77%) after 200 cycles. The insights provided in this work can be used to further optimize high Si loading (>70% by weight) based anode in future high energy density batteries.

3:00 PM *EN10.02.06

Microscopic Insights into Ion Conduction at Solid-Solid Interfaces Miaofang Chi; Oak Ridge National Laboratory, United States

Solid-state electrolytes are currently being investigated as a highly promising solution to overcome various challenges in battery technology. The ideal solid electrolyte material should exhibit high ionic conductivity while maintaining stability with metallic lithium. In recent decades, significant progress has been made in the development of solid electrolyte materials with high conductivity comparable to organic liquid electrolytes. However, a major limitation in practical applications of these materials is the unexpectedly high resistivity observed at grain boundaries and electrolyte-electrode interfaces. Elucidating the complexities of these interfaces is challenging due to spatial confinement, structural intricacies, and chemical complexities, posing obstacles for both experimental and theoretical approaches. In this talk, I will discuss our recent efforts to probe interfacial phenomena in solid electrolytes using advanced techniques such as in situ and atomic-resolution scanning transmission electron microscopy (STEM) and electron energy loss spectroscopy (EELS). Additionally, I will introduce 4D-STEM and vibration EELS, which enable the investigation of interfacial charge distribution and ion conduction behavior. Through these electron microscopy techniques, I aim to demonstrate their significant potential in providing valuable insights for the design and synthesis of high-performance solid-solid interfaces.

Thermodynamic Stability Dynamics during Delithiation of LiCoO₂ Spencer Dahl¹, Luelc Costa², Jefferson Bettini² and Ricardo Castro³; ¹University of California, Davis, United States; ²National Center for Research in Energy and Materials - CNPEM, Brazil; ³Lehigh University, United States

Cathode cycling leads to critical instabilities of the structures, being one of the most critical causes for battery failure. Interfacial properties are critical in this scenario, but there is a lack of fundamental experimental studies concerning the evolution of surface energies during delithiation and how to control them using thermodynamic strategies to improve cathode performance. Here we report experimental data on the thermodynamics of surfaces in nanocrystalline LiCoO₂ using microcalorimetry and how it relates to stability against dissolution/degradation. By testing chemically de-lithiated states using microcalorimetry and EELS/HRTEM, we were able to quantify the thermodynamic changes between lithiated and delithiated states for a direct evaluation of driving force for growth and degradation. Further, we demonstrate how a dopant (lanthanum) designed to segregate to the surface lowers the excess energy of the interface, causing nano-LiCoO₂ to show greater resistance to dissolution/growth/degradation.

founded on the dopant impact interface energies. Although LiCoO₂ was used as a model material, we discuss here the design principle behind interface stabilization to allow greater performance in liquid and solid state batteries.

3:45 PM EN10.02.08

Critical Deterioration Roots of Ni-Rich Cathode during Long-Term Cycling: Material Degradation, Diffusion Limit or Interfacial Instability? Jiyu Cai¹, Natasha Chernova², Brad Prevel³, Feng Wang¹ and Zonghai Chen¹; ¹Argonne National Laboratory, United States; ²Charge CCCV, United States; ³Primet Precision Materials, United States

Severe performance deterioration in long-term cycling is a long-standing challenge for practical applications of high-energy-density Ni-rich LiNi_{1-x-y}Mn_xCo_yO₂ (NMC, x+y < 0.5) cathodes at high potentials (>4.3V vs. Li/Li⁺). Great efforts have correlated the performance deterioration to many physical observations, while the critical deterioration roots of Ni-rich cathode during long-term cycling are not well elaborated. Herein, we perform a systematic and in-depth investigation to probe the critical contributions from observed deterioration roots of Ni-rich LiNi_{0.83}Mn_{0.1}Co_{0.07}O₂ cathode in full cells with graphite anode after 1000 cycles at different upper potentials. Intriguingly, the severe capacity retention in electrochemical evaluation of recovered cathode half cells is contrail to the insignificant structural changes and transition metal loss via post-mortem characterizations of bulk material. GITT tests unveils that chemical diffusion limit is the dominant deterioration root of Ni-rich cathode at high potential. The severe chemical diffusion of Li⁺ is strongly correlated to the exacerbated surface reconstructions at the cathode surface. Our study suggests that stabilizing the cathode interface and mitigating the surface reconstructions is the most crucial for enabling long lifespan of Ni-rich cathodes at high potentials.

4:00 PM EN10.02.09

Interfacial Aluminum Corrosion Reactions with Lithium Bis(fluorosulfonyl)imide (LiFSI) in Fluorinated and Non-Fluorinated Ether-Based Solutions for Li-Metal Batteries Taegyu Jang and Hye Ryung Byon; KAIST, Korea (the Republic of)

Lithium-metal batteries (LMBs) have garnered significant attention as a potential replacement for graphite-based lithium-ion batteries due to their superior energy density. However, a critical challenge in LMBs is stabilizing the metallic lithium (Li) electrodes, which face continuous decomposition of the electrolyte solution and the formation of dendrites. It is crucial to develop a desired solid electrolyte interphase (SEI) that contains lithium fluoride (LiF) to protect the Li surface. For this purpose, the bis(fluorosulfonyl)imide (FSI⁻) anion has been widely employed, as it readily forms abundant LiF through defluorination. However, the use of FSI⁻ is accompanied by the corrosion of aluminum (Al), the current collector in the positive electrode, which often leads to cell failures. Although recent studies reported mitigated Al corrosion through the use of fluorinated ethers and locally high concentrated electrolytes (LHCE), there is a lack of study on the interfacial reactions between these electrolytes and Al, as well as their ability to inhibit corrosion.

Herein we studied the Al corrosion with 1 M LiFSI in 1,2-dimethoxyethane (DME), tetraethylene glycol dimethyl ether (G4), 2,2,3,3-tetrafluoro-1,4-dimethoxybutane (FDMB), and LHCE comprising DME and 1,1,2,2-tetrafluoroethylene 2,2,3,3-tetrafluoropropyl ether (TTE). The corrosion of Al was evaluated through chronoamperometry tests conducted from room temperature to 60 °C. The applied potential for each test was kept below the oxidation potential of the electrolyte solutions (4~4.3 V for DME and G4, and 4.5 V for FDMB and LHCE). In contrast to a significant increase in current observed with DME, the other electrolyte solutions exhibited low and stable leakage currents at room temperature. X-ray

photoelectron spectroscopy revealed the formation of the $\text{Al}(\text{FSI})_3$ complex on Al from G4 and LHCE, indicating a low solubility of $\text{Al}(\text{FSI})_3$. On the other hand, AlF_3 was detected when FDMB was used, which was likely formed through the defluorination of FDMB, leading to the replacement of Li^+ coordination with Al^{3+} in the presence of LiFSI. At 60 °C, the leakage currents with DME, G4, and LHCE significantly increased, in the order of $\text{DME} > \text{G4} > \text{LHCE}$. It is attributed to the increased solubility of $\text{Al}(\text{FSI})_3$ and the exacerbation of Al corrosion. Open circuit potentials (OCPs) measured after tests were 0 to 0.3 V with DME, G4, and LHCE, indicating the significant dissolution of Al^{3+} that was deposited on the Li electrode. In comparison, FDMB with LiFSI provided a low and stable current even at 60 °C and 4.5 V. The OCP also remained above 3 V, suggesting the preservation of the Al_2O_3 surface and the mitigated Al corrosion. I will discuss the details of interfacial reactions between Al and electrolyte solutions in the presentation.

4:15 PM EN10.02.10

Ultrathin Semiconductor Interphase Regulated Electric Double Layer Enabling High-Stable Zinc Metal Anode Yimei Chen; University of Alberta, Canada

The practical application of aqueous zinc-ion batteries for large-grid scale systems is still hindered by uncontrolled zinc dendrite and side reactions. Regulating the electrical double layer via the electrode/electrolyte interface layer is an effective strategy to improve the reversibility and stability of Zn anodes. Herein, the ultrathin zincophilic ZnS layer synthesized via a facile electrodeposition method is selected as a model regulator. At a given cycling current, the cell with Zn@ZnS electrode displays a lower potential drop over the Helmholtz layer across the electrode surface and a suppressed diffuse layer, indicating the regulated charge distribution and decreased electric double layer repulsion force. This protective layer also enables redistributed uniform electric fields and highly suppressed side reactions. Consequently, the cell with the ZnS protection layer exhibits a long cycling stability of around 3000 hours at 1 mA cm^{-2} , accompanied by a high reversibility of 98.9% over 2500 cycles at 5 mA cm^{-2} . When coupled with I_2/AC cathode, the cell demonstrates a high rate performance of 160 mAh g^{-1} at 0.1 A g^{-1} and long cycling stability of over 10000 cycles at 10 A g^{-1} . The $\text{Zn}||\text{MnO}_2$ also sustains both high capacity and long cycling stability of 130 mAh g^{-1} after 1200 cycles at 0.5 A g^{-1} .

Single Metal Site Oxygen-Reduction Catalysts: From Atomic Active Site Structures to Fuel Cell Cathode Performance Gang Wu; University at Buffalo, SUNY, United States

Recently, scientists have identified the newly emerging atomically dispersed transition metal (M: Fe, Co, or/and Mn) and nitrogen co-doped carbon (M–N–C) catalysts as the most promising alternative to PGM catalysts. In this talk, I will provide a comprehensive review of significant breakthroughs, remaining challenges, and perspectives regarding the M–N–C catalysts in terms of catalyst activity, stability, and membrane electrode assembly (MEA) performance. The most considerable challenge of current M–N–C

catalysts is the unsatisfied stability and rapid performance degradation in MEAs. Therefore, we further discuss practical methods and strategies to mitigate catalyst and electrode degradation, which is essential to make M–N–C catalysts viable in hydrogen fuel cell technologies.

9:00 AM *EN10.03.02

Nano Catalysts for Water Electrolysis: The Importance of Catalyst Layer Conductivity Shougo Higashi; Toyota Central R&D Labs., Inc./ Toyota Motor North America, United States

Humanity has been benefiting from the development of internal combustion engines for several decades. With the emergence and explosive increase of automobiles around 1980's, there has been a demand for environmental catalyst technologies to process exhaust gases such as CO (carbon monoxide), NO_x (Nitrogen oxides). Since then, a significant amount of knowledge about catalysts to reduce the usage of precious metal catalysts, which play a crucial role in automotive applications, has been obtained, leading to the current research and development of single-atom and few-atom cluster catalysts. We have seen that the chemical potential of the material can be modulated by tuning the size, shape, and introducing supporting oxides to achieve low-mass loading, high performance environmental catalyst. In the future, the roles played by batteries and catalysts will become increasingly important, and there is a need for next-generation electrochemical catalyst technologies to produce energy carriers, including hydrogen, at a low cost.

In this presentation, I will briefly review the knowledge of catalysts that we have accumulated since the rise of internal combustion engines and discuss the challenges and opportunities in electrochemical catalysis, with a specific focus on our research efforts in hydrogen production.

Enhancing Metal-Sulfur Batteries with Single Atom Catalysts and Graphitic Carbon Nitride: Addressing the Polysulfide Shuttle Effect Aliakbar Yazdani, Jyoti Pandey, Veronica Barone, Valeri Petkov and Bradley Fahlman; Central Michigan University, United States

Metal-sulfur batteries, including lithium-sulfur batteries, have attracted significant attention as promising energy storage systems. However, the presence of the polysulfide shuttle effect poses a major challenge, which leads to poor cycling stability and limited capacity retention. This research focuses on the exploration of novel strategies to overcome this issue and improve the performance of metal-sulfur batteries. One effective approach to mitigate this effect is the utilization of single atom catalysts. These catalysts have demonstrated promising results in enhancing the cell performance of metal-sulfur batteries, particularly in terms of higher C-rates and improved capacity retention. By providing active sites for polysulfide adsorption and conversion, single atom catalysts effectively trap and immobilize polysulfide intermediates, preventing their dissolution and subsequent migration between counter electrodes.

In this study, we investigated the incorporation of Fe, Co, and Ni single atom catalysts onto a carbon substrate for metal-sulfur batteries. Specifically, we explored the use of graphitic carbon nitride (g-C₃N₄) and reduced graphitic carbon nitride (r-g-C₃N₄) as suitable carbon substrates for sulfur and single atom catalysts. These materials possess desirable properties such as high surface area, excellent electrical conductivity, and good chemical stability, making them ideal candidates for enhancing the cathode performance of metal-sulfur batteries. Through systematic characterization and electrochemical testing, we will demonstrate the performance of metal-sulfur batteries that incorporate single atom catalysts and graphitic carbon nitride in the cathode. The effect of dispersed single atom catalysts in the suppression of polysulfide migration, as well as the cycling stability and prolonged capacity retention of metal-sulfur batteries, will be described.

Overall, our findings will highlight the potential of single atom catalysts and graphitic carbon nitride as effective strategies to address the polysulfide shuttle effect in metal-sulfur batteries. This research aims to contribute to the advancement of energy storage technologies, paving the way for the development of more efficient and sustainable battery systems.

9:45 AM EN10.03.04

Characterization and Modeling of Rhodium Single-Atom Catalysts on Porous Carbon Supports

Jyoti Pandey; Central Michigan University, United States

Due to worldwide interest in expanding the electrification of the transportation sector, there is never-ending research carried out on the development battery materials. Sulfur being one of the least expensive elements, is an attractive choice for battery cathode but it comes with various limitations which includes the insulating behavior of polysulfides, poor reversibility and slow kinetics of the metal-S conversion reactions. The single-atom catalysts (SACs) open up a new avenue towards their use as catalysts and to increase the commercial applications. They are known to exhibit improved kinetics of metal-S conversion reactions through the redox kinetics. This work focusses on the characterization and modeling of Rh-SAC-functionalized porous carbon supports. Extended X-ray absorption fine structure (EXAFS) measurements were recorded on the Rh K-edge for the four different samples to study the coordination environment. An analysis of the EXAFS scattering contributions revealed that out of the four different samples, two of the samples, viz. Fibrous materials (CF) and carbon nano fibers (CNF) were explicitly possessing Rh single atoms dispersed on the carbon support. The other two samples, Carbon nano tube (CNT) and few layer graphene (FLG) were proven to possess Rh single atoms with some dimers/trimers, and Rh clusters, respectively. EXAFS fitting gives a good overlap between the DFT-optimized structures and the experimental spectra up to a range of around 3 Å around the scattering atoms. The insights gained from the characterization and modeling efforts will pave the way for improved understanding of the catalyst's behavior and facilitate the design of more efficient and effective catalyst systems. The outcomes of this study hold significant potential for enhancing the performance and commercial viability of sulfur-based batteries in the pursuit of widespread research in the field of cathode materials for the battery sector.

Photochemically Deposited Single Platinum Atoms Supported on Exfoliated WS₂ Nanosheets for Hydrogen Evolution Reaction Doo Young Kim, Nadeesha L. Kothalawala, Tawabur Rahman, Manisha Goonatilleke, Nipun Chandrasiri, Beth S. Guiton and Aron J. Huckaba; University of Kentucky, United States

2-D transition metal dichalcogenides (TMDs) serve as an ideal platform for electro- and photo-catalysis. For example, TMDs can be interfaced with another layered material to constitute a heterojunction or can stabilize efficient catalysts (e.g., single atom catalysts) without chemical ligands. In this work, we report platinum single-atom-catalysts (Pt-SAC) decorated tungsten disulfide (WS₂) nanosheets for electrochemical hydrogen evolution reaction (HER). A green liquid-phase exfoliation method was employed to produce highly exfoliated (mono, bi- and few-layered) WS₂ nanosheets. This method involved a probe ultra-sonication in a low-boiling-point solvent mixture, water and ethanol, combined with a solvothermal process. These exfoliated WS₂ nanosheets were crystalline and possess clean surfaces with high aspect ratio without any surface ligands or impurities. The synthesized nano sheets were

predominantly semi-conducting hexagonal (2H) phase.

We found that these exfoliated WS₂ nanosheets are an ideal support material to stabilize catalytic Pt-SAC. For the deposition of Pt-SACs on WS₂, H₂PtCl₆ precursor was photochemically reduced through a short exposure of high-energy Xe flash lamp. High-resolution scanning transmission electron microscopic (HR-STEM) images probed that the deposited Pt atoms were single- or nanoclustered. Pt-SACs demonstrate excellent performances for hydrogen evolution reaction. The mass activity (A/g_{Pt}) of Pt-SAC on WS₂ is ~ 20x higher than that of commercial platinum nanoparticle catalyst (Pt/C) in both acidic and alkaline electrolytes.

10:45 AM EN10.03.09

Predicting Catalytic Activity of Single Atom Catalysts in Oxygen Evolution Reaction via First-Principles Simulations and Symbolic Regression Satadeep Bhattacharjee¹, Swetarekha Ram¹, Albert S Lee² and Seung-Cheol Lee¹; ¹Indo Korea Science and Technology Center, India; ²Korea Institute of Science and Technology, Korea (the Republic of)

Efficient energy conversion and storage require the development of effective electrocatalysts for the oxygen evolution reaction (OER). In this regard, single-atom catalysts (SACs) with 100 % active sites for OER are promising [1-6]. This study investigates the OER activities of Co single atoms (CoSA) on metallic MXenes, namely Ti₃C₂O₂ and Mo₂CO₂, considering both stoichiometric and oxygen vacancy (Ov) configurations. Spin-polarized first-principles calculations were used to determine the rate-limiting step, the conversion of oxygen from hydroxyl species. The presence of oxygen vacancies resulted in decreased OER activity and higher overpotential for CoSA on Ti₃C₂O_{2-δ}, while it increased OER activity for CoSA on Mo₂CO₂. Insights from the density of states, the variation of the charge density and the bonding analysis provide information about the observed results. Furthermore, the critical role of hybridization between the d states of CoSA and the transition metal sites of the catalyst bed (Ti/Mo) is demonstrated. Furthermore, we investigated the potential of designing SACs on Mo₂CO₂ MXenes for electrochemical OER using first-principles modeling simulations. The Electrochemical Step Symmetry Index (ESSI) method is used to fine-tune activity and identify optimal SACs, with both Ag and Cu showing potency in enhancing OER activity. Cu stands out among the chosen transition metals (TMs) as the best catalyst for reducing the overpotential, while Ag poses challenges in tuning its overpotential. Symbolic regression analysis is employed to identify key descriptors affecting catalytic efficiency, resulting in the derivation of mathematical formulas for the OER overpotential. This comprehensive investigation provides insights into the potential of SACs and MXenes in advanced electrocatalytic processes, offering prospects for improved OER activity and selectivity.

Structure Stabilization in Layered Transition Metal Oxide Positive Electrodes for Sodium Ion Batteries Dewen Hou^{1,2}, Eric Gabriel^{1,2}, Kincaid Graff¹, Yifan Dong¹, Tianyi Li², Yuzi Liu², Chengjun Sun² and Hui Xiong¹; ¹Boise State University, United States; ²Argonne National Laboratory, United States

Sodium-ion batteries (SIBs) have stepped into the spotlight as a promising alternative to lithium-ion batteries (LIBs) for large-scale energy storage systems. However, the stability and performance of sodium ion battery electrode materials are lacking compared to their lithium counterparts as a consequence of the larger size of the Na⁺ ion compared to Li⁺. The layered transition metal oxide (LTMO) positive electrodes have attracted extensive attention for SIBs due to its favorable electrochemical performance. However, they suffer from complex and irreversible phase transitions during cycling, which leads to the chemomechanically-induced structural degradation and rapid capacity decay, limiting its practical applications. In this talk, we will discuss our recent progress in stabilizing LTMO structures during cycling and the origin of the phase interface's influence on the Na⁺ storage and transport properties. *In situ/operando* spectroscopic techniques used in our work to track the phase transitions will also be discussed.

2:00 PM EN10.04/SF02.04.02

Engineering Multifunctional Interfaces for Forming and Recycling Composite Electrodes Bo Nie and Hongtao Sun; The Pennsylvania State University University Park, United States

Lithium-ion batteries (LIBs) have emerged as the leading energy storage technology, dominating the market over the past decade. While significant progress has been made in developing high-performance electrode materials, the overall performance of LIBs is often compromised when including other passive components (e.g., 40-60 wt%) such as current collectors, separators, and packaging. This study demonstrates an alternative approach to achieve high performance at the device level by increasing the electrode thickness and reducing the weight percentage of passive components in LIB systems. We present an effective and sustainable manufacturing process for engineering multifunctional interfaces in thick composite electrodes (e.g., LiNi_{0.8}Co_{0.1}Mn_{0.1}O₂). By integrating hybrid materials into artificial “grain boundaries (GB),” we can consolidate, densify, and recycle electrode active material powders to

fabricate thick cathode composites with improved volumetric and areal performance. To this end, the cold sintering process (CSP) was employed to co-sinter all constituents into a highly dense form ($2.7\text{--}3.2\text{ g cm}^{-3}$) with good interfacial stability. Notably, the introduction of a transient solvent (e.g., 5 vol% DMF) enables the integration of distinct materials (e.g., hybrids and NMC811 powders) under low processing temperature (120 deg C) and appropriate uniaxial pressure (300 MPa).

Moreover, the resulting artificial hybrid “GBs” consist of an electrically conductive network (e.g., carbon nanofiber and graphene) and an ionic conductive network (e.g., polymer-ionic liquid gel (PILG)), facilitating fast charge transport pathways. The co-sintered thick electrodes ($550\text{ }\mu\text{m}$) exhibit outstanding battery performance in gravimetric (194 mAh g^{-1}), volumetric (418 mAh cm^{-3}), and areal (23 mAh cm^{-2}) metrics. This improvement enables enhanced energy and power outputs while reducing the weight and cost of passive components. Furthermore, the polymer component (e.g., PVDF-HFP) can be dissolved in a selective solvent, allowing for the collection and reforming/resintering of NMC powders from the sintered electrodes, enabling direct recycling.

In addition, in-situ electrochemical impedance spectroscopy was employed to monitor impedance information during both the densification of the sintering process and the evolution of artificial “GBs” during the lithiation/delithiation process. By combining the variables of the sintering process and the composite composition, a data-driven model was developed to successfully predict the dominant variables and their corresponding optimal value ranges, showing promise for optimizing the composite electrode design.

Overall, our interface engineering approach provides a sustainable solution to address critical challenges in the fabrication, efficient charge transports, and recycling of high-performance battery electrodes.

2:15 PM EN10.04/SF02.04.03

A Study of Lithiation-Delithiation Kinetics for Porous 1D Silicon-Based Anodes Nancy Chen¹, Mihir Parekh¹, Morteza Sabet¹, Yi Ding² and Apparao M. Rao¹; ¹Clemson University, United States; ²U.S. Army DEVCOM GVSC, United States

While today’s lithium-ion batteries (LIBs) use graphite anodes, their limited specific capacity (372 mAh g^{-1}) has pushed researchers towards exploring alternative anodes with high specific capacity. Silicon (Si) anodes with a specific capacity of 4200 mAh g^{-1} offer an attractive solution, especially because of silicon’s abundance in the earth’s crust. However, high volume expansion (400%) during lithiation-delithiation leads to fracture and rapid capacity deterioration. This has limited the widespread adoption of Si-based anodes. We developed electrodes based on porous one-dimensional (1D) quill-like structures, aka Si nano-quills (SiNQ), to overcome these issues. Half cells equipped with SiNQ-graphite electrodes (containing 15 wt% SiNQ as the active material) exhibited an impressive initial reversible capacity of $527\text{ mAh g}_{\text{Si}}^{-1}$ at a current density of 90 mA g^{-1} , along with an outstanding capacity retention of 80.2% across 200 cycles. This starkly contrasts with anodes containing 15 wt% commercial Si nanoparticles, which could only manage an initial reversible capacity of $375\text{ mAh g}_{\text{Si}}^{-1}$ and a significantly lower capacity retention of 44.8% over the same number of cycles. Intrigued by this superior performance, we studied the lithiation-delithiation kinetics of SiNQ electrodes via the galvanostatic intermittent titration technique (GITT). GITT testing was performed between 0.01 V and 1 V with current pulses of 0.05C ($210\text{ mA g}_{\text{Si}}^{-1}$). Current pulses of 30 min duration were followed by a 6-hour rest period to allow the potential and built-up concentration gradients to relax. Unlike graphite intercalation electrodes, Si-based electrodes are phase transformation electrodes. So, lithiation-delithiation is accompanied by phase transformation in Si-based electrodes. While GITT-based models for phase transformation electrodes such as LiFePO_4 exist in the literature [1], they do not account for electrode porosity and curvature. As a result, a novel model that accounts for the effects of phase transformation, electrode porosity, and electrode curvature on lithiation-

delithiation kinetics was developed to fit the experimental data. Diffusion coefficients as a function of the state of charge were obtained and will be presented.

[1] Y. Zhu and C. Wang, "Galvanostatic intermittent titration technique for phase-transformation electrodes," *J. Phys. Chem. C*, vol. 114, no. 6, pp. 2830–2841, Feb. 2010, doi: 10.1021/JP9113333/ASSET/IMAGES/MEDIUM/JP-2009-113333_0015.GIF.

2:30 PM EN10.04/SF02.04.04

Controlling Electrochemical Deposition of 2D Zinc Metal Plates on Copper Substrates in Aqueous Electrolytes Ying Xia^{1,2}, Jinhui Tao², James J. De Yoreo^{2,1} and Jun Liu^{1,2}; ¹University of Washington, United States; ²Pacific Northwest National Laboratory, United States

Polyethylene glycol (PEO) is a commonly used polymer in the field of batteries for achieving flat and uniform electrodes to enhance the performance of batteries, such as lithium batteries and zinc (Zn) batteries. However, the impact of PEO on the electrochemical deposition of Zn metal on electrodes remains uncertain. In this study, we selected ZnSO₄ solution as electrolyte and copper (Cu) substrates as electrodes, which are widely applied in Zn batteries. We used *in situ* electrochemical atomic force microscopy (EC-AFM) to observe the nucleation and growth of Zn metal plates on the Cu substrate in the presence of different concentrations of ZnSO₄ and PEO additives. Our results indicate that PEO biases the crystallographic orientation of the initially deposited Zn metal nuclei, but does not have an obvious influence on subsequent growth. Based on our findings, we hypothesize that PEO primarily interacts with the Cu substrate to adjust the interfacial energy of the Cu-electrolyte interfaces. In contrast, due to the lack of apparent change in the Zn growth rate, we postulate that PEO has limited interaction with Zn²⁺ ions in the ZnSO₄ solution and thus does not strongly influence the activity coefficient of Zn²⁺ ions. The consistent aspect ratio of the Zn plates combined with the lack of an effect on growth rates further suggests that PEO does not interact significantly with the surface of the newly formed Zn plates. Our findings provide both insight into the underlying mechanism by which PEO promotes electrode flattening in Zn batteries and a standardized protocol for elucidating the impact of additives on the morphological evolution of interfaces during electrochemical deposition.

2:45 PM EN10.04/SF02.04.05

Directing Polymorph Specific Calcium Carbonate Formation with *De Novo* Protein Templates Fatima Davila-Hernandez¹, Biao Jin², Pyles Harley¹, Shuai Zhang¹, Zheming Wang², Timothy F. Huddy¹, Chun-Long Chen², James J. De Yoreo² and David Baker¹; ¹University of Washington, United States; ²Pacific Northwest National Laboratory, United States

Biomolecules modulate inorganic crystallization to generate hierarchically structured biominerals, but the atomic structure of the organic-inorganic interfaces that regulate mineralization remain unknown. We hypothesized that heterogeneous nucleation of calcium carbonate could be achieved by a structured flat molecular template that pre-organizes calcium ions on its surface. To test this hypothesis, we designed helical repeat proteins (DHRs) displaying regularly spaced carboxylate arrays on their surfaces and found that both protein monomers and protein-Ca²⁺ assemblies directly nucleate nano-calcite with non-natural (110) or (202) faces while vaterite, which forms first absent the proteins, is bypassed. The nanocrystals then assemble by oriented attachment into calcite mesocrystals. We find further that nanocrystal size and polymorph can be tuned by varying the length and surface chemistry of the designed protein templates. Thus, bio-mineralization can be programmed using de novo protein design, providing a route to next-generation hybrid materials.

3:30 PM *EN10.04/SF02.04.06

Interfacial Engineering of Catalyst and Battery Materials using Atomic Layer Deposition Neil P. Dasgupta; University of Michigan, United States

The ability to manipulate the properties of surfaces and heterogeneous interfaces using atomically-precise synthesis methods is of critical performance in electrochemical applications. In particular, the ability to “turn on” desirable properties (such as fast interfacial kinetics and stable activity), while “turning off” undesirable properties (such as chemical and/or morphological instability) is of increasing importance as the demands for high performance, long lifetimes, and stability continue to increase. To address these challenges, in this talk, I will describe key advances in the application of Atomic Layer Deposition (ALD) as an enabling technology platform for the atomically-precise modification of surfaces and interfaces for applications in two key electrochemical application spaces: electrocatalytic CO₂ reduction and rechargeable batteries.

I will demonstrate how ALD modifications can allow for rational control of interactions at heterogeneous interfaces, which can be used to tune the thermodynamic stability, kinetic activity, and mass transport properties of these integrated material systems. I will describe examples of the ALD process for conformal modification of gas diffusion electrodes and composite battery electrodes. I will also provide a perspective on challenges to scale-up design and manufacturing of these energy material systems at length scales ranging from atoms to meters.

4:00 PM EN10.04/SF02.04.07

Fabricating Dendrite-Free Porous Hosts of Li for Li-Metal Batteries via Electrodeposition. Yifan Ma and Hailong Chen; Georgia Institute of Technology, United States

Li metal anode is the ultimate choice for Li-chemistry-based batteries owing to its highest theoretical capacity (3860 mAh/g). Yet, the safety problems and low Coulombic efficiency resulting from Li dendrites are the remaining challenges for commercial applications.

Previously, we reported a 3D porous Cu current collector fabricated via a facile one-step electrodeposition method directly on commercial Cu foils. [1] This 3D porous Cu current collector showed stable long-term cycling with a high areal capacity up to 6 mAh/cm² without Li dendrites formation. However, for this one-step electrodeposition method, the thickness of the porous Cu layer is limited. Recently, we developed a new two-step electrochemical process to fabricate thick and porous Cu layers [2]. A thick Cu-Zn alloy was first electrodeposited on commercial Cu foil, and Zn was then removed electrochemically, leaving a thick and highly porous 3D Cu layer. Compared to our previous method, this 3D Cu layer has a high thickness of ~14 μm and porosity of ~72%. This new 3D Cu current collector can achieve stable Li cycling up to 230 h at a high areal capacity of 10 mAh/cm² at a current density as high as 10 mAh/cm², demonstrating its high commercial application potential in Li-metal batteries. In situ XRD method was used to reveal the deposition of CuZn alloy and the electrochemical dissolution of Zn.

Computational Modeling of Nucleation at the Anode-Electrolyte Interface in Lithium Batteries

Madison Morey and Emily Ryan; Boston University, United States

The Lithium (Li) Metal Battery (LMB), which possesses a Li Metal anode has come to the forefront of many researchers' efforts to combat the energy storage limitations of the Li-Ion Battery (LIB). This is due to the large theoretical capacity that the Li metal anode ($\sim 3860 \text{ mA h g}^{-1}$) possesses in comparison with the graphite anode ($\sim 372 \text{ mA h g}^{-1}$) of the LIB. However, a main hindrance to the commercialization of these batteries is an unstable interface and uncontrolled dendrite growth, which pose serious safety concerns. While the growth process has been extensively studied, little is known about the nucleation process and how early nucleation effects dendrite growth throughout cycling. Due to the nature of the anode-electrolyte interface, it is difficult to study experimentally so we can use computational methods to resolve this interface and track the complex chemical and physical phenomena at this location. In this work we propose a computational model that uses a nucleation rate equation, stemming from Classical Nucleation Theory, to study how the electrochemical nucleation rate is impacted by varying parameters at the anode-electrolyte interface. The rate equation is then coupled with an extended, concentration dependent, Butler-Volmer equation to solve for the flux at the interface. Finally, the model is used to evaluate how surface energy impacts Li dendrite nucleation and growth.

4:30 PM EN10.04/SF02.04.09

***In Situ* Formation of Li^+ Ion Conductive Layers as the Solid Electrolyte Interphase (SEI) in**

Lithium Metal Batteries Daewook Kim and Hye Ryung Byon; Korea Advanced Institute of Science and Technology, Korea (the Republic of)

The desired solid electrolyte interphase (SEI) on metallic Li plays a crucial role in preventing continuous electrolyte decomposition and Li dendrite growth. Promising SEI components such as lithium fluoride (LiF), lithium nitride (Li_3N), lithium oxide (Li_2O), and lithium carbonate (Li_2CO_3) exhibit reasonable conductivity and mechanical robustness. In contrast, carbonaceous components are soluble and loosely cover the Li surface, leading to ongoing electrolyte decomposition. Typically, these inorganic and organic species are randomly mixed and form passivating films along with dead Li^0 . Recent advancements have introduced localized high-concentration electrolytes or weakly coordinating solvents to establish inorganic-rich SEI composites. However, there is a lack of comprehensive studies on Li deposition and stripping processes over the SEI for long-term cycling, leaving the question of the cell-degradation process unanswered.

Herein, we demonstrate the formation of two passivating films by controlling 1,2-dimethoxyethane (DME)/1,3-dioxolane (DOL) ratios, while maintaining fixed concentrations of the lithium bis(fluorosulfonyl)imide (LiFSI) and LiNO_3 in Li|Li symmetric cells. The electrolyte solutions with a higher proportion of DME formed porous films after 30 cycles. Remarkably, continuous Li deposition was observed above these porous films, indicating their mixed ionic and electronic conduction properties. A passivating film grew as cycling proceeded, reaching a thickness of $\sim 40 \text{ }\mu\text{m}$ after 100 cycles. In contrast, the electrolytes with a higher proportion of DOL formed dense and particulate-shaped films. Interestingly, Li deposition occurred beneath these films, maintaining a thickness of $< 15 \text{ }\mu\text{m}$. Thus, it is plausible that the dense film acted as a Li^+ ion conductor. X-ray photoelectron spectroscopy and titration gas chromatography revealed the presence of predominant dead Li, Li_2O , and Li_2CO_3 in both passivating

films. However, the dense film exhibited a higher Li content and a lower carbon atomic ratio (less than 5 atomic %) than the porous film. We attributed the predominant DOL-based electrolyte with weak coordination properties to contribute to forming anion-derived inorganic components. Cell degradation started over 400 h, accompanied by increased carbon contents on the film surface and reduced Li contents. In the presentation, I will discuss the role of electrolytes in the formation of distinct passivating films and their impact on the overall performance of LiFePO₄-based full-cell configurations.

4:45 PM EN10.04/SF02.04.10

Electrodeposition of Conformal Ultrathin Functional Polymer Interphases Joerg G. Werner, Wenlu Wang, Zhaoyi Zheng and Ruiyang Chen; Boston University, United States

Sub-micron interphases and coatings determine surface and interfacial properties of materials, which in turn are often dominant factors in defining their performance in applications and devices. Especially in electrochemistry, interfacial processes including charge and mass transfer depend on the nanometric environment around the electrode surface, which can be tailored with functional interphases. Polymer chemistry offers a large toolbox of molecular functionalities to create coatings and interphases with desired properties, but conformal deposition of uniform ultrathin films on micro- and nanostructured electrodes in batteries, fuel cells, and electrocatalytic systems remains elusive. Hence, new coating methods are required to achieve ultrathin uniform interphases that allow for tuning and tailoring of interfacial electrochemical processes in application-relevant electrodes. Here, we present a strategy to achieve conformal ultrathin coatings of functional polymers on porous and conductive materials with arbitrarily complex architecture through a novel electrodeposition paradigm. Our fabrication method separates the controlled deposition chemistry from the polymer properties through rational molecular design, making it agnostic and applicable to many polymer compositions and functionalities. We demonstrate how deposition and molecular parameters determine the interphase properties, including molecular permeability and thickness from 10s to 100s of nanometers, which in turn enables tunability over interfacial properties under electrochemical conditions such as modulation of the double layer and activation/passivation of molecular species. We envision our process to enable novel electrochemical material, composite, and device architectures with advanced performance characteristics, and serve as tailored model systems in mechanistic studies from electrocatalysis to energy storage.

SESSION EN10.07: Poster Session

Session Chairs: Zhenxing Feng and Hua Zhou

Wednesday Afternoon, November 29, 2023

Hynes, Level 1, Hall A

8:00 PM EN10.07.01

Direct Observation of Lattice-Strain-Induced Oxygen Release in LiCoO₂ and Li₂MnO₃ Bypassing Electrochemical Cycling Dongho Kim¹, Jaemin Hwang², Pilgyu Byeon¹, Jaekwang Lee² and Sung-Yoon Chung¹; ¹Korea Advanced Institute of Science and Technology, Korea (the Republic of); ²Pusan National University, Korea (the Republic of)

As the layered Li transition-metal oxides are a well-known material family for cathodes in Li-ion batteries, intensive studies have been carried out to elucidate the correlation between structural change

and capacity/voltage fading. Among the several phenomena, the significant role of oxygen redox in enhancing the capacity of these cathode materials has brought critical issues of oxygen release with structural change and subsequent capacity fading, which should be addressed to improve electrochemical performance. Previous research predominantly employed electrochemically cycled cathodes, resulting in notable findings regarding cation migration, phase transformation, nanoscale voids/cracks formation, and even molecular O₂ trapped within the bulk during oxygen release. Despite recent studies focusing on the influence of microstrain to comprehend the correlation between structural degradation, oxygen loss, and voltage/capacity fading, the simultaneous integration of electronic, electrochemical, and mechanical factors presents a formidable task.

In this study, we examine the local variations of the atomic structure and oxygen content of single-crystalline layered Li transition-metal oxide model system to investigate the role of lattice strain in the oxygen release phenomena. In addition to mechanical surface polishing, the nanoindentation technique is also utilized to apply concentrated load to cathode materials. With intensive acquisition of conventional scanning transmission electron microscopy (STEM) and phase-contrast high-resolution electron microscopy (HREM) images at the atomic scale, we confirm that both types of mechanical strain induce local disordering of Li-*M* (*M* = Co, Mn) and subsequent amorphization. To establish the generality of this hypothesis, two single-crystalline layered oxide cathode materials, LiCoO₂ and Li₂MnO₃ were employed. Spectroscopic analyses also reveal a significant oxygen deficiency in the structurally altered regions, which is confirmed by the energy-dispersive X-ray spectroscopy (EDS) and electron energy loss spectroscopy (EELS) spectrum. Density functional theory (DFT) calculations further support the energetic preference of oxygen vacancy formation under shear strain compared to other types of strain. The most remarkable finding of this paper is that significant oxygen release can be induced solely by mechanical strain, even without electrochemical cycling. Moreover, this study highlights effective strain relaxation as a promising approach to enhance the structural stability of the anion framework in layered oxide cathodes.

8:00 PM EN10.07.02

Acid-and Gas-Scavenging Electrolyte Additive Improving the Electrochemical Reversibility of Ni-Rich Cathodes in Li-Ion Batteries Chaeun Song¹, Hyeongyu Moon¹, Kyungeun Baek², Chorong Shin³, Kwansoo Lee³, Seok Ju Kang² and Nam-Soon Choi¹; ¹Korea Advanced Institute of Science and Technology, Korea (the Republic of); ²Ulsan National Institute of Science and Technology, Korea (the Republic of); ³LG Energy Solution Ltd., Korea (the Republic of)

In view of their high theoretical capacities, nickel-rich layered oxides are promising cathode materials for high-energy Li-ion batteries. However, the practical applications of these oxides are hindered by transition metal dissolution, microcracking, and gas/reactive compound formation due to the undesired reactions of residual lithium species. Herein, we show that the interfacial degradation of the LiNi_{0.9}Co_xMn_yAl_zO₂ (NCMA, $x + y + z = 0.1$) cathode and the graphite (Gr) anode of a representative Li-ion battery by HF can be hindered by supplementing the electrolyte with *tert*-butyldimethylsilyl glycidyl ether (tBS-GE). The silyl ether moiety of tBS-GE scavenges HF and PF₅, thus stabilizing the interfacial layers on both electrodes, while the epoxide moiety reacts with CO₂ released by the reaction between HF and Li₂CO₃ on the NCMA surface to afford cyclic carbonates and thus suppresses battery swelling. NCMA/Gr full cells fabricated by supplementing the baseline electrolyte with 0.1 wt% tBS-GE feature an increased capacity retention of 85.5% and deliver a high discharge capacity of 162.9 mAh/g after 500 cycles at 1 C and 25 °C. Thus, our results demonstrate that the molecular aspect-based design of electrolyte additives can be efficiently used to eliminate reactive species and gas components from Li-ion

batteries and increase their performance.

Modified Viologen-Assisted Reversible Bromine Capture and Release in Flowless Zinc–Bromine Batteries Seung Hee Han¹, Seoyoung Kim², Hyeong Yong Lim², Sewon Park¹, Kyungjae Shin¹, Seungwon Kim¹, Hee-Tak Kim¹, Sang Kyu Kwak³, Changduk Yang² and Nam-Soon Choi¹; ¹Korea Advanced Institute of Science and Technology, Korea (the Republic of); ²Ulsan National Institute of Science and Technology, Korea (the Republic of); ³Korea University, Korea (the Republic of)

Flowless Zn–Br₂ batteries exhibit considerable potential for energy storage system applications, which require the principal features of high safety, low cost, and long-term cycle stability. However, central challenges such as uncontrolled bromine crossover to anodes and aqueous electrolyte decomposition producing gases lead to a low cycle performance of batteries. Herein, we demonstrate that the introduction of bis(2-trimethylammonio) propyl viologen tetrabromide (PV(Br)₄) onto a graphite felt (GF) electrode (PV(Br)₄/GF) improves the cycle stability of flowless Zn–Br₂ batteries comprising a 2.5 M aqueous ZnBr₂ electrolyte as the Zn and Br sources. During charging, PV(Br)₄ entraps corrosive and volatile Br₂ formed inside the GF electrode via favorable interactions with the four Br[−] anions of PV(Br)₄, while polybromide anions are produced via an electrochemical-chemical growth mechanism. Furthermore, the PV(Br)₄ on the GF electrode reversibly releases Br[−] into the electrolyte through the electrochemical reduction of entrapped polybromide anions during discharging. In addition, the spatially anchoring PV(Br)₄ on a GF electrode suppresses undesired oxidative decomposition of water by minimizing the physical contact with the electrode, thereby mitigating the depletion of the electrolyte during cycling. Suppression of O₂ evolution contributes to mitigation of inhomogeneous plating and vertical growth of Zn metal at the Zn anode. Consequently, a flowless Zn–Br₂ battery with a PV(Br)₄/GF electrode exhibits a high Coulombic efficiency of 95.6% over 400 cycles with a current density of 10 mA cm^{−2} and high areal capacity of 24.3 mAh cm^{−2}.

Single-Phase Perovskite BaIrO₃ Nanofibers as an Efficient pH Sensor Hee Ah Oh, Kyungmin Kim, Juhee Yang, Yejin Kim, Subin Choi, Youngmi Lee and Myung Hwa Kim; Ewha Womans University, Korea (the Republic of)

pH sensors are utilized in various fields such as biomedical applications, food quality evaluation, and the nuclear and gas industries. Metal oxide pH sensors are extensively studied due to their biocompatibility. When a sensor is immersed in the analyte, water is adsorbed onto the surface, and this adsorbed water interacts with the hydronium ions of the analyte through proton hopping. Consequently, pH can be measured by monitoring the potential change on the sensor's surface. Among these sensors, IrO_x is recognized as the most efficient pH sensor due to its ability to be manufactured through electrodeposition, its wide range of stable reactivity, and its suitability for in vivo use. However, IrO_x is prohibitively expensive and has limitations for long-term use due to delamination. To address these issues, extensive researches are being conducted to reduce the unit price and improve sensitivity by alloying Ir with other metals. This study introduces BaIrO₃, a perovskite-structured material in which Ba and Ir are alloyed using electrospinning which is a well-known and facile method for synthesizing metal oxide nanofibers. The single-phase perovskite BaIrO₃ is then characterized using Field Emission Scanning Electron Microscopy (FE-SEM) and X-ray Diffraction (XRD) techniques, and it is compared with IrO₂. Subsequently, the pH sensitivity of BaIrO₃ is demonstrated potentiometrically, in comparison to IrO₂. The sensing performance of BaIrO₃ nanofiber was found to be comparable to IrO₂. It indicates that even with

half of the amount of Ir, BaIrO_3 exhibits similar reactivity, making it much more cost-effective than using Ir alone. Additionally, BaIrO_3 demonstrated greater stability in extreme pH conditions. While further research is needed, these findings suggest that BaIrO_3 could be utilized as a pH sensor that is not only more economical but also highly stable. Subsequent studies will explore the commercial potential of BaIrO_3 for practical applications.

8:00 PM EN10.07.05

A Sustainable Cycle to Extract Valuable Metals and Green Hydrogen from Waste Brines Dongqi Yang¹, Saowaluk Soonthornkit¹, Alvin Chang¹, Chih-hung Chang¹, Kelsey Stoerzinger¹, Astrid Layton² and Zhenxing Feng¹; ¹Oregon State University, United States; ²Texas A&M University, United States

Driven by the global goal of achieving a net-zero emissions economy, green hydrogen (GH_2) has emerged as a prominent solution for energy storage. However, its widespread adoption is hindered by high production costs. Similarly, the production of critical metals such as lithium has been limited in certain geographical locations, leading to uncertainty in the supply chain and the price increase. Additionally, the production of saline waste presents an environmental challenge, with potential damage amounting to over \$1 million per 100 gallons per minute. To address these issues, a dual solution is proposed: coupling mineral desalination, such as Lithium extraction, with cost-effective GH_2 production through water splitting. This integrated approach establishes a sustainable and circular process that extracts GH_2 and value-added minerals from waste brines (e.g., seawater) while addressing environmental concerns.

Our project aims to create value by extracting Lithium and other valuable metals from the waste brines of desalination plants, oil or gas industries, and semiconductor companies. A significant portion of Lithium salt will be extracted and sent to companies for further processing, while the purified water will be produced simultaneously in this process. The purified water will be subjected to water splitting, generating green hydrogen that can be utilized in various sectors, including agriculture, transportation, and the electricity grid. The extraction of additional metals from brines is possible when combining membrane technologies. We will create a circular process for its self-sustainability and energy efficiency. A model that can extract 368 kg lithium per day from seawater via solar thermal energy was already under testing and a prototype of a small 4cm*4cm PEME using a double perovskite OER catalyst was under construction.

Interface Controlled Hybrid Carbon Bilayer Anode for Improved Ion Transport and Reaction Stability of Li Ion Battery Myoung-Ho Kim, Minsub Oh, Hye-Mi So, Niguss h. Hatsey and Seungmin Hyun; Korea Institute of Machinery and Metals, Korea (the Republic of)

Li ion batteries (LIB) with high energy density and high power density are required due to the emerging market of electrical vehicles and other smart products. The dominant anode in current commercial LIBs is graphite owing to its low redox potential, good stability, and low cost. However, its effective capacity is drastically reduced owing to poor reaction rate during fast charge and discharge. To overcome this, graphite is mixed with other carbon materials, such as soft carbon (SC) and hard carbon (HC), as well as non-carbon materials. Carbon-based materials have a low cost and require relatively simple processing, and they are more chemically and mechanically stable than non carbon materials. They are the primary choices for mixtures with spherical crystalline graphite(SCG). Among carbon-based materials, SC is less expensive than HC and does not require high-temperature heat treatment. Although SC has a lower energy density than SCG, it allows for the rapid movement of ions through multiple edge planes. In this

study we fabricated a novel bi-layered and patterned anode electrode to enhance the performance of the electrode by converging the idea of material blending, bi-layer structure, and patterned interface. The bilayer structure, which is different from that of the conventionally blended SCG/SC electrode, aims to stabilize the reaction with the electrolyte at the electrode surface while fully utilizing the bottom section of the electrode. Specifically, in our bilayer structure, the blended SC/SCG material was placed at the bottom and SCG alone was coated onto the top to maintain a stable electrode surface. The electrode pattern interfaces, which are optimized by controlling the pattern size, secure excellent mechanical adhesion and low internal resistance. The electrochemical performance of the bi-layered and patterned electrode was measured and compared with a single SCG electrode and with a conventionally blended SCG/SG electrode. The discharging current density, initial coulombic efficiency, and voltage plateau of these alternative structures were also compared by fabricating half cell. The improved performances of bi-layered and patterned electrode in the half-cell battery achieved high capacity retention of 85.9% after 500 cycles at 1C. In addition, the full cell also attained a high energy density of 178.7.7Wh kg⁻¹ at 10C, which is 2.3 times higher than that of the single-layer SCG electrode

8:00 PM EN10.07.08

Surface Stabilization of Single-Atom Catalyst on Metal Oxide Derived by Metal Hydroxide-Organic Frameworks Sungyoon Woo; Korea Advanced Institute of Science and Technology, Korea (the Republic of)

Single-atom catalysts (SACs) have been attracted as promising sensitizers in gas sensors due to their high catalytic activity and efficient atomic utilization. To synthesize SACs-anchored materials, metal-organic frameworks (MOFs) have been widely employed as sacrificial templates owing to their structural flexibility and high surface area. However, in this approach, only carbon-based materials have been allowed as target products since structural deformation between ligand and metal nodes should be sufficiently minimized to stabilize SACs during the transformation. Herein, we propose a novel synthetic route to fabricate metal-oxide-supported SACs by utilizing metal hydroxide-organic frameworks (MHOFs) with noble metal chelated linkers as templates. Highly ordered metal hydroxide layers and numerous π -stacked MHOFs linkers provide stable binding sites for SACs during the complete transformation from MOFs to metal oxide. Thereby, a high concentration of SACs can be stabilized on metal oxide without aggregation and doping of catalysts. The resultant Pt SACs-anchored NiO showed enhanced activity for chemiresistive sensing of H₂S. Furthermore, the high structural diversity of MHOFs would allow the extension of this approach to other catalysts and metal oxides for targeting various analytes.

8:00 PM EN10.07.10

First Principles Modeling of Polaron Formation and Optical Signature on Titanium-Based Oxides for Oxygen Evolution Reaction Photocatalysis Shay McBride¹, Michael Paolino², Tanja Cuk² and Geoffroy Hautier¹; ¹Dartmouth College, United States; ²University of Colorado Boulder, United States

The exact mechanism and surface coverage present on (photo)-catalysts used for the oxygen evolution reaction (OER) remain elusive. Ultra-fast spectroscopy on model single crystal surfaces has started to clarify these questions but would benefit from more first principles theoretical support to facilitate the interpretation of the spectroscopic signatures. Here, we focus on the first principles modeling of the optical signature of polarons on OER intermediates on titanium-based photocatalysts (e.g., SrTiO₃ and TiO₂). The trapping of photo-generated holes by polarons on adsorbs at the catalyst surface is a key step in the photo-driven OER. We report from first principles on how the polarons formation process and

optical signature changes with adsorbates (OH_2 , OH , O) on different surfaces and compare with experimental results when available. Our work is a first step towards a better connection between ultrafast spectroscopy and first principles computations.

8:00 PM EN10.07.12

***In-Situ* AFM Observation of Solid Layer Formation at a Superconcentrated Electrolyte/Electrode Interface** Akito Kobayashi¹, Taketoshi Minato², Katsuyoshi Ikeda¹ and Kenta Motobayashi¹; ¹Nagoya Institute of Technology, Japan; ²Institute for Molecular Science, National Institutes of Natural Sciences, Japan

1. Introduction

Lithium-ion batteries have high convenience and prevalence but have safety issues due to the volatility and flammability of organic electrolytes. Superconcentrated electrolytes have attracted considerable attention for their low volatility and flammability owing to extremely high electrolyte concentration in which all solvent molecules interact with Li^+ [1]. For reversible charge/discharge, solid layers on the electrode surfaces play important roles and are known to be produced by reductive decomposition of solvents for dilute electrolytes which limits the choice of available solvents [2]. On the other hand, reversible charge/discharge can be realized with various solvents for superconcentrated electrolytes [1], indicating different origin of the interfacial layers; however, details are still under discussion. To elucidate the origin and formation process of the interfacial layers, we performed *in-situ* chemical and mechanical analysis of the superconcentrated electrolyte/electrode interface. Here we focus on potential-dependent mechanical properties of the interface analyzed by atomic force microscopy (AFM) combined with electrochemical techniques.

2. Experimental

Lithium bis(trifluoromethanesulfonyl)amide (LiTFSA) was dissolved in acetonitrile at concentration of 4.2 M to obtain the superconcentrated electrolytes. Au thin film deposited on a cleaved mica substrate (Au/mica), Pt mesh, and Pt wire were used as the working, counter and quasi-reference electrodes, respectively. Mechanical properties of the interface were analyzed through force curve measurements with AFM at 1024 points at each potential (4.0 V to 1.0 V vs Li/Li^+ where negligible Faradaic process was observed). All the measurements were carried out in an Ar atmosphere.

3. Results and Discussion

The Young's modulus of the interface derived from a force curve measurements were ~ 58 GPa at the potential more positive than 1.5 V, corresponding to that measured for bare Au/mica in air, and decreased to 30 GPa at more negative potentials. On the other hand, simultaneously derived adhesion force shows an increase at 1.5 V, suggesting an increase in local viscosity at the interface, and decreased again at more negative potentials. These results are compared with our model for solid layer formation based on the insights from interface-selective spectroscopy. At 1.5 V, Li^+ was attracted to the negatively charged electrode, and TFSA anions are also come to the vicinity of the electrode because of Li-TFSA interaction. Then, as a results of oversaturation, a solid salt layer of LiTFSA is deposited on the electrode surface. The change in the Young's modulus of the interface observed in this study is consistent with this model where bare Au surface is covered by solid salt layer at more negative potentials. Increase in local viscosity probably reflects the locally oversaturated solution on the electrode exists at the start of the solid layer deposition. Thus, the quantitative analysis of viscoelasticity using AFM combined with spectroscopic results enabled us to identify the formation process of the solid layer at the superconcentrated electrolyte/electrode interface.

WITHDRAWN 11/29/23 EN10.07.14 *In Situ* X-Ray Absorption Spectroscopy Study of Monodispersed Cobalt Phthalocyanine on Carbon Nanotubes as Electrocatalyst for Carbon Dioxide Reduction to Methanol Mason Lyons¹, Conor Rooney², Hailiang Wang² and Zhenxing Feng¹;
¹Oregon State University, United States; ²Yale University, United States

Carbon dioxide (CO₂) is accumulating in the atmosphere, causing entrapment of thermal energy and more chaotic weather. To sustainably decumulate the atmospheric CO₂ and sequester future emissions, it must be utilized in a circular economy. Upcycling of CO₂ to value added products such as hydrocarbons and alcohols requires the use of catalysts, among which molecular catalysts are the most promising due to their product selectivity and high utilization of metals. Unlike many other catalysts which primarily produce the undesired carbon monoxide (CO) intermediate, cobalt phthalocyanine (CoPc) non-covalently anchored on carbon nanotubes (CNTs) exhibits preferential formation of methanol (MeOH) from CO₂ due to a modified Co electronic structure. To investigate the electronic and geometric arrangements of CoPc-CNTs during CO₂ reduction, *in-situ* X-ray absorption spectroscopy (XAS) was employed. The pre-edge peaks at 7710 eV related to orbital mixing increased while the 7715 eV peak related to bonding centro-symmetry decreased, when scanning from open circuit voltage to -1.1 V vs Reference Hydrogen Electrode (RHE) indicating a higher density of states in Co 3d_z² and axial coordination from CNT as well as C adsorbate, respectively. An absorption edge shift associated with Co reduction to Co(I) was also observed and persisted at MeOH producing conditions, previously only reported for CO producing systems. Fitting of the extended X-ray absorption fine structure (EXAFS) spectra confirmed the CoPc coordination and bond lengths with theoretical calculations as well as the presence of a carbon adsorbate at potentials more negative than -0.5 V vs RHE, enabling further CO reduction to MeOH. The rich information from *in-situ* XAS elucidated the structure-property relationship of this catalyst to explain the superior performance of CoPc dispersed on CNTs for CO₂ upgrade.

Designing Bilayer Oxide Chemiresistors Consisting of Rh Nanoparticle Loaded TiO₂ Catalytic Overlayer and SnO₂ Sensing Layer for Highly Selective and Sensitive Detection of Volatile Aromatic Compounds Young Kook Moon; Korea Institute of Materials Science, Korea (the Republic of)

Oxide chemiresistors have mostly been used to detect reactive gases such as ethanol, acetone, formaldehyde, nitric dioxide, and carbon monoxide. However, the selective and sensitive detection of volatile aromatic compounds such as benzene, toluene, and xylene (BTX), which are extremely toxic and harmful, using oxide chemiresistors remains challenging because of the molecular stability of benzene rings containing chemicals. Moreover, the performance of the sensing materials is insufficient to detect trace concentration levels of BTX, which lead to harmful effects on human beings. Herein, novel bilayer sensors consisting of a SnO₂ sensing layer and three different xRh-TiO₂ catalytic overlayers (x = 0.5, 1, and 2 wt%) are designed for the selective detection, discrimination, and analysis of benzene, toluene, and p-xylene. The 2Rh-TiO₂/SnO₂ bilayer sensor shows a high selectivity and response toward trace concentration of benzene over a wide range of sensing temperatures. An array of three Rh-TiO₂/SnO₂

sensors can quantitatively discriminate aromatic compounds. The conversion of gases into more active species by gas reforming or into non-reactive forms by excessive catalytic promotion through the reaction with volatile aromatic compounds and nanosize noble metal catalysts are proposed as the reasons behind the enhancement and suppression of analyte gases, respectively. Analysis using proton transfer reaction-quadrupole mass spectrometer (PTR-QMS) is performed to verify the above proposals.

8:00 PM EN10.07.16

Polysulfide Chemisorption in Multiferroic Doped Sulfur/CNT Composite Cathode for High Energy Densities Li-S Batteries Mohan K. Bhattarai¹, Balram Tripathi^{1,2}, Shweta Shweta¹, Rajesh Katiyar¹, Claudia Zuluaga Gomez¹, Brad Weiner³, Ram Katiyar¹ and Gerardo Morell¹; ¹University of Puerto Rico, Río Piedras, United States; ²S.S Jain Subodh PG College, India; ³University of Puerto Rico, Río Piedras, United States

Herein, we are reporting the chemisorption effect of multiferroic doped sulfur/SWCNT cathode for Li-S batteries. Bismuth ferrite (BFO) is versatile multiferroic material having high polarization. We modified the composite cathode hydrothermally for the encapsulation of sulfur using SWCNT. The physical, morphological, and elemental analyses of cathode materials were studied using X-ray diffraction, Raman spectroscopy, SEM, EDX, and XRF techniques.

The electrochemical performance has been checked at various C-rates. In various C-rates conditions, we observed good cycle stability ~ 500 mAhg⁻¹ above 100 cycles at C/16 rate, and stable CE ~ 98% due to injection of BFO nanoparticles for chemisorption of polysulfide in the modified cathode. The detailed analysis will be presented during the meeting.

8:00 PM EN10.07.18

Relationship between Time-Dependent Schottky Parameters and Doping Concentration during Resistance Relaxation in Pt/Nb:SrTiO₃ Junctions Hayato Nakamura, Yumeng Zheng and Kentaro Kinoshita; Tokyo University of Science, Japan

Resistive switching (RS) devices of Pt/Nb-doped SrTiO₃ (STO) Schottky junctions have been the subject of considerable interest in terms of both non-volatile and volatile resistance relaxation nature. When used as general non-volatile memory, the continuously tunable write/erase characteristics are advantageous for multibit application. In this sense, resistance state retention characteristics are important and improving resistance volatility is crucial. On the other hand, when used in new computational paradigm for the breakthrough of von Neumann-type computing, controllability of resistance relaxation phenomenon (RRP) is critically important. It has been reported that the RRP after RS in Pt/Nb(0.5 wt%):STO can be used to mimic synaptic plasticity for AI applications [1]. The development of nanoscale devices with this neuromorphic function is the basis for hardware implementation of artificial neural networks. For practical application, details of the resistive relaxation phenomenon is required to be understood. Schottky parameters (SPs) such as barrier height (SBH) and depletion width (W_D) can be determined by combining *I-V* and *C-V* measurements. SPs had been estimated only for two extreme states, high-resistance states (HRS) and low-resistance states (LRS) [2], and we reported on the time dependence of SPs during the resistance relaxation last year [3]. Since carrier concentration (*n*) strongly influences SPs, it is important to clarify the time dependence of SPs as a function of *n*. In this study, we revealed the time dependence of SPs of Nb:STO as a function of Nb doping concentration, for the first time.

Therefore, in this study, we conducted a comparative analysis using devices with varying doping concentrations (0.1, 0.5, 1.0 wt%) to investigate the control of volatility in Pt/Nb:STO junctions. Sequential *I-V* and *C-V* measurements were performed on the same junction to extract the time evolution

of SPs during the relaxation. Additionally, we investigated the location of electronic traps using the conductance method. "I-V measurement" and "C-V measurement and conductance method" were performed by the two-terminal method using a semiconductor parameter analyzer and impedance analyzer, respectively. Since the resistance value changes logarithmically after RS, the switching unit was employed to quickly switch from the circuit for I-V measurements, which set the junction to HRS or LRS, to the circuit for AC measurements.

We measured the relaxation phenomenon up to 1000 s after RS. After setting the Nb 1.0 wt% device to LRS, SBH was estimated to increase by 0.12 eV from 0.54 to 0.66 eV by I-V measurement and from 0.76 to 0.90 eV by C-V measurement. At the same time, the donor concentration (N_D) decreased from 5.8×10^{19} to $4.2 \times 10^{19} \text{ cm}^{-3}$, and the W_D increased from 20.8 to 26.6 nm. It was observed that all SPs exhibited a linear dependence on the logarithm of time during the resistance relaxation. Furthermore, these trends of temporal changes in SPs were confirmed to be consistent regardless of doping concentrations.

On the other hand, from the results obtained by the conductance method, it was discerned that traps tend to be positioned at deeper locations as the doping concentration decreases. This observation aligned with the 0.2 eV difference in SBH between 0.5 and 1.0 wt% cases. Furthermore, it was found that their respective time dependencies also shift in a direction indicative of traps becoming deeper with time. This result is consistent with the 0.12 eV increase in SBH. Consequently, it is suggested that this effect is attributed to interface-layer traps that become deeper as SBH increases. Therefore, RRP is suggested to occur due to the re-trapping of electrons by defects after they were de-trapped by applying forward bias to set to LRS.

Surface Restructuring and Stability of Perovskite Oxide Electrocatalysts Studied by Surface X-Ray Diffraction and Grazing Incidence X-Ray Absorption Spectroscopy Alvin Chang, Rajkumar Jana, Kelsey Stoerzinger and Zhenxing Feng; Oregon State University, United States

In recent years, the trend towards clean and renewable energy sources has led to an increased interest in water-based electrocatalysis (i.e., producing green hydrogen from water as fuels and chemicals) for energy conversion and storage, but a key barrier for efficient water splitting is the high overpotential of the sluggish oxygen evolution reaction (OER).¹⁻³ To overcome this, earth-abundant perovskite oxides of chemical formula AMO_3 with compositional substitutions have shown drastically improved OER activities and are particularly attractive due to their high activity, low cost, high tunability of composition, and controllable electronic structures.^{2,3} For many metal oxides it was discovered that the surface can reconstruct under the oxidative conditions imposed by OER, forming (hydr)oxides prior to the onset of the reaction, and resulting in a different surface termination than that expected from the bulk. This restructuring is varied among materials and plays a critical role in determining the stability and activity of an electrocatalyst material during and after electrochemical cycling. Thus, understanding the drivers of transformation at electrocatalyst interfaces towards the development of materials design is a key research direction in many fields.¹ In this work we examine the impact of electrochemical cycling on surface reconstruction of Lanthanum Nickel Iron Oxide ($\text{LaNi}_{1-x}\text{Fe}_x\text{O}_3$; $x=0-0.375$) and Lanthanum Strontium Nickel Iron Oxide ($\text{La}_{0.5}\text{Sr}_{0.5}\text{Ni}_{1-x}\text{Fe}_x\text{O}_3$; $x=0-0.625$) epitaxial thin films. Surface X-ray diffraction (SXRD) is employed to investigate the relationship between complex oxide bulk composition and terminal surface OER activity and stability. X-ray reflectivity (XRR) is used to probe the electron density

of surface layers and crystal truncation rod (CTR) is used to study atomic reconstruction at the surface. In select compositions, in-situ XRR and CTR illuminate the reconstruction and amorphization process during cycling under OER conditions. Furthermore, grazing incidence X-ray absorption spectroscopy (GIXAS) is performed to capture the evolution of local coordination environments with increasing compositional substitutions and soft XAS is used to explore local electronic structures. Our findings uncover the role of underlying bulk descriptors in modulating OER performance through cycling-induced restructuring and unearth the fundamental driving forces behind surface transformations in perovskite oxide materials which will provide invaluable understanding to aid in the development of electrocatalytic surfaces under OER conditions for effective materials design towards high-performance electrolyzers and batteries for renewable energy storage and conversion.

Coupled Ion-Electron Transfer Reactions: Dynamically-Evolving Electrodes William C. Chueh; Stanford University, United States

Most non-metallic electrocatalysts and battery electrodes change composition during operation. This change in the composition directly modifies the kinetics of heterogeneous reactions at the electrode/electrolyte interface, whether it is the lithium intercalation reaction in Li_xFePO_4 , oxygen evolution reaction in CoO_xH_y , or oxygen incorporation in CeO_{2-x} . While it is possible to infer the composition of the electrode via electrochemical measurements, knowing the composition at or near the active site is challenging. In this talk, I will present on the development of operando nanoscale microscopy (specifically, X-ray and scanning probe) and spectroscopy to track the dynamic evolution of electrocatalysts and battery electrodes during operation, and how the composition of the active site modifies reaction kinetics.

8:30 AM *EN10.05.01

Transition Metal K Edge Spectra under OER Working Conditions Frank de Groot; Utrecht University, Netherlands

Transition metal K edges are related to excitations of the transition metal 1s core electron to empty states. The K edges can be divided into the excitonic 3d pre-edges and the main edge that describes the excitations to the empty metal p-states. Using High-Energy-Resolution-Fluorescence-Detection (HERFD), one can sharpen the pre-edge structures revealing their multiplet nature. They can be calculated from the transition from the $3d^N$ ground state to the $1s^1 3d^{N+1}$ final state [1]. The main edge is usually interpreted

from the calculation of the transitions to empty states, using DFT theory, for example multiple scattering (FEFF). The 1s XPS spectra of transition metal oxides show multiple peaks, implying that one photon energy gives rise to electrons with multiple kinetic energies. This implies that the 1s XAS spectral shape must be described as the convolution of the empty states with the 1s XPS spectral shape [2].

We measured the iron, cobalt and nickel K edges of thin film perovskite-based electrodes at the solid-liquid interface to probe the oxygen evolution reaction (OER). The 3 nm thin perovskite films are measured in fluorescence yield through the backside of the membrane electrodes.

***In-Situ* XAS Studies of Cu-S Complex Catalysts for Electrochemical CO₂ Reduction Reaction**

Chun-Wai Chang¹, Xinyu Wang², Zhenxing Feng¹ and Zhe Weng²; ¹Oregon State University, United States; ²Tianjin University, China

The increasing level of carbon dioxide (CO₂) was known to be one of the reasons causing global warming by greenhouse effects. Therefore, it is crucial to reduce the CO₂ level. The application of restructuring-induced catalytic activity has shown a remarkable effectiveness in reducing carbon dioxide electrochemically to value-added products, such as methane (CH₄), ethylene (C₂H₄), etc. This research examined the *in-situ* electrochemical CO₂ reduction process of a Cu-S centered metal organic complex. The Cu-S complex exhibited a high Faradaic efficiency for CO₂ reduction and selectivity of 52% CO₂-to-CH₄ and 16% CO₂-to-C₂H₄. Combining cyclic voltammetry (CV) and in-situ X-ray absorption spectroscopy (XAS) results, we found the high performance of Cu-S complex catalysts is attributed to the reversibly reconstructed Cu nanoparticles formed during electrochemical reaction, rather than the molecule itself. In addition, the formed Cu nanoparticles, which are identified as the reaction active sites, are allowed to reverse back into the complex structure after the reaction. The relative intensities of interfacial H₂O/*CO obtained from operando infrared spectroscopy suggests that a higher amount of H₂O molecules is accumulated on the surface of catalysts. Moreover, time-of-flight mass spectrometry (TOFMS) demonstrates that the structure of catalyst can be maintained after CO₂ reduction reaction (CO₂RR) at -1.6V vs Ag/AgCl for 10 hr. Our study provides deeper understanding toward designing metal-complex molecular structures for controllably generating active species under reaction conditions to catalyze desirable chemistry.

Operando EXAFS to Determine the Mechanism of Bi Dopant at Low Concentration in

Rechargeable MnO₂ Cathodes Eric K. Zimmerer, Dominick Guida and Joshua W. Gallaway; Northeastern University, United States

The rechargeable Zn-MnO₂ battery system is one few systems in development capable of meeting the extreme cost requirements needed for global integration of battery storage in the power grid. Doping the MnO₂ cathode with Bi allows it to cycle reversibly between layered Mn oxides δ-MnO₂ and Mn(OH)₂, without detrimental formation of Mn₃O₄. This provides a cathode capacity of 617 mAh/g, which modeling has shown to enable costs below \$50/kWh. However, to achieve commercial adoption, cycling stability must be improved. The mechanism through which the Bi dopant improves rechargeability remains largely unknown, and this must be clarified to rationally improve the system. Our previous work has established that the mechanism involves structurally disordered intermediates, and thus

characterization techniques based on short-range order need to be used. This talk will demonstrate rapidly collected, operando extended x-ray absorption fine-structure (EXAFS) data collected on MnO_2 cathodes with and without Bi dopant. Operando techniques are scientifically powerful as they reduce experimental uncertainty resulting from destructive preparation of samples for ex-situ analysis. In addition, rapid EXAFS collection allows for analysis of the kinetics of Mn coordination changes.

The Bi-modified alkaline MnO_2 cathode has been of much interest in literature as only a small amount of Bi_2O_3 additive (Bi:Mn molar ratio 0.075) incorporated by high-energy ball-milling enables rechargeable behavior. Previously, a disordered $\delta\text{-MnO}_2$ phase with no diffraction signal was identified during the first charge of Bi-modified MnO_2 cathodes.¹ In this work, operando X-Ray Absorption Spectroscopy (XAS) was employed to further compare Mn coordination environments in standard and Bi-modified cathodes throughout cycling. Specifically, EXAFS analysis was used to visualize the dynamic first shell (Mn-O) and second shell (Mn-Mn) interatomic distances during the first cycle. Comparison with theoretical EXAFS modeled from CIF allows for “fingerprinting” of the charge/discharge products, while rapid EXAFS collection time allows for identification of intermediates and precise analysis of the potentials and states of charge at which materials deform. In the first discharge an earlier conversion to $\text{Mn}(\text{OH})_2$ is observed in the Bi-modified MnO_2 cathode. Upon charge, deformation of $\text{Mn}(\text{OH})_2$ is observed at the same potential energy in both cases, demonstrating that the thermodynamic stability of $\text{Mn}(\text{OH})_2$ is not affected by Bi-modification. Finally, the formation of Mn_3O_4 is identified in the standard MnO_2 cathode during the conversion reaction that occurs upon charge. These findings suggest that Bi dopant blocks the pathway leading to the formation of Mn_3O_4 through interfacial effects rather than bulk incorporation.

Probing the Distribution of Alkali Cations at the Au/Electrolyte Interface with Vibrational Spectroscopy Yu Shen S. Hsu and Matthias Waegele; Boston College, Department of Chemistry, United States

The electrode/electrolyte contact represents a material interface whose catalytic properties are determined by the interaction of the solid and liquid sides. This interaction gives rise to the electrochemical double layer (EDL), which forms the reaction environment of electrocatalytic processes. Therefore, understanding how the structure of the EDL emerges from the coupling between the solid and liquid phases is central to the development of efficient energy storage and conversion devices. Of particular interest is the distribution of cations of the supporting electrolyte in the EDL; it has been found that cations of the supporting electrolyte influence numerous electrocatalytic processes. However, our understanding of the distribution of these cations at the electrode/electrolyte interface is still poorly understood due to numerous experimental challenges in probing (alkali) metal cations at electrocatalytic interfaces. In this study, we use operando surface-enhanced infrared absorption spectroscopy (SEIRAS) to probe the distribution of alkali cations in the EDL. We demonstrate that the asymmetric CH_3 deformation mode of tetramethylammonium ($\text{methyl}_4\text{N}^+$) is a powerful probe of the distribution of alkali cations in the EDL. The vibrational probe simultaneously characterizes the populations of alkali cations in the inner and outer Helmholtz planes. We found that Cs^+ has a higher tendency to accumulate in the inner and outer Helmholtz planes of the EDL compared with Li^+ under CO_2 -to- CO conversion conditions. We rationalize these findings in terms of the hydration free energies of the cations and electrostatic interactions with the electrode. These observations contribute to a deeper understanding of the electrode/electrolyte material interface and how interfacial properties can be tailored for energy storage and conversion.

Surface Dynamics under Reaction Conditions Edvin Lundgren; Lund University, Sweden

During recent years, 2D Surface Optical Reflectance (2D-SOR) [1,2] microscopy [3] has emerged as a valuable surface characterization tool for model catalysts or electrodes [4] when performing operando investigations in harsh environments. In particular, 2D-SOR microscopy is favorably used as a complementary technique to other photon-in-photon-out techniques which do not carry direct information on the surface 2D morphology. In this presentation we will present the development and examples of 2D-SOR instrumentation and investigations from single and poly-crystalline samples in combination with Planar Laser Induced Fluorescence (PLIF) [2, 3], High Energy Surface X-Ray Diffraction (HESXRD) [5,6,7] and Polarization Modulation-Infrared Reflection Absorption Spectroscopy (PM-IRRAS) [8] coupled to Mass Spectrometry (MS) and Cyclic Voltammetry (CV) in thermal catalysis, electrocatalysis and corrosion.

Illustrating examples of the versatility of the technique will be shown including reflectance changes during the thermal CO oxidation over Pd(100) and Pd polycrystalline surfaces. We show that reflectance changes during the reaction can be associated with the formation of thin Pd oxides by the combination of 2D-SOR and Surface X-Ray Diffraction (SXRD). The combined measurements demonstrate a sensitivity of 2D-SOR to the formation of a 2-3 Å thin Pd oxide film.

During Cyclic Voltammetry (CV) in an acidic electrolyte using a Au(111) surface as an electrode, we show that the differential of the change in 2D-SOR reflectance correlate to various current features in the CV curve. This observation can be used to differentiate current features in the CV curve from a polycrystalline Au surface, demonstrating that the different grains contribute to the current at different potentials due to the different surface orientations.

Finally, we show that 2D-SOR is a cheap and useful technique to investigate the corrosion of applied materials such as duplex stainless steels and Ni alloys.

Atomic Probing Surface Restructuring of Epitaxial IrO₂ Thin Films Towards Extreme Oxygen Evolution Reaction Conditions Hua Zhou¹, Maoyu Wang¹, Perrin Godbold², Sreejith Nair³ and Bharat Jalan³; ¹Argonne National Laboratory, United States; ²University of Virginia, United States; ³University of Minnesota Twin Cities, United States

Electrochemical water splitting offers efficient energy conversion potential, but it faces hurdles in the form of slow oxygen evolution reaction (OER) kinetics and harsh acidic conditions. Acidic OER electrocatalysis directly impacts making the proton exchange membrane viable on an industrial scale. IrO₂ is widely recognized as a benchmark electrocatalyst for OER which dictates the overall performance

on electrochemical water splitting, in particular in regard with its superior catalytic stability under long term operations. Investigating the interaction between IrO₂ and aqueous solutions is crucial for understanding the intriguing properties and active sites of this catalyst in operation. Recently, many groups have used epitaxial single crystal films as model surfaces to address these fundamental questions. These developments enable for the first time the ability to assess the activities on different facets, which has significantly improved the understanding of the OER and degradation mechanism. However, there is no deep understanding of IrO₂ atomic level surface structure during electrocatalytic reactions due to the extreme challenge of synthesizing epitaxial IrO₂ thin film. Very recently, our collaborators have demonstrated the successful growth of atomically smooth epitaxial IrO₂ films on TiO₂ single crystal substrates by the unique hybrid oxide MBE growth method, which allows us to utilize in-situ surface scattering techniques, including crystal truncation rod (CTR) analysis and X-ray reflectivity (XRR), to examine epitaxial IrO₂ thin films with various crystallographic orientations and their relationship with OER performance. By employing coherent Bragg rod analysis during in-situ electrochemical reactions, the interfacial structure, specifically the presence of oxygenated adsorbed species, can be resolved as a function of potential. Our study endeavors to uncover the surface chemistry of IrO₂, shedding light on its activity, stability, and degradation mechanisms under extreme electrochemical conditions.

In the talk, we will present our investigation of epitaxial IrO₂ films with three distinct crystallographic orientations (e.g., 001, 101, and 110 orientations) using in-situ CTR and XRR techniques, which could comprehend the influence of orientation or facet dependence on surface structuring when exposed to controlled OER conditions. Additionally, we will demonstrate surface modifications induced by different electrolytes (KOH, H₂SO₄, and HClO₄) that lead to diverse catalytic performance and stability. Preliminary synchrotron in-situ grazing incident X-ray absorption spectroscopy (GIXAS) measurements have revealed surface structure modifications, which will be further elucidated using CTR/XRR analysis. By employing energy-modulated measurements at the element-specific Ir L-edge, taking advantage of the resonant anomalous effect, we can gather detailed information on the concentration of Ir cations at each monolayer, providing direct experimental evidence on surface composition. The resulting quantitative structural and compositional information from CTR measurements will be correlated with electrochemical properties, enabling profound mechanistic insights into the activity and stability of IrO₂ toward extreme OER conditions. Our experimental results offer a comprehensive understanding of the surface properties and electrochemical behavior of IrO₂, contributing to the rational design and development of efficient catalysts for the oxygen evolution reaction.

11:00 AM EN10.05.07

In-Situ XAS Studies of the Reconstruction of Nickel Selenide OER Electrocatalysts Felix Hiege¹, Chun-Wai Chang², Alvin Chang², Maoyu Wang³, Seyed Pouya Hosseini Yazdeli⁴, Julia Linnemann¹, Zhenxing Feng² and Kristina Tshculik¹; ¹Ruhr-Universität Bochum, Germany; ²Oregon State University, United States; ³Argonne National Laboratory, United States; ⁴Max Planck Institute for Iron Research, Germany

Nickel selenides are one of the state-of-the-art electrocatalysts for full water splitting and are especially efficient for catalyzing the oxygen evolution part reaction (OER) in alkaline media. They are cost-effective due to the consistency of earth-abundant elements. [1] Under OER conditions, nickel selenides are converted to the real catalytically active species nickel (oxy)hydroxides. [1,2]

In this work, we investigated the OER performance of in-situ generated nickel (oxy)hydroxides from nickel selenides using in-situ X-ray absorption spectroscopy (XAS). Nickel selenides were electrodeposited on a gold-coated carbon paper and fluorescence XAS spectra were recorded using a

home-designed cell [3] at different OER overpotentials. The as-deposited nickel selenides were first transformed via cyclic voltammetry (CV) under OER conditions to a nickel (oxy)hydroxide species. Afterward, the catalyst behavior was monitored during a series of chronoamperometry experiments at different OER overpotentials. In-situ X-ray near-edge spectroscopy (XANES) on the nickel edge was used to extract the oxidation states and electronic structure of the catalyst at each overpotential. [4] Furthermore, information about the local atomic structure of the active nickel centers (e.g., bond distances and coordination numbers) were extracted from the extended X-ray absorption fine structure (EXAFS) regions of the in-situ XAS spectra. [5] Additionally, we gained information about transformational and pseudo-capacitive processes of the catalyst from electrochemical impedance spectroscopy (EIS) [6] and related them to those extracted from XANES and EXAFS analyses. EIS spectra were recorded at each investigated OER overpotential before and after the CA experiments. With this combined approach, we have a better understanding of transformation processes in highly active nickel-selenides-based OER electrocatalysts under working conditions.

Application of Dark Field X-Ray Microscopy in Epitaxial Thin Film Zhan Zhang¹, Seohyoung Chang² and Hua Zhou¹; ¹Argonne National Laboratory, United States; ²Chung-Ang University, Korea (the Republic of)

While the atomic structure is fundamental to the understanding of the static and dynamic properties of functional materials, it was realized that some phenomena emerge because of the collective behavior of a large number of atoms. One of such collection of atoms is domains in the material, whose formation, interaction, and evolution under external stimuli would dictate success or failure of the material. Studying domains would require tools with good spatial-resolution as well as large enough sampling area/volume. A diffraction based, dark field X-ray microscopy method, the X-ray reflection interface microscopy (XRIM), can be very useful in studying domains at the surfaces, buried interfaces, and inside of thin film material systems, with sub-nanometer sensitivity in the surface normal direction and better than 100 nm lateral resolution.

With the penetrating power of hard X-rays, XRIM can emphasize the features at different depth from the top surface by selecting proper scattering conditions, making it an excellent candidate to study the films in-operando in real time. Combined with the reciprocal space mapping (RSM), the spatially resolved structure evolution can be identified. A couple examples will be discussed to demonstrate the capability of XRIM method and its potential applications in a broader field.

Electrochemistry in the Light of In Situ Bragg Coherent Diffraction Imaging Clément Atlan¹, Corentin Chatelier¹, Kyle Olson¹, Arnaud Viola², Frédéric Maillard² and Marie-Ingrid Richard¹; ¹CEA, France; ²Centre National de la Recherche Scientifique, France

The advent of the new 4th generation x-ray light sources represents an unprecedented opportunity to conduct *in situ* and *operando* studies on the structure of nanoparticles in reactive liquid environments. Here, we will illustrate how Bragg coherent x-ray imaging [1] allows to image in three dimensions (3D) and at the nanoscale the strain and defect dynamics inside nanoparticles during an electrochemical reaction. First, we successfully imaged the lattice displacement and the strain inside a single Pt nanoparticle in electrochemical environment. The new Extremely Brilliant Source at the European synchrotron, with unmatched brilliance and coherence, allowed monitoring the changes in structure and morphology of nanocatalysts during *in situ* conditions. Our results reveal that the strain is heterogeneously distributed between highly- and weakly-coordinated surface atoms, and propagates from the surface to the bulk of the Pt nanoparticle under polarisation [2]. Secondly, we will show how *in situ* and *operando* Bragg coherent x-ray imaging allows to study the structural evolution of single Pd nanocrystals at various electrode potentials typical of H adsorption, H absorption, and H₂ evolution. Open questions remain regarding the maximal quantity of H that can be inserted into a Pd nanocrystallite, the mechanism and kinetics of hydride (PdH_x) nucleation (preferential sites for nucleation or homogeneous nucleation at the whole particle surface) and growth (α/β sharp transition or two-phase coexistence).

Correlating Charge and Ion Kinetics in Defective Metal Chalcogenide Systems under Solid-State Confinement Edwin J. Miller and Luisa L. Whittaker-Brooks; University of Utah, United States

Realizing fast ion kinetics in solid-state materials is of critical interest for the development of technologies including energy storage, neuromorphic computing, water desalination, and selective ion extraction. Development in these areas hinges on one fundamental challenge: facilitating ion transport through a host material. Layered van der Waals (vdW) structures stand out as a promising class of materials for reversible ion insertion, as ion intercalation can occur in the interstitial layers without permanent structural alterations. Of these vdW materials, titanium disulfide (TiS₂) is an attractive candidate for study due to its wide inter-lamellar spacing, continuous single-phase solid-solution lithiation, and material stability. While Li⁺ ion kinetics in TiS₂ itself have been well-characterized, our group seeks to further advance its development by studying the effect of selenium (Se) doping on Li⁺ ion kinetics in TiS₂ nanobelts. To pursue this goal, a synthesis of TiS_{1.8}Se_{0.2} nanobelts has been developed. Since both TiS₂ and TiS_{1.8}Se_{0.2} share the same nanobelt morphology, differences in ion kinetics between the two materials can purely be ascribed to the doping process. Compositional changes to nanostructured materials become important as it become increasingly apparent that nanostructured materials improve ion

kinetics; thus, by realizing the need for nanoscaling *and* altering composition, we are including factors that will allow this study to remain relevant in the fast-paced development of ion kinetics.

Our synthesis of $\text{TiS}_{1.8}\text{Se}_{0.2}$ nanobelts predictably increases the interlayer spacing and electronic conductivity of the doped material versus pure TiS_2 ; both properties are expected to improve ion kinetics in these doped systems. Rate-dependent cyclic voltammetry (CV) and electrochemical impedance spectroscopy (EIS) are both used to investigate the effect of Se doping on ion kinetics in layered TiS_2 nanobelt systems. Analysis via these methods indicates that $\text{TiS}_{1.8}\text{Se}_{0.2}$ nanobelts do indeed display a charge storage process that is less diffusion-limited than their TiS_2 analogues. Lower electrochemical impedance across faster frequency ranges for $\text{TiS}_{1.8}\text{Se}_{0.2}$ also indicates a decrease in resistances across the cell for the doped material. This insight into the effects of chalcogen doping on the charge storage process of TiS_2 nanobelts informs future development of layered vdW materials.

Engineering Surface Dipoles on Mixed Conducting Oxides with Ultra-Thin Oxide Decoration

Layers Matthäus Siebenhofer^{1,2}, Andreas Nenning¹, Markus Kubicek¹, Peter Blaha¹ and Jürgen Fleig¹;

¹TU Wien, Austria; ²Massachusetts Institute of Technology, United States

The surfaces of mixed ionic and electronic conducting (MIEC) materials play a crucial role in a wide range of applications within energy and sensing technologies, including solid oxide cells, catalysts, and oxygen permeation membranes. Consequently, the optimization of these surfaces and interfaces has become a focal point for research efforts aimed at advancing energy materials and devices. Recent studies have unveiled the significant impact that even small amounts of surface modifications, in sub-monolayer quantities, can have on the electrochemical properties of MIEC oxide surfaces. These modifications can alter the work function and the catalytic activity, demonstrating promising potential for targeted material and device optimization [1,2,3].

In this contribution, we conducted a comprehensive investigation into the effects of ultra-thin oxide layers on the electronic and ionic properties of different MIEC oxide surfaces, combining experimental and computational approaches. We employed in-situ impedance spectroscopy during pulsed laser deposition (i-PLD) and near ambient pressure X-ray photoelectron spectroscopy (NAP-XPS) to assess the impact of surface decorations on the properties of uncontaminated, pristine surfaces of epitaxial thin films of MIEC oxides such as $\text{La}_{0.6}\text{Sr}_{0.4}\text{CoO}_{3-\delta}$ or $\text{Pr}_{0.1}\text{Ce}_{0.9}\text{O}_{2-\delta}$. Building on these results, we employed density functional theory (DFT) to elucidate the atomic scale processes responsible for these effects.

Our study demonstrates that the electrochemical properties of MIEC oxide surfaces can be tailored systematically by decorating them with oxides of different ionic potential or acidity. Basic oxides with low ionic potential, such as SrO , lead to a reduction in the work function, while acidic oxides with high ionic potential, such as SnO_2 , lead to an increase in the work function. As the fundamental underlying mechanism we could identify charge redistribution and dipole formation processes at the heterojunction between host material and decoration. To illustrate the potential of this surface modification method, we explored its impact on the oxygen exchange reaction kinetics on various solid oxide fuel cell (SOFC) cathode materials, highlighting the broad applicability of ultra-thin oxide layers in tuning reaction rates on MIEC surfaces.

***In-Situ* Vibrational Spectroscopic Analysis of Solid Layer Formation at a Superconcentrated Electrolyte/Electrode Interface** Kenta Motobayashi, Masanori Nagasaka and Katsuyoshi Ikeda; Nagoya Institute of Technology, Japan

Superconcentrated electrolytes have been attracted considerable attention for battery applications for their useful properties such as low flammability, high oxidation stability, etc. Reversible charge/discharge processes were reported, suggesting the successful formation of appropriate solid electrolyte interphases (SEI) in superconcentrated electrolytes, which prevents co-intercalation of solvent molecules. The origin of SEI was reported to be anion species,¹ while that for conventional dilute electrolytes consist of decomposition products of the organic solvents. This feature leads to wide variety of applicable solvents for superconcentrated electrolytes. However, details of the origin of SEI in superconcentrated electrolytes are still under debate. Therefore, we performed in-situ chemical and mechanical analysis of the superconcentrated electrolyte/electrode interface by using surface-enhanced infrared absorption spectroscopy (SEIRAS) to elucidate the origin and formation process of SEI.

We employed 4.2 M LiTfSA/acetonitrile (AN) solution on an Au electrode as a model system for interface analysis. For a negative-going potential scan, SEIRA spectra showed that both TfSA anions and Li⁺ coordinated by AN move toward the electrode when the surface charge of the electrode is switched from positive to negative. It means increased density of the solution on the surface, which can be explained as follows; Li⁺ is drawn to the negatively charged electrode, and then AN and TfSA anions directly interacting with Li⁺ are drawn to the electrode together. Thus, characteristic coordination structure in superconcentrated electrolytes (anion-Li⁺ bond which is absent in dilute concentration) is responsible for such a phenomenon.

At more negative potentials (< 2.0 V), the local concentration of AN decreased and instead that of TfSA forming aggregated network structure with Li⁺ started to increase. Such a structure appears at oversaturated concentration in the bulk. It means that local ionic concentration increased at this potential range, and finally LiTfSA was deposited on the electrode together with small amount of AN by exceeding the saturation concentration. This model is supported by our in-situ AFM analysis of the viscoelasticity of the deposits.

Uncovering Photoinduced Charge Transfer Dynamics in Thin Films and Devices of the Extremely-Thin Absorbing Material Sb₂S₃ Elizabeth R. Young¹, Julien Bachmann² and Robert Hamburger¹;

¹Lehigh University, United States; ²Friedrich Alexander University Erlangen-Nürnberg, Germany

Widespread energy conversion from sunlight requires solar cells fabricated using stable, sustainable, non-

toxic semiconductors based on earth-abundant elements. The continually shrinking feature sizes in nanoelectronics and the drive for inexpensive solar energy conversion systems make fundamental understanding of charge transfer processes at interfaces and within actual devices essential to next generation photo and photoelectrochemical systems. Such devices are comprised of stacks of light-absorbing layers and hole and electron transporting materials forming thin film p-i-n structures. Necessarily, they must operate under both electrochemical applied potentials (*in situ*) and constant steady-state irradiation (*operando*) conditions. However, when measuring the photophysics and photo-induced chemical processes of these materials, experiments have thus far primarily been carried under *ex situ* conditions – with either the material alone or in partly formed semi-conductor stacks. More real-life conditions are needed to fully understand how charge carriers are generated, how they flow through materials and how material interfaces mediate charge transfer across multiple layers in these photophysical mechanisms. I will discuss our initial efforts at designing and developing experimental probes and data analysis tools capable of characterizing photochemical reactions under more realistic operating conditions. Using transient absorption spectroscopy (TAS), we *directly* observe carrier diffusion, electron transfer, hole transfer and charge recombination through uniform ultra-thin (< 3 nm) layers of insulating or transport materials deposited by atomic layer deposition (ALD) that are coupled to photoactive materials. Our work focuses on stibnite (Sb_2S_3) as the photo-active layer, which is of particular interest due to the suitable band gap of 1.7 eV and high absorption coefficient ($1.8 \times 10^5 \text{ cm}^{-1}$ at 450 nm). We quantify the dynamics that can be observed in thin transparent films through the use of *in situ* and *operando* TAS. Use of *in situ* and *operando* TAS affords the opportunity to study these materials in operating conditions and gain a quantitative understanding of the electron transfer dynamics at play in thin films.

4:00 PM EN10.06.05

Epitaxial Growth of Defect-Free Yttrium-Doped Barium Zirconate Films by Co-Sputtering for Improved Protonic Conductivity in Protonic Ceramic Fuel Cells Jaewon Hwang, Suhyuk Ko and Suk Won Cha; Seoul National University, Korea (the Republic of)

Protonic ceramic fuel cells (PCFCs) have emerged as a promising technology for the generation of clean energy for their low operating temperature ($< 600^\circ\text{C}$) and high efficiency. Among the various proton-conducting materials, yttrium-doped barium zirconate (BZY) is commonly utilized as an electrolyte material due to its high bulk conductivity and high chemical stability in H_2O and CO_2 environments. However, owing to the poor sinterability of protonic ceramic materials, conventional slurry-based fabrication methods require high-temperature sintering above 1500°C , resulting in detrimental effects such as the evaporation of constituent elements and the formation of secondary phases. To mitigate these issues, we investigated a novel approach for fabricating yttrium-doped barium zirconate (BZY) through the co-sputtering of BaCO_3 and yttrium-stabilized zirconia (YSZ) targets at a significantly lower temperature than that required for conventional wet processes. We explored various sputtering parameters and substrates to fabricate BZY films with different microstructures and compositions.

The incorporation of carbon from the BaCO_3 target and undesirable carbonate formation in the film was prevented by investigating different sputtering parameters related to the thermodynamics and kinetics of carbonate deposition, including radio frequency (RF) power applied to the targets and oxygen partial pressure. Sputtering parameters that influence the growth kinetics, including deposition rate, deposition pressure, and substrate temperature, were controlled to minimize the structural defects that reduce the film's proton conductivity. Successful deposition of stoichiometric, defect-free epitaxial BZY film on a MgO substrate was confirmed by advanced characterization techniques, including transmission electron microscopy (TEM), depth-profile X-ray photoelectron spectroscopy (DP-XPS), X-ray energy dispersive

spectroscopy (EDS), X-ray diffraction (XRD), and field emission scanning electron microscopy (FE-SEM). The epitaxial BZY film had no grain boundaries, thereby minimizing the negative contribution of the grain boundaries to proton conductivity. Consequently, the in-plane proton conductivity of the epitaxial BZY film measured via the AC impedance method was significantly higher than that of wet-processed polycrystalline BZY. Our results demonstrate the potential of co-sputtering as a low-temperature fabrication approach for producing high-quality BZY electrolytes with improved protonic conductivity and reduced thickness for PCFC applications.

This work was supported by the Hyundai Motor Chung Mong-Koo Foundation.

4:15 PM EN10.06.06

Electronic and Ionic Effects of Acidic Adsorbates on Solid Oxide Fuel Cell Cathode Surfaces

Matthäus Siebenhofer^{1,2}, Andreas Nenning¹, Markus Kubicek¹, Jürgen Fleig¹ and Peter Blaha¹; ¹TU Wien, Austria; ²Massachusetts Institute of Technology, United States

The oxygen exchange reaction is an important reaction for various applications in energy- and environment-related technologies. For example, during operation of low and intermediate temperature solid oxide fuel cells (SOFCs), the kinetics of this fundamental reaction is often regarded as the bottleneck for the overall performance. To tackle this issue, research and development of new SOFC cathode materials are focused on high intrinsic catalytic activity and high degradation stability. For promising cathode materials, this degradation is commonly attributed to poisoning effects due to different elements in the environment, such as S, Si or Cr, as well as to cation segregation, for example Sr segregation for perovskites like $\text{La}_{0.6}\text{Sr}_{0.4}\text{CoO}_{3-\delta}$ (LSC) and $\text{SrTi}_{0.3}\text{Fe}_{0.7}\text{O}_{3-\delta}$ (STF). In particular, it was recently shown that acidic adsorbates, such as SO_4^{2-} , originating from trace impurities, which are omnipresent in nominally pure measurement atmospheres, readily adsorb on the surfaces of different SOFC cathode materials and cause a sudden and strong degradation [1]. However, the underlying mechanism of these effects has so far been unclear.

In this contribution, the effects of adsorbed SO_2 and other typical solid oxide fuel cell (SOFC) poisons, such as CO_2 and CrO_3 , on the electronic and ionic properties of an SrO-terminated $(\text{La,Sr})\text{CoO}_{3-\delta}$ (LSC) surface and on its oxygen exchange kinetics have been investigated experimentally with near ambient pressure X-ray photoelectron spectroscopy (NAP-XPS), low energy ion scattering (LEIS) and impedance spectroscopy, as well as computationally with density functional theory (DFT) [2]. The investigations revealed that acidic adsorbates induce the formation of a surface dipole and extract charge from the LSC surface. As a result, they strongly increase the surface work function and alter the energetics of molecular oxygen adsorbates and oxygen vacancies in LSC.

Interestingly, the total work function changes as well as the redistributed charge for different acidic adsorbates scale quantitatively with the Smith acidity of the adsorbed oxide, which has recently been identified as a descriptor for the effect of binary oxide infiltrations on the oxygen exchange kinetics of $\text{Pr}_{0.1}\text{Ce}_{0.9}\text{O}_{2-\delta}$ [3]. We suspect that the here presented concept of charge redistribution and its impact on the oxygen exchange reaction is highly relevant for multiple phenomena on mixed conducting surfaces and that it is a further step on the way to a detailed understanding of the oxygen exchange reaction on these surfaces.

Enhanced Electrokinetic Streaming Potential Generation Through Surface Modulation on Microfluidic Li Cheng¹, Bei Fan² and Prab Bandaru¹; ¹University of California, San Diego, United States; ²Michigan State University, United States

The generation of electrical voltages and currents through aqueous electrolyte flow on charged surfaces is of significant interest for insights into surface-fluid interactions as well as for the development of new energy sources. The related phenomena broadly involve the attraction of counterions in the electrolyte to a charged surface forming an electric double layer (EDL). An electrical charge separation in the EDL may be obtained through a pressure difference (DP) applied to the electrolyte along the channel length, and results in a streaming potential (V_s). It has been determined that both the surface electrical potential, *i.e.*, the zeta potential (z), as well as the electrolyte slip length (b) contribute to the V_s .

We investigate through detailed experiments and subsequent theoretical analysis, the influence of various patterned surfaces, comprised of grooves, meshes, and pillars, in modulating the electrolyte flow for obtaining large V_s . We have obtained fascinating insights into how such *patchy* surfaces may be utilized in further increasing the figure of merit (related to the V_s/DP ratio) to a record 0.1271 mV/Pa - three-fold larger compared to what was previously obtained, through such investigations. We have probed flow on the patterned surfaces with *both* impregnated air and electrolyte immiscible oil, *i.e.*, an air-filled surface (AFS) as well as a liquid filled surfaces (LFS), respectively. We note that crucial to obtaining a large V_s is the optimization of the product of the effective slip length (b_{eff}) and the zeta potential (z). While a larger b_{eff} may be obtained from the AFS, the effective z is shown to be larger through the use of the LFS. Consequently, the interplay of the z and b_{eff} , with respect to the underlying patterned surface was considered in detail. On this basis, we posit a modified *effective* zeta potential which may be of significant use for modeling flow over patterned or non-homogeneous surfaces.

While the use of hydrophobic surfaces was advocated to increase the b , related surfaces are difficult to fabricate and maintain. Much less attention has been paid to methods for enhancing z . We then proposed the use of plasma processing of surfaces to modulate *both* the b as well as the z over silicon surfaces. Such methodology is shown to result in a larger V_s and a record figure of merit (FOM) of 0.1 mV/Pa – a factor of two larger compared to what was previously obtained. In our work we deployed CF_4 based plasmas for the possibility of creating of a thin fluorocarbon film over the surface, which may increase the hydrophobicity. Moreover, the ions in the plasma would also have a role in increasing the surface charge density and the resultant z . It was then determined experimentally that the latter effect predominates. In contrast, Ar-based plasmas are often preferred for their relatively simple constitution (with only Ar^+ ions and absence of chemical reactions). However, it was seen that such plasmas were more influential in only roughening the surface with minimal influence on the z or b . Generally, with the estimated b at less than 2 nm, the contribution to the increased V_s is typically small. Consequently, the major contributor to the record V_s values obtained in our study was due to the enlarged z .

Our results have major implications in enhancing the understanding of electrokinetic phenomena with respect to the variation of the electrical and mechanical attributes of surfaces. Further development

Updated as of October 28, 2024

through deploying hydrophobic surfaces *coupled* with plasma processing, and related principles outlined in our work, could yield much larger V_s and pave the way for large scale voltage sources. Our two articles, entitled *The influence of surface texture on the variation of electrokinetic streaming potentials* and *The Modulation of Electrokinetic Streaming Potentials of Silicon-Based Surfaces through Plasma-Based Surface Processing*, were published at *Langmuir*.

Finding Infinities in Nanoconfined Geothermal Electrolyte Dielectric Properties, and Implications on Ion Adsorption/Pairing Kevin Leung; Sandia National Laboratories, United States

Infinities should naturally occur in the dielectric responses of ionic solutions relevant to many geochemical, energy storage, and electrochemical applications at strictly zero frequency. Using molecular dynamics simulations cross-referenced with coarse-grained Monte Carlo models, nano-slit pore models at hydrothermal conditions, and treating confined mobile charges as polarization, we demonstrate the far-reaching consequences. The dielectric permittivity profile perpendicular to the slit $\epsilon_{\text{perp}}(z)$ increases, not decreases, with ionic concentration, unlike in the more widely studied megahertz-to-gigahertz frequency range. In confined electrolytes the divergences in $\epsilon_{\text{perp}}(z)$ correctly describe cross-overs between bulk- and surface-dominated dielectric behavior. Nanoconfinement at low ionic concentrations changes monovalent ion energetics by 1-2 kJ/mol, but no dielectric property studied so far is universally correlated to ion adsorption or ion-ion interactions. We caution that infinities signal violation of the “electrical insulator” dielectric assumption.

This work is based on materials support by the U.S. DOE Office of Basic Energy Sciences, Division of Chemical Sciences, Geosciences, and Biosciences under Field Work Proposal Number 21-015452. at Sandia National Laboratories. High Voltage Electrolytes Development for High-Ni Cathodes Laisuo Su; The University of Texas at Dallas, United States

Electrolytes connect the two electrodes in a lithium battery by providing Li^+ transport channels between them. Recently, ether-based localized high-concentration electrolytes have been developed for lithium-metal batteries and show a great success. Despite their high Coulombic efficiency ($\sim 99.5\%$) with lithium metal, the relatively high highest occupied molecular orbital (HOMO) of ethers limits their application at high voltages (> 4.4 V). To tackle this issue, we proposed a new concept of electrolyte, namely localized saturated electrolyte (LSE), based on carbonate solvents that have lower HOMO levels than ether solvents. The formation of a special Li^+ solvation structure can further reduce the HOMO level of the electrolyte, increasing its oxidative stability. We demonstrate that the developed LSE can stabilize various types of cathodes at high voltages up to 4.85 V. Materials characterizations were further conducted to uncover the mechanisms. And we found that advanced electrolytes help form close-packed homogeneous Li morphology on the anode, generate thin and inorganic-rich interphase layers on both electrodes, and reduce surface degradation into spinel and rock-salt phases of high-Ni cathodes, leading to superior cycling performance of lithium batteries. Our work highlights the importance of developing advanced electrolytes for stabilizing cathodes at high voltages in next-generation batteries.

9:15 AM EN10.08.03

Enhancing the Durability of Silicon Anodes by Anchoring Carbon-Coated Active Particles to Reduced Graphene Oxide Nawraj Sapkota¹, Nancy Chen¹, Morteza Sabet¹, Mihir Parekh¹, Yi Ding², Srikanth Pilla¹ and Apparao M. Rao¹; ¹Clemson University, United States; ²U.S. Army DEVCOM GVSC, United States

Conventional graphitic anodes are quickly approaching their theoretical capacity limits. Among potential candidates, silicon (Si) is recognized as an alternative active material for next-generation lithium-ion batteries (LIBs) owing to its high theoretical capacity and earth abundance. However, the practical implication of Si in LIBs has been hindered by its low electrical conductivity, large volume change during charge/discharge processes, and rapid capacity fading during cycling. In the current study, we modified the Si/electrolyte interface by developing a low-cost, scalable, dual-carbon protection technique to mitigate these issues. After introducing a thin polydopamine coating on commercial Si nanoparticles (SiNPs, solid spherical, 100-nm dia.), the coated particles were combined with graphene oxide, subjected to sudden freezing and freeze drying, and finally annealed in an environment of argon and hydrogen. Microstructural studies confirmed the formation of micron-sized composite particles in which a thin nitrogen (N)-doped carbon layer was formed on individual SiNPs, denoted here by SiNP@NC, and the SiNP@NC particles were wrapped/anchored by a reduced graphene oxide sheet, denoted by SiNP@NC@rGO. Pristine SiNPs and SiNP@NC@rGO were utilized as active materials to prepare identical anodes with water-based formulation and SiNP mass loading of $\sim 1.0 \text{ mg cm}^{-2}$. Electrochemical impedance spectroscopy showed a reduction in the internal impedance by applying our dual-carbon protection technique. While the SiNP anode exhibited a reversible capacity of 500 mAh g^{-1} at a current density of 2100 mA g^{-1} , the SiNP@NC@rGO anode displayed a reversible capacity of 1400 mAh g^{-1} . After 200 cycles at 420 mA g^{-1} , the capacity retention of SiNP and SiNP@NC@rGO anodes were 54% (from 1300 to 700 mAh g^{-1}) and 72% (from 2370 to 1700 mAh g^{-1}), respectively. The enhanced initial capacity and superior capacity retention of SiNP@NC@rGO indicate the effective protection of SiNPs by applying our synthesis method. The post-mortem characterizations of cycled electrodes also confirmed the effectiveness of our protection strategy.

Understanding Lithium-Solid Electrolyte Interfaces from a Single-Atom Level Yifei Mo; University of Maryland, United States

The interfaces between lithium metal and solid electrolytes are critically important for enabling solid-state lithium batteries but remain less understood, especially at the atomistic level. Atomistic modeling allows for the direct observation of atomic dynamics, which can be challenging to assess directly in experiments. In this talk, I will discuss how we have addressed the following key questions using large-scale atomistic modeling:

- 1) What are the atomistic structures of the lithium interfaces with solid electrolytes?
- 2) How do these interface structures affect the atomistic-level mechanisms of Li stripping and plating under electrochemical cycling?
- 3) How do electrochemically deposited Li-ions transition into crystalline Li metal, and what are the corresponding kinetic processes and energy barriers?

By using large-scale atomistic modeling, we aim to offer insights into these questions and propose strategies to address some of the key limitations or failure mechanisms.

10:30 AM EN10.08.07

Electrode Coating and Electrolyte Dependent Intercalation Rates and Activation Energies of Lithium-Ion Battery Electrodes Sravani R. Duggirala¹, Yirui Zhang², Cristina Grosu¹ and Armando Neto¹; ¹Massachusetts Institute of Technology, United States; ²Stanford University, United States

Lithium-ion batteries continue to be an attractive choice for electronics and larger sustainability applications, however the reaction kinetics of various chemistries are poorly understood. The intercalation rates determine the power densities of Li-ion batteries, but the energy barriers and microscopic interfacial processes are not known. Here we understand and model the electrochemical intercalation kinetics of various electrode-electrolyte interfaces through systematically tested experiments on a list of thin oxide electrodes (LiCoO₂, LiNi_xMn_yCo_zO₂ materials) with controlled surface coatings and different organic electrolytes. Through temperature-dependent measurements, we extract the activation energy for moving an ion near the intercalation material interface and intercalating the ion, where LiCoO₂ electrodes shows higher activation energy than LiFePO₄ and LiNi_xMn_yCo_zO₂ electrodes, and LiCoO₂ in LiPF₆-containing electrolytes gives similar action energy compared to LiClO₄-containing electrolytes. The coupled-ion electron transfer theory is used to extract the reorganization energy and reaction rates which can be used to predict materials with optimal kinetic properties for electrified interfaces. These results provide a fundamental understanding of ion intercalation kinetics and new directions for interfacial engineering of Li-ion batteries to boost power density.

10:45 AM EN10.08.08

Binder-Free Silicon-Impregnated Carbon Paper Electrodes Peshal Karki¹, Morteza Sabet¹, Mihir Parekh¹, Yi Ding², Srikanth Pilla¹ and Apparao M. Rao¹; ¹Clemson University, United States; ²U.S. Army DEVCOM GVSC, United States

During cycling, the Si-based electrodes suffer from a large volume change, which leads to electrode pulverization and an unstable solid-electrolyte interphase (SEI) growth. Silicon-carbon (Si@C) materials have proved meritorious in mitigating the detrimental effects of large volume change of Si-based electrodes during cycling. The use of C-rich biorenewable materials for producing sustainable Si@C materials is continuously expanding. Aligned with this approach, we developed a simple, environmentally

friendly technology based on low-cost biorenewable resources to create a Si@C material in which Si particles are uniformly dispersed in a matrix of porous C (i.e., embedded in a carbon cloud). In this method, commercial Si nanoparticles (solid spherical, 100-nm dia.) and lignin were dispersed in epoxidized soybean oil and subjected to oil-in-water emulsion polymerization, followed by low-temperature (500 °C) carbonization. The scanning transmission electron microscopy studies confirmed the production of micron-sized hybrid particles with Si nanoparticles embedded in a porous carbon cloud. Thermogravimetric analysis showed the presence of 40 wt.% Si in the Si@C material, which showed a reversible capacity that was two to three times higher than conventional Si nanoparticles-based electrodes. Although Si@C material increased the specific capacity of the anode, the presence of high-density metallic foil and inactive materials (such as binder and conductive carbon) would adversely affect the electrode-level specific capacity. As a next step we produced binder-free, flexible, and robust anodes by directly incorporating Si@C or pristine Si in separate porous Bucky Papers (BP, 60 gsm) made out of carbon nanotubes. Eliminating the copper foil, binder, and conductive carbon resulted in a 30% weight reduction of the electrode when Si mass loading was set to 1 mg cm⁻². These BP-based electrodes impregnated with Si nanoparticles or Si@C active material (and Si loading of 1 mg cm⁻²) exhibited an initial electrode-level capacity of 320 or 280 mAh g⁻¹, respectively, at a current density of 0.42 mA cm⁻². At this Si mass loading level, electrodes with Si nanoparticles cast on copper foil exhibited an initial electrode-level capacity of 155 mAh g⁻¹ at a current density of 0.42 mA cm⁻². These results indicate that the electrode-level capacity doubled when Si-based active materials were impregnated into porous BP. After 150 cycles, the Si@C-impregnated BP electrode showed 84% capacity retention, while the pristine Si nanoparticle-impregnated BP electrode retained only 54% of its initial capacity. The superior capacity retention of the Si@C electrode is due to the carbon-cloud protection during cycling.

11:00 AM EN10.08.09

Filament Growth and Related Instabilities during Adsorbate Suppressed Electrodeposition Trevor Braun, William Osborn and Thomas Moffat; NIST, United States

Anisotropic electrochemical deposition and whisker growth is shown to be a consequence of operating a bistable active-passive critical system under galvanostatic control. Specifically, whisker growth is examined during galvanostatic Cu electrodeposition from an electrolyte containing suppressor additives. Disruption of the passivating polyether-halide bilayer triggered by metal deposition leads to positive feedback and highly localized deposition. On macroscale electrodes active-passive Turing patterns develop while on micrometer-sized electrodes the bifurcation is frustrated and proceeds as a single active zone reinforced by hemispherical transport fields. Extended electrodeposition leads to symmetry breaking and lateral propagation of a single whisker. An increasing fraction of the applied current supports expansion of the passive sidewall area and eventually results in termination of anisotropic deposition. The dynamic range between passive versus active growth determines the shape and extent of whisker formation. Similar critical behavior may account for reports of whisker growth in certain metal/metal ion battery systems.

On the Mechanism of Mossy Zn Deposition Zhibin Yi, Kevin Chan and Qing Chen; Hong Kong University of Science and Technology, Hong Kong

Electrochemical deposition of Zn metal from a zincate electrolyte can lead to a peculiar mossy morphology comprising numerous slim kinky filaments. Like mossy Li in Li metal batteries, mossy Zn is considered detrimental to the stability of rechargeable Zn batteries. Yet unlike Li, the cleaner interface

Updated as of October 28, 2024

and the easier characterizations of Zn metal offer us an opportunity to dig deeper into the mechanism of mossy deposition. With well-polished and annealed polycrystalline Zn foil as an electrode, we show that the mossy deposition, occurring at a low overpotential, is localized at the surface intersects of defects such as grain boundaries. Through the measurements of cross-sectional microstructures, stress, and surface composition, we gain insights into the formation sites, the driving force, and the kinetics, drawing a close comparison to both mossy Li and metal whiskers.

Core/Shell Nanocrystals with Ordered Intermetallic Single-Atom Alloy Layers for Efficient Ammonia Synthesis Huiyuan Zhu; University of Virginia, United States

Single-atom alloys (SAAs) in which precious metal single atoms are embedded into a host metal, are an emerging class of catalytic structural motifs. Benefitting from the free-atom-like *d*-states, SAAs have been proved in theory to have the potential to break the linear scaling relations inherent to metal catalysts and improve the selectivity toward desired products. In this talk, we will discuss our recent efforts in developing a facile, direct solution-phase synthesis of Cu/CuAu core/shell NCs with tunable single-atom alloy (SAA) layers. This synthesis can be extended to other Cu/CuM (M = Pt, Pd) systems, in which M atoms are isolated in the Cu host and can be considered the highest density of single-atom sites. The density of single-sites and the number of atomic layers can be synthetically controlled. The ligand and strain effects of Cu/CuAu for electrocatalytic ammonia synthesis will also be discussed in this talk.

Ultrarapid Photothermal Annealing Synthesis of Single-Atom Catalysts-Stabilized Carbon Nano-Onion Dogyeong Jeon, Hamin Shin, Jun-Hwe Cha and Il-Doo Kim; Korea Advanced Institute of Science and Technology, Korea (the Republic of)

Carbon nano-onions (CNO) with nanometer-scale surface curvature and versatile functionalization have attracted attention in energy and environmental applications. However, conventional methods for synthesizing CNOs, and post-synthesis treatments for functionalization are extremely time consuming and energy intensive. Here, we present an ultrarapid photothermal annealing (UPA) platform for millisecond-scale synthesis of CNO and simultaneous surface functionalization with single-atom catalysts (SACs). The UPA platform reaches up to 3030 K within 1.4 ms ($2.2 \times 10^6 \text{ K s}^{-1}$), achieving full conversion from nanodiamond to CNO within 20 ms, significantly improving energy consumption efficiency. Moreover, we demonstrate the universal applicability of SACs functionalization on the outer surface of CNOs with eight different transition metal elements. In a case study, Pt SACs-functionalized CNO exhibit outstanding catalytic performances in hydrogen evolution reaction (HER), with an overpotential of 13.9 mV at 10 mA cm^{-2} and a Tafel slope of 52 mV dec^{-1} .

Computational Modeling of Atomically Dispersed Iron/Nitrogen Carbon Electrocatalysts for Proton Exchange Membrane Fuel Cells Guofeng Wang; University of Pittsburgh, United States

Proton exchange membrane fuel cells (PEMFCs) can convert chemical energy stored in hydrogen fuels to electricity and produce environmentally benign product water. However, the emergent application of PEMFCs is hindered by the requirement of expensive Pt group metals as their electrocatalysts. To advance PEMFC technology, it is of great interest to develop earth-abundant, non-precious metal-based catalysts in replacement of Pt, especially for oxygen reduction reaction (ORR) occurring at the cathode of PEMFCs. In this regard, atomically dispersed iron/nitrogen carbon catalysts (denoted as Fe-N-C) have drawn wide attention since they exhibited promising ORR activity close to Pt and improved stability than macrocyclic molecules. However, the structure of the active sites in these Fe-N-C catalysts and their catalytic mechanism for ORR have not been fully understood. Recent study reveals that there exist two distinct types of FeN₄ sites, namely porphyrin-like S1 FeN₄ sites and S2 FeN₄ sites containing four pyridinic nitrogen, in Fe-N-C catalysts active for ORR. In this study, we have performed density functional theory (DFT) calculations to predict the reaction energetics of ORR on both S1 and S2 FeN₄ sites. We calculated the adsorption energies of all the possible chemical species and the activation energies for O-O bond dissociation reactions involved in ORR on the FeN₄ sites. Our DFT calculations predicted that the ORR could happen through 4e⁻ associative pathway on the FeN₄ sites and with higher kinetic rate on S1 FeN₄ sites than S2 FeN₄ sites. The theoretical results are in agreement with experimental observations. Furthermore, we predicted the Gibbs free energy change for demetallation of Fe from both S1 and S2 FeN₄ sites. We assume that the demetallation of Fe from FeN₄ sites consists of two steps. At the first step, the Fe atom moves away from the N₄-coordinated state to an inactive N₂-coordinated state, with two N atoms passivated by H from the acidic environment. At the second step, the Fe atom with ORR adsorbates will be desorbed from the catalytic surface. Our computational results show that the tendency of demetallation is much higher for S1 FeN₄ sites than that for S2 FeN₄ sites. Consequently, computational modeling provides in-depth atomistic understanding of the chemical nature of active sites in Fe-N-C catalysts for PEMFCs.

3:30 PM EN10.09.06

Mechanistic Insight into Dual-Metal-Site Catalysts for the Oxygen Reduction Reaction Guoxiang (Emma) Hu; Georgia Institute of Technology, United States

Incorporating a second transition metal to iron–nitrogen–carbon single-atom catalysts (Fe–N–C SACs) to design dual-metal-site catalysts (DMSCs) was demonstrated to offer a promising opportunity to enhance the oxygen reduction reaction (ORR). However, due to the many possible structural configurations and the dynamic structure evolution of metal centers under reaction conditions, it is challenging to clearly elucidate the structure–property relationship at the atomic level. Here, we develop a computational workflow integrating configuration generations, phase diagram constructions, and reaction free energy calculations to provide an insightful understanding of the active site structures and catalytic mechanisms of ORR on DMSCs. Using Fe–Cu as an example, we generate 31 configurations by tiling the hexagonal lattice of graphene and investigate their atomic structures under reaction conditions. We find that for a wide range of electrode potentials, the Fe site is covered by an *OH intermediate, while the Cu site is not covered by any intermediate. With the OH-ligated structures, we identify the configurations which

possess higher catalytic activity than Fe–N–C and Pt(111). We demonstrate that ORR on Fe–Cu DMSCs proceeds *via* the associative pathway, and the desorption of *OH is the rate-determining step. Further analysis reveals a linear correlation between the limiting potential and the magnetic moment on Fe and suggests a closer distance between the two metal sites benefits the catalytic activity. These mechanistic insights pave the way for the rational design of efficient platinum group metal-free DMSCs for ORR.

3:45 PM EN10.09.07

Computational Quest for High-Performance Single-Atom Electrocatalysts and Beyond Zhongfang Chen; University of Puerto Rico at Río Piedras, United States

Nanocatalysis holds immense promise for achieving significant breakthroughs in various fields. Among the most remarkable advancements are single-atom catalysts (SACs), renowned for their exceptional activity, selectivity, and stability. However, catalysts beyond SACs, such as dual-atom catalysts (DACs), have the potential to outperform SACs in specific reactions. In this talk, we will unveil our recent computational advancements in designing SACs and DACs based on two-dimensional nanosheets, specifically focusing on their application in crucial electrochemical reactions. Moreover, we will underscore the significance of emerging big-data techniques for the computational screening and design of such catalysts.

4:00 PM EN10.09.08

Calculations of the Voltage Dependent Mechanisms and Rates of HER, ORR and CO₂RR under Electrochemical Conditions Hannes Jonsson; University of Iceland, Iceland

Theoretical calculations of electrocatalytic reactions such as the hydrogen evolution reaction (HER), oxygen reduction reaction (ORR) and CO₂ reduction reaction (CO₂RR) in order to determine the mechanism and estimate the rate of the various elementary steps can be carried out various levels of theory. At the simplest level, only the free energy of intermediates is estimated from calculations in the absence of applied voltage and dielectric solution and corrections later made to account for the electrochemical environment, the so-called thermochemical model. More detailed and reliable calculations involve estimates of the activation energy barrier as well as chemical interaction with solvent molecules, and going beyond the usual generalised gradient approximation for the functional. Such calculations can give significantly different results as has been shown for HER [1], ORR [2] and CO₂RR [3,4]. Still, the effect of the dielectric solution and the role of dissolved ions remains elusive [5] and calls for methodology that can be used for larger systems and longer time scale, such as hybrid simulations where the central part of the system is described using electronic structure theory while the rest is described with a potential energy function that includes polarisation [6]. Several results of ORR and CO₂RR calculations will be presented and the various levels of theory compared in order to identify what is required to obtain reliable results of electrocatalysis by electronic structure calculations and rate theory.

Tuning the Bio/Electrode Interface for Direct Bioelectrocatalysis Shelley D Minteer; Missouri University of Science and Technology, United States

Oxidoreductase enzymes are of interest in the electrochemical energy conversion field, because they catalyze important transformations (oxygen reduction, hydrogen oxidation, hydrogen evolution, nitrogen reduction, carbon dioxide reduction, etc.) at low overpotentials. However, there are challenges interfacing oxidoreductase enzymes with electrode surfaces to promote electron transfer between the enzyme catalyst and the electrode. Therefore, mediators or mediated electron transfer is typically utilized, but it results in substantial potential inefficiencies. In this paper, we will discuss polymer design for providing an ideal interface for maintaining the activity and preventing denatures of oxidoreductase enzymes at the electrode interface. We will discuss the use of biocompatible linear polyethyleneimine hydrogels and hydrophobic modifications to tailor the interface for direct bioelectrocatalysis.

8:30 AM EN10.10.04

Revealing of Effects of Surface on Nickel-Rich Layered Cathodes Enabling High-Performance Lithium Rechargeable Batteries by Preventing Irreversible Phase Transition Merry Lee¹, Hyung Mo Jeong¹ and Ji Hoon Lee²; ¹Sungkyunkwan University, Korea (the Republic of); ²Kyungpook National University, Korea (the Republic of)

With the increasing demand for high-performance lithium (Li) rechargeable batteries, nickel (Ni)-rich layered cathodes which have chemical formula of LiNi_xCo_yMn_zO₂ (x>0.8, x+y+z=1) have attracted attentions; however, the capacity fade is their main obstacle for commercializing high-quality cathodes as a trade-off of high-capacity as increased amount of Ni which has a high redox capability. One of the main

reasons is caused by that Ni can easily diffuse into vacant site of Li during charging process because of similar ionic radius each other. This makes Ni-rich layered cathodes undergo irreversible phase transition resulted from Li-moving blockage when they naturally change their phase into hexagonal H1, H2, and H3 sequentially as a level of Li-extraction during charge and H3, H2, and H1 as a level of Li-insertion again during discharge. To suppress this culprit in degradation of Ni-rich layered cathodes, previous studies have tried to solve this issue through a lattice doping with other elements; incompletely, this strategy cannot solve much important surface-triggered Li-moving blockage. Moreover, since the surface is more susceptible to unwanted side reactions by directly contacting with electrolytes, the surface can seriously influence on degradation of Ni-rich layered cathodes. In this study, we created selectively functionable surface on Ni-rich layered cathodes by utilizing unconventional materials, enabling Li-ion to move easily and smoothly in and out through the Ni-rich layered cathode. This newly created surface on the Ni-rich layered cathode was investigated through various analysis for understanding its effects on electrochemical performances when the cathode was composed in Li rechargeable batteries. Notably, in situ synchrotron X-ray diffraction (in situ synchrotron XRD) spectroscopy and ex situ X-ray absorption fine structure (ex situ XAFS) spectroscopy revealed that the new surface induced the Ni-rich layered cathode not to undergo irreversible phase transition during charging and discharging process. In addition, spherical aberration-corrected scanning transmission electron microscopy (Cs-corrected STEM) and further electrochemical analysis techniques also supported the abovementioned findings. With the aid of these affirmative effects, our cathode showed increased capacity of 218.42 mAh g⁻¹, improved rate capability of having capacity of 128.65 mAh g⁻¹ at 5C, and superior cycle performance of having capacity of 177.65 mAh g⁻¹ after 300 cycles with the capacity retention of 91.7%. This remarkable electrochemical performance was obviously contrasting results of that of pristine cathode, which was capacity of 192.51 mAh g⁻¹, rate capability of having 72.21 mAh g⁻¹, and cycle performance having capacity of 127.03 mAh g⁻¹ after 300 cycles with the capacity retention of 77.2%. This research shines on the complex surface-triggered degradation phenomena on Ni-rich layered cathodes with the concrete interpretation, suggesting a solution of creating a new functionable surface.

8:45 AM EN10.10.05

Exploring Catalytic Active Sites in Covalent Organic Frameworks for Oxygen Evolution Reactions

Seyed Pouya Hosseini Yazdeli¹, Andrés Rodríguez-Camargo², Liang Yao², Bettina V. Lotsch² and Kristina Tschulik³; ¹Max-Planck-Institut für Eisenforschung, Germany; ²Max Planck Institute for Institution Solid State Research Institution, Germany; ³Ruhr-Universität Bochum, Germany

Enhancing the efficiency and stability of catalysts for the oxygen evolution reaction (OER) is crucial for the advancement of renewable electrochemical energy conversion and storage technologies. The OER process, which plays a pivotal role in emerging technologies like water splitting, suffers from slow kinetics, leading to decreased overall device efficiency [1]. Addressing global energy and environmental challenges necessitates substantial research efforts in improving OER catalysts.

Covalent organic frameworks (COFs) offer great promise as a versatile class of materials with applications spanning multiple domains. These frameworks are constructed from light elements using reversible covalent bonds, resulting in crystalline structures characterized by high surface area, low density, and well-defined channels. Such properties render COFs suitable for a broad range of applications, including gas adsorption, chemical sensing, and heterogeneous catalysis. Furthermore, the facile functionalization of COFs grants them exceptional adaptability and versatility to cater to diverse requirements. [2]

Updated as of October 28, 2024

In this study, we assessed the performance of a cobalt-modified bipyridine-based covalent organic framework (Co-TpBpy) as a heterogeneous catalyst for OER under alkaline conditions. To evaluate its effectiveness, we employed techniques such as voltammetry and differential electrochemical mass spectrometry (DEMS). Additionally, operando EC-SEIRAS experiments and post-mortem analyses involving TEM, XPS, XRD, and SEM-EDX were conducted to investigate the structural and compositional changes occurring during OER. The observations revealed the formation of cobalt oxide nanoparticles, serving as active sites for OER catalysis, embedded within the organic framework of Co-TpBpy. This phenomenon led to improved stability and catalytic performance. Our findings suggest that COFs can be utilized as templates to facilitate the uniform distribution of highly active cobalt oxide nanoparticles, thus enhancing the OER process.

Engineering Single Photon Emission and Collective Phenomena with Lead Halide Perovskite

Nanocrystals Maksym V. Kovalenko^{1,2}; ¹ETH Zurich, Switzerland; ²Empa–Swiss Federal Laboratories for Materials Science and Technology, Switzerland

Colloidal lead halide perovskite (LHP) nanocrystals (NCs), with bright and spectrally narrow photoluminescence (PL) tunable over the entire visible spectral range, are of immense interest as classical and quantum light sources. Attaining pure single-photon emission is key for many quantum technologies, from optical quantum computing to quantum key distribution and quantum imaging. Across single CsPbX₃ NCs (X: Br and I) of different sizes and compositions, we find that increasing quantum confinement is an effective strategy for maximizing single-photon purity due to the suppressed biexciton quantum yield. We achieve 98% single-photon purity ($g(2)(0)$ as low as 2%) from a cavity-free, nonresonantly excited single 6.6 nm CsPbI₃ NCs, showcasing the great potential of CsPbX₃ NCs as room-temperature highly pure single-photon sources for quantum technologies [1]. In another study, we address the linewidth of the single-photon emission from perovskite NCs at room temperature. By using ab-initio molecular dynamics for simulating exciton-surface-phonon interactions in structurally dynamic CsPbBr₃ NCs, followed by single quantum dot optical spectroscopy, we demonstrate that emission line-broadening in these quantum dots is primarily governed by the coupling of excitons to low-energy surface phonons. Mild adjustments of the surface chemical composition allow for attaining much smaller emission linewidths of 35–65 meV (vs. initial values of 70–120 meV), which are on par with the best values known for structurally rigid, colloidal II-VI quantum dots (20–60 meV) [2]. Many-body interactions and exciton complexes are of essential role, for example, for stimulated emission, LED efficiencies, or the single-photon purity in quantum light sources. We studied the size-dependent trion and biexciton binding energies in CsPbX₃ NCs of 9–30 nm in size [3]. NC self-assembly is a versatile platform for materials engineering, particularly for attaining collective phenomena with perovskite NCs, such as superfluorescence [4, 5, 6]. The NC shape anisotropy leads to structures not observed with spherical NCs. We present a broad structural diversity in multicomponent, long-range ordered superlattices (SLs) comprising highly luminescent cubic CsPbBr₃ NCs (and FAPbBr₃ NCs) co-assembled with the spherical, truncated cuboid, and disk-shaped NC building blocks. We also discuss a critical role of the ligand-deformability on the outcome of co-crystallization, or even for the formation of single-component SLs [7]. Perovskite SLs exhibit superfluorescence, characterized, at high excitation density, by emission pulses with ultrafast (22 ps) radiative decay and Burnham-Chiao ringing behavior with a strongly accelerated build-up time.

11:00 AM QT01.01.02

Excitonic Coupling in Gradually Fluorinated β -Phase Zinc Phthalocyanine Lisa Schraut-May¹, Kilian Strauß¹, Sebastian Hammer², Luca Nils Philipp¹, Krzysztof Radacki¹, Holger Braunschweig¹, Roland Mitric¹ and Jens Pflaum¹; ¹Julius-Maximilians-Universität Würzburg, Germany; ²McGill University, Canada

Understanding how the crystallographic structure influences the excitonic properties of novel organic semiconductors plays a crucial role in fundamental research on this material class as well as for its implementation in devices with new functionalities. The class of phthalocyanines provides a perfect

model system to study this relationship, as it offers a wide range of different crystallographic phases and the possibility to reliably steer the structural and electronic parameters by gradual fluorination of the molecular ligands [1]. The shift of the respective frontier orbital energies caused by fluorination while, simultaneously, leaving the optical properties almost unchanged has already led to phthalocyanine based devices with advanced functionalities, such as dual emitting organic LEDs or color-switchable subwavelength plasmonic organic light emitting antennas [2,3].

In this contribution, we report on a comprehensive study on the interplay between molecular spacing and excitonic coupling in β -phase zinc phthalocyanine (ZnPc) single crystals. Temperature dependent photoluminescence measurements were performed on non-fluorinated ZnPc, partially fluorinated F₄-ZnPc crystals as well as their co-crystals, all of which grown by horizontal vapor deposition. Our measurements yield clear evidence for a change in the emission characteristics as function of temperature and polarization. For neat ZnPc crystals, a narrow emission of only 20 meV linewidth occurs below about 100 K, which we attribute to a superradiant enhancement caused by the coherent excitation of next neighboring molecules within the crystal lattice perpendicular to the crystallographic b-direction. In contrast, this phenomenon is absent in pure F₄-ZnPc as well as mixed ZnPc:F₄-ZnPc crystals, where already at small admixtures of the fluorinated counterparts, the intermolecular arrangement and coupling is changed in such a way that a coherently coupled state between adjacent molecules is strongly suppressed or energetically less favorable than a coexisting charge-transfer state as in case of the co-crystals. This hypothesis is corroborated by temperature dependent x-ray structural analyses on the investigated crystals in combination with extended theoretical simulations by means of time-dependent DFT, which highlight the role of the anisotropic coupling of the excitonic states and its spatial variation with temperature.

Our results demonstrate the potential inherent to this material class and the possible strategy of tuning the excitonic properties of molecular semiconductors by controlling their crystalline packing via gradual chemical substitution.

LSM and JP thank the Bavarian Ministry of Science and the Arts for the generous support by the research program Solar Technologies Go Hybrid.

Two-dimensional (2D) materials allow for the construction of heterostructures without the constraint of

lattice matching. This increased flexibility enables novel proximity effects through the stacking of strongly correlated 2D materials on 2D semiconductors. Here we use temperature-dependent photoluminescence (PL) microscopy to reveal a new proximity effect where excitons in monolayer MoSe₂ interact with the commensurate charge density wave (CDW) in bulk TiSe₂ [1]. Below the CDW ordering temperature we observe a new PL emission line (H1) on the TiSe₂-MoSe₂ interface that is 30 meV higher in energy than the neutral exciton. This observation is unique compared to other examinations of 2D heterostructures where additional spectral features appear at lower energies compared to the neutral exciton. Power and temperature-dependent measurements show that H1 behaves as a free exciton, therefore excluding interface trapping or localization as an explanation. Most interestingly, we find that H1 disappears above the TiSe₂ CDW ordering temperature, which suggests that the CDW plays a vital role in activating this previously unobserved exciton. We discuss possible CDW-based origins of H1 and outline future opportunities for using proximity effects to engineer novel excitonic states.

Interfacing Colloidal Er-Doped SiO₂ Thin-Film with p-Type Cz-Silicon For Enhanced Emission via Excitonic-Correlated e-h Recombination Sufian Abedrabbo¹, Anthony T. Fiory² and Nuggehalli M. Ravindra³; ¹Khalifa University, United Arab Emirates; ²Integron Solutions LLC., United States; ³New Jersey Institute of Technology, United States

Czochralski silicon (Cz-Si) indirect bandgap has been a hampering point in realizing efficient bandgap emission. In this work, we report our studies of interfacing Cz-Si with Er-doped SiO₂ thin films prepared by sol-gel processes. Colloidal interfacial reactions with Cz-Si surface results in significant improvements in Si bandgap emission. Model fitting the room-temperature photoluminescence spectra indicates correlated carrier recombination interactions; and the random strain fields are theorized to be the cause. Given that the optically active region is estimated to be of similar thickness to the coating thickness, it is anticipated that interfacial excitons are playing a role in shielding the e-h pairs from Auger recombination, thereby increasing the radiative recombination activities. The presentation will include comparative study of the bandgap emission of thermally oxidized Cz-Si with the colloidal prepared spin-coated silica on Cz-Si.

SESSION QT01.02: Excitons in Novel Materials II

The Surface Chemistry of Halide Perovskite and Perovskite-Related Nanocrystals Liberato Manna;

Updated as of October 28, 2024

Instituto Italiano di Tecnologia, Italy

Halide perovskite semiconductors can merge the highly efficient operational principles of conventional inorganic semiconductors with the low temperature solution processability of emerging organic and hybrid materials, offering a promising route towards cheaply generating electricity as well as light. Following a surge of interest in this class of materials, research on halide perovskite nanocrystals (NCs) has gathered momentum in the last years. While most of the emphasis has been put on led-based perovskite NCs, more recently the so-called double perovskite NCs, having chemical formula $A^+_2B^+B^{3+}X_6$, have been identified as possible alternative materials, together with various other metal halide structures and compositions, often doped with different elements. This talk will discuss the synthesis efforts of our group towards all these materials and our current understanding of their surface chemistry. I will highlight how for example halide double perovskite NCs are less surface tolerant than the corresponding Pb-based perovskites. Other topics that will be covered are the role of ligands, exogenous cations and acid-base equilibria on stabilizing the NCs and controlling their size and shape evolution.

2:30 PM *QT01.02.02

2D Perovskite: Exciting Playground for Exciton and Polaron Studies Paulina Plochocka; CNRS, France

High environmental stability and surprisingly high efficiency of solar cells based on 2D perovskites have renewed interest in these materials. These natural quantum wells consist of planes of metal-halide octahedra, separated by organic spacers. The unique synergy of soft lattice and opto-electronic properties are often invoked to explain superior characteristic of perovskites materials in applications. At the same time such unique synergy creates fascinating playground for exciton physics which challenges our understanding of this elementary excitation. I will demonstrate that even after decade of intense investigation the notation "unique" so often used in case of perovskites deserves serious scrutiny. First, I will show that in 2D perovskites, the distortion imposed by the organic spacers governs the effective mass of the carriers. As a result, and unlike in any other semiconductor, the effective mass of the carriers in 2D perovskites can be easily tailored. Secondly, I will highlight controversy related to exciton fine structure in different perovskite compounds and demonstrate that the soft lattice can suppress relaxation of excitons to dark state making 2D perovskites great light emitters. I will further demonstrate the optical evidences of the polaron formation. In the end I will present excitonic properties in novel type heterostructures: a combination of the monolayer transition metal dichalcogenides with layered organic inorganic perovskites, where spin injection into 2D perovskites has been achieved.

3:00 PM BREAK

3:30 PM *QT01.02.03

Origin of Broadband Emission in Low Dimensional Halide Perovskites Dinesh Kabra; Indian Institute of Technology Bombay, India

In this talk, I will provide an overview on research activities of our research group with emphasis on electroluminescent devices. Majority of this work is focused on molecular semiconductor and halide perovskites. In this talk I would show results of single junction OLEDs, single color tandem OLEDs and color tuneable vertically stacked tandem OLEDs. Further, triplet excitons are key aspects to enhance the

efficiency and hence understanding triplet excitons is key for the success of these devices. Which will be further extended to halide perovskites too.

Here in this talk, we will discuss the origin of broadband illumination and other emission peaks using temperature-dependent time-resolved photoluminescence (PL) spectra of 2D layered halide perovskites semiconductors. For temperatures below 100 K, (PEA)₂PbBr₄ film gives broad PL emission, stoke shifted by 750 meV from narrow exciton emission peaks, whereas (PEA)₂PbI₄ film does not show any broad emission. Kinetics of various peaks could provide useful insight to propose a consistent energy level scheme associated with a barrier (PEA) and well (PbX₆⁴⁻) material system's electronic states. This broad emission in (PEA)₂PbBr₄ perovskite is observed due to coupling of electronic states in inorganic well part and organic barrier part, which is in contrast to a proposed model based on self-trapped-exciton.

4:00 PM *QT01.02.04

Excitons in the Layered Magnetic Semiconductor CrSBr Julian Klein; Massachusetts Institute of Technology, United States

Materials with a correlated degree of spin, lattice, and charge are attractive platforms for the study of fundamental magneto-correlated phenomena and for realizing spin-based devices for spintronic applications. Such physics was initially explored in dilute magnetic semiconductors; however, their structural inhomogeneity limited their study. Fortunately, such ideas transfer to the emerging class of layered magnetic semiconductors with chromium sulfide bromide (CrSBr) as a prime candidate for such explorations. Unlike dilute systems, materials such as CrSBr are structurally homogenous and benefit from the well-known property enhancements that layered materials exhibit. In this unique combination, new opportunities arise for the study of a breadth of quasiparticle excitations immersed in magnetic environments.

In my talk, I will elaborate on the rich excitonic physics of CrSBr and showcase new opportunities for its control. I will start by showing that CrSBr is a quasi-1D material. The extreme anisotropy is manifested in its excitons, electronic band structure, a Peierls-like structural instability, and strong exciton-phonon and electron-phonon interactions. [1] As such, CrSBr is best rationalized as a stack of weakly coupled monolayers, each hosting tightly bound quasi-1D excitons. Second, I will discuss the crystal defects in CrSBr and provide a link to their optical emission properties. In particular, I will discuss the correlation of defects with a defect-magnetic order. [2] Lastly, I will demonstrate that CrSBr is an exceptional material for the controlled generation of crystal defects using a focused electron beam. [3] I will provide an outlook and motivate this as a key ingredient for controlling quasiparticle excitations and magneto-correlated phenomena one atom at a time.

Strongly Bound Excitonic States and the Exciton Dispersion of the Layered Semiconductor BiI₃

Alejandro Molina-Sanchez and Jorge Cervantes-Villanueva; University of Valencia, Spain

BiI₃ is a layered semiconductor with extraordinary excitonic effects in the visible range of the optical spectra, both in the case of bulk and monolayer systems. The excitonic binding energy of bulk is to that of the paradigmatic monolayer MoS₂ and the BiI₃ monolayer has even a higher excitonic binding energy, of more than 0.5 eV. The lower dielectric screening of this trihalide material explains in part these extraordinary exciton binding energy. Therefore, this layered material has a great potential for the design of optoelectronic devices and the realization of the experiments looking for exciton physics. In addition to the interesting excitonic properties, BiI₃ is also remarkable for the strong spin-orbit interaction, which makes the material suitable to have a strong Rashba effect under electric field or to tune the spin properties using magnetic proximity effects.

In this work we present a theoretical study of the electronic and optical properties of BiI₃ bulk and monolayer, within the framework of *ab initio* many-body perturbation theory, using the GW method and the Bethe-Salpeter Equation. We analyze the excitonic states, the influence on the spin properties of magnetic proximity effect and the possibilities to generate Rashba effect on BiI₃ monolayers. We analyze also the exciton dispersion of BiI₃ bulk and monolayer, of importance to understand the exciton dynamics. Our results are very promising for experiments like time-resolved angle-resolved photoemission and other time-resolve spectroscopies.

SESSION QT01.03: Different Varieties of Excitons

Session Chairs: Deep Jariwala and Atikur Rahman

8:00 AM *QT01.03.01

High-Lying Excitons and Excitonic Quantum Interference in 2D Semiconductors Kaiqiang Lin;

Xiamen University, China

Two-dimensional transition-metal dichalcogenides (TMDCs) show a wealth of exciton physics. We present the existence of a new excitonic species, the high-lying exciton (HX), in transition metal dichalcogenide monolayers with almost twice the band-edge A-exciton energy and with a linewidth as narrow as that of band-edge excitons [1]. The HX is populated through momentum-selective optical excitation in the K-valleys, and is identified experimentally in upconverted photoluminescence (UPL) and theoretically in *ab initio* GW-BSE calculations. These calculations suggest that the HX is comprised of electrons of negative effective mass. The coincidence of such high-lying excitonic species at around twice the energy of band-edge excitons rationalize the efficient exciton-exciton annihilation in TMDC monolayers, and enables the excitonic quantum-interference phenomenon revealed in optical second-harmonic generation (SHG) [2]. We probe the excitonic temporal dynamics in such three-level system through time-resolved sum-frequency generation (SFG) and four-wave mixing (FWM) [3]. High-lying excitons in bilayer WSe₂ can be largely tuned by twisting [4], electrical gate [5] and Stark effect, which gives control over the excitonic quantum interference and the corresponding optical nonlinearity.

8:30 AM *QT01.03.02

Spatially Indirect Interfacial Excitons in c-Oriented n-ZnO/p-GaN Heterostructures Subhabrata Dhar, Simran Arora and Amandeep Kaur; Indian Institute of Technology Bombay, India

Zinc oxide (ZnO) with wide direct band gap (3.37 eV) and large excitonic binding energy (~60 meV) has significant prospects in UV optoelectronics. However, stable p-type doping is a big challenge. Recently, there are efforts to study ZnO/GaN np-heterojunctions as GaN, which is a semiconductor with a direct band gap of ~3.5 eV, has a very close lattice matching with ZnO and can be controllably doped p-type. A type-II band alignment at the interface is expected between the two materials. Moreover, the difference in spontaneous polarizations along the c-direction for the two semiconductors can result in a net positive polarization charge at the interface. We have shown theoretically that the combination of the two effects can lead to the formation of a unique type of spatially indirect excitons (SIDXs) at the n-ZnO/p-GaN interface. While the electron part of such excitons is quantum confined along c-direction in the ZnO side, the hole part stays at the GaN side of the junction[1]. Like interlayer excitons reported in homo-/hetero-bilayers of transition metal dichalcogenides (TMDs), these excitons have planer nature with finite dipole moment along c-direction. Unlike conventional direct excitons, SIDXs can interact repulsively with each other through dipole-dipole coupling, which should favour Bose-Einstein condensation (BEC). Though, BEC of the excitons has long been anticipated theoretically, its experimental demonstration remains to be elusive until now. Moreover, due to the spatial separation between the electrons and holes, SIDXs are expected to have lifetime much longer than that of the conventional direct excitons. Long lifetime means that the excitons can travel long distances before annihilation. The added advantage of the present system is that the lifetime of the SIDXs is expected to be controlled by applying bias across the junction. Note that the longer is the survival of the excitons, better would be the scope for controlling their spins. Long lifetime of the excitons as well as a control over their lifespan are essential for the development of exciton-based logic circuits, which are supposed to be better than the electronic devices in terms of the energy efficiency and compatibility with the optical communication. Experimentally, we investigate the behaviour of electroluminescence (EL) as a function of applied bias at different temperatures in pn-heterojunctions consisting of c-oriented n-ZnO layer grown epitaxially on p-type c-GaN/sapphire templates [1]. In certain samples, where the acceptor concentration in GaN is more than a critical value, an EL peak is found at low temperatures, which shows a redshift with increasing forward bias. Our study assigns this peak to the SIDXs. Binding energy of these excitons can be significantly increased by changing the applied bias and can even be made larger than that of ZnO bulk. We also study the time dynamics of electroluminescence (EL) in these heterostructures. EL is found to have an extremely slow rise (decay) time (hundreds of milliseconds). Our study finds a strong connection between the existence of SIDXs and the extraordinarily slow EL rise(decay) property observed in these structures. The effect can thus be attributed to the SIDXs, meaning that the lifetime of SIDXs in this system must be hundreds of milliseconds and the lifespan can be controlled by external bias. All these features make ZnO/GaN pn-heterojunction system a unique platform not only to study the physics of excitonic Bose-Einstein condensation but also to investigate the transport of the excitonic spin and its manipulation via electrical means towards the realization of exciton-based electronics.

Self-Hybridized Polaritons in a Van der Waals Magnet Pratap Chandra Adak, Biswajit Datta, Sichao Yu and Vinod Menon; City College of New York, United States

Recent discoveries of van der Waals magnetic materials have opened up new possibilities for exploring magnetic order in reduced dimensions, with implications for quantum phenomena and device applications. Among these materials, CrSBr stands out as a promising candidate. It consists of monolayer ferromagnets stacked into an A-type antiferromagnetic structure and exhibits a high Neel temperature. Furthermore, as a semiconductor with strong coupling between excitons and magnetism, CrSBr provides a novel platform for optical manipulation of its magnetic properties. With tightly-bound excitons and large oscillator strength, CrSBr supports strong light-matter coupling, leading to the formation of polaritons—hybrid quasi-particles formed by the coupling of excitons and photons. Our study focuses on self-hybridized polaritons in CrSBr samples, capitalizing on the material's high refractive index to achieve strong light confinement without external mirrors. In particular, we utilize polarization-resolved photoluminescence excitation (PLE) spectroscopy to comprehensively investigate the anisotropic properties of CrSBr. Our work sheds light on the light-matter coupling in CrSBr, offering insights for optically accessible device applications in spintronics and magnonics.

Exciton Evolution by Singlet Fission and Excimer Formation in DNA-Semiconductor π -Stacks Jeffrey Gorman^{1,2}, Sarah Orsborne¹, Florian Auras¹ and Richard H. Friend¹; ¹University of Cambridge, United Kingdom; ²MIT, United States

Natural photosystems control sub-nm interchromophore coupling using a protein scaffold to evolve remote singlet excitons into free charges at the reaction centre. Nature must achieve this with a limited set of pigments, necessitating exquisite control over excitonic coupling. In contrast, traditional organic electronic devices lack such nano-structural fidelity. This has limited our understanding over electronic coupling and our ability to optimize condense-phase organic semiconducting aggregates. To address this disparity, we have developed efficient methods for the insertion of perylene diimides or pentacenes into DNA.^{1,2} DNA's selective self-assembly yields size-defined aggregates of pseudo-1D π -stacked organic semiconductors. We selectively program size and exciton delocalization to vary from isolated monomers up to strongly coupled pentamers.

We characterize excited evolution using transient absorption and spin resonance spectroscopy, we track the evolution of singlet excited states in our aggregates, showing results are well-matched to traditional—but disordered—thin films. In size-controlled pentacene monomers, the excited singlet state remains localized to single chromophore. In larger pentacene assembly size we observe singlet exciton evolution <0.5 ps triplet formation by singlet fission. We interrogate this process further using cryogenic transient electron spin resonance spectroscopy. This reveals the initial singlet exciton evolves into a bound triplet pair quintet state (ca. $0.5 \mu\text{s}$), which subsequently converts into free triplets. Interestingly, we can tune the rate of singlet fission through DNA programmed assembly alone. In the case of perylene diimides, we can controllably tune the extent of excimer formation as a function of DNA-directed aggregate size. These results point towards a more rational design process for organic semiconductor clusters, where kinetics can be tuned through extrinsic assembly rather than chemical change to the semiconductor skeleton. Our modular DNA-based assembly offers real opportunities for the rapid development of bespoke

semiconductor architectures with molecule-by-molecule precision, a material 'toolbox' for spectroscopic study.

Tuning the Interlayer Exciton in Bilayer MoS₂ by Means of Self-Assembled Monolayers Mostafa Shagar¹, Christian Imperiale², Felix Thouin², Luca Razzari¹, Stephane Kena-Cohen² and Emanuele Orgiu¹; ¹Institut National de la Recherche Scientifique, Canada; ²Polytechnique Montréal, Canada

The field of study surrounding Transition Metal Dichalcogenides (TMDs), a class of two dimensional materials that can be exfoliated down to a single molecular level, has recently seen large improvements and advancements. Whether in the study of monolayer properties or in the various possibilities that stacking different materials as heterostructures allow for. However, one interesting application of these materials is in their natural homobilayer form. For example, in molybdenum disulfide (MoS₂), there exists an interlayer exciton that emerges purely out of the interlayer interaction inside the natural homobilayer.

This exciton is unique in its ability to couple to its environment due to having both strong in-plane and out-of-plane dipole sensitivity. This project attempts to leverage this sensitivity by utilizing self-assembled organic monolayers (SAMs), a method of dielectric tuning that is not commonly used for two dimensional materials. Our SAM is formed by a monolayer of non-conjugated organic molecules that spontaneously assemble and are covalently tethered to a substrate. By using SAMs with a strongly dipolar functional group, it is possible to create an effective electric field across the homobilayer to couple with the interlayer exciton without external electrical bias [1] or optical pumping.

In this project, we use SAMs with different dipole moments and sign. These molecules will form SAMs with a very strong electrostatic dipole (of opposite signs) in the vertical direction which makes them prime candidates for exerting a local electric field to the bilayer MoS₂. We then perform optical reflectance measurements in order to directly probe the interlayer exciton and the effects of the SAM interface.

We observed a clear reorganization of the excitonic properties of the MoS₂ and a splitting of the interlayer exciton due to the existence of an external electric field causing Stark splitting. We also observed a very strong dependence on annealing on our structures, where the existence of randomly oriented water dipoles completely screens the effect of the SAM dipole on the MoS₂ exciton.

Additionally, Angle Resolved Photoemission Spectroscopy (ARPES) is being performed in order to better understand the band structure of the coupled system. This method of interfacing organic molecules to TMDs is vastly unexplored and opens a new range of possibilities for materials by using two classes of materials both known for their versatility. The development of bias free local tuning of TMDs that is easily deposited on a wide array of substrates offers a unique set of advantages compared to typical coupling methods such as depositing contacts, doping or coupling to optical cavities.

Plexcitons for Solar Energy Harvesting and Sensing Devices Karthik Shankar; University of Alberta, Canada

Excitons and plasmons are both quantum quasiparticles. While excitons are bound electron-hole pairs, plasmons are the collective and coherent oscillations of conduction band electrons (typically in coinage metals) at metal-dielectric interfaces. Plasmons can interact with excitons in several different ways. When plasmonic and excitonic resonances are spatially and energetically close to one another, the two resonators can be strongly coupled. The strong coupling regime is characterized by a significant Rabi splitting and anti-crossing behavior.

Strongly coupled plexcitonic states are entangled quantum systems which can be used to construct quantum sensors. Plasmons and excitons can also be weakly coupled to each other. The weak coupling regime is characterized by an anomalously broadened absorption band, and is particularly beneficial in light harvesting devices such as solar cells, photodetectors and photocatalysts. The Shankar Lab has found that strongly coupled plexcitons in gold nanoparticle (NP)-cyanine dye J-aggregate assemblies are excellent platforms for chemical sensing due to their sensitivity to the dielectric permittivity. The Rabi splitting (as large as 217 meV) decreases upon exposure to humidity and eventually disappears as the plexcitonic interaction moves into the weak coupling regime. Once humidity is expelled, the large Rabi splitting is recovered. Plasmons and excitons also interact through the PIRET effect, which stands for plasmon-induced resonance energy transfer, a plasmonic analog of the more well-known Förster resonance energy transfer. The PIRET effect involving Au NP plasmons and excitons in n-type carbon nitride NPs enabled a huge improvement in photoelectrochemical water-splitting performance, achieving a photocurrent density as high as 3 mAcm⁻².

Design of Dimer, Oligomer and Polymer Acceptors for Efficient and Stable Organic Solar Cells Bumjoon Kim; Korea Advanced Institute of Science and Technology, Korea (the Republic of)

High power conversion efficiency (PCE) and long-term stability are important requirements for commercialization of organic solar cells (OSCs). Small-molecule acceptors (SMAs) are the core materials that have led to remarkable advances in the PCEs of the OSCs, but the resulting OSCs typically have poor long-term stability. The low glass transition temperatures (T_g s) and rapid diffusion of SMAs owing to their small molecular sizes are recognized as the main causes of the poor stability of OSCs. In addition, the PCEs of OSCs are still lower than those of other types of photovoltaic devices, such as perovskite solar cells, mainly because of their relatively low open-circuit voltage ($V_{oc} < 0.90$ V). In this talk, we present the development of different dimer and oligomer acceptors for improving the V_{oc} and PCE values

of the OSCs. Interestingly, dimer and oligomer acceptors have significantly higher T_g and lower diffusion coefficient compared to SMAs, which enhances the photo and thermal stabilities of the OSCs. Finally, by adding the examples of polymer acceptors, we discuss the impact of molecular sizes of acceptors in the device stabilities and mechanical properties of the OSCs.

11:15 AM QT01.04.03

Photon Upconversion in ‘FuLEDs’ and in Hybrid Materials Le Yang^{1,2}; ¹Institute of Materials Research and Engineering A*STAR, Singapore; ²National University of Singapore, Singapore

Triplet-triplet annihilation (TTA) enables photon or energy upconversion in organic semiconductors – advantageous in that they are more efficient in the upconversion process and that they are more versatile in the visible light range. The same photophysical process of TTA, when occurring in a electronic device (an OLED), also known as triplet fusion, is one strategy to enhance the device efficiency from typical fluorescent emitters by utilising all the triplet “dark” states. In this talk, we will explore 2 main ideas, exploring the process of TTA across optically-excited systems (in photon upconversion) to electrically-excited systems (in triplet fusion enhanced ‘FuLEDs’).

Firstly, for functionally viable single-colour organic light emitting diodes (OLEDs), we believe they must satisfy three criteria: efficiency, lifetime, and colour (sharpness, gamut). However, for the significant advances in device efficiencies achieved in new classes of emitters (phosphorescence, TADF), they often tend to have less decent stability and colour sharpness. We have demonstrated strategies in lifting the device efficiencies of simple fluorescent systems.^{1,2} This includes single-dopant triplet fusion enhanced OLEDs (‘FuLEDs’).^{3,4} We also advocate that all (blue) TTA upconverters will make suitable (blue) FuLED emitters. This is because we are utilising the same photophysical process in both cases, and that TTA/triplet fusion is a naturally energetically uphill process, encouraging high-energy emission, and thus suitable for blue or deep-blue higher efficiency OLEDs.⁴

Lastly, we turn our attention to a new system of TTA-upconversion, using perovskite nanocrystals as triplet sensitizer and a nested, Russian-doll-like system of two TTA upconverters, to achieve a much enhanced photon upconversion.⁵ We provide available experimental data to speculate on possible pathway for this enhancement.

Monolayer WS₂ Electro- and Photo-Luminescence Enhancement by TFSI Treatment Alisson R. Cadore; Brazilian Nanotechnology National Laboratory, Brazil

Light-emitting diodes (LEDs) based on layered material heterostructures (LMHs) allow the fabrication of electroluminescent (EL) devices operating in the visible spectral region. A major advantage of LMH-

LEDs is that the EL emission wavelength can be tuned among different types of exciton complexes by controlling the charge density. However, these devices display EL quantum efficiency, i.e. the ratio between emitted photons and injected electrons, as low as $\sim 10^{-4}\%$, and mostly limited by non-radiative recombination processes. Here, we perform EL measurements before and after chemical treatment with superacid TFSI in monolayer WS₂-LEDs. We demonstrate that TFSI boosts the EL emission by over one order of magnitude at room temperature. Moreover, we observe that non-treated devices emit light mainly from negatively charged trions, while the emission in TFSI-treated WS₂-LEDs predominantly involves radiative recombination of neutral excitons due to activation of trapping states in WS₂. We then present simulations and modeling of the integration of LMH-LEDs with photonic cavities for further enhancement of EQE. Our observation opens up a route to obtain more efficient and tunable LMH-LEDs, unveiling additional insights into the nature and behavior of the exciton dynamics in the TFSI-treated TMDs, as well as suggesting an additional route towards LEDs engineering [1].

11:45 AM QT01.04.05

Improving Substrate Mode Outcoupling in Organic Light-Emitting Diodes on Polymer Microlens Arrays with Very Low Index Coatings Claire Arneson, Hafiz K. Sheriff and Stephen R. Forrest; University of Michigan, United States

Increasing the external efficiency of organic light-emitting diodes (OLEDs) is essential for their use in mobile applications where battery life is a primary concern. However, an even more important consideration is that the device reliability is improved by increased efficiency since the OLED can be operated at a lower current to achieve the same luminance. [1] OLEDs can achieve internal quantum efficiencies as high as 100% using either phosphorescence or thermally activated delayed fluorescence. However, the external quantum efficiency for OLEDs are $\sim 20\%$ for devices grown on planar glass substrates, as the majority of photons are coupled to modes trapped within the device. Approximately 40% of photons, which are emitted from a high-index organic layer with $n \sim 1.7$, are trapped within waveguide and substrate modes because of the index mismatch between these layers and the substrate, and between the substrate and air. In this work, we introduce a new, and potentially inexpensive and scalable method to improve on existing sub-electrode and conventional external microlens-array (MLA) technology by incorporating optically designed low-index coatings on the MLA surface to achieve substrate mode outcoupling efficiencies approaching 100%. We use porous thin organic and ALD films on the polymer MLA surface to achieve refractive indexes from 1.5, matching with glass, to 1.1, approaching that of air. Through the use of outcoupling structures external to the organic device stack, and that exhibit no wavelength or viewing angle dependence, we demonstrate a method for achieving high-efficiency devices with applicability in both lighting and display applications.

Photophysics, Photochemistry and Optoelectronics of Singlet Fission Organic Materials in

Microcavities Winston Goldthwaite¹, Roshell Lamug¹, Gina Mayonado¹, Ahasan Ullah¹, John Anthony², L.-J. Cheng¹, Matt W. Graham¹ and Oksana Ostroverkhova¹; ¹Oregon State University, United States;

²University of Kentucky, United States

Organic (opto)electronic materials have been explored in a variety of applications in electronics and photonics, driven by several advantages over traditional silicon technology, including low-cost processing, fabrication of large-area flexible devices, and widely tunable properties through functionalization of the molecules. Over the past decade, remarkable progress has been achieved in understanding physical mechanisms and in developing guidelines for the material design, which boosted the performance of organic devices that rely on photophysics and/or (photo)conductive properties of the material. However, further improvements in device performance are desirable, and challenges related to (photo)stability of organic devices need addressing.

One of the major thrusts in developing new organic materials and device concepts has focused on materials exhibiting singlet fission, which is a carrier multiplication process which would enable, for example, enhanced power conversion efficiencies in solar cells. Nevertheless, fundamental questions pertaining to exciton physics in singlet fission materials, and how it can be manipulated by material design and external parameters, remain. Some of these questions will be addressed in this presentation using model singlet fission organic materials, exemplified by functionalized acene and anthradithiophene derivatives, and combinations of photoluminescence and ultrafast transient absorption time-resolved spectroscopy carried out in a broad range of temperatures and magnetic fields.

Strong exciton-photon coupling that occurs when an organic film is placed in a microcavity, enabling formation of a light-matter hybrid state (polariton), presents a largely unexplored opportunity to control photophysics, photochemistry, and optoelectronic characteristics in existing singlet fission materials and devices by using polaritons. This presentation will summarize our efforts aiming to understand and tune exciton polariton properties in model singlet fission organic materials, towards exploiting these properties in optoelectronic devices and controlling photochemical reactions directly relevant to photostability.

2:30 PM QT01.05.02

Exciton-Polaritons Facilitated Photogeneration and Charge Carrier Transport in Solution-

Processed Cavity Organic Solar Cells Yahui Tang^{1,2}, Alexandra Stuart¹, Timothy van der Laan² and Girish Lakhwani¹; ¹The University of Sydney, Australia; ²Commonwealth Scientific and Industrial

Research Organisation, Australia

Strong light-matter coupling in organic solar cells (OSCs) has recently shown great potential in increasing the power conversion efficiencies of light.¹⁻⁴ Strong light-matter coupling creates new hybrid states termed exciton-polaritons, and the formation of polaritons in OSCs can significantly influence device performance. It has been shown in thermally evaporated planar heterojunction OSCs that exciton-polaritons can reliably exist at room temperature and leads to more efficient energy transfer.¹ Yet, it has not been demonstrated for solution-processed bulk-heterojunction OSC devices, whereas the latter is more scalable for practical applications. Here, we report that exciton-polaritons can reliably exist in solution-processed bulk-heterojunction OSCs and their influence on device properties. Combining time-resolved spectroscopic measurements for thin films and transient photocurrent/photovoltage decay measurements for devices, we investigated the photo- and device physics of cavity OSCs. We find that

the benefits of strong coupling to OSCs are two-fold. Firstly, the charge photogeneration through the new pathway facilitated by the exciton-polaritons is enhanced compared to the reference OSC devices. Secondly, we find that the energy of the charge transfer state is blue-shifted, accompanied by the longer charge carrier lifetime observed in the transient photovoltage decay measurements. Our work demonstrates that strong coupling is a promising avenue for further improving the device properties of OSCs.

Analysis of Interfacial Charges by Spontaneous Orientation Polarization in the Co-Host EML Organic Light-Emitting Diodes with Impedance Spectroscopy So-Young Boo, Akeem Raji, Jae-Yong Park, Somi Park, Eun-Jeong Jang, Jonghee Lee and Jae-Hyun Lee; Hanbat National University, Korea (the Republic of)

Organic light-emitting diodes (OLED) consist of a multi-layer such as hole injection layer (HIL), hole transport layer (HTL), emission layer (EML), electron transport layer (ETL), and electron injection layer (EIL) between two electrodes. By applying an external voltage, electrons and holes are injected and transported from the respective electrodes, resulting in light emission in the EML. In OLED, the presence of interfacial charges at the organic interface allows charge injection before applying voltage to the device. This property can be originated from the permanent dipole moment (PDM) of organic molecules. Most organic molecules used as electron transport layer, such as 2,2',2''-(1,3,5-Benzinetriyl)-tris(1-phenyl-1-H-benzimidazole) (TPBi) and tris-(8-hydroxyquinoline)aluminum (Alq₃), and 4,6-Bis(3,5-di(pyridin-3-yl)phenyl)-2-methylpyrimidine (B3PyMPM) possess PDM, aligned spontaneously during the vacuum deposition process. The non-vanishing net aligned PDM, known as spontaneous orientation polarization (SOP), induces interfacial charges and affects charge injection properties. When the electron transport material of ETL forms a positive SOP against the cathode, the ETL shows negative interfacial charge (NIC) at the EML/ETL interface, influencing hole injection. Consequently, holes are injected and accumulated before the applying voltage to the device, and it can be shown in the capacitance-voltage (C-V) characteristics as the transition voltage (V_t). However, holes injected by NIC can lead to exciton-polaron quenching (EPQ) within the emissive layer. Therefore, it is important to understand the interface characteristics where holes accumulated by NIC. In this presentation, we investigated the difference in charge accumulation property caused by SOP at the ETL/EML interface in co-host EML OLED using impedance spectroscopy (IS). IS was employed to analyze the accumulation and transportation of charges in the co-host EML OLED.

External Radiative Efficiency of Organic Semiconductor Materials Doped with Organometallic Phosphors Jinyu Chong; Rutgers, The State University of New Jersey, United States

Organic photovoltaics (OPVs) can have certain desirable properties, such as, lightweight, adjustable bandgap, semitransparency, low toxicity, and solution processability, that differentiate them from inorganic and perovskite solar cells. However, the current record efficiency of OPVs (~19%) is still less than for many other solar cell technologies, which limits their application. Shockley-Queisser theory helps to elucidate the efficiency limit of a solar cell, and it assumes that the highest efficiency can be achieved when the external radiative efficiency (ERE) of the solar cell is equal to unity. ERE quantifies the radiative recombination of excitons under total dark current recombination. For the power conversion efficiency (PCE) of solar cells, the best performing solar cells display high EREs due to low nonradiative recombination. One major nonradiative loss pathway in OPVs that suppresses ERE, and hence PCE, is non-emissive triplet states in organic semiconductors.

In this work, we introduce organometallic phosphors into organic semiconducting donor:acceptor OPV films with the goal of converting non-emissive triplet states into emissive phosphorescence and, thereby, increasing ERE. An iridium-based organometallic phosphor with a low triplet energy level, tris(1-phenylisoquinoline) iridium, Ir(piq)₃, is incorporated into bilayer OPV films composed of polyfluorene polymers - poly(9,9-di-n-octylfluorenyl-2,7-diyl), PFO, as the electron donor, and poly(9,9-dioctylfluorene-alt-benzothiadiazole), F8BT, as the electron acceptor. The photophysical properties of PFO, F8BT and PFO/F8BT donor:acceptor bilayer films with Ir(piq)₃ phosphor doping are studied. Additionally, both OPV and photodetector devices are fabricated and tested with and without Ir(piq)₃. Photoluminescence (PL) spectroscopy confirms that photoexcitation of PFO/Ir(piq)₃ films results in efficient triplet exciton transfer from PFO to the triplet state of the Ir(piq)₃ phosphor. In addition, when the phosphor doping concentration is increased, there is an increase in PL quantum yield (PLQY), from 38% to 56%, attributed to reduced nonradiative recombination from the PFO triplet state. In contrast, the PLQY of PFO/F8BT and [PFO/Ir(piq)₃]/F8BT bilayer films decreases with increasing doping concentration, which indicates that the photogenerated triplet state of Ir(piq)₃ is quenched by the presence of the F8BT acceptor. In addition, time-resolved PL measurements show that the average lifetime of PFO decreases from 964 ps to 219 ps in the presence of phosphor, which further indicates efficient energy transfer. We also perform PL lifetime measurements of PFO/F8BT and [PFO/Ir(piq)₃]/F8BT bilayer films and the lifetime changes from 930 ps to 770 ps in the presence of phosphor, which show that efficient energy transfer occurs from the donor to the acceptor. Transient absorption spectrum of PFO and PFO(Ir) films shows that there is singlet exciton absorption peak at a wavelength of 826 nm, around 1.5 eV. OPV devices are fabricated with the following configuration, indium-tin oxide (ITO)/PEDOT:PSS/PFO/F8BT/Ca/Al, with and without phosphor doping in the PFO layer. The OPV devices are tested under one sun illumination. Due to the bilayer structure of PFO/F8BT, the PCE is extremely low, which is ~0.02%; however, the open-circuit voltage is improved by 0.1 V in the presence of the phosphor, suggesting reduced nonradiative recombination. The devices are also tested as organic photodetectors (OPD). PFO(Ir)/F8BT has a responsivity of 0.64 mA/W, the detectivity of 3.25E10 Jones. As for PFO/F8BT devices, their responsivity is 0.48 mA/W, and the detectivity is 3.28E10 Jones. The OPD test indicates that their responsivity is comparable with other photodetector devices.

Acridine-Based TADF Molecules in Organic Light-Emitting Transistors (OLETs) Caterina Soldano, Ornella Laouadi, Vladimir Kornienko and Katherine Gallegos-Rosas; Aalto University, Finland

Organic light-emitting transistors are photonic devices combining the function of an electrical switch with the capability of generating light under appropriate bias conditions. Achieving high-performance light-emitting transistors requires high mobility organic semiconductors, optimized device structures and

highly efficient emissive layers. Thermally-activated delayed-fluorescence (TADF) has enabled the possibility to achieve heavy-metal-free phosphorescent emitter-based devices with high brightness and state-of-the-art color coordinates, with efficiency exceeding 30%. Since the first report on delayed fluorescence in 2012, TADF molecules have been successfully exploited mainly in OLEDs emissive layers, where host(s)-guest configurations are commonly adopted, mainly to suppress concentration quenching arising from the long-lived triplet excitons.

Here, we present our recent results on the use of an acridine-based TADF molecule (DMAC-DPS) in a host-guest configuration and its optoelectronic behavior in the limit of *field-effect* devices. First, we studied the optical response of these blends by tuning the doping concentration to optimize light generation, for which we observed a quenching of the photoluminescence signal for increasing dye concentration. These blends are then implemented in multilayer organic light-emitting transistors; by engineering the structure (*i.e.*, organic stack), we achieved a large improvement in the light output (~ 4 times). We analyzed our results in terms of balanced charge transport in the emissive layer as well as the device, which, in the limit of horizontal charge transport, leads to an improved exciton formation and decay process.

While the efficiency of our devices is yet to achieve state-of-the-art diode counterpart, this work demonstrates that using TADF molecule while engineering the emissive layer is a promising approach to enhance the light emission in field-effect devices. This opens the way for a broader exploitation of organic light-emitting transistors as alternative photonic devices in fields ranging from display technology to flexible and wearable electronics.

Study of Interface Effect on InP/ZnSe QDs' Non-Linear Properties Luca Giordano, Pieter Schiettecatte and Zeger Hens; Ghent University, Belgium

QDs show size-tunable opto-electronic properties and are highly suitable for solution-based processing. In this field, Cd-based QDs are the materials with most promising results, but the use of Cd in electronic appliances is restricted by the European Commission's ROHS directive. Considering this, sustainable alternatives are strictly needed, and InP-based QDs are the most promising ones thanks to their high level performance, showing, for example, a near-unity photoluminescence quantum yield across the full visible spectrum. However, opposite from such a linear optical property related to the formation of single electron-hole pairs in InP-based QDs, the characteristics of multiple electron-hole pairs within a single InP-based QDs remain poorly understood. For Cd-based QDs, multiple electron-hole phenomena, such as optical gain, stimulated emission and lasing, have been mostly demonstrated using CdSe QDs, for which the growth of core/shell CdSe/CdS architectures with an alloyed interface was decisive to slow down biexciton Auger recombination and attain stimulated emission under continuous wave optical or electrical pumping.

In this work, we analyze the Auger recombination rate of biexcitons in InP/ZnSe core/shell QDs, where the synthesis protocol was adapted to obtain 4 different interfacial compositions. A first set of two

InP/ZnSe samples was formed by purifying or not the InP reaction mixture prior to ZnSe formation. Here, the one-pot approach without intermediate purification may lead to the incorporation of In within the ZnSe shell, while a neat ZnSe shell will grow when starting from purified InP core QDs. A second set of two samples was formed by adding gallium as a second group III precursor at the end of the InP core formation, where again cores were either purified or not before ZnSe shell growth. We found that in particular the addition of GaCl₃ leads to the incorporation of Ga at the InP core QD surface. Interestingly, we observed a systematically higher photoluminescence quantum yield for the samples formed through a one-pot procedure, i.e., without intermediate purification. In addition, a well-defined biexciton Auger recombination rate was only observed for the InP/ZnSe core/shell QDs formed by the one-pot approach. For all other samples, a significantly faster and multi-exponential Auger decay of multi-excitons was observed. The relation between these observations and the elemental and structural characteristics of the core/shell interface will be discussed. We conclude that, not unlike the seminal example of CdSe/CdS, the interfacial composition strongly affects the properties of multi-excitons of InP/ZnSe core/shell QDs.

8:00 PM QT01.06.02

Influence of Y6 Aggregation on Energetics and Charge Generation in High Performance OPV Blends John B. Asbury; Pennsylvania State University, United States

We investigated the origin of the high ratio of open circuit voltage to charge transfer state energy (eV_{OC}/E_{CT}) of OPV polymer blends consisting of the electron donating polymer PM6 and the non-fullerene electron acceptor Y6. PM6-Y6 and related donor-acceptor OPV blends exhibit remarkable optoelectronic properties and record power conversion efficiencies in part because of their unusually high eV_{OC}/E_{CT} ratios, which is believed to be related to the small energetic offset of the HOMO levels of PM6 and Y6. In this study, we varied the amount of Y6 in PM6 blends as a means to control the aggregation of Y6 molecules. We examined the corresponding influence that Y6 aggregation has on the energetic offsets and the charge generation efficiency of the materials by probing the appearance of polaron absorption signals in the mid-infrared using time-resolved infrared spectroscopy. Furthermore, we examined the optical absorption and emission spectra of the PM6-Y6 blends over the range of compositions to correlate the efficiency of charge generation with the signatures of Y6 aggregation in the optical spectra. We observed an abrupt transition around 30 mass% Y6 content at which polarons were efficiently generated by charge separation from PM6 to Y6. Comparison to composition dependent GIWAXS studies of PM6-Y6 blends revealed the formation of Y6 aggregates around the same 30 mass% threshold. These observations demonstrate that aggregation of Y6 molecules is required for charge separation to occur from PM6 to Y6 as measured through the mid-infrared absorption of polarons in the TRIR spectra. Although charges were efficiently generated in blends with only 30 mass% Y6 content, OPV device studies revealed that 50-60 mass% Y6 was needed to reach optimized short-circuit current and OPV device efficiency because these measurements convolve charge generation with charge transport. These findings clarify the optoelectronic properties of the novel class of Y6 acceptors and emphasize the importance of molecular aggregation for tuning the energetics of high performance systems that minimize energy offsets for maximum OPV power conversion efficiencies.

8:00 PM QT01.06.03

Enhancing Structural Integrity and Emission Efficiency of Two-Dimensional Supramolecular Structures Through Silica Encapsulation Dimuthu H. Thanippuli Arachchi, Ulugbek Barotov, Alexander E. Kaplan, Tara Sverko, Collin F. Perkinson and Mounji G. Bawendi; Massachusetts Institute of Technology, United States

The optical properties of J-aggregates are closely linked to their structural integrity, making them susceptible to chemical environments and mechanical stresses. We explore the use of silica encapsulation to enhance the structural rigidity and light emission efficiency of 5,5',6,6'-tetrachloro-1,1'-diethyl-3,3'-di(4-sulfobutyl)-benzimidazolocarbocyanine (TDBC) two-dimensional sheet-like J-aggregates. Silica as an encapsulating matrix provides optical transparency, chemical inertness, and ease of functionalization while rigidifying the J-aggregate structure. Our novel in-situ encapsulation process results in silica-encapsulated J-aggregates whose light absorption and emission properties show no significant change from those of bare J-aggregates, indicating that encapsulation preserves the excitonic structure in TDBC J-aggregates. Microscopic analysis confirms successful and homogeneous silica coating on J-aggregate sheets through cryogenic-TEM images and Scanning Transmission Electron Microscopy with Energy Dispersive X-Ray Analysis (STEM-EDX). Dynamic Light Scattering (DLS) reveals smaller sizes for silica-coated J-aggregates compared to uncoated ones. Stability studies involving dilution demonstrate that silica coating enhances structural integrity, enabling extensive dilutions without a breakdown of J-aggregates into monomers. Silica-coated TDBC J-aggregates achieve a quantum yield of ~95%, the highest recorded for such aggregates, and an ultrafast emissive lifetime of ~200 ps. The absorbance and emission line widths, already quite narrow at room temperature, exhibit further narrowing upon cooling to 79 K. The silica shell allows attaching functional groups on the shell surface or embedding them in the silica shell, permitting hybrid systems without disturbing the assembly of J-aggregates. Encapsulated J-aggregates provide (1) a platform for further manipulation of J-aggregates as building blocks for integration with other optical materials and structures, and (2) a platform for fundamental studies of exciton delocalization, transport, and emission dynamics within a rigid matrix.

Keywords: J-aggregates, silica-encapsulation, quantum yield, cyanine dyes

Intramolecular Locking-Induced Triplet Exciton-Harvesting Emitters with Aggregation-Induced Emission Effect for Non-Doped OLEDs Taehyun Kim, Dae Hwan Lee and Taiho Park; Pohang University of Science and Technology, Korea (the Republic of)

Conventional triplet exciton-harvesting organic emitters can attain high internal quantum efficiency (IQE). Despite their advantages, these emitters suffer from the need to introduce heavy atoms and elongated skeleton structures leading to concentration quenching problems. Therefore, heavy-atom-free (HAF) triplet exciton-harvesting emitters have been promising due to unique photophysical characteristics and high photoluminescence quantum yield (PLQY). However, their device application to organic light emitting diodes (OLEDs) has been rarely explored since the performance of non-doped devices is inferior to that of doped devices because of the lack of suitable molecular design strategies. Therefore, the exploration of structural design is essential for decreasing reorganization energy of molecular structures to achieve high PLQY by utilizing triplet-excitons and aggregation-induced emission (AIE) characteristics in a non-doped system. Herein, we synthesized three asymmetric HAF triplet-harvesting emitters. The effect of non-covalent interaction for intramolecular hydrogen bonding between the N atoms and adjacent H atoms of emitters were detected in single-crystal XRD. Hydrogen bonding channel induced intramolecular locking reduced reorganization energy effectively, that increased the intersystem crossing (ISC; k_{ISC}), reverse intersystem crossing (RISC; k_{RISC}) rate and enhanced radiative decay (k_r) process. As a result, intramolecular hydrogen bonding assisted Qx-Py-2DMAC exhibited fast k_{ISC} ($3.52 \times 10^7 \text{ s}^{-1}$), k_{RISC} ($2.54 \times 10^6 \text{ s}^{-1}$), k_r ($3.47 \times 10^7 \text{ s}^{-1}$), and high PLQY (0.94). Besides, hydrogen bonding produced conformation-locked crystal structures were deeply investigated by two-dimensional grazing-incidence wide-angle X-ray diffraction (2D-GIWAXD). H-bond based emitters formed enhanced

dense packing modes with a large coherence length (L_c) and preferred horizontal orientations, and exhibited the AIE property that can be applied to non-doped OLEDs. Moreover, molecular locking effect triggered spin-forbidden triplet excitonic emission known as room-temperature phosphorescence (RTP) with a lifetime of milliseconds in the neat film. By utilizing Qx-Py-2DMAC as the emitter, a un-optimized non-doped device, exhibiting a high current efficiency of 33.6%, a power efficiency of 30.1%, and an external quantum efficiency of 11.1% representing relatively high efficiency among RTP emissive and AIE featuring non-doped OLEDs.

Probing the 2D Momentum Space of an Excitonic Bose-Einstein Condensate using a Modified Michelson Interferometer S.V.U. Vedhanth and Shouvik Datta; IISER Pune, India

Excitons as bound electron-hole pairs can undergo interesting phase transitions such as Bose-Einstein Condensation (BEC). This is marked by a spontaneous, long range spatial order below a critical temperature. Physics of such phase transitions can be probed by measuring the 1st order, transverse, spatial correlation/coherence $|g^{(1)}(x,y)|$ with optical interferometry assuming that the BEC ground state of these excitons is 'bright'. We know that the Wiener-Khintchine Theorem in statistical physics relates any 2D mapping of $|g^{(1)}(x,y)|$ with the 2D momentum space (k-space) distribution of the emitted light. Consequently, we demonstrated [1] a modified Michelson Interferometer, which can first measure the 2D map of $|g^{(1)}(x,y)|$ of the excitonic light emission and then subsequently determine its 2D k-space.

Usually k-space measurements are often done by scanning the Back Focal Plane (BFP) image of a 'Bertrand lens' for excitonic samples which are kept inside a low temperature cryostat. One requires a high numerical aperture lens very close to these low temperature samples for BFP imaging. Alternatively, performing Young's double slit experiment with varying slit widths and adjustable slit separations kept within such low-temperature cryostat to measure $|g^{(1)}(x,y)|$ is also a challenging task in terms of instrumentations. These methods can, however, substantially introduce additional heat loads to the sample due to its proximity to various optical elements which are at room temperature. Moreover, the setup doesn't suffer from problems associated with the use of Cat-Eye retroreflector (CER), Dove prisms which were used in past studies of 2D mapping of $|g^{(1)}(x,y)|$. So we first collimate the light coming out from the sample and then measure its $|g^{(1)}(x,y)|$ over a selected area using our setup [1]. This method is certainly simpler and advantageous - specifically in cases where the sample under study is kept at a low temperature, so that k-space distributions of excitonic light emission can still be measured using optical instrumentations placed totally outside the low temperature cryostat at a distance away from the sample itself. This areal mapping of the $|g^{(1)}(x,y)|$ is obtained from the visibility factor from observed interference fringes using the required temporal filtering method [2]. Unlike earlier [2], this time our instrumentations for imaging 2D k-space, involved non-coplanar retroreflectors. So we had introduced additional mirrors to compensate for the displacements of the reflected beams. As a result, we can now monitor and control the fringe width by simply tilting only one such additional mirror(s). This actually enabled us to study even smaller emission patterns. There were reports [3] of k-space studies with spatial coherence measurements but only in 1D. Whereas, here we obtain the full 2D in-plane k-space distribution of light. Moreover, if we want to increase the resolution of the 2D k-space map, then the range over which the $|g^{(1)}(x,y)|$ is measured has to be increased.

Therefore, we have used this setup to measure the $|g^{(1)}(x,y)|$ and study the evolution of 2D k-space distribution before and after the onset of lasing. Most importantly, this experimental design is helpful in probing not only Bose-Einstein Condensate of excitons, but also it can be used to study BEC of

polaritons, photons etc. by observing the narrowing of k-space of light emission as an evidence for the presence of the off-diagonal long-range order.

Enhancing Near-infrared (NIR) Multi-Exciton Dynamics Through Quantum Shell Architecture

Dulanjan Harankahage; Bowling Green State University, United States

Semiconductor quantum dots (QDs) have faced significant limitations in their photonic applications due to ultrafast Auger decay of multiple excitons, leading to non-radiative processes that impede the performance of high-brightness light-emitting diodes and lasing devices. However, the introduction of colloidal quantum shell (QS) architecture, featuring a semiconductor quantum shell with an inverted QD geometry, has successfully suppressed Auger recombination. The QW morphology, characterized by a quantum confined HgS layer sandwiched between two large CdS domains, offers an extended biexciton lifetime and substantial biexciton quantum yields due to the increased exciton volume. Furthermore, the architecture-induced exciton-exciton repulsions have led to the separation of exciton and biexciton optical transitions, resulting in broad optical gain bandwidths. The remarkable longevity of single and biexciton states, along with extended single exciton gain lifetime, positions this geometry as a promising candidate for the development of optically and electrically pumped gain media.

Quantum Shell in a Shell: Engineering Colloidal Nanocrystals for a High-Intensity Excitation

Regime Jiamin Huang; Bowling Green State University, United States

The efficiency of many optoelectronic processes in colloidal semiconductor nanocrystals (NCs) tends to decline when subjected to high-intensity excitation. This decline is primarily attributed to Auger recombination, where multiple excitons result in the conversion of NC energy into excess heat. As a consequence, the efficiency and life span of NC-based devices such as photodetectors, X-ray scintillators, lasers, and high-brightness light-emitting diodes (LEDs) are negatively impacted. Although semiconductor quantum shells (QSs) have recently emerged as a promising approach to address Auger decay, their optoelectronic performance has been impeded by surface-related carrier losses. To deal with this issue, we propose the implementation of quantum shells with a CdS–CdSe–CdS–ZnS core–shell–shell–shell multilayer structure. The presence of a ZnS barrier effectively inhibits surface carrier decay, resulting in a significant increase in the photoluminescence (PL) quantum yield (QY) to 90%, while maintaining a high biexciton emission QY of 79%. Furthermore, the enhanced morphology of the quantum shells allows for one of the longest Auger lifetimes observed in colloidal NCs to date. The reduction of nonradiative losses in QSs also leads to diminished blinking in single nanoparticles and low-threshold amplified spontaneous emission. We expect that the ZnS-encapsulated quantum shells will be widespread across various applications in high-power optical or electrical excitation regimes.

Energy Transfer in Organic Exciton Polariton Condensate Regime

Rishabh Kaurav¹, Ravindra Kumar Yadav², Amar Flood³, Bo W. Laursen⁴ and Vinod Menon²; ¹The Graduate Center of the City University of New York, United States; ²Center for Discovery and Innovation, The City College of New

York, United States; ³Indiana University, United States; ⁴University of Copenhagen, Denmark

Here we report the study of energy transfer between organic molecules where the excitons in the donor molecules are strongly coupled to cavity photons and in the polariton condensate phase. We use a host-guest system where the dye is incorporated into a small-molecule ionic isolation lattices (SMILES). This system exhibits significantly enhanced photoluminescence (PL) in the solid state overcoming the limitation of aggregation induced quenching and has allowed us to realize polariton condensation [1]. Here we study energy transfer between donor, Rhodamine (R3B) and acceptor, Nile Blue (NB) embedded in host Cyanostar to form the SMILES complex. In the mixed R3B-SMILES with NB-SMILES system, we observe significant energy transfer between the donor and the acceptor surpassing what is seen in the bare mixed dye system thus indicating the advantage of the SMILES system in molecular energy transfer. Going further, we investigate the role of the donor being in a condensate phase where coherent emission is observed on the energy transfer process. We use a combination of steady state, time resolved, and momentum resolved spectroscopy to investigate the energy transfer process. The role of the host matrix and the coherence of the donor molecule on energy transfer will be discussed.

Luminescent Mechanisms of Crystalline and Amorphous Carbon Dots Yongqi Yang and Deirdre O'Carroll; Rutgers, The State University of New Jersey, United States

Luminescent carbon dots (CDs), as an emerging material class, have been actively investigated for applications in bioimaging, photocatalysis, and optoelectronic devices. However, standard synthesis procedures have not been established for carbon dots and the mechanism for the luminescence is still unclear, especially the effect of the crystallinity. In this work, we study and compare the optical properties of both crystalline and amorphous CDs in the bulk solution, as well as in thin films. We report on the microwave synthesis method to prepare both crystalline and amorphous CDs. Starting from citric acid and urea as precursors, and phosphoric acid as an additional reagent, we synthesize CDs with different crystallinity by controlling the amount of phosphoric acid during the microwave treatment. The crystallinity and structure of the nanoparticles are characterized by powder X-ray diffraction (XRD) techniques. No peaks are observed in the XRD patterns of CDs synthesized without phosphoric acid, while several peaks are observed in the CDs synthesized with the acid, which indicates the crystallinity in the structure. The size and morphology of the CDs are studied by transmission electron microscopy (TEM) and dynamic light scattering. The sizes of the two types of CDs (with and without phosphoric acid) are both around 20-30 nm, while fast-Fourier-transforms of the TEM images indicate crystallinity at the single particle level for the CDs synthesized with phosphoric acid. The structure and composition of the CDs are also analyzed by high-resolution TEM. The luminescence spectra of amorphous and crystalline CDs are similar in emission wavelength and intensity, while the quantum yield of amorphous CDs is higher than crystalline CDs, with values of 33 % and 24 %, respectively. We will also present single-particle photoluminescence spectroscopy studies of CDs with different crystallinity to assess their size and composition-dependent luminescence. This study sheds new light on the role of crystallinity in the luminescence properties of CDs and the performance of CDs for use as emissive nanomaterials.

Improved Device Performance of Quantum Dot Light Emitting Diodes by an Insertion of Thermal Activated Delayed Fluorescent Layer for Utilizing the Excess Exciton Jeong-Yeol Yoo, Yoon-Jeong

Choi, Chil Won Lee and Byung Doo Chin; Dankook University, Korea (the Republic of)

Quantum dots (QDs) are promising light emitters for the next-generation display, especially in the form of QD light-emitting diodes (QLED). Recently, PL-type QD display was successfully implemented in commercial products, including recent QD-OLED with superior properties. In spite of the great success of PL-type QD display, however, self-emissive electroluminescence (EL) type QD display is still under development.^{1,2}

Recent issues on EL-type QLED studies the imbalance between the holes and electrons causes over-injection of electrons compared to holes, electron leakage from the QD emission layer (EML), and accumulation of charges at the EML/hole transporting layer (HTL) interfaces. As a result, the efficiency and lifetime of the device were reduced. Therefore, controlling the charge balance is essential for realizing highly efficient QLED.³

Several studies have been focused on charge balance by improving the hole injection and suppressing the electron injection. Nevertheless, in most of the QLEDs reported so far, electron injection was always too efficient. In addition, the incorporation of phosphorescent sensitizer into QLED devices enhanced energy transfer and promoted to harvest the energy of the excitons to the QD EML, which were regarded as an effective method to enhance the efficiency of QLEDs. However, it is expected that Dexter energy transfer occurs by T_1 excitons, which has a too short transfer distance (<1 nm).^{4,5}

In this study, a blue thermally activated delayed fluorescence (TADF) material layer between EML and HTL was employed for utilizing the leaked electron and promote exciton harvesting. In the TADF layer, the leaked and accumulated electrons can form exciton with holes injected from HTL, energies by S_1 exciton were transferred from TADF layer into QDs and emission of QDs via Förster resonance energy transfer mechanism (FRET).⁵ The critical radius of FRET (R_{FRET}) can be calculated from the spectral overlap of TADF materials and QDs. As a result, maximized efficiency R_{FRET} is calculated to be about 4.25 nm. Compared with the control QLED device without TADF layer, the QLED with TADF layer showed about 2-fold increment for external quantum efficiency and current efficiency and 4-fold improvement for maximum luminance. Moreover, significant improvements in device lifetime. The EL properties indicate that the devices exhibit a symmetric EL peak emission. These results clearly reveal that TADF materials can be successfully applied to utilize excessive electrons, generally improving the overall performance of QLED. The proposed approaches are expected to provide a possible realization of highly efficient QLEDs where the analysis of detailed mechanism is studied.

Control of the Exciton and Spin/Valley Properties in Atomically Thin Transition Metal Dichalcogenides Marie Xavier; Institut National des Sciences Appliquées - LPCNO, France

Encapsulation of TMD monolayers in hexagonal boron nitride (hBN) yields narrow optical transitions approaching the homogeneous exciton linewidth^{1,2,3}. We have demonstrated that the exciton radiative rate in these van der Waals heterostructures can be tailored by a simple change of the hBN encapsulation layer thickness as a consequence of the Purcell effect⁴.

We also measured the exciton fine structure by magneto-photoluminescence spectroscopy in magnetic fields up to 30 T^{5,6}. I will show that the bright-dark exciton splitting can be tuned by a few meV, as a result of a significant Lamb shift of the optically active exciton which arises from emission and absorption of virtual photons triggered by the vacuum fluctuations of the electromagnetic field⁷.

Finally I will present recent experimental results on spin/valley pumping of resident electrons in WSe₂ and WS₂ monolayers⁸. Using a spatially-resolved optical pump-probe experiment, we measure the lateral transport of spin/valley polarized electrons over very long distances (tens of micrometers)⁹. These results highlight the key role played by the spin-valley locking effect in TMD monolayers on the pumping efficiency and the polarized electron transport.

Quantum Shells Versus Quantum Dots—Suppressing Auger Recombination in Colloidal Semiconductors Mikhail Zamkov; Bowling Green State University, United States

The quantum efficiency of many optoelectronic processes in colloidal semiconductor nanocrystals (NCs) declines with increasing optical or electrical excitation intensity. This issue is caused by Auger recombination of multiple excitons, which converts the NC energy into excess heat, whereby reducing the efficiency and lifespan of NC-based devices, including lasers, photodetectors, X-ray scintillators, and high-brightness LEDs. Recently, semiconductor quantum shells (QShs) have emerged as a viable nanoscale architecture for the suppression of Auger decay. The spherical-shell geometry of these nanostructures leads to a significant reduction of Auger decay rates, while exhibiting a near unity photoluminescence quantum yield. In this talk, I will compare the optoelectronic properties of quantum

shells against other low-dimensional semiconductors and discuss their emerging opportunities in solid-state lighting and energy-harvesting applications.

Flattening Conduction and Valence Bands for Interlayer Excitons in Twisted Van der Waals

Bilayers Andrey Chaves^{1,2}, Sara Conti², Tribhuwan Pandey², Lucian Covaci², Francois Peeters², David Neilson² and M. V. Milosevic²; ¹Universidade Federal do Ceara, Brazil; ²University of Antwerp, Belgium

Recent advances in fabrication and manipulation of two-dimensional (2D) materials have enabled the control over stacking and twisting between layers of transition metal dichalcogenides (TMDs) in van der Waals (vdW) heterostructures. In these systems, the moiré pattern created by the lattice mismatch between the layers plays an important role: it produces a periodic potential profile along the plane for electrons and holes, with potential minima in regions with specific stacking orders. Such moiré superlattice potential leads to a band structure for the bilayer that is tunable e.g. by inter-layer twisting. The recent observation of Mott insulator and superconducting phases in twisted bilayer graphene [1,2], due to the band flattening induced by interlayer twist, has brought even further excitement into this field, towards controlling transport and opto-electronic properties of TMDs vdW heterostructures by similar moiré pattern effects. [3]

In this work, we explore the flatness of conduction and valence bands of interlayer excitons in MoS₂/WSe₂ van der Waals heterobilayers, tuned by interlayer twist angle, pressure, and external electric field. We employ an efficient continuum model [4] where the moiré pattern from lattice mismatch and/or twisting is represented by an equivalent mesoscopic periodic potential. We demonstrate that the mismatch moiré potential is too weak to produce significant flattening. Moreover, we draw attention to the fact that the quasi-particle effective masses around the Γ -point and the band flattening are *reduced* with twisting. As an alternative approach, we show (i) that reducing the interlayer distance by uniform vertical pressure can significantly increase the effective mass of the moiré hole, and (ii) that the moiré depth and its band flattening effects are strongly enhanced by accessible electric gating fields perpendicular to the heterobilayer, with resulting electron and hole effective masses increased by more than an order of magnitude leading to record-flat bands. These findings impose boundaries on the commonly generalized benefits of moiré twistrionics, while also revealing alternate feasible routes to achieve truly flat electron and hole bands to carry us to strongly correlated excitonic phenomena on demand.

Strong and Tunable Light-Matter Interactions in Excitonic Semiconductors Deep M. Jariwala;

University of Pennsylvania, United States

The isolation of stable atomically thin two-dimensional (2D) materials on arbitrary substrates has led to a revolution in solid state physics and semiconductor device research over the past decade. A variety of other 2D materials (including semiconductors) with varying properties have been isolated raising the prospects for devices assembled by van der Waals forces.¹ Particularly, these van der Waals bonded semiconductors exhibit strong excitonic resonances² and large optical dielectric constants as compared to bulk 3D semiconductors. .

First, I will focus on the subject of strong light-matter coupling in excitonic 2D semiconductors, namely chalcogenides of Mo and W. Visible spectrum band-gaps with strong excitonic absorption makes transition metal dichalcogenides (TMDCs) of molybdenum and tungsten as attractive candidates for investigating strong light-matter interaction formation of hybrid states.³⁻⁵ We will present our recent work on the fundamental physics of light trapping in multi-layer TMDCs when coupled to plasmonic substrates.⁶

Next, we will show the extension of these results to halide perovskites^{7,8} and superlattices of excitonic chalcogenides.⁹ These hybrid multilayers offer a unique opportunity to tailor the light-dispersion in the strong-coupling regime.⁹ We will discuss the physics of strong light-matter coupling and applications of these structures. If time permits, I will also present our recent work on van der Waals semimetals,¹⁰ control of light in magnetic semiconductors¹¹ and extending some of these concepts to 1D carbon-nanotubes.¹²

Our results highlight the vast opportunities available to tailor light-matter interactions¹¹ and building practical devices with 2D semiconductors. I will conclude with a broad vision and prospects for 2D materials in the future of semiconductor opto-electronics and photonics.

Trion Photoluminescence and Trion Stability in Atomically Thin Semiconductors Raul Perea-Causin¹, Samuel Brem², Ole Schmidt² and Ermin Malic²; ¹Chalmers University of Technology, Sweden; ²Philipps University of Marburg, Germany

The optical response of doped monolayer semiconductors is governed by trions [1], i.e. three-particle complexes consisting of a photoexcited electron-hole pair bound to a doping charge. While photoluminescence (PL) signatures of trions have been identified in experiments [2], the microscopic description of trion recombination and trion stability is still incomplete.

In this work, we derive a generalized trion PL formula on a fully quantum-mechanical footing, considering both direct and phonon-assisted recombination mechanisms [3]. Considering WSe₂ as exemplary material, we access the trion energy landscape by solving the trion Schrödinger equation with a variational approach [4] and reveal the important impact of the mass imbalance between equal charges on the trion stability. Finally, we compute the temperature-dependent PL spectra for n- and p-doped monolayers and find a good agreement with experimental data. Moreover, we predict additional signatures originating from trions with an electron located at the Λ point, which, interestingly, exhibit a higher three-body energy than their K-point counterpart but a lower recombination resonance. Although these signatures have not been clearly observed in experiments yet, we expect that Λ -point trions play a relevant role in the dynamics and can be experimentally accessed via strain engineering [5] or in time-resolved PL spectra [6]. Our work presents an important step towards a microscopic understanding of the quantum nature of trions, which determines their stability and optical fingerprint.

Modulating Optical Properties of Monolayer WS₂ by Dielectric and Substrate Engineering

Tamaghna Chowdhury, Gokul M. A and Atikur Rahman; IISER Pune, India

The optical properties of monolayers of transition metal dichalcogenides (TMDs) are profoundly influenced by the surrounding dielectric environment. Defect states within the substrate introduce uncontrolled doping in the TMD monolayer, thereby altering the photoluminescence (PL) spectra. In this study, we systematically investigated the influence of surface defects by gradually increasing the separation between the WS₂ monolayer and the substrate. This allowed for precise modulation of the exciton and trion contributions in the PL spectra of WS₂. By performing excitation power-dependent measurements on dielectric-engineered and patterned substrates, we gained insight into the mechanism behind the PL modulation in monolayer WS₂. Furthermore, we examined the impact of the charged nature of substrate defects on the PL spectra. These findings present a novel pathway for modulating and obtaining desired PL spectra of TMDs through substrate engineering.

11:45 AM QT01.07.09

Tunable Localized Charge Transfer Exciton in a Mixed Dimensional Van der Waals

Heterostructure Mahfujur Rahaman¹, Emanuele Marino¹, Alan G Joly², Seunguk Song¹, Zhiqiao Jiang¹, Brian T. O'Callahan², Daniel J. Rosen¹, Kiyoun Jo¹, Gwangwoo Kim¹, Patrick Z. El-Khoury², Christopher B. Murray¹ and Deep M. Jariwala¹; ¹University of Pennsylvania, United States; ²Pacific Northwest National Laboratory, United States

The observation of interlayer excitons (ILX) in van der Waals heterostructures (vdWHs) based on 2D-2D systems makes them a very promising candidate for next generation photonic and valleytronic devices. However, the true potential of ILXs depends on spatially confining and isolating them below their de Broglie wavelength^{1,2}. One approach that has garnered significant attention in this regard, is the formation

of moiré superlattices in twisted van der Waals 2D homo/hetero stacks³. Though the material modulation through moiré superlattices faces challenges, including limited control over the energy and position of the trapping potential due to the delicate alignment required between 2D sheets, crystal imperfections over large areas, and repulsive interactions among the trapped ILXs^{4,5}. In this contribution⁶, we demonstrate the formation of highly localized ILX analogous charge transfer (CT) excitons in a 2D/quasi-2D system comprising MoSe₂ monolayers and CdSe/CdS based core/shell nanoplates (NPLs). We employ room temperature nano-PL to resolve the spectral signature of CT excitons in our MDHs, which are spatially confined within the dimension of single NPL ($\sim 10 \times 10 \text{ nm}^2$). Moreover, we are able to tune the energy of the CT excitons up to 120 meV via tuning the NPL thickness and achieve an electrostatic gating tunability of 0.8 eV/(V/nm), which surpasses the ILX tunability in 2D-2D systems^{7,8}. Our finding is a significant step towards the realization of highly tunable MDH-based next generation photonic devices.

SESSION QT01.08: Excitonic Phenomena II

Session Chair: Stefan Zollner

Wednesday Afternoon, November 29, 2023

Sheraton, Fifth Floor, Public Garden

1:30 PM *QT01.08.01

Excitonic Absorption in Semiconductors with Low and High Carrier Densities Stefan Zollner¹, Carola Emminger^{2,3} and Jose Menendez⁴; ¹New Mexico State University, United States; ²Universität Leipzig, Germany; ³Humboldt-Universität zu Berlin, Germany; ⁴Arizona State University, United States

Spectroscopic ellipsometry is an optical reflection technique with polarized light. Most commonly, it is used to measure the thicknesses of thin-film layers, such as SiO₂ on Si. But it can also be used to study the energies and broadenings of elementary excitations in solids, such as free carriers (electrons and holes, band gaps, transport), excitons, infrared active phonons, and their interactions. We previously reported precision measurements of the complex refractive index of germanium due to the absorption of photons by excitons near the direct band gap. These results were compared quantitatively with theoretical

predictions from Fermi's Golden Rule, based on k.p theory and including the excitonic interaction between electrons and holes (Sommerfeld enhancement). Going further, we can investigate how many-body effects impact the excitonic absorption of photons in highly excited semiconductors. Large carrier concentrations can be achieved through doping, thermal excitation of electron-hole pairs in small band-gap semiconductors, or optical excitation with ultrafast lasers. In this talk, we will report recent ellipsometry results for the temperature-dependent dielectric function of InSb near the direct band gap and the transient dielectric function of Ge near the E_1 and $E_1 + \Delta_1$ transitions from femtosecond pump-probe ellipsometry. We will also point out the theoretical approach needed to explain these data sets, especially the Fermi-Dirac distribution functions of carriers (Burstein-Moss shift) and the screening of the excitonic effects at high carrier densities.

2:00 PM *QT01.08.02

Exciton Transport in a Van der Waals Antiferromagnet Florian Dirnberger¹, Sophia Terres¹, Mikhail Glazov² and Alexey Chernikov¹; ¹TU Dresden, Germany; ²Ioffe Institute, Russian Federation

Optical spectroscopy of van der Waals magnets recently unveiled *magnetic excitons* – a rare type of optical excitation emerging from spin-polarized electronic states in magnets. With properties that have no analogue amongst excitons in conventional band semiconductors, these optical quasiparticles not only inherit tremendous potential for optoelectronic devices with new functionalities, they provide insight into elementary interactions between electron-hole pairs, magnons, and light. A strongly bound example of such *magnetic excitons* was recently discovered in the prototypical layered antiferromagnetic semiconductor CrSBr. In this contribution, we will present its fundamental optical properties and discuss our latest experimental results on the spatio-temporal transport of excitons in the presence of large structural anisotropy and magnon coupling.

Impact of Excitons on the Non-Linear Optical Properties of 2D Materials Su Ying Quek; National University of Singapore, Singapore

Non-linear optical phenomena are at the core of many important technologies and spectroscopic techniques. The second-order optical susceptibility is responsible for spontaneous parametric down conversion (SPDC) which generates entangled photon pairs, shift currents which give rise to bulk photovoltaic effects, and second harmonic generation that is useful for spectroscopy. In recent years, there has been increasing interest in studying non-linear optical phenomena in the 2D limit, where phase-matching conditions are eliminated while allowing for more facile integration with hybrid quantum photonic platforms. Reduced electronic screening in 2D leads to enhanced excitonic effects, and it is therefore critical to elucidate the impact of excitons on non-linear optical properties. We develop a theory for the second-order optical susceptibility that takes into account excitonic effects with a first principles GW-Bethe-Salpeter-Equation (GW-BSE) approach. We apply the theory to niobium oxydihalides (NbOX_2 , $X = \text{Cl, Br, I}$) [1], a material of significant current interest in non-linear optics [2]. We predict that excitonic effects greatly enhance the probability for SPDC [3] and increase the magnitude of the shift currents in this material. We further benchmark our approach by comparison with experiment for the shift current in bulk BaTiO_3 and the SHG spectra for layered NbOI_2 , where we clearly demonstrate the important role of excitons in non-linear optics. Our work provides a fundamental understanding of non-linear optical phenomena in excitonic materials and paves the way for 2D non-linear quantum photonics.

Exciton-Plasmon Interactions in Binary Superlattices of Infrared Colloidal Nanocrystals Sarah Brittan, Patrick Yee, Veronica Policht, Paul Cunningham and Janice Boercker; U.S. Naval Research Laboratory, United States

Semiconductor colloidal nanocrystals have immense potential to contribute to efficient and inexpensive infrared optoelectronics. State-of-the-art devices made from colloidal nanocrystals contain films of randomly arranged nanocrystals that do not exhibit long-range order. Controlling the ordering of these nanocrystals into superlattices has the potential to generate engineered metamaterials that exhibit properties not achievable in natural semiconductors or in films of disordered nanocrystals. The current size of individual ordered domains in these materials (analogous to grain size in polycrystalline materials), however, is typically microscopic, so the field lacks detailed structure-property relationships. Expanding on our previous work [1, 2], we have engineered the surface chemistry of our nanocrystals to create enlarged (>1 micron) domains of binary nanocrystal ordered solids of infrared plasmonic Cu₂-xS/PbS core/shell and excitonic PbS nanocrystals. We then directly correlate photoluminescence microscopy performed in an air-free environment on single ordered domains with transmission electron microscopy of the binary PbS and Cu₂-xS nanocrystal solids. Initial results from our correlative microscopy indicate that energy transfer does occur between the excitonic emitters and plasmonic nanocrystals and suggest that fine-tuning the geometry and energetics of the binary system will optimize this composite material's properties. We envision that combining single-domain measurements and optical modeling will generate well-defined structure-property relationships that will further our understanding of multicomponent ordered nanocrystal solids and allow us to design solids with desired properties.

4:00 PM QT01.08.05

Linear and Non-linear Optical Properties of Semiconductor Quantum Dots Chandler Martin¹, Anaira Jalan² and Arindam Chakraborty¹; ¹Syracuse University, United States; ²Westminster School, United Kingdom

This computational work presents a systematic investigation of linear and non-linear optical response

properties of CdSe, CdS, PbSe, and PbS quantum dots in the size range of 1-10 nm. First-principles quantum mechanical calculations were performed using the frequency-dependent geminal screened electron-hole interaction kernel (FD-GSIK) method, and the polarizability and hyper-polarizability were evaluated from the time-dependent correlated electron-hole reduced density matrix. The FD-GSIK is a real-space method that uses an explicitly-correlated operator to include many-body quasiparticle correlation effect. The results from the real-time propagation approach will be compared with the sum-over-states approach, and analysis of the key differences will be presented. The scaling law for the polarizability and hyper-polarizability as a function of dot size will be presented, and the impact of material type and surface defects will be discussed.

4:15 PM QT01.08.06

Exciton Transport and Dissociation in Molecular Photocells Chumin Wang, Fernando Sanchez and Vicenta Sanchez Morales; Universidad Nacional Autonoma de Mexico, Mexico

Sunlight is the most plentiful source of clean energy providing to the earth in one hour enough energy for current human needs of one year [1]. In addition, photovoltaic devices based on organic semiconductors possess many remarkable advantages in comparison with the inorganic technology, such as flexibility, transparency, low weight and inexpensive manufacture. Hence, understanding the kinetics of light-generated excitons around the organic donor-acceptor heterojunction may significantly improve the performance of solar cells. In this work, we present a quantum model of molecular photocells based on a coarse-grained attractive Hubbard Hamiltonian, where the transport and dissociation of excitons are analyzed on an excitonic state lattice containing impurity sites originated from the attractive electron-hole interaction [2]. The presence of these impurity sites prevents the use of reciprocal space and then, the numerical calculation was carried out by means of an independent channel plus real-space renormalization method, where the competition between the driving force from heterojunction and the Coulomb attraction leading to an electron-hole recombination has been explicitly addressed [3]. The results reveal an optimal distance between molecular photocells to achieve the maximum quantum efficiency, in accordance with various experimental reports about the optimal concentration of donor molecules [4]. Moreover, the calculated quantum efficiency has a good agreement with those obtained from diverse organic photovoltaic devices, such as bilayer, perovskite and inverted solar cells [5].

This work has been partially supported by projects UNAM-IN112522, UNAM-IN110823 and CF-2023-I-830. Computations were performed at Miztli of DGTIC-UNAM.

8:30 AM *QT01.09.02

Bose Polaron Interactions in a Cavity-Coupled Monolayer Semiconductor Martin Kroner; ETH Zurich, Switzerland

The interaction between a mobile quantum impurity and a bosonic bath leads to the formation of quasiparticles, termed Bose polarons. The elementary properties of Bose polarons, such as their mutual interactions, can differ drastically from those of the bare impurities. Here, we explore Bose polaron physics in a two-dimensional nonequilibrium setting by injecting left hand circular polarised exciton-polariton impurities into a bath of coherent right hand circular polarised polaritons generated by resonant laser excitation of monolayer MoSe₂ embedded in an optical cavity. By exploiting a biexciton Feshbach resonance between the impurity and the bath polaritons, we tune the interacting system to the strong-coupling regime and demonstrate the coexistence of two new quasiparticle branches. Using time-resolved pump-probe measurements we observe how polaron dressing modifies the interaction between impurity polaritons. Remarkably, we find that the interactions between high-energy polaron quasiparticles, that are repulsive for small bath occupancy, can become attractive in the strong impurity-bath coupling regime.

9:00 AM *QT01.09.03

Proximity Effects and Excitons in Van der Waals Heterostructures Jaroslav Fabian; University of Regensburg, Germany

Excitonic spectra of 2D semiconductors are known to be very sensitive to the dielectric surroundings. But they can also be tailored by weak van der Waals hybridizations across the layers---the so called proximity effects. Placing a transition metal dichalcogenide, such as WSe₂, in contact with a ferromagnetic CrI₃, results in exchange induced valley-resolved single-particle spectral shifts which can be probed by excitonic absorption. I will present our theoretical efforts in ab initio modeling of the proximity effects and the Bethe-Salpeter equation simulation of the excitonic spectra affected by the proximity. I will also argue that in addition to pure dielectric screening effects, there are also hybridization signatures in the g-factor of excitons in transition metal dichalcogenides in contact with graphene. Finally, I will present an analysis of the excitonic g-factors in strained TMDCs in which a hybridization between inter and intraband transitions can be tuned by strain. Support from DFG SFB 1277, SPP2244, and FLAG-ERA is acknowledged.

Anisotropic Excitons and Polaritons Hui Deng; University of Michigan, United States

Anisotropy is a fundamental property of materials widely exploited in science and engineering. However, the interplay between the material and engineered photonic anisotropies has been difficult to access. Van der Waals materials open the opportunity to explore a wide range of anisotropic materials and to integrate them with photonic structures. We show here a matter-light hybrid system, exciton-polaritons in a 2D antiferromagnet, CrSBr, coupled with an anisotropic photonic crystal cavity, where the spin, atomic lattice, and photonic lattices anisotropies intertwine and give rise to unusual properties of the hybrid system. We measure strong coupling between engineered anisotropic optical modes and anisotropic excitons in CrSBr, which is stable against excitation densities a few orders of magnitude higher than polaritons in isotropic materials. Moreover, the polaritons feature a highly anisotropic polarization tunable by tens of degrees by controlling the matter-light coupling via, for instance, spatial alignment between the material and photonic lattices, magnetic field, temperature, cavity detuning and cavity quality-factors.

Efficient Light Collection from Single-Photon Emitters in 2D Materials Rudolf Bratschitsch; University of Muenster, Germany

Single-photon sources are crucial components for quantum networks and communications. Recently, single-photon sources in 2D materials have emerged as robust solid-state light emitters. For collecting and making use of single photons emitted from 2D materials, different strategies can be envisioned, whether the photons are needed on-chip or in free space.

We present waveguide-coupled single-photon emitters in the layered semiconductor GaSe as promising on-chip sources [1]. GaSe crystals are placed on Si₃N₄ waveguides, resulting in a modified mode structure efficient for light coupling. Using optical excitation from within the waveguide, we find nonclassicality of the generated photons routed on a photonic chip. Thus, our work provides an easy-to-implement and robust platform for integrated photonic quantum technology.

For far-field collection, we present polymer microlenses, which are 3D-printed directly on single-photon emitters in commercially available hBN nanocrystals. First, a regular array of hBN nanocrystals is created using capillary assembly [2]. Subsequently, we 3D-print elliptical polymer microlenses onto the nanocrystals. The light emission is efficiently collimated to angles below 5° [3]. The small angle of emission of the new single-photon source allows for using collection lenses with very low numerical apertures > 0.06, including optical fibers.

In summary, we have demonstrated two methods to efficiently harvest single photons from 2D materials, rendering these single-photon sources highly promising for quantum optics and photonic quantum technologies.

Excitonic Tuning Through Dynamic Modulation of Moiré Potential Kausik Majumdar¹, Medha Dandu², Pushkar Dasika¹, Garima Gupta¹, Mayank Chhaperwal¹, Rabindra Biswas¹, Kenji Watanabe³, Takashi Taniguchi³, Varun Raghunathan¹ and Suman Chatterjee¹; ¹Indian Institute of Science, India; ²Lawrence Berkeley National Laboratory, United States; ³National Institute for Materials Science, Japan

Moiré superlattice created by stacking two monolayers of transition metal dichalcogenides at different twist angles is an excellent testbed for exciton physics. In this work, we explore dynamic tuning of the moiré excitons through external stimulus in different moiré configurations, including homo-bilayer, hetero-bilayer, and hetero-bilayer on a nanopillar-induced strain well. We specifically show a large tunability of the confinement potential, spectral position, lifetime, and polarization characteristics of the exciton in these different types of moiré-superlattices under the influence of a gate voltage and excitation power. The experimental results corroborate well with a tunable two-dimensional quasi-harmonic oscillator model for the moiré-trapped exciton. Such strong tunability of moiré exciton has intriguing implications towards moiré-inspired device applications.

Quantum Melting Phase Diagram of a Two-Dimensional Electron Wigner Crystal Jiho Sung¹, Jue Wang¹, Ilya Esterlis¹, Pavel A. Volkov¹, Giovanni Scuri¹, You Zhou², Elise Brutschea¹, Takashi Taniguchi³, Kenji Watanabe³, Yubo Yang⁴, Miguel Morales⁴, Shiwei Zhang⁴, Andrew Millis⁴, Mikhail D. Lukin¹, Philip Kim¹, Eugene Demler⁵ and Hongkun Park^{1,1}; ¹Harvard University, United States; ²University of Maryland, United States; ³National Institute for Materials Science, Japan; ⁴Flatiron Institute, United States; ⁵ETH Zürich, Switzerland

Strongly interacting electrons can form novel quantum states of matter, exhibiting rich phase diagrams and exotic physical phenomena. The two-dimensional (2D) electron gas provides a paradigmatic example, where competition between Coulomb repulsion and kinetic energy leads to quantum melting of an electron Wigner crystal on increasing electron density. Despite nearly a century of intensive research, however, the detailed nature of this transition is not fully understood. Here, using cryogenic reflectance and magneto-optic spectroscopy, we provide clear experimental evidence for long-standing theoretical predictions that the density-driven quantum melting of a Wigner crystal proceeds through an electronic mixture phase characterized by a microscopic coexistence of crystal and liquid states. At densities below $\sim 3 \times 10^{11} \text{ cm}^{-2}$, electrons in a MoSe₂ monolayer form a two-dimensional Wigner crystal. As the electron density increases, we observe abrupt changes in the spin susceptibility, excitonic reflection spectrum, and charge-order-induced exciton scattering. These anomalies mark clear phase boundaries separating a Wigner crystal, intermediate quantum melting phase(s), and a Fermi liquid state. The experimentally determined phase diagram reveals the prominent Pomeranchuk effect arising from the enhanced stability of the crystalline phase upon heating due to its large spin entropy. Our study reveals the interplay between distinct electronic states and establishes the multi-staged nature of the quantum melting in a 2D correlated electron system. Atomically thin semiconductors thus provide a unique experimental platform to study the universal properties of quantum phase transitions in correlated electron systems in two dimensions.

SESSION QT01.10: Time Resolved Studies of Excitons

2:00 PM *QT01.10.02

Ultrafast Nonlinear Spectroscopy of 2D Excitons: Local Field Effects and a New Destructive Photon Echo Daniel Wigger; Trinity College Dublin, Ireland

Over the last several years, two-dimensional semiconductors, especially in the form of transition metal dichalcogenides, have gained considerable attention in several areas of physics. One of the reasons for this is their strong excitonic optical response, which makes them attractive for future optoelectronic or quantum applications. Their remarkable brightness allows to efficiently study them with ultrafast nonlinear spectroscopy to learn about their fundamental excitonic properties and the excitons' coupling to other quasi-particles. We have recently studied how the spectral dynamics of pump-probe [1] and four-wave mixing signals [2,3] can be interpreted by an exactly solvable model that extends the basic optical Bloch equations by a local field effect [4]. This local field coupling takes into account the exciton-exciton interaction between the optically generated excitons in the 2D systems on a mean field level and leads to spectral shifts depending on the excitonic occupations.

We then went a step further and studied six-wave mixing (SWM) signal dynamics and discovered a peculiar temporary signal depression, depending on the considered delay between the two applied laser pulses [5]. In this contribution, we will report on this experimental finding and demonstrate that the observed signal dynamics can be understood as a new destructive photon echo. With our local field model we are able to attribute this effect to the interaction between the excitons. We show that the two main contributions to the SWM signal interfere destructively for certain times. Already in his first report of the spin echo effect in 1950, E. Hahn has used the Bloch vector description to illustrate his newly discovered phenomenon [6]. Inspired by this, we developed a similar Bloch vector description for the destructive photon echo. Interestingly, we found that the Bloch vectors contributing to the SWM signal form Lissajous figures that get distorted with progressing time [5]. The new destructive photon echo effect allows to efficiently and systematically study the exciton-exciton interaction across 2D semiconductor samples with a spatial resolution which is only restricted by the diffraction limit of the applied laser pulses. Thereby we will be able to learn more about the potential interplay between exciton-exciton interaction and for example local strain distributions.

Nanoplatelet-Like Ultrafast Dephasing Behavior of CdS/CdSe/CdS Spherical Quantum Wells

Tomas A. Ferreira¹, Albert Liu², Guk Jeong Byeong³, Wan Ki Bae⁴, Steven Cundiff⁵, Diogo B. Almeida⁶ and Lazaro Padilha¹; ¹Unicamp, Brazil; ²Max Planck Institute for the Structure and Dynamics of Matter, Germany; ³Pusan National University, Korea (the Republic of); ⁴Sungkyunkwan University Advanced Institute of NanoTechnology, Korea (the Republic of); ⁵University of Michigan, United States; ⁶Universidade Federal do ABC, Brazil

Carrier dynamics in colloidal nanostructures has been the subject of scrutiny for several decades, given the possibility of tuning these materials' optical and electronic properties by the proper choice of size, shape, and composition. The ever-growing possibilities regarding architecture and composition still translate into a great demand for a comprehensive understanding of the dynamics of the many-body phenomena involved in nanomaterial systems, especially coherent exciton dynamics, with potential applications to emerging quantum systems.

In this work we perform optical multidimensional coherent spectroscopy (MDCS) on different samples of CdS/CdSe/CdS colloidal spherical quantum wells (SQWs), probing their exciton dephasing times and population dynamics, at a series of cryogenic temperatures.

Colloidal nanostructures, in general, have inherently large inhomogeneous spectral broadening due to the size distribution of the probed ensemble, hindering the characterization of the system's homogeneous responses. In addition to the temporal resolution, common on nonlinear optical spectroscopies, MDCS allow the probing of homogeneous responses even in the presence of large size inhomogeneity. Additionally, by spectrally resolving the signal, one can measure coupling strengths between quantum states.

Spherical quantum wells are nanoparticles consisting of a nucleus, enveloped by a layer of different composition that, in turn, is covered by another layer of distinct composition. The middle layer (well) material (CdSe) has an optical gap smaller than the nucleus and the outer shell (CdS) subjecting the excitons to confinement in the middle layer, effectively creating a quantum well with spherical symmetry. The SQW architecture results in higher quantum-yields and absorption cross-sections when compared to their CdSe/CdS quantum dots counterparts. Additionally, our results indicate that the strong quantum

confinement of the hole wave-function in the CdSe well indeed renders to excitons in such structures dephasing times comparable to those of CdSe nanoplates (NPLs).

Our results show that excitons confined in SQWs can become spatially separated along the spherical surface of the well analogous to the spatial separation of excitons across the lateral dimensions of CdSe NPLs, reducing the Auger recombination rates. The SQWs examined in this work differ in the width of the outer CdS shell, which translates in different strengths of the electron wave-function confinement, giving extra insight to the role of electron confinement on the exciton dephasing times.

We measured sub-ps dephasing times, at 6K, for our samples. These values are, at least, one order of magnitude shorter than those for spherical CdSe/CdS core/shell quantum dots. Additionally, we observe a decrease in dephasing time with increasing the electronic wavefunction delocalization by increasing the outer shell thickness, the opposite of what is reported on core/shell systems. Finally, our temperature series measurements corroborate with acoustic phonon population increase and coupling behaviors similar to core/shell quantum dots, indicating a similar (additional) dephasing route.

3:45 PM QT01.10.04

Emission Dynamics of Hexagonal-Boron Nitride (hBN) Single Photon Emitters (SPEs) Pumped by High Power Density Laser Excitation Kristina L. Malinowski, Hamidreza Akbari and Harry A. Atwater; California Institute of Technology, United States

Color centers in thin hBN crystals are promising candidate single photon emitters (SPEs), as they exhibit bright single photon emission at room temperature. We find that at high pump power densities (~ 70 kW/cm² at 532 nm wavelength), single photon emitting defects in hBN exhibit unstable emission around 600 nm wavelength under pulsed or continuous wave lasers. We observe both blinking (switching between a state of radiative emission and no radiative emission on long time scales), and long-term irreversible degradation of the SPE character of individual defects. To characterize the SPE at a given power, we scanned over the area containing the color center (~ 9 μm^2) with a confocal luminescence microscope to measure the emission of the color center at each wavelength. This measurement produces both a visible emission spectrum for each scan point, as well as the emission integrated over wavelength for each point, which can be arranged in a photoluminescence (PL) map indicating how total emission changes spatially. We found, the full width half maximum (FWHM) at the zero-phonon line (ZPL) increases from 27 nm to over 88 nm when the power is increased from 25 kW/cm² to 165 kW/cm² at 532 nm. This broadening coincides with a transition from photon anti-bunching to bunching, quantified with second-order correlation (g^2) measurements. The PL maps also show that under increased pump powers the radius of strong emission increases over 3-fold from 0.4 μm to 1.25 μm . This implies that at high pump powers, the color centers evolve from localized SPEs to classically emissive defects, capable of transporting the excited charge on the order of microns prior to radiative emission. Further, increasing the power causes a blue shift in the emission wavelength of the photons, indicating modification of the radiative emission pathway. We also observe a self-recovery of radiative emission over extended (336 hour) times. Fast, self-recovery of emitters, suggests there may be a relation between the blinking and apparent irreversible degradation, with blinking occurring over minutes or hours and degradation occurring over days or weeks. The observed self-recovery phenomenon points to the dynamics of photoexcited trapped charges in emission. This hypothesis will be further addressed by Kelvin probe force microscopy to reveal the spatial profile and role of trapped charges on hBN single photon emitter electrostatic charging and discharging.

4:00 PM QT01.10.05

Exciton Dynamics and Anisotropy in 2D Silver Phenylchalcogenolates Woo Seok Lee, Yeongsu Cho, Peter Müller, Ruomeng Wan, Eric Powers, Watcharaphol Paritmongkol, Tomoaki Sakurada, Nicholas Samulewicz, Heather J. Kulik and William Tisdale; Massachusetts Institute of Technology, United States

Silver phenylselenolate (AgSePh) and silver phenyltelluroate (AgTePh) are novel two-dimensional (2D) van der Waals semiconductors. However, despite having a similar crystal structure and composition, AgSePh and AgTePh exhibit strikingly different excitonic properties. While the three distinct excitonic absorption resonances of AgSePh are close in energy, AgTePh exhibits a large energetic separation between the two lowest excitonic absorption resonances. More strikingly, whereas AgSePh exhibits narrow, fast luminescence with a minimal Stokes shift, AgTePh exhibits comparatively slow, significantly red-shifted and broadened luminescence. In this presentation, we will present the synthesis, structural and optical properties of single crystals and thin films of AgSePh and AgTePh. Using time-resolved and temperature-dependent optical spectroscopy, combined with sub-gap photoexcitation studies, we will show that exciton dynamics in AgTePh films are dominated by intrinsic exciton self-trapping behavior, whereas dynamics in AgSePh films are dominated by the interaction of free-excitons with extrinsic defect states. Furthermore, using polarization-dependent optical spectroscopic studies on single crystals of AgSePh and AgTePh, we will show the strikingly different exciton anisotropy in these materials. Whereas the lowest and the second lowest free-excitons in AgSePh are polarized along [010] and [100] direction, respectively, the two lowest free-excitons and self-trapped excitons in AgTePh are all polarized along [010] direction. Finally, we will discuss GW plus Bethe-Salpeter equation calculations to understand anisotropic excitons in these materials. Overall, this work highlights the properties of a novel class of 2D excitonic semiconductors and lays the foundation for understanding exciton dynamics and anisotropy in these materials.

Engineering Qubits in Silicon with Atomic Precision Michelle Y. Simmons; University of New South Wales, Australia

The realisation of a large-scale error corrected quantum computer relies on our ability to reproducibly manufacture qubits that are fast, highly coherent, controllable and stable. The promise of achieving this in a highly manufacturable platform such as silicon requires a deep understanding of the materials issues that impact device operation. In this talk I will demonstrate our progress to engineer every aspect of device behaviour in atomic qubits in silicon. This will cover the use of atomic precision lithography to achieve fast, controllable exchange coupling [1], fast, high fidelity qubit initialisation and read-out [2]; low noise all epitaxial gates allowing for highly stable qubits [3]; and qubit control [4] that provide a deep understanding of the impact of the solid-state environment [5] on qubit designs and operation. I will also discuss our latest results in [6] analogue quantum simulation.

Bose-Einstein Condensation of Excitons in a Bulk Semiconductor at Sub-Kelvin Temperatures

Kosuke Yoshioka, Yusuke Morita and Makoto Kuwata-Gonokami; University of Tokyo, Japan

It has long been a major problem in solid state physics and quantum statistical physics to experimentally clarify whether excitons, which are bound pairs of electrons and holes in bulk semiconductors, can spontaneously form Bose-Einstein condensates or not. The 1s para exciton of cuprous oxide has been studied for many years from both theoretical and experimental aspects as the most promising candidate for the realization of BEC, because it has an extremely long lifetime and behaves as a pure matter-like quasiparticle with finite mass. In this talk, we will present a study that demonstrates for the first time by real-space imaging that 1s para excitons form condensates in the temperature range of a few hundred mK [1].

BEC in this system was expected to be possible at superfluid helium temperatures by the production of high-density excitons by relatively intense laser irradiation. However, experimental evidence of BEC has not been observed. It has turned out that exciton loss processes resulting from two-body collisions between excitons occur with orders of magnitude higher efficiency than expected [2]. In such a case, the excitons cannot have a long enough lifetime for cooling, which was the reason why BECs did not appear. Therefore, during the last decade or so, the transition temperature setting has been lowered to sub-Kelvin temperatures, and the search for BEC at lower BEC transition densities has been conducted [3].

In recent years, we have realized an experimental setup in which a semiconductor crystal is cooled using a cryogen-free dilution refrigerator and laser beams in the visible and mid-infrared wavelength regions are introduced. Through exciton accumulation in an inhomogeneous strain-induced harmonic trap potential and activation of cooling channels effective for slow excitons through exciton-phonon interactions in the strain field, we have achieved exciton ensembles at approximately 100 mK [4], which is the lowest temperature in exciton systems. By evaluating the induced absorption associated with the 1s-2p transition located in the mid-infrared wavelength range, we can quantitatively evaluate the density of the exciton system [5], which is a key quantity for BEC. We have extended this measurement method to absorption imaging [6] and have utilized it in low temperature experiments in a dilution refrigerator. This was essentially important for the observation of the real image of the condensate.

The exciton condensate is a brand-new quantum many-body physical system. When the BEC criteria are satisfied, a localized density distribution appears at the bottom of the trap potential. As the exciton

number is increased, the spatial broadening of the condensate increases, and this behavior can be interpreted in the same way as BEC of real particles, from which the elastic scattering length of the repulsive interaction between excitons can be derived. While those phenomena are within the framework of conventional BEC theory, the observed small fraction of condensates cannot be understood by conventional theory. This may be characteristic of quantum statistical phenomena in non-equilibrium and open systems of quasiparticles.

Enhancing the Light Emission of 2D-TMDs and MXene Quantum Dots Jeongyong Kim;
Sungkyunkwan University, Korea (the Republic of)

Quantum-confined semiconductors with light-emitting properties offer tremendous opportunities in photonic devices with the advantages of high efficiency, tunability and flexibility. Photoluminescence quantum yield (PL QY) is one of fundamental performance parameters of these quantum optical semiconductors. In this presentation, I will discuss some of the strategies we developed to enhance the PL QY of two-dimensional (2D) transition metal dichalcogenides (TMDs) and MXene quantum dots (MQDs).

While the structural defects are the main cause that degrades the PL QY of monolayer (1L) TMDs, Auger process represented by exciton-exciton annihilation (EEA) is the major non-radiative decay channel of excitons of 1L-TMDs in high exciton density regime [1,2]. We demonstrate that combined use of proximal Au plate and negative electric gate bias for 1L-WS₂ provides the dramatic enhancement of QY and exciton lifetime at high exciton densities [3]. QY was enhanced by 30 times and the EEA rate constant decreased by 80 times. Suppression of EEA by negative electric bias is attributed to the reduction of defect-assisted EEA process, which was then explained by the theoretical model. Our results provide a synergetic solution to cope with EEA to realize the high-intensity 2D light emitters using TMDs.

MQDs, obtained by fragmenting MXene into quantum dimension, provide the light emission properties with the advantages of the low cost and the biocompatibility [4,5]. However, because of active surface trap sites of MQDs, PL QY of MQDs is low in their pristine states. We show that a dramatic enhancement of PL QY of MQDs can be achieved by removing the F- termination during the synthesis, resulting in 25% PLQY in UV emission [6]. We also observed the degradation of PL QY with the increasing excitation intensity, of which details will be discussed. This work was supported by National Research Foundation of Korea (2021R1A6A1A03039696; 2022R1A2C2009412; 2022K2A9A1A06093582)

Excitonic Behavior in Perovskite Nanoplatelets—The Role of Defects and Achieving Linearly Polarized Electroluminescence Robert Hoyer; University of Oxford, United Kingdom

Linearly polarized light is important for a wide range of applications, such as 3D displays and optical communications. However, linear polarization is typically achieved by filtering unpolarized light, which leads to significant losses in energy. This talk examines the use of nanostructured lead-halide perovskites to directly achieve polarized light emission.

Although nanostructured halide perovskites have important advantages in terms of color purity and tunability, they are strongly affected by surface defects. Thus, the first half of this talk examines how the surface chemistry of $\text{CsPb}(\text{Br}_x\text{I}_{3-x})$ nanocrystals can be controlled through the polarity of the antisolvent used during purification. Through detailed nuclear magnetic resonance, Fourier transform infrared spectroscopy and X-ray photoemission spectroscopy measurements, we show that higher polarity antisolvents lead to increased selective etching of the iodide species due to the removal of the long-chain organic ligands through condensation reactions [1].

The second half of the talk discusses the use of self-assembled CsPbI_3 perovskite nanoplatelets to achieve polarized light emission. We show that the high dielectric and quantum confinement in these nanoplatelets leads to a large splitting in the exciton fine structure. In the edge-up perovskite nanoplatelet superlattices, we achieve strong emission from the out-of-plane dipole for the optically bright excitons. In light-emitting diodes, this led to a high degree of polarization in electroluminescence of 74.4% without requiring the use of any photonic structures [2].

Emergent Optical Properties of 2D Materials Xiaolong Zou¹, Nannan Luo² and Dan Wang¹; ¹Tsinghua University, China; ²Hunan University, China

Two-dimensional (2D) materials are ideal platforms for exploring emerging optical behaviors, at unprecedentedly high temperature and feasible control. Here, we report our systematic study on the effects of different band topologies on the optical properties of 2D systems and their control by twisting and proximity. Different 2D materials with characteristic band topologies can be adopted to achieve various long-sought high-temperature excitonic quantum behaviors, including electron-hole liquid in a new-phase (γ -phase) group IV monochalcogenides, excitonic Bose-Einstein Condensation in TiS_3 , and

Updated as of October 28, 2024

saddle excitons in β -phase group IV monochalcogenides. While twist can introduce remarkably strong moiré optical resonances in trilayer black phosphorous even at a large twist angle of 19° , its combination with pressure or electric field leads to controllable tuning of bandgap, bandwidth, and dimension of moiré bands. Further, by turning the interlayer orbital hybridization in stacked heterobilayer, large valley band splitting and valley exciton splitting can be achieved in VSe_2/MSe_2 ($M = Mo$ or W) at room temperature. These results show great potential of 2D materials in future opto-electronic applications.

X-Ray Spectroscopy for 2D Quantum Materials Riccardo Comin; Massachusetts Institute of Technology, United States

Over the past two decades, Resonant Inelastic X-ray Scattering (RIXS) has become an essential tool for investigating the microscopic interactions and low energy dynamics in various quantum materials. RIXS possesses a unique capability to probe the spin, charge, and orbital degrees of freedom with a shallow probing depth in the range of 50-100 nm. Consequently, RIXS has gained prominence as a fundamental spectroscopic technique for investigating a broad spectrum of materials, including bulk, thin films, and more recently, few-layer 2D materials.

In this presentation, I will focus on recent advancements that have facilitated RIXS studies of two-dimensional quantum materials exhibiting emergent properties in the ultrathin limit. Specifically, I will

discuss two recent investigations involving unconventional superconductor FeSe and type-II van der Waals multiferroic NiI₂. In the case of FeSe, I will present RIXS data that elucidate the evolution of spin excitations from bulk FeSe to its monolayer form. For NiI₂, I will discuss the progression of low-energy orbital and spin excitations as the material is thinned down from bulk crystals to few-layer flakes.

11:00 AM QT02.01.02

Noise Magnetometry of Topological BKT Transition in Two-Dimensional Superconductors

Jonathan Curtis¹, Nicholas Poniatowski², Pavel Dolgirev², Ilya Esterlis³, Bertrand Halperin², Amir Yacoby², Eugene Demler⁴ and Prineha Narang¹; ¹University of California, Los Angeles, United States; ²Harvard University, United States; ³University of Wisconsin–Madison, United States; ⁴ETH Zürich, Switzerland

The Berezinskii-Kosterlitz-Thouless (BKT) transition is an exotic type of phase transition present in two-dimensional systems that spontaneously break a U(1) type of symmetry. This transition is characterized by the proliferation of topological defects (vortices) above the transition temperature T_{BKT} , which then destroy the quasi-long-range order (QLRO) present below T_{BKT} . While superconductors in the extreme two-dimensional limit should in principle show such a transition, it is often hard to conclusively demonstrate the presence of BKT physics and even more difficult to fully characterize beyond DC transport.

Here we will show how, using diamond nitrogen-vacancy center (NV) noise magnetometry, the BKT transition can be carefully studied across different length scales and dynamical regimes, offering new insight and more detail into the nature of the transition. NV noise magnetometry is a new non-invasive technique for the quantum sensing of magnetic fields, where highly coherent spin-qubits, hosted by nitrogen-vacancy point defects in lattice of diamond, can be used to precisely measure dynamical magnetic field fluctuations as a function of frequency and length scale. Since the BKT transition is characterized by the proliferation of vortices, which each carry magnetic flux, NV noise magnetometry is in fact perfectly suited for studying how these vortices unbind and proliferate beyond simple DC transport considerations. We show how using this technique, new insights in to the dynamics and scaling of two-dimensional superconductors near the transition can be studied in the atomically-thin limit.

Highly Tunable Electronic Structures in Kagome Magnet Fe_xSn_y Thin Films Zheng Ren^{1,2}, Ilija Zeljkovic² and Ming Yi¹; ¹Rice University, United States; ²Boston College, United States

The kagome lattice is a corner-sharing triangular lattice that hosts flat bands, van Hove singularities and Dirac crossings. Recent experimental discoveries in kagome metals have showcased that they are an excellent platform for studying emergent charge, magnetic, superconducting orders as well as topological electronic structures. Fe_xSn_y (Fe_3Sn_2 and FeSn) has been shown to exhibit (massive) Dirac fermions, anomalous Hall effect, flat bands and more. Here, we selectively synthesize Fe_3Sn_2 and FeSn thin films using molecular beam epitaxy. In Fe_3Sn_2 , using spectroscopic-imaging scanning tunneling microscopy, we discover a number of dI/dV spectral peaks. These peaks show a prominent magnetic-field-tunability. The features point to the theoretically-predicted tunable Weyl points near the Fermi level. In FeSn , we use angle-resolved photoemission spectroscopy to resolve the band structure, which is significantly tunable as we change the temperature of the sample. Our findings suggest highly tunable electronic structures in the kagome magnet Fe_xSn_y thin films.

11:30 AM QT02.01.04

Sharp Band Renormalizations in Superconducting LiTi_2O_4 Thin Films Observed by Angle-Resolved Photoemission Spectroscopy (ARPES) Zubia Hasan¹, Grace Pan¹, Matthew Barone², Alberto de La Torre Duran³, Austin Kaczmarek², Shekhar Sharma⁴, Katja Nowack², Antia Botana⁴, Brendan Faeth² and Julia Mundy¹; ¹Harvard University, United States; ²Cornell University, United States; ³Brown University, United States; ⁴Arizona State University, United States

The mechanisms behind unconventional superconductivity have been intensely studied over the past few decades. Leading this thrust has been the high T_c cuprates, whose pairing ‘glue’ has been widely debated. LiTi_2O_4 , a spinel oxide material, is an unconventional superconductor that preceded the cuprates [1]. However, despite having one of the highest T_c (~13.7 K) for a non-cuprate oxide, little is known about its superconducting mechanism, with reports of both unconventional pairing [2] and traditional phonon-mediated BCS-like behavior [3]. There have also been signs of orbital and spin fluctuations persisting up to ~100 K, based on angle-dependent transport data [4]. Nevertheless, it remains unclear which mechanisms—spin fluctuations, electron-phonon coupling or mixed valency—are essential for superconductivity in LiTi_2O_4 . Here, we use angle-resolved photoemission spectroscopy (ARPES) with molecular beam epitaxy (MBE) to interrogate the electronic band structure of LiTi_2O_4 thin films on MgAl_2O_4 (111) substrates. Our work shows the first-ever experimentally-determined band structure of LiTi_2O_4 . The bands intriguingly show kinks resembling cuprate-like band renormalizations. Our data indicates the presence of strong correlations: the band centered at Γ shows a ‘kink’ at around $E_B \sim 40$ meV and a quasi-particle peak and incoherent tail suggestive of coupling to a bosonic mode. We see that this mode is present at all values of k_F and k_Z and persists above T_c . We discuss the origin of the kinks in LiTi_2O_4 , providing broader insight into the pairing symmetry present in this superconducting system.

11:45 AM QT02.01.05

Individual Ultrabright Fluorescent Nanoparticles as Nanothermometers Mahshid Iraniparast; Tufts University, United States

Temperature measurement at the nanoscale is important in various scientific and engineering studies, from assessing temperature distribution in the cellular medium to conducting thermal imaging of integrated circuit devices. A serious challenge in nanoscale temperature measurement lies in achieving high spatial resolution, which can be overcome by utilizing individual nanoparticles.

For this purpose, we selected fluorescent silica nanoparticles with mesoporous structure, which have encapsulated fluorescent dyes. As has been shown, such particles demonstrate ultrahigh fluorescent brightness, which is sufficient to image single nanoparticles. To be used as thermometers, two different types of dye molecules, reference molecules, and temperature-sensitive ones, were used. The measured sensitivity, reversibility, and reproducibility of measurements of temperature using these individual nanoparticles have shown the superiority of the reported particles compared to the previously reported ones. For example, the obtained individual nanothermometers exhibited a temperature fluctuation of ~0.5 K at the measurement time of 0.69 msec and excitation power density of (temperature resolution of $0.22 \text{ K.Hz}^{-1/2}$), showing a relative sensitivity of 8% within the physiologically relevant range of 25-50°C. This sensitivity is ~4 times better and the temperature resolution (at an excitation power of $0.26 \mu\text{W}$) is ~2

Updated as of October 28, 2024

times better than the previously reported best temperature measuring fluorescent particles.

These superior properties are presumably the result of the fluorescence resonance energy transfer (FRET) between the encapsulated dye molecules, which act as donors and acceptors. The enhanced brightness of these nanosensors offers numerous benefits, including the improved signal-to-noise ratio and the ability to locate the particles with high spatial precision. This work was supported by NSF grants CBET 1911253 and 2110757 (IS).

SESSION QT02.02: Characterization of Low-Dimensional Quantum Systems II

1:30 PM *QT02.02.01

Emergent Topological and Magnetic Phases in 2D Van der Waals Materials Ming Yi; Rice University, United States

The recent discoveries of long-range magnetic order in van der Waals materials have established a new platform for probing emergent orders in correlated quantum materials. In this talk I will present our recent studies on the Fe_xGeTe_2 ($x=3,5$) family of 2D ferromagnets. In particular, I will report the observation of a quantum phase switching between a Weyl nodal line phase and a topological flat band phase in Fe_5GeTe_2 via a thermal annealing process. We further demonstrate that the switching of the electronic properties is associated with a crystal symmetry change driven by a Fe site ordering that is modulated by the thermal annealing process. The presence or absence of the ordering modifies the global crystal symmetry and gives rise to either magnetic nodal lines in one case or geometrically frustrated flat bands in the other. The modified crystal and electronic structures subsequently affect the magnetism of the two phases. We further demonstrate that this phase switching is reversibly controlled via the thermal annealing and quenching method. Our work not only reveals a rich range of quantum phases emergent in 2D van der Waals ferromagnets, but also uncovers the potential of utilizing site occupancy as a novel degree of freedom for tuning symmetry and therefore topology in quantum materials for the realization of exotic emergent phases.

2:00 PM QT02.02.02

Spectroscopic Signature of 3D Magnetism in a Van der Waals Ferromagnet Fe_5GeTe_2 Vivek Bhartiya¹, Jiemin Li¹, Taehun Kim¹, Jonathan Pelliciani¹, Xiadong Xu², Dimitri Basov³, Andrew May⁴ and Valentina Bisogni¹; ¹Brookhaven National Laboratory, United States; ²University of Washington, United States; ³Columbia University, United States; ⁴Oak Ridge National Laboratory, United States

The recently discovered family of van der Waals itinerant ferromagnets $\text{Fe}_{5-x}\text{GeTe}_2$ ($0 < x < 2$) are strongly correlated electronic systems and realize intriguing ground states i.e. heavy fermions and charge density wave [1-3]. Moreover, the *cleavable* Fe_5GeTe_2 displays the highest $T_c \sim 315$ K and has the potential for miniaturized spintronic devices operating at room temperature [4-5]. However, it is not yet known if the magnons in Fe_5GeTe_2 are confined in 2D or propagate in 3D. To date, investigation of magnons via inelastic neutron scattering is not feasible due to the small size of the available single crystals. In this study, we overcome this issue by employing a high-resolution resonant inelastic X-ray scattering (RIXS)

on a mm-size single crystal of Fe_5GeTe_2 [5]. A broad magnetic continuum stretching up to 150 meV and displaying a strong intensity modulation along $(0\ 0\ L)$ is observed [6]. We show that this intensity modulation is compatible with a dominant inter-slab magnetic interaction enabling 3D propagation of magnons in the room-temperature ferromagnet Fe_5GeTe_2 [6].

Combined Nano-Optical/Scanning Tunneling Microscopy of Localized Excitons in 1L-WSe₂

Thomas P. Darlington, Xuehao Wu, Madisen Holbrook, Kevin W. Kwock, Dimitri Basov, P. James Schuck and Abhay Narayan Pasupathy; Columbia University, United States

The transition metal dichalcogenides (TMDs) are among the most studied low dimensional material classes largely due to their tightly bound exciton states which strongly interact with light. Extensive experimental and theoretical work has shown that monolayer TMDs host a rich variety of exciton complexes, from dark excitons, biexcitons, to moiré excitons. Because of this strong light-matter coupling, optical probes are often the tool of choice, however for a full understanding combined electronic, optical, and structural probes are needed to disentangle the many degrees of freedom. Combining these probes is however experimentally challenging because of the large scale mismatch of light, ~500 nm, and high resolution electronic/structural techniques such as scanning tunneling microscopy (STM), ~1 nm.

In this presentation, I will show results from a newly constructed scanning tunneling microscope integrated with a nano-optical probe that allows for co-localized near-field light delivery, at high excitation intensities, with tunneling current measurements. I will show the application of this tool to strain-localized excitons in nanobubbles of monolayer WSe₂. We observe strong modification of the density of states in scanning tunneling spectroscopy as a function of pump fluence. Further, by hole tunneling we are able to map the STM-luminescence, revealing a localized exciton edge state with a resolution <10 nm. Our work represents a novel demonstration of the effect of optical pumping on the single particle electronic structure in TMDs at the exciton's native length scale.

New Features in Phonon Spectra from Highly Anharmonic Crystals Found by Inelastic Neutron Scattering Brent Fultz, Vladimir Ladygin, Claire N. Saunders and Camille Marie Bernal-Choban; California Institute of Technology, United States

Textbook phonons are bosonic quasiparticles that populate vibrational modes of a crystal. Classical dynamics is often used to find the vibrational modes, which are then quantized in units of $h\nu$, where ν is frequency and h is Planck's constant. This approach is extended to "quasiharmonic" theory, where ν is a function of volume, and to "anharmonic" theory, where a phonon self-energy depends on interactions with other phonons through cubic or quartic perturbations to the potential. Larger deviations of the potential from harmonic can be accommodated by molecular dynamics simulations. Combining these simulations with inelastic neutron scattering (INS) experiments revealed two new types of nonlinear vibrational behavior. Both are interpreted with the quantum Langevin equation.

A phonon potential with forces that depart from linearity produces spectral features found in other nonlinear media, such as crystals for nonlinear optics. Our INS measurements on rocksalt NaBr found intermodulation phonon sidebands (IPS) at frequencies approximately equal to the sum and difference of strongly-interacting TA and TO phonon modes [1]. The "input-output theory" of quantum optics [2] was successful for predicting the intensities and shapes of the intermodulation sidebands, although the wavevector dependence of phonons adds complexity. Very recent measurements on NaBr show frequency doubling at elevated temperatures.

A second nonlinear phenomenon was found in cuprite, Cu₂O. At temperatures above room temperature, a diffuse inelastic intensity (DII) replaced the optical modes. Again, the Schrödinger-Langevin equation could predict the general appearance and perhaps the shape of the DII. It originates with phase shifts in the oscillations of oxygen atoms caused by slower movements of neighboring Cu atoms. The DII requires both anharmonicity and some temporal randomness in the nonlinear forces between neighboring atoms. Experiments to isolate the IPS and DII were performed with single crystals on a direct-geometry Fermi chopper spectrometer, ARCS, at the Spallation Neutron Source. Background removal was a challenge, but the experiments could not have been done without the low background, high flux, and detector efficiency of the ARCS spectrometer. Advances in experimental capabilities will allow other studies of nonlinear phenomena in phonon physics, and new insights into phonon anharmonicity.

PRX: What Quantum-Materials Papers are suitable? Yiming Xu; American Physical Society, United States

PRX is published by the American Physical Society, a nonprofit membership society of scientists. Its mission goal is to select around 250 *landmark* papers a year from all fields of physics and showcase them to a broad and multidisciplinary readership. Quantum Materials is undoubtedly a field of high interest to PRX, and also to the Physical Review journal family.

Is your paper a good match for PRX? Or asked differently, what papers qualify as *landmark* papers, especially in the field of quantum materials?

How do the PRX editors actually select such papers? Are such selections always accurate?

Updated as of October 28, 2024

How can you, as an author, navigate PRX's editorial and peer-review process effectively and get the most out of your interactions with the editors and referees?

Many of these questions do not have a black-and-white answer in the case of a single paper. Open-minded, reasoned, and constructive dialogues amongst the authors, the editors, and the referees are key to making each concrete process a meaningful and productive experience, and sometimes even a pleasure, for everyone. I will use the talk to discuss with you how to answer these questions.

Observation of Pines' Demon in Sr_2RuO_4 Peter Abbamonte; University of Illinois at Urbana-Champaign, United States

The characteristic excitation of a metal is its plasmon, which is a quantized collective oscillation of its electron density. In 1956, David Pines predicted that a distinct type of plasmon, dubbed a "demon," could exist in three-dimensional metals containing more than one species of charge carrier. Consisting of out-of-phase movement of electrons in different bands, demons are acoustic, electrically neutral, and do not couple to light, so have never been detected in an equilibrium, three-dimensional metal. Nevertheless, demons are believed to be critical for diverse phenomena including phase transitions in mixed-valence semimetals, optical properties of metal nanoparticles, soundarons in Weyl semimetals, and high temperature superconductivity in, for example, metal hydrides. Here, we present evidence for a demon in Sr_2RuO_4 from momentum-resolved electron energy-loss spectroscopy (M-EELS). Formed of electrons in the β and γ bands, the demon is gapless with critical momentum $q_c = 0.08$ reciprocal lattice units and room temperature velocity $v = (1.065 \pm 0.12) \times 10^5$ m/s, which undergoes a 14% renormalization upon cooling to 20 K due to coupling to the particle-hole continuum. The momentum dependence of the intensity of the demon confirms its neutral character. Our study confirms a 66-year old prediction and suggests that demons may be a pervasive feature of multiband metals.

Deciphering the Nature of Cation Disorder via Vibrational Structure Characterizations

Dongchang Chen, You Wang, Basirat Raji-Adefila and Alexandra Outka; The University of New Mexico, United States

Cation disordering, a fascinating phenomenon that represents random cation distribution in a long range, has brought about numerous novel materials for battery applications. As a key to the performance of a cation-disordered battery material, how the cations are arranged in a shorter range is an intriguing question. In this talk, we will present our study in understanding the nature of cation disordering for a series of cation-disordered electrode materials via analyzing their vibrational structures. Owing to the unique working principle of vibrational spectroscopy, it generates critical information of cation arrangement, which cannot be feasibly obtained via diffraction analyses. Furthermore, the spectroscopic information allows to locate a few hidden key factors that control the electrochemical performance and help us build models to better understand the role of these factors.

Synthesis and X-Ray Absorption Spectroscopy of $\text{Nd}_{2-x}\text{Sr}_x\text{NiO}_4$ Thin Films ($0 \leq x \leq 1.4$) Nicole K. Taylor, Dan Ferenc Segedin, Grace Pan, Spencer Doyle, Ari Turkiewicz, Charles Brooks and Julia Mundy; Harvard University, United States

Ruddlesden-Popper nickelates have been studied extensively over the last three decades due to their structural similarities to the high T_c superconductivity cuprates. In particular, the layered nickelate $\text{La}_{2-x}\text{Sr}_x\text{NiO}_4$ is analogous to the high T_c superconductor, $\text{La}_{2-x}\text{Sr}_x\text{CuO}_4$. Using reactive oxide molecular beam epitaxy (MBE), we synthesis $\text{Nd}_{2-x}\text{Sr}_x\text{NiO}_4$, thin films for $x = 0, 0.50, 1, 1.2$, and 1.4 . We observe metallic conductivity for $x=1.2$ and 1.4 thin films whereas the lower doping shows semiconducting transport over the full temperature range. We present polarization-dependent O-K and Ni-L_{2,3} XAS spectra for our Sr-doped Nd_2NiO_4 thin films. We track the evolution of the oxygen-nickel hybridization, distribution of holes between O 2p and Ni 3d states and the nickel oxidation state across the series. Our results are consistent with previous work on bulk layered nickelates [1].

Towards Floquet Engineering of Ferroelectric Semiconductors via Coherent Multidimensional Spectroscopy Ryan P. McDonnell, Daniel D. Kohler, Yueai Lin, Willa Mihalyi-Koch, Song Jin and John C. Wright; University of Wisconsin–Madison, United States

Bismuth telluroiodide (BiTeI) is a prototypical, ferroelectric Rashba semiconductor (FERSC) which possesses a myriad of interesting electronic and optical properties.^{1,2} Multiple optical transitions throughout the infrared and visible in BiTeI make it a promising material for understanding spin states in Rashba materials. However, the most promising methods for Floquet engineering of spin states in FERSCs are $\chi^{(2)}$ and $\chi^{(3)}$ dependent spectroscopies, e.g., sum frequency generation (SFG), pump-probe spectroscopy.^{3,4} The electronic structure of BiTeI is well studied, making it an ideal candidate for understanding its nonlinear response. Previous experiments reported the relative prevalence of second harmonic (SHG) over third harmonic generation (THG) output from BiTeI with an input fundamental of 0.80 eV.^{5,6} To our knowledge, there are no reports regarding frequency dependent SHG and THG output of BiTeI. Here, we use coherent multidimensional spectroscopy to probe the frequency dependence of SHG and THG output of BiTeI and perovskite FERSCs throughout the visible.⁷ Since the Rashba splitting in BiTeI varies as a function of temperature,⁸ multidimensional harmonic generation experiments on these materials are performed at cryogenic (*ca.* 90 K) and room temperatures (*ca.* 293 K) to probe the effect of temperature on SHG and THG output. These results will have implications on identifying spectroscopies for understanding and controlling the electronic structure of FERSCs.

Second Harmonic Generation Spectroscopic Study of Weyl Semimetal Mn₃Sn with Broken Time-Reversal Symmetry Ziyad Thekkayil¹, Somaiyeh Dadashi¹, Prajwal Laxmeesha², Steven May² and Eric Borguet¹; ¹Temple University, United States; ²Drexel University, United States

Topological Weyl semimetals constitute an important class of quantum materials, characterized by a chiral band structure resulting from the breaking of inversion and/or time-reversal symmetries. However, their experimental identification typically relies on techniques such as angle-resolved photoelectron spectroscopy or ultrahigh vacuum scanning tunnelling microscopy which require demanding conditions including low temperatures and ultrahigh vacuum environments. Consequently, there is a growing need for experimental techniques capable of identifying signatures of topological states under ambient conditions. Second-order nonlinear optical processes, such as second harmonic generation (SHG), have emerged as promising tools for studying Weyl semimetals and other topologically nontrivial systems due to their sensitivity to symmetry-breaking effects. However, most previous SHG studies on Weyl semimetals have been limited to systems with broken inversion symmetry or a combination of broken inversion and time reversal symmetries. There has been a scarcity of investigations focusing solely on Weyl semimetals with broken time-reversal symmetry. In this study, we employ reflection SHG measurements to investigate the surface of thin films of the Weyl semimetal Mn₃Sn, which exhibits broken time-reversal symmetry. Our findings demonstrate that the surface SHG response of this system exhibits significant dependence on the excitation wavelength and polarization geometry. These observations provide valuable insights into the understanding of surface electronic properties and spin chirality in these materials. By employing these experimental techniques under ambient conditions, our research contributes to the broader goal of developing efficient methods for characterizing topological states in Weyl semimetals, paving the way for potential applications in electronic and spintronic devices.

8:00 PM QT02.04.04

Probing the Triplet Exciton in Singlet Fission Tetracene with Inelastic Neutron Scattering from First Principles Farahnaz Maleki¹, Daniel Vong¹, Eric Novak², Luke Daemen² and Adam J. Moule¹; ¹University of California, Davis, United States; ²Oak Ridge National Laboratory, United States

Singlet fission (SF) is the process of converting an excited singlet into a pair of excited triplets. Harvesting two charges from a single photon has the potential to increase photovoltaic device efficiencies. In this study, we have used Inelastic Neutron Scattering (INS) spectroscopy to investigate the phonon density of states (pDOS) of photoexcited tetracene, in order to study its singlet fission mechanism. For the first time, our group has reported in-situ excited state INS measurements on organic chromophores using a recently developed sample environment on the indirect geometry VISION neutron spectrometer at Oak Ridge National Laboratory. We employed a DFT based open source Davis computational spectroscopy (DCS) workflow to simulate INS data in the ground state of tetracene. To model the excited state of INS spectra, we performed spin-polarized calculations with triplet spin multiplet setting. It is also the first simulation of the excited state of INS data. The modeled INS spectra

show the effect of the triplets on the pDOS and verifying the validity of the periodic exciton structure. The structure is used in TD-DFT to calculate the electronic states. Analysis of the results suggests that the deformations from the excited state and neighboring molecules may induce local electronic shifting, allowing E(2T1) to lower until the SF barrier reduces to be more easily overcome.

ARPES Characterization of the Insulator-Metal Transition in Sr-Doped Nd_2NiO_4 Thin Films Dan Ferenc Segedin¹, Nicole K. Taylor¹, Ari Turkiewicz¹, Grace Pan¹, Charles Brooks¹, Luca Moreschini^{2,3} and Julia Mundy^{1,1}; ¹Harvard University, United States; ²University of California, Berkeley, United States; ³Lawrence Berkeley National Laboratory, United States

The layered nickelates, $R_{2-x}\text{Sr}_x\text{NiO}_4$ (R = trivalent rare-earth cation), and high- T_c cuprate superconductor, $\text{La}_{2-x}\text{Sr}_x\text{CuO}_4$, are isostructural and both exhibit the suppression of antiferromagnetism, charge/spin strip order, and an insulator-metal transition upon hole-doping. However, no superconductivity has been observed in $R_{2-x}\text{Sr}_x\text{NiO}_4$ to date. Differences in the electronic structure between the layered nickelates and cuprates may shed light on the key ingredients for high-temperature superconductivity. Here, we present the ARPES characterization of $\text{Nd}_{2-x}\text{Sr}_x\text{NiO}_4$ ($x = 0.8, 1.0, 1.2$, and 1.4) thin films grown on LaAlO_3 (100). We observe a large hole pocket of x^2-y^2 character at the M-point and an electron pocket of z^2 character at the Γ -point, consistent with previous work [1]. We track the volume of the electron and hole pockets upon hole-doping and characterize the quasi-particle peak across the insulator-metal transition at $x = 1.0$. Finally, we observe no k_z -dispersion in either the hole or electron pockets, in contrast to $\text{Eu}_{0.9}\text{Sr}_{1.1}\text{NiO}_4$ [1, 2] and the three-dimensional electronic structure of NdNiO_3 .

8:30 AM QT02.05.02

Electric-Field Driven Domain Reconfiguration in The Charge Density Wave 1T-TaS₂ Yue Cao; Argonne National Laboratory, United States

Charge density wave (CDW) is ubiquitous in quantum materials. Under a minor electric field, CDWs fluctuate giving rise to increased electric conductivity long believed to arise from the depinning and sliding of CDWs. In real space, sliding of CDW will lead to the reconfiguration of CDW domains on the nano and mesoscale. Direct observation of sliding CDW is challenging. The nature of such reconfigurations, e.g., whether they are stochastic, as well as the relevant timescales, remains elusive.

We used X-ray Photon Correlation Spectroscopy (XPCS) for revealing E-field-driven domain reconfigurations in the canonical CDW material 1T-TaS₂. Combining in-situ XPCS studies with few-seconds counting time at the Advanced Photon Source (APS) and the 100 fs X-ray pulses at the MID endstation of the European XFEL, we show the CDW domain reconfigure above few microseconds and reaches ergodicity in domain configuration by seconds. These results shed light on the nature of the CDW fluctuation in 1T-TaS₂ as a stochastic process. Our results also provide quantitative measure of the depinning energy landscape in the material, which is critical to the macroscopic transport material property.

Beyond Perturbation Theory: Multi-Photon and Non-Radiative Recombination Effects in Spectroscopies Adrian E. Feiguin; Northeastern University, United States

The conventional calculation of scattering cross sections relies on a treatment based on time-dependent perturbation theory that provides formulation in terms of Green's functions in the frequency domain. In equilibrium, it boils down to evaluating a simple spectral function equivalent to Fermi's golden rule, which can be solved efficiently by a number of numerical methods. However, away from equilibrium, the resulting expressions require a full knowledge of the excitation spectrum and eigenvectors to account for all the possible allowed transitions and intermediate states, a seemingly unsurmountable complication. We have recently presented a new paradigm to overcome these hurdles[1-4]: we explicitly introduce the scattering particles (neutron, electron, photon, positron) and simulate the full scattering event by solving the time-dependent Schrödinger equation. The spectrum is recovered by measuring the momentum and energy lost by the scattered particles, akin an actual energy-loss experiment. I here show how these ideas can be generalized to study multi-photon processes such as coincidence ARPES, and the interplay between radiative and non-radiative recombination channels in X-ray spectroscopies.

Prediction of the Optical Properties of Spin Defects in Semiconductors and Insulators using Time-Dependent Density Functional Theory Yu Jin¹, Marco Govoni^{2,1,3}, Victor Wen-zhe Yu³, Andrew C. Xu¹ and Giulia Galli^{1,3}; ¹University of Chicago, United States; ²University of Modena and Reggio Emilia, Italy; ³Argonne National Laboratory, United States

Optically active point defects in semiconductors and insulators hold great potential for quantum technology applications. First-principles investigations of excited state properties of point defects are instrumental in characterizing the defects through the interpretation of spectroscopic experimental results [1-3] and in predicting spin defects with tailored optical properties [4]. Time-dependent density functional theory (TDDFT) allows for exploring not only excited-state energies and wavefunctions of localized defect states but also potential energy surfaces by performing geometry optimizations [1]. Here, I will present the study of the properties of several spin-defects using TDDFT, including the absorption spectra of the negatively charged nitrogen-vacancy center in diamond [1], the neutral silicon-vacancy center in diamond, and the neutral oxygen-vacancy center in magnesium oxide. Our calculations were made possible by our recent implementation of TDDFT with analytical forces in the West code [5,6], which

enables TDDFT calculations with hybrid functionals for systems containing thousands of atoms and detailed investigations of excited-state geometries and finite-size effects.

9:45 AM QT02.05.06

Absolute Superconducting Spin Valve Effects in Superconductors with a Spin-Splitting Field and Spin-Orbit Coupling Hisakazu Matsuki¹, Alberto Hijano^{2,3}, Miguel Agueda Velasco⁴, Grzegorz P. Mazur⁵, Stefan Ilic², Beilun Wu⁴, Edwin Herrera Vasco⁴, Hermann Suderow⁴, Guang Yang⁶, Sebastian Bergeret² and Jason W. Robinson¹; ¹University of Cambridge, United Kingdom; ²Centro de Física de Materiales (CFM-MPC) Centro Mixto CSIC-UPV/EHU, Spain; ³University of the Basque Country UPV/EHU, Spain; ⁴Universidad Autónoma de Madrid, Spain; ⁵Delft University of Technology, Netherlands; ⁶Beihang University, China

At a thin-film superconductor (S) interface with a ferromagnetic insulator (FI), the magnetic proximity effect (MPE) can spin-split the superconducting density of states and suppress the critical temperature (T_c) of S. For S metals with weak spin-orbit coupling (SOC), the spin splitting can translate to several Tesla [1, 2] and the T_c suppression can reach tens of mK [3]. For a FI/S/FI spin switch, the T_c suppression is reduced for antiparallel (AP) FI magnetizations due to a net cancellation effect of the MPE in S; conversely, for parallel (P) magnetizations, the exchange fields add, enhancing the suppression of T_c with the spin switch efficiency defined as $\Delta T_c = T_c(\text{AP}) - T_c(\text{P}) > 0$ [4].

In the presence of SOC, the spin-splitting in S should smear out, reducing ΔT_c . Here, however, we show that in optimized EuS/Nb/EuS (FI/S/FI) structures, ΔT_c can reach 1 K and achieve an absolute spin-valve effect with $\Delta T_c/T_c$ close to 1 by inserting a thin layer of Au at a single interface - i.e., EuS/Nb/Au/EuS. Scanning tunneling spectroscopy on Au in Au/Nb and Au/Nb/EuS structures show evidence for a modification of the superconducting state due to the presence of EuS. These results demonstrate new physics in which ΔT_c is boosted by SOC.

States; ³Indian Institute of Technology Kharagpur, India; ⁴University of Bristol, United Kingdom;

⁵RRCAT, Indore, India

The concept of nematicity is still not well settled in case of Fe based Superconductors. Signatures of nematic ordering exist well above the structural transition temperature i.e. the presence of orthorhombic distortion in the tetragonal symmetry broken phase. Tetragonal symmetry dictates that both Fe d_{xz} and d_{yz} orbitals should be degenerate, whereas studies like ARPES, X-ray pair distribution function etc. show the unequal occupation of Fe d_{xz} and d_{yz} orbitals in the symmetry broken orthorhombic phase. By using Raman spectroscopy, we have studied P doped BaFe₂As₂ for $x \sim 0.23$, whose doping composition lies near quantum criticality and enhanced nematic fluctuation in the doping temperature phase diagram. From transport measurement it is observed that P doped BaFe₂As₂ exhibits a tetragonal to orthorhombic phase transition around 60K followed by a superconducting transition below ~ 16 K. A room temperature micro-Raman spectrum of the studied compound shows a phonon mode around $\sim 211 \text{ cm}^{-1}$ with two broad high frequency modes around 515 cm^{-1} and 635 cm^{-1} . The separation between these two modes remains around 15 meV at room temperature. Temperature dependent Raman measurement shows that the B_{1g} mode (phonon mode around $\sim 211 \text{ cm}^{-1}$) follows standard anharmonicity behavior within a temperature range from 80 to 300K, whereas with varying temperature these broad modes show a drop in intensity which is typically observed for electronic Raman modes. In the non-superconducting state, strong anisotropic behavior is observed for these BMs in polarization dependent Raman scattering. Electronic structure calculations for P doped and undoped BaFe₂As₂ show that while Fe d_{xz} and d_{yz} orbitals do not split in the tetragonal phase, the splitting energy is 13.5 meV in the orthorhombic phase of the doped system, which is reasonably close to the experimentally observed value of the energy separation of the BMs. Hence, we believe that these reported broad modes bear signatures of crystal field splitting of Fe d orbitals due to local breaking of tetragonal C_4 symmetry in the doped system.

Advances in Zinc Oxide Materials for Quantum Applications Vishal Saravade^{1,2}, Chuanle Zhou³, Zhe Chuan Feng², Benjamin Klein² and Ian T. Ferguson²; ¹Pennsylvania State University, United States;

²Kennesaw State University, United States; ³Missouri University of Science and Technology, United States

Advanced characterizations of zinc oxide-based materials for spintronic and quantum applications are investigated. Zinc oxide (ZnO) based materials have been explored for various applications in electronics, nanotechnology, biomedicine, power devices, and so on. Zinc oxide doped with transition metals (ZnTMO) has a potential for spintronic and quantum applications. However, its properties in this area are not well understood. In this work, characterizations of transition metal-doped zinc oxide are systematically performed and investigated to gain insights into their spin-related properties. Sets of Mn-doped ZnO and Ni-doped ZnO were epitaxially grown on sapphire substrates using metal-organic chemical vapor deposition (MOCVD). X-ray diffraction showed a nearly monocrystalline structure in the (002) direction, along with appearances of low intensity secondary phases related to the transition metal

materials and host ZnO. A systematic reducing trend in the bandgap was observed in both Ni-doped and Mn-doped ZnO with increased transition metal dopant concentration. This could be due to the energy states that are introduced with the transition metals, and this shows a potential controllability in spin-inducing energy states by transition metal-doping. As per photoluminescence measurement, transition-metal doping attenuated the ultraviolet narrow band and increased emissions in the yellow-green regions. This could be due to secondary phases of TM-oxides that were formed during the MOCVD growth. Advanced Hall Effect characterizations were done to understand the inherent spin-related properties of ZnTMO. ZnTMO exhibited Anomalous Hall Effect (AHE). The transverse Hall resistivity overlapped with the longitudinal resistivity, and both these resistivity were not linear. This indicates spin-polarization in ZnTMO that is not induced by intrinsic carriers. The spin polarization in ZnTMO could be the result of TM-TM clusters, secondary phases, defects, and extrinsic carrier scattering. Annealing reversed the AHE response and indicated the influence of annealing on spin-polarizations of the AHE-causing components of ZnTMO. The mechanism for spin in ZnTMO is based on extrinsic scattering by TM centers/clusters or secondary phases. Understanding of spin mechanism in ZnTMO can help in the investigation of ZnO for quantum and other spintronic applications.

Recreating the Physics of a Doped Mott Insulator on a Silicon Surface Steven Johnston; The University of Tennessee, Knoxville, United States

Sn adatoms on a Si(111) substrate with 1/3 monolayer coverage form a two-dimensional triangular lattice with one unpaired electron per site and an antiferromagnetic Mott insulating state. The Sn layers can be modulation hole-doped and metalized using heavily-doped p-type Si(111) substrates and become superconducting at low temperatures, recreating cuprate-like physics on a Si template. Here, the combination of repulsive interactions and frustration inherent to the triangular adatom lattice opens up the possibility for a chiral order parameter. In this talk, I will discuss recent theoretical and experimental studies leveraging scanning tunneling microscopy/spectroscopy and quasi-particle interference imaging to study this novel system. We find evidence for a doping-dependent T_c with a fully gapped order parameter, time-reversal symmetry breaking, and a substantial enhancement of the zero-bias conductance near the edges of the superconducting domains. While each piece of evidence could have a more mundane interpretation, our combined results suggest the tantalizing possibility that Sn/Si(111) is an unconventional chiral d-wave superconductor, consistent with theoretical models.

Synchrotron Spectroscopy of Epitaxial Rare Earth Nickelates Charles Ahn; Yale University, United States

The rare-earth nickelates display a broad range of phenomena, including functional behavior such as antiferromagnetism and superconductivity. The ability to synthesize heterogeneous epitaxial thin film structures out of nickelates enables one to control and modify these functional properties via the creation of atomically abrupt interfaces. Advanced synchrotron characterization can then be used to measure the resulting electronic and magnetic properties of these atomically engineered systems. For example, the

Updated as of October 28, 2024

antiferromagnetic order parameter of nickelate superlattices can be imaged using resonant soft x-ray diffraction, and information about the dynamics can be accessed by x-ray photon correlation spectroscopy (XPCS) measurements using coherent soft x-rays. In this talk, we focus on synchrotron characterization of the square-planar nickelates, which are a novel class of superconductors. We use in situ aluminum reduction of the perovskite nickelates to achieve superconducting $\text{Nd}_{1-x}\text{Eu}_x\text{NiO}_2$ (NENO) thin films grown by molecular beam epitaxy (MBE). Atomic structure is characterized using crystal truncation rod (CTR) analysis, and electronic structure is characterized using diffraction-based X-ray absorption near edge structure (dXANES). We also report on the superconducting transport properties of NENO films.

U.S. National Academies Report Identifies Measurements and Infrastructure Needs for QIS Research Linda Nhon; NASEM, United States

Scientific progress in the field of Quantum Information Science (QIS) will pioneer the development of cutting-edge technologies in computing, sensing, and communications. These efforts will strengthen key sectors of the United States economy and workforce. To achieve this innovation landscape, a robust QIS research enterprise needs to be established. This ecosystem includes state-of-the-art instrumentation and tools that are required for in-depth characterization of quantum molecular materials. A 2023 U.S. National Academies of Sciences, Engineering, and Medicine report, *Advancing Chemistry and Quantum Information Science*, identifies fundamental research priorities that should be targeted to enhance the measurement and control of quantum systems. The study provided recommendations for advancing these fields to federal agencies such as the U.S. Department of Energy and the National Science Foundation, U.S. Congress, the research community, and other stakeholders. Spearheaded by a committee of chemists and physicists, the study assessed a wide range of techniques, chemical approaches, and tools that would offer more precise measurements of molecular-scale quantum devices in different environments (e.g., on surfaces or at complex interfaces). Addressing facility maintenance concerns and broadening access to laboratory- and mid-scale instrumentation were also discussed. Here, the research opportunities, infrastructure and facility needs, and workforce development strategies identified in the National Academies report will be presented.

8:30 AM *QT02.07.02

Electronic Structure, Magnetic Interactions and Charge Order in Low Valence Nickelates Probed by Resonant Inelastic X-Ray Scattering Mark P. Dean; Brookhaven National Laboratory, United States

After a 30-year quest, researchers recently succeeded in realizing superconductivity in low-valence nickelates [1]. This ignited a vigorous debate regarding the essential electronic properties of these materials and their similarity to cuprates. Some important questions include: Do these materials have appreciable oxygen charge-transfer character and superexchange akin to the cuprates or are they in a distinct Mott-Hubbard regime where oxygen plays a minimal role and superexchange is negligible? Given

that cuprates have a propensity to host proximate competing phases such as charge and spin order, one might ask whether the nickelate's phase diagrams also host competing orders and to what extent they are similar to those in cuprates? In this talk, I will describe our use of resonant inelastic x-ray scattering to solve these questions [2-4].

Resolving Emergent Structure States in Quantum Materials by Total X-Ray Scattering Valeri Petkov; Central Michigan University, United States

Materials with properties rooted in the quantum world exhibit coupled electronic, magnetic and lattice degrees of freedom leading to fascinating properties. However, the lattice degrees of freedom often appear as lattice distortions which are not necessarily amenable to crystallographic description, hampering the understanding of the underlying physics. In the talk, we will show that the problem may be solved by total x-ray scattering and show examples from our recent studies on dual heavy fermion liquid UPt_2Si_2 , which exhibits antiferromagnetism consistent with localized 5f-electron states and transport properties characteristic to Kondo lattice systems (1), layered transition metal dichalcogenide 1T-TaS_2 , which is a putative Mott insulator (2), and NbTe_4 topological superconductor, where double Dirac points emerge thanks to the emergence of charge density wave order (3).

Case Studies of Quantum Materials via RIXS Wei-Sheng Lee; SLAC National Accelerator Laboratory, United States

Quantum materials exhibit extraordinary properties stemming from the interplay of different degrees of freedom, encompassing quantum topology, orbital, spin, lattice, and charge interactions. However,

comprehending and manipulating these underlying degrees of freedom presents a substantial challenge. Resonant inelastic X-ray scattering (RIXS) has emerged as a powerful technique for studying elementary excitations associated with these fundamental degrees of freedom, including orbital, magnon, phonon, and charge excitations, in the energy-momentum domain. This capability offers great opportunities to unravel the intricate phenomena exhibited by quantum materials.

In particular, the recent advancements in X-ray free-electron laser have heralded a new era of time-resolved RIXS, enabling the measurement of elementary excitations when they are driven out of equilibrium. In this presentation, I will showcase our latest investigations employing RIXS and time-resolved RIXS on unconventional superconductors and related compounds. Our findings highlight how RIXS can illuminate the microscopic behaviors, thereby contributing to a broader understanding and potential control of quantum materials.

Next-Nearest-Neighbor Hopping and Charge-Ordering Tendencies in a Cuprate Ladder Hari Padma¹, Jinu Thomas², Sophia TenHuisen¹, Wei He³, Ziqiang Guan¹, Jiemin Li³, Yu Wang⁴, Zhiqiang Mao⁴, Valentina Bisogni³, Jonathan Pelliciari³, Mark P. Dean³, Steven Johnston² and Matteo Mitrano¹; ¹Harvard University, United States; ²The University of Tennessee, Knoxville, United States; ³Brookhaven National Laboratory, United States; ⁴The Pennsylvania State University, United States

The competing nature of charge-order and superconductivity in the cuprates is an open experimental and theoretical problem in condensed matter physics. Recent theoretical studies on the Hubbard model have revealed that the next-nearest neighbor hopping t' is a key tuning parameter that destabilizes charge-ordered phases in favor of superconductivity¹. However, the influence of t' remains relatively unexplored experimentally. Quasi-1D systems are an ideal platform to study the microscopic physics of the cuprates, owing to the availability of reliable theory that may be rigorously compared to experimental results. Here we consider the quasi-1D cuprate ladder system $\text{Sr}_{14-x}\text{Ca}_x\text{Cu}_{24}\text{O}_{41}$, which exhibits a gapped spin singlet ground state² that is charge ordered at ambient pressure³ and superconducting at high pressure⁴ ($x > 11$, $T_C = 9$ K at 3.5 GPa). Focusing on the hole self-doped parent compound ($x = 0$), we map the spectrum of dispersive two-triplon spin fluctuations as a function of temperature across the CO phase transition using high-resolution resonant inelastic X-ray scattering at the Cu L -edge. We identify a substantial downturn in the two-triplon dispersion near the zone boundary, a feature that is at odds with predictions of the Hubbard model with only nearest-neighbor hopping. Furthermore, we observe a dramatic reshaping of the two-triplon spectrum across the CO transition temperature. We fit the experimental two-triplon dispersion measured in the CO ground state using DMRG calculations and unbiased Bayesian optimization to extract the Hubbard model parameters including the exchange anisotropy and t' . We examine the role of t' in the reshaping of the spin fluctuations across the CO transition, in particular identifying signatures of hole pairing and hole-triplon bound states, which have been hypothesized to be precursors to superconductivity in spin ladders^{5,6}. Our work provides a rigorous experimental quantification of t' in cuprates and clarifies its influence over spin fluctuations and electronic ordering.

Lead-Reduced Halide Perovskite Solar Cells with Photo-Assisted Kelvin Probe Force Microscopy

Ming-Chung Wu; Chang Gung University, Taiwan

With the intensification of the global energy crisis, characterized by increasing demand and diminishing fossil fuel reserves, it has become imperative to explore sustainable and efficient energy-harvesting technologies. Perovskite solar cells (PSCs) have rapidly gained prominence as a promising photovoltaic device, boasting power conversion efficiencies (PCE) exceeding 26%. However, the widespread use of lead (Pb) in PSCs introduces environmental and health hazards that pose challenges to their broad commercialization. In this presentation, I will introduce the strategic research roadmap of our group in advancing perovskite solar cell technology. Our discussion will be divided into four key areas: (1) high-efficiency perovskite solar cells employing metal-doped TiO_2 as the electron transport layer (ETL); (2) the design of side-chain modulated, carbazole-based bifunctional hole-shuttle interlayers; (3) the development of lead-reduced perovskite solar cells; and (4) the exploration of lead-free Ag_3BiI_6 rudorffite solar cells. Predicting the quality of photovoltaic (PV) materials necessitates a thorough understanding of the material properties, manufacturing processes, and the long-term performance of solar cells or modules. To this end, we utilize various methods and techniques. Photoluminescence (PL) and time-resolved photoluminescence (TRPL) is utilized to determine charge carrier lifetimes, recombination mechanisms, and assess the impact of defects on material quality. Generally, higher-quality PV materials are indicated by lower recombination rates, which can lead to potentially higher efficiencies in solar cell applications. The photo-assisted Kelvin Probe Force Microscopy (photo-assisted KPFM), an adaptation of traditional KPFM that includes sample illumination during measurement, proves especially beneficial for PV materials. It allows for the investigation of surface electron accumulation under conditions that closely replicate the operational environment of the solar cells. Our research group is committed to spearheading innovative solutions in PSCs that prioritize both high efficiency and environmental

stewardship.

Light-Induced Floquet Effects in Graphene under Continuous-Wave Mid-Infrared Irradiation

Yijing Liu¹, Gabriel Gaertner², John Huckabee², Alexey Suslov³, Luis E.F. Foa Torres⁴, Paola Barbara¹ and Nikolai Kalugin²; ¹Georgetown University, United States; ²New Mexico Tech, United States; ³National High Magnetic Field Laboratory, United States; ⁴University of Chile, Chile

Light-matter interaction in 2D materials is predicted to induce Floquet-Bloch states with non-trivial topology [1,2,3]. We report on the experimental observation of photoinduced transverse voltage and photoinduced current in graphene Hall bars irradiated with high-power linearly and circularly-polarized mid-Infrared radiation at cryogenic temperatures. The radiation wavelength is 10.6 μm and the power density is larger than 1 mW/ μm^2 . We investigate the dependence of the photoresponse on the temperature, position of Fermi level, and light polarization. The observation of Floquet signatures at lower power densities and in the CW regime lifts substantial experimental restrictions, helping to unlock potential applications for light-induced manipulation of material properties [4].

We acknowledge support from NSF (projects DMR CMP #2104755 and DMR CMP #2104770). The National High Magnetic Field Laboratory is supported by the National Science Foundation through NSF/DMR-2128556 and the State of Florida.

Spin Dynamics in a Photoexcited Mott Insulator on a Square Lattice Takami Tohyama; Tokyo University of Science, Japan

The recent development of time-resolved resonant inelastic x-ray scattering (trRIXS) opens a new avenue for probing collective two-particle excitations, from which one can investigate novel photoinduced nonequilibrium phenomena in the wide range of momentum and energy spaces. RIXS can probe not only charge excitation but also single-magnetic excitation if one uses incident x rays tuned for L edge in transition metals. Therefore, trRIXS is a good tool to investigate single-magnon excitation in photoexcited Mott insulators. On the other hand, time-resolved two-magnon Raman scattering (trTMRS) is suitable for investigating two-magnon excitation in photoexcited Mott insulators. In order to give theoretical predictions to trRIXS, we investigate momentum dependent single-magnon excitation that evolves after pumping within a femtosecond timescale in an antiferromagnetic Mott insulator on a square lattice [1]. Using a numerically exact-diagonalization technique based on the time-dependent Lanczos method for a half-filled Hubbard model on a square lattice, we find a characteristic temporal oscillation for the intensity of the dynamical spin correlation function describing single-magnon excitation. This oscillation shows an antiphase behavior for two orthogonal directions that are parallel and perpendicular to the electric field of a pump pulse. The same behavior is also seen in the static spin structure factor. Their oscillation period in time is determined by two-magnon excitation in the Mott insulator. This theoretical prediction will be confirmed for Mott insulating cuprates and iridates once TRRIXS is ready for a femtosecond timescale. The photoexcitation of the Mott insulator on a square lattice weakens the

intensity of two-magnon excitation as observed in trTMRS [2]. However, the spectral changes in the low-energy region below the two-magnon excitation have not yet been clearly understood. After turning off a pump pulse tuned for an absorption edge, we find that a new magnetic signal clearly emerges well below the two-magnon energy [3]. We find that low-energy excitation is predominantly created via an excitonic state at the absorption edge. This exciton-assisted magnetic excitation may provide a possible explanation for the low-energy spectral weight in the recent trTMRS experiment [2].

Ultrafast Nonsymmorphic Symmetry Breaking by Strong Light-Matter Interaction Changhua Bao¹, Shaohua Zhou¹, Benshu Fan¹, Peizhe Tang², Wenhui Duan¹ and Shuyun Zhou¹; ¹Tsinghua University, China; ²Beihang University, China

In condensed matter physics, symmetry breaking lays the cornerstone of the formation of rich phases of matter, such as charge density waves and magnetism. Symmetry breaking can be on-demand controlled in equilibrium states by external fields, including electric/magnetic field and strain, leading to intriguing phase transitions and collective modes, such as tailoring topological Dirac nodal line, Mobius, and hourglass fermions by breaking nonsymmorphic symmetry. Beyond equilibrium states, strong light-matter interaction potentially provides unprecedented opportunities for breaking symmetry on an ultrafast timescale and even realizing exotic quantum states which have no counterpart in equilibrium states.

Here, by utilizing time- and angle-resolved photoemission spectroscopy (TrARPES), we demonstrate the realization of ultrafast symmetry breaking by strong light-matter interaction in a two-dimensional semiconductor. Driven by a strong mid-infrared light field, an emerged band crossing nodal ring is observed, which is gapped by the interactions and leaves nonsymmorphic symmetry-protected Dirac nodes. Interestingly, when the driving light field is tuned to polarize along the direction which breaks the nonsymmorphic symmetry, Dirac nodes are further gapped to form a fully gaped nodal ring, indicating a light-induced nonsymmorphic symmetry breaking. Moreover, the Dirac nodes are gapped only in the presence of the light field and recover gapless almost instantaneously ($\ll 100$ fs) when the light field is turned off, suggesting an ultrafast nonsymmorphic symmetry breaking. This work not only demonstrates light-matter interaction as an effective way to manipulate symmetry in quantum materials but also paves an important step for the long-sought Floquet topological insulator.

Exploring Novel Quantum Materials under High Pressure and High Temperature Weiwei Xie; Michigan State University, United States

Pressure, an intensive variable, is a virtually unexplored pathway to new quantum materials. The application of high pressure can yield dramatic new examples of quantum materials. In this presentation, I will discuss how high pressure can be used to tune unexpected physical properties in magnetic topological materials and low dimensional materials. The use of high pressure and high temperature synthesis can stabilize the exotic quantum phenomena detected by high pressure X-ray and neutron scattering. I will also introduce our new lab-based in-situ high pressure and high temperature single crystal X-ray diffraction technique, which can guide us to synthesize materials rationally under high pressure and high temperature. High pressure synthesis techniques will be the focus of the discussion, novel iridates (Sr_2IrO_4 , SrIrO_3), and tetragonal BaCoO_3 .

From Mathematics to Algorithms—Obtaining Spectral Information from Real-and Imaginary-Time Response Functions Emanuel Gull; University of Michigan, United States

Numerical simulations of equilibrium systems are often performed in 'imaginary' time, using the Matsubara formalism of statistical quantum field theory; or in 'real' time, using a time-evolution of the system. This talk will analyze the mathematical properties of response functions in these formalisms and show how they can be integrated into efficient numerical algorithms that can capture the spectral information of quantum systems with unprecedented accuracy.

2:30 PM BREAK

3:30 PM *QT02.09.03

Photoemission Studies of Ferroelectric Rashba Semiconductors—From Static to Transient Properties Claude F. Monney¹, Frederic Chassot¹, Geoffroy Kremer², Aki Pulkkinen³, Christopher Nicholson⁴, Hugo Dil^{5,6}, Juraj Krempasky⁶, Jan Minar³, Gunther Springholz⁷, Julian Maklar⁸, Ralph Ernstorfer⁸, Laurenz Rettig⁸, Changming Yue¹ and Philipp Werner¹; ¹University of Fribourg, Switzerland; ²Université de Lorraine, France; ³University of West Bohemia, Czechia; ⁴Specs, Germany; ⁵EPFL, Switzerland; ⁶Paul Scherrer Institute, Switzerland; ⁷Johannes Kepler Universität, Austria; ⁸Fritz-Haber Institute, Germany

Ferroelectric Rashba semiconductor are bulk materials with noncentrosymmetric atomic structures in their ferroelectric phase combined with a significant spin-orbit interaction, leading to a strong coupling between spins, electrons and the underlying lattice. These properties are directly imprinted on their electronic structure through the occurrence of a giant Rashba splitting in their valence band. This gives the possibility of studying their paraelectric-to-ferroelectric phase transition in the momentum space with angle-resolved photoemission spectroscopy (ARPES). α -GeTe and α -SnTe are two prime examples of such a class of materials. Moreover, it has been recently demonstrated that it is possible to reversibly manipulate the spin polarization in GeTe by an external electric field, a promising behavior for spintronics applications.

A stimulating direction of research is now to investigate how it is possible to modify the ferroelectric properties of these materials with temperature or light pulses.

In this talk, I will start with the case of SnTe and will show high-energy-resolution ARPES data acquired as a function temperature across its ferroelectric phase transition. Our excellent experimental resolution and unprecedented thin film quality allow us to follow the evolution of the Rashba splitting induced by the ferroelectric distortion in the bulk bands and to reveal drastic deviations from a mean-field-like

transition. I will discuss how the persistence of a splitting at room temperature supports an order-disorder type of transition and will elaborate on the implications for the topological nature of surface states in SnTe.

In a second part, I will move to the case of GeTe. Upon photoexcitation, we have driven GeTe out-of-equilibrium and probed its transient low-energy electronic structure with time-resolved ARPES. As a consequence, the Rashba splitting of its bulk states is enhanced after 200 fs, a very surprising result, especially given that bulk-sensitive time-resolved experiments have only led to a suppression of ferroelectric upon photoexcitation. In addition, our data show a coherent modulation of the Rashba splitting with a frequency that corresponds to the amplitude mode of the ferroelectric distortion. I will explain what is the physical mechanism behind this unexpected behavior.

4:00 PM *QT02.09.04

Resolving States of Matter in Space and Time by Coherent Soft X-Ray Scattering Claudio Mazzoli; Brookhaven National Laboratory, United States

Recently we succeeded in showing how states of matter - magnetic domain configurations in the specific - can be recognized and accessed by the novel Coherent Soft X-ray Scattering full field imaging, or other more traditional techniques when special analysis is added. Building on our experience in dynamics and time domain analysis, we proved the ability to disentangle intertwined details in space and time, thus accessing microscopic information in a completely new way. In my talk, I will show the proof of principle of the above approach, and conclude by surfing across some long standing problems in condensed matter physics which could naturally benefit from this new approach.

4:30 PM *QT02.09.05

Nonlinear Coupled Magnonics Edoardo Baldini; The University of Texas at Austin, United States

Tailored light excitation and nonlinear control of lattice vibrations have emerged as powerful strategies to manipulate the properties of quantum materials out of equilibrium. Generalizing the use of coherent phonon-phonon interactions to nonlinear couplings among other types of collective modes would open unprecedented opportunities in the design of novel dynamic functionalities in solids. For example, the collective excitations of magnetic order – magnons – can carry information with little energy dissipation, and their coherent and nonlinear control would provide an alternative route to achieve collective-mode-based information processing and storage in forthcoming spintronics and magnonics. In this talk, I will show that intense terahertz (THz) fields can initiate processes of magnon up-conversion mediated by an intermediate magnetic resonance. By using a suite of advanced spectroscopic tools, including a newly demonstrated two-dimensional THz polarimetry technique enabled by single-shot detection, we unveil the unidirectional nature of coupling between distinct magnon modes of a canted antiferromagnet. These results demonstrate a route to inducing desirable energy transfer pathways between coherent magnons in solids and pave the way for a new era in the development of ultrafast control of magnetism.

8:00 AM *QT02.10.01

Phase Transitions and Spin Dynamics of the Quasi-One Dimensional Ising-Like Antiferromagnet BaCo₂V₂O₈ in a Longitudinal Magnetic Field Virginie Simonet¹, Quentin Faure², Shintaro

Takayoshi³, Sylvain Petit², Béatrice Grenier⁴ and Thierry Giamarchi⁵; ¹Institut Néel, France; ²Laboratoire Léon Brillouin, France; ³Konan University, Japan; ⁴Grenoble Alpes University, France; ⁵University of Geneva, Switzerland

Combining inelastic neutron scattering and numerical simulations, we study the quasi-one-dimensional Ising anisotropic quantum antiferromagnet BaCo₂V₂O₈ in a longitudinal magnetic field. This remarkable material shows a quantum phase transition from a Néel ordered phase at zero field to a longitudinal incommensurate spin density wave at a critical magnetic field of 3.8 T. Concomitantly, the excitation gap almost closes and a fundamental reconfiguration of the spin dynamics occurs. These experimental results are well described by the universal Tomonaga-Luttinger liquid theory developed for interacting spinless fermions in one dimension. We especially observe the rise of mainly longitudinal excitations, a hallmark of the unconventional low-field quantum regime in Ising-like quantum antiferromagnetic chains. If the field is increased further, another transition into a transverse antiferromagnetic phase takes place at 9 T. In contrast to this abrupt change of magnetic ordering, the spectrum is not much altered at the transition at 9 T. The spin dynamics indeed reflects the 1D character of the system well accounted by Tomonaga-Luttinger liquid excitations. At the same time, the succession of magnetic phases reflects the competition between longitudinal and transverse correlations expected in the model, which can be experimentally investigated for the first time. Such an apparent disconnection of the static and dynamical properties is another nice property of the rich physics observed in the low-dimensional quantum antiferromagnet BaCo₂V₂O₈, which is proved to be a precious material to test universal behaviors described by the Tomonaga-Luttinger liquid theory.

8:30 AM *QT02.10.03

Inelastic Spectroscopies of The Physics of Quantum Spin Liquid Materials Young Lee^{1,2}; ¹Stanford University, United States; ²SLAC National Accelerator Laboratory, United States

Quantum spin liquids (QSL's) are novel states of matter possessing long range quantum entanglement. Inelastic spectroscopies are the preeminent tool for exploring their rich physics. An important experimental signature of such novel phases is the presence of spin excitations characterized by fractionalized quantum numbers. For the kagome quantum spin liquid candidate materials Zn-barlowite and herbertsmithite, our inelastic scattering measurements (using both neutron and x-ray probes) provide evidence for fractionalized spinon excitations. Furthermore, experiments on closely related materials with competing states allow us to determine the most important magnetic interactions and to identify signatures of broken symmetry states. In addition, our high energy resolution studies shed light on the role that impurities play in the QSL ground state physics. We discuss the implications our recent experimental investigations of the spin excitations which span low energies (~J/100) to high energies (~10J) on our powder and single crystal samples of QSL and related materials.

Machine Learning-Enabled Real Time Analysis in Ultrafast X-Ray Scatterings Zhantao Chen^{1,2};

¹Stanford University, United States; ²SLAC National Accelerator Laboratory, United States

Updated as of October 28, 2024

The X-ray free-electron laser (XFEL) has opened up numerous unique scientific opportunities for ultrafast dynamics and particle imaging studies. However, obtaining meaningful experimental signals for complex samples remains a significant challenge. In this talk, we present two recent works to help address this issue by integrating machine learning techniques into data collection and analysis. Firstly, we combine neural network (NN) models with Bayesian experimental design algorithms for real-time experiment steering. The NN facilitates uncertainty quantifications in experimental settings and provides immediate parameter estimations, leading to physics-informed experimental decisions and more meaningful experimental measurements, as demonstrated through simulated X-ray Photon Fluctuation Spectroscopy (XPFS) measurements on magnetic excitations. In the second topic, we present an NN-based reconstruction algorithm for X-ray single particle imaging (SPI), capable of simultaneously estimating particle orientations and recovering the complete reciprocal space information. Our method remains robust under challenging experimental conditions, including strong shot-to-shot photon count fluctuations. It enables successful reconstructions from datasets with limited and highly-noisy diffraction patterns, surpassing limitations of the conventional algorithm.

Plastic Deformation of Quantum Materials Martin Greven; University of Minnesota, United States

Plastic deformation is the permanent distortion that occurs when a material is subjected to stresses that exceed its yield strength. While plastic deformation has been used by blacksmiths and engineers for thousands of years, its effects on the electronic properties of quantum materials have been largely unexplored. In this talk, I will review our recent [1,2] and ongoing efforts to understand the effects of compressive plastic deformation in complex oxides. For example, we have uncovered that the classic perovskite SrTiO_3 exhibits enhanced, low-dimensional superconductivity and ferroelectric quantum criticality correlated with the appearance of self-organized dislocation structures, as revealed by diffuse neutron and X-ray scattering [2,3]. These results as well as unpublished work for related oxides demonstrate the potential of plastic deformation and dislocation engineering for the manipulation of electronic properties of quantum materials.

Work funded by the US Department of Energy through the University of Minnesota Center for Quantum Materials, under grant number DE-SC-0016371.

Polar Textures in Ferroelectrics Ramamoorthy Ramesh¹ and Peter Meisenheimer²; ¹Rice University, United States; ²University of California, Berkeley, United States

Complex topological configurations are a fertile playground to explore novel emergent phenomena and exotic phases in condensed-matter physics. I will describe the discovery of polar skyrmions in a lead-

titanate layer confined by strontium-titanate layers by atomic-resolution scanning transmission electron microscopy (STEM). Phase-field modeling and second-principles calculations reveal that the polar skyrmions have a skyrmion number of +1 and resonant soft X-ray diffraction experiments show circular dichroism confirming chirality. Such nanometer-scale polar skyrmions exhibit a strong signature of negative permittivity at the surface of the skyrmion, which is furthermore highly tunable with an electric field. They are a new state of matter and electric analogs of magnetic skyrmions. In this talk, we will describe results of our on going work on controlling the long range order in the skyrmions and vortices as well as rigorously understanding the origins of chirality (and its electric field manipulation) in the vortex structures.

Ferroelectric Incommensurate Spin Crystal Dorin Rusu^{1,2}, Ana M. Sanchez¹, Thomas Hase¹, Richard Beanland¹ and Marin Alexe¹; ¹University of Warwick, United Kingdom; ²University College London, United Kingdom

Ferroics can form complex topological spin structures such as vortices and skyrmions, especially when subjected to particular boundary conditions. In ferroelectrics vortex-like electric dipole-based topological structures have been observed in dedicated ferroelectric systems, especially PbTiO₃/SrTiO₃ ferroelectric/insulator superlattices, which have proven to be an ideal model system due to their high depolarising field. The large electrostatic energy is minimised by local rotations of surface dipoles, similar to ferromagnetic Kittel domains, in the which local dipoles rotate in such a way to reduce both the depolarization and stray fields, avoiding the suppression of the ferroelectricity in the thin films. In single PbTiO₃ epitaxial layers sandwiched between SrRuO₃ electrodes we observe a more complex domain structure analogue of the double- magnetic spin crystal phase. This comprises of periodic clockwise and anti-clockwise ferroelectric vortices which are modulated by a second cycloidal ordering along their toroidal core. Thus, one vector determines the periodicity of vortices and a second vector breaks the uniformity of the domains in the perpendicular direction, leading to a state described by a double- modulation. The interplay of only two orthogonal periodic modulations results in the so-called incommensurate spin crystal. [1]

The presence of such a double- structure, mediated by incommensurate interactions, would require an electric counterpart of the magnetic Dzyaloshinskii-Moriya interaction (DMI). Such an electric DMI could provide the phenomenological explanation of the emergence of magnetic-like phases in ferroelectric systems.

11:30 AM *QT03.01.03

Antiferroelectric-Like Behaviour in Ferroelectric Superlattices Chunhai Yin¹, Yaqi Li¹, Edoardo Zatterin², Evgenios Stylianidis¹, Marios Hadjimichael^{1,3}, Hugo Aramberri⁴, Jorge Iniguez^{4,5}, Shelly Michele Conroy⁶ and Pavlo Zubko¹; ¹University College London, United Kingdom; ²European Synchrotron Radiation Facility, France; ³University of Geneva, Switzerland; ⁴Luxembourg Institute of Science and Technology, Luxembourg; ⁵University of Luxembourg, Luxembourg; ⁶Imperial College London, United Kingdom

Ferroelectric superlattices have proven to be an exciting platform for exploring nanoscale ferroelectricity, complex polarisation patterns, and unusual functional properties such as negative capacitance. This talk will focus on how electrostatic and mechanical boundary conditions can be exploited to realise antiferroelectric-like behaviour in ferroelectric-dielectric superlattices. Using a combination of laboratory

Updated as of October 28, 2024

and synchrotron X-ray diffraction, scanning probe microscopy, transmission electron microscopy, electrical measurements and simulations, we investigate the structure of these artificially layered materials and the origin of the antiferroelectric-like switching.

Polarization Dynamics during Ferroic Oxide Thin Film Growth Morgan Trassin; ETH Zurich, Switzerland

Ferroelectric oxide films with a thickness of just a few atoms can now be grown with a precision matching that of semiconductors. This opens a whole world of functional device concepts and fascinating phenomena that would not occur in the expanded bulk crystal. The successful integration of ferroelectrics into nanoscale devices relies however on our ability to engineer deterministically polarization states in the application relevant ultrathin regime. Here I will show how nonlinear optics enables the in-situ investigation of the ferroelectric polarization during the thin film epitaxial growth. Beyond the unprecedented access to the emergence of ferroelectricity and domain formation during the epitaxial deposition, we investigate transient polarization states originating from the evolving charge-screening environment of the oxide thin film growth process. We show the impact of lattice chemistry, depolarizing field-related effects in-situ and identify routes towards the establishment of robust polarization states in the ultrathin regime. Our work provides new insights dealing with the physics of ultrathin ferroelectrics and further control of ferroelectric-based heterostructure.

Functional Topological Defects: Materials at the Edge of Order Jan Seidel; University of New South Wales, Australia

Topological structures in ferroic functional materials such as domain walls and skyrmions attract attention due to their intriguing properties and application potential in nanoelectronics. I will discuss our recent work on various ferroelectric and multiferroic materials systems using scanning probe microscopy as the main investigative tool, which is combined with insight from electron microscopy and ab-initio theory, and discuss future prospects of this evolving research field.

2:30 PM *QT03.02.03

Modeling Spin-Control by Ferroelectric Switching Katherine Inzani; University of Nottingham, United Kingdom

A key advantage of spin-defect based quantum technologies is the potential to engineer the defect properties by modifying the atomic environment. Systems which exhibit coupling between magnetic and electric degrees of freedom provide a route to manipulate spins by applying an electric-field, suggesting the prospect of localized spin-control via electrostatic gating.

We have elucidated the fundamental limit of magnetoelectric coupling by electric-field control of magnetic dopants in ferroelectric hosts, demonstrating through combined first principles calculations and electron-paramagnetic resonance measurements that the spin directionality evolves following a switching path coupled to polarization switching.[1]

We further leverage the versatility of the ferroelectric oxide platform by modifying the crystal field environment of the defect through epitaxial strain, low symmetry hosts and emergent topological polarization textures.[2,3] Results demonstrating spin-control in these systems provide an enhanced understanding of spin-charge coupling in defect systems and offer novel routes to tailored spin-control in ferroelectric crystals.

Translational Boundaries of Antiferroelectrics as Topologically-Protected Polar Domains Gustau Catalan^{1,2} and Ying Liu³; ¹Institut Catala de Nanociencia i Nanotecnologia, Spain; ²ICREA, Spain; ³The University of Sydney, Australia

Antiferroelectric materials are characterized by their antipolar dipole arrangement. Such antipolar arrangements can be disrupted by so-called translational boundaries, which separate antiferroelectric domains where the dipolar ordering is the same, but shifted by an integer number of sub-lattice units. The simplest manifestation of such translational boundaries are antiphase boundaries, where two adjacent domains are separated by half a unit cell. The antiferroelectric archetype, PbZrO_3 , has an unit cell that contains four dipoles, and in theory it can therefore have up to three types of translational boundaries, whereby the dipolar arrangement across the boundary is shifted by $\pi/2$, π or $3\pi/2$. Experimentally, however, we have observed “translational boundaries” with an arbitrary number of unit cells, resulting in phase shifts bigger than 2π . These are de-facto polar domains with their own internally symmetry, polarization and electric field response. But, while they are domains, they are also, still, translational boundaries topologically constrained by their adjacent antiferroelectric domains. The dual nature of these ultra-wide translational boundaries and their functional consequences will be discussed in the talk, together with experimental evidence for their existence.

Intertwined Dislocation Grids and Nematic Domains in an Iron-Based Superconductor Thin Film

Zheng Ren, Hong Li, He Zhao, Sharma Shrinkhala, Ziqiang Wang and Ilija Zeljkovic; Boston College, United States

A dislocation is a topological defect in a crystal lattice and can be associated with many functional properties. Dislocations can spontaneously form in epitaxial thin films as a strain relief mechanism. Here, we synthesize an iron-based superconductor thin film FeSe epitaxially on the SrTiO₃ substrate. Using scanning tunneling microscopy, we discover a structural modulation network, corresponding to a grid of edge dislocations at the film/substrate interface. We observe a striking change of the orientation of the dislocation lines as a function of the film thickness. Interestingly, since the edge dislocation grid gives rise to a spatially-varying uniaxial strain field, the formation of the nematic domains in FeSe is intimately intertwined with the dislocation grid. We further analyze their relationship by extracting the strain maps from the atomically-resolved topographs. Our finding provides an unexpected example of the formation and evolution of a dislocation grid in an epitaxial film, which is closely tied to the emergent nematic order of the iron-based superconductor FeSe.

Multiphoton Spectroscopy of a Dynamical Axion Insulator Olivia Liebman, Jonathan Curtis, Ioannis Petrides and Prineha Narang; UCLA, United States

The unusual magnetoelectric transport present in Weyl semimetals can be compactly understood as manifestations of an underlying axion field, which itself is determined by the microscopic band structure. The axion couples nonlinearly to electric and magnetic fields and possesses a signature topological magnetoelectric response, leading to a modified form of Maxwell's equations known as axion electrodynamics. Axions are naturally present in Weyl semimetals relating to the separation of the Weyl nodes in energy and in crystal momentum. In the presence of strong interactions, charge density-wave (CDW) order may develop which serves to gap the Weyl nodes and introduces corresponding collective excitations. When the inherent chiral symmetry of Weyl semimetals is spontaneously broken by the formation of CDW order, the resultant chiral condensate is endowed with intrinsic dynamics which yields a dynamical contribution to the axion field. However, unambiguous identification of this dynamical axion mode is challenging due to its inherent nonlinear coupling to electromagnetic fields. Therefore, we propose an all-optical protocol for verifying and characterizing dynamical axion collective modes in Weyl semimetals with CDW order. First, we show that axion collective mode can be excited using two-photon excitation schemes. Following excitation, the collective axion oscillations are then diagnosed by measuring the time-resolved Kerr rotation. Our results demonstrate a pathway towards utilizing multi-photon and entangled pair spectroscopies to identify new correlated phases in quantum matter.

Controlling Magnetotactic Bacteria, Their Topological Properties and Generating Skyrmions in Their Polar and Non-Polar Velocity Vector Fields Noah Kent^{1,2}, Colin Gates², Bohdan Senyuk², Jan Bart Ten-Hove², Jeffery Cameron² and Ivan Smalyukh^{2,2}; ¹Massachusetts Institute of Technology, United States; ²University of Colorado Boulder, United States

Magnetotactic bacteria are microorganisms containing magnetite magnetic nanoparticle (MNP) bacteria organelles called magnetosomes. Magnetosomes are often arrayed in a specific pattern for a given strain of magnetotactic bacteria (i.e. a line along the long axis of the bacterium) and are made via biomineralization of ferromagnetic elements [1]. Previous work on the behavior of magneto-tactic bacteria in magnetic fields has assumed that the magnetic structure is a rigid dipole fixed along the

bacteria's long axis – the direction of bacterial propulsion [1,2]. Such models have successfully elucidated the bacteria's behavior in rotating external fields, and magnetic field gradients. However, such models fail to explain the bacteria's behavior in a uniform magnetic field, do not allow for direct directional control over a set of bacteria, and do not address the inherent energetic degeneracy present in uniaxial magnetic systems [1,2].

Additionally, in recent years there has been significant research on topological structures, such as skyrmions and hopfions, in both magnetic [3] and soft matter liquid crystal systems [4] due to their stability and technological potential. Magnetic systems and soft matter systems typically differ in the nature of their order parameter: Magnetic systems have a polar order parameter and soft matter systems have a non-polar (axial) order parameter. No topological structures have been observed in magnetotactic bacteria despite both their magnetic and soft matter properties.

In this work we combine nanomagnetic simulations of magnetosome arrays distributions with transmission electron microscopy to simulate the magnetic behavior of the magnetotactic bacteria. Combining this with experiments using phase contrast optical microscopy and in-situ magnetic fields allowed us to understand the magnetic field response of bacteria based on how their magnetosomes are arranged. This allows us to explain previously anomalous behavior in the bacteria, control large, in phase groups of bacteria directly with external uniform magnetic fields, selectively change the topological parameter space from polar to non-polar, and generate topological structures in both the polar and the non-polar velocity vector fields of the bacteria. Being able to directly control these bacteria with external magnetic fields opens up the possibility of using them as guided microrobots in biomedicine (e.g. magnetic hyperthermia, drug delivery) and bio-spintronics.

Modified Landau-Lifshitz-Gilbert Dynamics Elucidating Asymmetric Spin Transport in NM/FM System Chanho Park and Sangkwon Lee; Chung- Ang University, Korea (the Republic of)

Spin pumping, usually referred as the injection of the spin current pumped by thermal agitation of non-equilibrium magnetization in ferromagnetic (FM) or ferromagnetic insulator (FMI) materials,¹ has been granted trivial without any further discussion on the pumped direction (FM to NM / NM to FM, where NM refers to normal metal). The pumped spin current from FM to NM results from temperature gradient ranged between FM and NM. Over the decade, spin pumping has been investigated thoroughly armed

with theories such as linear response theory,¹ and considered consistent with conducted experiments on spin-to-charge conversion. Theoretically, reversing the direction of the temperature gradient should invert the sign of the spin current signal, but its intensity is identical between the two configurations. On the other hand, repeated experiments on Pt/YIG bilayer structure with temperature gradient up to 20 K (-20 K for opposite direction) shows inconsistency between the experiment and theory, where the experiment kept showing nonlinearities between FM \rightarrow NM, NM \rightarrow FM pumped spin current. Herein, we assumed there exists corrections on some parameters when changing the injected direction of the pumped spin current, and carefully suggest modified LLG approach where different magnon lifetime contributes to the asymmetric spin transport across NM/FM interface. However, these kind of minor rectification cannot be solely explained with modified LLG, as additional experimental factors also contributes to the nonlinearities of the spin current signal, such as the change in the average temperature at the Pt/YIG interface depending on the direction of thermal gradient and resultant temperature-dependent spin voltage originated from the temperature dependence of the spin-Seebeck coefficient $S(T)$,² and turned out to be sometimes more dominant than purely rectified spin current originated from interface-dependent magnon lifetime in our model. Nevertheless, the model suggested would provide meaningful applications for pure spin accompanied transport aided by material selection, configuration of spin voltage detecting device.

8:00 PM QT03.03.02

Nonreciprocal Edge Transport in Superconducting Devices with Magnetic Control Junyi Zhao¹, Kieran Bozier¹, Anna Chesca¹, Hisakazu Matsuki¹, Adrian Ionescu¹, Leyla C. Arslan², Nadia Stelmashenko¹, Francesca Chiodi³ and Jason W. Robinson¹; ¹University of Cambridge, United Kingdom; ²Gebze Technical University, Turkey; ³Université Paris-Saclay, France

The proximity effect at a superconductor interface with a ferromagnet layer (S/F) can lead to unconventional electron pairing [1-3] and nonreciprocal edge transport (i.e., a superconducting diode effect (SDE)) [4,5]. The underlying mechanism of the SDE can have mixed origins related to spin-orbit coupling (SOC) or vortex flow with a geometrically asymmetric pinning potential in S and at S/F interfaces in mesoscopic wires [6-8]. Here we report an experimental investigation of the SDE and edge transport in superconducting (Nb, V and RhS) wires interfacial magnetism and/or Rashba SOC versus layer thickness, wire width, temperature and microstructure. The F layer in conjunction with interfacial SOC should affect the pinning potential along the edge regions of an S/F wire and modulate vortex dynamics, driving a nonreciprocal supercurrent [9,10]. Our experiments form a framework for understanding and optimizing the SDE in superconducting wires with the aim of achieving full magnetic control of charge and potentially spin for superconducting quantum devices.

Martin^{1,2,9}; ¹University of California, Berkeley, United States; ²Lawrence Berkeley National Laboratory, United States; ³The Pennsylvania State University, United States; ⁴Cornell University, United States; ⁵Westlake University, China; ⁶Westlake Institute for Advanced Study, China; ⁷Indian Institute of Science, India; ⁸University of Southern California, United States; ⁹Rice University, United States

Emergent topological polar textures, including vortices, dipolar waves, skyrmions, merons, hopfions, and more, have generated considerable interest in ferroelectrics and wider condensed-matter physics communities. The delicate balance of electric, elastic, and gradient energies of ferroelectrics can be tailored in low-dimensional forms and nanostructures to manipulate the order parameters. Exotic functional properties (*e.g.*, the coexistence of phases, chirality, negative capacitance, and emergent ultrafast dynamical responses) make them interesting candidates for devices. Ferroelectric-dielectric superlattices such as $(\text{PbTiO}_3)_n/(\text{SrTiO}_3)_n$ have been widely studied as a model system in part due to the high depolarizing field boundary condition provided by the SrTiO_3 layer. Such layers, however, limit the incorporation of such heterostructures into devices that could use the electronic characteristics of these polar topologies.

Looking to expand upon this rich design space, we ask a simple question: can similar emergent dipolar textures be produced in all-ferroelectric heterostructures while providing additional tunability based on the susceptibilities of the constituent layers? Here, we demonstrate the formation of polar vortices in all-ferroelectric $\text{Pb}_{1-x}\text{Sr}_x\text{TiO}_3/\text{PbTiO}_3/\text{Pb}_{1-x}\text{Sr}_x\text{TiO}_3$ trilayer and $(\text{Pb}_{1-x}\text{Sr}_x\text{TiO}_3)_n/(\text{PbTiO}_3)_n$ superlattice structures wherein $0.5 < x < 1$ grown on DyScO_3 (110) substrates. Unlike their counterparts with SrTiO_3 , the $\text{Pb}_{1-x}\text{Sr}_x\text{TiO}_3$ layers exhibit robust, in-plane ferroelectric polarization and domain structures, but still provide the appropriate boundary condition for the formation of polar vortices in the PbTiO_3 layers. We describe the manifestation of complex polar order in these structures that combines traditional ferroelectric order with emergent dipolar textures. Reciprocal space mapping studies reveal that the

strontium content in the $\text{Pb}_{1-x}\text{Sr}_x\text{TiO}_3$ provides a fine control knob over the vortex periodicity; as supported by molecular-dynamics simulations. Furthermore, while recent studies on in-plane ferroelectric switching of polar vortices showed classical bi-stable switching, here, the in-plane polarization component of the vortices in the PbTiO_3 layers and the ferroelectric domains in the $\text{Pb}_{1-x}\text{Sr}_x\text{TiO}_3$ layers exhibit strong elastic and dipolar coupling, leading to a coercivity enhancement of the trilayer stack upon decreasing the strontium content of the $\text{Pb}_{1-x}\text{Sr}_x\text{TiO}_3$. Phase-field simulations further explain the polarization arrangement in the trilayer and the system's subsequent collective switching pathway of the two order parameters. Formation of such in-plane domains in the $\text{Pb}_{1-x}\text{Sr}_x\text{TiO}_3$ leads to the formation of a labyrinthine vortex arrangement, unlike the highly unidirectional vortices observed in $(\text{PbTiO}_3)_n/(\text{SrTiO}_3)_n$ superlattices. Further, we have explored the coupling between different emergent dipolar heterostructures of the form $\text{Pb}_{1-x}\text{Sr}_x\text{TiO}_3/\text{PbTiO}_3/\text{Pb}_{1-x}\text{Sr}_x\text{TiO}_3/\text{SrTiO}_3/\text{PbTiO}_3/\text{SrTiO}_3$. Therein, the thickness of the SrTiO_3 layer separating the two vortex structures controls the strength of the elastic and electric fields that extend between layers, affecting the sequence in which each trilayer would switch and the number of switching events. The result is an ability to produce low-field multi-state, four-step switching with robust retention and fatigue performance. Finally, in $(\text{Pb}_{1-x}\text{Sr}_x\text{TiO}_3)_n/(\text{PbTiO}_3)_n$ superlattices, we have explored the dielectric tunability, ac electric-field-induced surface displacement, and out-of-plane switching and found improved tunability as a function of the chemistry of the $\text{Pb}_{1-x}\text{Sr}_x\text{TiO}_3$ layer, antiferroelectric-like switching due to an unraveling of the vortex phase upon application of the electric-field, and strong back switching on releasing the same leading to improvements in the low-field energy storage as compared to $(\text{PbTiO}_3)_n/(\text{SrTiO}_3)_n$.

9:00 AM *QT03.04.02

Electric Bubble Quasiparticles Jorge Iniguez^{1,2}; ¹Luxembourg Institute of Science and Technology, Luxembourg; ²University of Luxembourg, Luxembourg

My group is interested in the behavior of ferroelectric materials that present non-trivial polar orders and properties in situations of reduced dimensionality (ultra-thin layers or films) or subject to suitable electric and mechanical boundary conditions. Such intriguing phenomena include vortices [1], skyrmions [2], chirality [3] and negative capacitance [4,5], to name a few. In this talk I will review our most recent theoretical results for one of the model systems in the field, the $\text{PbTiO}_3/\text{SrTiO}_3$ ferroelectric/dielectric superlattices where many of the above effects were first demonstrated. In particular, I will discuss the dynamical behavior of the polarization in these nano-ferroelectrics, paying especial attention to the state we call "domain liquid" [4], which is characterized by a spontaneous stochastic motion of the domains. I will further show that, under the action of an external electric field, the domains break into electric bubbles (e-bubbles) that can be very long-lived and display (fast) Brownian dynamics. I will show quantitative results for e-bubble stochastic diffusion, compare with the behavior of Brownian skyrmions [6], and briefly discuss potential applications in unconventional computing.

Work done in collaboration with Hugo Aramberri (Luxembourg Institute of Science and Technology), F. Gómez-Ortiz and J. Junquera (University of Cantabria, Spain). My work is funded by the Luxembourg National Research Fund through Grants C18/MS/12705883/REFOX and C21/MS/15799044/FERRODYNAMICS.

10:00 AM *QT03.04.08

Interferometric Nano-Electromechanics: Accurate, Real Space Measurements of Textured Nanoscale Polar Structures Roger Proksch; Asylum Research, United States

Last year marked the 30th anniversary since piezoresponse force microscopy (PFM) was demonstrated on ferroelectric polymers by Güthner and Dransfield. Since then, it has emerged as the preeminent nanoscale approach to characterizing electromechanical response and is commonly used to map nanoscale polar structure. The recent trend of non-conventional, weaker materials has accelerated the PFM reporting of “strange ferroelectrics” – synonymous with materials that are mistakenly interpreted as ferroelectric due to measurement crosstalk and other artifacts. Interferometric AFM has proven to be a powerful tool for eliminating crosstalk and accurately quantifying nanoscale polar structures in a variety of emerging 2D and beyond Moore’s law materials. Building on those past successes, we have developed a new quadrature phase differential interferometer (QPDI) based detector. The QPDI detector allows crosstalk-free mapping of polarization structures with a detection noise floor of . This low noise translates to a >10x noise improvement in typical sub-resonant PFM measurements. We will discuss recent measurements using this detector, with a focus on textured polar materials.

10:30 AM QT03.04.05

Mapping Local Topology, Defects and Emergent Order of Picometer-Scale Periodic Lattice Modulations Benjamin H. Savitzky; Lawrence Berkeley Laboratory, United States

In complex condensed matter systems, patchworks of order and disorder can form in competing order parameters, with localized pockets of emergent symmetry breaking which may be mere nanometers across. Measuring the real space variation of emergent order and its defects is therefore essential. By combining in-situ cryogenic (77K) high-angle annular dark-field scanning transmission electron microscopy, fast-acquisition low-SNR referenceless image registration with lattice-hop-error correction, picometer precision atomic column gaussian fitting, and isolation and reconstruction of both the underlying and symmetry broken lattices in Fourier space, it becomes possible to map modulations of the lattice parameter at each atomic site with picometer precision. Alternatively, real space measurement of periodic lattice modulations is possible using phase lock-in methods popular in scanning tunneling microscopy, geometric phase analysis more common in transmission electron microscopy, pairwise atomic distance histograms in one or two dimensions, and other methods. The advantages and drawbacks of these various approaches to uncovering the structure and topology of lattice symmetry breaking in real space will be discussed and compared, with examples drawn from complex oxides and transition metal dichalcogenides.

10:45 AM *QT03.04.06

Imaging Topological Textures from the Pico to Micro Scale with Electron Ptychography David A.

Muller; Cornell University, United States

The discovery of non-trivial topological textures, including flux-closure, vortices, skyrmions, merons and hopfion in both ferromagnetic and ferroelectric systems have required electron microscopy to resolve their internal structures. Here, enabled by a new design of electron detector [1] that is capable of measuring the complete distribution of momentum transfers at every probe position, we construct a 4-dimensional phase space from which we solve the inverse multiple scattering problem and retrieve the underlying 3-dimensional potential of the sample. The lateral resolution of less than 20 pm is now limited not by the instrument, but by the thermal vibrations of the atoms themselves, and the precision is improved to well below 1 pm [2]. The resulting ptychographic reconstructions have allowed us to image the internal structures of both magnetic and ferroelectric vortices, skyrmions and merons, including their singular points that are critical for accurately describing the topological properties of these field textures. Emergent Picosecond-Scale Dynamics of Nanoscale Ferroelectric Polarization Configurations Paul G. Evans; University of Wisconsin, United States

Ferroelectric thin films and superlattices with nanoscale dimensions exhibit a competition of energetic phenomena that produce configurations of the polarization that are distinct from bulk materials. These configurations have a profound effect on the equilibrium and driven dynamics of the nanoscale material. These dynamics are coupled to the structure of these layers and can be observed in synchrotron radiation or free-electron-laser structural studies. For example, the nanoscale polarization configuration of $\text{PbTiO}_3/\text{SrTiO}_3$ (PTO/STO) superlattices, for example, exhibits equilibrium fluctuations that arise from the existence of many configurations with nearly identical free energy. The optically driven dynamics of the PTO/STO superlattice include a picosecond-scale distortion of the polarization in response to the optically induced acoustic pulse and a change in the magnitude of the polarization of the PTO due to polarization screening. The effect of polarization screening is comparatively larger in a strongly $\text{BaTiO}_3/\text{CaTiO}_3$ (BTO/CTO) superlattice. In BTO/CTO superlattice screening effects following above-bandgap excitation lead to a reduction in the polarization of the CaTiO_3 layer, evident as a contraction of the out-of-plane lattice parameter of the CaTiO_3 component. The characteristic timescale for the development of these effects is on the scale of several picoseconds to tens of picoseconds, set by the

propagation of acoustic pulses through the system. Further picosecond-scale diffraction studies reveal that the nanoscale structure affects the longitudinal acoustic sound velocity. There are prospects to employ these effects to affect structural parameters such as the oxygen octahedral tilt that affect other properties of ferroelectrics as well as the magnetism of multiferroics.

Transferring Orbital Angular Momentum to an Electron Beam Reveals Toroidal and Chiral Order Kayla X. Nguyen^{1,2}; ¹University of Illinois at Urbana-Champaign, United States; ²University of Oregon, United States

Orbital angular momentum and torque transfer play central roles in a wide range of magnetic textures and devices including skyrmions and spin-torque electronics. Unlike magnetic toroidal order, electric toroidal order, found in analogous topological structures in ferroelectrics, do not couple directly to linear external fields. Instead, we show that the presence of an electric toroidal moment in a ferro-rotational phase transfers a measurable torque and orbital angular momentum to a localized electron beam in the ballistic limit. We record these torque transfers from a high-energy electron beam using a momentum-resolved detector. This approach provides a high-sensitivity method to detect polarization fields and their more complex order parameters and topologies. In addition to toroidal order, we also demonstrate high-precision measurements of vorticity and chirality for polar vortex-like phases¹.

Phase Transformations in 2D Van der Waals Trichlorides: Insights from Cryogenic Scanning Transmitting Electron Microscopy Miaofang Chi; Oak Ridge National Laboratory, United States

Two-dimensional (2D) van der Waals (vdW) materials and their heterostructures offer an exceptional platform for investigating intriguing physical phenomena and implementing diverse applications. While it is widely acknowledged that lattice structural transformations often coincide with changes in electronic and spin structures, leading to the emergence of exotic quantum phenomena, it remains uncertain whether the same structural transformations observed in bulk materials also occur in thin flake samples. As a result, a comprehensive understanding of the structure-property relationship in multi-layered 2D vdW materials is often lacking. In our recent studies, we aim to unveil the thickness-dependent phase transformations and changes in exciton states in several model 2D vdW trichlorides. To achieve this, we employ state-of-the-art techniques such as cryogenic atomic-resolution scanning transmission electron microscopy (STEM) and monochromated electron energy loss spectroscopy (EELS). By analyzing these materials with different numbers of layers at the atomic level, our findings provide insights into the layer-number-dependency that are crucial for harnessing the unique quantum characteristics of thin-layer 2D vdW materials in various device applications.

Differential Phase Contrast STEM Imaging of Topological Structures Naoya Shibata; The University of Tokyo, Japan

Differential phase contrast scanning transmission electron microscopy (DPC STEM) is a powerful

technique for directly characterizing local electromagnetic field distribution inside materials and devices. In recent years, new magnetic objective lens system that realizes a magnetic field free environment at the sample position has been developed [1]. The novel electron microscope with this new objective lens system (Magnetic-field-free Atomic Resolution STEM: MARS) combined with DPC imaging is very useful for characterizing many important topological structures. In this talk, some recent applications using MARS will be presented. The topics include atomic-scale grain boundary structure analysis in Fe-Si soft magnet [2], domain wall width measurements in magnets [3], magnetic field imaging of spin devices [4], domain imaging in magnetic quasicrystals, imaging of magnetic skyrmions, imaging of ferroelectric domain walls and so on.

The Dynamics of Magnetic Helices in an Amorphous Material with Coherent X-Rays Sophie Morley¹, Arnab Singh¹, Ryan Tumbleson^{1,2}, Emily Hollingworth³, Ahmad Us Saleheen¹, Margaret McCarter¹, Peter Fischer^{1,2}, Frances Hellman³, Stephen Kevan¹ and Sujoy Roy^{1,2}; ¹Lawrence Berkeley National Laboratory, United States; ²University of California, United States; ³University of California, Berkeley, United States

Synchrotron x-rays are a powerful element-specific probe for the electronic and magnetic ordering of a material. Here we measure the diffraction from a magnetic helix of pitch ~ 80 nm in a structurally amorphous FeGe thin film through its magnetic phase transition. We select the coherent part of the x-ray beam to produce an interference pattern known as speckle. The speckle pattern acts as a fingerprint of the specific microscopic configuration of the helical domains and their disorder. Taking speckle patterns as a function of time gives us a way to characterise the dynamics over ~ 10-micron field of view but with nanoscale spatial sensitivity and ms to hour time sensitivity. We identify static and dynamic parts of the speckle throughout the transition which follow a universal behavior over several compositions [1]. We extract faster dynamics at temperatures much lower than the transition temperature which we attribute to the motion of topological defects and on increasing temperature we observe on average slower fluctuations but from a larger volume of the sample. We have also performed micromagnetic simulations to model these disordered helical spin structures in support of our experimental findings.

Behavior of Magnetic Skyrmions Lattices at the Nanoscale Observed using *In Situ* Lorentz

Transmission Electron Microscopy Amanda K. Petford-Long^{1,2}, Yue Li¹, Arthur McCray^{2,1} and Charudatta Phatak^{1,2}; ¹Argonne National Laboratory, United States; ²Northwestern University, United States

Understanding the behavior of nanoscale magnetic structures relies on being able to understand the complex interplay of the energy terms that control this behavior at a local scale. The relative contribution of these energy terms can be modified by parameters such as geometric confinement and interactions between adjacent magnetic nanostructures. In addition, it is important to be able to explore how a magnetic nanostructure responds to an external driving force, such as temperature, and electric or magnetic fields. We use Lorentz transmission electron microscopy (LTEM) combined with in-situ magnetizing and cooling experiments to elucidate the micromagnetic behavior at the sub-micron scale in nanomagnetic structures. By comparing the experimental and simulated results we gain a detailed understanding of the way in which the various energy terms contribute to the behavior that we observe.

The focus of this presentation will be on thin films of van der Waals materials that host magnetic skyrmions and other topological spin structures in which we make use of cryoEM to explore the way in which order in the skyrmions lattices evolves, the origin of this behavior, and the energy terms that control the behavior as a function of temperature and applied field.

Observation of Magnetic Resonance Modes in Polar Skyrmion Material VOSe₂O₅ Araki Tomonao¹, Takashi Kurumaji¹, Masahito Mochizuki², Yoshinori Tokura^{1,1,3}, Rina Takagi^{1,4} and Shinichiro Seki^{1,4}; ¹The University of Tokyo, Japan; ²Waseda University, Japan; ³Japan Science and Technology Agency (JST), Japan; ⁴RIKEN, Japan

The magnetic skyrmion is a vortex structure of electron spins that behaves as a stable particle protected by topology. VOSe₂O₅ is a magnetic insulator with a polar crystal structure (space group *P4cc*) and is one of a few materials that have been confirmed to exhibit a Néel-type magnetic skyrmion lattice [1, 2]. In this study, we experimentally investigate the microwave response of VOSe₂O₅ to clarify the magnetic resonance dynamics. As a function of temperature and magnetic field, this compound hosts a rich variety of magnetic phases, including the triangular skyrmion lattice (tri. SkL) and cycloidal spin states. In the tri. SkL phase, clockwise mode (CW), counterclockwise mode (CCW), and breathing mode (BR) have been identified. We also identified three distinctive magnetic resonance modes in the cycloid spin state, which corresponds to the rotational oscillation of local magnetic moment around the *x*, *y*, and *z* axes, respectively. The observed magnetic resonance spectra are well reproduced by theoretical calculations based on the magnetic Hamiltonian considering the Dzyaloshinskii-Moriya interaction and uniaxial anisotropy. The present results will contribute to the general understanding of the coherent dynamics of skyrmion and helical spin states in polar magnetic systems.

9:15 AM QT03.06.03

Effects of Dirac Band Tilting on Thermomagnetic Properties in Weyl Semimetals Eleanor Scott¹, Poulomi Chakraborty², Satya Guin^{3,4}, Brian Skinner² and Sarah J. Watzman¹; ¹University of Cincinnati, United States; ²The Ohio State University, United States; ³Max Planck Institute for Chemical Physics of Solids, Germany; ⁴Birla Institute of Technology and Science, India

The topological and semimetallic effects of Weyl semimetals make them excellent candidates for magneto-thermoelectric transport. Previous work in the thermoelectric properties of Type I Weyl semimetals (WSMs) has found that this class of materials possess both a large magneto-Seebeck effect and Nernst effect simultaneously, is very sensitive to doping, and that magneto-thermoelectric effects are maximized when the temperature is comparable to the Fermi energy. [1, 2]. Here, we shift our focus to Type II WSMs, which possesses asymmetric Dirac bands, unlike the band symmetry assumed in Type I WSMs. Our candidate material is WTe₂, and previous single-crystalline data observed an extremely large Nernst thermopower, exceeding 7,000 $\mu\text{V K}^{-1}$ at 11.3 K and 9 T [3]. However, literature does not include full magneto-thermoelectric transport data over a broad temperature range, which we present here in polycrystalline WTe₂. Experimental results indicate that unlike the behavior observed in the Type I WSM [1], the magneto-Seebeck effect is significantly reduced and is not maximized in the same temperature range as the Nernst effect. Additionally, the Nernst thermopower of this Type II WSM did not exhibit an anomalous Nernst effect beyond cryogenic temperatures, while NbP, a Type I WSM, exhibited anomalous behavior over a broad temperature range.

Our experimental work is complemented by theoretical models of the thermoelectric transport behavior. Previous theoretical models created for the NbP work matched well with the transport behavior seen in the experimental results. This model is then altered to account for the tilted band structure and transport properties specific to WTe₂. By comparing both the experimental and theoretical results of thermoelectric transport in NbP and WTe₂, we can determine how the tilting of Dirac bands effects magneto-thermoelectric transport behavior in WSMs.

Thin-Film Realization of an Improper Ferroelectric Quantum Spin Liquid Candidate Johanna Nordlander^{1,2}; ¹Harvard University, United States; ²Paul Drude Institute for Solid State Electronics, Germany

Magnetically frustrated materials offer a playground for realizing exotic magnetic ground states such as quantum spin ices and spin liquids that have been proposed as building blocks in quantum computing and as potential hosts for unconventional superconductivity. The ability to synthesize such materials in thin-film form is necessary for their integration into the proposed device architectures and also allows further tuning of the magnetic ground state with dimensionality and epitaxial strain. However, thin-film realizations of quantum spin liquid candidate materials remain scarce. Here, we use reactive oxide

molecular beam epitaxy to synthesize the first thin films of hexagonal TbInO_3 , a magnetically frustrated rare-earth system that was recently proposed as a spin liquid candidate. In bulk, TbInO_3 exhibits geometrically driven improper ferroelectricity similar to the multiferroic hexagonal manganites, and displays the same topologically protected vortex domain pattern. The underlying lattice distortion causing this domain pattern imposes a stuffed honeycomb geometry on the quasi-two-dimensional Tb^{3+} sublattice which harbors the magnetic frustration in TbInO_3 . Here, we investigate the ferroelectric distortion in our epitaxial TbInO_3 thin films using in-situ RHEED and post-deposition HAADF-STEM. We furthermore use SQUID magnetometry and X-ray spectroscopy to investigate the low-temperature magnetic behavior. Our work constitutes one of the few thin-film realizations of a quantum spin liquid candidate, and opens up for the use of epitaxy to further manipulate the unusual coexistence of ferroelectricity and spin liquid physics in this thin-film system.

Large Anomalous Frequency Shift in Perpendicular Standing Spin Wave Modes in BiYIG Films Induced by Thin Metallic Overlayers Byunghun Lee, Takian Fakhrol, Caroline A. Ross and Geoffrey Beach; Massachusetts Institute of Technology, United States

Interface-driven phenomena in magnetic insulators is gaining attention owing to the possibility to control magnetization dynamics and magnetic textures in low-dissipation materials. Pure spin signals can be transported in magnetic insulators through magnon excitations, and controlling the nature of these excitations may lead to new insights into magnetization dynamics and novel spin wave devices. [1] In this work, the influence of metallic overlayers on the spin wave dynamics of thin Bi-substituted yttrium iron garnet films is studied using Brillouin light scattering spectroscopy. [2] It is found that the magneto-static Damon-Eschbach modes exhibit a significant frequency shift when Pt, Au, or Cu films are deposited upon them, which arises from an interfacial contribution to the effective magnetic anisotropy. In addition, there is an unexpectedly large shift in the perpendicular standing spin wave mode frequencies that cannot be explained by anisotropy-induced surface spin pinning. Rather, the experimental observations are consistent with an interface-induced decrease in the effective thickness within which the standing waves are confined, increasing the exchange contribution to the mode frequency. It is suggested that this additional confinement may result from spin pumping at the insulator/metal interfaces, which results in a locally-overdamped interface region. We propose a phenomenological model that can describe the observation in terms of an interfacial region where the spin-orbit coupling plays a crucial role and the local effective damping associated with spin-pumping torque is relatively large, which would qualitatively explain the anomalously-large metal-induced frequency shifts. [3] These results uncover a previously-unidentified interface-driven change in magnetization dynamics that may be exploited to locally control and modulate magnonic properties in extended films.

10:45 AM QT03.06.06

The Effects of Doping on the Magnetic Transition Regions of the Skyrmion Hosting Material, Cu_2OSeO_3 Marco Vas^{1,2}, Alexander Ferguson^{1,2}, Joseph Vella^{1,2}, Clemens Ulrich³, Samuel Yick^{1,2}, Tilo Soehnel^{1,2} and Elliot Gilbert⁴; ¹The University of Auckland, New Zealand; ²MacDiarmid Institute of Advanced Materials & Nanotechnology, New Zealand; ³University of New South Wales, Australia; ⁴Australian Nuclear Science and Technology Organisation, Australia

The Cu_2OSeO_3 material system has gained a lot of interest over the last 10-15 years because it is the only multiferroic insulator known to host magnetic skyrmions. This material falls into a B20 class which has a non-centrosymmetric cubic crystal lattice and crystallises in a $P2_13$ space group. Most materials in this class, such as MnSi , FeGe , and $\text{Fe}_{1-x}\text{Co}_x\text{Si}$, despite having different compositions, have been observed to host magnetic skyrmions.¹ This suggests that the role of the crystal structure might influence the capability of the material to host skyrmions. The skyrmion formation is a result of the four different Cu^{2+} sites, which have a 3-down 1-up spin arrangement with Ferromagnetic (FM) and Antiferromagnetic (AFM) super-exchange interactions being present.² The lack of inversion symmetry in the corner shared O- Cu_4 tetrahedra result in an appreciable Dzyaloshinskii–Moriya interaction (DMI) between Cu^{2+} sites; this competes with the super-exchange interactions leading to spin canting that underpins the formation of helical/conical spin textures (depending on temperature and applied magnetic field strength).³ However, due to these systems' complex spin and charge interactions, the underlying quantum-mechanical processes behind these phenomena are still not fully understood. Further experiments are required; as such, this project aims to provide details on the roles played by the crystal structure that may enable the magnetic structures observed in different conditions.

For this project, the focus is on the relationship between the crystal structure and the magnetic structures observed in the Cu_2OSeO_3 material system. By manipulating the magnetic Cu sites and non-magnetic Se sites, the spin interactions between the magnetic sites will change, resulting in changes to the interacting Heisenberg and Dzyaloshinskii-Moriya interactions that are known to form skyrmions. These interactions are highly localised between magnetic ions, which makes them sensitive to spatial changes. Non-magnetic doping of substituting Te into the Se sites results in chemical pressure and expansion of the unit cell, which changes the spacing between atoms and the subtle crystal distortions should have an impact on these interactions. While magnetic doping by substituting Co^{2+} into the Cu^{2+} sites should have a large impact on these magnetic interactions due to the Co^{2+} ion having a stronger moment than Cu^{2+} . This, in turn, should change the nature of the formation of magnetic skyrmions in this material. Understanding the role that subtle distortion to the magnetic network plays on the formation and stability of topological spin structures will be vital in designing materials for spintronics. This might, in fact, provide a guide in developing ambient condition spintronics materials, in which their absences have hindered the technological application of these topological spin structures.

We will present data from high-resolution synchrotron powder XRD and neutron powder diffraction to present the effects of magnetic and non-magnetic doping on both the crystal and magnetic structure of the material. Along with small-angle neutron scattering to confirm the presence of the helical and skyrmion phases. While in-depth SQUID magnetometry measurements were carried out to see the effects of doping on magnetisation. This collection of data aims to build an understanding of how the crystal structure plays a more important in the formation of skyrmions than is currently believed in literature.

11:00 AM QT03.06.07

Characterization of the Anisotropic Anomalous Nernst Effect in Canted Antiferromagnetic YbMnBi_2 and YbMnSb_2 Katherine A. Schlaak¹, Shuou Liu², Chenguang Fu² and Sarah J. Watzman¹;

¹University of Cincinnati, United States; ²Zhejiang University of Technology, China

Recent research in the field of thermoelectrics (TEs) has been focused on transverse TE devices which surpass their traditional longitudinal counterparts in a few facets, including their elimination of complex n- and p-type legs in exchange for one material whose TE output scales with device size. However, transverse TE materials require a magnetic field for operation, which can increase the complexity of device design. Though ferromagnetic materials have been shown to exhibit anomalous thermoelectric transport in the absence of magnetic field, these materials often have a large magnetization which can negatively impact electronic components in device applications. Canted antiferromagnetic topological semimetals, such as YbMnBi₂ and YbMnSb₂, have been shown to exhibit these large anomalous effects with low magnetization and high mobility, thus making them reasonable candidates for transverse TE applications.

Previous research on single crystalline YbMnBi₂, a Weyl semimetal, reported a notably large anomalous Nernst conductivity of $\sim 10 \text{ A m}^{-1} \text{ K}^{-1}$ near 80 K, owing to the contribution of Mn to a non-zero Berry curvature and the strong spin-orbit coupling associated with Bi [1]. In addition to this large anomalous Nernst conductivity, YbMnBi₂ is highly anisotropic, which is beneficial in device applications as it allows for simultaneously low electrical resistivity and thermal conductivity in different crystallographic directions. While these results are intriguing, polycrystalline materials are more applicable to TE devices as single crystals can be challenging to synthesize. In this work, polycrystalline samples of YbMnBi₂ are synthesized, and their magneto-thermoelectric transport is characterized as a function of temperature and externally applied magnetic field. Transport data is analyzed with an emphasis on the anisotropy present in single-crystalline samples being removed in polycrystalline samples.

YbMnSb₂ is a similarly anisotropic, canted antiferromagnetic Weyl semimetal. Previous work has reported a large, longitudinal thermopower of $\sim 160 \text{ mV/K}$ near 300 K [2]. However, transverse thermoelectric transport has yet to be characterized. In this work, the anomalous Nernst and magneto-Seebeck effects of YbMnSb₂ are characterized as functions of temperature and magnetic field. Special attention is given to crystallographic orientation as well, as Dirac bands are expected to dominate transport in the ab-plane while parabolic bands dominate parallel to the c-axis.

Dy-Doping of Zn/Al Substituted Nickel Ferrite for Non-Collinear Magnetic Order Verena Ney¹, Celina Parzer¹, Fabrice Wilhelm², Andrei Rogalev² and Andreas Ney¹; ¹Johannes Kepler University, Austria; ²European Synchrotron Radiation Facility, France

Zn/Al substituted nickel ferrite (NiZAF) has been reported to be a very promising ferrimagnetic insulator with a Curie temperature well above room-temperature which exhibits a very low intrinsic magnetic damping [1]. Thin films of this magnetic spinel can be prepared using pulsed laser ablation [1] or reactive magnetron sputtering from single targets [2] as well as co-sputtering to vary the individual constituents independently [3]. Element selective characterization allows to determine the incorporation of the cationic species [1,2] and correlate them with the desired magnetic properties [3]. Besides an intrinsic low magnetic damping also non-collinear spin textures such as skyrmions are of potential interest for

spintronic or magnonic applications [4]. For magnetic spinel such non-collinear magnetic textures have been reported to be generated either by structural effects in nanoparticles or ultrathin films, e.g. [5] or by doping with trivalent rare earth ions such as Dy [6]. In this work we will report on a systematic growth series of NiZAF films which were doped with Dy by means of co-sputtering. Due to its large ionic radius Dy distorts the crystal structure of the hosting spinel and the low coercive field as well as the low magnetic damping significantly increase. Nonetheless, the Curie temperature well-above room-temperature remains and the spinel structure is maintained on a local scale as evidenced by x-ray linear dichroism studies. Upon Dy doping a local minimum in the zero-field cooled $M(T)$ curves develops which can be taken as a first indication for a non-collinear spin-arrangement which will be subject to further investigations and the latest results for the magnetic texture will be presented.

Formation and Structural Transition of Magnetic Skyrmion Lattices in a Centrosymmetric Metallic Magnet Rina Takagi^{1,2}; ¹The University of Tokyo, Japan; ²JST PRESTO, Japan

Topological objects in condensed matters have attracted attention as the source of rich electromagnetic phenomena. Magnetic skyrmions are topologically protected particle-like objects appearing as swirling spin texture in magnets and intensively studied as the potential candidate of high-density information carrier in magnetic memory [Y. Tokura and N. Kanazawa, Chem. Rev. **121**, 2857 (2021)]. Magnetic skyrmions were originally observed in noncentrosymmetric magnets, in which a competition between the ferromagnetic exchange and Dzyaloshinskii-Moriya interactions stabilizes a triangular skyrmion lattice (SkL) state. Recently, on the other hand, SkL states are also found for centrosymmetric rare-earth intermetallic compounds, which commonly host nanoscale skyrmions, leading to relatively large topological Hall effect. In the latter systems, so far, the SkL always reflects the symmetry of underlying crystal lattice, and a different mechanism of skyrmion formation via itinerant electrons has been proposed.

Here we report the discovery of multiple topological magnetic phases in a centrosymmetric metallic magnet EuAl_4 [R. Takagi *et al.*, Nat. Commun. **13**, 1472 (2022)]. By means of neutron and resonant X-ray scattering experiments, EuAl_4 turns out to show multiple-step reorientation of the fundamental

magnetic modulation vector as a function of external magnetic field, which leads to the appearance of two distinctive SkL states, i.e., square and rhombic lattices of skyrmions with a diameter of 3.5 nm. We also found several other double- Q states in this compound, one of which corresponds to the superposition of four sinusoidal magnetic orders, suggesting the topological magnetic state with the skyrmion number of 2.

The appearance of such multiple SkL states is distinctive from the previously reported centrosymmetric rare-earth intermetallic compounds, where the magnetic modulation vector is always fixed along the one specific direction and the symmetry of the SkL reflects that of underlying crystal lattice. The present results demonstrate that various skyrmion orders can be realized even in simple centrosymmetric magnets, which highlights rare-earth intermetallic compounds as a promising platform to control the competition of multiple topological magnetic phases in a single material.

8:30 AM *QT03.07.02

Real-Space Control of Topological Skyrmions and Antiskyrmions Licong Peng; Peking University, China

Magnetic skyrmions, characterized as topological "particles", and antiskyrmions, their corresponding "antiparticles", which host opposing topological numbers, have become the focus of significant interest within the realms of fundamental physics and spintronics. The potential for driving and controlling their movements will open the door for a new generation of skyrmion/antiskyrmion-centric spintronic devices. Here I will introduce the in-situ Lorentz TEM imaging of topological spin textures and their dynamical behaviors. First, I will show the manipulation of a single skyrmion at room temperature in the chiral-lattice magnet $\text{Co}_9\text{Zn}_9\text{Mn}_2$ -based microdevice using nanosecond current pulses. We have directly observed the skyrmion translation and transverse Hall motion and a dynamic transition from the static pinned state to the linear flow motion via a creep event using Lorentz TEM. Furthermore, we have evaluated the intrinsic skyrmion Hall angle and the skyrmion velocity. Our experimental observations of skyrmion flow motion qualitatively coincide with numerical calculations, suggesting the pinning effect on the skyrmion dynamics [1]. In addition to skyrmions, I will also discuss the real-space control of room-temperature antiskyrmions in magnets exhibiting D_{2d} [2] and S_4 [3-4] symmetries. By adjusting the external magnetic field, temperature, thickness, and sample geometries, we have induced topological transformations among the antiskyrmions, elliptical skyrmions, and non-topological bubbles. This was achieved through the creation, propagation, and annihilation of Bloch line pairs, accompanied by changes in their helicity, lattice form, and topological number.

SESSION QT04.01: Exotic Properties of 2D Topological Materials I

Session Chairs: Paolo Bondavalli, Bruno Dlubak and Guy Le Lay

Monday Morning, November 27, 2023

Sheraton, Fifth Floor, Riverway

11:00 AM *QT04.01.02

Spin-Orbit Torques Induced by Topological Insulators of the Bi_2Te_3 Family of Materials Thomas Guillet¹, Regina Galceran¹, J.F. Sierra¹, Marius Costache¹, Matthieu Jamet², Frederic Bonell² and Sergio O. Valenzuela^{3,1}; ¹Catalan Institute of Nanoscience and Nanotechnology, Spain; ²Université Grenoble Alpes, France; ³ICREA, Spain

Van der Waals (vdW) heterostructures, including those comprising topological insulators (TIs) of the Bi_2Te_3 family of materials, have disruptive potential for magnetic random-access memory applications [1]. The boundary states of a TI can generate a non-equilibrium spin density to control the magnetization of a ferromagnet (FM) by means of the spin-orbit torques (SOTs). Recent reports have demonstrated large SOT efficiencies with TIs, however, to identify the microscopic mechanisms at play, as well as to maximize the SOT, a deep understanding and control of the properties of the TI/FM interface is needed. In this talk, I will first introduce the potential advantages of vdW heterostructures and of TIs for non-

volatile spintronics memories. I will then describe the relevance of their boundary states and of preserving the quality of the TI/FM interface. I will show that the introduction of a (non-magnetic) metallic [2] or graphene [3] interlayer between the TI and the FM, when FM is a transition metal, can notably suppress Te diffusion into the FM and change the nature of the SOT and its efficiency [2]. Finally, I will argue that the discovery of vdW FMs, which can be grown as high-quality thin films [4,5], can further improve the TI/FM interface, as the weak vdW interaction between the TI and the vdW FM can limit chemical reactions, intermixing and electronic hybridization. Our recent results using Fe_3GeTe_2 demonstrate large SOTs and magnetization switching with currents densities of about 10^{10} A/m^2 [6].

11:30 AM QT04.01.03

Topological Properties of Superconducting $\text{Pd}_3\text{Bi}_2\text{Se}_2$ Ramakanta Chapai¹, Gordon Peterson¹, Matthew Smylie^{1,2}, Xinglong Chen¹, Jidong Samuel Jiang¹, David Graf³, Wai-Kwong Kwok¹, John F. Mitchell¹ and Ulrich Welp¹; ¹Argonne National Laboratory, United States; ²Hofstra University, United States; ³National High Magnetic Field Laboratory, United States

The Parkerite-type transition-metal chalcogenides $\text{Pd}_3\text{Bi}_2\text{Se}_2$ is a superconductor with $T_c \sim 0.8 \text{ K}$. Recently, a non-zero Z_2 topological index has been predicted in $\text{Pd}_3\text{Bi}_2\text{Se}_2$, and subsequently unusual magneto-transport attributed to two-dimensional fermions is reported. By measuring the field dependence of magnetic torque in bulk single crystalline $\text{Pd}_3\text{Bi}_2\text{Se}_2$ we observe de Haas-van Alphen (dHvA) oscillations. Through the analysis of the dHvA oscillations with $H \parallel c$, three frequencies are identified: $F_\alpha = 150 \text{ T}$, $F_\beta = 471 \text{ T}$ and $F_\gamma = 979 \text{ T}$ with the low frequency dominating the spectrum. The Lifshitz-Kosevich analysis yields a small effective mass ($0.11m_0$) and nontrivial Berry phase ($\sim\pi$) for the dominant orbit, indicating nontrivial topology. The presence of nontrivial topology in a superconducting system makes $\text{Pd}_3\text{Bi}_2\text{Se}_2$ a promising candidate to explore topological superconductivity.

11:45 AM QT04.01.04

Artificial Graphene Nanoribbons with Tailored Topological States Nathan Guisinger, Pierre T. Darancet and Saw Hla; Argonne National Laboratory, United States

Low-dimensional materials functioning at the nanoscale are a critical component for a variety of current and future technologies. From the optimization of light harvesting solar technologies to novel electronic and magnetic device architectures, key physical phenomena are occurring at the nanometer and atomic length-scales and predominately at interfaces. In this presentation, I will discuss low-dimensional material research occurring in the Quantum and Energy Materials (QEM) group at the Center for Nanoscale Materials. Specifically, the synthesis of artificial graphene nanoribbons by positioning carbon monoxide molecules on a copper surface to confine its surface state electrons into artificial atoms positioned to emulate the low-energy electronic structure of graphene derivatives. We demonstrate that the dimensionality of artificial graphene can be reduced to one dimension with proper “edge” passivation, with the emergence of an effectively-gapped one-dimensional nanoribbon structure. Remarkably, these one-dimensional structures show evidence of topological effects analogous to graphene nanoribbons.

Updated as of October 28, 2024

Guided by first-principles calculations, we spatially explore robust, zero-dimensional topological states by altering the topological invariants of quasi-one-dimensional artificial graphene nanostructures. The robustness and flexibility of our platform allows us to toggle the topological invariants between trivial and non-trivial on the same nanostructure. Our atomic synthesis gives access to nanoribbon geometries beyond the current reach of synthetic chemistry, and thus provides an ideal platform for the design and study of novel topological and quantum states of matter.

SESSION QT04.02: Growth and Synthesis of 2D Topological Materials

Germanium, a Unique Template for 2D Materials Growth: From Germanene to Antimony

Telluride Synthesis Marco Minissale¹, Eric Salomon², Thierry Angot² and Guy Le Lay²; ¹CNRS, PIIM Laboratory, France; ²Aix-Marseille Université, France

Germanene is an artificial two-dimensional graphene-like germanium allotrope predicted to be a near room temperature topological insulator, belonging to the class of so-called Xenes. It was synthesized in 2014, exactly ten years after the isolation of graphene, and just two years after the archetype growth of silicene, the first Xene ever produced. The canonical germanene paper, described its top-down synthesis by Ge deposition onto a Au(111) crystal, but revealed multi-phases [1]. Instead, we will show that a single germanene phase, as evidenced in Scanning Tunneling Microscopy in situ imaging, is obtained by Ge segregation on top of a thin Au(111) film epitaxially grown under ultra-high vacuum on a Ge(111) template through a bottom-up approach. [2] A comparison with studies performed on thin gold film epitaxially grown on a Ge(110) template will be presented.

Eventually, we will describe the growth of antimony telluride films on Ge(111) surface using a single evaporator cell. Moreover, we will discuss the structural and electronic characterization of such films, studied using standard surface science techniques (LEED, STM, PES).

2:00 PM DISCUSSION TIME

2:30 PM QT04.02.03

Synthesis of Transition Metal Ditellurides (TMTs) Nanosheets: MoTe₂ and PtTe₂ Through

Simulation-Guided Tellurization Pinaka Pani Tummala^{1,2,3}, Sara Ghomi^{1,4}, Alessandro Molle¹, Christian Martella¹ and Alessio Lamperti¹; ¹Consiglio Nazionale delle Ricerche, Italy; ²KU Leuven, Belgium; ³Università Cattolica del Sacro Cuore, Italy; ⁴Politecnico di Milano, Italy

In the classification of Transition metal ditellurides (TMTs), Molybdenum ditelluride (MoTe₂) received significant emphasis due to its multiple polymorphic states including semiconducting, metallic, and topological semimetal phases.[1] Specifically, MoTe₂ is an ideal candidate for creating 2D hetero phase

homojunctions due to its minimal energy barrier between the 2H and 1T' phases, as well as the negligible difference between their moduli, making it effortless to switch between the two phases. The 1T' phase, with an orthorhombic structure, is significant for accessing topological properties and has potential as a host for the quantum spin hall effect and type-II Weyl semi-metallic state while the 2H-phase is useful as a 2D layered material in nanotechnologies due to its semiconducting properties. As the thickness decreases, MoTe₂ exhibits an indirect-to-direct bandgap transition with a relatively lower bandgap than other transition metal dichalcogenides (TMDs).[2][3] So far, countless efforts have been undertaken for developing MoTe₂ which are essential for the fabrication of devices to be integrated in different applications from nano-electronics to thermoelectric and energy sectors. Among the proposed methods, chemical vapor deposition (CVD) is considered as one of the reliable deposition methods.[4] In this context, here we report on the simulation guided CVD synthesis for obtaining MoTe₂ nanosheets with pure 1T' and 2H phases on SiO₂/Si substrates with extensive coverage of 4 cm × 1 cm. The CVD based tellurization process involves a vapor-solid reaction between the pre-deposited molybdenum film and tellurium vapor, and we have optimized this process to improve the quality and scalability of the MoTe₂ nanosheets. We found that the MoTe₂ growth and its phase are primarily determined by the growth kinetics, tellurium concentration, and the configuration of the CVD furnace.[5] Further, by precisely controlling the temperature, we have extended our simulation-based tellurization approach to produce other TMTs, including PtTe₂ and NiTe₂. In particular, we were able to produce PtTe₂ with a sharp 1T phase from the tellurization of a pre-deposited Pt of varying thickness. The so-grown PtTe₂ recasts as a topological type-II Dirac semimetal and as such, it is expected to be optically tunable in the THz spectral range [6]. In this respect, we reduced the flat PtTe₂ film to an array of microscale stripes so as to fabricate PtTe₂-based plasmonic gratings where to measure optical resonances in the THz regime.

We believe this work may represent a substantial advance in facilitating the direct integration of TMTs in electronic and photonic applications where to test the intrinsic topological features.

Surface-Guided Growth of Bi₂Se₃ Nanowires Tamir Forsht, Noga Levinson, Lothar Houben, Katya Rechav, Olga Brontvein and Ernesto Joselevich; Weizmann Institute of Science, Israel

Topological materials exhibit exotic electronic properties, which make them promising for non-conventional electronics and spintronics. For instance, integrating nanowires of topological insulators into devices could be used for dissipationless electronics, quantum switches, generating and braiding Majorana fermions and quantum computing. However, the assembly of nanowires with controlled orientation on surface remains one challenge preventing their integration into practical devices. A possible solution that was demonstrated in our group in the past few years is the guided growth of horizontal nanowires by epitaxy or graphoepitaxy on crystal surfaces.

In this work, we demonstrate the guided growth of Bi₂Se₃ nanowires on flat and faceted sapphire surfaces. Bi₂Se₃ is a layered material with weak VdW interaction between its layers. It is also a topological

Updated as of October 28, 2024

insulator with narrow band gap in the bulk and topologically protected conducting states on its surface, as well as a thermoelectric material. The growth direction of these nanowires and their crystallographic orientation are controlled by the relations with the sapphire substrate, allowing the growth of ordered nanowires without the need for post-growth processes. To the best of our knowledge, this is the first example of guided growth of nanowires made of layered materials, which demonstrates the generality of the guided growth approach.

Synthetic Tuneability of the 1T' -1T Phases in TMDs Cecilia Mattevi; Imperial College London, United Kingdom

In this talk, I will present our recent work on the precise synthesis of different metastable 2D Transition Metal Dichalcogenides and their use in spintronics, electrocatalysis and energy storage. I will provide an overview of the tuneability between magnetic and topologically insulating phases (1T' and 1T) and their corresponding 2H phases at the synthesis level, which we have demonstrated for different TMD materials. The synthesis precision is scalable and based on the kinetic versus the thermodynamic control of the nucleation process, which enable the determination of the crystal structure preferentially leading to either the thermodynamically stable 2H phase or the metastable 1T' and 1T phases. The possible mechanisms of crystallization of metastable polymorphs will be discussed and liquid phase synthesis versus chemically vapour deposited materials approaches will be compared in the light of phase control. Ultimately, the functional properties of the 1T' and 1T phases, such as magnetism and electrocatalysis will be discussed.

4:00 PM QT04.02.07

Epitaxy of Bi₂Se₃ Thin Film by Chemical Vapor Deposition Skye Williams, Edwin Fohntung and Jian Shi; Rensselaer Polytechnic Institute, United States

Spin-momentum locking materials present large prospects to the design of spintronic devices. One of the figures of merit of spintronic materials is the spin-charge conversion efficiency. Bi₂Se₃ is a topological insulator with an impressive spin-charge conversion efficiency on its conductive surface states. Epitaxial Bi₂Se₃ is highly demanded for optimized conversion efficiency. In this work we present a chemical vapor deposition approach to grow Bi₂Se₃ epitaxially that have grain sizes exceeding 200 micrometers. We identify the existence of sub-unit cell layers in the epitaxial crystal. We apply the spin pumping approach to characterize the spin-charge conversion efficiency and compare it with reported values of Bi₂Se₃ synthesized by approaches such as sputtering. The work suggests chemical vapor deposition is a viable approach for producing high-quality large-scale topological Bi₂Se₃.

SESSION QT04.03: Theory, Modeling of Topological Features

8:30 AM *QT04.03.01

Tuning Topology in 2D Materials Zeila Zanolli; Utrecht University, Netherlands

In a few years, the energy consumption for information processing will constitute more than 25% of the total electrical energy consumption. Topological materials allow for symmetry-protected dissipationless electron transport along the edges of 2D materials, which offers a possible solution to the sustainability issue of electronics. However, controlling the topological properties of a material is an open research question.

We use first-principles Density Functional Theory simulations to predict pathways to control topological properties in 2D materials and, possibly, induce or strengthen the topological phase transition. The different strategies include proximity interaction with a magnetic substrate [1, 2], van der Waals interaction with the substrate [3, 4], twisting 2D heterostructures [5], and using an external electric field to manipulate spins in a Quantum Spin Hall insulator [6]. Going further, I will discuss the role of dimensionality in going from a 3D topological insulator to the 2D limit [7].

Efficient Quantum Transduction using Magnetic Topological Insulators Haowei Xu, Paola Cappellaro and Ju Li; Massachusetts Institute of Technology, United States

Transduction of quantum information between distinct quantum systems is an essential step in various applications, including quantum networks and quantum computing. Efficient quantum transduction necessitates transducers that can strongly interact with photons with vastly different frequencies. In this work, we propose that solid-state magnetic topological insulators can potentially serve as highly effective transducers, thanks to their topologically enhanced optical responses, robust spin-orbit coupling, as well as substantial spin density. Using MnBi₂Te₄ as an example, we showcase that unit transduction fidelity can be achieved with modest experimental requirements, while the transduction bandwidth can reach the GHz range.

9:15 AM QT04.03.03

Super Flat Graphene Grown on Substrate Selected by using Molecular Dynamics Calculation

Satoru Kaneko^{1,2}, Takashi Tokumasu³, Manabu Yasui¹, Masahito Kurouchi¹, Daishi Shiojiri¹, Chihiro Kato¹, Satomi Tanaka¹, Shigeo Yasuhara⁴, Musa Can⁵, Ruei-Sung Yu⁶, Sumanta Sahoo⁷, Kripasindhu Sardar⁸, Masahiro Yoshimura⁸, Akifumi Matsuda² and Mamoru Yoshimoto²; ¹KISTEC, Japan; ²Tokyo Institute of Technology, Japan; ³Tohoku University, Japan; ⁴Japan Advanced Chemicals, Japan; ⁵Istanbul University, Turkey; ⁶Asia University, Taiwan; ⁷Radhakrishna Institute of Technology and Engineering, India; ⁸National Cheng Kung University, Taiwan

Choice of substrate is one of most important factors for thin film growth. An extensive interdiffusion or chemical reaction might happen between substrate and target materials. For oxide materials, Schlom et. al. comprehensively investigate the thermodynamic stability of binary oxides for epitaxial growth on silicon (Si) substrates[1]. However, the thermodynamic stability does not include any crystal information such as lattice constants, orientation of crystal growth. In order to predict the orientation of crystal growth, molecular dynamics (MD) is employed to evaluate the stability of oxide cluster on Si substrates[2].

In this study, MD was used to select suitable substrates for graphene growth with flat surface. Supercell was consisted of carbon clusters placed on variety of substrates with vacuum slab. As carbon clusters, (1) C atom, (2) six-membered ring (6-ring) and (3) seven six-membered rings (nanographene) were placed on SrTiO, silicon and sapphire substrates. On the surface of sapphire substrate, carbon clusters were placed on either aluminum or oxygen atoms, and the absorption energy was estimated by using the density functional theory (DFT) with a semi-core pseudopotential. The generalized gradient approximation (GGA) method was used to obtain the electron density. Materials Studio and DMol3 were used for preparing and optimizing supercells, respectively[3].

The surface of substrate was optimized, and then the carbon clusters were placed on the candidate substrates. Although the absorption energies showed not large differences on various surfaces, 6-ring, for an example, stood vertically up on Si(001) substrate and covered flatly on SrTiO substrate. Only SrTiO surface was flatly covered by both 6-ring and nanographene after optimization by MD simulation. The SrTiO substrate was the first choice for flat graphene.

Super flat graphene is prepared by chemical vapor deposition (CVD) with post annexing in carbon dioxide atmosphere. Amorphous carbon is selectively etched in carbon dioxide atmosphere[4]. In this study, carbon films were experimentally deposited on target substrates in carbon dioxide atmosphere by pulsed laser deposition (PLD), and super flat surface (~60 pm) was observed on only SrTiO substrate, which agreed with the results of MD simulation. Since CVD graphene usually grows with intrinsic contamination on graphene surface during film growth, a post annealing is required to obtain a flat surface. However PLD prepared as-grown flat surface in carbon dioxide atmosphere.

Topological Textures in Artificial Van der Waals Multiferroics with Twisted Two-Dimensional Materials Jose Lado; Aalto University, Finland

Twisted van der Waals materials have risen as a powerful platform to engineer artificial quantum matter. Artificial moire heterostructures, in general, display two length scales, the original lattice constant and the emergent moire length. Here we reveal a microscopic mechanism to engineer van der Waals multiferroics from the interplay of non-collinear magnetism and spin-orbit coupling, both in van der Waals monolayers [1] and twisted multilayers [2]. First, focusing on the recently isolated NiI₂ multiferroic monolayer, we reveal the origin of the helimagnetic order and the critical role of halide spin-orbit coupling in driving a ferroelectric distortion. We demonstrate that the electronic reconstruction accounting for the ferroelectric order emerges from the interplay of such a non-collinear magnetism and spin-orbit coupling. Second, we show the emergence of multiferroic order in twisted chromium trihalide bilayers, an order fully driven by the moiré pattern and absent in aligned multilayers. We show that a spin texture is generated in the moiré supercell of the twisted system as a consequence of the competition between stacking-dependent interlayer magnetic exchange and magnetic anisotropy. An electric polarization arises associated with such a non-collinear magnetic state due to the spin-orbit coupling, leading to the emergence of a local ferroelectric order following the moiré. Among the stoichiometric trihalides, our results show that twisted CrBr₃ bilayers give rise to the strongest multiferroic order. We further show the emergence of a strong magnetoelectric coupling, which allows the electric generation and control of magnetic skyrmions. Our results put forward van der Waals materials as a powerful platform to engineer artificial multiferroic order and electrically control exotic magnetic textures.

First-Principles Transport Including Magnetic and Spin-Orbit Effects Matthieu J. Verstraete^{1,2}; ¹University of Liege, Belgium; ²University of Utrecht, Netherlands

Topology is the next frontier in materials science, opening possibilities for ultra low power devices, exquisite sensing capabilities, and synergies with quantum computing through the protection of state coherence.

We will showcase recent advances in the theory and applications of first-principles transport calculations, to include magnetism and spin-orbit interactions, and what will be needed to tackle the most complex topological materials, which contain both effects. Using spinor wave functions and SOI naturally incorporates spin-flip processes in electron-phonon scattering. Comparisons to experiments on "simple" 3d ferromagnetic metals require the inclusion of electron-magnon scattering, both in resistivity and in magnon drag.

As a next step into topology, we showcase the first-principles conductivity of Weyl semi-metals, in particular TaAs for which our calculations are in very good agreement with available experiments.

Finally, magnetoelectrically-active 2D Nickel Iodide (NiI₂) can host topological magnetic states, and we find that it shows strong sensitivity to pressure. Combining experimental characterization with first and second principles simulations, we determine the pressure dependency (up to 20 GPa) of the electronic band structure, magnetic phase transition, and spinwave dispersion.

11:00 AM QT04.03.06

Logic Gate Analysis for Quantum Phase Differences in Systems with Multiple Degenerate Points

Tatsuki Tojo and Kyozauro Takeda; Waseda University, Japan

The field of quantum information has been extensively researched, and an important concept here is the phase difference between the two basis states ($|0\rangle$ and $|1\rangle$) in a qubit, which is an important concept used to distinguish quantum logic from classical logic. Hence, manipulating this phase difference is a prerequisite for quantum arithmetic. Consequently, various methods for quantum (phase) operations have been proposed, and one such method uses the non-Abelian Berry phase [1]. Because the non-Abelian Berry phase has a characteristic structure, particularly at *quasi*-degenerate points (QDPs) in the parameter space, combining QDPs with quantum operations becomes important. However, a QDP exists alone in the parameter space, complicating its combination with quantum operations. Nevertheless, heavy-mass holes (HHs) in SiGe two-dimensional quantum wells, where Rashba and Dresselhaus spin-orbit interactions (SOIs) coexist, feature multiple spin QDPs near point Γ in the Brillouin zone (BZ) [2]. In the vicinity of these QDPs, a characteristic structure is observed in the non-Abelian Berry phase when the wave vectors are chosen as parameters. Because these QDPs lie close to each other, they can realize novel quantum operations.

Here, we focus on the HH with multiple QDPs in the BZ and discuss the features of quantum operations based on the non-Abelian Berry phase near these QDPs. We choose the $|0\rangle$ and $|1\rangle$ states as the SOI-stabilized (+) and -destabilized (-) HH (HH+/-) states, respectively, including the dynamical phases, and discuss the change in hybridization and phase difference between the $|0/1\rangle$ states. A Bloch sphere is used to visualize the hybridization ratio and phase difference. Further, we construct a time-evolution operator that reproduces the motion on the Bloch sphere and decompose it into quantum logic gates to interpret changes in the state vector as quantum operations. We assume that the wave vector moves under the energy conservation law and recreate this motion as “cyclotron motion” under a perpendicular weak magnetic field. The time evolution of the state and wave vectors is determined by the simultaneous rate equation and semi-classical equation of motion.

In addition to point Γ , an HH has the following QDPs: M_1 and M_2 (16 meV) along the $[1-10]$ and $[-110]$ directions and D_1 and D_2 (24 meV) along the $[-1-10]$ and $[110]$ directions, respectively. To discuss such QDP-induced modulation, we consider the lower-energy region away from M and D (10 meV), and just above M (16 meV) and D (24 meV). We set the initial states of the wave vector along the $[100]$ direction and the state vector to the $|0\rangle$ state (HH+).

At 10 meV, the state barely moves from the $|0\rangle$ state (+z direction on the Bloch sphere), and no operation is apparently performed. However, the rate-equation-based time-evolution operator is equivalent to the R_z gate, and its rotation angle is 2π . This rotation angle corresponds to the (Abelian) Berry phase difference

of HH \pm at 10 meV ($\pm\pi$). This Berry phase can be attributed to the QDP at point Γ . This implies that even in the region away from the QDP, the state vector is operated by R_z corresponding to the Berry phase of the QDP surrounded by the parameter (wave vector) trajectory. By contrast, at 16 meV (point M), the state flip-flops during the passage of M, and the states $|0\rangle$ and $|1\rangle$ change completely to $|1\rangle$ and $|0\rangle$, respectively. Through logic gate decomposition, we obtain the R_y gate corresponding to M, whose rotation angle is π . At 24 meV, the R_y gate corresponding to D is also obtained. However, the rotation angle is less than π , and the state transition is incomplete. Therefore, the state is operated by the R_y gate when it passes just above the QDP, and the rotation angle depends on the QDP.

11:15 AM QT04.03.07

Designing Quantum States in Two Dimensional Heterostructures Orlando J. Silveira¹, Mohammad Amini¹, Liwei Jing², Viliam Vano¹, Yan Linghao³, Ondrej Krejci¹, Somesh Ganguli¹, Shawulienu Kezilebieke², Jose Lado¹, Adam Foster^{1,4} and Peter Lijeroth¹; ¹Aalto University, Finland; ²University of Jyväskylä, Finland; ³Soochow University, Taiwan; ⁴Kanazawa University, Japan

Vertical heterostructures have emerged as a promising route for designing quantum materials with extraordinary properties. In particular, the interplay between magnetism and superconductivity has garnered significant attention, driven by the potential realisation of topological superconductivity [1]. This research presents notable progress in the synthesis and characterization of two-dimensional materials in ultra-high vacuum environments. By employing scanning tunnelling microscopy (STM) and spectroscopy (STS), along with tight-binding (TB) and density functional theory (DFT) calculations, a comprehensive understanding of these materials has been achieved.

We propose a novel approach utilizing a heterostructure composed of a supramolecular complex (SMC) on a van der Waals (vdW) superconductor. Through our investigations, we demonstrate that the combination of a magnetic SMC with a quasi-2D superconductor, specifically NbSe₂, leads to the emergence of Yu-Shiba-Rusinov (YSR) bands—a crucial element for realizing topological superconductivity. The presence of these bands, together with the exotic magnetic ground state of the SMC, is thoroughly examined using scanning tunneling microscopy (STM) and X-ray magnetic circular dichroism (XMCD), complemented by density-functional theory (DFT) calculations. Notably, our approach offers the advantage of employing diverse molecules, atoms, and substrates, enabling highly tunable YSR bands.

Furthermore, we investigate the electronic structure of a ferroelectric 001 SnTe grown on NbSe₂. Our DFT calculations reveal a strong binding between Sn and Se atoms within the substrate, resulting in significant modifications to the overall electronic structure and its dependence on the number of atomic layers of SnTe. We also extend the study to SnTe deposited on other vdW layered materials such as TMDs by means of DFT calculations.

Overall, this research contributes to the understanding and advancement of quantum materials, demonstrating the synthesis and characterization of versatile heterostructures and providing insights into their unique properties.

Spin Transport Proximity Phenomena in Van der Waals Heterostructures J.F. Sierra, Luis Antonio Benítez, Josef Svetlik, Williams Saverio Torres, Lorenzo Camosi, Marius Costache and Sergio O. Valenzuela; Catalan Institute of Nanoscience and Nanotechnology, Spain

The vast collection of two-dimensional materials and their co-integration in van der Waals heterostructures enable innovative device engineering. Their atomically thin nature promotes the design of artificial quantum and topological materials by proximity-induced effects with physical properties not readily found in their single material forms [1]. Such a flexible design approach is especially compelling for the development of spintronic devices, which usually harness functionalities from thin layers of magnetic and non-magnetic materials and their interfaces. In this talk, I will summarize recent experimental progress toward investigating proximity-induced phenomena in hybrid graphene-transition metal dichalcogenides systems through spin transport dynamics [2,3] and charge-spin interconversion experiments [4]. I will focus on the relevance of crystal symmetries in the emergence of unconventional charge-spin conversion components and anisotropic spin dynamics [5], [6].

Kramers Nodal Lines, Weyl Fermions and Large AHE in SmAlSi Emilia Morosan and Ming Yi; Rice University, United States

Kramers nodal lines (KNLs) are special type of Weyl line degeneracy that connects time reversal invariant momenta. KNLs are robust to spin orbit coupling (SOC), and are inherent to all non-centrosymmetric achiral crystal structures. In this talk I will present magneto-transport and ARPES experimental data together with DFT calculation, pointing to the existence of novel KNLs in SmAlSi. SmAlSi is a non-centrosymmetric metal that develops incommensurate spin density wave AFM order at low temperatures. I will show evidence for the symmetry-protected KNLs, as well as Weyl fermions under the broken inversion symmetry in the paramagnetic phase of SmAlSi. In the AFM state, angle-dependent quantum oscillations (AQOs) provide evidence for the Weyl points, while large AHE is observed in both the AFM and the PM states. We propose a new mechanism to explain AHE in non-FM materials, based on magnetic field-induced Weyl-nodes evolution in non-centrosymmetric Weyl

semimetals. The proposed mechanism qualitatively explains the temperature dependence of the anomalous Hall conductivity (AHC) in SmAlSi.

On-Surface Synthesis of Silicon Nanoribbons Maria E. Davila; ICM-ICMM-CSIC, Spain

Abstract

In recent years, the scientific community has put a lot of efforts into trying to artificially grow new functional materials by reducing their dimensionality from 2D to 1D or even 0D. However, it is not a simple task, which includes synthetic methods that could go in both possible top-down or bottom-up approaches.

Our group, working on the bottom-up approach through on-surface synthesis has been able to develop unprecedented new 0D, 1D or 2D silicon nanoshapes[1,2]. Here, we demonstrate the on-surface synthesis of atomically precise silicon nanoribbons by utilizing the Ag(110) surface and also we have unmasked the unique 1D pentagonal silicon structures formed on it, which had been elusive for over 10 years. Further, we will see how the different single crystals substrates greatly affects the growth of silicon and the new structures that can be formed on it[3].

Promising applications of new silicon nanoforms range from nanoelectronics to transistors or embedded sensors; however, one of the important challenges that we have to overcome is the isolation, through the separation of the substrates, of these interesting nanoforms.

Keywords: Silicon nanoribbons, 1D-Silicon.

3:00 PM BREAK

3:30 PM *QT04.04.04

Magnetic and Charge Order in Transition Metal Dichalcogenide Heterostructures Daniel K. Bediako; University of California, Berkeley, United States

Next-generation electronic devices will exploit correlated electronic phenomena in quantum materials to encode information for ultra-fast, ultralow-power, and non-volatile storage and retrieval. Spin-spin correlations in exotic magnetic materials are one basis for this new paradigm of compact, energy-efficient electronic systems, but these will require a nanoscale control over long-range magnetic ordering.

Conceptually, this may be realized by designing materials that are inherently two-dimensional in their atomic connectivity, or by harnessing nanoscale, non-collinear spin textures in three-dimensional crystals. Likewise, electronic correlations that produce complex charge order can be manipulated to exhibit multi-state resistance phenomena, analogous to phase change materials, but without fatigue.

This talk will describe how transition metal dichalcogenides (TMDs) intercalated with open-shell transition metals represent a family of materials allowing fine control over the chemical and electronic structure of a magnetic material to tailor the interplay between (anti)ferromagnetic exchange, magnetocrystalline anisotropy, and anisotropic exchange (Dzyaloshinskii–Moriya interactions) to bring about exotic magnetic orders in two-dimensional (2D) materials or bulk crystals. The talk will show how soft-chemical methods can be used to prepare the highly coercive 2D ferromagnetic intercalation compound, Fe_xTaS_2 , and the use of angle-resolved photoemission spectroscopy to understand differences in chiral helimagnetic order in related 3D compounds, $\text{Cr}_{1/3}\text{NbS}_2$ and $\text{Cr}_{1/3}\text{TaS}_2$. The role of intercalant disorder on magnetic order will be explored in these chiral helimagnets as well as the intrinsically disordered $\text{Fe}_{0.17}\text{ZrSe}_2$. Finally, the talk will show how endotaxial polytype heterostructures of TaS_2 enable multistate resistivity and chirality switching of charge density wave phases.

4:00 PM QT04.04.05

Interplay between Magnetism and Topology: Large Topological Hall Effect in an

Antiferromagnetic Topological Insulator, EuCuAs Subhajit Roychowdhury¹, Kartik Samanta¹, Premakumar Yanda¹, Bernard Malaman², Mengyu Yao¹, Walter Schnelle¹, Emmanuel Guilmeau³, Procopios Constantinou⁴, Sushmita Chandra¹, Horst Borrmann¹, Maia G. Vergniory¹, Vladimir Strocov⁴, Chandra Shekhar¹ and Claudia Felser¹; ¹Max-Planck-Institute for Chemical Physics of Solids, Germany; ²Institut Jean Lamour-Universite de Lorraine, Centre National de la Recherche Scientifique, France; ³CRISMAT, CNRS, Normandie University, ENSICAEN, UNICAEN, France; ⁴Paul Scherrer Institute, Switzerland

Magnetic interactions in combination with nontrivial band structures can give rise to several exotic physical properties such as a large anomalous Hall effect, the anomalous Nernst effect and the topological Hall effect (THE). Antiferromagnetic (AFM) materials exhibit THE due to the presence of nontrivial spin structures. EuCuAs crystallizes in a hexagonal structure with an AFM ground state (Néel temperature ~16 K). In this work, we observe a large topological Hall resistivity of $\sim 7.4 \mu\Omega\text{-cm}$ at 13 K which is significantly higher than the *giant topological Hall effect* of Gd_2PdSi_3 ($\sim 3 \mu\Omega\text{-cm}$). Neutron diffraction experiments reveal that the spins form a transverse conical structure during the metamagnetic transition, resulting in the large topological Hall effect. In addition, by controlling the magnetic ordering structure of EuCuAs with an external magnetic field, several fascinating topological states such as Dirac and Weyl semimetals have been revealed. These results suggest the possibility of spintronic devices based on antiferromagnets with tailored noncoplanar spin configurations.¹

Nonlinear Transport Effects in Chiral Elemental Tellurium Albert Fert¹, Manuel Suárez-Rodríguez², F. Calavalle², Beatriz Martín-García², A. Johansson³, Diogo C. Vaz², F. de Juan⁴, I. Sousa⁵, Andrey Chuvilin², I. Mertig⁶, M. Gobbi², F. Casanova² and L. E. Hueso²; ¹Université Paris-Saclay, France; ²CIC nanoGUNE, Spain; ³Max Planck Institute of Microstructure Physics, Germany; ⁴Donostia International Physics Center, Spain; ⁵University of the Basque Country, Spain; ⁶Martin Luther University Halle-Wittenberg, Germany

Chiral materials are an ideal playground for exploring the relation between symmetry, relativistic effects, and electronic transport [1]. Indeed, the role of low symmetry on electronic transport has been studied on chiral organic molecules, but their poor electronic conductivity limits their potential for applications. Conversely, chiral inorganic crystals, such as elemental Tellurium (Te), present excellent electrical conductivity and strong spin-orbit coupling [2]. Therefore, Te become a perfect material for studying the connection between nonlinear transport phenomena, such as unidirectional magnetoresistance (UMR) [3] or nonlinear Hall effect (NLHE) [4], and chirality. Here, we synthesized single crystalline Te nanowires (NWs) and flakes with both handedness. On one hand, we report a chirality-dependent and gate-tuneable Edelstein effect in the naturally hole-doped Te NWs [5]. By recording a UMR dependent on the relative orientation of the electrical current and the external applied magnetic field, we link the direction of the spin polarization to the handedness of the crystal. The measured UMR is explained on the basis of a chirality-dependent Edelstein effect arising from the radial spin texture at the H-point of the valence band of Te, which dominates the transport in our hole-doped Te NWs. In addition, an electrostatic gating enables the tuning of the Edelstein effect, leading to a modulation of the UMR amplitude by a factor of 6. On the other hand, we explore the NLHE in Te flakes. The symmetry of the measured second harmonic voltage under zero field, which is a consequence of the inversion symmetry breaking in Te, follows strictly the constraints for Te point group and is different from any material reported before. Moreover, by measuring flakes with opposite handedness, we were able to explore experimentally the effect of an inversion symmetry operation [6]. The all-electrical generation, control, and detection of spin polarization and second-order voltage in chiral Te NWs open the path to exploit chirality in the design of solid-state spintronic and energy harvesting devices.

Spin-based electronics, recently highlighted as a leading candidate for highly efficient and ultrafast embedded memories (such as MRAMs) and post-CMOS unconventional electronics strategies (including spin logics, stochastic, neuromorphic and quantum computing), have enjoyed considerable growth. Beyond the fundamental spin transport properties of graphene, 2D materials have unleashed a multitude of previously untapped possibilities for spintronic devices in terms of functionality and performance, ranging from gate control to topology.

Indeed, 2D materials offer the unlimited possibility of exposing their electronic structure to manipulation by proximity effects. We will demonstrate that this could be harnessed to shape the properties of 2Ds and van der Waals heterostructures in quantum devices[1] and materials. We will more specifically focus on how this can be leveraged in devices such as 2D based Magnetic Tunnel Junctions (2D-MTJs)[2,3].

Relying mostly on large scale 2D materials, we will give examples of spin manipulation and new mechanisms ranging from almost perfect 2D spin-filtering with -98% spin polarization in graphene [4] and up to 500% MR in black-phosphorous, to 2D material proximity hybridization leading to insulator-to-metal transition (spinterface) [5]. We will finally focus on 2D-magnets, and moreover show how this proximity effect can also be pushed further to create an artificial 2D magnet [6] relying on proximity interaction of graphene with a ferromagnetic insulator, towards a fully gateable 2D-MTJ for spin logics.

Thanks to their original properties, magnetic skyrmions have many promising applications, from sensors through data storage to non-conventional computing [1-3]. Among the main advantages of magnetic skyrmions are their sub-micronic size, their particle-like behavior, their stability and non-volatility at room temperature and the low energy requirement for their motion. It has been shown, most often separately, that magnetic skyrmions can be experimentally nucleated [4-7], moved [4,7], annihilated [6] and detected electrically using Anomalous Hall effect [8] in metallic multilayers.

In this talk, we will propose a neuromorphic device design using full-electrical manipulation and detection of skyrmions to perform basic operations required for neuromorphic computing. Indeed, the operating principle of an artificial neuromorphic component is to work by performing a simple operation: it multiplies various input signals with corresponding synaptic weights and sums them up [9]. Mathematically, this can be represented as $y = \sum(w_i x_i)$, where x_i are the inputs and w_i are the synaptic weights. All the building blocks necessary to achieve the demonstration of a weighted sum of skyrmions will be presented, from the nucleation and motion of a controlled number of magnetic skyrmions in multilayer tracks using electrical current pulse parameters to the electrical detection of a sum of skyrmions through anomalous hall effect.

The demonstrated skyrmion-based neuromorphic device paves the way to skyrmionic low-energy devices contributing to a global reduction of the environmental impact of AI applications.

2D Topological Insulators for New Generation Thermoelectrics: Technological Development Paolo Bondavalli¹, Pierre Legagneux¹, Eva Desgue¹, Olivier Bourgeois², Dominique Carisetti¹ and Yannick Fagot-Revurat³; ¹Thales Research and Technology, France; ²Institut néel, France; ³Université de Lorraine, France

The implementation of 2D topological materials is a potential revolution in this domain. During the NEXTOP project, funded by French Research Agency, we are working on a new generation of 2D topological insulators to demonstrate a ZT larger than 7. Two major issues are to be overcome: the growth of 2D topological insulators on different kinds of substrates (insulating and conducting ones) and their implementation for thermoelectric tests. We are developing a new technique for growing WTe₂ using sort of steps with different widths that will allow controlling its crystallinity and number of layers. Thanks to that, we will be able to perform thermoelectric measurements on this topological insulator which is up to now the only 2D material whose topological features have been demonstrated. This will be the first time that measurements will be performed. Techniques for stanene growth will be also presented during the meeting. Bottlenecks for in-situ tests to identify band structures will be also presented.

11:15 AM QT04.05.07

A New Platform for Spin-Polarized Majorana Zero Modes: Penta-Silicene Nanoribbons Guy Le Lay¹, Marco Minissale¹, R. C. Bento Ribeiro², Mucio A. Continentino², J. H. Correa³, L. S. Ricco⁴, I. A. Shelykh⁵, A. C. Seridonio⁶ and M. S. Figueira⁷; ¹Aix-Marseille University, France; ²CBF, Brazil; ³Universidad Tecnológica del Perú, Peru; ⁴University of Iceland, Iceland; ⁵ITMO University, Russian Federation; ⁶Sao Paulo State University, Brazil; ⁷Universidade Federal Fluminense, Brazil

We report the possibility of obtaining Majorana zero modes (MZMs) in straight, highly perfect, and massively aligned atom-thin penta-silicene nanoribbons (p-SiNRs) with a very high aspect ratio, purely composed of silicon pentagonal building blocks, and grown by molecular beam epitaxy on the (110) surface a silver crystal template^{2,3}. They could constitute the experimental realization of the generic Kitaev toy model^{3,4}. The spinless and full spin p-SiNRs with p-wave superconducting pairing reveal the emergence of topologically protected MZMs at opposite ends of the p-SiNRs. Besides the first nearest neighbor hopping term and p-wave superconducting pairing we consider an external magnetic field perpendicularly applied to the nanoribbon plane and an intrinsic Rashba spin-orbit coupling. The dispersion relation profiles show the closing and reopening of the superconducting gap for only one spin component, suggesting a spin-polarized topological phase transition (TPT). Along with this TPT, the energy spectrum as a function of the p-SiNR chemical potential exhibits zero-energy states and preferential spin direction. It is associated with nonoverlapping wave functions well-localized at the opposite extremities of the superconducting p-SiNRs. Hence, we show theoretically that the p-SiNRs could constitute a tantalizing new platform for MZMs⁵.

Band-Gap Landscape Engineering in Large-Scale 2D Semiconductor Van der Waals

Heterostructures for Spintronics Bruno Dlubak¹, Victor Zatzko¹, Hao Wei¹, Frederic Brunnett¹, Simon Dubois^{1,2}, Julian Peiro¹, Marta Galbiati^{1,3}, Florian Godel¹, Jean-Christophe Charlier², Mauro Och⁴, Cecilia Mattevi⁴, Aymeric Vecchiola¹, Karim Bouzehouane¹, Sophie Collin¹, Frédéric Petroff¹, Marie-Blandine Martin¹ and Pierre Seneor¹; ¹Université Paris-Saclay, France; ²Université Catholique de Louvain, Belgium; ³Universidad de Valencia, Spain; ⁴Imperial College London, United Kingdom

The discovery of graphene has opened novel exciting opportunities in terms of functionalities and performances for spintronics devices. This started a wide exploration of a large variety of 2D crystals for spintronics with the hope to exploit some of their unique topological properties. We will present here experimental results concerning integration of 2D materials in vertical Magnetic Tunnel Junctions (MTJ). We will in particular focus the discussion on a novel pulsed laser deposition (PLD) approach for the definition of complex van der Waals heterostructures of 2D materials in magnetic tunnel junctions.[1][2] This PLD growth approach unlocks the association in heterostructure of wide families of multifunctional 2D materials, including the most delicate ones. The direct growth of the 2D layers prevents the oxidation of the ferromagnet, enabling the use of these van der Waals materials for spintronics devices. Overall, the presented experiments unveil promising approaches for the quantum engineering of multifunctional 2D materials heterostructures for spintronics.

Pseudomagnetic Fields in Graphene Strain Superlattices Nadya Mason¹, Iva Srut Rakic², Preetha Sarkar¹, Yingjie Zhang¹, Matthew Gilbert¹ and Vidya Madhavan¹; ¹University of Illinois at Urbana-Champaign, United States; ²Institute of Physics, Serbia

Straining graphene can modify the electronic band structure and lead to the formation of giant pseudomagnetic fields. Recently it was shown that addition of superlattice periodicity to strain leads to global electronic band flattening and signatures of correlated states. Here we show an engineered approach to producing a strained graphene superlattice system. Using scanning tunnelling spectroscopy and transport measurements, together with numerical simulations, we demonstrate that a graphene monolayer placed on a SiO₂ nanosphere superlattice undergoes a band structure change with observable pseudo-Landau level formation, not only integer ones but also with fractional indices. The results are consistent with significant flattening of the electronic bands, making it ideal playground for exploring other related interaction phenomena and possibly the emergence of correlated states.

Two-Dimensional Easy-Plane Magnets Grown by MBE: A Fertile Platform for Unconventional Topological Spin Textures Amilcar Bedoya-Pinto; Universitat de València, Spain

In this talk, I will focus on the van-der-Waals epitaxy of a nearly-ideal two-dimensional magnet, a CrCl₃ monolayer grown on Graphene/6H-SiC(0001). *In-situ* X-ray magnetic circular dichroism reveals intrinsic ferromagnetic order with easy-plane anisotropy and a 2DXY universality class [1], indicating the realization of a Berezinskii-Kosterlitz-Thouless (BKT) phase transition in a quasi-freestanding monolayer magnet. The important role of the van der Waals substrate interaction and the underlying crystal symmetry will be discussed, thereby highlighting routes on how to control the anisotropy of 2D magnets via growth engineering. Moreover, the crucial role of a robust easy-plane anisotropy for the emergence of in-plane topological spin textures -merons and anti-merons- will be showcased for monolayer CrCl₃, both from a theoretical and experimental perspective.

2:30 PM QT04.06.03

Effect of Molecular Beam Epitaxy (MBE) Growth Conditions on the Structural and Magnetic Properties of High Curie Temperature (MnSb₂Te₄)_x(Sb₂Te₃)_{1-x} Magnetic Topological Insulators Candice Forrester^{1,2}, Christophe Testelin³, Kaushini Wickramasinghe⁴, Ido Levy⁵, Xiabin Ding⁴, Lia Krusin-Elbaum^{4,1}, Gustavo Lopez^{1,2} and Maria Tamargo^{1,4}; ¹The Graduate Center, CUNY, United States; ²Lehman College, CUNY, United States; ³Sorbonne Université, CNRS, Institut des NanoSciences de Paris, France; ⁴The City College of New York, United States; ⁵New York University, United States

Recently it has been shown that structural disorder in 3D Topological Insulators (TIs) has considerable

effects on the properties of the materials. The addition of magnetic ions like Mn breaks time reversal symmetry and opens a gap in the Dirac point.¹ This addition also changes the crystal structure from the typical quintuple layer (QLs) structure of non-magnetic TIs to a septuple layer (SLs) structure.² Furthermore, addition of a Mn flux during MBE growth results in self-assembled structures of mixed QLs and SLs.²

Previously we reported the MBE growth of self-assembled structures of $(\text{MnSb}_2\text{Te}_4)_x(\text{Sb}_2\text{Te}_3)_{1-x}$ magnetic topological materials,³ and showed that their Curie temperature (T_C) is dependent on the composition x (or %SL).⁴ Samples with $0.7 < x < 0.85$ exhibit very high T_C values. Additionally, it was observed that as the Mn beam equivalent pressure (BEP) ratio used was increased, there was a corresponding increase in T_C . Decreasing the growth rate further increased T_C to >100 K, the highest values reported for this material system. An understanding of how the changes in growth conditions lead to the T_C enhancement is not well-established.

Here we investigate the structural properties of the materials as they relate to the growth conditions, specifically Mn flux ratio during growth and reduced growth rate (GR). Samples grown at slow GRs (0.4 – 0.6 nm/min) were compared to samples grown at fast GRs (0.8 – 1.0 nm/min). Samples were investigated using several characterization techniques including X-ray diffraction, Energy Dispersion X-Ray Spectroscopy (EDS), Hall effect and scanning transmission electron microscopy (STEM).

We found that for the same Mn BEP ratio, low GR yields similar composition, x , as fast GRs. On the other hand, EDS showed that for $x > 0.7$, there was increased intermixing between Sb and Mn in both the fast and the slow GR samples. Furthermore, the samples grown with slow GR showed much greater Mn and Sb intermixing, as well as Mn and Te intermixing, suggesting increased Mn incorporation at the slow GR, as well as more disorder. Cross sectional EDS studies reveal a high Mn content in the QLs, consistent with $(\text{Sb}_{1-y}\text{Mn}_y)_2\text{Te}_3$ alloy formation. Hall effect measurements show that GR does not significantly affect the electrical doping in $(\text{MnSb}_2\text{Te}_4)_x(\text{Sb}_2\text{Te}_3)_{1-x}$ supporting the proposal that a super-exchange magnetic mechanism is likely at play. Other techniques, such as magnetic force microscopy (MFM) are being explored to better understand the magnetic mechanisms leading to high T_C values and Raman spectroscopy is being explored to understand the disorder in these materials. Our results provide insight as to how to achieve on-demand magnetic TIs with enhanced properties.

Poster Spotlight: π Quantization in the Berry Phase by the Multiple Degenerate Points Fuka Watanabe, Keijiro Hirata, Tatsuki Tojo and Kyozauro Takeda; Waseda University, Japan

Physicomathematics can create new frontiers in condensed-matter physics. The application of *topology* proposes a novel concept, topological materials, that can deepen our understanding regarding quantum phenomena, particularly those related to spin and spin-orbit interactions (SOIs), such as the spin current, spin Hall effects, and spin-Zeeman effect [1]. In these topological materials, the SOI around the degenerate point is key in inducing a characteristic effective magnetic field (EMF). The degenerate state determines its own orthogonal eigenvectors but is not unique because of the “phase” indefiniteness. The Dirac cone is a prime example and results in a topological singularity originating from degeneracy. Spatial asymmetry can generate singularities in the EMF distribution, such as vortices, sources, and sinks, via the SOI around the degenerate point; subsequently, the spin is polarized characteristically therein, particularly when the system exhibits bulk inversion asymmetry (BIA) and/or structure inversion asymmetry (SIA). In this study, we investigate the manner by which multiple degenerate points in the Brillouin zone (BZ) modify the topological features. We focus on a semiconductor system with a two-dimensional quantum well structure and investigate topological modifications via numerical calculations of the EMF, Berry connection, and curvature. Next, we reveal the energy dependence of the Berry phase modulated by the interaction between the degenerate points. We employ the Hamiltonian, in which the spatial asymmetry of the SIA and/or BIA is considered [1]. The effect of the competition between the SIA and BIA is investigated using tunable parameters a and b . To provide multiple degenerate points in the BZ, we locate the degenerate state at point Γ and then transfer it to a peculiar direction by $\pm k_i$. We vary the locations of the degenerate points by appropriately substituting a value for k_i and examine the directional dependence of the synthesized EMF distribution. We further introduce anisotropy by changing the directional effective mass.

In the SIA system, each degenerate point presents a SIA-like singularity and the concentric EMF distribution results. The synthesis of these two concentric distributions generates a source and a sink at the middle position between the two prepared degenerate points when the points ($\pm k_i$) are located in the $\langle 110 \rangle$ direction. Accordingly, the EMF is distributed hyperbolically, and the BIA-like singularity newly results. By contrast, the topological singularity in the BIA system distributes the EMF hyperbolically around each degenerate point. The synthesis of these two hyperbolic distributions results in a new concentric EMF distribution at the middle position. These newborn singularities in the EMF distribution results in accidental degeneracy at the middle position. The sign of the Berry curvature around the newly generated point is opposite to that at the prepared degenerate points.

Finally, we discuss the energy dependence of the Berry phase based on the calculated Berry connection and curvature. Since each degenerate point results in the Berry phase of $\pm\pi$, the multiple degenerate points quantize the Berry phase by π and result in a plateau profile against energy. We further demonstrate that this π quantization can be understood by counting the number of degenerate points in the BZ in addition to identifying the sign of the Berry curvature [2].

Poster Spotlight: Spin Transport Through Superconductor / Weyl Semimetal Heterodevices

Xiaodong Hu, Jason W. Robinson, Adrian Ionescu, Nadia Stelmashenko, Leyla C. Arslan, Francesca Chiodi, Hisakazu Matsuki, Sijie Wang and Jiahui Xu; Cambridge University, United Kingdom

Transport of spin information over large distances is key for many applications in spintronics. Achieving spin transmission within superconducting devices should lead to reductions in Joule heating and massive

improvements in device efficiency and performance. The Weyl semimetal Mn_3Ge [1, 2, 3, 4] with an antiferromagnetic or ferrimagnetic phase has recently emerged as a promising material for spin transmission studies in the superconducting [1] and normal [3, 4] states. In this poster, we report the fabrication of magnetron-sputtered thin-films of Mn_3Ge and superconducting heterostructures with sub-nanometer-thickness-control in order to investigate the interplay between superconductivity and spin transport in Mn_3Ge . The results build a framework for spin-transport control in the superconducting state.

Poster Spotlight: Orientation Control of MBE Grown SnTe Layers on GaAs Substrates [Masakazu Kobayashi](#)^{1,2} and Su Nan¹; ¹Waseda University, Japan; ²Material Research Technology Institution, Japan

SnTe is one of the attractive material for a topological crystalline insulator (TCI). SnTe films have been grown directly on GaAs (100) substrates by molecular beam epitaxy, and single domain SnTe layers preferentially oriented to (100) were achieved by now. The (111) oriented SnTe domains and Te were easily included in the film. The crystallographic orientation control and surface smoothness improvement was mainly performed in this study.

SnTe layers were grown on (100) and (111)B oriented GaAs substrates by molecular beam epitaxy (MBE). Most of structures were formed on (100) GaAs substrates with (100) oriented ZnTe buffer layers. Elemental sources were used and the molecular beam intensity ratio ($J_{\text{Te}}/J_{\text{Sn}}$) was varied between 0.6~2.9. The beam intensity ratio was tuned by changing the beam intensity of Te. The substrate temperature was calibrated using the oxide desorption temperature of chemically etched GaAs substrates prior to the film growth, and it was varied from 200 °C to 300 °C. The film thickness of SnTe was about 100 nm.

The introduction of the ZnTe buffer layer was effective to improve the crystallographic properties of SnTe layers. Atomic force microscopy observation revealed that plateaus with atomically smooth surfaces were obtained for SnTe layers prepared on ZnTe buffer layers. On the other hand, samples prepared without ZnTe buffer layers haven't exhibited the atomically smooth surfaces. The size of the plateau was increased by increasing the molecular beam intensity ratio up to 1.0.

Since the growth temperature was relatively low, the inclusion of the excess material was not negligible. According to the result of X-ray diffraction (XRD) measurement, a diffraction peaks originated from hexagonal Te was observed with SnTe peaks when samples were grown with Te rich ($J_{\text{Te}}/J_{\text{Sn}}$ was between 2.9 and 1.5) conditions. In the secondary electron microscopy measurements, featureless surface was confirmed when the XRD of the sample exhibited no Te peak while dotted materials were clearly observed on the surface when the hexagonal Te peak was observed. The distribution density of the dot was high when the Te diffraction peak signal intensity was strong. Those dotted materials are presumed to be the residual of Te.

The orientation of the material was affected by the growth temperature. When the substrate temperature was raised, (111) SnTe domains were started to appear. The XRD peak intensities of (100) and (111) domains were comparable when the substrate temperature was 250 °C. In order to eliminate the (111)

domain inclusion, the substrate temperature needed to be maintained below 240 °C.

In order to enhance the (111) domain formation, (111)B oriented GaAs substrates were employed. (100) domains could be mostly eliminated when the substrate temperature was raised to 270 °C.

A standard van der Pauw Hall measurement was performed to characterize the electrical property at room temperature. The (100) sample that didn't include the Te residual exhibited the resistivity of about ohm*cm. The resistivity has increased as the presence of Te residual became noticeable. Based on the literatures, the room temperature resistivity of SnTe and Te were about ohm*cm^[1] and 0.3 ohm*cm^[2], respectively. The higher resistivity obtained for the grown film might be originated from the mixing of Te residual. Although the surface morphology was improved by the introduction of the ZnTe buffer layer, the electrical properties were not improved. Boundaries of plateau probably became the center of carrier scatterings.

Poster Spotlight: Near-Absolute Spin-Valve Effect at f-Orbital Magnet/Superconductor Interfaces with Controlled Orbital-To-Spin Moments Sijie Wang¹, Karine Dumesnil², Harry Bradshaw¹, Nadia Stelmashenko¹ and Jason W. Robinson¹; ¹University of Cambridge, United Kingdom; ²Institut Jean Lamour, France

The proximity effect between a thin-film superconductor (S) and a ferromagnet (F) can lead to a spin-splitting of the quasiparticle density of states and suppression of the superconducting critical temperature (T_C) (1). At an S/F interface, the average magnitude of the spin-splitting in S can be tuned via the micromagnetic state of F with shifts in T_C between magnetized ($T_{C,m}$) and de-magnetized ($T_{C,dm}$) ferromagnet states being dependent [1-3] on the ratio of the superconducting coherence length (ξ) to the domain wall width (d_w) ^{3/4} i.e., $(T_{C,m} - T_{C,dm})/T_{C,dm} = \Delta T_C/T_{C,dm} \propto \xi/d_w$ can theoretically be infinite for an appropriate combination of S and F thin films in which S is thinner than ξ . Experimentally, however, such an absolute spin-valve effect is hard to achieve with $\Delta T_C/T_{C,dm}$ ratios tending to be a small fraction of $T_{C,dm}$, indicating physics beyond the standard picture of the S/F proximity effect. Here we report S/F bilayers and F/S/F spin-valves in which F is an f-orbital ferromagnet (HoGd) with a controlled composition to tune the ratio of the orbital to spin components of the magnetization. The results demonstrate that $\Delta T_C/T_{C,dm}$ can approach infinity for a large ratio of the orbital moment to spin moment, which enables a near-absolute spin-valve effect. Our results demonstrate that the band structure of the ferromagnet in conjunction with the ξ/d_w can be tuned to enable high-performance superconducting memory for energy efficiency electronics. A first principle theory is required in order to understand the relationship between $\Delta T_C / T_{C,dm}$ and the ratio of the orbital to spin moment of the F metal.

Poster Spotlight: Towards Quantum Transport in Metal and Ferromagnetic Semiconductor Thin Films Structures with Absorbed Chiral Molecules Jiahui Xu¹, Jason W. Robinson¹, Hisakazu Matsuki¹, Nadia Stelmashenko¹, Shira Yochelis² and Yossi Paltiel²; ¹University of Cambridge, United Kingdom; ²The Hebrew University of Jerusalem, Israel

Chiral molecules (CMs), such as alpha-helix polyalanine, exhibit chiral-induced spin-selectivity (CISS) characteristics, which means that a flow of electron charge across a layer of CMs can result in a spin-filtering effect and phase coherent transport (1, 2). Recently, for example, we have demonstrated low temperature phase-coherent transport through thin-film wires of Au and Cu with absorbed CMs (2). For Au, we also observed evidence for induced ferromagnetism associated with the thiol-Au bonding and for Au and Cu, we detected an enhancement of spin-orbit coupling. Here, we systematically study charge transport and magnetic anisotropy in thin films and wires of Au and Au/EuS where EuS is a ferromagnetic semiconductor. The thickness of Au is varied in the 1-10 nm range in order to optimise magnetic hysteresis in Au and magnetic anisotropy modification in Au/EuS structures. The results provide a platform for detailed studies of quantum behaviour including magnetic control of phase coherence transport and potentially a quantum anomalous Hall effect.

Poster Spotlight: π Quantization in the Berry Phase by the Multiple Degenerate Points Fuka Watanabe, Keijiro Hirata, Tatsuki Tojo and Kyozauro Takeda; Waseda University, Japan

Physicomathematics can create new frontiers in condensed-matter physics. The application of *topology* proposes a novel concept, topological materials, that can deepen our understanding regarding quantum phenomena, particularly those related to spin and spin-orbit interactions (SOIs), such as the spin current, spin Hall effects, and spin-Zeeman effect [1]. In these topological materials, the SOI around the degenerate point is key in inducing a characteristic effective magnetic field (EMF). The degenerate state determines its own orthogonal eigenvectors but is not unique because of the “phase” indefiniteness. The Dirac cone is a prime example and results in a topological singularity originating from degeneracy. Spatial asymmetry can generate singularities in the EMF distribution, such as vortices, sources, and sinks, via the SOI around the degenerate point; subsequently, the spin is polarized characteristically therein, particularly when the system exhibits bulk inversion asymmetry (BIA) and/or structure inversion asymmetry (SIA). In this study, we investigate the manner by which multiple degenerate points in the Brillouin zone (BZ) modify the topological features. We focus on a semiconductor system with a two-dimensional quantum well structure and investigate topological modifications via numerical calculations of the EMF, Berry

connection, and curvature. Next, we reveal the energy dependence of the Berry phase modulated by the interaction between the degenerate points. We employ the Hamiltonian, in which the spatial asymmetry of the SIA and/or BIA is considered [1]. The effect of the competition between the SIA and BIA is investigated using tunable parameters a and b . To provide multiple degenerate points in the BZ, we locate the degenerate state at point Γ and then transfer it to a peculiar direction by $\pm k_i$. We vary the locations of the degenerate points by appropriately substituting a value for k_i and examine the directional dependence of the synthesized EMF distribution. We further introduce anisotropy by changing the directional effective mass.

In the SIA system, each degenerate point presents a SIA-like singularity and the concentric EMF distribution results. The synthesis of these two concentric distributions generates a source and a sink at the middle position between the two prepared degenerate points when the points ($\pm k_i$) are located in the $\langle 110 \rangle$ direction. Accordingly, the EMF is distributed hyperbolically, and the BIA-like singularity newly results. By contrast, the topological singularity in the BIA system distributes the EMF hyperbolically around each degenerate point. The synthesis of these two hyperbolic distributions results in a new concentric EMF distribution at the middle position. These newborn singularities in the EMF distribution results in accidental degeneracy at the middle position. The sign of the Berry curvature around the newly generated point is opposite to that at the prepared degenerate points.

Finally, we discuss the energy dependence of the Berry phase based on the calculated Berry connection and curvature. Since each degenerate point results in the Berry phase of $\pm\pi$, the multiple degenerate points quantize the Berry phase by π and result in a plateau profile against energy. We further demonstrate that this π quantization can be understood by counting the number of degenerate points in the BZ in addition to identifying the sign of the Berry curvature [2].

Poster Spotlight: Orientation Control of MBE Grown SnTe Layers on GaAs Substrates Masakazu Kobayashi^{1,2} and Su Nan¹; ¹Waseda University, Japan; ²Material Research Technology Institution, Japan

SnTe is one of the attractive material for a topological crystalline insulator (TCI). SnTe films have been grown directly on GaAs (100) substrates by molecular beam epitaxy, and single domain SnTe layers preferentially oriented to (100) were achieved by now. The (111) oriented SnTe domains and Te were easily included in the film. The crystallographic orientation control and surface smoothness improvement was mainly performed in this study.

SnTe layers were grown on (100) and (111)B oriented GaAs substrates by molecular beam epitaxy (MBE). Most of structures were formed on (100) GaAs substrates with (100) oriented ZnTe buffer layers. Elemental sources were used and the molecular beam intensity ratio ($J_{\text{Te}}/J_{\text{Sn}}$) was varied between 0.6~2.9. The beam intensity ratio was tuned by changing the beam intensity of Te. The substrate temperature was calibrated using the oxide desorption temperature of chemically etched GaAs substrates prior to the film growth, and it was varied from 200 °C to 300 °C. The film thickness of SnTe was about 100 nm. The introduction of the ZnTe buffer layer was effective to improve the crystallographic properties of SnTe layers. Atomic force microscopy observation revealed that plateaus with atomically smooth surfaces were obtained for SnTe layers prepared on ZnTe buffer layers. On the other hand, samples prepared without ZnTe buffer layers haven't exhibited the atomically smooth surfaces. The size of the plateau was increased by increasing the molecular beam intensity ratio up to 1.0.

Since the growth temperature was relatively low, the inclusion of the excess material was not negligible. According to the result of X-ray diffraction (XRD) measurement, a diffraction peaks originated from hexagonal Te was observed with SnTe peaks when samples were grown with Te rich ($J_{\text{Te}}/J_{\text{Sn}}$ was between 2.9 and 1.5) conditions. In the secondary electron microscopy measurements, featureless surface was confirmed when the XRD of the sample exhibited no Te peak while dotted materials were clearly observed on the surface when the hexagonal Te peak was observed. The distribution density of the dot was high when the Te diffraction peak signal intensity was strong. Those dotted materials are presumed to be the residual of Te.

The orientation of the material was affected by the growth temperature. When the substrate temperature was raised, (111) SnTe domains were started to appear. The XRD peak intensities of (100) and (111) domains were comparable when the substrate temperature was 250 °C. In order to eliminate the (111) domain inclusion, the substrate temperature needed to be maintained below 240 °C.

In order to enhance the (111) domain formation, (111)B oriented GaAs substrates were employed. (100) domains could be mostly eliminated when the substrate temperature was raised to 270 °C.

A standard van der Pauw Hall measurement was performed to characterize the electrical property at room temperature. The (100) sample that didn't include the Te residual exhibited the resistivity of about $\text{ohm}\cdot\text{cm}$. The resistivity has increased as the presence of Te residual became noticeable. Based on the literatures, the room temperature resistivity of SnTe and Te were about $\text{ohm}\cdot\text{cm}$ ^[1] and $0.3 \text{ ohm}\cdot\text{cm}$ ^[2], respectively. The higher resistivity obtained for the grown film might be originated from the mixing of Te residual. Although the surface morphology was improved by the introduction of the ZnTe buffer layer, the electrical properties were not improved. Boundaries of plateau probably became the center of carrier scatterings.

8:00 PM QT04.08.07

WTe₂ Topological Insulator: Synthesis, Characterizations and Applications Dimitre Dimitrov^{1,2}, Vera M. Gospodinova², J.F. Sierra³ and Sergio Valenzuela³; ¹Institute of Solid State Physics, Bulgarian Academy of Sciences, Bulgaria; ²Institute of Optical Materials and Technologies (IOMT), Bulgarian Academy of Sciences, Bulgaria; ³Catalan Institute of Nanoscience and Nanotechnology (ICN2), Spain

Since the discovery of a new material phase, topological quantum materials (TQMs), [1] tremendous effort has been made to explore a wide variety of novel and abundant physics appearing in topological insulators (TIs), topological superconductors (TSCs), and Weyl semimetals for creating novel electric and spintronics devices. WTe₂ belongs to the family of transition-metal dichalcogenides (TMDs) and crystallizes naturally in a non-centrosymmetric orthorhombic structure (also known as the Td or distorted 1T phase, in which the tungsten atoms are octahedrally coordinated by the tellurium atoms) with polar space group Pmn2₁. The polar axis in WTe₂ is oriented along the stacking direction of layers. Unlike other TMDs, WTe₂ is a Weyl semimetal in its native crystal phase [2]. Among Weyl semimetals, Td-type WTe₂ is a new class, a type-II Weyl semimetal, where the Weyl points appear at the crossing of the oblique conduction and valence bands due to the broken inversion symmetry and non-saturating giant positive magnetoresistance is a manifestation of the type-II Weyl character [3]. In this presentation the current status of the research and emerging applications of WTe₂ are reviewed.

SESSION QT04.09: Exotic Properties of 2D Topological Materials III

Session Chairs: Paolo Bondavalli and Bruno Dlubak

Thursday Morning, November 30, 2023

Sheraton, Fifth Floor, Riverway

8:30 AM *QT04.09.01

Low Secondary Electron Emission 2D Surfaces Isabel Montero; CSIC. Insituto de Ciencia de Materiales de Madrid, Spain

The secondary electron emission is the feedback mechanism of the resonant avalanche of electrons or Multipactor discharge in high- power RF devices onboard satellites. The multipactor discharge is a severe problem which limits the maximum power of RF instrumentation in space missions, it can cause RF signal loss and distortion and it can increase the noise figure or bit-error-rater even total mission failure. The search for surfaces with a low secondary electron emission yield (SEY) is considered one of the main research areas to reduce the multipactor effect in high-power RF devices used in spacecraft and other important technological fields such as high-energy particle accelerators. In this study, RF devices were made using aluminum alloy AA6061. The RF insertion losses of the devices were improved, meaning they were reduced, when AA was silver-coated. However, the SEY of silver, although lower than that of AA, still needs to be reduced to prevent multipactor. The SEY of silver exposed to air is greater than 2. The aim of this study was to deposit a 2D MoS₂ layer on silver coatings that are suitable for reducing SEY and preventing multipactor discharge. Prior to the deposition of the silver coating, the aluminum alloy of the RF devices was zincated, followed by the deposition of intermediary layers of Ni and Cu. We used deep eutectic ionic liquids (2:1 ethylene glycol-choline chloride) instead of water to deposit these coatings. Finally, the MoS₂ was deposited on the external silver coating using an optimized electroless process. As a result, we have developed an electroless plating process for growing 2D nanostructures with a high aspect ratio. The characterization was performed in an ultra-high vacuum (UHV) system composed of three interconnected chambers at a pressure of less than 10⁻⁹ hPa, while the fast entry chamber remained at 2x10⁻⁷hPa. SEY is defined as the number of emitted electrons per incident electron, that is, $SEY = I_e/I_p$, where I_e is the emitted current and I_p is the primary or incident current. SEY was measured in the primary electron energy range from 0 to 1000 eV. The samples were also analyzed by x-ray photoemission spectroscopy (XPS) and field-emission scanning electron microscopy (FESEM). In this study, we report an extremely low SEY of this multi-layer coating. The SEY as a function of primary electron energy curves show a maximum value close to 0.8. Furthermore, a linear translation of the SEY curve towards the region where $SEY > 1$ for oxygen content $> 0.3\%$ is observed. The energy distribution curves (EDC) or energy spectra of secondary electrons also exhibit a significant decrease in the signal for kinetic energies $< 50\text{eV}$, which is consistent with the SEY results.

Low-Temperature Microwave Impedance Microscopy of Topological Materials Monica Allen;
University of California, San Diego, United States

Quantum-relativistic materials often host electronic phenomena with exotic spatial distributions. We employ microwave impedance microscopy (MIM), which characterizes the local complex conductivity of a material, to directly visualize chiral edge modes and phase transitions in a quantum anomalous Hall insulator. This near-field imaging technique detects the unique fingerprint of topological edge modes in the GHz regime and spatially disentangles them from trivial states in the bulk of the material. Motivated by these experimental findings, we model the microwave response of topological edge states in a Chern insulator and demonstrate an enhanced MIM response can appear at the crystal boundaries due to collective edge magnetoplasmon excitations. The resonance frequency of these plasmonic modes should depend quantitatively on the topological invariant of the Chern insulator state and on the sample's circumference, which highlights their non-local, topological nature. Looking forward, we will also discuss progress on the construction of a new milliKelvin MIM, which will support spatially-resolved detection of topological states at low temperatures.

High-Mobility Two-Dimensional Carriers from Surface Fermi Arcs in Ferromagnetic Weyl

Semimetal SrRuO₃ Films Yuki K. Wakabayashi¹, Shingo Kaneta-Takada², Yoshiharu Krockenberger¹, Toshihiro Nomura², Yoshimitsu Kohama², Hiroshi Irie¹, Kosuke Takiguchi¹, Shinobu Ohya², Masaaki Tanaka², Yoshitaka Taniyasu¹ and Hideki Yamamoto¹; ¹NTT Basic Research Laboratories, Japan; ²The University of Tokyo, Japan

Leveraging two-dimensional quantum transport phenomena and exploiting them in topological and spin electronics require thorough investigation into magnetic Weyl semimetals. Two-dimensional charge/spin carriers arising from pairs of Weyl nodes are realized in the presence of surface Fermi arcs in topological semimetals. To demonstrate such topological quantum transport phenomena, high-quality epitaxial films of Weyl semimetals are vital. Prior to the present study, we recently demonstrated that ultrahigh-quality thin films of SrRuO₃ exhibit quantum transport phenomena specific to bulk three-dimensional Weyl fermions [1,2], implying that they serve as a promising platform also for investigating novel two-dimensional transport in a topological state.

Here we present our findings on the thickness- and angle-dependent magnetotransport properties of SrRuO₃, a magnetic Weyl semimetal. Utilizing machine-learning-assisted molecular beam epitaxy [3], we grew SrRuO₃ films with 10 nm and 63 nm thicknesses. Quantum oscillations in the 10-nm film demonstrate a high quantum mobility of $3.5 \times 10^3 \text{ cm}^2/\text{Vs}$, a light cyclotron mass of $0.25m_0$ (m_0 : the free electron mass in a vacuum), and two-dimensional angular dependence. The two-dimensional, angular transport dependence might be regarded within two scenarios: (1) the surface Fermi arcs, or (2) the quantum confinement of the three-dimensional Weyl fermions. The former is plausible as the identical angular dependence is also observed in the 63-nm film, which is too thick to observe the quantum confinement effect in it. In addition, the linear thickness dependence of the phase shift provides evidence of the non-trivial nature of the quantum oscillations mediated by the surface Fermi arcs. Furthermore, magnetoresistance (MR) measurements while applying magnetic field parallel to the film surface up to 52 T confirmed the saturation of negative MR in the quantum limit (chiral anomaly), assuring that the carriers arise from a pair of Weyl nodes. These results endorse SrRuO₃ as a promising material for topological oxide electronics and for physics investigation of two-dimensional quantum transport phenomena in magnetic Weyl semimetals [4].

Optical Nonlinearities in Hexagonal and Triangular Graphene Quantum Dots Suresh Gnawali and

Vadym Apalkov; Georgia State University, United States

Graphene quantum dots (GQDs), the graphene nanoparticles of a few nanometers excited by an ultrafast optical pulse of a few femtoseconds, exhibit several optical nonlinearities, including residual population and high harmonic generation (HHG). By introducing dephasing, we addressed nonlinearity, namely HHG in GQDs placed in a short linearly polarized optical pulse. At short finite dephasing times, the ultrafast electron dynamics show significant irreversibility with a large residual population of the excited quantum dot levels. When dephasing time increases, intensities correspond to a low-frequency boost, while the cutoff energy decreases regarding the high harmonic spectra. The cutoff energy's dependence on the optical pulse's amplitude is also sensitive to the frequency of the pulse. This dependence in hexagonal GQDs is almost linear when the optical pulse frequency is much less than the quantum dot band gap. However, when the pulse frequency is comparable to the band gap, the cutoff energy shows saturation behavior at a large field amplitude, $>0.4 \text{ V/\AA}$. In triangular graphene quantum dots with zigzag edges, the intensities of high harmonics show a strong dependence on the initial electron population of the edge states of the quantum dot. If a zigzag triangular quantum dot possesses an even number of edge states, then even high harmonics are strongly suppressed when half of the edge states of the quantum dots are populated before the pulse. For any other populations of the edge states, the odd and even harmonics are of comparable intensities.

8:30 AM QT04.10 .04

Probing the Quality of Bi_2Se_3 Films Grown by Molecular Beam Epitaxy *In-Situ* with Spectroscopic Ellipsometry Aofeng Bai¹, Maria Hilse², Prasanna Patil³, Roman Engel-Herbert⁴ and Frank Peiris¹;

¹Kenyon College, United States; ²The Pennsylvania State University, United States; ³Southern Illinois University Carbondale, United States; ⁴Paul-Drude-Institut für Festkörperelektronik, Germany

Quantum materials such as topological insulators (TI) like Bi_2Se_3 feature massless Dirac-like states due to their spin-momentum coupling and time reversal invariance. Those massless topological surface states (TSS) enable the study of new quantum physics and with that allow access to a plethora of technological advancements and the realization of applications with new functionalities for more energy efficient and faster computation schemes. The key to exploiting the unique properties of TIs lies in high-quality materials synthesis. However, Bi_2Se_3 synthesis is plagued with a large number of unintentional carriers, shifting the Fermi level up into the conduction band and masking the TSS. Methods like compensation doping, or cation/anion mixing are being pursued successfully to prevent the Fermi level drift out of the band gap, but the price paid is a substantial carrier mobility reduction in the film limiting TSS observation to very low temperatures. To date, best results for achieving low bulk carrier concentrations and high mobilities are reported for a meticulously designed buffer layer (BL) growth approach consisting of Bi_2Se_3 , In_2Se_3 , and $(\text{Bi}_x\text{In}_{1-x})_2\text{Se}_3$ layers. This approach, on the other hand, is slow and thus expensive due to the complexity of the BL- Bi_2Se_3 synthesis engineering and subsequent TSS probing iteration. Developing a fast, ideally *in-situ* feedback loop between growth and electronic properties is highly advantageous to speed up this approach and realize meaningful progress towards highest-quality Bi_2Se_3 thin film fabrication.

In this talk, we elucidate how *in-situ* spectroscopic ellipsometry (SE) can be employed as a non-invasive, non-contact, real-time, ultra-fast probe of the electronic properties of Bi_2Se_3 during growth. Evaluating the *in-situ* SE data obtained before and after growth of each layer from differently designed Bi_2Se_3 , In_2Se_3 , and $(\text{Bi}_x\text{In}_{1-x})_2\text{Se}_3$ heterostructures, we found that the observed SE measurables for Bi_2Se_3 depend sensitively on the sample heterostructure design. To gain deeper insights about the observed differences, we developed oscillator models for the dielectric functions of Bi_2Se_3 , In_2Se_3 , and $(\text{Bi}_x\text{In}_{1-x})_2\text{Se}_3$, and compared the weighted average of the broadening parameter of the oscillators that make-up the dielectric function. As a result, we found that the weighted average broadening parameters for the Bi_2Se_3 oscillators

Updated as of October 28, 2024

of films grown on a In_2Se_3 , and $(\text{Bi}_{0.7}\text{In}_{0.3})_2\text{Se}_3$ heterostructure were 20 % smaller than those of films grown directly on Al_2O_3 . Smaller broadening parameters are generally associated with the degree of momentum-conservation between electronic transitions due to less pronounced electron scattering. Our finding thus indicates that the Bi_2Se_3 grown on the In_2Se_3 , $(\text{Bi}_{0.7}\text{In}_{0.3})_2\text{Se}_3$ heterostructure has superior quality compared to films grown on bare Al_2O_3 . This conclusion was corroborated by Hall mobility measurements conducted at room-temperature, which ranged highest for Bi_2Se_3 films grown on In_2Se_3 , $(\text{Bi}_{0.7}\text{In}_{0.3})_2\text{Se}_3$ heterostructures. Based on the presented data, *in-situ* SE has the potential to serve as an ultra-fast, real-time probe of the electronic properties of Bi_2Se_3 , and is thus highly advantageous for speeding up the engineering process of high-quality TIs growth.

8:45 AM QT04.10 .05

Analysis of the Moving Boundary Problem for Spinodal Transformations in Thin Films Rahul Basu^{1,2}; ¹VTU, India; ²Jawaharlal Nehru Technological University, India

The equations of Spinodal Decomposition as postulated by Cahn and Hilliard involve a fourth order pde which to date has not been solved analytically. In this article these equations are examined in their various versions, and solutions obtained for the steady state and transient forms using various methods. Then the moving boundary associated with transformation is examined using a heat transfer approach and a solution attempted using a series and a similarity transformation approach. The equation is postulated to have two contributions one from the usual Laplacian and Fickian contribution part for which Stefan solutions are known, and one with a Double Laplacian which has not been examined. The thin film approximation is applied to simplify some parts of the analysis and to try to get a numerical solution.

Silk-Based Technology to Boost Food Security Benedetto Marelli; Massachusetts Institute of Technology, United States

The infrastructure of agro-food systems is responsible for more than 25% of anthropogenic greenhouse gas emissions while facing pressure to support an increasing world population. For the first time in history, the availability of arable land has plateaued, and crop yields are threatened by stressors such as soil salinity and drought that are further exacerbated by climate change. Food security and food waste are twin crises; more than 800 million people are undernourished, and 30% of food is lost or wasted from farm to fork. As new technologies that are economically sustainable, scalable, and rapidly deployable to market are needed to address these challenges, an opportunity lies for biomaterials to lead innovation in the agro-food industry. Our laboratory strives to reinvent silk proteins as advanced materials for boosting food security. Here, we will highlight recent developments in the nanomanufacturing of silk to design: (i) physical unclonable functions for food traceability, (ii) packaging that is biodegradable yet possess good membrane properties, sense spoilage and mitigate biotic decay, (iii) microenvironments that boost seed germination in marginal land, and (iv) different solutions to precisely deliver payloads in planta. These examples will provide an opportunity to discuss how the establishment of a prolonged biointerface between biomaterials and plants tissues requires the development of basic scientific knowledge on material-plant host response, mechanics of disorder-to-order transitions in proteinaceous materials during condensation phenomena, fluid mechanics, and transport phenomena in plants vasculature, and swelling of porous materials exposed to plant fluids.

9:15 AM SB01.01.02

From Idea to Product—Leveraging Materials to Reduce Food Waste Louis Perez; Apeel Sciences, United States

According to the United Nations - Food Agricultural Organization (UN-FAO), we will need 56% more food to feed the growing global population by 2050. In addition, with more than 800 million people who are affected by hunger today, we need solutions that can address food production and supply challenges in short order. One way to address these challenges is to reduce food waste and loss which is reported between 30 and 50% based on geography and product category by the UN-FAO. Beyond the challenge of continuing to feed a growing population, the environmental and economic impacts of food waste are staggering: 8% of greenhouse gas emissions globally and a total cost of \$2.6 trillion dollars annually are due to food waste.

In this talk, we will address how Apeel Sciences, a start-up based in Santa Barbara, CA, is approaching tackling food waste and loss by developing new plant based technologies and products that 'work with nature'. The talk will review the process and the journey of an 'idea' to a product via a multidisciplinary approach inspired by Materials Science and Engineering principles to develop a plant based edible coating and other technologies utilizing data science and computer vision to make quantitative produce quality tools and shelf life prediction models to address food lo

9:30 AM SB01.01.03

Metabolomics in a Circular Bioeconomy: A Case for Fruit/Vegetable Waste Material Residuals

Nancy A. Elnaker¹, Michael A. Ochsenkühn², Shady A. Amin², Matteo Chiesa^{1,3} and Lina F. Yousef⁴;

¹Khalifa University of Science and Technology, United Arab Emirates; ²New York University Abu Dhabi, United Arab Emirates; ³UiT The Arctic University of Norway, Norway; ⁴DeL'Arta-Outdoor Living Laboratory, United Arab Emirates

Research is accelerating towards establishing a circular bioeconomy to achieve the United Nations Sustainable Development Goals (SDGs) and drive sustainable development. Here, we applied untargeted metabolomics as an assessment tool for homogeneous food waste residuals, providing an assessment of their marketability in the circular bioeconomy. The circular bioeconomy involves the comprehensive conversion of biological resources into renewable biobased products, which contributes to climate action and environmental well-being. One strategy for embracing a circular bioeconomy is the discovery of vertical conversions of food and agricultural waste residues, transforming them into value-added commodities. This article applies an untargeted metabolomics approach to gain insights into the phytochemical profile of fruit and vegetable residual wastes (FVRs). Through this analysis, 472 known and 542 unknown compounds were identified, with their relative abundances determined. Among the most prevalent 50 annotated metabolites in FVRs, a significant proportion consisted of natural products or bioactive compounds (64–86%), functional foods (7–12%), fragrances (0–8%), pesticides (0–6%), and intriguingly, environmental contaminants (7–23%). Homogenous waste residuals resulting from fruit and vegetable processing emerge as a promising source of bioactive nutraceuticals, functional food derivatives, and biomaterials. This study proposes using untargeted metabolomics as a rapid method to evaluate extracts obtained from homogenous food waste residuals. This approach provides a pre-assessment of their potential market value within the context of the circular bioeconomy.

Near-Infrared Optical Gas Sensor for Intelligent Food Packaging Niloufar Sharif, Mohammed Mouhib and Ardemis Boghossian; École Polytechnique Fédérale de Lausanne (EPFL), Switzerland

Aim:

This project focuses on the design and fabrication of an intelligent packaging system based on a gas-phase optical sensor. The optical sensor emits near-infrared light that is able to penetrate through visibly opaque materials, including plastics, paper, and cardboard. The sensor will provide real-time monitoring of the quality of packaged food products using a specialized, near-infrared camera.

Method:

The near-infrared signal from the optical sensor is based on the fluorescence emissions of carbon nanotubes (CNTs). The CNTs are wrapped with single-stranded DNA that is able to spontaneously assemble onto the nanotubes following sonication. This wrapping not only solubilizes the CNTs in aqueous solutions but also controls the optical responsivity of the CNTs towards different gases. The resulting solutions are then incorporated into an agar hydrogel. We subsequently investigate the response of the sensor in the presence of ammonia, a gas associated with food spoilage. Finally, we investigate the selectivity of the sensor in the presence of other gases.

Results:

Our results show that the fluorescence intensity of the AT₍₁₅₎-wrapped CNTs increases upon exposure to ammonia. Interestingly, we observe distinct responses from different CNT chiralities. We also observe a concentration-dependent and selective response of the AT₍₁₅₎-wrapped CNT sensor to the target gas, with no significant response to the other gases used in this study.

Conclusion:

Here, we developed an optical sensor based on the fluorescence of CNTs for intelligent food packaging applications. The sensor can be used to monitor food quality in real-time, notifying the user on onset of food spoilage. This sensor thus offers both consumers and manufacturers a quick and accessible means of ensuring food quality and safety.

10:30 AM SB01.01.05

Highly Moisture Resistant Super Gas Barrier Polyelectrolyte Thin Films Ethan T. Iverson, Hsu-Cheng Chiang, Kendra Schmieg, Hudson Legendre and Jaime Grunlan; Texas A&M University, United States

Flexible, thin coatings with high barrier to oxygen are widely used for improving the lifespan and shelf life of flexible organic electronics and perishable food products, respectively. While metalized plastic and metal oxide thin films exhibit excellent barrier, they also have unique drawbacks. The lack of transparency and recyclability of metalized plastic, and the rigidity and poor adhesion of metal oxide films (e.g., SiO_x and Al_xO_y), severely limit their benefit, especially in food packaging. The utilization of polyelectrolytes to develop high gas barriers with exceptional transparency, adhesion, and flexibility has long been realized. These barriers can be deposited utilizing layer-by-layer (LbL) assembly, providing nanoscale control over film structure and a high degree of tunability in barrier performance. Another approach utilizes a one-pot polyelectrolyte complex deposited via rod or dip coating in a single step. This film is then buffer cured, which generates ionic crosslinks between the polyelectrolytes and therefore minimizes oxygen diffusion through the film. While polyelectrolyte-based barriers typically lose their efficacy in high humidity, a LbL generated barrier, which is only 132 nm thick, provides a 99x reduction of the oxygen transmission rate of PET at 0% and 90% relative humidity (RH). This barrier retains nearly 81% of its performance at high humidity, a feat that is typically only possible with chemical crosslinking. Another impressive barrier was prepared via a simple dip-coating process of polyethyleneimine (PEI) and poly(acrylic acid) (PAA), which was then cured with a citric acid buffer solution. Through simple ionic crosslinking, undetectable oxygen transmission rate (OTR < 0.005 cc/m²*day), at both 0% and 90% RH, can be achieved with a PEI:PAA molar ratio of 1:1. The strong complexation from ionic crosslinking creates an unusually dense thin film that is promising for various packaging applications (food, electronics, etc.). These thin film exhibit some of the best-ever polymer-based oxygen barriers at high humidity.

10:45 AM SB01.01.06

FODMAP: Food and Agriculture-Friendly, Organic Compound-Based, Degradable Nanozymes

Integrated with an Optical Sensing Platform for Toxic Molecules Detection on The Food Samples

Dong Hoon Lee and Mohammed Kamruzzaman; University of Illinois at Urbana-Champaign, United States

Nanozyme has recently expanded applications in the field of food and agricultural science, offering the potential to enhance food safety by detecting toxic molecules. However, most of the nanozymes are derived from conventional chemistry and material science such as MOF/metal-based NP. These nanozymes encounter challenges related to their intrinsic toxicity and low-cost effectiveness when applied in food and agriculture. Thus, novel nanozymes that are highly suitable for food and agriculture for future applications are desired.

To address this need, we have introduced a novel type of nanozyme, called OC nanozymes, which are food and agriculture friendly. These nanozymes are composed of polymer and organic compounds and exhibit decent peroxidase-like catalytic activity. The customized, chelation-driven self-assembled particle generation process was contrived to provide spherical-shaped nanozymes containing partially mimicked cofactor sites (e.g., Fe-N or Fe-O) of the natural enzyme without using the conventional engineering process, including pyrolysis, organic solvent, and ionic gelation. In contrast to conventional nanozymes, OC nanozymes exhibit decent eco-compatibility, and cost effectiveness with satisfactory catalytic performance (e.g., K_m = at least 0.074mM/H₂O₂). These nanozymes, when integrated with colorimetric sensing platforms, enable rapid and selective detection of antioxidant (LOD = at least 7.27 μ M), and toxic herbicide detection (LOD = 10 pg mL⁻¹) within 7 minutes. Additionally, some OC nanozymes are designed to degrade at a moderate temperature (around 45 Celsius) after use, which provides benefits for further waste management issues. We envision that OC nanozymes can be utilized in further practical food applications.

11:00 AM *SB01.01.07

Business Collaborative Research on Novel Strategies in Functional and Active Packaging for the Food Industry Concha Bosch-Navarro, Encarna Gómez and Begoña Ruiz; AINIA, Spain

Microbial contamination supposes an issue of major concern in the food industry that affects both industrial processes and food products. Consequently, food industry is seeking for novel strategies that prevent surface contamination and microorganism proliferation during fabrication, and also innovative packaging materials that contributes to increase shelf-life of packaged food while being more environmentally friendly.

The development of functional and/or active coatings that could be applied over industrial equipment to prevent microbial growth or over packaging materials to incorporate advanced functionalities appears out as outstanding strategies that different companies in the food and packaging industry are exploring and implementing. A functional coating refers to a formulation that incorporates, for example, antimicrobial activity. To this end, different active substances can be considered. Traditionally, different preservatives and plant extracts have been used. Currently, novel strategies include the use of pro/prebiotics, peptides, endolysins or nanobodies, amongst others. Besides, a functional coating in packaging refers to a specialized type of coating applied to the surface of packaging materials to provide additional functionalities and benefits, such as gas barrier, water resistance or oil repellency. Different strategies are being followed, including the formulation of coatings based on natural ingredients such as proteins, fatty acids or lignocellulosic materials in order provide with functionality while contributing to create a circular economy model.

Updated as of October 28, 2024

Several developments in the field of novel functional coatings carried out by AINIA together with different companies in the food and packaging sectors, will be presented. These developments are the result of R&D projects in which synergies between different knowledge fields have been exploited, such as biotechnology, hygienic surfaces, material's science, and packaging. The common point being the agrifood industry focus and the need to fight against food waste while guiding sustainability to the highest standards that current regulations are demanding.

11:30 AM *SB01.01.08

Biomaterials and Food-Opportunities and Challenges Fiorenzo Omenetto; Tufts University, United States

Natural materials offer new avenues for innovation across fields, bringing together, like never before, natural sciences and high technology.

Significant opportunity exists in reinventing naturally-derived materials, such as structural proteins, and applying advanced material processing, prototyping, and manufacturing techniques to these ubiquitously present substances. This approach help us imagine and realize sustainable, carbon-neutral strategies that operate seamlessly at the interface between the biological and the technological worlds.

Some of these attributes make these materials ideally suited for interfaces with food from multiple perspectives, ranging from the aesthetic, to flavors, to therapeutics to name a few. These applications leverage functional aspects that include biomaterials-based applications in edible and implantable electronics, food preservation, energy harvesting, wearable sensors, compostable technology, distributed environmental sensing. These opportunities will be outlined in this talk presenting a survey of the possibilities that lie ahead.

SESSION SB01.02: Engineering Future Food Materials II

Session Chairs: Leila Deravi and Varsha Rao

Tuesday Afternoon, November 28, 2023

Hynes, Level 1, Room 105

1:30 PM *SB01.02.01

Food via Tissue Engineering – Challenges and Opportunities David L. Kaplan; Tufts University, United States

The need for future foods for the ever-growing population requires consideration of alternative approaches toward food sustainability, nutrition and security. To address this need, we pursue a cell-based, tissue engineering approach, eliminating animals from the process. Our central hypothesis is that sustainable, cost-effective, and scalable cultivated-meat and alternative proteins will provide new food availability options and healthier food alternatives, while decreasing environmental impact. Towards this goal there is much progress, with cell and tissue biomanufacturing central to the approaches. Further, there remain many challenges and opportunities ahead, from cells, media, safety and scale up, to tuning nutrition, composition and overall food quality and health. These topics will be discussed in the context of

this emerging food frontier, where the impact is potentially transformative.

2:00 PM *SB01.02.02

The Development of High Protein Plant-Based Cheese Alejandro G. Marangoni and Stacie Dobson; University of Guelph, Canada

Animal proteins and animal by-products, such as milk and cheese, generate the greatest amounts of greenhouse gas emissions in the food sector. This, coupled with the demonstrably worsening climate crisis, means that there needs to be a shift to more sustainable alternatives in the form of plant-based foods. In particular, the plant-based cheese industry is relevant, as the products lack critical functionalities and nutrition compared to their dairy-based counterparts. Waxy starch, plant-protein isolate, and coconut oil were combined to create a novel high-protein (18w/w) plant-based cheese. We determined that by using native waxy starch, we can enhance its existing viscoelastic properties by modulating gelatinization through the addition of plant protein and fat. Texture profile analysis indicated that the cheese analogues could reach hardness levels of 15-90N, which allowed samples to be tailored to a wider range of dairy products. We determined that plant proteins and fat can behave as particulate fillers and enhance network strength but also create strategic junction zones during starch retrogradation. The degree of melt and stretch of the high protein plant-based analogues were 2-3times greater than those observed for commercial plant-based cheeses and significantly more similar to dairy cheese. The rheological melting kinetics saw that the high protein plant-based cheese displayed more viscous properties with increasing temperature. $\tan(G''/G')$ at 80°C was used as an indicator for sample meltability where, values indicate better melt and more viscous systems. The high protein plant-based cheese reached tan values upwards to 0.8, whereas commercial plant-based cheese only reached tan values around 0.1. Synchrotron micro-CT as well as synchrotron mid-IR imaging was utilized to characterize structure and interactions between components.

2:30 PM SB01.02.03

Generating Animal-Free Protein Scaffolds using Antisolvent Precipitation under Couette Flow Patrick A. Sullivan, Ying Wang, Lasanthi Sumathirathne and Leila Deravi; Northeastern University, United States

A common feature of animal-based proteins is their ability to self-assemble into continuous protein fibers, as seen in muscle and connective tissues. Their fibrous nature has inspired research and development in the tissue engineering, textile, and synthetic meat industries, to find methods of replicating this aligned fiber structure in nonanimal-based proteins. Zein is a nitrogen storage protein that is primarily found in corn, that has become popular due to its status of Generally Regarded As Safe (GRAS), its biocompatibility, its fabrication flexibility and its unique solubility, solvating in 60-90% mixtures of ethanol and water. This makes it a prime candidate for antisolvent precipitation and extrusion methods to produce zein fibers for food industry applications. However, extrusions methods produce a rapid but random generation of fibers in terms of diameter and alignment when utilizing this antisolvent precipitation, and the conclusion has been drawn that further antisolvent zein fiber formation should focus on fiber orientation as a next step in development. In this work we aimed to produce aligned fibrous microstructures on zein scaffolds like those found in animal-based proteins. We investigate how salt concentration and identity influence the aggregation patterns of zein as it precipitates into nanoparticles through its addition to an aqueous antisolvent. We then use the conclusions drawn from these findings in combination with a custom-built device to induce anti-solvent precipitation under Couette-flow to produce continuous fibrous scaffolds, demonstrating their use as scaffolds for future tissue engineering

applications.

2:45 PM SB01.02.04

Cephalopod-Inspired Material Design for Potential Food Applications Bianca C. Datta; Ronin Institute for Independent Scholarship, United States

As the global population rises alongside a worsening climate outlook, alternative proteins such as plant and cell-based meat provide exciting avenues for meeting the increasing demand for meat sourced from animals and have implications for planetary and human health. While food science is a well-established field with a rich history, inclusion of methods and research paradigms from the materials community can accelerate the development of promising food technologies. In this work, we review the complex and interesting structure and functionality of cephalopods, the landscape of existing materials advances towards replicating these creatures, and extensions towards food and edible materials. In doing so, we bridge the rich culinary traditions around cuttlefish, octopus, and squid⁷ with advancements in tissue engineering and bio-inspired design.

Few creatures generate as much wonder and curiosity as cephalopods. Renowned for their protective and communicative capabilities (camouflage, texture and shape change), they also demonstrate fascinating behavioral and cognitive abilities⁶. Researchers have looked to cephalopods for inspiration in designing systems as varied as displays¹, programmable coloration², self-healing coatings³, mechanochromic windows⁴, and bioelectronics⁵. We now look to their unique structure and properties to inspire a new domain of compelling alternative food materials.

Understanding Structure in Methylcellulose Solutions using Machine Learning Enhanced Scattering Analysis (CREASE), Coarse-Grained, and Atomistic Molecular Dynamics Simulations Audrey Collins, Zijie Wu and Arthi Jayaraman; University of Delaware, United States

Methylcellulose (MC) is cellulose derivative in which some of the hydroxyl groups are replaced by methoxy(-OCH₃) groups. Aqueous solutions of MC exhibit unique phase behavior wherein at low temperatures MC chains are soluble in water and at high temperatures MC chains assemble into semi-flexible fibrils and fibrillar networks. Fibrillar networks exhibit mechanical and rheological properties that make them useful as food and pharmaceutical ingredients. Structural characterization of MC aqueous solutions through small angle X-ray scattering (SAXS) experiments show that MC fibrils exhibit a consistent fibril diameter with varying MC concentration and molecular weights; however, the molecular underpinnings of this observation are unclear. Our work aims to elucidate these molecular underpinnings using computational techniques from top-down (machine learning enhanced computational reverse engineering analysis of scattering experiments: CREASE) and bottom-up (molecular dynamics simulations). In the top-down approach, (Macromolecules 202255(24), 11076-11091), Wu and Jayaraman found consistent MC fibril diameter distributions using CREASE and analytical model fits, confirming the results by Lodge, Bates, and co-workers (Macromolecules, 2018, 51, 7767–7775) that MC forms fibrils with consistent average diameters of ~15–20 nm regardless of the chain length and concentration of MC chains. In the bottom-up approach, which is the focus of this talk, we use both coarse-grained (CG) and atomistic (AA) molecular dynamics (MD) simulations to capture macromolecular-scale fibril assembly and the molecular-level interactions between MC chains that drive that assembly, respectively. In the CG MD simulations, we observe MC chains assemble in parallel fashion to form fibrils with consistent diameter for varying MC chain length and concentration. Guided by those CG MD chain configurations where solvent is implicit, we use atomistic MD simulations with explicit water, and uncover a potential explanation for the consistent fibril diameter: inter-MC chain twisting. We find that a combination of favorable hydrogen bonds and hydrophobic interactions drives the twisting of MC chains during fibril formation. Our work provides a holistic understanding of MC chains assembly in water and aids material development for application of MC in various industries.

Whey Protein Isolate Composites as Tunable Scaffolds for Cultured Meat Christopher Foley, Irfan Tahir, Patrick Charron and Rachael Floreani; The University of Vermont, United States

INTRODUCTION The rising global population and increasing prevalence of food insecurity highlights the need for alternative food sources. New developments in biotechnology have given rise to many alternative food and protein options, including the research and development of cultivated meat. Cultivated meat is produced via *in vitro* animal cell culture and their incorporation into manufactured scaffolds. Plant-based, alginate scaffolds are a common material used during manufacturing, due to the tunability of their mechanical properties through modification of molecular weight, chemical composition, and structure; however, alginate does not have the necessary cell adhesion ligands. Whey protein isolate (WPI) is a byproduct of the dairy processing industry, is a food additive, and has recently been shown in the literature to encourage cell adhesion in bone and cartilage tissue engineering. The objective of our study was to investigate the effect of WPI-based scaffolds on muscle cell adhesion and viability for the production of scaffolding for cultured meat. **METHODS** The AlgMA was synthesized by dissolving sodium alginate in deionized (DI) water at a 1% (w/v) and a 20-molar excess of methacrylic anhydride. WPI was dissolved in 1x phosphate buffered saline (PBS) at 5.25% (w/v). After 24 hours, the solutions were dialyzed (MWCO = 6-8 kDa) against chilled DI water for three days to remove any residual reactants. Polymer solutions were then frozen and lyophilized. With these dry polymers, 3% (w/v) AlgMA solutions were prepared in DI water at room temperature, to which WPI or WPI-MA, was added to bring the protein concentration to 10% (w/v). One mM eosin Y, 125 mM triethanolamine, and 20 mM 1-vinyl-2-pyrrolidinone were mixed with the control (AlgMA) and experimental samples

(WPI/AlgMA, WPI-MA/AlgMA). These solutions were then cast into circular molds and exposed to the green light (525 nm) for 10 minutes for crosslinking to occur. The crosslinked polymer solutions were characterized through proton nuclear magnetic resonance ($^1\text{H-NMR}$), scanning electron microscopy (SEM), rheological & compression testing, swell/weight-loss studies, and immunofluorescent staining of C2C12 myoblast cells. **RESULTS AND DISCUSSION** A 3D interconnected porous network was created, showing differences compared to an AlgMA control. WPI-based scaffolds exhibited more ordered structures compared to that of the AlgMA control. Pore sizes ranged between 50-200 μm . While moderate weight loss was experienced by the non-modified WPI, the WPI-MA and AlgMA hydrogels displayed minimal weight loss after a period of seven days. Under a compressive load, the WPI-MA/AlgMA scaffolds were more compliant compared to the AlgMA control, and the WPI-based scaffolds exhibited moduli that closely resembled the mechanical properties of native muscle tissue. WPI-based scaffolds were non-toxic to C2C12 cells, and increased cell density over the course of seven days compared to controls. WPI/AlgMA and WPI-MA/AlgMA materials were found to be non-toxic to murine C2C12 myoblast cells and promoted increased adhesion and proliferation compared to the AlgMA control. The incorporation of non-modified and chemically modified WPI in alginate scaffolds shows encouraging data that supports the use of WPI-based scaffolds for engineering muscle tissue *in vitro*. Also, the tunability of composition and mechanical properties will allow these materials to be fine-tuned for other properties such as texture and flavor. **CONCLUSION** Scaffolds were formulated using methacrylated alginate (AlgMA), WPI, and methacrylated WPI (WPI-MA). The resultant scaffold product was a photo-crosslinked, porous network that displayed marked differences compared to the AlgMA control scaffold. In summary, our study provides compelling evidence supporting the use of WPI-based scaffolds in 3D cultivated meat production, highlighting its substantial prospects and benefits.

Biomaterials and Bioprinting of Skeletal Muscle Spheroids for use as Building Blocks for Engineered Muscle Tissue Kent Leach, Nicholas Johnson, Andrea Filler and Alex Kermani; University of California-Davis, United States

Skeletal muscle tissue engineering has the potential to address key clinical and societal challenges such as traumatic muscle injury, our fundamental understanding of skeletal muscle development and disease, and the future of meat production *via* cell cultured meat. Preclinical animal models and monolayer culture have driven our understanding of skeletal muscle biology and differentiation. However, two-dimensional (2D) cell cultures lack complex cell-cell and cell-extracellular matrix (ECM) interactions that provide essential biochemical and biomechanical signals directing cell function *in vivo*. Engineered tissue must sufficiently model the complexity of native muscle, which has led to the innovation of advanced fabrication methods such as 3D bioprinting.

Bioprinting is a promising biofabrication technique for generating structured tissue due to the potential to precisely pattern multicellular constructs of relevant cell types. The most common bioprinting applications use monodisperse cells, which requires disruption of essential cell-cell and cell-matrix interactions. A growing body of research confirms the benefits of retaining the endogenous ECM to mimic the native extracellular environment and support cell function, hence exposing a key current limitation of bioprinting.

Spheroids are dense cellular aggregates that exhibit promise as building blocks for tissue engineering due to their retention of endogenous ECM, upregulated cytokine production, and increased cell-cell interactions. Spheroids are advantageous for use in tissue engineering due to their enhanced

differentiation, angiogenic potential, and cell survival *in vitro* and *in vivo* compared with monodisperse cells. Spheroids have been fabricated from a wide variety of cell types yet literature on skeletal muscle spheroids, sometimes referred to as myospheres, is sparse. The study of myospheres has primarily been focused on understanding cell behavior of primary muscle cells, but their application in tissue engineering lags behind other tissues types such as bone, heart, and adipose, among others. While work utilizing muscle spheroids from immortalized cell lines has been limited, initial studies have shown promising results in regard to cell survival and differentiation. For example, C2C12 spheroids, once dissociated, exhibited higher proliferation, upregulated MyoD expression, and enhanced myogenic potential in both 2D and 3D culture. Furthermore, C2C12 spheroids have upregulated myogenic factors compared to monodisperse cells and can differentiate into aligned myotubes on electrospun substrates. However, little is known about how muscle cell spheroids function in contiguous matrices such as bioinks, representing a key information gap in the field.

We hypothesized that skeletal muscle cell spheroids will function as potent building blocks of muscle tissue when embedded in 3D microenvironments. We bioprinted skeletal muscle spheroids to assess cell function and tissue forming potential compared to monodisperse cells. We utilized 3D bioprinting as a proof-of-concept to determine whether bioprinting may adversely affect cell viability. Experiments were first performed using C2C12 spheroids before translating to more clinically and culinarily relevant primary bovine satellite cells. Both C2C12 and primary bovine SCs formed spheroids of similar sizes, remained viable after bioprinting, and exhibited similar spreading characteristics within an alginate matrix. When bioprinted with alginate as a bioink, spheroids of both cell types fused into larger tissue constructs over time and exhibited tissue formation potential similar to monodisperse cells. These data demonstrate that skeletal muscle spheroids are promising building blocks for muscle tissue and validate 3D bioprinting as a compatible fabrication technique. I will also highlight other studies illustrating the synergy of engineered biomaterials and muscle cell response.

SESSION SB01.03: Poster Session

8:00 PM SB01.03.01

Electrohydrodynamics for Efficient Droplet Coalescence in Food-Grade Non-Aqueous Pickering Emulsions Bruno Telli Ceccato^{1,2}, Namrah Azmi^{1,3}, Andrew N. Akanno¹, Paul G. Dommersnes¹, Rosiane Lopes da Cunha², Lucimara Gaziola de la Torre² and Jon Otto Fossum¹; ¹NTNU, Norway; ²University of Campinas, Brazil; ³Stayfit Nutrisupplies, Tanzania, United Republic of

Coalescence is a fundamental process in emulsion synthesis. It can have positive effects depending on the approach. The emulsion stabilization can be reached when emulsifiers occupy all the droplet surface, and when low quantities of solid particles (Pickering emulsions) are used, stabilization can be reached under controlled arrested coalescence [1].

The application of electro hydrodynamics on non-aqueous emulsion systems can produce emulsion droplets with controlled size distribution and coverage, and also induce coalescence. In the latter case, when an electric field is applied, dipolar emulsion droplets can be generated and short-range dipolar

droplet-droplet interactions can take place. Positive surface charges on a droplet can attract negative charges on a neighboring droplet, eventually leading to so-called electro coalescence [2], [3]. Here, we explore the electro-coalescence of food-grade droplets [4] of a non-aqueous system. Non-aqueous food-grade systems are scarcely investigated due to the miscibility of most edible oils, and the limitations of suitable polar protic solvents [5]. In this work, the electro-induced coalescence is shown for a non-aqueous Pickering emulsion with rapeseed or moringa oleifera oils as continuous phase, glycerol or lactic acid in ethanol as dispersed phase, and ethyl-cellulose or moringa oleifera leaf-based stabilizer particles.

Our preliminary results provide insights into the application of electro hydrodynamics in the emulsification processing of food-grade Pickering systems.

Reaction Kinetics and Physical Properties of Carboxymethyl Cellulose-Based Hydrogel Blends for Food Packaging Samudra Gupta and Javen Weston; University of Tulsa, United States

Carboxymethyl cellulose (CMC) is a commonly studied polymer made by chemically modifying cellulose to increase water dispersability. CMC is widely used in hydrogel applications because of its biocompatibility and biodegradability. CMC hydrogels are used as absorbents, for food packaging, as additives in pharmaceutical formulations, and for other applications. CMC hydrogels can be synthesized using a variety of chemical and physical crosslinking agents. Here, ethylene glycol diglycidyl ether (EGDE) is used as a chemical crosslinker. The optimal cross-linking temperature and EGDE concentration were determined using *in-situ* oscillatory shear rheology, and other properties, such as the water vapor permeability, swelling ratio, tensile strength, and % elongation at break of the hydrogels were also measured to assess their usefulness for food packaging applications. These hydrogels were found to have unsatisfactory bulk and mechanical properties for food packaging materials, so blends of CMC with various polysaccharides have been investigated to search for synergy between the different biopolymers. In particular, κ -Carrageenan and Xanthan gum were chosen for this study; both are common anionic polysaccharides with excellent gelling, stabilizing ability, emulsifying, and thickening properties. These

blends were chosen due to CMC being easy to use, readily available, and cheap. Additionally, this study focuses on finding a correlation between rheology, and bulk properties, such as tensile strength, water vapor permeability, and % elongation at break.

Magnetic Field-Made Capsules to Fight Food Waste Arne T. Skjeltorp; Instiute For Energy Technology, Norway

The European Union (EU) funded PICKFOOD project [1] addresses the 80 million tonnes of food waste generated in the EU annually. It focuses on combating quality deterioration caused by lipid oxidation and other factors. The project aims to enhance the stability and affordability of Pickering emulsions, a promising alternative. Through collaboration with the food industry, PICKFOOD will develop frameworks and methodologies to assess Pickering emulsion applications in safe, healthy, and functional foods.

In this project, magnetic fields are envisioned to make capsules, but this requires very forceful magnets. Many permanent magnets on the market have large magnetic fields, but weak field gradients. The GIAMAG magnets have unique and patented designs that produces both very large magnetic fields and high field gradients, resulting in the most forceful magnets available on the market [2].

Surface Functionalization of Pickering Emulsion Stabilized by Silk Fibroin Microparticles and Enhanced Adhesion for Foliar Spray Yue Hu and Benedetto Marelli; MIT, United States

Pickering emulsion is a category of emulsion that is stabilized by solid particles. Compared to emulsions stabilized by molecular emulsifiers, Pickering emulsion has high stability, low cytotoxicity, and good biocompatibility. Solid particle emulsifiers could also be modified by functional groups or antibodies to achieve different demands. Thus Pickering emulsion is widely used in the food, pharmaceutical, and cosmetic industries. Silk-fibroin regenerated from silk cocoons is a natural protein. This fibrosis protein has been widely investigated and applied in the fields of biomedicine, cosmetics, and food coating. In our study, we developed biocompatible protein particles synthesized from silk fibroin to stabilize oleic acid oil-in-water Pickering emulsion. Those Pickering emulsions could be applied to agricultural and food industries.

Specifically, water-insoluble silk fibroin microparticles (SFMPs) with a diameter of approximately 2 μm were synthesized through the salting-out method. These microparticles can act as emulsifiers, stabilizing alkane-in-water Pickering emulsion. In addition, polar oil oleic acid with payloads possessing a pKa below 5 can be stabilized by SFMPs to generate a Pickering emulsion. The research also delves into the mechanism and ability of SFMPs to stabilize both nonpolar and polar oil-in-water Pickering emulsion, as evidenced by the measurement of three-phase contact angles. To functionalize Pickering emulsion, we synthesized antibody-labeled SFMPs, which can partially replace the emulsifier on the surface of Pickering emulsion droplets and improve the droplets' affinity to antibody binding sites. In this work, anti-pectic polysaccharide antibody-labeled Pickering emulsion loaded with plant hormone jasmonic acid exhibited strong binding to the waxy layer weaker part of the leaf even after the wash and effectively

boosted the trichome number of *Arabidopsis* new leaf.

Harnessing Satellite Imagery and Geospatial Analysis for Sustainable Nutrient Management in Agricultural Systems Olatunde D. Akanbi, Deepa Bhuvanagiri, Erika I. Barcelos, Brian Gonzalez Hernandez, Arafath Nihar, Laura Bruckman, Yinghui Wu, Jeffrey Yarus and Roger H. French; Case Western Reserve University, United States

The excessive use of fertilizers in agricultural practices poses significant challenges to environmental sustainability and food security. A substantial portion of applied fertilizers from farms, and concentrated animal feeding operations (CAFOs) and urban activities, more specifically in wastewater treatment plants, are lost through runoff, leading to water pollution, ecosystem degradation, and economical loss. To address these critical issues, this research aims to develop an innovative approach utilizing satellite imagery and geospatial analysis to enable efficient and sustainable nutrient management in agricultural systems. The study leverages the Normalized Difference Vegetation Index (NDVI) derived from satellite imagery to monitor crop growth on a daily basis and optimize fertilizer application. By regularly assessing the NDVI metrics, farmers can precisely determine the timing and location for fertilizer application, ensuring optimal nutrient uptake by crops and minimizing wastage. This approach allows for large-scale monitoring, offering a valuable tool to farmers for daily decision-making in fertilizer management. Furthermore, the research incorporates geospatial analysis and spatiotemporal modeling to monitor nutrient flow from farms and CAFOs to nearby water bodies. Utilizing and integrating data (different resolutions and types) from MODIS satellite imagery, Aster GDEM on elevation, USGS Stream Water, USDA Historical Crop, and Soil, a spatial model is developed to track and quantify nutrient runoff. By understanding the movement and accumulation of nutrients, effective mitigation strategies can be formulated to prevent pollution and minimize water contamination. The outcomes of this research contribute to the overarching goal of enhancing food production while minimizing the environmental footprint of agricultural practices. By implementing satellite-based monitoring and geospatial analysis techniques, we can empower farmers and stakeholders to make informed decisions about nutrient management. This approach not only helps reduce fertilizer usage and associated costs but also protects water quality, mitigates algae blooms, and preserves aquatic ecosystems. This provides a practical and scalable solution for addressing the fertilizer application problem, ensuring long-term agricultural sustainability, and meeting the increasing global food demand.

8:00 PM SB01.03.06

Biopolymeric Microneedles for Underwater Fish Vaccination Meng Li, Yunteng Cao, Colleen Wolfe and Benedetto Marelli; Massachusetts Institute of Technology, United States

Over the next 30 years, with the world population continues to grow, food supplies will have to increase by 70%. Addressing challenges in food security by promoting healthy and sustainable protein sources is crucial. Aquaculture plays a vital role in meeting these requirements, and fish vaccination is integral to preventing disease spread in densely populated farming environments. However, traditional methods involving intramuscular or intraperitoneal injections require fish sedation, administration outside of water, and poses safety concerns for workers due to accidental needlestick injuries.

In this work, we aim to develop an automatic system capable of precise vaccine delivery in aquaculture settings. We adapted microneedle design and fabrication for plants and mammals to meet the requirements for underwater applications.

To ensure successful fish skin penetration, we have employed proteinaceous silk fibroin microneedles

encapsulated with a water-proofing coating layer of food-grade natural resin. This coating layer preserves the mechanical strength of the silk fibroin microneedles in water for hours. The water-proofing coating layer prevents water absorption and swelling of silk fibroin microneedles, which could otherwise weaken their mechanical strength. The coating layer preserves the mechanical strength of silk fibroin microneedles in water for hours.

Additionally, the coating layer prevents the loaded substance from prematurely releasing into the aquatic environment, ensuring controlled release after fish skin penetration. Our results demonstrate that once the microneedles pierce the fish skin, the cargo is released within hours primarily through diffusion.

Our study presents a novel microneedle strategy designed specifically for precise injection and substance delivery in aquaculture, offering a promising solution for enhancing fish health, productivity, and sustainability.

8:00 PM SB01.03.07

Supporting Hydroponic Crop Growth using UV-C Light Douglas X. Shattuck^{1,2}, Sophia Salinas^{3,2}, Grace Gunning^{3,2}, Emily Parker^{3,2} and Saman Abbas^{3,2}; ¹St Joseph School Wakefield, United States; ²National STEM Honor Society, United States; ³Malden Catholic High School, United States

Preliminary results indicate that intermittent exposure to UV-C radiation can enhance the hydroponic production of food crops by stimulating plant growth and inhibiting the growth of pathogenic organisms. However, in addition to its benefits, prolonged exposure to UV-C has been known to be harmful to plants (1, 2, 3). Watercress, a specie of aquatic flowering plant in the mustard family, was selected for this investigation. It is fast growing, can be eaten raw or cooked, and is rich in vitamins K, A, C, riboflavin, B₆, Ca, and Mn(4). It is closely related to the Arabidopsis sp. being studied for germination in lunar regolith(5).

We designed and constructed a hydroponic system that exposed Watercress to commercially available grow lights and UV-C radiation lamps. By exposing the plants to UV-C in monitored 5 or 15 minute intervals we hoped to maximize its growing process and kill any pathogens while minimizing the damage done by the radiation.

The watercress seeds were placed in net pots with moist growing medium and placed in a water-filled box and then exposed to grow lights. The plants were then exposed to five-minute of UV-C radiation followed by long periods of darkness. After each exposure to the UV-C, plants were observed and the growth and general characteristics of the plant recorded. After two days, the plants were exposed to fifteen-minute radiation intervals, following the same schedule. Each of the six boxes of plants underwent the same testing procedures for four days. The UV-C plants appeared equally as healthy as the control group but grew taller and tilted towards the lights more—exaggerated phototropism.

At the end of the test, we observed mold growing in both the control and UV-C groups. Initially, we observed much more mold in the control group. After being untreated for a week, the group exposed to UV-C light had a considerable amount of mold compared to the control group. This difference suggests that during UV-C light treatment, the mold's growth was curtailed. In conclusion, we believe the UV-C radiation did have a positive effect on the plants as we hypothesized.

In-Situ Corona Discharge Non-Thermal-Plasma based Modification of Bio-Ingredients in an Integrated Food Printer: Towards Developing Novel Methodologies for Characterization of Engineered Food Materials Derek Xiong¹, Prakhyat Gautam¹, David Ryman¹, Edbertho Leal-Quiros², Saquib Ahmed³ and Sankha Banerjee^{1,4}; ¹California State University, Fresno, United States; ²University of California, Merced, United States; ³Buffalo State College, United States; ⁴University of California, Davis, United States

The current work involves the development of novel in-situ non-thermal plasma treatment methodologies of 3D printed starch-based bio-ingredients towards tailoring the properties of starch granule-surface proteins (SGSP). This work also includes the evaluation of continuous and discontinuous gluten networks through the surface interaction of SGSPs with quasi-static corona discharge plasma regimes. The work further studies the binding characteristics of starch-based bio-ingredients based on the plasma current-voltage characteristics. The cured starch-based sample surface will be characterized using profilometry. The binding characteristics, gluten networks, and porosity characteristics will be analyzed using microstructure evaluation through electron microscopy. Advanced hybrid machine learning models will also be developed in combination with analytical methods and empirical data sets to develop strategies for tailoring the surface and bulk properties of these materials.

8:00 PM SB01.03.09

The Impact of Titanium Dioxide Nanoparticles on Keratinocyte Proliferation and Differentiation Derek Zhang¹, Ashley Huang², Shi Fu³, Marcia Simon³, Miriam Rafailovich³, Dina McGinley⁴ and Alice Shih³; ¹The Wheatley School, United States; ²Syosset High School, United States; ³Stony Brook University, The State University of New York, United States; ⁴State University of New York at Farmingdale, United States

TiO₂ nanoparticles are still widely used as food additives in the United States for their whitening properties, UV absorption capabilities, and their potential usage as antibacterial reagents. In fact, these particles are considered valid organic additives and can be incorporated at concentrations as high as 1%. When ingested these particles can circulate in the body coming in contact with viable cells and the long term impacts of TiO₂ build up is currently of concern for the European Food Safety Authority [1].

Additionally, even though nanoparticles may not penetrate the stratum corneum and hence do not come into direct contact with viable keratinocytes, if they are used in wound care treatments, they can come into direct contact with viable epidermal and dermal cells and influence cell function and tissue healing. In early experiments producing skin equivalents with keratinocytes exposed to 0.8 mg/mL rutile TiO₂ nanoparticles, we observed nanoparticle aggregation with premature stratum corneum formation and aberrant expression of filaggrin, a late stage multifunctional differentiation marker.

Keratinocytes were grown with lethally irradiated 3T3 cells [2] with media modifications previously described [3]. At 70% confluence feeder cells were removed and cultures were treated with rutile TiO₂ (0.4 mg/mL); no TiO₂ cultures served as control. After 24 hours cultures were rinsed twice with Ca and Mg free phosphate buffered saline, resuspended in buffered saline with BSA and cells sorted at the Stony Brook University Flow Cytometry Core Facility using a FACS Aria IIIU cell sorter.

Cells associated with TiO₂ were separated from TiO₂-free cells based on side scatter using flow cytometry; cells showing low and high side scatter were collected. In these cultures, 90% of the cells exhibited low side scatter, consistent with the absence of nanoparticles. This compares with a low and high scatter population of 57.2% and 42.8%, respectively, in the TiO₂ treated cultures.

The impact of 0.4 mg/mL TiO₂ on keratinocyte proliferative capacity was also explored as a function of

colony forming efficiency (CFE), and the colony forming efficiency of keratinocytes with low and high side scatter was determined; TiO₂-free keratinocyte cultures served as control [4]. 12 culture dishes containing 1000 cells each were plated: 4 control plates (low side scatter), 4 plates of TiO₂ treated high side scatter, and 4 plates of TiO₂ treated low side scatter. Following 12 days of incubation, each culture dish was rinsed with Ca and Mg free phosphate buffered saline and stained with Rhodamine B. Colonies ≥ 1 mm were counted. In these cultures, CFEs are about three-fold lower in the high side scatter population suggesting NP inhibition of plating efficiency or proliferation. To assess the full impact of these NPs in this system and in skin equivalents, ongoing work includes SEM analyses to determine NP location within the cell and differentiation assessment by RT-PCR to determine overall skin development.

Microfluidic Tools to Monitor Dynamic Processes Occurring during Emulsion and Foam Formation Karin Schroen^{1,2} and Boxin Deng¹; ¹Wageningen University, Netherlands; ²University of Twente, Netherlands

Humanity faces the huge challenge to supply a growing world population with sufficient and healthy food. To make this a reality we need to rethink how we produce food at large scale. This implies rethinking production ‘on the land/in the greenhouse’, fractionating raw materials, understanding their functionality during processes used in food production, as well as under digestive conditions to make the connection to health effects that can be created by smart food design.

A big challenge that needs to be addressed to make smarter food design a reality is the investigation of processes that take place at micrometre scale, and even smaller scales, and often within very short times. These dynamic processes underly the food structure that we get, but the dynamics thereof are very difficult to capture due to time and size challenges, and the inaccessibility of food production line for analysis of these processes.

Microfluidics allow visualisation of very fast processes occurring during the production of for example, two phase systems such as emulsions and foams. Various tools have been developed within our lab that allow to focus on interface formation and stabilisation at very short time scales. These tools also allow

distinction of interfacial tension effects from coalescence effects in relation to the size of the structures that are formed, which is a classical dilemma that until now has not been addressed at this level of detail. These new techniques will contribute to more flexible use of ingredients, allowing product design based on the actual functionality of components. For example, replacement of animal-based products with their plant-based counterparts, and also the use of biomass (e.g., leaves and stems) that are currently considered waste can truly contribute to more sustainable food production practice, but only if the functionality of these components is such that they lead to stable products. I could imagine that the techniques developed are ultimately used to do fast screening, comparison of ingredients, and even to establish a connection with more classic processing technologies, such as high pressure homogenization and foaming techniques given the similarity in conditions.

9:30 AM SB01.04.02

Thermoplastic Molding of Silk-Curcumin Composites to Enhance Biological Properties Arjak Bhattacharjee, Sara Rudolph, Ying Chen and David L. Kaplan; Tufts University, United States

Silk fibroin protein is a natural protein biopolymer generated from the cocoons of *Bombyx mori* silkworms and a useful biomaterial for many different tissue engineering applications. Flexible process engineering, versatile chemistry, and aqueous processing allow morphological and structural modifications that tailor the physical, chemical, biological, and mechanical properties of this biomaterial. However, conventional solution-based processing methods can impose limitations in terms of solubility, stability as well as scalability. Recently, we reported a thermal processing technique to fabricate dense, regenerated silk fibroin-based structures (plastics) using solid-state thermoplastic molding to address these limitations. The present work expands the utilization of thermoplastic molding of silk-fibroin to enhance the biological properties of plant-derived compounds like curcumin, the active compound of turmeric (*Curcuma longa*). Curcumin is widely used in traditional medicines. The objective of this study was to study the feasibility of fabricating silk-curcumin composite thermoplastics with enhanced biological properties. The hypothesis was that protective silk thermoplastic formation after curcumin incorporation would enhance the biological properties of curcumin, via the protective features of silk combined with the sustained slow release of the compound to reduce toxicity without affecting anti-bacterial properties. The results show that significantly higher levels of curcumin (~25-fold) can be incorporated into thermoplastic molded silk compared with solution formulations, attributed to the hydrophobic nature and low solubility of curcumin in solution-based processing. The fabricated curcumin incorporated thermoplastics show excellent stability in harsh acidic conditions (e.g., gut-like environment) and low curcumin (~ 3% over 14 days) release. The protective silk-curcumin formation led to enhanced cytocompatibility of the curcumin with immortalized human colorectal adenocarcinoma (Caco 2) cells even at higher doses when compared to curcumin without silk. The intestinal epithelial barrier integrity based on zonula occluden 1 (ZO-1) assessments indicated that higher doses of curcumin in the thermoplastic molded silk did not result in detrimental effects to the intestinal barrier. Further work is ongoing to assess additional biological outcomes as well as potential areas of utility for these systems.

Coupling Waste Feedstocks to Microbial Protein for a Circular Food System Taylor Uekert, Alissa Bleem, Christopher Johnson and Gregg Beckham; National Renewable Energy Laboratory, United States

The global food system is responsible for approximately 34% of annual greenhouse gas (GHG) emissions

and up to 85% of water consumption. This critical sector suffers from intensive and inefficient land and water use, the generation of multiple (solid, liquid, and gaseous) waste streams, and high fuel, fertilizer, and pesticide consumption. The production of waste-derived microbial protein (MP) represents a promising alternative for reducing the environmental impacts of protein production relative to conventional agriculture. MP can be mass-produced in volumetrically scalable cultivation processes on short timescales, enabling facile up-scaling with lower greenhouse gas emissions, land use, and water impacts than animal and, in some cases, plant protein production. MP can also be produced from waste feedstocks, diverting waste from landfills or the natural environment. Here, we present the availability and suitability of waste feedstocks for MP production, as well as the fermentation and downstream processes required to convert MP into human food products. We discuss the challenges and opportunities facing waste-derived bacterial MP and highlight key areas for innovation in both the microbiology and process design space for a more sustainable and circular food system.

10:30 AM SB01.04.04

Design of Biodegradable, Climate-Specific Packaging Materials that Sense Food Spoilage and Extend Shelf-Life Yangyang Han¹, Song Wang¹, Michael S. Strano² and Benedetto Marelli²; ¹Singapore-MIT Alliance for Research and Technology (SMART) Centre, Singapore; ²Massachusetts Institute of Technology, United States

The AgriFood systems in tropical climates are under strain due to a rapid increase in human population and extreme environmental conditions that limit the efficacy of packaging technologies to extend food shelf-life and guarantee food safety. To address these challenges, we rationally designed biodegradable packaging materials that sense spoilage and prevent moulding. We nanofabricated the interface of 2D covalent organic frameworks (COF) to reinforce silk fibroin (SF) and obtain biodegradable membranes with augmented mechanical properties and that displayed an immediate colorimetric response (within 1 second) to food spoilage, using packaged poultry as an example. Loading COF with antimicrobial hexanal also mitigated biotic spoilage in high temperature and humidity conditions, resulting in a four-order of magnitude decrease in the total amount of mould growth in soybeans packaged in silk-COF, when compared to cling film (i.e., polyethylene). Together, the integration of sensing, structural reinforcement, and antimicrobial agent delivery within a biodegradable nanocomposite framework defines climate-specific packaging materials that can decrease food waste and enhance food safety.

10:45 AM SB01.04.05

Microneedles Carrying Nanosensors for Real-Time Detection of Abiotic Stress in Planta Raju Cheerlavancha¹, Benny Sng Jian Rong², Khong Duc Thinh¹, Yunteng Cao³, Yangyang Han¹, Mervin Ang Chunyi¹, Song Wang¹, Gajendra Pratap Singha¹, Michael S Strano³, In-Cheol Jang^{2,1} and Benedetto Marelli^{3,1}; ¹Singapore-MIT Alliance of Research and Technology, Singapore; ²Temasek Life Sciences Laboratory, Singapore; ³Massachusetts Institute of Technology, United States

Abiotic stress refers to adverse environmental conditions that negatively impact plant growth, development, and productivity. These stressors include extreme temperatures, drought, salinity, heavy metals, and radiation. Understanding plant responses and adaptation to abiotic stress is crucial, especially with the increasing severity and frequency of such stressors due to climate change. However, conventional methods for studying plant responses have limitations such as indirect measurements, low spatial resolution, and the inability to visualize real-time changes.

To overcome these limitations, we developed a delivery system using microneedles (MNs) to carry

nanosensors. These MNs can be inserted into both soft and hard plant tissues without leaving any residues. By incorporating the nanosensor into the MNs, we successfully demonstrated real-time sensing of abiotic stress in Bok Choy and *Nicotiana benthamiana*. The embedded nanosensor, designed specifically for abiotic stress, enables rapid and sensitive detection of near-infrared (nIR) fluorescence signals. This allows for accurate measurement and visualization of abiotic stress levels. Furthermore, we confirmed the compatibility of the MNs with the abiotic stress nanosensors.

In summary, the integration of nanosensors with non-invasive delivery systems like MNs presents exciting opportunities for studying abiotic stress in plants. These innovative approaches help us gain a deeper understanding of how plants perceive and respond to environmental challenges. Ultimately, this knowledge can inform the development of stress-tolerant crops, sustainable agricultural practices, and strategies to mitigate the impacts of climate change on plant productivity and food security.

Time-Resolved Roasting-Induced Microstructural Evolution of Arabica Coffee Beans using X-Ray Computed Micro-Tomography Eshan Ganju¹, Kunal Chawla², Samuel Yang¹ and Nikhilesh Chawla¹;

¹Purdue University, United States; ²Carmel High School, United States

The aroma of coffee is deeply connected to the roasting process, which leads to notable changes in the bean's structure and chemistry. While many research studies have explored the chemical alterations occurring in the coffee bean during roasting, the structural changes have typically only been observed broadly, quantified by changes in size, density, fracture strength, or basic sectional views of the coffee bean. Traditional microscopy techniques are insufficient in providing an in-depth understanding of the coffee beans' microstructure, primarily due to their resolution, two-dimensional (2D) limitations, and the destructive nature of the analyses. These limitations are further exacerbated by the fact that the coffee bean undergoes significant three-dimensional (3D) structural changes during the roasting process. These changes are impacted by the coffee bean variety's properties, the bean's initial microstructure (which is affected by the local environment, including altitude, humidity, etc.), and the roasting process. As a result of the limited information about the initial 3D microstructure of the bean, its impact on the evolution of the emergent microstructure during roasting has been largely unexplored. Furthermore, while global measurements in porosity or pore volume at different roast levels have been reported, the heterogeneity in the evolution of porosity in different regions of the bean, which impacts the uniformity of the ground beans, has not been described. In this study, we conducted a time-resolved study of the roasting-induced microstructural evolution of Arabica coffee beans using X-ray computed micro-tomography (XCT). We combined high-resolution XCT data with computational image analysis techniques to examine the evolution of the microstructure of *Coffea arabica* beans during roasting. Beans sourced from Brazil, Colombia, and Ethiopia were tracked individually throughout the roasting process going from the green bean to the dark roast stage. The individual beans were tracked and scanned at multiple stages of roasting to capture the 3D tomography data of the entire bean. The XCT data, captured at different roasting levels, revealed detailed, time-resolved information about porosity, pore size distribution, and cracking within different regions of the beans. Results showed a significant increase in porosity and pore size from green-bean to dark-roast state, but the rate of increase wasn't linearly dependent on roasting time. Furthermore, beans from different regions showed markedly difference spatial heterogeneity in porosity and cracking. The effects of the initial green bean microstructure, as influenced by the growth environment, on the subsequent structural evolution will be discussed. The data and analyses presented in this study can assist in advancing research in the realm of food engineering by enabling a deeper understanding of the structural characteristics of coffee beans from various regions of the world and by clarifying the link between the processing and microstructure of the bean at different roasting levels. Furthermore, the 3D

Updated as of October 28, 2024

characterization and analysis presented here can be applied as a framework to study a diverse class of food materials.

11:15 AM SB01.04.07

Living Filters for Sustainable and Selective Treatment of Drinking Water and Beverages Vicki L. Colvin; Brown University, United States

Many communities in the U.S. and globally suffer because of a lack of access to safe drinking water. Cleaning water, however, using conventional technology is a dirty business that is expensive as well as material and energy intensive. There is a need to broaden access as well as provide more sustainable solutions that can improve people's water and their health. Living filters are cultures of living microbes that are engineered to both sense and treat contaminants at the very low concentrations relevant for drinking water. Here we demonstrate a system that targets the removal of arsenic from drinking water and beverages such as fruit juice and wine. Conventional remediation based on chemical sorption is challenging because of interferences from phosphates, silicates, flavor compounds, and organic matter; membrane-based separations also can be impacted by these species and more critically will remove all compounds including those that should be preserved for flavor in the case of beverages. Here, we exploit the extraordinary selectivity of biological recognition to solve this problem. Microbial engineering is applied to generate *E. Coli* that contain multiple copies of arsenic-binding proteins that are highly selective for arsenic and effectively no binding to smaller anions. When protein expression is induced, bacteria remain healthy and produce thousands of copies of Ars-R and when exposed to arsenic, the organisms within 30 minutes will reduce arsenic to sub-ppb levels. Sorption isotherms reveal at low concentrations (<50 ppb) sorption is defined by cellular transport while at higher concentrations the intracellular protein-arsenic interaction is limiting. The sorption behavior of these bacteria is insensitive to millimolar concentrations of phosphates, silicates, and many salts and is unaffected by the components of wines or fruit juices. Conventional microfiltration systems can be applied to remove all microbes down to levels suitable for meeting stringent EPA standards for drinking water. The integration of magnetic separation allows the capture of arsenic-laden microbes attached to magnetic nanoparticles which can be reused for future separations. Flavor compounds as measured by mass spectrometry in beverages remain unaffected by these treatment processes. Most recently we have incorporated bioluminescent reporters into the living filters which permit the detection of arsenic to optimize the treatment system. These engineered materials can be freeze-dried with modest impact on performance. Dry powders can be shipped easily under ambient conditions and then cultivated at the site prior to their integration into the treatment system. An important benefit of these materials is that the sorbent is in effect living, allowing for sustainable and low-cost manufacturing.

Home Composting Doesn't Work as an Environmentally Beneficial Method for Managing Biodegradable and Compostable Packaging Danielle Purkiss, Ayse Allison, Fabiana Lorencatto, Susan

Michie and Mark A. Miodownik; University College London, United Kingdom

Compostable and biodegradable plastics are growing in popularity but their environmental credentials need to be more fully assessed to determine how they can be a part of the solution to the plastic waste crisis. We present results and analysis on home compostable packaging. This type of packaging requires the citizen to be able to correctly identify the packaging as 'home compostable', to have composting facilities at home, and to successfully compost the plastic. Using a citizen science approach, we engaged with 9701 UK citizens geographically spread across the UK to examine their capability, opportunity, and motivation to do this. Of this cohort 1648 citizens performed home compost experiments to test the environmental performance of compostable plastics. We report on the type of plastics they tested and their disintegration under real home composting conditions. The results show that the public are confused about the meaning of the labels of compostable and biodegradable plastics. 14% of sampled plastic packaging items tested were certified 'industrial compostable' only and 46% had no compostable certification. Of the biodegradable and compostable plastics tested under different home composting conditions, the majority did not fully disintegrate, including 60% of those that were certified 'home compostable'. We conclude that for both of these reasons, home composting is not an effective or environmentally beneficial waste processing method for biodegradable or compostable packaging in the UK. This talk also outlines the requirements to make industrial composting a viable and sustainable method for managing compostable packaging.

8:45 AM SB01/SB02/SB04/SB10.03

Moringa Oleifera Proteins as Pickering Stabilizers: From Nanostructures to Rheology Namrah Azmi^{1,2}, Andrew N. Akanno¹, Matti Knaapila¹, Adrian Rennie³, Leonard Rweyemamu^{2,4} and Jon Otto Fossum¹; ¹Norwegian University of Science and Technology, Norway; ²Stayfit Nutrisupplies Co. Ltd, Tanzania, United Republic of; ³Uppsala University, Sweden; ⁴University of Dar Es Salaam, Tanzania, United Republic of

Substantial food waste as a result of chemical decay of food enormously impacts the environment, henceforth the need for stabilization by surfactants but the associated carbon footprints possess a threat to the industry. Thus, Pickering emulsions, stabilized by solid- particles, residing at droplet interfaces come into the picture, providing more stable systems than surfactants. In terms of resistance against fusion (coalescence) and coarsening (Ostwald ripening) Pickering emulsions are thermodynamically stable systems with good biocompatibility and can be utilized as carriers for delivery of bioactive compounds, thus applied in food to control and enhance texture and taste and improve stability¹.

Plant proteins attract great interest and the stability of Pickering emulsions is governed by protein properties, protein concentration, and environmental factors. The Moringa protein has been chosen because it is inexpensive, with great nutritional benefits and wide availability, and has been scientifically proven to have excellent anti-oxidant, anti-hypertensive, and anti-diabetic properties².

Protein particle interactions are very much dependent on pH. Such protein-based nanoparticles have proven to be advantageous as they are biodegradable, non-toxic, and provide the large possibility for surface modification³.

All this motivates our study to investigate the Moringa protein as Pickering particles for emulsions fabricated at different pH and ionic strengths. The rheology and corresponding macroscopic gel properties of such emulsions can be designed by arrested coalescence for producing food spreads with desired rheological properties⁴. During this, aggregates are formed with the interaction between denatured non-absorbed proteins and absorbed ones at the emulsion droplet interfaces which can be impact from lipid oxidation, which influences emulsion particle interactions. Proteins can form gels after aggregation at

different pH or ionic concentrations. It is difficult to separate the association mechanism of gelation and emulsification through protein aggregation⁵ which is another motivation for our studies.

We have undertaken a program to distinguish the “good” and “not so good” Moringa-based protein stabilizers by utilizing microscopic observations and rheometry and using Small-Angle X-ray-Scattering (SAXS) to examine structural stability and aggregations of the same stabilizing proteins, thus gathering information on protein⁶, and how this is connected to the rheological properties. Further works include formulating food spread using this emulsion and studying its smell and mouthfeel quantification.

ACKNOWLEDGEMENTS:

Asymmetric Polymersomes with Photothermal Responsiveness Jingxin Shao¹, Yingtong Luo¹, Hanglong Wu², Jianhong Wang¹, Shoupeng Cao³, Loai K. Abdelmohsen¹ and Jan Van Hest¹; ¹Technische Universiteit Eindhoven, Netherlands; ²Massachusetts Institute of Technology, United States; ³Max Planck Institute for Polymer Research, Germany

Photo-mediated micro/nanorobots have found widespread interest over the past decade because of their application potential in many areas, especially in nanomedicine. By converting light energy into mechanical work, micro/nanorobots can be propelled to achieve active cargo transportation into cells with enhanced therapeutic effect. Most of the current micro/nanorobots are either based on inorganic particles or hybrid particles, such as Janus nanoparticles with a hemispherical Au shell.¹⁻⁵ The construction of fully organic-based micro/nanorobots is still underexplored. Here, a new type of light propelled nanorobots is created based on biodegradable polymersomes. Photothermal agents (PA) were co-assembled with polymer building blocks to form polymersomes with an asymmetric morphology, resembling a hot-air-balloon structure. With cryogenic transmission electron microscopy (Cryo-TEM) and cryo-electron tomography (Cryo-ET), this structure was confirmed. The formation mechanism of these asymmetric polymersomes was thereafter investigated by in situ observation of the dynamic assembly process with liquid phase transmission electron microscopy (LP-TEM). In combination with the cryo-TEM data, the LP-TEM results revealed that liquid-liquid phase separation was the main leading force for the formation of asymmetric polymersomes. Upon infrared laser irradiation (808 nm), the PA nano-assemblies in the polymersome structure provided photothermal heating and propelled the polymersomes in a controllable way regarding both direction and speed. This study demonstrates the formation of a new nanomotor

topology which is driven by the photothermal effect and fully composed of organic building blocks. This nanomotor is further investigated for its application in active drug delivery.

9:05 AM SB01/SB02/SB04/SB10.05

Encapsulation and Delivery of Biomolecules with Cell-Mimicking Nanolipogel Bertrand Czarny^{1,1}, Wen Jie Melvin Liew¹, Abdullah Alkaff¹, Atul Parikh^{2,3} and Subramanian Venkatraman^{4,5}; ¹Nanyang Technological University, NTU, Singapore; ²University of California, Davis, United States; ³Nanyang Technological University, Singapore; ⁴National University of Singapore, Singapore; ⁵University of California, San Diego, United States

High initial burst release of biomolecules is just one of the many challenges faced by lipid based nanoparticulate formulations, even though it is widely used for drug encapsulation and delivery studies. One of the emerging potential strategies is the use of nanolipogels (NLG) to encapsulate biomolecules, which can suppress the initial burst release. This gives a level of control and sustain to the release of hydrophilic drugs. However, current works are short on characterisation of the release mechanistic. Therefore, varying molecular weight of Poly (ethylene glycol) Diacrylate (PEGDA) were used for the fabrication of PEGDA NLG, to study the mechanism for release of Dextran-Fluorescein Isothiocyanate (DFITC). Fluorescence Recovery after Photobleaching (FRAP), were performed on cell derived microlipogels (MLG), a novel system developed as a solution to limitations of FRAP with NLG. Results from the studies has shown that the NLGs' mesh sizes are controllable via the use of different Mw of PEGDA, where a lower Mw used resulted in a smaller mesh size of the nanogel core, by having a higher crosslinking density. This in turn gave higher suppression of the initial burst release of DFITC, up to a 10-fold difference. FRAP results then gave further validation by showing that the smaller mesh size restricted the diffusion of DFITC, consequential of a lower mobile fraction. These gave clear insight into the possibility of controlling the encapsulation and release of biomolecules, by targeting the fabrication of nanogel core. From this, Chitosan Methacrylate (CMA) NLGs was then studied to expand into other ways in manipulating the nanogel core for greater control, such as a differently charged core. Results was shown that CMA NLGs are also able to suppress the initial burst release of DFITC and it can be controlled by using a different concentration of CMA. This increases the possible strategies for consideration during the design of NLG systems and especially CMA NLGs opens up the possibility of encapsulation of negatively charge biomolecules, such as siRNA. As the NLG system involves two critical components, namely the nanogel core and the bilayer coating, the membrane properties are essential for the designing of NLGs. Herein, cell membrane coating for NLG was studied, with the development of a novel Chitosan Methacrylate-Tripolyphosphate (CMATPP) nanoparticle systems, which allows for the co-extrusion with cell membrane vesicles. The coating of CMATPP nanoparticles can possibly confer the membrane properties, such as prolonged *in-vivo* circulation and improved cellular uptake, to CMATPP nanoparticles. Coating was validated through flow cytometry with characteristic membrane proteins of cell derived nanovesicles (CDN), namely CD9, CD81, TSG101, or with RBC membrane vesicles, CD47. RBC CMATPP NLGs were also shown that it can further suppress the initial burst release and sustained release compared to Liposome CMATPP NLGs. All in all, it was shown that cell mimicking NLG system was able to provide a controlled release of hydrophilic biomolecule, and the release mechanism was studied and characterized using FRAP. Relationships with changes to the nanogel core as well as membrane coatings were also explored and proven to be viable and plausible expansions to other membrane origins were discovered. This study has provided a guide on the design of NLGs for a multitude of needs with regards to encapsulation and delivery, as well as for future *in vivo* performance

9:20 AM SB01/SB02/SB04/SB10.06

Spiky Silica Nanoparticles Embedded with ZIF-90: A Promising Approach for Intracellular Drug Delivery Manoj Kumar Sharma^{1,2}, Dan Chang², Jingjing Qu², Hao Song², Chengzhong Yu², Ashok Kumar Ganguli¹ and Jie Tang²; ¹IIT Delhi, India; ²The University of Queensland, Australia

Nanotechnology has emerged as a promising field in treating various diseases, offering significant advancements in drug delivery systems (DDS).^[1] These systems offer advantages such as improved drug bioavailability, controlled release kinetics, and prolonged circulation time, leading to increased safety and efficacy. Mesoporous Silica (MSN)-based carriers exhibit desirable properties, including high porosity, biocompatibility, and tunable particle size. The introduction of spiky nanotopography on silica nanoparticles has garnered significant scientific interest due to its unique capabilities, including enhanced bacterial adhesion, intracellular drug delivery, and protection of genetic material.^[2] Nonetheless, challenges persist in MSN-based DDS, encompassing limitations such as low drug loading capacity and premature release of anticancer agents.^[3] To address these challenges, promising strategies have been explored, such as functionalizing silanol groups on mesoporous silica nanoparticles (MSN) with amine moieties or integrating organic compounds and metal-organic frameworks (MOFs). The literature provides limited information on silica-Zn-MOF composites. Previous studies have predominantly focused on ZIF-8 formation on silica nanoparticles.^[4]

This study successfully synthesized a novel nanocomposite consisting of nature-inspired spiky silica nanoparticles (SNP) embedded with zeolitic imidazolate framework-90 (ZIF-90). The resulting SNP-ZIF-90 composites retained their spiky morphology and demonstrated enhanced drug-loading capacity for doxorubicin (Dox) compared to bare SNP. Furthermore, the modified SNP-ZIF-90 composites exhibited improved cellular uptake and pH-responsive drug release, highlighting their potential as an efficient drug delivery system.

Ultrathin Hydrogel Biosensor with Controllable Self-Adhesion Properties for Electrophysiology Measurement Shuyun Zhuo, Alexandre Tessier and Shideh Kabiri Ameri; Queen's University, Canada

Hydrogel has recently been utilized to develop health monitoring sensors and devices such as bioelectrodes. Owing to their good electrical conductivity, ultra-softness, and self-adhesion, current hydrogel sensors have found their application in electroencephalogram (EEG), electromyogram (EMG), and electrocardiogram (ECG) recording. However, the highly adhesive hydrogels are hard to peel off from the surface of the skin after laminating it and they are susceptible to losing the water content and unfavorable changes in the electrical conductivity and mechanical softness. Here we report an ultrathin hydrogel-based sensor with controllable self-adhesion properties that can fully conform to the skin and perform reliably for an extended period. An ultrathin, conformable biosensor with a thickness of less than 10 µm is fabricated based on gelatin-acrylamide-polypyrrole hydrogel, where the sol-gel transition of the gelatin is utilized to control the modulus and adhesion force. The ultralow thickness and good stretchability of the gelatin-acrylamide-polypyrrole hydrogel contribute to a seamless interface between the biosensor and human skin, which is desired in wearable devices for high-quality bio-signal

acquisitions such as electrocardiography (ECG) and electromyography (EMG).

9:50 AM *SB01/SB02/SB04/SB10.10

From Sub-Micron Resolution Towards 3D-Printing at the Speed of Light: Pushing the Boundaries to Serve Health Quinten Thijssen¹, Laurens Parmentier¹, Hayden Taylor², Steven Ballet³ and Sandra Van Vlierberghe¹; ¹Ghent University, Belgium; ²University of California, Berkeley, United States Minor Outlying Islands; ³Vrije Universiteit Brussel, Belgium

Current thoroughly described biodegradable and cross-linkable polymers mainly rely on acrylate cross-linking. However, despite the swift cross-linking kinetics of acrylates, the concomitant brittleness of the resulting materials limits their applicability. Here, photo-cross-linkable poly(ϵ -caprolactone) (PCL) networks through orthogonal thiol-ene chemistry are introduced. The step-growth polymerized networks are tunable, predictable by means of the rubber elasticity theory and it is shown that their mechanical properties are significantly improved over their acrylate cross-linked counterparts. Tunability is introduced to the materials, by altering M_c (or the molar mass between cross-links), and its effect on the thermal properties, mechanical strength and degradability of the materials is evaluated. Moreover, excellent volumetric printability is illustrated and the smallest features obtained via volumetric 3D-printing to date are reported, for thiol-ene systems. Finally, by means of in vitro and in vivo characterization of 3D-printed constructs, it is illustrated that the volumetrically 3D-printed materials are biocompatible.

In an attempt to mimic nature's ability to adhere cells, PCL is often coated with nature-derived polymers or its surface is functionalized with a cell-binding motif. However, said surface modifications are limited to the material's surface, include multiple steps, and are mediated by harsh conditions. In a second part, we introduce a single-step strategy toward cell-adhesive polymer networks where thiol-ene chemistry serves a dual purpose. First, alkene-functionalized PCL was crosslinked by means of a multifunctional thiol (*vide supra*). Second, by means of a cysteine coupling site, the cell-binding motif C(-linker-)RGD was covalently bound throughout the PCL networks during crosslinking. Moreover, the influence of various linkers (type and length), between the cysteine coupling site and the cell-binding motif RGD, was investigated and the functionalization was assessed by means of static contact angle measurements and X-ray photoelectron spectroscopy. Finally, successful introduction of cell adhesiveness was illustrated for the networks by seeding fibroblasts onto the functionalized PCL networks.

This combination of mechanical stability, tunability, biocompatibility, no post-processing functionalization required and rapid fabrication by volumetric 3D-printing charts a new path toward bedside manufacturing of biodegradable cell-interactive, patient-specific implants.

In addition to photo-crosslinkable polyesters, also progress in the field of high resolution two-photon polymerization and volumetric additive manufacturing of gelatin-based hydrogels will be addressed. Hence, our material platform can serve both hard and soft tissue engineering applications.

Smart and Programmable Crystalline Sponges for Protection Omar K. Farha; Northwestern University, United States

This talk will focus on metal–organic frameworks (MOFs) from basic research to implementation and commercialization. MOFs are a class of porous, crystalline materials composed of metal-based nodes and organic ligands that self-assemble into multi-dimensional lattices. In contrast to conventional porous materials such as zeolites and activated carbon, an abundantly diverse set of molecular building blocks allows for the realization of MOFs with a broad range of properties. We have developed an extensive understanding of how the physical architecture and chemical properties of MOFs affect material performance in applications such as catalytic activity for chemical warfare agent detoxification.

11:00 AM *SB02.01.02

Supramolecular Design of Mesoporous 2D Covalent Organic Frameworks for the Encapsulation of Large and Small Guests Ronald A. Smaldone; The University of Texas at Dallas, United States

Interlayer interactions in 2D covalent organic frameworks (COFs) have been shown to be important factors in both their formation and bulk properties. There are many previous examples of controlling interlayer interactions in COFs by tuning the monomer or geometry. However, the use of hydrogen bonding is much rarer. The highly directional nature of a hydrogen bonding interaction makes it difficult to orient properly in a COF structure. To accomplish this, we have designed monomers with a non-planar structure that arises from steric crowding, forcing the amide side groups out of plane with the COF sheets

orienting the hydrogen bonds between the layers. The presence of these hydrogen bonds provides significant structural stabilization as demonstrated by comparison to control structures that lack hydrogen bonding capability, resulting in lower surface area and crystallinity. We have characterized both azine and imine-linked versions of these COFs for their surface areas, pore sizes and crystallinity. The rigidified structure that results from these supramolecular interactions can enable the production of COFs with mesopores capable of hosting large protein guests. In addition to more conventional COF characterization methods (such as powder X-ray diffraction and porosity analysis), we also used variable temperature infrared spectroscopy (VT-IR) methods and van der Waals density functional calculations to directly observe the presence and character of the hydrogen bonding interactions. This talk will also discuss the importance of mesopore design in COFs for the adsorption of different guests in aqueous solutions, ranging from proteins, to small molecule pollutants.

Insights into MOF Chemical Biology—Biocatalysts Encapsulated within MOFs Fa-Kuen Shieh¹, Lien-Yang Chou² and Chia-Kuang Tsung³; ¹National Central University, Taiwan; ²Shanghai Tech University, China; ³Boston College, United States

Metal-organic frameworks (MOFs) have found diverse applications in bio-sensing, biomass utilization, and catalysis. This study introduces a novel concept in material biology known as MOF Chemical Biology. It focuses on investigating the impact of containing biomolecules, such as protein enzymes, within synthetic MOF biocomposites, referred to as enzyme@MOFs. These biocomposites are prepared using a *de novo* biomineralization synthesis route, conducted under mild and aqueous conditions. The framework of these biocomposites possesses apertures that enable the free movement of substrates, while the encapsulated enzymes or bacteria remain confined within the structure, thereby shielding them against most structural changes.

Furthermore, we present the first successful demonstration of encapsulating enzymes into robust Zirconium-based MOFs, specifically UiO-66, using a solid-state mechanochemical process. The enzymes encapsulated through this method retain their desired functionality and exhibit resistance to proteases, even under acidic conditions. These innovative approaches provide an alternative system, exploiting the structural confinement effect, for expanding the application of MOFs in studying the biochemical functionalities of prokaryotes, eukaryotes, mammalian cells, and more.

SESSION SB02.02: Biomimetic Materials for Encapsulation II

Session Chairs: Christian Doonan and Niveen Khashab

Monday Afternoon, November 27, 2023

1:30 PM *SB02.02.01

Biocompatible Robust MOFs for New Wound Healing Solutions Christian Serre; CNRS, ENS, ESPCI Paris, PSL University, France

The development of new wound healing solutions is still a critical issue in order to treat infectious diseases. Biocompatible metal organic frameworks (MOFs) have long term been considered mainly against cancer. We will show in this presentation two new strategies to take benefit from their open metal

sites and/or ordered porosity to propose new solutions out of traditional antibiotics treatments.

A first strategy relies on the controlled delivery of Nitric oxide (NO), a powerful gaseous therapeutic agent of interest to treat a wide variety of disease states. As it can overcome the bacterial resistance to antibiotics, it is an appealing alternative to conventional drugs, and the development of efficient NO-donating drugs is being demanded. However traditional NO carriers are often toxic which precludes their practical use. It is crucial to find biocompatible carriers with prolonged biological half-life. MOFs have been previously proposed as antibacterial or anti-thrombogenic carriers but only in gas phase mainly through a coordination on their unsaturated metal sites. However once in contact with body fluids, the release of NO occurs within minutes compromising their practical use.^[1] We have therefore selected a robust biocompatible Ti-MOF such as MIP-177^[2] that is able to release NO within 2 hours in phosphate buffer, due to an unprecedented NO adsorption/release mechanism. Very recently, we also designed a new ultra-narrow pores iron bisphosphonate MOF, denoted MIP-210^[3], that is stable in PBS while adsorbing NO on its metal sites. Due to the combination of a novel adsorption mechanism, an exceptional stability in PBS and its narrow pores, it leads to a record ca. 3 days of NO release in biological media; in both cases we demonstrate how these controlled releases lead to cell migration or even angiogenesis that are of a crucial importance for wound healing applications, paving the way for the design of new wound healing therapies.

A second strategy consists of encapsulating dyes into biocompatible large pores Fe-MOFs. Through the protective effect of the pores' confinement considerably slowing down the bleaching of the dye under near infra-red irradiation, as well as the slow release of Fe³⁺ ions once in contact with body fluids leading to the formation of ROS, we demonstrate how these new MOF-dyes composites, through a multimodal based on PTT/PDT and chemo-dynamic therapy, are of interest to treat successfully different anti-biotic resistant infections (Chlamydia...)^[4-5]

Multifunctional Enzyme Nanocapsules Boost T Cell Immunity and Efficacy of Cancer

Immunotherapy Zheng Cao, Wenting Chen, Duo Xu, Jing Wen and Yunfeng Lu; University of California, Los Angeles, United States

Cancer immunotherapy has reshaped the landscape of cancer treatment, but its effectiveness in treating solid tumors is hindered by overproduction of lactate by cancer cells. Extensive trials are being conducted to regulate lactate levels by inhibiting lactate dehydrogenase, however, such inhibitors can disrupt the metabolism of healthy cells and cause severe non-specific toxicity. In contrast to those strategies, we innovatively target lactate itself by an enzyme, lactate oxidase, which effectively reduces the lactate levels

and releases hydrogen peroxide, an immunostimulatory molecule, in the tumor microenvironment. However, recombinant lactate oxidase from microorganisms possesses short circulating half-life, low enzyme activity, and immunogenicity. To circumvent this limitation, we innovatively report herein a nano-encapsulating strategy to encapsulate individual lactate oxidase molecules within a thin polymer shell by in-situ polymerization of monomers and crosslinkers, affording the synthesis of nanocapsules. The nanocapsules stabilize lactate oxidase and prevent it from proteolysis and denature, minimize the immunogenicity, prolong the circulating half-life, enabling their use as a potent therapeutic for cancer immunotherapy. Lactate oxidase nanocapsules can promote the proliferation and activation of effector T cells and suppress tumor-resident regulatory T cells *in vitro*. As further demonstrated in a murine melanoma model and a humanized mouse model of triple-negative breast cancer, nanocapsules of lactate oxidase avert tumor immunosuppression and enhance anti-cancer T cell immunity by upregulating gene expression for T cell recruitment and activation, as confirmed by single-cell RNA sequencing. Such multifunctional lactate oxidase nanocapsules lead to improved efficacy of immunotherapies for solid tumors.

2:30 PM *SB02.02.04

Metal-Organic Frameworks for the Encapsulation of Bio-Entities Ioanna Christodoulou¹, Jonathan Bachir¹, Effrosyni Gkaniatsou¹, Nathalie Steunou¹ and Clemence Sicard^{1,2}; ¹Institut Lavoisier de Versailles, France; ²Institut Universitaire de France, France

Bio-entities benefit from unparalleled activities of high interest in many applications such as high catalytic activities under mild conditions (aqueous media, room temperature). However, these are fragile entities, easily degraded under non-native conditions. Encapsulation, i.e. inclusion within a host matrix, is particularly interesting for bio-entities stabilization and protection as it can provide controlled environment and protection. Metal-Organic Frameworks (MOFs) have arisen as a host matrix of choice to answer the limitations of traditional immobilization matrices, resulting in the design of novel functional biomaterials.[1] The MOF-bio-entity composites exhibit promising properties, since the biological activity can be preserved while the stability of bio-entities in non-natural environments could be improved. Encapsulation can be performed by diffusion of the biological entities into the porosity of preformed MOF. Alternatively, the MOF can be formed “in-situ” around the bio-entities. Both strategies are limited to a number of MOF/bio-entities couples either due to size matching constraints or to a narrow window of compatible synthetic conditions.

In this communication we will present our efforts to expand synthetic routes and processing methods to explore new compositions and hierarchical structures of bio-entities-MOFs hybrids. We will describe the synthesis and characterization of MOFs-based living materials.[2] The mesoporous iron polycarboxylate MIL-100(Fe) was synthesized in the presence of *Pseudomonas putida* bacteria. The synthesis conditions (aqueous media, 30 °C) were compatible with the preservation of the bacteria integrity. High resolution microscopic techniques (TEM, STEM-XEDS) were applied on cross-sections to study the interface between the two components, revealing the presence of an exoskeleton encapsulating individual bacteria cells. We will also discuss our latest finding on the design of novel bio-entities-porous materials with unique properties for potential application in biocatalysis.[3]

Advanced Porous Framework Materials for the Immobilization of Biomolecules: Beyond Host Matrix Materials Shengqian Ma; University of North Texas, United States

Advanced porous framework materials as represented by metal–organic frameworks (MOFs) and covalent organic frameworks (COFs) represent a new class of crystalline materials, and one of their striking features lies in the tunable, designable, and functionalizable nanospace, which allows designed incorporation of different functionalities for targeted applications, such as gas storage/separation, sensing, drug delivery, catalysis, conductivity. We will discuss the systematic development of MOFs and COFs as a new platform for immobilization of biomolecules for applications in biocatalysis and beyond.

4:00 PM SB02.02.06

Supercritical CO₂ Precipitation of Porphyrin-Based MOFs as Potential Materials for Photodynamic Therapy Ana M. Lopez-Periago¹, Marta Kubovics¹, José A. Ayllon², Concha Domingo¹ and Carme Nogués²; ¹Consejo Superior de Investigaciones Científicas (CSIC), Spain; ²Universitat Autònoma de Barcelona, Spain

In the past few years, our research group has focused on synthesizing metal-organic frameworks (MOFs) using environmentally friendly methods based on supercritical CO₂ (scCO₂)^[1], where synthesis and pore activation can occur, in many cases, in a single step.

Building upon these advancements, the preparation of MOFs containing porphyrin linkers were of great interest to us, as porphyrins are fundamental building block precursors in various domains of synthetic chemistry. For example, porphyrins can form coordination networks with potential applications in fields such as catalysis, sensors, as well as for cancer treatment.^[2]

In the latter, porphyrin and its derivatives remain the most extensively employed materials for photodynamic therapy (PDT)^[3], an anticancer therapy based on the local application of a photosensitizer in the affected area that, by light radiation of a certain wavelength, produce reactive oxygen species (ROS)^[4], which are able to destroy the harmful cells through either necrosis or apoptosis.

In our research, we focused our interest into the possibilities of precipitating MOFs using a porphyrin linker with pyridyl motifs, specifically 5,10,15,20-Tetra(4-pyridyl)porphyrin (H₂TPyP) using exclusively scCO₂ as reaction media. The reaction involved the coordination of the binding sites (pyridyl moieties in *meso*- position, and the inner tetrapyrrole ring) with different metals. For this purpose, we employed four metal hexafluoroacetylacetonate complexes (M(hfac)₂, M = Cu, Zn, Co, Ni) as metal precursors in the production of the metal-organic materials.

Among the obtained samples, the scCO₂-precipitated Zn(II) MOF demonstrated exceptional performance when tested as a potential photosensitizer in PDT therapy against the SKBR-3 tumoral cell line. This MOF resulted to be nontoxic, but after 15 min of irradiation at 630 nm, using either 1 or 5 µM concentration of the product, almost 70% of tumor cells died after 72 h.

The most interesting results of this work were recently published in the journal Chemistry of Materials^[5].

Broadening the Scope of MOFs for *In Situ* Biomolecule Encapsulation Mónica Giménez-Marqués, Jesús Cases Díaz and Jana Glatz; University of Valencia, Spain

The use of metal–organic frameworks (MOFs) as robust coating of fragile biomacromolecules has been demonstrated a valuable strategy for their preservation, enabling their ample implementation in biomedical and biotechnological processes. Essentially, this biomolecule encapsulation requires the MOF assembly under biocompatible conditions and the existence of favorable electrostatic surface conditions at the biomolecule-MOF interface.

Despite recent growth in the field of MOF mineralization, only a limited number of MOFs have been accessed, being ZIFs the most widely explored materials for biohybrid synthesis. However, next directions in the field require revealing the hierarchical organization of these assemblies and for that, it is essential to expand the biohybrid family by using MOFs with distinct nature.

Herein we present alternative synthetic approaches to access previously elusive MOFs that permit to study new biohybrid architectures with undisclosed functionalities.

SESSION SB02.03: Biomimetic Materials for Delivery I

8:30 AM *SB02.03.01

Enhancing Vaccine Stability and Immunogenicity Through Biomimetic Mineralization using Zeolitic-Imidazole Frameworks (ZIFs) Jeremiah J. Gassensmith; University of Texas-Dallas, United States

Vaccines are susceptible to structural conformational changes under environmental and chemical stressors, compromising their therapeutic efficacy. This lecture presents three innovative case studies that address this challenge to enhance the stability, preservation, and immunogenicity of protein, DNA, and lipid nanoparticle based vaccines.

First, we discuss using zeolitic imidazolate framework-8 (ZIF-8) as a protective agent for a model viral vector against denaturing conditions. Immunoassay and spectroscopy analysis reveal that ZIF-8 provides enhanced thermal and chemical stability to the conformational structure of the encapsulated viral nanoparticle. Long-term biological activity studies in animal models demonstrate the integrity, biosafety, and immunogenicity of the virus-ZIF composite. Furthermore, histological analysis confirms the absence of tissue damage, highlighting ZIF-based protein composites as promising candidates for preserving proteinaceous drugs, ensuring biocompatibility, and controlling drug release in vivo.

Next, we explore stabilizing proteoliposomes, supramolecular lipid-protein assemblies that mimic cellular membranes. We demonstrate that metastable lipid, protein-detergent, and protein-lipid complexes can be successfully immobilized within zeolitic-imidazole framework (ZIF) bio-composites. This immobilization strategy enhances their stability against chemical and physical stressors such as elevated temperatures, chemical denaturants, aging, and mechanical stresses. Extensive morphological and functional characterization confirms that the encapsulated complexes maintain their native morphology, structure, and activity, which would otherwise rapidly degrade without immobilization.

Lastly, we address the pressing need for effective vaccines against pathogenic bacteria in the face of increasing antibiotic resistance. The genetic diversity of bacteria poses challenges in selecting appropriate antigens, hindering vaccine development. We present a proof-of-principle method to enhance the immunogenicity of a model pathogenic *E. coli* strain by forming a slow-releasing depot. Biomimetic mineralization within a metal-organic framework (MOF) effectively encapsulates the *E. coli* strain, enhancing antibody production and improving survival in a mouse bacteremia model. This approach surpasses the limitations of whole-cell formulations and demonstrates the potential for successful clinical translation.

These innovative strategies utilizing ZIFs and MOFs hold great promise for revolutionizing vaccine design, preservation, and immunogenicity. By enhancing stability and ensuring effective immune responses, these advancements contribute to developing next-generation approaches for combating bacterial infections and preventing the spread of pathogens.

9:00 AM *SB02.03.02

Immune/Chemo-Active Nanomofs Multitherapy Patricia Horcajada; IMDEA Energy Institute, Spain

The involvement of Metal-Organic Frameworks (MOFs) in biomedical applications is currently one of the hot topics in the emerging field of hybrid porous solids.^[1] Despite their already proven high loadings and progressive release of a wide variety of active ingredients (e.g. drugs, cosmetics, biological gases,

macromolecules), the control of the biodistribution of MOF nanocarriers and their involvement as a non-passive carriers (bioactive) is still a challenge.

Several examples of successful formulations able to bypass specific physiological barriers will be presented.^[2] In particular, pulmonary administration is a convenient route not only for the treatment of respiratory diseases (e.g. COPD, asthma, tuberculosis, infection, cancer) but also systemic ones. In this sense, a pioneer combined anti-COVID multi-therapy (3-in-1 effect) will be described, paving the way to future treatment of challenging infectious and/or pulmonary pathologies.^[3]

Design of Highly Porous MOFs for Drug Delivery David Fairen-Jimenez; Department of Chemical Engineering & Biotechnology, University of Cambridge, United Kingdom

Metal-organic frameworks (MOFs) are ideal candidates for payload delivery in drug delivery applications due to their highly tuneable surface properties, with drug capacities as high as 60 wt.%. The use of MOFs can lower the required amount of active pharmaceutical ingredient (API), providing a more efficacious therapy while also decreasing the potential for untargeted and undesired effects. Their controlled and autonomous delivery utilizing such a porous high-capacity loading material ultimately could reduce high dependence on patient compliance.

We have developed a series of nano-sized Zr-MOFs with different pore sizes and volumes, from the microporous UiO-66 family of materials to mesoporous NU-1000, all of them showing minimal cytotoxicity. On the one hand, we show how the post-synthetic modification of the MOFs can allow the controlled release of different payloads, extending the release time from 2 days to 30 days. On the other hand, we show how the particle size and surface chemistry allow tuning the final fate of the MOFs and the metabolic pathways of how they are endocytosed by the cells. By modifying the external surface chemistry of the MOFs or by grafting different motifs, we can extend the release time of the drugs, and improve the efficiency of the MOFs to penetrate the cells and target specific organelles.

Our work has allowed us to understand the fundamental biophysical and biochemical mechanisms of cancer cell death upon treatment with MOFs. The fundamental understanding of the biological aspects of cancer has allowed us to advance not only in small-drug molecule delivery but also in novel solutions based on photodynamic therapy and gene therapy.

10:00 AM BREAK

10:30 AM SB02.03.04

Using Zeolitic Imidazolate Frameworks for Creating an Intranasal Depot Effect and Development of a Novel Tuberculosis Subunit Vaccine Sneha Kumari¹, Ryanne N. Ehrman¹, Jonathan Martinez-Garcia¹, Yalini Wijesundara¹, Thomas Howlett¹, Lenette Lu², Angelo Izzo³, Gabriele Meloni¹ and Jeremiah J. Gassensmith¹; ¹University of Texas at Dallas, United States; ²University of Texas at Southwestern, United States; ³Centenary Institute, Australia

Tuberculosis (TB) is the second leading cause of deaths from infectious diseases in the world after Covid-19. Despite the great strides taken in vaccine development over the last few decades, TB prevention still relies on the century-old BCG formulation, whose efficacy widely varies amongst different populations. Whole cell attenuated vaccines for such pathogenic diseases are a risky avenue of research. Decades of subculturing are required to attenuate the strains, and yet there is always a risk of reverting to virulence. We have hence developed a subunit vaccine candidate which combines two novel antigens, a powerful adjuvant, and a slow-release system using MOFs for depot effect. CtpV and MctB are two membrane-bound metal transporter proteins present on the surface of Mycobacterium tuberculosis that are potential virulence factors of TB and can be used to induce a T-cell mediated response upon vaccination. Class A CpG—a synthetic reproduction of bacterial DNA—has been widely investigated as an adjuvant in research models and fits into our formulation well as it also activates T-cells. It is worth noting that many similar subunit vaccines that fall short in clinical trials are unable to produce high enough antibody titers compared to whole cell vaccines. This is primarily attributed to short exposure time of delicate biomaterials like liposomes, that degrade in the body fast. Our goal is to combat this using zeolitic imidazolate frameworks (ZIF), a metal-organic framework that can be synthesized in biofriendly conditions to build a protective coating around the biomaterial. ZIF degrades slowly inside the body, and a vaccine coated with ZIF would slowly release antigens and provide prolonged presentation, giving the immune system time to develop more antigen-specific antibodies. This formulation also allows us to vary the ZIF coating thickness in order to optimize the duration of antigen presentation. We recently concluded an extensive study which demonstrates the biosafety of a wide range of ZIF doses when delivered intranasally in mice as a first step of this investigation. We found that there was no significant difference in the serum protein and enzyme levels and the lung diffusing capacity of mice administered even up to 1 mg ZIF per animal. No tissue damage was observed in the nasal turbinates, trachea, or lungs either. We are currently working on optimizing the various aspects of our vaccine for an ideal immune response and benchmarking our vaccine candidate's performance against BCG.

10:45 AM SB02.03.05

Label-Free Pore-Level Virus and Particle Detection with Bioinspired Inverse Opal Photonic Crystals Natalie Nicolas and Joanna Aizenberg; Harvard University, United States

For most methods of viral imaging, it is necessary to bind bulky fluorescent molecules to the virus in order to visualize its location with optical microscopy. This increases the complexity of sample processing and may change viral behavior. In this research, we instead electrostatically bind viruses or charged particles to the surface of an inverse opal, which is a bioinspired self-assembled ordered porous material, to create a label-free method for imaging the location of a virus with a light microscope. Attached viruses increase the energy barrier to liquid infiltration in the re-entrant pores of the inverse opal, such that they remain dry when a test solution fills the non-occluded pores. Polarized light

microscopy can then be used to distinguish the non-wetted pores, revealing location and concentration information about the viruses. This can create a customizable label-free tool to study viral behavior in laboratory or medical settings.

11:00 AM SB02.03.06

Alzheimer's disease (AD) is the most common form of senile dementia, with few effective treatments. AD pathology is characterized by extracellular amyloid plaques and intraneuronal neurofibrillary tangles. A promising drug discovery approach is to develop molecules capable of targeting both hallmarks of AD, by inhibiting A β and tau aggregation. In recent years, carbon dots (CDs) have emerged as novel drug nanocarriers with high biocompatibility, low cytotoxicity, and the ability to cross the blood-brain barrier (BBB). This talk will describe a new type of CDs, Congo red-derived CDs (CRCDs), synthesized using Congo red and citric acid as precursors. We will discuss how different mass ratios of the two precursors can produce CDs with different physicochemical properties. We will describe the successful synthesis of CRCDs which can cross the BBB in a zebrafish model. In addition, our synthesized CRCDs show the ability to inhibit both tau and A β aggregation. Our findings demonstrate that CRCDs can function as dual inhibitors for tau and A β aggregation, in addition to its capacity to cross BBB, enter the central nervous system (CNS), and to carry drugs. Thus CRCDs-based compounds may be a novel formulation component for the development of multi-functional AD therapeutics.

11:15 AM *SB02.03.07

Smart Materials for Precized Drug Delivery Ali Trabolsi; New York University Abu Dhabi, United Arab Emirates

The development of multifunctional drug delivery systems (MDDS) targeting diseased areas arose from the need to overcome drug limitations such as cytotoxicity, immunogenicity, short circulation times, uncontrolled bio-distribution, and the inability to target specific tissues. Significant advances in nanobiotechnology have led to the development of MDDS to serve diagnostic and therapeutic purposes through a single medical device capable of performing bioimaging tasks while improving the therapeutic efficacy of marketed drugs. Stimuli-responsive nanostructures can take advantage of changes in the biological microenvironment of the disease in question and respond to changes in temperature, pH, redox conditions, reactive oxygen species (ROS), and enzyme concentration, with combinations of stimuli increasing the therapeutic versatility of MDDS. This approach, defined as a new paradigm in nanomedicine, has applications in several fields, including cancer therapy, drug delivery, tissue engineering, and even bionics. In this scenario, the intrinsic properties of nanoparticles are used to develop active devices with diagnostic, therapeutic, or even theranostic functions.

Our group has developed several theranostic covalent organic frameworks (COFs) as smart trigger-responsive MDDSs that cover a wide range of applications from cancer therapy to bioimaging to diabetes control. Nanoscale COFs have shown tremendous potential as new candidates for nanomedicine due to their unique properties-large surface area, tunable pore geometry, crystallinity, versatility, as well as responsiveness to physiological environments. COFs exhibit a long-range ordered structure that results in

regular pores with diameters that facilitate the loading and controlled release of prominent drugs and proteins/enzymes. Moreover, their high flexibility in molecular design makes them versatile and uniquely responsive to their environment. Recently, we published the formation of imine-linked nanoscale COFs linked for cancer therapy. The resulting COFs were stable under physiological conditions but disintegrated in an acidic medium, an essential property of the microenvironment of most solid tumors, and facilitated site-specific drug release. On the other hand, we reported a triazine-based COF with high stability under harsh acidic environmental conditions for oral insulin delivery to diabetic rats. The insulin-loaded COF crossed the intestinal barrier and sustainably lowered blood glucose levels in vivo in diabetic rats (T1D), and blood glucose levels completely returned to normal without causing systemic toxicity compared with the control group of nondiabetic rats.

In my talk, I hope to offer some key elements to answer the question, "Can COF nanoparticles serve as effective therapeutics for various disease treatments?"

SESSION SB02.04: Biomimetic Materials for Delivery II

Session Chairs: Niveen Khashab and Jonathan Sessler

Tuesday Afternoon, November 28, 2023

1:30 PM *SB02.04.02

Three-Dimensional Visualization of Proteins within Metal-Organic Frameworks Joe P. Patterson;
University of California, Irvine, United States

Electron tomography holds great promise as a tool for investigating the three-dimensional (3D) morphologies and internal structures of metal-organic frameworks (MOFs). Understanding the 3D spatial arrangement and density of proteins within protein@MOF biocomposites is paramount for developing synthetic methods to control the location of proteins within the MOF material. The direct visualization of the protein Ferritin (Fn) in Fn@MOF biocomposites was probed through a combination of scanning electron microscopy (SEM), transmission electron microscopy (TEM), and electron tomography (ET). Using con-trolled-dose dry-cryogenic electron tomography (dry-cryoET), we obtain a direct 3D visualization of protein@MOFs with individual protein resolution. These direct observations show that ligand-to-metal ratios for Fn@MOF biocomposites can be tuned to change the spatial arrangement and localization of the proteins within the MOF crystals.

2:00 PM *SB02.04.03

Enzyme-Mimicking of Copper-Sites in Metal-Organic Frameworks for Oxidative Degradation of Phenolic Compounds Aina Valverde¹, Stefan Wuttke^{1,2}, José María Porro^{1,2}, Mónica Jiménez-Ruiz³, Pedro Luis Arias⁴, Iker Agirrezabal-Telleria⁴ and Roberto Fernández de Luis¹; ¹Basque Center for Materials, Applications and Nanostructures, Spain; ²Ikerbasque, Spain; ³Institut Laue Langevin, France; ⁴University of the Basque Country (UPV/EHU), Spain

Through the sequential assembly of simple repetitive units, biology has built up complex three-dimensional scaffolds of metalloproteins, which deposit functional amino acid residues able to coordinate the metal catalytic site in specific spatial configurations. The chemical arrangement of the amino acid residues that conforms the first and second coordination environment of the metal-sites plays a key role in

defining the activity and selectivity of metalloenzymes. Thus, an alteration of any of the amino acid sequence into the heart of the metalloenzyme sites, affects drastically their efficiency, selectivity and function. An important example is the case of copper metalloenzymes, where the coordination of copper ions is usually completed by histidine, cysteine and carboxyl amino acid residues. Depending on the copper-biocatalyst, Cu^{II/I} ions are stabilized as isolated and/or clustered sites able to carry out oxidative catalytic reactions. The overall selectivity and oxidoreductive efficiency of copper-enzymes over a specific substrate is partially defined by the coordination modes of the copper sites. Furthermore, their oxidative capacity has important technological implications in water remediation, since it can be adapted to degrade phenolic pollutants via Catalytic Wet Peroxide Oxidation (CWPO).

Extensive research is being carried out to replicate and expand the metalloenzymes' pockets and catalytic activity to robust porous materials. In this regard, the chemical encoding of bio-catalytic like sites into a particular class of porous ordered materials called Metal-Organic Frameworks (MOFs) holds an enormous promise. MOFs are crystalline solids built from metal ions or clusters that are connected by organic linkers to form extended, ordered, and highly porous networks. Thanks to their (i) impressive and ordered porosity metrics and (ii) their versatility to be encoded with functionalities placed surgically at specific positions of their frameworks, MOFs have been successfully employed as matrixes to install amino acids and peptides. Once the pore space has been decorated with specific amino acid moieties, metal-sites can be easily installed by adsorbing them from aqueous or non-aqueous solutions.

In this work, we have decorated the mesopore space of the MOF-808 with amino acid and carboxylic acid molecules, to later, stabilize coppers ions with varied coordination modes and clustering degrees. In a second step, we have unraveled the impact of the characteristics of the metal-sites on the catalytic wet oxidation (CWPO) of phenolic compounds. The features of the copper-sites installed within the framework have been studied by a combination of Infrared (IR), Raman, X-ray photoelectron (XPS), electron paramagnetic (EPR) and inelastic neutron scattering (INS) spectroscopies. Local structural models for the copper sites have been proposed after a crystallochemical analysis of the copper coordination modes with (amino)acid molecules found in the Cambridge Structural Database. The efficiency and selectivity of our system to oxidize phenolic pollutants through CWPO have been duly assessed, confirming that both the coordination modes and the clustering degree of the copper sites modulate its efficiency and selectivity to oxidize phenols through the hydrogen peroxide activation. The results presented in this work represent a milestone for the installation of metal-amino catalytic sites into the robust architectural backbone of MOFs, which successfully mimic those oxidative functions of metalloenzymes.

3:00 PM SB02.04.04

Bio-Inspired Photonic Microcapsules that Change Colors via Reversible Osmotic Actuation Ji-Young Lee¹, Jaehyun Kim², Jaekyoung Kim², Daeyeon Lee² and Leila Deravi¹; ¹Northeastern University, United States; ²University of Pennsylvania, United States

Animals have evolved complex and sophisticated mechanisms to control coloration, employing a

combination of small molecules and nanostructured composites. Notably, chromatophores, specialized organs found in animals such as squids and octopuses, play a crucial role in dynamic color change. Chromatophores have the unique ability to modify their physical shape and size by expanding or contracting pigment-containing cells. This study introduces an artificial chromatophore system that uses osmotic annealing to trigger reversible color switching. To achieve this, we fabricate double emulsion droplets using polystyrene nanoparticles functionalized with the xanthommatin, the primary pigment found in the skin of cephalopods. The particle size and the pigment loading density into the system are influential factors in controlling the oscillation between pigmentary and structural colors which can be manipulated through annealing. We compared the reflectance spectra of photonic capsules from the presence and absence of pigments. Our findings highlight a distinctive and scalable approach for producing color-changing materials, providing a versatile range of tunable visible colors.

Delivery of AuNCs into eXtracellular Vesicles by Fusion Using Ionizable Liposomes Cargos Ester Butera^{1,2}, Anis Ouzaid³, Solene Ducarre², Giuseppe Maccarrone¹, Annalinda Contino¹, Pascale Even-Hernandez², Celia Ravel^{3,4} and Valérie Marchi²; ¹University of Catania, Italy; ²Université de Rennes 1, France; ³CHU Rennes, France; ⁴University of Rennes 1, France

Extracellular vesicles (EVs) are well-known membrane-limited particles secreted by healthy and cancerous cells. EVs have heterogeneous size and three subtypes are described depending on the location of secretion: microvesicles, myelinosomes and exosomes. EVs are identified in human follicular fluid as a mode of communication in the ovarian follicle.¹ In addition EVs involved in cell-cell communication are considered as biomarkers for early cancer diagnosis. The analysis of their content and their labeling with easily detectable nanoparticles could enable the development of a powerful tool for the early diagnosis of specific diseases

In this view, gold nanoclusters (AuNCs) appear as a recent class of non-toxic fluorophores. Their brightness, their ultrasmall size (< 2 nm) and large window of fluorescence lifetime (1 ns - 1 μ s) and their good biocompatibility make them an attractive alternative as fluorescent probes for biological labeling and bioimaging.² In addition, their ultra-small size facilitates their clearance when they are injected into the body. Their small size makes them attractive to encapsulate them into liposomes without damaging the compartment integrity and then to be delivered into the extracellular vesicles. We previously demonstrate that their direct attractive electrostatic interaction with extracellular vesicles result into the labelling of their membrane or disruption of the EVs into multilamellar structures.³

We investigated encapsulation of ultra-small-sized red and blue emitting Au NCs into liposomes of various sizes and chemical compositions. The efficiency of the process was correlated to the structural and morphological aspect of the AuNCs encapsulating vesicles via complementary analyses by SAXS, cryo-TEM, and confocal microscopy techniques. We confirmed the possible encapsulation of ultra-small-sized red and blue emitting Au NCs into liposomes of various sizes and chemical compositions. Cell-like-sized vesicles (GUVs) encapsulating red or blue Au NCs were successfully obtained by an innovative method using emulsion phase transfer. Finally, exosome-like-sized vesicles (LUVs) containing Au NCs were obtained with an encapsulation yield of 40%, as estimated from ICP-MS.⁴

Herein, we investigate the interaction of fusogenic liposomes encapsulating the AuNCs with EVs

extracted from human seminal fluids. The composition of the membrane was optimized to improve the fusion properties of the liposomes. The mixture of the liposomes and EVs results in lipid exchange as demonstrated by FRET experiments and in increased size revealed by flux cytometry. The resulting fused hybridosomes were successfully isolated by size exclusion chromatography. They exhibit typical fluorescence of the AuNCs together with an increased size in agreement with the expected size of the fused exosomes. Besides their interest to analyze the EVs content, such hybridosomes could serve as drug or macromolecule carriers or nanosensors in living organisms.

3:30 PM SB02.04.06

Potential of Dendrimer-like Silica Nanoparticles Loaded with Cisplatin and Immune-checkpoint Inhibitors for Direct and Indirect Tumor Regression Taihyun Kim and Jinkee Hong; Yonsei university, Korea (the Republic of)

Since the development of cancer immunotherapy using immune checkpoint inhibitors (ICIs), significant improvements have been made in cancer treatment. However, there are still limitations in their clinical effectiveness, particularly in terms of low delivery to target sites. To address these limitations, we aimed to enhance the existing ICI-based immunotherapy strategies by combining them with chemotherapeutic agents.

To achieve this goal, we employed a one-pot sol-gel reaction to prepare dendrimer-like porous silica nanoparticles (DPSNs). These DPSNs possess a larger surface area compared to spherical particles of the same size, resulting in enhanced stability during long-term storage. Initially, we focused on conjugating cisplatin, a widely used chemotherapeutic anti-cancer agent, onto the surface of DPSNs. By modifying the DPSNs with carboxyl groups and loading cisplatin as a model anticancer drug, we investigated the release behavior of the drug molecules. Our findings revealed that cisplatin remained intact under neutral conditions but was released under acidic conditions, indicating the successful development of pH-responsive DPSNs (referred to as DPSN-cis).

Furthermore, we performed an EDC/NHS-sulfo reaction to modify aPD-1, one of the ICIs, onto the surface of DPSN-cis. This allowed us to create DPSN-ICIS, where both cisplatin and aPD-1 were simultaneously conjugated. Importantly, DPSN-ICIS exhibited no cytotoxicity even after three days of cell culture and demonstrated long-term physicochemical stability. To evaluate the effectiveness of DPSN-ICIS, we conducted in vitro experiments to assess its binding to PD-1 on T cells and its ability to induce cancer cell death. Subsequently, we validated these findings in vivo by demonstrating that DPSN-ICIS effectively performed both functions and led to tumor eradication. These results were further supported by analyzing immune responses to examine the behavior of DPSN-ICIS within a living organism.

Overall, our study highlights the potential of next-generation cancer immunotherapy by simultaneously loading chemotherapeutic agents capable of directly killing tumors and functionalizing various immune enhancers. The development of DPSN-ICIS addresses the limitations of current immunotherapy approaches, offering a promising strategy for more effective cancer treatment.

3:45 PM SB02.04.07

Vitalizing Immortal Nanodendritic Cells Functionalized with Immune-checkpoint Inhibitors for Tumor-localized Immunotherapy Taihyun Kim and Jinkee Hong; Yonsei University, Korea (the Republic of)

Recently, cancer immunotherapies combining nanotechnology have been highlighted due to the high impact of substantial clinical potential in various types of solid cancers. Especially, nanoparticle (NP)-based technology is a well-known and powerful tool for manipulating functionalities and ensuring in vivo stability, making it suitable for personalized cancer therapy. As an advanced form of immunotherapy using nanotechnology, the combination of cell-based therapy and NP technology has been emerging, for example, introducing cellular membranes or extracellular vesicles onto the NPs. This delivers the entire information of the cell membrane to the NP surface without damage and could be regarded as a useful technology for cell mimicking.

Meanwhile, dendritic cells (DCs) have been recognized as promising targets for immunotherapy due to their crucial role in T cell activation. However, administrated DCs in patients showed poor lifetime in vivo, which resulted in limited antigen-presenting capabilities in clinical trials. Furthermore, the storage and recovery of DCs for further usage are also challenging to retain DC survival rate and functionalities. To overcome these limitations, we have developed immortalized nanodendritic cells for cancer immunotherapy by combining DC therapy with cell-mimicking nanotechnology.

By utilizing immortalized DCs with extended lifetimes, we believe that continuous antigen presentation and T cell activation can be achieved in vivo. Our idea to prepare immortalized DC was inspired by cell membrane clocking technology which was first developed by L. Zhang et al. Using this technique, the whole DC membrane could be successfully decorated onto gold nanoparticle (Au NP), which is named artificial nanoDCs (anDCs). We optimized the manufacturing process of anDCs both biologically and thermodynamically to enhance their therapeutic efficacy. The optimized anDCs demonstrated thermodynamic stability and retained their functional abilities even after long-term storage of up to 30 days. We also confirmed the strong tumor regression effect of anDCs due to the fact that the nanosized DC can accumulate in the tumor site or lymph node without degradation, resulting in enhanced T cell activation in vivo.

Finally, to boost the T cell activation effect, the anDC was engineered with immune-boosting agents, immune-checkpoint inhibitors (ICIs). By direct engineering anDC with anti-CTLA-4 (aCTLA-4), we could obtain potent anDCs to induce T cell effector function efficiently. In our research, we validated the efficacy of aCTLA-4-conjugated anDCs in three different tumor models (MC38, CT26, and TC-1). Surprisingly, aCTLA-4-conjugated anDCs exhibited substantial tumor regression compared to the control group, as confirmed by in vivo immune analysis, which showed augmented tumor-infiltrating lymphocytes.

In summary, our objective was to develop optimized therapeutic drugs for cancer immunotherapy that can mimic the behavior of DCs. We successfully created a DC-mimicking therapeutic anticancer drug that can continuously and strongly activate tumor-specific T cells, thereby resulting in dramatic tumor regression. Furthermore, by conjugating various immune-boosting agents to anDC, we strongly anticipate that our material could be manufactured as desired and provided for patient-specific needs.

SESSION SB02.05: Poster Session

Metal-Organic Framework Coordinated with Single Fe Nanozymes and Gold Cluster for Biomedical Applications Subin Yu^{1,2} and Luke Lee²; ¹Ewha Woman's University, Korea (the Republic of); ²Harvard Medical School, United States

Metal-organic frameworks (MOFs) have been extensively utilized as substrates for constructing single-atom catalysts (SACs) due to their abundant ligands, enabling nanozyme-mediated biomedical applications. However, the preparation of SACs using MOF substrates typically involves harsh calcination processes to stabilize the single metal atom catalysts, which can lead to uncertain changes in the oxidation state of the metal centers, impacting the overall catalytic reaction. In this study, we have developed ultrasmall MOF-based single iron (Fe) atom Fenton-like nanozymes (referred to as Fe/MOF) by employing a simple mixing method. These nanozymes were combined with a gold nanocluster-embedded MOF mimic of glucose oxidase (referred to as Au/MOF), enabling cascade enzymatic reactions within living systems. To harness the abundant porosity of MOF and enhance cell cytotoxicity, the anticancer drug doxorubicin (DOX) was loaded inside Fe/MOF (referred to as Fe/DOX/MOF). Additionally, Au/MOF was further modified with a mitochondrial targeting moiety (triphenylphosphonium, TPP) to target the mitochondria and disrupt the cellular redox system. Internalization of Au/MOF into mitochondria resulted in glutathione (GSH) depletion through thiol-gold interactions, leading to mitochondrial excess lipid peroxidation. The constructed Fe/MOF exhibited an oxidation state of 2+ with Fe-N coordination bonds, demonstrating well-established Fenton-like nanozymes characteristics. The overall cascade enzymatic activity effectively generated hydroxyl radicals from glucose as a substrate. The generated gluconic acid induced an acidic environment that further accelerated the overall Fenton reaction. In vitro, studies demonstrated effective cancer eradication through cascade glucose oxidation and hydroxyl radical generation. GSH depletion-mediated down-regulation of GPx4, along with the delivered Fe²⁺, induced Fenton reaction-mediated lipid peroxidation, indicating ferroptosis. In vivo, studies further confirmed the overall therapeutic effects of the cascade enzymatic activity of Fe/MOF and Au/MOF. Our novel and straightforward synthesis process for MOF-based single-atom nanozymes and metal clusters present a new paradigm for fabricating single-atom nanozymes for multimodal cancer treatment.

8:00 PM SB02.05.02

Antibody Pre-Coated Zr-MOF as a Cloaking and Plug&Playable Platform for Targeted Delivery System Jun Yong Oh, Batakrishna Jana, Junmo Seong, Eun Min Go, Seongeon Jin, Jong-hoon Bae, Chaiheon Lee, Seonghwan Lee, Tae-Hyuk Kwon, Jeong Kon Seo, Eunshil Choi, Sang Kyu Kwak, Myoung Soo Lah and Ja-Hyoung Ryu; Ulsan National Institute of Science and Technology, Korea (the Republic of)

Metal-organic framework (MOF)-based targeted drug delivery systems have made great strides and are widely used in a variety of scientific disciplines. Nevertheless, the biomolecular corona phenomenon makes it difficult to directly translate MOF agents into focused medication delivery systems. Here, we have established that pre-absorption of antibodies to MOF particle surfaces by supramolecular mixing can decrease protein adhesion in biological contexts, with effects akin to those of stealth shields. Furthermore, we further demonstrated that this mechanism may be influenced by the MOF's surface's pore size. The MOF particle was neither readily swapped with nor covered by biomolecule protein once the antibodies had been stably attached to it, indicating a stealth effect and an improved capacity to target both in-vitro

and in-vivo. In addition, the generated antibodies-MOF platform may target various cancer cell lines by plugging multi-antibodies (dual and triple kinds). This study provides insights into the use of “antibody pre-absorption” as a promising method for developing MOF-based drug delivery systems.

8:00 PM SB02.05.03

Dual Drug Delivery Systems Based on Porous Fibers Grafted with ZIF67 Jooran Kim; Korea Institute of Industrial Technology, Korea (the Republic of)

Metal-organic frameworks (MOFs) have emerged as promising materials for various applications due to their exceptional tunability and high surface area. In recent years, the integration of MOFs with fibers has gained significant attention in the field of drug delivery systems. The combination of MOFs and fibers offers a unique platform for controlled release, targeted therapy, and enhanced drug stability, ultimately revolutionizing the field of therapeutics.

Moreover, researchers have explored the application of dual drug delivery using porous fibers with MOFs in various therapeutic areas, including cancer therapy, antimicrobial treatments, and regenerative medicine. These studies have demonstrated the potential of these systems to overcome drug resistance, reduce side effects, and enhance treatment efficacy by delivering multiple drugs simultaneously.

In this study, we developed porous poly(caprolactone) (PCL) fibers through liquid-liquid phase separation, and then ZIF-67 was grown on the porous PLA fiber through in-situ synthesis. These carriers were investigated the relationship among pore formation, physical properties, and antibacterial activities of the fibers for identifying their potential as drug delivery carriers. Studies have focused on optimizing the synthesis techniques to achieve uniform ZIF67 coatings on the surface of porous PCL fibers.

Suggested dual drug delivery system using porous PCL fibers with ZIF67 are the co-delivery of two drugs including lysozyme and gentamicin with complementary antibacterial effects. By encapsulating dual drugs inside pores of PCL and ZIF67, the dual drug delivery system achieves synergistic effects, improved drug stability, and controlled release kinetics. Furthermore, the selection of appropriate drugs and their optimal ratios play a crucial role in achieving desired antibacterial outcomes.

Overall, the research on dual drug delivery using porous fibers with ZIF67 highlights the potential of these drug carrier systems in achieving controlled release, synergistic effects, and improved antibacterial outcomes. Further advancements in the synthesis techniques, optimization of drug ratios, and comprehensive understanding of the in vivo behavior are crucial to translate these innovative systems into clinical applications and address the challenges associated with their practical implementation.

8:00 PM SB02.05.04

Capping UiO-Based and HKUST-Based Metal Organic Frameworks Towards Trapping and Controlled Release of Guest Molecules Samuel Darer, Cal G. Lebak, David S. MacLeod, Abigail Berube, Shawn C. Burdette and Ronald L. Grimm; Worcester Polytechnic Institute, United States

Molecular caps for metal organic frameworks (MOFs) are particularly compelling for enabling capping and controlled release of guest payloads. Previously we utilized bulky triphenylacetate-based caps to trap guests within the pores of MOF-5. Presently, we extend these efforts to the UiO and the HKUST families for their tunable porosity, high stability, and varying chemistry to explore the interplay between interfacial chemical properties on the MOFs and the necessary capping chemistry. We utilized capping reactions including acetate exchange, growth with terminating single-acetate-group organics, and established functionalities for monolayer chemistries. Utilizing fluorine-tagged capping organics, X-ray photoelectron spectroscopy established which chemistry successfully capped each MOFs, and supported models of interfacial chemical states that exist on the MOF themselves. We aim to further develop

capping abilities, expanding the control and variability of the caps that can be applied to MOFs and applying this research to wider potential applications.

8:00 PM SB02.05.05

Janus Hydrogel-Based Fuel Stimulant Powered Amplification for Multiple Detections of miRNA Biomarkers in Gastric Cancer Eun-Kyung Lim; Korea Research Institute of Bioscience & Biotechnology, Korea (the Republic of)

MicroRNAs (miRNAs) circulating in body fluid have emerged as potential biomarkers for various diseases; however, owing to their low concentrations and short lengths (~22 nt), their clinical applications are still limited. Therefore, a highly sensitive and selective novel diagnostic platform for miRNA detection is required. Here, we present a hydrogel-based fuel stimulant-powered (FSP) amplification of fluorescent signals to detect circulating miRNAs from clinical samples of human serum. The advantage of this method is that it has high sensitivity as a fuel-assisted DNA cascade reaction that does not require temperature control and enzymes used for nucleic acid amplification. Further, we developed a Janus-type hydrogel for the simultaneous detection of the gastric cancer-associated miRNAs, miR-135b and miR-21. The detection limit of this hydrogel-based FSP amplification using synthetic miRNAs was estimated as < 10 fmol. We also validated the performance of this amplification process in in vitro and in vivo models and clinical samples. Therefore, we demonstrate that Janus hydrogel-based FSP amplification can selectively and sensitively identify the overexpression of miR-135b and miR-21 in clinical samples, thereby helping distinguish gastric cancer patients from healthy donors.

8:00 PM SB02.05.07

Host Cell-Mimetic Hybrid Nanoparticles as Antiviral Therapeutic Nano-Inhibitors for Influenza Virus Eunji Jeong, Geunseon Park and Seungjoo Haam; Yonsei University, Korea (the Republic of)

Unpredictable pandemic caused by respiratory virus such as coronavirus disease (COVID-19) poses a great threat to public health due to numerous infections and deaths. Despite the emergence of various diagnostic methods and vaccines, limitations persist in the development of effective antiviral therapeutic agents for promptly addressing newly emerging viruses. Host cell mimetic nanodecoy is an effective strategy to protect against the advancement of infection by neutralizing the virus, impeding its binding and entry into the lung cell membrane, which is the ultimate target of the virus. Herein, we develop an advanced biomimetic nanodecoy capable of trapping the target virus and preventing host cell infection using gold nanoparticles with various topologies and sizes through encapsulating by coating host cell membranes. We fabricated cell membrane-coated Spiky Gold nanoparticles (CM-SGNP) with various topologies, each ranging in size from 50 nm to 120 nm, using a seed-mediated growth method and physical extrusion. The CM-SGNP coated with the Madin-Darby canine kidney cell membrane could efficiently capture Influenza A virus (IAV) virions, providing evidence that the binding event and subsequent infection between host cells and virions will be inhibited. Interestingly, geometry matching between IAV virion and CM-SGNP according to the topology of CM-SGNP suggests that this system has the potential to be customized according to virus type and appearance by controlling the structure of CM-SGNP. Furthermore, CM-SGNP is expected to provide successful delivery and therapeutic effects in-vivo due to its superior biocompatibility characteristics. This system suggests the powerful strategy for treating infectious diseases by combining synthetic and biological materials. It is also the next-generation therapeutic agent that can be widely applied to various virus mutant and newly emerging disease X by setting the ultimate target of the virus to be a nanoinhibitor.

SESSION SB02.06: Biomimetic Self-Assembled Materials I

Session Chairs: Jonathan Sessler and Stefan Wuttke

Wednesday Morning, November 29, 2023

Hynes, Level 3, Room 307

8:30 AM *SB02.06.01

Self-Assembled Metal-Organic Framework Monolayers (SAMMs) Seth M. Cohen and Minjung Kang; University of California, San Diego, United States

The combination of polymers and metal-organic frameworks to obtain composite materials can take a number of forms, including mixed-matrix membranes (MMMs) prepared with MOFs, polymer-decorated MOF particles, and MOFs constructed from polymer building blocks referred to as polyMOFs. It has been demonstrated that polymer-decorated MOF particles, under the correction conditions, can form self-assembled MOF monolayers (SAMMs). These unusual materials allow for the formation of ultrathin MOF membranes and coatings that may find use in a range of MOF-based applications. This presentation will describe the synthesis, characterization, and properties of SAMMs as an interest MOF-polymer composite material.

9:00 AM *SB02.06.02

Supramolecular Self-Associating Amphiphiles (SSAs) – A Therapeutic Technology Platform? Plus, Can You Stop a Bullet with Protien? Jennifer Hiscock; University of Kent, United Kingdom

Our novel patented (European Patent Application No. 18743767.8, U.S. Patent Application No. 16/632,194), Supramolecular Self-associating Amphiphile (SSA) technology currently incorporates a library of ~ 120 amphiphilic salts and associated compounds, with structures containing an uneven number of hydrogen bond donating and accepting moieties. The anionic component of this class of compounds have been shown to self-associate through the formation of intermolecular hydrogen bonds producing anionic dimers in the polar organic solvent DMSO. Moving into aqueous conditions, SSAs self-associate to form spherical aggregates between 100 nm and 550 nm in hydrodynamic diameter. However, the presence of inorganic salt can cause these spherical aggregates to morph from sphere to fibre, producing a series of hydrogel materials.

Within a biological context we have shown these SSAs to:

- act as antimicrobial agents;¹
- increase the efficacy of other antibiotic/antiseptic agents and anticancer agents against bacteria² and ovarian cancer cells respectively;³
- selectively interact with phospholipid membranes of different compositions;⁴
- have the potential to act as drug delivery vehicles;⁵

- exhibit a druggable profile when delivered via i.v. in vivo to mice.⁶

Plus, some novel work from our group - can protein be engineered into a material that can capture supersonic impacts?⁷

Molecular and Polymeric Architectures Enabled by Dynamic Spiroborate Chemistry Wei Zhang;
University of Colorado-Boulder, United States

Dynamic covalent chemistry (DCvC) has proven to be highly effective toward the construction of well-defined molecular and polymeric architectures. The error-correction mechanism enabled by the reversible formation of dynamic covalent bonds leads to the formation of structurally ordered, thermodynamically favored species. One such example is the solvothermal synthesis of covalent organic frameworks (COFs) with periodic structural order and low defect density. The chemical compositions of such frameworks are usually well-defined and inter-monomer connectivity (covalent bonding) is robust. Bottom-up synthesis of covalently linked polymers through DCvC has many critical advantages, such as easy tunability of functional and structural properties in a controlled fashion through rational design of the precursors, formation of highly stable linkages, minimized structural defect, and possible access to sophisticated architectures that are hard to obtain otherwise. This talk will focus on our recent progress in the development of DCvC, specifically spiroborate bond exchange. This powerful transformation enabled the bottom-up design and synthesis of novel functional materials, such as unprecedented single-crystal DNA-like helical covalent polymers (HCPs) and shape-persistent redox active organic molecular cages.

Engineering Metal-Phenolic Materials via Supramolecular Assembly Zhixing Lin^{1,2}; ¹The University of Melbourne, Australia; ²The University of Melbourne, Australia

Coordination polymers (CPs) and their higher-dimensional and potentially porous subset, metal-organic frameworks (MOFs), are supramolecular materials comprising metal nodes and organic ligands. Over the past three decades, CPs in the crystalline state have been the primary focus of the field due to their defined structures, high internal surface areas, and potential for crystal engineering. The periodic arrangement of metals and ligands has facilitated fundamental research on controlling pore size and surface area, which are crucial for achieving improved performance in various applications. However, the practical application of these crystalline materials poses challenges in terms of maintaining accessible pore volumes, integrating into existing infrastructure, and addressing safety concerns arising from the use of toxic precursors and solvents during synthesis, as well as the rigid, brittle, and often unstable nature of crystalline CPs. In contrast, amorphous CPs have gained significant attention over the past decade due to the presence of amorphous domains, which increase pore size, mechanical robustness, and chemical stability of the materials, leading to improved functionality.

One type of amorphous CPs, known as metal-phenolic networks (MPNs), consists of metal ions and phenolic ligands and can be adhesive to diverse surfaces. Due to their ability to coat nanoscopic and macroscopic templates, MPNs have garnered considerable interest in various applications, including biomedicine, photonics, forensics, and biomolecule and fruit preservation. Different metal ions can be employed to confer specific functionalities to MPNs, such as fluorescence, magnetic resonance imaging, and catalytic activity, or to produce synergistic effects in combination with the phenolic ligand, such as buffering effects. Additionally, the amorphous structure of MPNs can endow them with unique material properties, such as higher mechanical robustness, increased stability, and improved processability. This presentation aims to provide an introduction to MPNs, covering their fundamental aspects and will highlight our recent significant progress in developing MPNs for various biomedical applications, including catalysis, intracellular tracking, and drug delivery.

Structure and Dynamics of Self-Assembled Lipid Nanoparticles for Nucleic Acid Delivery Shayna Hilburg and Lilo D. Pozzo; University of Washington, United States

Nucleic acids can revolutionize human health outcomes, as evidenced by the mRNA vaccines used to combat COVID-19. Despite the success of these therapeutics, the fundamental physicochemical properties of the non-viral delivery vectors must be better understood to be more easily tuned and optimized. In this work, we use small-angle X-ray (SAXS) and neutron scattering (SANS) to assess how the storage and delivery conditions of the nanoparticles impact their structure and dynamics. The components which come together to encapsulate the nucleic acids have complex non-covalent interactions at the nanoscale which dictate their ability to withstand storage conditions and transport to cells while also disassociating upon intracellular delivery to release cargo. Here we show that the molecular interactions within the drug delivery vehicles, including exchange kinetics of the self-assembled molecules, are impacted by relevant environmental factors, including pH. Such information demonstrates what drives degradation and what parameters can be changed to improve delivery by increasing the efficiency of endosomal escape. Ultimately, these results can be used to optimize efficacy, enabling more flexible storage requirements, lower dosages, and improved therapeutic tolerances.

Visible Light as a Benign Stimulus for Additive Manufacturing of Hydrogels Zachariah A. Page; The

Updated as of October 28, 2024

University of Texas at Austin, United States

Light as an energy source has enabled transformative technologies in imaging, lithography, adhesives, and 3D printing. Its broad utility arises from the unparalleled spatiotemporal control over chemical transformations that it offers. However, contemporary methods rely on high energy UV light (< 400 nm), which limits biocompatibility due to degradation and attenuation that occurs upon absorption and/or scattering. Excitingly, the recent commercialization of inexpensive light emitting diodes has opened up an avenue to examine mild visible-light induced reactions in the fabrication of biologically relevant scaffolds. This presentation will focus on how the *ZAP Group* has developed low energy light driven reactions to create macroscopic water-swollen scaffolds (i.e., hydrogels) with unprecedented speed and precision. Specifically, catalyst design principles to enable rapid solidification of photopolymer resins using visible-light will be discussed, along with their utility and optimization in high resolution additive manufacturing.

SESSION SB02.07: Biomimetic Self-Assembled Materials II

Mimicking Melanin: Nature's Biopolymer of Intrinsic Microporosity as a Therapeutic Material for Tissue Repair Nathan C. Gianneschi and Kurt Lu; Northwestern University, United States

Melanin is a class of essential biopolymer found across plant, animal, bacterial and fungal kingdoms with an astonishing array of functions, including pigmentation, radical scavenging ability, radiation protection, and thermal regulation. Nature synthesizes melanin of five known kinds: eumelanin, pheomelanin, allomelanin, neuromelanin and pyromelanin. Among them, eumelanin (black and brown pigment in dark hair) and pheomelanin (the pigment in red hair) are the two most commonly considered forms. The past two decades have witnessed a flourish of eumelanin-based materials, especially polydopamine. In our own work, we have endeavored to explore synthetic analogues that enhance, extend and build on these biomimetic systems to enrich melanin and melanin-like materials with desirable properties for a range of applications. A key property of interest here is the ability of properly engineered synthetic melanins to perform as high surface area “sponges” for absorbing toxins and to act as an efficient and stable scavenger of radicals. These synthetic porous melanin materials and a variety of modified analogues will be described in terms of their function in tissue repair. Specifically in topical applications for healing damaged skin from chemical and radiation induced injury.

Construction of Smart Supramolecular Drug Delivery Systems for Biomedical Applications Ying-Wei Yang and Chinedum Osuji; Jilin University, China

The design, synthesis, recognition, and assembly of functional macrocyclic receptors have been playing a critical role in supramolecular chemistry. Due to their superior properties and functions, supramolecular macrocycles, including cyclodextrins, cucurbiturils, calixarenes, and pillararenes, have attracted broad

attention in the fields of organic supramolecular chemistry and materials science. Meanwhile, nanoparticles with unique characteristics and particular properties, such as mesoporous silica nanoparticles, metal-organic frameworks, gold nanoparticles, magnetic nanoparticles, and semiconductor nanocrystals, have shown ever-increasing importance in chemistry, materials science, nanoscience, and biomedicine. Upon combining the porous/nonporous inorganic solid nanoplateforms or even organized organic/polymeric nanosystems with supramolecular macrocycles, there is great potential to enhance the photophysical, chemical, electronic, and other related properties of solid supports and the host-guest property of supramolecular macrocycles expanding and advancing the applications of the resulting organic-inorganic hybrid materials.¹⁻⁸ In this talk, I will present our methodology and research progress of the chemical construction of smart supramolecular drug delivery systems hybridized with synthetic macrocycles and nanoparticles and showcase their applications in the areas of antimicrobial, anticancer, cell imaging, crop protection, biosensing, etc.

Engineering of Advanced Biomaterials by Harnessing Biological Organization Principles Alvaro Mata; Nottingham University, United Kingdom

Living systems have evolved to grow and heal through biological organization principles (BOPs) capable of organizing molecular and cellular building-blocks at multiple size scales. These BOPs emerge from cooperative interactions and chemical networks between multiple components, which allow biological systems to diversify, respond, and optimize. This talk will present our laboratory's efforts to combine supramolecular events found in nature such as self-assembly, disorder-to-order transitions, or diffusion-reaction processes with engineering processes to design bioinspired materials and devices (Figure 1). I will also describe recent efforts aiming to go beyond "bioinspiration" and into "biocooperation". I will describe methodologies to develop a) dynamic hydrogels and in vitro models for cancer [1,2], b) self-assembling fluidic devices [3,4], and c) regenerative implants [5,6].

Biofilm-Inspired Underwater Peptide Adhesives Jing Yan, Xin Huang and Sarvagya Saluja; Yale University, United States

Bio-adhesives are extensively used in biomedical applications including suture-less seal and wearable electronics, where there is a need to adhere two wet surfaces together. However, existing products, largely inspired by mussel adhesives, are expensive to produce and sensitive to environmental conditions limiting their wide application. We recently made a serendipitous discovery regarding how bacterial biofilms formed by *Vibrio cholerae*, the pathogen responsible for pandemic cholera, adheres to various surfaces using a unique short peptide. In this study, we will show a range of both biotic and abiotic surfaces suitable for this biofilm-inspired glue, and the molecular mechanism underlying the adhesive property of this

peptide. Finally, I will discuss about our effort in establishing a fermentation-based process to scale up the production of the peptides.

11:15 AM SB03.01.03

Cephalopod-Inspired Optical Engineering of Mammalian Cells Georgii Bogdanov, Nikhil Kaimal, Aleeza Farrukh, Aleksandra A. Strzelecka, Atrouli Chatterjee and Alon Gorodetsky; University of California, Irvine, United States

During the last several decades, cephalopods (e.g., squids, octopuses, and cuttlefish) have emerged as a powerful source of inspiration for the engineering of dynamic optical systems, due to their complex nervous systems, diverse behavioral patterns, and tunable structural coloration. We drew inspiration from the tunable optical functionality of cephalopod skin cells to engineer human cells for production of reflectin-based high refractive index subcellular architectures and, as a result, to possess tunable transparency-changing and light scattering capabilities (1). Additionally, we improved our control over the production of reflectin in human cells by genetically engineering cell lines to stably express reflectin, which enabled more extensive studies of reflectin-based subcellular architectures under physiological conditions (2). Moreover, we evaluated the optical properties of single cells with three-dimensional label-free holotomographic microscopy and quantitatively characterized their subcellular reflectin-based architectures without and with external chemical stimuli (1,2). Finally, we demonstrated the potential applications of high refractive index reflectin-based subcellular architectures as high contrast genetically encoded biomolecular reporters for various types of microscopy techniques (2,3). Our combined findings validate prior postulates about the mechanisms of cephalopod tunable skin coloration and may lead to the development of unique protein-based tools for various applications in biophotonics and bioengineering.

11:30 AM +SB03.01.04

Molecular Biomimetics - Molecular Technologies of the Future Through Biology Mehmet Sarikaya; University of Washington, United States

Proteins are the workhorses in biology as they are the fundamental building blocks making up the hierarchical structures of the cells, establishing biomolecular communications via signal transduction, transporting ions, and carrying out enzymatic processes, all vital for life's functions. The proteins, therefore, could be useful tools in developing functional molecular devices, if they can be designed and engineered to function similar to that in organisms. Despite the enormous opportunities provided by proteins as fundamental molecular tools, their utility in engineering and practical technology has not been fully realized, and their use has so far been highly limited for single purposes, e.g., enzymatic functions. In addition to their complexity and cumbersome handling issues, at least for the practical engineer, the main reasons for the limited use of proteins in engineered systems are because of their long amino acid sequences, i.e., 100s of AAs and even 1000s, that lead to unpredictable folding patterns and the resulting functionalities that are not easily predicted or controlled. On the other hand, polypeptides, i.e., short amino acid sequences (10-50 AAs), functional components of proteins, offer similar opportunities as proteins, with the advantage of being easily designed and manipulated, although their folding structures and functions are difficult to control. Despite these difficulties, for more than last two decades, peptides have been used in a variety of practical implementations such as tiny enzymes, drugs, biofunctionalization

of nanoparticle drug carriers, probe design for specific targets, and for biomineralization. Especially useful are the fact that peptide sequences can be designed such that they may self-assemble into predictable tertiary structures in aqueous solutions with controlled geometries and shapes such as nanofibers, strips, and 3-dimensional gel-like molecular scaffolds. Since the first publication (below), molecular biomimetics has been emerging as a convergent science and technology field in which hybrid technologies are developed by the tools of molecular biology, genetics, computational sciences, and machine intelligence combined with materials science and engineering. For the last 2+ decades, our laboratory has adapted directed evolution approaches and identified thousands of short peptide sequences (7-15AA) and utilizing them as molecular tool sets in developing molecular technologies. These genetically engineered proteins for inorganics, GEPIs, also dubbed as solid binding peptides, SBPs, can be used as tiny enzymes in, e.g., remineralization, surface functionalization in implants, designing heterofunctional probes and molecular constructs for molecular and ionic targets, and key components of functional nanodevices, such as peptide-enabled field effect transistors. Recent discovery of coherent bio/nano soft interfaces between the self-assembled solid binding peptides forming monomolecular two-dimensional molecular crystals on, and having chiral crystallographic relationships with, single atomic layer solids provides the key element in the development of brain-inspired molecular probes and logic devices by seamlessly integrating biology and solid-state materials at their smallest respective functional units. Based on the three fundamental biological principles of molecular recognition, gene manipulation, and self-assembly, molecular biomimetics is opening a new era in truly genetically engineered functional molecular materials and system of the future. M. Sarikaya et al., *Molecular Biomimetics: Nanotechnology through Biology*, Nature Mater., 2, 577-585, 2003.

SESSION SB03.02: Applications and Devices in Materials and Medicine

1:30 PM SB03.02.01

A Novel Bio-Adhesive for Wet Surfaces from *Vibrio Cholerae* Sarvagya Saluja, Jing Yan and Xin Huang; Yale University, United States

Effective adhesion of surfaces in a wet environment is very useful for the biomedical and engineering fields (wearable electronics, suture-less seals, underwater pipeline repair, etc.). However, underwater adhesion has remained a significant challenge. Water prevents effective molecular contact between the adhesive and the substrate, a key step, and prolonged exposure to the aqueous environment deteriorates the adhesive, leading to cohesive failure. Currently, research efforts are taking inspiration from mussels and bacteria, creatures that overcome these challenges and can strongly adhere to underwater surfaces. We recently discovered that a sequence of 57-amino acids (57-aa) in *Vibrio cholerae* biofilms is the primary contributor to their adherence to a variety of surfaces, both biotic and abiotic, such as glass, plastic, and lipid membranes. We have developed several biochemical and biophysical *in vitro* characterization methods to demonstrate the polypeptide's potential to function as a wet adhesive. Modifying the sequence and applying it to different surfaces has allowed us to identify key parameters of the polypeptide's adhesion ability, including aromaticity, positive charge, linkers, and repeating motifs. We also tested multiple *Vibrio cholerae* mutants to understand the surface adhesion as a biofilm. Finally,

Updated as of October 28, 2024

we collaborated with simulation groups to corroborate experimental data with theory. Understanding and establishing a model for the adhesion mechanism of the polypeptide enables better engineering of wet adhesives.

Overall, we demonstrate that a 57-aa sequence of a *Vibrio cholerae* biofilm adhesin could be used as a glue for different underwater surfaces. Our findings contribute to the general development of superior wet adhesives.

1:45 PM SB03.02.02

Intermolecular Interactions of Protein-Mimetic Random Heteropolymers Shayna Hilburg, Tianyi Jin, Priya Ganesh and Alfredo Alexander-Katz; Massachusetts Institute of Technology, United States

Amphiphilic synthetic random heteropolymers, specifically easily synthesized methacrylate-based polymers with side-chains selected to mimic peptide characteristics, have been demonstrated to provide a bio-inspired means for augmenting and even mimicking bio-macromolecular function. However, the statistical distribution of chains makes a nano-scale molecular analysis of particular moieties and motifs challenging experimentally. Through computational modeling, specifically atomistic molecular dynamics simulations, we provide nanoscale analysis of sequences to provide insight into how these synthetic polymers respond to their environments and interact with molecules around them. Having previously examined the self-assembly of single chains into globules with heterogeneous surfaces for the chains in solution, we now characterize their statistically derived properties in more complex environments. We show how the polymers which have limited dynamics on their own can change significantly as they interact with organic solvents, macromolecules, or surfaces. We explore environmentally-dependent driving forces and the stochastic behavior of the random polymers which impact kinetics and characterize resultant changes in polymer conformation. These changes are shown to be highly dependent upon the properties of both the polymer and the molecular interactions that take place. Our study, leveraging analysis techniques from both polymer physics and protein sciences, illuminates ways in which the polymers are similar to the proteins they are inspired by as well as avenues for applying the synthetic polymer assemblies in solution.

This work was supported by the Defense Threat Reduction Agency contract HDTRA11910011 and HDTRA12210005.

2:00 PM *SB03.02.03

Hierarchical and Stimuli-Responsive Hybrid Materials from High Information Content Building Blocks Francois Baneyx; University of Washington, United States

Solid-binding proteins are genetically engineered chimera that incorporate one or more solid-binding sequences at defined locations of their framework while retaining native function. These macromolecules are versatile building blocks for the fabrication of hybrid hierarchical materials that derive unique properties from the organization, interplay, and reconfiguration of organic and inorganic units. Here, I will discuss how solid-binding proteins can be combined with self-assembled peptoid nanostructures and pre-synthesized or mineralized inorganic elements to create layered 3D architectures, achieve precise control over nanocrystal size, and build photocatalytic nanocomposites. I will also describe recent progress on the use of thermos-responsive solid-binding proteins to control nanoparticle assembly and disassembly and manipulate the outcomes of biomimetic mineralization.

2:30 PM SB03.02.04

Silk-Nanotraps for Selective Molecular Targeting. Understanding Potentials and Limitations of Functional Protein Super-Assemblies Alessandra Maria Bossi¹ and Devid Maniglio²; ¹University of Verona, Italy; ²University of Trento, Italy

We report about the development of tailor-made biomimetics stemmed from merging biology with polymer chemistry and material science. Aqueous-soluble nanotraps that behave as biomimetic receptors were prepared in the form of proteinaceous disordered super-assemblies, fixed by non-natural crosslinking. The specific formation of the nanotrap started from the biocompatible, nontoxic material, already in use in regenerative medicine, that is silk fibroin [1].

Pioneering a paradigm change, the tailor-made molecular recognition was conveyed to the silk nanotrap by the unconventional exploitation of the molecularly imprinted polymers (MIPs) technique, that is a specifically designed strategy to entail molecular recognition to a nanomaterial by means of a template-assisted synthesis [2,3], but herein methacrylated silk fibroin polypeptides were used as macromolecular building blocks. Such MIP synthetic protocol was optimized with the aid of surface response method. The silk-nanotraps, called bioMIPs, were physically and functionally characterized, demonstrating high affinity binding (nM) for the targets and selectivity [4]. Enzymatic degradation of the bioMIPs was studied. The biocompatibility of the nanotraps was confirmed. The nanotraps were further labelled with fluorescent tags and tested for imaging in cell cultures [6]. The bioMIP's synthesis proved a general route for entailing recognition towards proteins or small molecules [4,5], which let foreseen applications in sequestering molecular players in the onset and progression of diseases, to tackle the onset of molecular changes in cells, and opening for translational studies with roles in long term pathologies.

Molecular Dynamics Simulations of cRGD-Conjugated PEGylated TiO₂ Nanoparticles for Targeted Photodynamic Therapy Giulia Frigerio, Paulo Siani, Edoardo Donadoni and Cristiana Di Valentin; Department of Materials Science, University of Milano-Bicocca, Italy

Active targeting strategies, exploiting the biological interaction between ligands on the surface of nanoparticles and the cell targets, are known to increase the therapeutic efficacy of cancer treatments with

respect to passive targeting strategies that are mainly based on the enhanced permeability and retention effect of tumor tissues. In this respect, the conjugation of nanoparticles with integrin $\alpha_v\beta_3$ -affine cyclic RGD peptides (cRGD) is a promising approach in nanomedicine to efficiently reduce off-targeting effects and enhance the cellular uptake by integrin-overexpressing cancer cells.

We used atomistic molecular dynamics simulations to evaluate key structural-functional parameters of cRGD ligands conjugated to PEGylated TiO_2 nanoparticles for an effective binding activity towards $\alpha_v\beta_3$ integrins. An increasing number of ligands has been conjugated to PEG chains, grafted to highly curved TiO_2 nanoparticles, to unveil the impact of cRGD ligand density on its presentation, diffusion, and conformation in an explicit aqueous environment.

We find that a low density leads to an optimal spatial presentation of cRGD ligands out of the "stealth" PEGylated layer around the nanosystem, favoring a straight upward orientation and a spaced distribution of the targeting ligands in the bulk-water phase. On the contrary, a high density favors the clustering of cRGD ligands, driven by a concerted mechanism of enhanced ligand-ligand interactions and reduced water accessibility to the ligand's molecular surface. These findings strongly suggest that the ligand density modulation is a key factor in the design of cRGD-conjugated nanodevices to maximize their binding efficiency to over-expressed $\alpha_v\beta_3$ integrin receptors.

3:30 PM *SB03.03.02

Computer Simulations of the Interaction of Anaesthetic Molecules Fentanyl and Propofol with Biological Membranes Nora H. de Leeuw; University of Leeds, United Kingdom

Computational techniques are well placed to investigate materials and processes in the body that are difficult to access experimentally. In this work we have used all-atom computer simulations to predict the structures and behaviours with biological membranes in the cell of two important molecules in the process to induce anaesthesia, i.e. propofol and fentanyl. The lipid membrane is considered a crucial component of opioid general anaesthesia and detailed atomic-level insight into the drug-membrane interactions could lead to a better understanding how different drugs exert their anaesthetic properties. First, we have investigated the opioid analgesic fentanyl on its own, using extensive umbrella sampling molecular dynamics simulations to study the permeation process into a variety of simple phospholipid membrane models, accurately predicting the permeability coefficients, followed by its interactions with the *Gloeobacter violaceus* ligand-gated ion channel (GLIC). The simulations have identified multiple extracellular fentanyl binding sites, which are different from the transmembrane general anaesthetic binding sites observed for propofol and other general anaesthetics, including a novel fentanyl binding site within the GLIC which results in conformational changes that inhibit conduction through the channel. The second part of our study explicitly includes the interactions between fentanyl and propofol. General anaesthesia is a multi-drug process and our work provides the first insight into how different components in the anaesthesia process interact with each other in a relevant biological environment. For example, using flooding style and gaussian accelerated molecular dynamics (GaMD) simulations, we show fentanyl acting as a stabiliser that holds propofol within binding sites in GLIC, whereas the simulations were also able to show the pathway by which propofol physically blocks the ion-conducting channel pore, which has previously been suggested as a mechanism for ion channel modulation by propofol.

4:00 PM *SB03.03.04

Multiscale Mechanics of Cancer Metastasis to Bone Dinesh R. Katti, Sharad V. Jaswandkar, Hanmant Gaikwad and Kalpana Katti; North Dakota State University, United States

The World Health Organization reported that over one million deaths occur worldwide due to breast and

prostate cancer. The majority of these deaths occur due to metastasis of the cancer to distant locations in the body, which for breast cancer and prostate cancer happens to be bone. At the bone site, the cancer cells colonize, proliferate, and have a very detrimental impact on the bone. Clinically, this is manifested as frequent skeletal failures. In order to recapitulate the metastasis process through a realistic testbed, we have developed an in vitro model of bone metastasis using nanoclay bone mimetic scaffolds. Experiments using commercial and patient-derived cancer cell lines to create metastasized tumors indicate significant changes to the morphology of the cancer cells based on the cancer phenotype. Also, depending on the phenotype, the mechanical properties of the cancer cells extracted from the tumors are dramatically altered. Associated with the observed changes, we observe significant changes in gene expressions related to actin and actin depolymerization factor cofilin (ADF/cofilin). Confocal imaging of cancer tumors during cancer progression reveals significant actin dynamics, both quantitatively and spatially. Label-free discrimination of cancer progression using Raman imaging and cluster analysis also reveals actin dynamics and changes to actin-related bands, which could serve as spectral biomarkers for cancer progression at the bone site. Steered molecular dynamics simulations of actin and actin with ADF/cofilin describe the mechanisms of the resilience of actin molecules and depolymerization of actin by ADF/cofilin, critical players in the actin dynamics during the cancer progression. Hence, actin remodeling plays a vital role in cancer metastasis progression and pertains to cellular behavior inside the cell. In order to evaluate the molecular phenomena outside the cell, we investigate the characteristics of integrin molecules. The integrin protein is a mechanotransducer establishing mechanical reciprocity between the extracellular matrix and cells at integrin-based adhesion sites. This protein plays a critical role in cell-ECM adhesion and cellular signaling. We conducted steered molecular dynamics (SMD) simulations to investigate the mechanical responses of integrin $\alpha v \beta 3$ with and without ligand binding for a variety of mechanical loading paths. The ligand-binding integrin confirmed the integrin activation during equilibration by opening the hinge between βA and the hybrid domain. This activation of liganded $\alpha v \beta 3$ integrin influenced the molecule's stiffness observed during tensile loading. Furthermore, we observed that the interface interaction between β -tail, hybrid, and epidermal growth factor domains altered integrin dynamics. The deformation of extended integrin models in the bending and unbending directions of integrin reveals the stored folding energy and the directionally dependent stiffnesses of the integrin molecule. Along with experimental data, the SMD simulations were used to evaluate the mechanical properties of integrin and identify the underlying mechanisms of integrin-based adhesion substrates. The investigation of the mechanics of integrin molecules provides new insights into understanding the mechanotransmission between cells, ECM, and the substrate. Overall the mechanotransduction facilitated by integrins to actin remodeling at the cellular insides is a critical molecular phenomenon that exists over a multiscale regime that synergistically creates the metastasis progression of cancer.

SESSION SB03.04: Synthesis, Restoration and Regeneration of Biological Hard Tissues

Session Chairs: Nurit Ashkenasy and Hanson Fong

Tuesday Morning, November 28, 2023

Hynes, Level 1, Room 101

8:30 AM SB03.04.01

Development of Self-Assembled Organothiol-Based Nanolithography Templates for Biomimetic Synthesis of Calcium Phosphate on Amyloid-Like Amelogenin Nanoribbons Jayesh Dua¹, Stefan Habelitz² and James J. De Yoreo^{1,3}; ¹University of Washington, United States; ²School of Dentistry,

University of California, San Francisco, United States; ³Pacific Northwest National Laboratory, United States

Tooth enamel is the hardest tissue in the body mainly due to the intricate interwoven structure of highly organized apatite filaments that form it. It has been theorized that unidirectionally aligned (co-aligned) amyloid-like amelogenin nanoribbons (Amel NR) guide the formation of apatite by providing an energetically and stereochemically favorable scaffold for nucleation and transformation of amorphous calcium phosphate (ACP) precursor to hydroxyapatite (HAP). To understand the efficacy with which protein structures direct the nucleation of ACP and the subsequent transformation to HAP, studies have been carried out to quantitatively analyze the nucleation of ACP by self-assembled NRs of the full-length protein as well as varying sequences of peptides made up of protein subsegments responsible for self-assembly and ACP binding. Supramolecular block-copolymer templates with alternating hydrophilic and hydrophobic regions were also used to direct the self-assembly of amelogenin-derived peptide nanoribbons having discrete, spatially separated domains. These domains in turn templated the mineralization of filamentous and plate-shaped calcium phosphate. To create more versatile templates, we are using AFM-based nanolithography to create highly modifiable nanopatterns of novel organothiol monolayers self-assembled on Muscovite Mica. By using AFM probes, we perform Nanografting on monolayers of hydrophobic organothiols on Mica in predetermined patterns and backfill the patterns with hydrophilic thiols. The proposed system is similar to the block-copolymer system in its basic function, but with the capability of modifying the design on-the-fly to study the effects of geometry. While similar thiol systems on metal substrates (like nearly-atomically flat Au substrates) have been extensively studied and are even now used for a multitude of applications, the proposed system offers significantly better reproducibility, reusability, and affordability. Although the proposed system has been developed for the use of templating the growth of Amel NRs, it has the potential to be employed for a variety of other applications by modifying the surface chemistry of the Organothiol headgroups. Additionally, since Mica is the preferred substrate for the study of many soft matter systems, it provides the possibility of the direct study of many of these systems, eliminating the need for the modification of the parent molecule to enable its binding to the substrate. Monolayers of long chain alkanethiols (like the ones used on gold substrates) with average roughness $\approx 0.2\text{nm}$ have already been achieved with extremely adaptable grafting pattern thicknesses ranging from 50 nm-200 nm. By manipulating the spacing and dimensions of the 2D-patterns, as well as the composition of the mineralizing solution, we seek to find understand the controls the of scaffold geometry on nucleation and growth rates of the ACP precursor domains, as well as their transformation to HAP. Understanding how manipulating the scaffold geometry affects the fidelity of guided mineralization will move us closer towards the biomimetic synthesis of enamel-like materials.

8:45 AM SB03.04.02

Peptoid-Controlled Synthesis of Hierarchical Composite Nanomaterials Chun-Long Chen; Pacific Northwest National Laboratory, United States

In nature, biominerals (e.g. bones and teeth) are excellent examples of hierarchical composite materials whose formation and functions are controlled over multiple length scales by high information content biomacromolecules. Inspired by nature, many biomimetic approaches have been developed for the design and synthesis of composite materials. These approaches are attractive because they generate complex, functional materials under mild aqueous synthetic conditions.^{1,2}

As one of the most advanced classes of sequence-defined peptide-mimetics, peptoids offer tremendous opportunities for bio-controlled synthesis of hierarchical composite materials,^{3,4,5} mimicking protein- and

peptide-like molecular recognition. Due to the lack of backbone hydrogen bonding, tuning peptoid-peptoid and peptoid-particle interactions can be done solely by varying side-chain chemistry.^{1,5} Peptoids have been exploited as programmable building blocks to assemble into highly ordered nanostructured materials with a variety of morphologies.^{3,6} In this presentation, we will report our recent progress of developing self-assembling peptoids for controlled formation and morphogenesis of hierarchical composite nanomaterials. A combination of *in situ* imaging and molecular simulations were used to elucidate the principles underlying peptoid-controlled inorganic crystallization with the ultimate goal of enabling predictive materials synthesis across scales.

Freeze Casting Peptide-Enabled Biomaterials for Tissue Regeneration Ulrike G. K. Wegst;
Northeastern University, United States

While considerable progress has been made over the past years and decades, the challenge persists to synthesize, ideally off-the-shelf materials and scaffolds, with structural, mechanical, and chemical cues akin to the natural tissue or custom-designed for a desired regenerative outcome. Freeze casting permits to manufacture such complex, hybrid materials with excellent control of structural and mechanical properties. As a cold process, freeze casting additionally offers several pathways to introduce what could broadly be called chemical cues such as growth factors, viral vectors and peptides at several processing steps to enhance the functional properties of the final biomaterial. Chemical cues can be introduced already before the freeze casting step through peptide loading and peptide-functionalized components, such as collagen, chitosan, and nanocellulose for soft and hydroxyapatite and tricalcium phosphate for hard tissues, for example. Alternatively, the hierarchical architecture of the freeze-cast scaffolds can be modified with peptides or peptide-enhanced entities once the structure has been ice-templated and lyophilized (freeze-dried). Freeze casting and related manufacturing techniques therefore hold great promise for the manufacture of peptide-enabled biomaterials.

9:30 AM SB03.04.04

Biomimetic Strontium Sulfate Mineralization Studied by Multiscale Microscopy and Vibrational Spectroscopy Andrienne Martin¹, Jordan Hachtel², Oliver Wang¹, Dawn M. Raja Somu¹, Steven A. Soini¹, Diannelle Lacambra-Rivera¹ and Vivian Merk¹; ¹Florida Atlantic University, United States; ²Oak Ridge National Laboratory, United States

In the present study, we investigated the in-vitro crystallization of strontium sulfate (celestite, SrSO₄) in the presence of organic matter, including the synthetic polymer poly(sodium 4-styrenesulfonate), the poly amino acid poly(L-glutamic acid), the polysaccharide poly(galacturonic acid) and the amino acid L-aspartic acid. In nature, biogenic SrSO₄ occurs in the skeleton of the unicellular plankton organisms

Acantharia^{[3],[4]}. These biomineral model systems closely mimic fundamental interactions between mineral and organic matrix in living organisms, while eliminating the complexity and heterogeneity associated with biological systems. This investigation enabled a focused fundamental investigation of SrSO₄ crystallization across multiple length scales, as biologically grown minerals often contain a variety of organic molecules in small weight percentages as well as considerable amounts of foreign ions, such as magnesium, which complicate data interpretation^{[1],[2]}. Even though all studied biomolecules were included into the growing crystals in high weight percentages, poly(*L*-glutamic acid) had the most profound impact on crystal morphology. Using Scanning Electron Microscopy and Atomic Force Microscopy, we observed mesocrystalline features on the crystal surface, which are consistent with biomolecule incorporation. Apart from studying the chemistry of the nanocomposites using bulk infrared spectroscopy, we discerned intracrystalline organics at the nanoscale using monochromated Electron Energy-loss Spectroscopy in the Scanning Transmission Electron Microscope^{[5],[6]}. By screening the organic-biomineral model systems with synchrotron X-ray powder diffraction^{[1],[2]}, we quantified the degree of internal residual strain resulting from biomolecules with diverse functional group chemistry.

9:45 AM BREAK

10:15 AM *SB03.04.05

Emulating Nature's Way of Making Materials James J. De Yoreo^{1,2}; ¹Pacific Northwest National Laboratory, United States; ²University of Washington, United States

From harvesting solar energy to capturing CO₂ to purifying water, living organisms have solved some of the most vexing challenges now faced by humanity. They have done so by creating a vast library of

proteins and other macromolecules that can assemble into complex architectures and direct the mineralization of inorganic components to produce materials characterized by a hierarchy of structure. While the high information content contained within the intricate sequences of the proteins is crucial for accomplishing these tasks, self-assembly and mineralization are nonetheless constrained to proceed according to the physical laws that govern all such processes, even in synthetic systems. An understanding of the mechanisms by which biological systems successfully manipulate those laws to create hierarchical materials would usher in an era of materials design to address our most pressing technological challenges. In this talk, I will present the results of recent research using in situ atomic force microscopy and in situ transmission electron microscopy to directly observe interfacial structure, protein self-assembly, and nanocrystal formation in biomolecular and biomimetic systems, including protein-directed nucleation of calcium carbonate and calcium phosphate and surface-directed nucleation of two-dimensional protein assemblies. The results elucidate the mechanisms by which the interface between biomolecules and materials directs nucleation, self-assembly and crystal growth, leading to unique materials and morphologies. The results reveal the importance of surface charge, facet-specific binding, solvent organization, and, more generally, the balance of protein-substrate-solvent interactions in determining how organized materials emerge in these systems.

10:45 AM SB03.04.06

Degradation of Natural Molecules on Mineral Surfaces [Colin Freeman](#)¹, Bia Fonseca², Matthew Collins^{2,3} and Karina Sand²; ¹University of Sheffield, United Kingdom; ²University of Copenhagen, Denmark; ³University of Cambridge, United Kingdom

Molecular binding at material interfaces is vitally important within a range of contexts. When a molecule has bound to a surface its structure and that structure of the local solvent can be very different to that in solution which can change its functionality and reactivity. In biology deamidisation and hydrolysis are two very common processes to break up peptides and both dependent on water molecules; therefore understanding the behaviour of the solvent molecules is equally important as that of the biologically active binding molecule. These decay processes are very important in a range of scientific fields including archaeology, palaeontology and surface fouling. Peptides extracted from archaeological digs can be used to indicate the diet and patterns of early humans, while DNA and proteins can be used to provide information on evolution in the fossil record.

We present a combined molecular dynamics and atomic force microscopy study on the binding of biological relevant molecules to calcite mineral surfaces. Our study examines and identifies the key factors involved in the binding of these molecules to the surfaces. We then explore the structural changes in these molecules and how this exposes/shields them from reactive processes that could lead to their decay. Finally we examine the behaviour of the other reactant species (solvent) and determine the role of the surface in enhancing or hindering their contribution to degradation reactions [1]. With this information we are able to comment on recent experimental findings and the potential preservation of different biological molecules.

Multiplexed Breath Biopsy of Lung Disease by Controlled Chemical Signal Activation Shih-Ting Wang, Melodi Anahtar, Daniel Kim, Tahoura Samad, Cathy Wang, Sahil Patel, Chayanon Ngambenjawong, Jesse Kirkpatrick, Heather Fleming and Sangeeta Bhatia; Massachusetts Institute of Technology, United States

Breath testing is a fast, non-invasive diagnostic method that can link specific volatile organic compounds (VOCs) in exhaled breath to medical conditions. Complementary to blood and urine assays in clinical disease diagnosis, breath is an informative analyte that can provide real-time information of changes in the body's metabolome affected by disease activity. However, few breath tests are currently used in the clinic to monitor disease due to bottlenecks in biomarker identification and differentiation of endogenous VOCs in complex breath signatures. One approach to overcome this challenge is the in vivo administration of orthogonal exogenous agents with controlled properties that can be expelled from breath upon being metabolized by disease-specific molecular processes. Exogenous agents have been used in clinical breath tests for gastrointestinal and liver diseases and are more recently developed for respiratory disease. As the direct source of breath, the lungs are particularly suited for enzymatic activity-based breath tests. The multiplexed capabilities of designing reliable in vivo probes that release detectable and distinguishable exogenous VOCs are still in the early stages. Here, we report engineered breath biomarkers by protease-sensing nanoparticles for multiplexed detection of dysregulated activities of pulmonary proteases in response to disease and produce volatile reporters that can be detected in the exhaled breath. We show that the nature of proteolytic hydrolysis generating peptide fragments can be engineered to activate and release various types of volatile reporters. Using viral infection and *Alk*-mutant lung cancer mouse models, we show that multiplexed volatile-releasing activity-based nanosensors (vABNs) can detect and dynamically monitor diseases and treatment response.

Peptide-Functionalized Graphene Sensors for Selective Odorant Detection Yuhei Hayamizu; Tokyo Institute of Technology, Japan

Gas sensing based on graphene field-effect transistors (GFETs) has gained broad interest due to their high sensitivity. Further progress in gas sensing with GFETs requires the detection of various odor molecules for applications in environmental monitoring, healthcare, food, and cosmetic industries. To establish an artificial sense of smell with electronic devices by mimicking olfactory receptors, it is desirable to use synthetic molecules with similar functionality. In this work, we designed three new peptides based on a motif sequence in olfactory receptors. These peptides were designed to have two domains: a bio-probe specific to the target molecules and a molecular scaffold [1,2]. The scaffold peptides have the ability to self-assemble into a molecular thin film on GFETs [3].

To demonstrate the biosensing capabilities, we employed limonene, methyl salicylate, and menthol as representative odor molecules of plant flavors. We investigated the conductivity change of GFETs upon binding to odor molecules at various concentrations. The dynamic response of the sensors revealed distinct signatures for each of the three different peptides against individual target molecules. The kinetic response of each peptide exhibited characteristic time constants in the adsorption and desorption

processes, which were further supported by principal component analysis. These results demonstrate the selectivity of the designed peptides in detecting odor molecules.

The development of graphene odor sensors using these designed peptides paves the way for future peptide-array sensors with multiple sequences, enabling the realization of an odor-sensing system with higher selectivity. Combining the bio-probe and electrical signal amplification functions, the peptide layer on graphene represents a novel and effective strategy for achieving selective odorant detection under normal atmospheric conditions. This research contributes to the advancement of biomimetic devices and holds potential for various applications in odor detection and identification.

This work was supported by the Cabinet Office (CAO), Cross-ministerial Strategic Innovation Promotion Program (SIP), “Intelligent Processing Infrastructure of Cyber and Physical Systems” (funding agency: NEDO).

2:00 PM SB03.05.03

Polymorphs of Short-Sequence Peptoid Assembly on MoS₂ Shuai Zhang¹, Chun-Long Chen² and James J. De Yoreo²; ¹University of Washington, United States; ²Pacific Northwest National Laboratory, United States

Peptoid is a biomimetic polymer inspired by peptide, with compatible bio-functions but better thermal and chemical stabilities. It has unique capabilities for creating hierarchical assemblies at solid-liquid interfaces, serving as templates for convincing applications in molecular recognition, fabrication of bio-hybrid materials, (bio)mineralization, energy conversion, storage, and transportation of matter and information, etc.

Recently, we designed short peptoid sequences with assembly capabilities on MoS₂. Using substrates with different hydrophobicity and adjusting the sizes of peptoid hydrophobic side chains and the dehydration process, we demonstrated that the peptoid assembly on MoS₂ could have diverse phases, including the monolayer hybrid film with high crystallinity, vesicles, lamella, and single-/multi-strands. We further resolved that these phases can co-exist in a complicated phase diagram and can go through phase transitions between each other. Specifically, the peptoid-peptoid interaction, peptoid-solvent interaction, and peptoid-MoS₂ interaction, mediated by pH, play crucial roles in this polymorph assembly. These results improve the knowledge of designing hierarchical architectures with biomolecules at solid-liquid interfaces. It also provides opportunities to optimize the future performance of 2D van der Waals materials-based devices.

2:15 PM *SB03.05.04

Subnanoscale Imaging of Nano-Bio Interfaces by 2D and 3D AFM Imaging Techniques Takeshi

Fukuma; Kanazawa University, Japan

Atomic force microscopy is a powerful technique that can visualize atomic- or molecular-scale structures, dynamics and properties even in liquids regardless of the conductivity of the sample. In the past decade, there has been significant advancement in the in-liquid AFM techniques. Owing to the development of low noise cantilever deflection sensors[1] and small amplitude operation mode, atomic or molecular resolution can be achieved routinely even with dynamic-mode AFM such as frequency modulation[2] and amplitude modulation AFM (FM- and AM-AFM). This allowed us to visualize subnanoscale surface structures of various biological samples[3]. In addition, the tip scanning scheme has been expanded from 2D to 3D[4] and now we can visualize the 3D distribution of water (i.e., hydration structures), organic solvents, ionic liquids and flexible molecular chains[5-7]. These unique capabilities should be particularly useful in the studies of nano-bio interfaces, where biomolecules, water and ions interact with each other to induce various biological phenomena. However, their applications to the studies on biomaterials have yet been limited. In this presentation, I would like to present our recent works to explore applications of high-resolution in-liquid AFM techniques to studies on nano-bio interfaces. Examples include molecular-scale investigations on cellulose[8] and chitin[9] nanocrystals and self-assembled structures of short peptides on graphite[10].

Atom-Condensed Reactivity Descriptors for the Prediction of Biomaterials Degradation Isaac Vidal-Daza^{1,2}, Anna Bachs-Herrera¹ and Francisco Martin-Martinez¹; ¹Swansea University, United Kingdom; ²University of Granada, Spain

Nature has been traditionally mimicked in the design of biomaterials for her capacity to achieve performance, but not that often for her ability to degrade at the end of life. To design materials for degradation as well as performance, molecular degradation needs to be better modelled. Degradation is a complex phenomenon largely dependent on the molecular system, the environmental conditions, and the timescales being considered. A common factor in the degradation process is molecular reactivity, which

can be predicted using conceptual density functional theory (DFT). Conceptual DFT reactivity descriptors either quantify the global tendency of a molecule to engage in chemical reactions or the areas of the molecule that would undergo such engagement, but these global and local reactivity descriptors are usually detached. Atomic reactivity is not usually quantified in relation to the global molecular reactivity, and it limits our ability to accurately predict degradation. In fact, quantifying the reactivity of any individual atom within the global reactivity of a molecule, is not a trivial task, and it requires the conjunction of different theories in the framework of quantum chemistry. In this work, we combine a topological analysis of the electron density with a non-arbitrary partition of the molecular space into atomic domains to define topology-based atom-condensed reactivity indexes to predict molecular degradation. High-throughput calculations of these *ab initio* atom-condensed reactivity descriptors enabled the analysis and identification of existing patterns among data, which provides a better understanding of molecular reactivity, and the definition of new indexes that describe the local reactivity of individual atoms, in the global reactivity of target molecules. The data generated can be used to train machine learning (ML) models that predict molecular and biomaterials degradation.

3:30 PM *SB03.05.06

Peptide Designs for On-Demand Multifunctional Surface Functionalization Nurit Ashkenasy; Ben Gurion University of the Negev, Israel

The development of high-performance devices demands tailoring the properties of surfaces and interfaces of materials. The control of surface properties can be achieved by attaching organic monolayers to the surface. In this talk, I will discuss the design of peptide-based functionalization layers and show that such functionalization layers exploit unique properties of proteins including diversity, modularity, and multifunctionality. Hence, open the way to design highly tunable and smart surfaces.

In the first part of the talk, I will demonstrate the use of surface binding peptides (SPBs) to tailor the electronic properties of surfaces. The effect of peptide side chains and their backbone connectivity and folding state on the resulting electronic properties will be discussed. I will further show that SPBs can be used to template syntheses of thin films with specifically tailored surface properties in an environmentally friendly approach. The use of such films for volatile organic compound sensing will be demonstrated. The utilization of the unique properties of peptides for the development of programmable surfaces will be demonstrated in the second part of the talk. I will present the design of a coiled-coil peptide system in which folding and chemical reactivity is responsive to external stimuli. The responsivity of the system facilitates the ability to control the binding of the peptides to the surface and/ or their folding state, which affects the surface's physico-chemical properties in a reversible manner. These smart dynamic surfaces enable the realization chemically induced computation elements using the surface properties as the readout. The feasibility of applying this approach in biosensing will be demonstrated.

Overall, our work provides a sophisticated surface engineering approach, based on peptide sequence design, which can be utilized in diverse electronics, biotechnology, and medical applications.

4:00 PM DISCUSSION TIME

4:30 PM *SB03.05.08

Complex Biomechanics: From Atoms to Patients Christian Hellmich, Johannes Kalliauer, Niketa Ukaj and Stefan Scheiner; TU Wien - Vienna University of Technology, Austria

Complex systems are characterized by an overall behavior which is different from that of the components making up the systems - hence, (nonlinear) interactions between the components play a very important

role. Taking an interdisciplinary approach rooted in theoretical and applied mechanics and engineering mechanics, we report on two types of recently studied systems where individual system components (atoms and patients) interact in a way which unfolds very interesting emerging patterns that can be mathematically quantified through concepts arising from (bio-)mechanics: (i) the interaction of atoms within a short thread of DNA, which, as a compound, result in a family of a highly nonlinear beam structures with varying, but always coupled torsion-stretching modes [1]; (ii) the compliance of sets of patients to the lethal effect of SARS-COV-2 [2,3], which follows integro-differential equations reminiscent of those introduced by Boltzmann in the context of creep (or hereditary) mechanics [4]. We conclude that smart classical concepts of applied mechanics and physics continue to show an unparalleled potential for solving pressing global problems in the context of computational modelling of living systems.

SESSION SB03.06: Poster Session

Session Chairs: Hanson Fong and Mehmet Sarikaya

Tuesday Afternoon, November 28, 2023

Hynes, Level 1, Hall A

8:00 PM SB03.06.01

Breast Cancer Detection using Shear Assay Based Creep Compliance and Functional Principal Component Analysis Jolene Cao¹, Killian Onwudiwe², Jingjie Hu³, Meenal Datta² and Winston O. Soboyejo¹; ¹Worcester Polytechnic Institute (WPI), United States; ²University of Notre Dame, United States; ³North Carolina State University, United States

This presents the mechanical responses of live cells that are subjected to shear flow in micro-fluidic channels under *in-situ* observation with optical, fluorescence, and confocal microscopy. The resulting time-dependent deformation of points within the cells is analyzed using Digital Image Correlation (DIC) techniques. These are used to extract deformation and strain maps of the nuclei, cytoplasm, and actin cytoskeletal structures at different stages of cell viscoelastic deformation. The measured temporal variations in strain are analyzed using Functional Principal Component Analysis (FPCA) approaches (from data science) that use time series data to extract critical features from the *in-situ* temporal creep responses of cells subjected to shear stress. Differences in the creep responses of the nuclei and cytoplasm are elucidated along with the local creep properties of the actin cytoskeletal structures of non-tumorigenic breast cells (MCF-10A), less metastatic triple-negative breast cancer (TNBC) cells (MDA-MB-468), and highly metastatic breast cancer cells (MDA-MB-231). The implications of the results are also discussed for the detection of non-tumorigenic and tumorigenic breast cells at different stages of cancer progression.

Keywords: breast cancer detection, micro-fluidics, shear assay creep compliance, functional principal component analysis, time series data, cell nuclei, cytoplasm and cytoskeletal structures.

8:00 PM SB03.06.02

Deep Learning-Assisted Sensitive Detection of Fentanyl using a Bubbling-Microchip Hui Chen, Sungwan Kim, Joseph Hardie, Prudhvi Thirumalaraju, Manoj Kanakasabapathy and Hadi Shafiee; Brigham and Women's Hospital, United States

Deep learning-enabled smartphone-based image processing has significant advantages in the development of point-of-care diagnostics. Conventionally, most deep-learning applications require task specific large scale expertly annotated datasets. Therefore, these algorithms are oftentimes limited only to applications that have large retrospective datasets available for network development. Here, we report the possibility of utilizing adversarial neural networks to overcome this challenge by expanding the utility of non-specific data for the development deep learning models. As a clinical model, we report the detection of fentanyl, a small molecular weight drug that is a type of opioid, at the point-of-care using a deep-learning empowered smartphone assay. We used the catalytic property of platinum nanoparticles (PtNPs) in a smartphone-empowered microchip bubbling assay to achieve high analytical sensitivity (detecting fentanyl at concentrations as low as 0.23 ng/mL in phosphate buffered saline (PBS), 0.43 ng/mL in human serum and 0.64 ng/mL in artificial human urine). Image-based inferences were made by our adversarial-based SPyDERMAN network that was developed using a limited dataset of 104 smartphone images of microchips with bubble signals from tests performed with known fentanyl concentrations and using our retrospective library of 17,573 non-specific bubbling-microchip images. The accuracy (\pm standard error of mean) of the developed system in determining the presence of fentanyl when using a cutoff concentration of 1 ng/mL, was $92.66 \pm 0.3\%$ in human serum ($n=100$) and $94.66 \pm 1.2\%$ in artificial human urine ($n=100$).

***Euglena gracilis*-Derived Extracellular Vesicles as a Natural Immune Modulator** Saetbyeol Jeon, Hwira Baek and Jin Woong Kim; Sungkyunkwan University, Korea (the Republic of)

Since extracellular vesicles (EVs) possess the same cell therapeutic effect due to its similar characteristics to parent cells, they have emerged as an attractive alternative to cell therapy. Taking advantage of this, a variety of EVs have been developed for tissue regeneration, anti-cancer immunotherapy, and intractable disease treatment. In terms of therapeutic application, microalgae-derived EVs has been of great interest because they contain unique physiologically active substances such as polysaccharides, minerals, vitamins and amino acids. However, most microalgae cells are structured with a strong cell membrane which is not easily cleaved and recombine to form EVs. The derivation of EVs from *Euglena gracilis* (EG), a microalgae species, warrants special attention due to its relatively flexible cell membrane. Moreover, it can be cultivated in substantial quantities, providing a valuable resource for production purpose while mitigating the risk of viral infection. In this study, we introduce an EG-derived EV (EV_{EG}) system with an enhanced immune performance. β -1,3-glucan, which is specifically accumulated in EG cells, is a representative substance that activates natural killer cells and macrophages to enhance natural immunity. To efficiently deliver β -1,3-glucan present in the EG to immune cells, the EV_{EG} are fabricated by cell extrusion method that can convert cells into vesicles by sequentially passing several micro-sized pores. Basically, the endocytosis mechanism study on the EV_{EG} exhibited notable cellular uptake compared to β -1,3-glucan only. We verified that the EV_{EG} fabricated in this study notably stimulated the

mitogen activated protein kinase (MAPK) pathway, resulting in release of inflammatory mediators such as nitro oxide, cyclooxygenase-2 (COX-2) and pro-inflammatory cytokines. The expression level of these immune factors was appropriately leveled to strengthen the immune system, not excessively inducing immune response such as cytokine storms. We also showed that the -1,3-glucan encapsulated in the EV_{EG}, like other polysaccharides, was readily recognized by receptors such as Dectin-1 and TLR4 present on immune cell membranes. These results highlight that our EV_{EG} immunomodulatory system has potential for health promotion and disease treatment in various biomedical applications.

Deep Learning-Assisted Nanoplasmonic Digital Immunoassay for Cytokine Profiling in Immune-Suppressed Patients using Designed Peptide Aptamers Shuai Wu, Lang Zhou and Pengyu Chen; Auburn University, United States

Cytokine profiling in immune-suppressed patients plays a critical role in understanding their immune status and evaluating the effectiveness of immunomodulatory therapies. However, current immunoassay technologies face challenges in achieving rapid and accurate detection of multiple cytokines over a wide dynamic range. In this study, we propose a novel approach that combines deep learning with a nanoplasmonic digital immunoassay using rationally designed peptide aptamers as probes.

The immunoassay system exhibits three notable features: (i) a simplified high-throughput biosensing chip fabrication process, (ii) an ultrasensitive nanoplasmonic digital imaging technique employing 50nm gold nanocubes (AuNCs) conjugated with antibody-mimicking peptide aptamers as detection probes, and (iii) a rapid and precise deep learning-based image processing method for digital signal analysis.

By utilizing our developed immunoassay, we successfully achieved cytokine profiling with a wide working range of 0.1-10,000 picograms per milliliter (pg/ml) and exceptional detection limits in the femtogram range. This level of sensitivity enables the accurate detection of even trace amounts of cytokines, critical for monitoring immune-suppressed patients.

Our findings demonstrate that this deep learning-assisted nanoplasmonic digital immunoassay, utilizing designed peptide aptamers, holds great potential for precise cytokine profiling in immune-suppressed patients. This innovative approach may contribute to improved clinical outcomes and informed treatment decisions for individuals with rapidly inflammatory disorders and immune suppression.

Electrochemical Activity of Molecular Hybrids: Self-Assembly of (XH)₄ Peptides and Hemin on Graphite Electrodes Marie Sugiyama, Wei Luo and Yuhei Hayamizu; Tokyo Institute of Technology, Japan

The development of artificial enzymes has gained interest in electrochemical biosensors because natural enzymes have a relatively short lifetime and high cost for practical applications. Peptides with a small number of amino acids compared with proteins can be synthesized and chemically stable, thus they can be a good candidate as an artificial enzyme. Short-chain peptides that self-assemble into fiber-like structures in liquid are known to be catalytically active by forming complex structures with cofactors [1]. These catalytically-active peptides often contain histidine, which plays a role in stabilizing the structure and coordinating with cofactors at the imidazole group on the side chain, enhancing the catalytic activity. In our previous work, we found that catalytic peptides containing histidine exhibited their self-assembly on graphite surfaces and revealed electrocatalytic activity combined with the coenzyme hemin [2]. More recent work showed that newly-designed peptides (XH peptides) consisting of a repeating structure of two amino acids with histidine and another amino acid, "X", also exhibited self-assembly on graphite

surfaces. These peptides are a useful tool for understanding the role of the counter amino acid X on their surface self-assembly and in tuning the hydrophobicity of the graphite surface [3].

However, the capability of this XH peptide to immobilize cofactor hemins has not yet been investigated. In this study, we studied the interaction between hemin and the (XH)₄ peptide on the surface of a graphite electrode by atomic force microscopy (AFM). Three counter amino acids, tyrosine (Y), valine (V), and leucine (L), were employed as counter amino acids X for this study, e.g. YHYHYHYH. AFM showed that each peptide formed uniform linear structures with a height of a few nanometers. They also showed a hexagonal symmetry on the graphite surface, which is commensurate with the lattice structures of graphite. When the cofactor hemin was added, dot-like structures with a height of 0.5 nm~1 nm appeared on the peptide nanowires. The peptide with the highest number of particles on the peptide and the smallest particle size was LH₄, followed by VH₄ and YH₄. Assuming that the particles on the wire were hemins, the XH peptide can be a suitable scaffold for immobilizing hemin. We also performed the electrochemical measurement to evaluate the hydrogen peroxide reduction capacity of the prepared XH peptide-hemin electrodes, and it was found that these peptides with a simple sequence of XH have enzymatic activity. The observations implied that the activity is closely related to the interactions with the hemin and peptides regarding the surface density of the immobilized hemins and their structural stability.

Graphene Biosensors for Probing Molecular Interactions of Peptides and RNA Forming Liquid-Liquid Phase Separation Kantaro Kikuchi, Yui Yamazaki and Yuhei Hayamizu; Tokyo Institute of Technology, Japan

Amyotrophic lateral sclerosis (ALS) is a fatal motor neuron disease affecting both upper and lower motor neurons. Frontotemporal dementia (FTD) is a type of brain disorder with degeneration of the frontal and temporal lobes of the cerebrum. These neurodegenerative diseases share the expansion of GGGGCC hexanucleotide repeats in the C9orf72 gene, identified as a major cause of the diseases [1]. The gene produces dipeptide repeat proteins (DPRs) that cause cell death. These peptides contained arginine (Arg) and counter amino acid in the dipeptide sequence and were found to form liquid-liquid phase separation (LLPS), closely related to their cytotoxicity. A previous report indicated that poly-R is highly charged and interacts with anionic molecules such as RNA but exerts no cytotoxic effect. Poly(PR) and poly(GR), on the other hand, entraps proteins via multivalent interaction in LLPS, impairing protein translation. Thus, it is known that the position of Arg in DPRs profoundly affects the interaction [2]. These findings indicate that the interactions between DPRs and RNA should be unique to form LLPS and entrapment the proteins. However, the understanding of the interactions of DPRs is still limited because of the lack of measurement techniques that can distinguish the weak interactions among them.

In this study, we applied graphene field effect transistors (GFETs) to evaluate the biomolecular interactions. Graphene has excellent electrical properties and high specific surface area and has recently shown promise as an ultra-sensitive biosensor. The interaction between biomolecules in the vicinity of the graphene surface can be detected as an electrical conduction change of graphene. We immobilized RNA on the graphene surface via pyrene anchors, as same in other works, and measured the interactions of RNA with DPRs known to form LLPS. The interactions are measured by incubating the DRPs of interest across the RNA-functionalized surface. Atomic force microscopy (AFM) was used to ensure these surface modifications. In electrical measurements, the peptides interacting with the RNA were quantified by the

shift of the charge-neutral points in their gate responses of GFETs, and differences in interactions due to peptide species were discussed. From the results, we succeeded in detecting the difference in interaction with RNA by peptide species with high sensitivity at the nano-molar level. We believe that this result is helpful in quantitatively discussing the effect of small amino acid domains of biomolecules on LLPS droplet formation, an event that occurs on a microscopic scale.

Layer-by-Layer Nanoparticles for Dexamethasone Targeted Delivery to Hematopoietic Progenitor Cells Alfonso Restrepo¹, Tamara Dacoba² and Paula T. Hammond^{1,2}; ¹Massachusetts Institute of Technology, United States; ²Koch Institute for Integrative Cancer Research, United States

Acute myeloid leukemia (AML) and acute lymphoblastic leukemia (ALL) have particularly dismal patient outcomes, with low 5-year survival rates in adult patients. Outcomes in pediatric patients are more optimistic, mainly due to their ability to withstand more aggressive treatment regimens. Glucocorticoids, although used as a standard treatment, can have severe adverse effects that limit dosing regimens. To address these challenges, directing drugs to hematopoietic progenitor cells implicated in these leukemias via targeted drug delivery therapies would allow for more aggressive and effective treatments, with reduced side effects. Layer-by-layer (LbL) nanoparticles (NPs) are a modular drug delivery system that enables the incorporation of a wide range of charged polymers on the surfaces of a drug-loaded NP core, to tune surface properties, targeting capacity, and biodistribution of NPs. The outer polymers can also be used as scaffolds to conjugate molecules, like antibodies, to aid in targeting drugs to cells of interest. In this work, we developed LbL NPs with dexamethasone loaded in the liposome core and functionalized them with polymers and antibodies to evaluate their targeting capacity to hematopoietic stem and progenitor cells (HSPCs) implicated in AML and ALL.

Dexamethasone palmitate (DXP) was incorporated as part of the lipid bilayer of liposomes using lipid hydration. Drug concentrations were measured via high-performance liquid chromatography (HPLC). Negatively-charged liposomes, empty or encapsulated with DXP, were layered with a cationic polypeptide, followed by a layer of anionic synthetic polymer on top. HSPC-targeting antibodies were then conjugated onto the top polymer layer. NP size and surface charge were monitored throughout the process via dynamic light scattering. NP concentration was determined via fluorescence intensity measurements of dye-conjugated lipids in the liposomal core. A bicinchoninic acid (BCA) assay was used to assess antibody concentration after purification. NP-cell association studies were conducted via fluorescence-activated cell sorting (FACS).

Antibodies were successfully conjugated to the NPs, with no notable impact on their physicochemical properties when measured over a 2-month period. Furthermore, antibody-functionalized LbL NPs demonstrated preferential association with a relevant myeloid progenitor-like cell line (ER-HOXB8), following 90-minute incubation. In fact, two candidate antibodies had a 1.5-fold increase in NP-cell association compared to unconjugated LbL NPs. For DXP-loaded NPs, it was found that the presence of the drug in the liposomal core had minimal impact on the stability of the NP throughout the layering process, with negligible changes in drug loading. Preliminary longitudinal studies found that the presence of the drug had no notable impact on the colloidal stability of the LbL NPs.

Overall, we have shown that LbL NPs can be functionalized with HSC-targeting antibodies, with a preferential association to relevant cell lines, and that the LbL construction of NPs is unhindered by the presence of DXP in the core. Future work would involve combining the drug-loaded NPs and functionalizing them with the candidate antibodies to ensure that similar preferential association is observed in relevant *in vitro* and *in vivo* models of acute leukemias.

8:00 PM SB03.06.09

A Molecular Dynamics Investigation of Synthetic Collagen Thermal Properties Marc Duchatelier and Kristen Rhinehardt; North Carolina Agricultural and Technical State University, United States

Composite biomaterials have been used for various medical applications as they contain specific physical, chemical and mechanical attributes while evading rejection by the body and encouraging proper function. One common material used for such function is collagen. As a triple helical, extracellular matrix (ECM) protein it constitutes approximately 25% of the total dry weight of mammals. The thermal properties of collagen can vary (320-370K) depending on the source, which impacts its physical properties, assembly, and stability. The social, physical, and financial expense of obtaining collagen, as its traditionally harvested from animals, has led to a need for synthetic collagen-like peptides. Synthetic collagen has a greater versatility due to their customizability, but a thorough investigation of their physical, and thermal properties as well as their binding capabilities must be completed prior to their production or use. This can be done by using computational modeling. In this study, we use molecular dynamics modeling to explore the structure and physics of synthetic collagen 1K6F in a solvent environment in response to thermal alterations. Simulations of 2 and 4 peptides showed a notable influence of structural orientation of the strands. Visual analysis of the simulations showed a interactions between the stands at low temperatures with some structural disturbance at after 330K. The radius of gyration (Rg) showed the backbone of the molecule start to fold over time around 20 ns. Further an exploration of the Radius of Fluctuation showed varying wave patterns with amplitudes between 1.5 and 7.5 nm. However, a sinusoidal behavior was noticeable at 320 and 330K indicating a possible transition point. The observed sinusoidal waveform in the atomic fluctuation can be ascribed to the thermal influences within the system. We found that a higher number of hydrogen bonds appear at low temperature as there was increased interactions below 320K, but the peptides appear to go to the process of denaturation as temperature increase to 340K. Furthermore, the assembly behavior and protein biding sites were analyzed through composite simulation of silk and collagen. Our results highlight that the interaction strength of synthetic collagen with silk depends on the proportion of collagen within the system.

8:00 PM SB03.06.10

Enhanced Detection of Influenza Virus by Viral Membrane Fusion with Membrane Rigidity Modulation of Sialic Acid-Expressing Liposomes Hongjun Park¹, Chaewon Park¹, Geunseon Park¹, Jong-Woo Lim², Sojeong Lee¹, Soohyun Chung¹, Eunjung Kim³ and Seungjoo Haam¹; ¹Yonsei University, Korea (the Republic of); ²Seoul National University, Korea (the Republic of); ³Incheon University, Korea (the Republic of)

Specific interactions between viruses and host cells provide essential insights into materials science-based strategies to deal with emerging viral diseases. In several viral families, pH-triggered viral fusion is universal and important for understanding the viral infection cycle. Inspired by this process, virus detection has been achieved using nanomaterials with host-mimetic membranes that allow interaction with amphiphilic viral haemagglutinin fusion peptides. Most research has focused on the design of

functional nanoparticles with fusogenic capability for virus detection, and there has been little exploitation of membrane rigidity to alter the ability of nanoparticles to interact with the viral membrane and improve their sensing performance. In this study, a homogeneous fluorescent assay using sialic acid-expressing liposomes with tunable responsiveness to external stimuli is developed for the rapid and straightforward detection of an activated influenza A virus. Membrane fusion between the liposome and virus can be easily controlled by varying the membrane rigidity, which is determined by the cholesterol ratio, resulting in fluorescent signals within 30 min and detection of several influenza viruses, including H9N2, CA04(H1N1) and H4N6. Therefore, the designs demonstrated in this study propose underlying approaches to utilize engineered liposomes by modulating their membrane rigidity for the direct and sensitive identification of infectious viruses.

8:00 PM SB03.06.11

Biomimetic Synthesis of ZnO Thin Films Ivan A. Melara, Jean-Edward Moise and Kristen Siaw; Gordon College, United States

Biomimetic reaction systems, where small proteins and peptides assist in the growth of inorganic materials, has the potential for making complex structures that are otherwise difficult to achieve. Living organisms use a peptide-inorganic matrix to control the morphology of the inorganic structures. Using this method as inspiration we sought a similar approach for novel materials. Zinc oxide as chosen as the target material due to its many exciting optoelectrical properties. Phage display was performed on ZnO sample and used to identify small peptides with high binding affinity for ZnO. By means of an aqueous based synthesis, these high affinity peptides were added at various concentrations to the solution so growth of the ZnO crystals could occur in the presence of the peptides. In the absence of peptides, the ZnO grows with a long needlelike morphology. When peptides are added to the growth solution they are found to dramatically alter the final morphology of the ZnO substrates. By altering the concentrations of these peptides, the morphology of ZnO nanorods can be controlled, ultimately allowing for the formation of thin films. Through the use of these peptides, we form ZnO thin films on a variety of substrates including glass and flexible PET plastic.

Demystifying The Synthesis and Preparation of Protein-Mimicking Random Heteropolymers Hao Yu, Ivan F. Jayapurna and Ting Xu; University of California, Berkeley, United States

Random heteropolymers (RHPs) with statistically distributed comonomers along the polymer chains are commonly used as functional materials for achieving biomimetic functionality. This is due to their capacity to replicate protein-like phase behavior and functions. However, unlike many branches of chemistry and biology where structures can be constructed precisely on the molecular level, the inherent stochastic nature of monomer sequences in RHPs raises concerns regarding their high material dispersity and difficulties in chemical characterization. Moreover, while extensive research has been conducted on synthesizing and understanding two-monomer systems, there have been limited studies and systematic guidance on the synthesis of multi-monomer copolymers such as RHPs, which involves complex, interdependent reaction kinetics among multiple comonomers. These knowledge gaps present barriers for researchers outside the polymer chemistry community who seek to create protein-mimicking RHPs with targetable structures and properties.

Towards these prospects, here we conduct a comprehensive investigation into the sequence heterogeneity and compositional drift in a family of 4-monomer-based RHPs. We commenced with experimentally determining the relative reactivities of a repertoire of four methacrylate monomers in reversible addition-

fragmentation chain-transfer (RAFT) copolymerization. These underlying kinetic factors dictate the sequence heterogeneity of as-synthesized RHPs. Combining with stochastic sequence simulation, we designed four new RHPs, with each ensemble designed to exhibit different levels of hydrophilicity. Of particular interest is our findings that the purification procedures used during RHPs preparation, including pentane precipitation and dialysis against water, can preferentially eliminate different RHP subpopulations. This selectivity can be attributed to the conformations and apparent solubilities exhibited by these subpopulations, which are due to their particular chemical compositions within the whole RHP ensembles. Additionally, we quantitatively mapped out the trajectory of monomer compositions during the whole RHP preparation process. The predicted RHP cumulative compositions are in close agreement with the experimental results. These results validate the fidelity of predictive modeling and multicomponent RHP copolymerization. There are potentially over 300 commodity methacrylate monomers that are available for synthesizing RHPs materials. These findings are readily applicable to study the structure and sequence of heteropolymers beyond those described in this work. Overall, this work provides critically needed information to design and understand RHPs as functional materials while addressing the concerns related to their sequence heterogeneities.

8:00 PM SB03.06.13

Computational Investigation of Unique Structural Proteins in Cephalopod Skin Arsenii P.

Panteleev¹, Christophe Magnan¹, Pierre Baldi¹, Alon Gorodetsky¹, Andrew Cannon², Albert Kwansa² and Yaroslava G. Yingling²; ¹University of California, Irvine, United States; ²North Carolina State University, United States

Cephalopods (e.g., octopuses, cuttlefishes, and squids) are renowned for their remarkable dynamic color-changing and camouflaging capabilities.^{2,4} These animals possess a skin architecture wherein different cells or organs known as chromatophores, iridophores, and leucophores modulate the transmission, absorption, and/or reflection of light.^{2,4} Interestingly, these cells or organs all contain light-manipulating nanostructures composed of unique high-refractive index proteins called reflectins.^{2,4} In our previous work, based on a bioinformatics analysis of the 51 reported reflectins, we had designed a truncated reflectin variant and studied the structure and self-assembly of this polypeptide via a combination of computationally driven experimental methods.⁶ Subsequently, we had selected a prototypical reflectin isoform and investigated the structure and hierarchical self-assembly of this protein via multiple computational and experimental techniques.¹ Recently, we have extended these studies to other truncated and full-length reflectins, obtaining extensive new fundamental insight into their structures and functionalities.^{3,5} When taken together, our experimentally validated computational findings provide additional insight into the camouflage capabilities of cephalopods and suggest new directions for the development of bioinspired optical materials and systems.

Bioinspired Cu^I Defective Sites in ZIF-8 for Selective Methane Oxidation Suman Bhaumik¹, Siriluk Kanchanakungwankul¹, Ying Yang², Donald G. Truhlar¹ and Joseph T. Hupp²; ¹University of Minnesota, Twin Cities, United States; ²Northwestern University, United States

Activating the C–H bonds of alkanes without further oxidation to more thermodynamically stable products, CO, and CO₂, is a long-sought goal of catalytic chemistry. Inspired by the monocopper active site of methane monooxygenase, a Cu-doped ZIF-8 metal–organic framework is synthesized with 25% Cu and 75% Zn in the nodes and activated by heating to 200 °C and dosing in stepwise fashion with O₂, methane, and steam. We found that it does oxidize methane to methanol and formaldehyde. The catalysis persists through at least five cycles, and beyond the third cycle the selectivity improves to the extent that no CO₂ can be detected. Experimental characterization and analysis were carried out by PXRD, DRUV-Vis, XANES, EXAFS, SEM, and XAS. The reaction is postulated to proceed at an open-coordination Cu^I site generated by defects, and the mechanism of methanol production was explicated by density functional calculations with the revMO6-L exchange–correlation functional. The calculations reveal a catalytic cycle of oxygen-activated Cu^I involving the conversion of two molecules of CH₄ to two molecules of CH₃OH by a sequence of hydrogen atom transfer reactions and rebound steps. For most of the steps in the cycle, the reaction is more favored by singlet species than by triplets. The singlet pathway consists of both closed-shell singlet and open-shell singlet species. The closed-shell singlet calculations were checked for wavefunction stabilities, to ensure the correctness of the calculations. The reaction mechanism along the singlet pathway goes through open-shell singlets until the final step where it passes through a closed-shell singlet transition state to give rise to closed-shell singlet final product, which is a van der Waals complex of Cu^I and CH₃OH. This work provides a bioinspired synthesis of a metal-organic framework, whose defective sites carry out selective methane oxidation to methanol. A biomimetic reaction mechanism is postulated and further validated by density functional theory calculations.

8:15 AM SB03.07.03

Deep Learning Analysis of Scattered Light Intensity for Shape Classification of Nanoparticles Measured by Nano Tracking Analysis Keisuke Yamamoto¹, Hiroaki Fukuda¹, Hiromi Kuramochi¹, Yasushi Shibuta¹ and Takanori Ichiki^{1,2}; ¹The University of Tokyo, Japan; ²Innovation Center of NanoMedicine, Japan

Characterizing particles with sizes below 100 nm, such as peptide or protein-based biopharmaceuticals, necessitates single-particle measurement and multi-parametric analysis to distinguish individual particles. Nano Tracking Analysis (NTA) is a widely used technique for single-particle measurement in liquid samples due to its simplicity. By capturing the scattered light from nanoparticles illuminated by laser light, NTA can measure individual particles [a]. To expand the range of evaluable properties, we are exploring the application of deep learning to the analysis of NTA data. Recently, by utilizing deep learning analysis, we have successfully detected the effect of shape anisotropy, demonstrating the potential for multiparametric analysis of nanoparticles in liquids[b]. In this study, to further enhance our

understanding of physical properties, we investigate the potential of shape classification using the luminance information derived from light scattering images of particles measured by NTA.

Experiments were conducted using two types of gold nanoparticles: spherical particles with a diameter of 80 nm and rod-shaped particles with a diameter of 40 nm and a length of 180 nm. The NTA method was employed to capture 100 consecutive frames of images at 100 frames per second. From these images, three types of features were extracted as luminance information: scattered light intensity, cross-sectional area of the scattering pattern, and aspect ratio. Subsequently, a dataset was constructed based on these features.

Our deep learning analysis, utilizing a one-dimensional Convolutional Neural Network (1D-CNN) model, successfully learned all the extracted features. The shape classification accuracy using scattered light intensity was found to be 92%, surpassing the 80% accuracy achieved through shape classification based on Brownian motion trajectories. Moreover, even with a limited number of data frames (20 frames), the accuracy for the analysis based on luminance information reached 85%, compared to 60% for the analysis based on Brownian motion trajectories. These results demonstrate the potential of accurately extracting properties in a shorter timeframe using deep learning analysis of scattered light intensity information acquired by the NTA method.

In conclusion, our study showcases the effectiveness of employing deep learning analysis of scattered light intensity for shape classification of nanoparticles measured by NTA. This approach not only enhances the accuracy of particle characterization but also reduces the analysis time. The proposed method holds promise for further advancements in the field of nanoparticle characterization and analysis.

Mineral: Peptide Interactions: Using Our Understanding of Molecular Interactions to Develop a Time Efficient Biopanning Approach Carole C. Perry and Valeria Puddu; Nottingham Trent University, United Kingdom

Minerals and biomolecules can interact via a range of binding modalities from electrostatic interactions, through hydrogen bonding to hydrophobic interactions and van der Waals interactions. These binding possibilities lead to a range of biomolecule sequences that can interact with a particular mineral. From our understanding of peptide-mineral interactions gained by extensive, detailed experimental and computational studies we have developed an optimised biopanning approach, utilising multiple chemical eluants that allows the identification and recovery of a wide mineral binder pool in just one or two biopanning rounds.

9:00 AM SB03.07.05

A Dynamics-Informed Approach to Prediction of Protein Melting Temperature via Graph Neural Networks Yen-Lin Chen and Shu-Wei Chang; National Taiwan University, Taiwan

A practical design of biomedical materials requires knowledge of their thermal properties. Melting temperature has a direct influence on molecular stability, functionality, and performance in the case of protein engineering. For example, biosensors and enzymes will only operate as intended within a limited

thermal range. As such, the prediction of the thermostability of proteins is a crucial factor with implications in various scientific disciplines and technical applications. This task requires an understanding of the hierarchical organization of proteins, which manifests in a dynamically coupled cellular system. The introduction of machine learning methods to biology brought about astounding breakthroughs, such as the prediction of protein structures by AlphaFold. It is a promising approach to undertaking convoluted relationships in protein science. In this study, we propose a machine learning method for the computation of the melting temperature of proteins, taking into account the amino acid sequence, protein structure, and dynamics. Graphs (as in graph theory) are chosen as our data representation due to their rotational invariance and their intuitive mapping to molecular structures. The sequential, structural, and dynamical information are represented as multigraphs, with residues as its nodes, and various node features and edge connections derived from each of these properties. To process the data, a graph neural network architecture that makes use of message passing layers was designed to accommodate the multiple types of connections. Protein structures were computed by AlphaFold and the dynamics were computed based on the torsional network model (TNM) for training. Hence, the learned features and parameters can be readily applied to protein sequences without known experimental structure, satisfying the goal of aiding the prediction of design proteins. We are also able to identify key domains that contribute to the thermal stability/instability of proteins by computing the graph regression activation map, which is based on the partial derivative of the predicted value with respect to features on the input nodes. Our method gives insight into the mechanism of natural proteins and provides critical information regarding design proteins.

Scientific Analysis of Synthetic Collagen Compounds using Computational Molecular Modeling

Methods Jordanne A. Davenport and Kristen Rhinehardt; North Carolina A&T State University, United States

Scientists have proven that the health regimen you follow can have a significant impact on the human body. Collagen is found on multiple parts of the body such as skin, bones, lymphatic, cardiovascular, liver, lung, spleen, and intestinal tissue. (Spano, 2019) Although it is prevalent that people lose 1% of collagen each year, there is a way to improve this by maintaining a healthy diet. “Collagen-derived dietary proteins are most commonly extracted from porcine skin (45%), bovine hide (30%), and the bones of both animals (23%) Chicken (bones) and fish (scales and bones) byproducts are also used as production sources of collagen-derived dietary protein” (Holwerda and Loon, 2022). In this research, a biomodel of three synthetic collagen molecules is used to bind biomarker properties including Aptamers, CNA, and Silk. Pymol is a molecular visualization tool that provides an ethically pleasing environment for a three-dimensional structure of a protein molecule to be cleaned by removing water, removing repeated molecules, and retrieving the model sequences. The results from PyMOL are then incorporated

into the Basic Local Alignment Search Tool (BLASTp) to generate alignments between a protein sequence (Wheeler, Bhagwat, 2007). The binding energy is calculated along with a visual model of the structural changes of the collagens reaction to its biomarker using HDock and PATCHDOCK servers. When docking with PatchDock, the results are collected and refined with a software named FireDock to retrieve the binding energies. The best conformations were compared with differing peptides to see which ligand showed the highest affinity. “While enzyme driven crosslinking plateaus at maturation, connective tissue stiffness has been shown to further increase with age and diabetes. This tissue stiffening has been associated with non-enzymatic, oxidative reactions between glucose and collagen which increases with increased plasma glucose end concentrations associated with advanced aging” (Snedeker, 2014). Further research will utilize molecular dynamics to explore conformational space and explicitly treat structural flexibility and entropic effects of synthetic collagen.

Phytochemical-Enriched Plant Extracts Induce Apoptosis in Bone Metastatic Breast Cancer Cells
Preetham Ravi, Haneesh Jasuja, Dipayan Sarkar, Kalidas Shetty, Dinesh R. Katti and Kalpana Katti;
North Dakota State University, United States

The WHO reports that breast cancer is the most common occurring type of cancer with nearly 2.26 million cases being diagnosed each year. Breast cancer is also the second leading cause of cancer-death in women. Majority of the deaths occur due to breast cancer metastasis to bone. Breast cancer cells at bone site experience altered growth and chemoresistance. Furthermore, the infrastructure of the bone is compromised, resulting in skeletal failures in patients. Currently, there is no cure for bone metastasis of breast cancer. There is a shortage of effective therapeutics for bone metastatic breast cancer, due to the reported inefficacy of commercialized drugs at bone metastatic site. There is a need for accurate drug screening cancer models, which recapitulate the bone-metastatic condition, to effectively test potential anti-cancer therapies. In addition, therapies are needed not only to treat the tumor, but to heal bone, with limited side-effects. In this study, we employ a unique 3D *in vitro* nanoclay based scaffold model, as a testbed for bone metastatic breast cancer, to screen three phytochemically-enriched plant extracts (Rhodiola Crenulata, Origanum vulgare, and Vaccinium Macrocarpon). These plant extracts have been tested against primary site breast cancer, however, their efficacy against bone metastasized breast cancer cells is unknown. We evaluated the cytotoxicity of the three extracts on bone metastatic breast cancer using the bone-mimetic scaffolds and compared the results with 2D cultured breast cancer cells (MDA-MB-231 and MCF-7). The cell viability studies showed that breast cancer cells growing, both in 2D and 3D Bone-metastatic cultures, were significantly reduced by increasing dosages of all three plant-extracts. Furthermore, it was observed that these extracts induced apoptosis in breast cancer cells grown in 2D and bone-metastatic culture, through upregulation of pro-apoptotic markers, p53, caspase-3, and caspase-9 and downregulation anti-apoptotic markers. Additionally, the bone metastatic breast cancer cultures experienced increased drug resistance. Lastly, we evaluated the effects of these plant extracts on bone cells, and found that they are unaffected after treatment. Overall, our data indicates that these phytochemically-enriched plant extracts can promote cytotoxicity in bone metastatic breast cancer, while unaffacting healthy bone cells. Moreover, these specialty derived compounds can be ideal candidates to be investigated as new therapies to treat bone metastasis of breast cancer.

10:30 AM SB03.08.03

Role of Fluid Induced Shear Stresses in Inducing Bone Metastasis in Prostate Cancer Kalpana Katti, Haneesh Jasuja, Sharad V. Jaswandkar and Dinesh R. Katti; North Dakota State University, United States

The World Cancer Research Fund International reports that prostate cancer is the second most commonly occurring cancer in men. In addition, 1,414,259 new cases of prostate cancer were reported in 2020. The World Health Organization, reports 375,304 deaths in 2020 due to prostate cancer. The majority of deaths due to prostate cancer result from the cancer relocating to a distant location in the body through the process of metastasis. The bone is a common niche of relocation of prostate cancer metastasis. Prostate cancer that has metastasized to bone is incurable. We have developed a novel nanoclay-based tissue-engineered polymeric scaffold in order to mimic the bone metastasis site through sequentially seeding with hMSCs and cancer cells. The role of blood flow in cellular processes is well known through the effect of shear forces exerted by the fluid. It is also known that the fluid flow provides unique biochemical cues for metastasis. We have designed and fabricated a bioreactor that enables physiologically relevant interstitial fluid-flow for prostate cancer bone metastasis. We have also conducted computational fluid dynamics studies to establish that a fluid flow of 0.05 ml/min recapitulates the physiological condition. We did extensive gene expression and protein evaluation studies on the cellular materials grown with and without the effect of fluid flow. We observe that the interstitial fluid-flow does not alter the CXCR4 level, an important regulator of metastasis and invasiveness of cancer. On the other hand, a large impact of bone proximity on the CXCR4 levels. The bone proximity upregulates CXCR4 levels enabling increased MMP-9 levels. We also investigated the levels of integrins which are important cellular adhesion proteins and found that $\alpha_v\beta_3$ integrins and MMP-9 levels are upregulated by fluid-flow causing increased migration under fluid-flow. Hence our studies indicate that $\alpha_v\beta_3$ integrins act as potential mechanosensory agents transducing mechanical signals via $\alpha_v\beta_3$ -MMP 9 signaling to promote flow induced motility of prostate cancer cells. Overall, these experiments describe the significant role of interstitial fluid-flow in prostate cancer metastasis.

Combining Surface-Enhanced Raman Spectroscopy and Electrokinetics for Bacterial Monitoring in Wastewater Yirui Zhang, Liam K. Herndon, Punag Padhy, Babatunde Ogunlade, Alexandria Boehm and Jennifer A. Dionne; Stanford University, United States

Wastewater-based epidemiology can monitor population-level infections, provide early warnings about disease outbreaks, and help to control disease spread at the community level [1]. However, bacterial identification in wastewater presents outstanding challenges; notably, current methods [2] to identify bacteria are slow and costly, not suitable for high-throughput screening of diverse bacterial species, and may not work well in the complex wastewater matrix. Here, we develop a new electro-optical method that has the promise to detect a wide range of pathogenic bacteria in wastewater.

We combine surface-enhanced Raman spectroscopy (SERS) [3] and electrified interfaces, further assisted with machine learning models [4] to realize rapid and amplification-free detection of bacteria, at cell concentrations as low as 10^5 cells/mL in filtered wastewater. First, we collect SERS from bacteria spiked into filtered wastewater, including *Staphylococcus aureus*, *Staphylococcus epidermidis*, and *Escherichia coli*. Here, plasmonic gold nanorods electrostatically bind to the bacteria surface, allowing for rapid biomolecular recognition of the cell surfaces. Additionally, two-dimensional gold microelectrodes are patterned on the sensor surface to apply electrical fields to wastewater, which selectively attracts and enriches bacteria present in the complex wastewater matrices within minutes, driven by dielectrophoretic effects [5]. The enrichment of bacteria is directly observed through microscopy, and Raman signal intensities are increased by five to ten fold under electrical fields for bacterial concentrations ranging from 100 cfu/mL up to 10^8 cfu/mL. Such enhancement enables the detection sensitivity to reach environmentally-relevant concentrations (typically below 10^7 cfu/mL) with just ten seconds of integration

times. Finally, using machine learning, we identify biologically-relevant “fingerprint” Raman peaks describing proteins, nucleic acids, and lipids from bacteria surfaces, and achieve rapid and accurate identification of bacteria species in wastewater. The method has the promise for future label-free detection and prediction of bacterial outbreaks through wastewater. It also opens up new directions for generalized pathogen detection and molecular recognition in a broader range of complex liquid samples including wastewater, blood, and seawater.

11:00 AM SB03.08.05

Peptidic Luminescent AuNCs for Biosensing Solene Ducarre¹, Raffaello Paolini¹, Ester Butera¹, Dorian Lemasson¹, Regina Cheichio¹, Pascale Even-Hernandez¹, Celia Ravel², Ludovic Jullien³ and Valérie Marchi¹; ¹Institut des Sciences Chimiques de Rennes, France; ²CHU Rennes, France; ³ENS PSL, France

Gold nanoclusters (AuNCs) appear as a recent class of non-toxic fluorophores. Their brightness, their ultrasmall size (< 2 nm) and large window of fluorescence lifetime (1ns – 1ms) and their good biocompatibility make them an attractive alternative as fluorescent probes for biological labeling and bioimaging.

We demonstrated their in vivo targeting ability because of specific peptidic recognition groups (R. Cheichio et al. ACS Nano materials **2023**)

Here we present the direct synthesis of original ultrasmall luminescent peptidic gold nanoclusters sensitive to pH. The versatility of small peptides permits to adjust the emission wavelength and the sensitivity of the emission intensity as well as the luminescent lifetime.

In addition due to their ultra-small size, we demonstrated that these probes are easily internalized into Arabidopsis plant from the roots and the leafs by adjusting the surface charge of the ligands. Their biodistribution in this model plant was evidenced by confocal microscopy. This chemical platform provides AuNC dual nanoprobe with potential sensitivity to the environment for biosensing applications. Such nanostructures offer promising candidates for fluorescent in vivo biosensing and biolabeling.

We also investigated the interaction of AuNC with Extracellular vesicles (EVs) which are well-known membrane-limited particles that are secreted by healthy and cancerous cells. EVs are heterogeneous in size and three subtypes are described depending on the location of secretion: microvesicles, myelinosomes and exosomes. EVs are identified in human follicular fluid as a mode of communication in the ovarian follicle (Neyroud A. S. et al. Int. J. Molecular Sci. **2022**). In addition EVs involved in cell-cell communication are considered as biomarkers for early cancer diagnosis. The analysis of their content thanks to AuNCs nanoprobe could provide informations about the origin and the biological function of the EVs. The EVs labeling with easily detectable nanoparticles could enable the development of a powerful tool for the early diagnosis of specific diseases.

Engineering Antigen Binding and Orientation on Alum Adjuvants for Enhanced Humoral Responses and Immunofocusing Duo Xu and Peter S. Kim; Stanford University, United States

A major challenge in vaccine development, especially against rapidly evolving viruses, is the ability to focus the immune response toward evolutionarily conserved antigenic regions to confer broad protection. For example, while many broadly neutralizing antibodies against influenza have been found to target the highly conserved stem region of hemagglutinin (HA-stem), the immune response to seasonal influenza vaccines is predominantly directed to the immunodominant but variable head region (HA-head), leading to narrow-spectrum efficacy. Here, I will first introduce an approach to controlling antigen orientation based on the site-specific insertion of short stretches of aspartate residues (oligoD) that facilitates antigen-binding to alum adjuvants. I will demonstrate the generalizability of this approach to antigens from the Ebola virus, SARS-CoV-2, and influenza and observe enhanced antibody responses following immunization in all cases. Next, I use this approach to reorient HA in an “upside down” configuration, which I envision increases HA-stem exposure, therefore also improving its immunogenicity compared to HA-head. When applied to HA of H2N2 A/Japan/305/1957, the reoriented H2 HA (reoH2HA) on alum induced a stem-directed antibody response that cross-reacted with both group 1 and 2 influenza A HAs. These results demonstrate the possibility and benefits of antigen reorientation by engineering the interaction between antigens and adjuvants, which represents a generalizable immunofocusing approach readily applicable for designing epitope-focused vaccine candidates.

11:30 AM *SB03.08.07

3D Inverse Modelling to Extract Local Hydrogel Remodelling and Stress Fiber Structure in Human Diseased Aortic Heart Valve Interstitial Cells Michael S. Sacks and Toni West; The University of Texas at Austin, United States

Direct assessment of three-dimensional (3D) cell single stress fiber (SF) structure and function remains technically challenging, due to the SF feature size falling well below the resolution of light microscopy. Therefore, computational approaches are needed to estimate the effective structures and contractile behavior of SFs in various states. Herein, we developed a 3D computational model of the contracting aortic heart valve interstitial cells (AVICs) embedded in 3D hydrogels to estimate their SF orientations and contractile forces. We first utilized our hydrogel inverse model to estimate the local hydrogel mechanical properties. Briefly, this approach produces a spatially varying hydrogel modulus field or profile that minimizes the error between the experimentally measured and simulated hydrogel deformations produced by a contracting AVIC. It was determined that AVICs both degrade the gel by enzymatic processes, as well as locally stiffen the gel by collagen deposition. Next, we developed two finite element based inverse models that utilized a single direction and dispersed orientation SF structures. Both models estimated that the greatest levels of SF forces occurred at AVIC protrusions. The second model estimated that the greatest levels of SF alignment occurred at AVIC protrusions while the AVIC midsection revealed less-aligned fibers. To the best of our knowledge, we report the first fully 3D computational contractile cell models which can predict locally varying stress fiber orientation and contractile force levels. Looking forward, these models may help us obtain an increased understanding of SF function at sub-cellular length-scales and can be incorporated into multi-scale models of tissue/organ function.

SESSION SB03.09: Applications and Devices in Materials and Medicine II

8:30 AM SB03.09.01

Application of eIF4E Protein-Ligand Modeling for Cancer Drug Discovery Melvin Thu^{1,2}, Parth Jain^{3,2}, Evan Xie^{4,2}, Karin Hasegawa² and Yuefan Deng²; ¹Great Neck North High School, United States; ²Stony Brook University, The State University of New York, United States; ³Bergen County Academies, United States; ⁴The Pingry School, United States

The eIF4F complex recruits ribosomal subunits (40S) to initiate translation and is composed of the eIF4E, eIF4G, and eIF4A subunits. eIF4E is the cap-binding protein and binds to the m7gtp mRNA 5' cap. eIF4G is the scaffolding protein in the complex and binds eIF4E.

The protein 4E-BPs can bind to eIF4E where eIF4G binds to prevent the eIF4F complex from forming. eIF4F plays a substantial role in cancers since eIF4F preferentially activates the translation of certain mRNAs, encoding proliferation and survival-promoting proteins such as cyclin D1, c-Myc, and VEGF. The pathway involving PI3K phosphorylation of 4E-BPs results in the unbinding of eIF4E from 4E-BPs and the formation of the eIF4F complex resulting in breast, lung, ovarian, and prostate cancers, and the pathway involving Ras phosphorylation of eIF4E results in the formation of an active eIF4F complex resulting in pancreatic, lung, and colorectal cancers.

Our approach to eIF4E inhibition involves designing a compound to restrain the movement of key eIF4E residues involved in the binding of eIF4E to m7GTP, such as W102, W56, and E103, to prevent binding. An issue with m7GTP analogues of similar structure and stronger binding affinity, however, is that many are negatively charged and thus can't pass through cell membranes. Molecular docking simulations can predict binding orientation and binding affinity of the ligand to target, producing samples of many ligand conformations in the target binding region to find the optimal conformation. However, high throughput screening through brute force molecular docking is computationally expensive and limited as there are only 1010 known compounds as opposed to the 1060 total compounds.

In order to design an effective ligand, we first have to study the structure of eIF4E, and investigate how key residues involved in eIF4E binding to m7GTP undergo conformational change with and without m7GTP. We optimize eIF4E models without m7GTP using principal component analysis (PCA) and free energy landscape (FEL) calculations. We performed PCA on the trajectory data of 2gpq, 4tpw, and AF protein sources of eIF4E to transform the set of possibly correlated variables (the positions of the protein atoms) into a set of values of linearly uncorrelated variables (the principal components). We then calculated FEL of the 2gpq, 4tpw, and AF protein sources of eIF4E using GROMACS to identify the most stable conformations of eIF4E. FEL is a graphical representation of the thermodynamically stable states of a protein and the transitions between them where the local minima represent the most stable protein conformations and the barriers represent the transition states. The stable conformations of 2gpq, 4tpw, and AF were then used in molecular docking simulations of the eIF4E-m7GTP complex in order to determine the m7GTP pose with the most favorable binding energy. It was confirmed that m7GTP binds to the W56, W102, E103 residues for all three sources of eIF4E. We then performed molecular dynamics simulations on the docked eIF4E-m7GTP complexes using GROMACS with the CHARMM36 force field and TIP3P water model.

We are currently working on identifying the regions of m7GTP that are interacting with W56, W102, and E103. We will use these results to design compounds to allosterically inhibit eIF4E binding to m7GTP, preventing the overexpression of cancer-causing mRNAs.

Viability of a Novel Peptide P12 as an Antithrombotic Agent Sai Pranav Kota¹, Richard A. Wong²,

Samuel D. Coopersmith³, Avi Talsania⁴, Pia V. Sodhi⁵, Sharis Hsu⁶, Adam Hansen⁷ and Miriam Rafailovich⁷; ¹Cedar Falls High School, United States; ²Plainview-Old Bethpage John F. Kennedy High School, United States; ³Casa Grande High School, United States; ⁴Sachem High School North, United States; ⁵The Brearley School, United States; ⁶Valley Christian High School, United States; ⁷Stony Brook University, The State University of New York, United States

Medical devices and implants are an ongoing point of research due to their impressive capabilities to enhance and support human infrastructure, but pose major challenges as they must incorporate a biocompatible material that can support endothelialization and prevent thrombosis. Specifically, current cardiovascular devices like stents lack reliable endothelialization and because of exposure to constant contact with blood flow within vasculature, result in life-threatening blood clots. Fibrinogen is a plasma-soluble protein that, once cleaved, results in fibrin monomer polymerization into fibrous clots. Previous studies have demonstrated that most stent materials are subject to fibrinogen deposition and denaturation, which results in conversion into fibrin monomers and polymerization through α C domain connections [1]. A multitude of possible solutions have been studied by utilizing varying hydrophobic or hydrophilic surface properties, which feature different materials or coatings with limited success. Here, we will explore incorporation of a surface coating using P12, a peptide derived from fibronectin, to prevent thrombosis.

Initial studies provided insight on how P12 is effective for inhibiting the fibrin polymerization process on polystyrene (PS) surfaces. We studied various fibrinogen and P12 concentrations, but ultimately we found that incorporation of P12 during the incubation of 4 mg/ml of fibrinogen, the concentration in blood, on PS surfaces prevented substantial fiber formations. We also analyzed this at the molecular level with low concentrations of fibrinogen and by using Atomic Force Microscopy and simulation technology, we concluded that the hydrophobic nature of P12 allowed it to bind to exposed α C domains of fibrin on the PS surface. This prevented aggregation of neighboring fibrin monomers and ultimately prevented polymerization into fibers.

Further studies were conducted to overcome the possible negatives of using P12, which includes the uncertainty of P12 reaching the implant or cytotoxic considerations. In order to utilize P12 properly, we investigated using it as a material coating to enhance its effectiveness in a controlled location. We studied this by applying 100 μ M of P12 solution onto PS surfaces until full coverage was achieved. Fibrinogen solutions of 4 mg/ml incubated the coated surface for one hour. The P12 coating resulted in <1% of the surface containing fibers and adversely, without the coating resulted in >50% of the surface covered in fibers. From this data, we concluded that a coating of P12 is very effective in thrombosis prevention. Cytotoxicity is another major problem with implementation of a biomaterial coating. We therefore plated fibroblasts on P12 coated tissue culture plastic (TCP) and added additional P12 to the media to directly test cell survivability. We found that there were no significant differences on P12 coating or adding P12 to cells. These results are indicative of no associated cytotoxicity of the P12 surface. We further investigated this by testing cell adhesion and proliferation on P12 coated polystyrene and found an increase in cell growth and adhesion by the addition of P12 on an otherwise non-biocompatible polystyrene surface. This data concluded that a P12 coating not only rendered surfaces non-thrombogenic and non-toxic, but also enhanced biocompatibility.

Future research will look to investigate the effects of a P12 coating on its ability to support endothelialization and look to create a robust interface that incorporates P12 directly into the matrix of the material chemically so that the coating cannot be degraded or dislodged from the surface.

9:00 AM SB03.09.05

Photo-Induced Structural Changes in Oxidoreductase-Inspired Nanogels Chae Gyu Lee and Tae-Hyuk Kwon; Ulsan National Institute of Science and Technology, Korea (the Republic of)

Under the reductive conditions in cancer cells, cysteine-containing oxidoreductases, such as thioredoxin (Trx), glutaredoxin (Grx), and protein disulfide isomerase (PDI), accelerate thiol-disulfide exchange reactions through a reversible reaction ($\text{CysS}-\text{SCys} \leftrightarrow \text{Cys}-\text{SH}$), rendering upstream and downstream signaling pathways to maintain redox homeostasis in metabolism-activated cancer cells. In addition, it is difficult to differentiate between tumorous and healthy tissues as the intracellular GSH concentrations of both cell types are approximately 2–10 mM. Therefore, disulfide-bond-based nanocarriers have potential to exhibit cytotoxicity due to the unmanageable drug release in normal cells. This study investigates the spatiotemporally-controlled irreversible degradation of Ir-based photosensitizer (Tlr3)- encapsulating nanogels (IrNG) through the hyperoxidation of resulting intracellular thiols using reactive oxygen species (ROS).^{1,2} By mimicking the reversible redox reaction of Trx and Grx, we developed IrNG that maintains the self-assembled nanostructure through hydrophobic interactions and reversible crosslinking between its disulfide bonds and thiols in the absence of light. When a highly cytotoxic Tlr3 was stably encapsulated within IrNG, it exhibited significantly enhanced biocompatibility under normal cellular conditions. However, upon photoirradiation, Tlr3 generated high levels of ROS, irreversibly oxidizing the thiols to induce electrostatic repulsion between the polymer molecules, resulting in the Tlr3 release and induction of cancer cell apoptosis. Therefore, we could obtain substantially increased changes in cell viability and *in vivo* tumor growth regarding the presence and absence of photoirradiation, confirming the manual control of cytotoxic drug release.

Functional Materials Integrating Synthetic Biological Modules Guided by Machine Learning Algorithms Candan Tamerler; University of Kansas, United States

Synthetic biology takes the bio-based and bio-enabled approaches to a step further to enable engineering biology in designing and producing materials and processes with previously unattainable functions. Nature has been a source of inspiration in engineering solutions for many. As our understanding of biological materials and structures expanded, mimicking biological systems for innovative engineering solutions has continued with growing intensity. Our group was among the early adapters of biomimetic principles for harnessing design strategies to develop innovative materials. Mimicking the molecular recognition in biological interactions, we have been exploring the smaller protein domains, i.e., peptides as the key fundamental building blocks. Peptides offer to design hybrid biomaterials that can mimic the functions of proteins, generate biomimetic platforms and modulate microenvironment. Using synthetic biology approaches, we expanded the use of peptide-based building blocks as bioactive modules and design bio-hybrid materials with diverse functions addressing medical and industrial applications. We incorporated machine learning (ML) methods to capture distinct peptide functionalities as elements of

critical modular building blocks. We adapted experimental and computational approaches demonstrated transparent ML frameworks for identifying relevant peptide structure features for targeted functions. For antimicrobial hybrid materials, we provided a method for selecting secondary structure features in related to antimicrobial peptides and expanded our predictions to design peptides for metals in biology as biocatalysts, metalation tools, and metal chelates in manufacturing and nutritional immunity. Using synthetic modular domains, we developed peptide-metal and peptide-polymer hybrids as integral of biomaterials and developed models for allosteric-dependent effects of selecting spacers to recover domain function activity. We generated knowledge-potential folded structures to discover rough set theory trends which showed to be relevant for recovering bioactivity. Our examples will include utilization of the biological activity imparted by each biomolecule toward prevention of dental and oral diseases as well as restoration of oral health. Engineered modular peptide and enzyme systems will be also provided as synthetic biohybrid material systems applicable to industrial applications. Enabling synthetic biological modular approach guided by ML algorithms offers a fascinating path to reshape our thinking in engineering and represent the functional frontiers to mimic biological systems.

Sequence-Tunable Materials for Silica Biomineralization [Kaylyn Torkelson](#)¹, Nada Y. Naser¹, Xin Qi^{2,1}, Chun-Long Chen^{3,1}, Francois Baneyx¹ and Jim Pfaendtner^{4,1}; ¹University of Washington, United States; ²Dartmouth College, United States; ³Pacific Northwest National Laboratory, United States; ⁴North Carolina State University, United States

Silica biomineralization is a naturally occurring process wherein proteins direct the formation of complex, hierarchical nanostructures. Knowledge of these proteins and their underlying mechanisms has spurred significant efforts to identify routes for biomimetic mineralization that aims to reproduce the exquisite shapes and size selectivity found in nature. A common strategy to achieve this has been the use of short peptide sequences with chemistry mimicking those found in natural systems, like the use of the silaffin-derived R5 peptide. While progress has been made using peptides for this approach, there are many limitations that have prevented substantial breakthroughs in biomimicry. To advance our ability to use charged macromolecules for silica formation, we propose to use sequence-defined synthetic polymers known as peptoids, or N-substituted polyglycines, that present significant capability for precise tuning of sequence and structure beyond what can often be achieved with peptides alone.

This work will highlight recent developments in computational methods for understanding the relationship between polymer aggregate structure, silica surface, silica surface adsorption, silicate precursor interactions, and morphology in the biomimetic mineralization process. We use molecular dynamics simulations with the metadynamics family of enhanced sampling methods to analyze binding mechanisms and energetics of the R5 system. Next, we synthesize two R5-inspired peptoids and validate our prediction through characterization using surface plasmon resonance and electron microscopy. This study holds promise for designing new sequences with unprecedented control of the placement of chemical functional groups, thus allowing for further unraveling of silicification mechanisms and eventual design of sequence-defined synthetic polymers leading to the predictive synthesis of nanostructured functional materials.

10:45 AM SB03.09.08

Modeling Molecular Machines with Dynamic Covalent Bonds using REACTER [Jacob Gissinger](#);

Stevens Institute of Technology, United States

Nanoscale devices are the ultimate in mechanical miniaturization. Molecular machines that perform directional transport of small molecules or filaments are a vital aspect of life, performing key biological functions during cell division and muscle contraction. These biomotors have inspired the creation of synthetic versions of molecular ‘walkers’ that can move directionally down a molecular track by the application of stimuli (pH and irradiation) in a specific sequence. The reconfiguration of covalent bonds is achieved by two orthogonal bond exchange reactions: disulfide exchange, which is activated in basic environments, and hydrazone exchange, which occurs under acidic conditions. In this work, we simulate the nanoscale dynamics of molecular machines using REACTER, a method for modeling chemical reactions in classical molecular dynamics (MD) simulations. Although external stimuli such as UV light cannot be modeled directly in classical MD simulations, the dynamics of a molecular walker can be captured explicitly by alternately activating the bond exchange and photoisomerization reactions using REACTER. Certain shape-memory polymers operate via similar bond exchange reactions, and a workflow to model shape-memory effects with atomistic resolution is proposed.

8:00 AM SB03.10.01

Zwitterion Functionalization of Polyurethanes via Thiol-ene Click for Antifouling Surfaces—Lessons from Nature Shantanu P. Nikam^{1,2}, Peiru Chen¹, Karissa Nettleton², Yen-Hao Hsu¹ and Matthew Becker²; ¹The University of Akron, United States; ²Duke University, United States

Inspired by the phospholipids on cell membranes, zwitterionic groups have been widely studied for their antifouling property. Equipped with two oppositely charged groups in the same moiety, zwitterions exhibit properties like super hydrophilicity through ionic solvation and tightly bound hydration layer that enables non-specific protein resistance. Additionally, zwitterionic materials also enhance biocompatibility and reduce immune response.

Catheter-associated infections (CAIs) have one of the highest mortality rates among healthcare-associated infections. Besides being a major cause of morbidity and mortality, CAIs also impose a heavy financial burden resulting from prolonged treatment and hospital stays. Increasing cost and health related complications necessitate the research for improving currently employed biomaterials for catheter applications. Creating antifouling surfaces by immobilizing zwitterion molecules on material surfaces has been proved to be a promising strategy. Herein, we investigated zwitterion surface-functionalized thermoplastic polyurethane (TPU) for use in antifouling catheter. The thermoplastic polyurethane was synthesized to have an allyl ether side functionality. Zwitterion surface-functionalization was achieved *via* thiol-ene ‘click’ chemistry in aqueous conditions. The XPS results confirmed the presence of chemically tethered zwitterion moieties on the zwitterion-TPU surface. The Quartz crystal microbalance (QCM) results show reduced fibrinogen attachment for the zwitterion-TPU when compared to its unfunctionalized controls. The zwitterion-TPU also showed a log scale reduction in bacterial adherence. For *P. aeruginosa* and *S. epidermidis*, the zwitterion-TPU resulted in around a 40% and 50% lower

bacterial biomass accumulation, respectively. The fibroblast cell viability of TPU remained unaffected by functionalization with zwitterion thiol. Our results suggest a zwitterion modified TPU is a promising candidate for antifouling catheters.

Carbon Nano-Interfaces for Medical and Biological Applications Roger Narayan; North Carolina State University, United States

Recent studies have evaluated the use of microcrystalline diamond, nanocrystalline diamond, and diamond particles for medical applications. In this talk, materials studies and *in vitro* studies describing the interactions between diamond and medically-relevant eukaryotic cells and prokaryotic cells will be considered. The attachment of eukaryotic cells and prokaryotic cells to diamond surfaces will be considered. In addition, recent developments involving the use of diamond in active medical applications, including electrochemical sensing, will be described. Our recent finding involving diamond surfaces indicate that diamond surfaces may offer significant improvements for the diagnosis and treatment of medical conditions over the next few decades.

8:45 AM *SB03.10.03

Multiscale Small Molecule Interactomics and Behavioural Biomimetics using the CANDO Platform Zackary Falls¹, William Mangione¹, Brennan Overhoff^{1,2}, Liana Bruggemann¹, Matthew Hudson¹, James Schuler¹, Manoj Mammen¹ and Ram Samudrala¹; ¹University at Buffalo, United States; ²Harvard University, United States

Our goal is to understand and engineer small molecule behavior and functionality at multiple scales. We accomplish this by developing technologies to describe small molecule behavior and function in terms of their multiscale signatures, which are utilised to engineer safe and effective chemicals and materials for the betterment of society by discovering optimal probes and therapeutics; generate safer and better chemicals and materials; and promote health, quality of life, and prosperity.

We elucidate the scientific tenets determining small molecule behavior in a variety of contexts, starting from the atomic and macromolecular scales, proceeding to pathways, cells and beyond, eventually reaching the phenotypic and population scales. The tenets are embedded in the form of multiscale signatures, comprising the sub-signatures at each scale, i.e., small molecule-macromolecule, -pathway, -cell and -phenotype signatures. At each scale, we determine the interaction signature using a combination of calculations and measurements, which will be enhanced with relevant information from lower scales.

We developed the Computational Analysis of Novel Drug Repurposing Opportunities (CANDO) platform for shotgun multitarget drug discovery, repurposing, and design, funded in part by a NIH Director's Pioneer Award and multiple NCATS ASPIRE Awards to implement this paradigm and overcome the limitations of traditional single target approaches. The open source platform screens and ranks drugs/compounds for every disease/indication (and adverse event) through large scale modelling and analytics of interactions between comprehensive libraries of drugs/compounds and protein structures. CANDO is agnostic to the interaction scoring method used; two primary pipelines within the platform allow for rapid screening and assessment of billions of drug/compound to protein interactions with fast bioanalytic docking and machine learning affinity regression protocols. CANDO implements a variety of benchmarking protocols for shotgun repurposing to determine how every known drug is related to every other in the context of the indications/diseases for which they are approved, which enables evaluation of

various pipelines and protocols within and external to the platform for their utility in drug discovery. We have performed predictive analytics on the CANDO interaction matrices to classify drug, protein, pathway, disease, and adverse event relationships accurately. The multiple fast and accurate interaction scoring/docking protocols, the proteomic scale, and rigorous all-against-all benchmarking used within the platform make it unique and ideal for the design of novel chemical entities that target a desired proteomic/interactomic space or objective.

CANDO has been extensively validated for drug discovery, repurposing, and design; recent work on COVID-19 shows 25% our top drug candidates having in vitro efficacy including two nanomolar concentration full virus inhibitors of SARS-CoV-2, one of which was ranked #1. We already produced preliminary designs for various indications (such as non-small cell lung cancer, opioid/substance use disorder and pain, and aging) using the design pipelines implemented in CANDO. CANDO is capable of performing analytics on any arbitrary drug/compound, including those chemicals relevant to industrial use such per-and polyfluoroalkyl (PFAS) substances to design safer and better compounds. The most potent designs will be pursued further for development and regulatory approval. Elucidating multiscale signatures of small molecules lends itself to a paradigm-shifting view of small molecule behavior and function that will enable detailed engineering of small molecules for myriad applications. This talk will describe the current state of the CANDO platform and future plans for use in materials research.

9:15 AM SB03.10.04

Harnessing Gradients for Self-Assembly of Peptide-Based Nanocapsules: A Pathway to Advanced Drug Delivery Systems Haopeng Li¹, Xuliang Qian¹, Harini Mohanram¹, Xiao Han¹, Huitang Qi², Guijin Zou³, Fenghou Yuan², Ali Miserez¹, Qing Yang⁴, Tian Liu², Huajian Gao^{1,3} and Jing Yu^{1,1}; ¹Nanyang Technological University, Singapore; ²Dalian University of Technology, China; ³A*STAR, Singapore; ⁴Chinese Academy of Agricultural Sciences, China

Biological systems often create materials with intricate structures to achieve specialized functions. In comparison, precise control of structures in man-made materials has been challenging. Here, we report a serendipitous discovery of insect cuticle peptides (ICPs) spontaneously forming nanocapsules through a single-step solvent exchange process, where the concentration gradient resulting from mixing of water and acetone drives the localization and self-assembly of the peptides into hollow nanocapsules. The underlying driving force is the intrinsic affinity of the peptides for a particular solvent concentration, while the diffusion of water and acetone creates a gradient interface that triggers peptide localization and self-assembly. This gradient-mediated self-assembly offers a transformative pathway towards next-generation drug delivery systems based on peptide nanocapsules.

9:30 AM SB03.09.04

Biomimetic Dentin Repair: Amelogenin-Derived Peptide Guides Occlusion and Peritubular Mineralization of Human Teeth Deniz T. Yucesoy¹, Hanson D. Fong², Sami Dogan² and Mehmet Sarikaya^{2,2,2}; ¹Izmir Institute of Technology, Turkey; ²University of Washington, United States

Dentin hypersensitivity, a widespread oral health concern, is primarily caused by the exposure of dentin tubules due to the loss of protective tissues. Despite being a widespread ailment, no permanent solution exists to address this oral condition. Current treatments aim to alleviate pain by employing desensitizing agents or blocking dentin tubules through mineral deposition or solid precipitates, yet these interventions often provide only short-term relief.

To restore the structural and mechanical integrity of teeth with lasting durability, there is a crucial need to

reproduce an integrated mineral layer that seals exposed dentin while promoting peritubular mineralization. In this study, we introduce a biomimetic treatment that promotes dentin repair, utilizing a mineralization-directing peptide known as sADP5, derived from amelogenin.

The occlusion of dentin tubules is achieved through a layer-by-layer peptide-guided remineralization process, resulting in the formation of an infiltrating mineral layer on the dentin. The structure, composition, and nanomechanical properties of the remineralized dentin were analyzed by cross-sectional scanning electron microscopy imaging, energy dispersive X-ray spectroscopy, and nanomechanical testing. Elemental analysis revealed calcium and phosphate compositions akin to hydroxyapatite.

Furthermore, the measured average hardness and reduced elastic modulus values of the mineral layer were significantly higher than those of the demineralized and sound human dentin. Thermal aging experiments provided evidence of the structural integration between the newly formed mineral layer and the underlying dentin, with no physical separation observed. These findings suggest the creation of a structurally robust and mechanically resilient interface that can endure long-term mechanical and thermal challenges commonly encountered in the oral environment.

The peptide-guided remineralization process outlined herein provide a foundation for the development of highly effective oral care products leading to novel biomimetic treatments for a wide range of demineralization-related ailments and offers a potent long-term solution for dentin hypersensitivity.

10:30 AM SB04.01.01

4D Printing of Hydrogels with Hierarchical Surface Wrinkling Patterns Murat Guvendiren; New Jersey Institute of Technology, United States

Additive manufacturing of stimuli responsive materials leads to 3D printed constructs that can adapt their properties in response to an external stimuli. This process is referred as 4D printing. 4D printing is commonly used to fabricate shape-shifting constructs, which change their asprinted shape into a preprogrammed shape post-printing with response to an external stimuli. Although 4D printing of shape-shifting objects have significantly expand the applications of 3D printing, novel ink formulations are needed for 4D printing to create 2D and 3D structures that allow dynamic control of properties beyond shape change. In this study, we present smart inks for material extrusion-based direct ink writing (DIW) printing that display preprogrammed surface wrinkling patterns on 2D and 3D surfaces post-printing, which appear only when exposed to a solvent. Hydrogels displaying surface wrinkling patterns with user-defined order and shape are useful for a range of applications, including microfluidics, flexible electronics, smart adhesives, optical sensors, and cell culture platforms. However, conventional techniques to fabricate wrinkling patterns involve multiple steps and are significantly limited to create hierarchical patterns, wrinkles on 3D and non-planar structure. It is also very difficult to scale-up the manufacturing process and to integrate surface patterning into a continuous manufacturing process. 4D printing is used in this work to overcome these issues. The use of photocurable ink formulations allow us to tailor flow properties and printability by controlling photopolymerization time and partial crosslinking time. The crosslinker concentration is varied to develop distinct ink formulations with preprogrammed wrinkling morphology, including lamellar, peanut and hexagonal patterns. We demonstrate 4D printing of optical devices, solvent sensors, anti-counterfeit devices and high-throughput cell culture platforms.

10:45 AM *SB04.01.02

Electronic Hydrogels for Plant and Environmental Monitoring Eloise Bihar^{1,2}, Elliot Strand¹, Catherine Crichton¹, Megan N. Renny¹, Robert McLeod¹ and Gregory L. Whiting¹; ¹University of Colorado-Boulder, United States; ²University at Buffalo, The State University of New York, United States

Significant progress has been achieved in the field of electronics dedicated to environmental monitoring in recent decades. Currently, a key challenge lies in establishing an enhanced interface between electronics and living tissues. The proliferation of miniaturized sensors designed for plant and environmental sensing necessitates the development of hybrid sensors that employ cutting-edge techniques and novel organic materials to mitigate the formation of fibrotic tissues.

In this context, we introduce a novel generation of biocompatible and stretchable electronic gels, which showcase remarkable mechanical properties and self-repair capabilities. These gels also exhibit a wide array of functionalities, including exceptional conductivity levels of up to 350 S cm⁻¹, high transconductance ranging within the mS range, and high capacitance values of up to 4.2 mF g⁻¹.

Leveraging the unique characteristics of these electronic gels, we can effectively stimulate or record ionic activities both in vivo and ex vivo, enabling the monitoring of plant electrophysiology or serving as energy storage systems for agricultural monitoring.

11:15 AM DISCUSSION TIME

11:30 AM SB04.01.04

Achieving Tissue-Like Properties in 3D Printed Conducting Polymer Hydrogels Somtochukwu S. Okafor¹, Tianran Liu¹, Anna P. Goestenors¹, Barbara A. Semar², Riley Alvarez¹ and Alexandra Rutz¹;

¹Washington University in St Louis, United States; ²Washington University in St. Louis, United States

Conducting hydrogels are sought for integration into bioelectronic devices to impart soft, hydrated, and tissue-like properties. However, the compatibility of these materials with advanced manufacturing and the ability to tailor functional properties for application remain limitedly reported. With regards to structural design, additive manufacturing offers customization and complexity with respect to object shape, dimensions, and internal microstructure. Additionally, materials processing as part of the additive manufacturing procedure can be used to control functional properties important for cell-material interactions and device performance. In this work, we developed methods for 3D extrusion printing conducting polymer hydrogels based on poly(3,4-ethylenedioxythiophene) polystyrene sulfonate (PEDOT:PSS). We demonstrate control of hydrogel properties by careful pre-printing ink formulation and appropriate post-printing processing. Shear-thinning and self-healing hydrogel inks were developed. Consistent rheological (viscosity, storage and loss modulus) and printing properties (mass flow rate, particle size) were maintained by manipulating the gelation kinetics of PEDOT:PSS using temperature. A gel-based support medium enabled fabrication of multi-layered structures after adding a gelation agent to increase structural resolution. Printed PEDOT:PSS hydrogels exhibited tissue-like properties including an elastic modulus of ~5 kPa and water content >99%. When further treated with heat or solvent, a wide range of conductivity (10 – 10,000 S/m) was achieved. Furthermore, hydrogels printed into microporous scaffolds were stable in physiological conditions for at least 28 days, and supported viability and proliferation of seeded human primary cells. Collectively, these results provide methods of fabricating PEDOT:PSS hydrogels that offer customization for various biointerfacing applications with regards to structural design and functional properties.

SESSION SB04.02/EL05.02: Joint Session: Neuro- and Neuro-Morphic Applications

Session Chairs: Cindy Harnett, Juejun Hu, Seungwoo Lee, Anna-Maria Pappa, Alexandra Rutz, Christina Tringides and Shiming Zhang

Monday Afternoon, November 27, 2023

Hynes, Level 1, Room 103

1:30 PM *EL05.02/SB04.02.01

Multifunctional Conducting Polymer Hydrogels for Regenerative Bioelectronics Maria Asplund^{1,2}, Sebastian Shaner³, Lukas Matter¹, Oliya Abdullaeva², Jose A. Leal Ordonez³, Anna Savelyeva³, Bruce Harland⁴, Brad Raos⁴, Han Lu³, Maximilian Lenz³, Christian Boehler³, Darren Svirskis⁴ and Andreas Vlachos³; ¹Chalmers University of Technology, Sweden; ²Luleå University of Technology, Japan; ³University of Freiburg, Germany; ⁴The University of Auckland, New Zealand

Bioelectronic medicine refers to technology which use electrical signals, either recorded from or injected into tissue, for therapeutic effect. To date, the focus of electrical stimulation has almost exclusively been on excitable tissue, such as nerve and muscle cells, which respond to short stimulation impulses. Nevertheless, a much broader range of cells are able to respond to direct current, e.g. many cells change shape, growth or align their migration trajectories in accordance with an applied electrical field. It is hypothesized that such effects can be used to steer regenerative processes, modulate neural function or explain cancer metastasis, however, there is little technology developed that allows for such investigations in complex biological models. In our research we are developing methodologies that would

make such exploration possible, in complex cell cultures, in vivo and at later stages also in patients. Key to success is to identify electrode materials that make it possible to interface intimately with living tissues and deliver direct current without corrosion. The typical noble metal materials have limitations in terms of charge injection and corrosion resilience, and their electrochemistry is in general not well-matched to ionic current stimulation. Meanwhile, conducting polymer hydrogels show great promise as they can transport and deliver ionic current via biocompatible charge injection mechanisms, even in the direct current domain.

In my talk I will showcase how we employ conducting polymer hydrogels for direct current stimulation, and how such technology allows for new discoveries as well as potential future therapies. One such application field is wound healing, where we have used conducting polymer hydrogels to show how direct current stimulation of an *in vitro* epithelial wound model resulted in 3 times accelerated wound closure. Another possibility is spinal cord repair where we are exploring how to integrate electrodes for direct current stimulation in a flexible implantable bioelectronic system. By paying close attention to aspects such as electrode/electrolyte reactions, substrate electrolyte reactions as well as the interplay between the fundamental properties of the conducting polymer hydrogel and polymer-substrate adhesion layers, we hope to build a concept for fully biocompatible and implantable regenerative DC stimulation.

This work was supported by the European Research Council (ERC) grant agreement No. 759655 (SPEEDER) the CatWalk Spinal Cord Injury Trust and the Health Research Council of New Zealand (Project grant and HRC/Catwalk Partnership 19/895). Further support was provided by the center for Innovative Brain Machine Interfacing Technology at the University of Freiburg.

2:00 PM *EL05.02/SB04.02.02

Conductive and Biofunctional Hydrogels for Regenerative Living Interfaces in the Nervous System
Rylie Green; Imperial College London, United Kingdom

Neurological disorders affect more than 60 million people every year and constitute a major clinical challenge. Due to the limited cellular turnover and the significant degeneration triggered by neural injury and disease, regenerative therapies constitute a promising strategy to ameliorate the symptoms. Living bioelectronics offer the potential to create living interactions between implants and the endogenous neural system. By providing a tissue engineered scaffolds containing neuroprogenitor (or stem) cells at the neural interface, this approach can grow connections, creating an intimate and regenerative cell-level interface. The major challenge in this technology is the need to support the cells and encourage their development into mature neurons, while creating functional synapses with target tissue. Hydrogels with conductive elements have been designed with degradation kinetics that are matched to neuronal differentiation and wound healing, while also being electrically addressable. Critically, these hydrogels provide biological and topographical cues that promote the survival of cells and ability to produce neurite processes. A system based on PVA and gelatin has been shown to support the differentiation of neuroprogenitor cells into functional neural networks at the interface of bionic devices. The incorporation of gelatin into poly(vinyl alcohol) - norbornene hydrogels (PVA-Gel-NB) was shown to provide biochemical cues that were able to be modified by the encapsulated progenitors, which ultimately integrated into brain tissue. In an alternate injectable system, self assembly peptides (SAPs) were modified to form fibers with conductive cores that supported cells in producing directional growth. The use of electrical stimulation that mimicked the pattern of brain activity experienced *in utero* by the developing mammalian CNS, was subsequently demonstrated to increase the number of mature differentiated neurons. Action potentials have been observed within both of the cell populations, showing their development into appropriate cells types. Ultimately, this work demonstrates the ability to bring

bioelectronics and tissue engineering concepts together to produce regenerative neural tissue constructs.

2:30 PM EL05.02/SB04.02.03

Development of a Hydrogel-Actuated 3D Micro Electrode Array (MEA) for Neural Spheroids and Organoids Outman Akouissi, Eleonora Martinelli, Luca Liebi, Janer Van der Graaf Mas, Silvestro Micera and Stephanie P. Lacour; Ecole Polytechnique Federale de Lausanne, Switzerland

Organoids and spheroids are versatile tools in research. Their 3D structure can faithfully replicate the complexity and functionality of human organs and tissues, enabling scientists to study biological phenomena in a dish. Specifically, neural organoids and spheroids offer exciting opportunities for understanding neuronal connectivity and exploring neurological disorders. Electrophysiological recordings play a crucial role in assessing these parameters. While micro electrode arrays (MEAs) are commonly used for such measurements, they are mostly limited to 2D (planar) configurations, which do not fully capture the complexity of three dimensional organoids and spheroids.

In this study, we present an intuitive 3D MEA platform based on shape-morphing bilayers to engulf the spheroid and enable recordings from its entire surface. The first layer forms the microelectrode arrays patterned as a thin metal film embedded in polymers such as polyimide and parylene. The second layer consists of a hydrogel membrane covalently grafted onto the MEA and capable of swelling upon immersion in cell culture medium thereby enabling actuation.

By precisely tuning the hydrogel formulation, bilayer thicknesses, and MEA geometry, we successfully designed 3D MEA platforms that accommodate a wide range of tissue sizes and shapes. One device included 32 electrodes, with a radius of 15 μm , distributed onto 4 bilayers folding with a radius of closure 300 μm . To expedite and guide the design and microfabrication process, we conducted comprehensive mechanical and electrical characterization of each component, and developed accurate in silico finite element models. The shape morphing MEAs interface reliably with commercial MEA readout platforms, requiring no additional instrumentation and minimal training.

We aim to study network patterns collected from the volumetric MEA over neural spheroids and hope to collect valuable insights into the connectivity, health, and functionality of neural organoids.

2:45 PM DISCUSSION TIME

3:00 PM BREAK

3:45 PM *EL05.02/SB04.02.05

Hydrogel-Based Flexible and Multifunctional Fibers for Next-Generation Neural Interfaces Seongjun Park; KAIST, Korea (the Republic of)

To understand the mechanism underlying the function and dynamics of the nervous system or to treat neurological disorders, it is essential to develop the techniques capable of modulating and recording a diversity of signals employed by neurons. However, current approaches are limited in terms of effectiveness, side effects, non-specificity, and mechanical invasiveness. Naturally, there is a huge need for new devices or materials allowing for minimally invasive manipulation and monitoring of neural activity. My talk will introduce the complementary strategy to address these challenges with hydrogel-based flexible and stretchable fiber-based probes for interfacing with the brain and spinal cord. This technology enabling the interrogation with neural circuits across their diverse signaling modalities without inducing a foreign-body reaction helps the study of information processing as well as pathologies of the nervous system.

4:15 PM EL05.02/SB04.02.06

Development of 3D Hydrogel-Based *In Vitro* Circuits with Cocultures of Human Sensory Neurons and Schwann Cells Blandine F. Clément¹, Christina M. Tringides¹, Vilius Dranseika², Jens Duru¹, Tobias Ruff¹ and Janos Vörös¹; ¹ETH Zürich, Switzerland; ²University of Zürich, Switzerland

Engineered *in vitro* neural networks are promising platforms to rapidly screen drugs and study information flow in the nervous system [1]. While existing polydimethylsiloxane (PDMS)-based microfluidic platforms offer precise architecture and connectivity, the cultured neurons grow inside microchannels on a planar multielectrode array (MEA) substrate in a two-dimensional fashion [2]. To better mimic the native extracellular matrix (ECM) microenvironment, 3D hydrogel scaffolds can be designed so that encapsulated cells can be expected to exhibit more physiological behavior [3]. Here, we propose a hybrid approach by filling the PDMS microstructure with hydrogels to offer both a controlled topology and a physiologically relevant microenvironment to the neuronal culture. First, a gelatin methacryloyl (GelMA) hydrogel was engineered by incorporating ECM components and tuning its mechanical properties to match the native niche environment. The hydrogel material was able to 1) support the growth of human iPSC-derived sensory neurons for more than 9 weeks 2) support co-culture with human Schwann cells where the latter could align along the axons. Next, microchannels were filled with the optimized hydrogel precursor, and after crosslinking, the neurons and glial cells were seeded as pre-aggregated spheroids in desired location(s). This enabled topologically defined growth of neurites in 3D.

By further tuning the hydrogel type and its physico-mechanical properties, the microstructures could be filled and tailored for specific cell types, while the underlying MEA allows for the recording of neuronal activity over time. This platform could offer a promising tool to study cell-cell interactions of single cultures or co-cultures, and to efficiently test the potential of various drugs in a more translational manner.

Biodegradable Materials for Optoelectronic Neural Modulation and Electronic Medicine Lan Yin;
Tsinghua University, China

Devices built on biodegradable materials possess unique characteristics that enable complete biodegradation in physiological environments, thus eliminating the need for retrieval surgery and minimizing the associated risks of infection. These devices can play a critical role in therapeutic and diagnostic processes, including neural modulation, tissue regeneration, etc. Herein, we introduce materials options and fabrication strategies that enable the development of a biodegradable and flexible optoelectronic device, capable of achieving efficient neural stimulation and functional recovery on peripheral nervous systems. Furthermore, we propose a bioresorbable and self-powered device as electronic medicine for peripheral nerve regeneration. Successful nerve regrowth and motor functional recovery are realized in rodent models. These works provide new insights for modulating neural activities and repairing nerve injuries.

SESSION SB04.03: Poster Session I

Reprocessable Ion-Conducting Elastomer Formed by Thiourea-Based Dynamic Covalent Network
Bitgaram Kim¹, Yeong Je Cho¹, Dong-Gyun Kim² and Ji-Hun Seo¹; ¹Korea University, Korea (the Republic of); ²Korea Research Institute of Chemical Technology, Korea (the Republic of)

The development of ionic conducting elastomer (ICE) with reprocessing capability is desirable to prevent resource wastage and environmental crises. Traditional elastomers with covalent cross-linking pose challenges for reprocessing due to their thermoset properties. To address this issue, a thiourea-based dynamic covalent network was employed to design the ICE. Through an analysis of the interaction between the lithium salt and the polymer chain, LiTFSI was selected as the ideal choice. Furthermore, the analysis revealed that the behavior of the dynamic covalent network was influenced by the interactions between the polymer chain and lithium salts, not just the network formation itself. The resulting dynamic covalent elastomer can be reprocessed multiple times using various methods such as hot-pressing and solution processes. It demonstrates good dimensional stability and exhibits an ionic conductivity.

8:00 PM SB04.03.02

Minimally Invasive Bioprinting of Conductive Hydrogel for *In Situ* Liver Regeneration Yueying Yang and Jianfeng Zang; Huazhong University of Science and Technology, China

In situ bioprinting is promising for developing scaffolds directly on defect models in operating rooms, which provides a new strategy for *in situ* tissue regeneration. However, due to the limitation of the printing depth and bioink, bioprinting scaffolds in deep dermal or extremity injuries remains a grand challenge. Here, we present a ferromagnetic intravital bioprinting approach for *in situ* tissue regeneration in a minimally invasive manner. The ferromagnetic intravital bioprinting system is able (1) to measure

and identify the geometry of organ defects by micro-CT, (2) to plan a matched printing path, and (3) to deliver multiple bioinks to fabricate scaffolds on defects in a minimally invasive manner. The minimally invasive bioprinter is composed of a ferromagnetic soft catheter robot (FSCR) nozzle that can arrive at the deep dermal (0-150 mm) through a small incision (2-4 mm) and a separated remote magnetic actuation system that numerically controls the movement of FSCR. The hydrogel bioink is designed to be electroactive, self-healing, biocompatible, biodegradable, tissue adhesive and extrusion printable. After 3D reconstruction of the defects with computed tomography (CT), conductive hydrogel scaffold is printed within a partial liver resection of live rat, and in situ tissue regeneration is achieved due to the electroactive hydrogel scaffold, promoting the orderly arrangement of fibroblasts and collagen *in vivo*.

8:00 PM SB04.03.03

Magnetic Nanogels for Combined Hyperthermia and Chemotherapy of Prostate Cancer Sofia Patri^{1,2}, Thanh T. Nguyen² and Nazila Kamaly¹; ¹Imperial College London, United Kingdom; ²University College London, United Kingdom

Iron Oxide Nanoparticles (IONPs) are FDA approved for biomedical applications, such as magnetic hyperthermia: IONPs can generate heat as a consequence of their relaxation mechanism after being placed in an Alternating Magnetic Field (AMF). The heat generation is measured in Specific Absorption Rate (SAR) and agglomerations of IONPs, known as NanoFlowers (NFs), have shown to have some of the highest SAR values out of all the variations of this material. The surface of IONPs and IONFs can be modified with an organic coating to increase their biocompatibility. By selecting the appropriate soft material, the organic shell can also encapsulate a cargo and release it over time: this kind of magnetic composite can combine hyperthermia with drug delivery, making it a highly effective treatment against cancer cells. Nanogels, which are hydrogels in the nanoscale, are highly biocompatible and stable in the biological environment thanks to their crosslinked network; more importantly, they can be engineered to respond to an external stimulus. By including a thermo-responsive unit in the nanogel, an increase in temperature will induce a coil-to-globule transition of the chains causing the shrinkage of the nanogel and the expulsion of water along with the encapsulated cargo.

In this multifunctional therapy, we aim to trigger drug release from a nanogel by using the heat generated by the IONFs in an AMF. To improve the stability of the nanocarrier in the physiological environment, we demonstrate the necessity to anchor the nanogel to the IONFs through a surface ligand. The development of functional and stable magnetic nanogels provides a more effective, localized, and precise therapy that combines the benefit of the monotherapies while minimizing their individual drawbacks whilst establishing synergistic actions.

8:00 PM SB04.03.04

Conducting Hydrogel Based on Novel Polymer Composite PEDOT:DBSA for Bioelectronic Applications Šárka Tumorová¹, Romana Malečková¹, Petr Smíšitel², Lubomír Kubáč³, Jirí Akrman³, Jirí Smilek¹, Michaela Pešková⁴, Jan Víteček⁴, Martin Vala¹ and Martin Weiter¹; ¹Brno University of Technology, Czechia; ²Central European Institute of Technology, Czechia; ³Centre for Organic Chemistry, Czechia; ⁴Institute of Biophysics of the Czech Academy of Sciences, Czechia

Organic bioelectronics represents a potential revolution in medicine as it holds the promise of personalised treatment with reduced side effects compared to conventional pharmaceutical drugs. Despite the big effort dedicated to this field, there are still challenges to be solved. One of them is the form of organic polymers acting as active material, as the commonly used thin films are not very favourable with regard to the tissues that are supposed to be in proximate contact with them. That is mainly due to the

dissimilarities in mechanical and physical properties of these two components, which might be an obstacle preventing the formation of a satisfactory interface, thus reducing the efficiency of signal transport. This properties mismatch arises especially from the differences in water content and elastic modulus values. Hence, there is a big demand for a more tissue-like form of these materials as it can significantly promote contact with tissues at the interface, thus reducing the adverse immune responses of the biological system, decreasing the interfacial impedance and enhancing the efficiency of both signal recording and stimulation. Among other structures, hydrogels seem to be the perfect interface to biological tissues due to their structural similarity with the extracellular matrix, tissue-like mechanical properties, water-rich nature, superior biocompatibility, flexibility and adjustable biochemical properties. In this work, we prepared and characterised a conductive hydrogel based on a completely new polymer composite – PEDOT:DBSA. The rheological characterization revealed that the mechanical strength of the hydrogel as well as the gelation time can be easily tailored to the desired application by changing the concentration of cross-linking agent. The electrical properties of the hydrogel were studied using impedance spectroscopy and cyclic voltammetry. It was shown that the total bulk conductivity of prepared hydrogel is 3.8 Sm^{-1} . The LDH cytotoxicity assay showed a very good biocompatibility of hydrogel compared to that of the culture plastic and glass dish. The structure of the hydrogel was investigated using scanning electron microscopy and was found to be of rough, spongy nature. These results indicate that PEDOT:DBSA hydrogel has great potential for creating an interface between the biological environment and electronic devices used in various fields of regenerative medicine.

8:00 PM SB04.03.05

Electrospun Hydrogel Nanoporous Scaffold for Cleaning Ultrafine Contaminants in Semiconductor Manufacturing Somin Shin, Ji-hun Jeong and Sanha Kim; Korea Advanced Institute of Science and Technology (KAIST), Korea (the Republic of)

In semiconductor manufacturing, chemical mechanical planarization (CMP) process is an essential step where wafers are polished via chemical and physical actions using externally supplied abrasives. After the CMP step, contaminants which include the remained abrasives and wear debris must be strictly removed from the wafer surface to prevent device failure via unintended particles. Accordingly, CMP cleaning always follows right after the CMP step. Post-CMP cleaning is particularly difficult as the contaminants are strongly adhered on the wafer surface due to as they are mechanical compressed during the polishing step. For such challenges, brush scrubbing techniques are widely employed due to their superb cleaning efficiency. The brush cleaning is in general conducted via porous polyvinyl alcohol (PVA) hydrogel brushes which make a physical contact with the wafer therefore can provide sufficient physical removal force to the surface particles for their removal.

The synthetic PVA hydrogel used as the wafer cleaning brushes comprises micropores, and has high swelling capacity against water-based cleaning solutions. The recent challenge arises as the pore sizes of commercial brush products remain in micro-scale whereas the size of the contaminants to be removed is ever shrinking to even few nanometers. Therefore, the existing brush products cannot effectively deliver the sufficient removal forces on ultrafine particles. In this research, we fabricate a PVA hydrogel scaffold comprising nano-scale porosity which can exhibit high effectiveness in particle removal for cleaning ultrafine contaminants. Insoluble polyvinyl formal (PVF), the raw material of cleaning brush, is synthesized via acid catalyzed acetalization of water-soluble PVA with formaldehyde which occurs with crosslinking of PVA chains by modifying hydroxyl groups. We produce nano-scale fibrous sheets using electrospinning process and investigate the effect of PVA/formaldehyde/sulfuric acid weight ratio as well as the processing conditions on the fiber formation. A heat treatment follows after the electrospinning step which reconstruct the fiber mat into a three-dimensional porous scaffold via creating fiber-to-fiber

junctions, resulting in suitable mechanical strength and resilience. To verify the correlation between structural scale and particle removal efficiency, we conduct lab-scale wafer cleaning experiments on substrates contaminated with particles of various sizes, from 12 μm to 80 nm, using conventional microporous brushes and fabricated nanoporous scaffolds. We further experimentally verify that the effect of the structural scale is significantly more dominant. Our new hydrogel nanoporous scaffold exhibit outstanding removal efficiency for ultrafine particles, thus can provide an effective engineering solution for the current limit in post-CMP ultrafine contaminant cleaning which is of-interest in semiconductor manufacturing industry.

8:00 PM SB04.03.06

Tissue-Adhesive and Anti-Swelling Hydrogel Based Multifunctional Implantable Sensor for Monitoring of Bladder Activity in Overactive Bladder with Surgical-Robot Assisted Laparoscopic Surgery Byungkook Oh and Steve Park; Korea Advanced Institute of Science and Technology, Korea (the Republic of)

Electrical properties and mechanical properties of a biological bladder tissue provide useful tissue information for preventing disabling condition of urinary systems as clinical treatments. Recently, there has been a great deal in designing implantable electronics that collect tissue information and provide fundamental treatments. However, intrinsic differences between biological tissues and conventional rigid and dry electronics pose problems with unstable interaction between both surfaces and infection of biological tissues. Here, a highly stretchable and tissue-adhesive multifunctional implantable sensor based on structurally engineered islets embedded in ultra-soft hydrogel is developed for real-time monitoring of bladder activity in overactive bladder (OAB) induced rat and anesthetized pig. One critical issue with hydrogel in general as implantable substrates, however, is their eventual change in mechanical properties and electrical properties due to the gradual absorption of biofluids in the body. To overcome the critical issue, an anti-swelling coating technique that can prevent absorption of water and biofluids in the body is developed. This coating technique is applicable to various hydrogels that have low sol-gel transition temperatures, while imposing negligible changes in mechanical properties. Using tissue-like, anti-swelling hydrogel, which can sustain its initial mechanical & electrical properties as a role of an insulating substrate, can bridge sensory systems to biological tissue with robust seamless interaction without infection of tissues. The sensory systems integrated to soft bridging materials (hydrogel) consist of strain sensors (directly printed micro-capsules of EGaIn on an anti-swelling hydrogel substrate) and multi-array electromyography (EMG) sensors (Ti/Au) on structurally engineered ferris wheel-shaped islets that can make it possible to collect tissue information during repetitive micturition of overactive bladder. On the OAB induced rat, stronger signals (change in resistance and EMG root-mean-square) were detected near intra-bladder pressure maxima, thus showing correlation to bladder activity. Moreover, using robot-assisted laparoscopic surgery, the hydrogel-based implantable sensor was placed onto the bladder of an anesthetized pig. During micturition cycle, bladder strain and EMG were monitored. These results confirm that our proposed sensor is a highly feasible, clinically relevant implantable device for continuous monitoring OAB for diagnosis and treatment.

Highly Stretchable Hydrogel Fiber Fabricated by a Self-Coiling Mechanism Maintaining High Water-Content Tao Li and Seon Jeong Kim; Hanyang University, Korea (the Republic of)

Hydrogels, which are polymer networks dispersed in water, are widely used in biomedical fields, among others, because of their excellent mass transfer efficiency and biocompatibility. However, hydrogels with

a high water content usually have poor mechanical properties and are easily broken. To address this issue, many researchers have incorporated one or more complementary materials into the polymer network of the hydrogel to limit its swelling. Although this method enhances the mechanical properties of hydrogels, it also limits the water content; therefore this method cannot be applied to improve the mechanical properties of high-water-content hydrogels. We have observed that a jellyfish called *Physalia physalis* preys on fish through its coiled stinging tentacles. Although the body of *P. physalis* has a water content above 95%, the coiled structure still provides high stretchability. In this study, we developed a coiled hydrophilic polyurethane hydrogel fiber with high stretchability and high water content by mimicking the coiled stinging tentacles of *P. physalis*. Dry hydrophilic polyurethane yarns produced by electrospinning were twisted under an applied load. When the twisted dry hydrophilic polyurethane yarn swelled with water, the change in Young's modulus and shear modulus elicited self-coiling within 1 s and resulted in a coiled hydrophilic polyurethane hydrogel fiber. The morphology of the formed coiled polyurethane hydrogel fibers can be tuned by adjusting the twist density and the stress resulting from the load applied during swelling. Compared with non-coiled hydrophilic polyurethane hydrogel fibers, the coiled hydrophilic polyurethane hydrogel fibers prepared by this method exhibited ultrahigh stretchability due to the coiled structure and elasticity of the material. When the coiled hydrophilic polyurethane hydrogel fibers are stretched, the uncoiling of the coiled structure provides stretchability, and the fibers can be further stretched due to the elasticity of the hydrophilic polyurethane hydrogel. In summary, we developed a coiled hydrophilic polyurethane hydrogel fiber that can rapidly swell and self-coil under aqueous conditions and possesses high stretchability, while maintaining high water content. It is expected to be used in biomedical fields for applications such as surgical sutures, drug delivery systems, and tissue regeneration.

Controllable Actuator by Reversible Clustering Transition Composed of Temperature-Responsive Hydrogel Jiseong Choi and Seongmin Kang; Chungnam National University, Korea (the Republic of)

Hydrogel-based soft actuators, which can change their shape according to the various environment and has safe for the human body, are being utilized in various fields such as smart windows, etc. Among the hydrogels, N-isopropylacrylamide (NIPAm), due to its swelling characteristics dependent on the critical solution temperature (32 degree), can be used as a suitable actuator for different situations. Additionally, micropillars with high aspect ratio easily are transformed to clustering state under external forces, and both their original state and clustering state are being utilized as actuators. However, micropillars of clustering state once do not naturally de-clustered, having limitation of application by its non-reversible property of clustering state. In this paper, we fabricate micropillars actuator of a reversible clustering transition composed of thermo-responsive poly(NIPAm-co-acrylamide) hydrogels, verifying the potential applications of soft actuators. The actuator is clustered due to the decrease in mechanical properties of hydrogels by water, but it is de-clustered due to the increase in mechanical properties by hot temperature. Based on this phenomenon, we demonstrated the potential applications of micro grippers for capturing and transporting micro particles in water, as well as smart windows capable of reversible transitions in surface transmittance outside the water.

An Efficient Self-Healable and Recyclable Conductive Polymeric Blend with Excellent Mechanical Properties Based on PEDOT:PSS/PU Jinsil Kim and Fabio Cicoira; Polytechnique Montreal, Canada

Self-healable conductive polymers have been attracting attention because of the promising advances in

electronic devices. Self-healable and conductive coating films are fabricated by blending a conductive polymer, poly (3,4-ethylenedioxythiophene): poly (styrene sulfonate) (PEDOT:PSS) with polyurethane (PU) having excellent mechanical properties. PEDOT:PSS/PU composites are characterized in terms of self-healing properties, recyclable properties, mechanical properties and electrical properties in this study. Polyurethane (PU) is synthesized by reacting with macro diol as a soft segment, isocyanate groups and extender as a hard segment. The two polymers have no noticeable phase separation in blending solutions. The self-healable coating materials exhibit outstanding self-healing capabilities and fast self-healing kinetics and therefore can be used for practical applications like flexible and stretchable electronic devices. The polymeric coating film is cut into two parts completely with a sharp blade then the damaged surfaces are connected under mild temperature for the healing process. The results from experiments exhibit using a mechanical tester to compare the mechanical properties of various compositions of PEDOT:PSS/PU and before and after self-healing processes, respectively. Regarding electrical performance, a cyclic tensile test is also performed to monitor the elasticity. The electrical conductivity maintains constant electrical conductivity under cyclic tensile stress when tensile stress is loaded up to 30% strain. The PEDOT:PSS/PU-based can be reused, improving the sustainability of electronic devices. All these results revealed that PEDOT:PSS/PU have the potential to enable to development of more sustainable and durable electronic devices by reducing electronic waste and improving the lifespan of electronic components.

8:00 PM SB04.03.10

Designing Azo-Based Color-Changing Hydrogels by Sensing pH Response Wei-Ting Chang, Violet Pratt, Neel Joshi and Leila Deravi; Northeastern University, United States

The wide applications for environmental sensing and responsible sensing materials using hydrogels can be excellent candidates across systems in biology. For instance, most living cells elicit pH changes during metabolism which we leverage as an actuator in the design of new pH-responsive hydrogels. We synthesized azo-based monomers from anthranilic acid and followed by azo coupling by the treatment of phenylpiperazine and acyl amide. These monomers can then be polymerized with bis-acrylamide, acrylic acid, and polyacrylamide as an adaptive hydrogel that change shape and color different pH environments. Applications of these gels are explored both with and without cells in different environments.

8:00 PM SB04.03.12

Hydrogel-Enhanced Supported Lipid Bilayers (SLBs) Offer Greater Stability and Functionality in Bioelectronic Devices Jordan P. Fitzgerald, Zhongmou Chao and Susan Daniel; Cornell University, United States

Supported lipid bilayers (SLBs) have emerged as an indispensable material to functionalize the surface of bioelectronic sensors that facilitates the exploration of cellular membrane interactions with a wide range of molecules. SLBs accurately mimic the structure, composition, and diffusive properties of natural membranes, providing a biomimetic experimental model. Particularly noteworthy is the compatibility of SLB bioelectronics with electrochemical impedance spectroscopy (EIS), allowing for real-time monitoring of changes in impedance across SLBs. Such measurements provide valuable insights into changes in membrane properties, drug interactions, and the behavior of embedded proteins and channels. However, one drawback of these sensors currently is their vulnerability and limited shelf-life that impedes their broader application.

In this study, we combine hydrogels with SLB bioelectronic devices and show that the usable shelf-life of these devices can be extended significantly. Our approach exploits a range of hydrogels, each with unique

characteristics that enhance system versatility. PEGDA, a UV crosslinked hydrogel, enhances the stability of both model POPC SLBs and native component SLBs. Other hydrogels, such as poloxamer based thermally reversible gel, and chitosan based chemically crosslinked gels, show potential for preserving UV- and temperature-sensitive components within the SLBs. Overall, this strategy extends the shelf life of the SLBs from a single day over 45 days, all while preserving the electrical signal integrity and functionality of proteins within the SLBs. This hydrogel-enhanced approach not only facilitates longer sensing periods, but also enables the long-distance shipping of functional SLB-based devices, necessary steps for translation to the field.

In addition to enhancing the shelf life and stability of the SLB-functionalized bioelectronic devices, the integration of hydrogels also boosts their functionality. The hydrogel layer not only facilitates improved stability but also enables the use of cell-free expression of proteins directly into the membrane. This expands the utility of our method, creating opportunities for more comprehensive investigations into the behavior of specific proteins and their responses to various agents within a highly stable, extended-lifespan SLB-based bioelectronic system. This research lays the groundwork for the development of sophisticated hydrogel-enhanced SLB systems capable of operating in complex environments, bringing us closer to the construction of advanced devices such as electrode arrays, sensors, and biomimetic devices, and expanding the scope of bioelectronic applications in biomedical research and beyond.

8:00 PM SB04.03.13

Thermo-Responsive Emulsion-Embedded Hydrogel Microparticle and Its Application to RT-qPCR
Seoyoung Lee, Lan Kyeong Yoon, Seungwon Jung and Sang Kyung Kim; Korea Institute of Science and Technology (KIST), Korea (the Republic of)

Water-oil-water double emulsions (DEs) have been widely used as compartmentalized systems to encapsulate components for controllable and targeted reagent delivery. The components encapsulated in DE could be efficiently released upon various stimuli, such as changes in temperature, light, and chemical environment. Among them, by utilizing the heating as a controllable release stimulus, we herein developed a novel thermo-responsive DE-embedded hydrogel microparticle reactor suitably applicable for one-step quantitative reverse transcription polymerase chain reaction (RT-qPCR), which minimizes the non-specific reaction in the reverse transcription step. For this strategy, we encapsulated target-specific nucleic acid reagents (PCR primers and probes) in DE and subsequently entrapped DE in a micro-sized hydrogel PCR reactor. First of all, we adjusted the surfactant concentrations of DE for enhancing the DNA encapsulation efficiency and optimizing the DNA release efficiency to be maximized in the PCR denaturation step (95 °C) as well as minimized in the reverse transcription step (55 °C). From the perspective of DE itself, DNA encapsulation and release efficiencies at both 95 °C and 55 °C increased and decreased, respectively, with increasing concentrations of hydrophobic surfactant, while they were independent of hydrophilic surfactant concentrations. Moreover, we also investigated the change in DNA release tendency and optimized the surfactant concentrations when DEs were embedded in hydrogel microparticles. As a result, and importantly, the DNA release efficiency of DE entrapped in hydrogel significantly increased about 4 times at 95 °C compared to that of DE itself, indicating that the DEs individually located within the hydrogel are more vulnerable to the release of DNA-encapsulated inner water phases. In addition, 8 CMC of hydrophobic surfactant and 37.5 CMC of hydrophilic surfactant were selected as the optimal conditions where 4.6 µM of DNA reagent was encapsulated, and 40% (1.80 µM) and 9% (0.15 µM) of reagent were released at 95 °C and 55 °C, respectively, demonstrating target-specific reagent delivery on demand. Consequently, under these conditions, we successfully confirmed the operation of one-step RT-qPCR in the thermo-responsive DE-embedded hydrogel microparticle and the developed hydrogel microparticle could be utilized as a powerful point-of-

care testing platform for the multiplexed detection of several RNA biomarkers.

8:00 PM SB04.03.14

Nanoemulsions-Containing Hydrogel Microparticle Array PCR for Multiplex Discrimination of SARS-CoV-2 Variants Yoon-ha Jang, Eui Ju Jeon, Seoyoung Lee, So Young Jeon, Lan Kyeong Yoon, Seungwon Jung and Sang Kyung Kim; Korea Institute of Science and Technology (KIST), Korea (the Republic of)

Over time, viruses continually produce new genetic variants of themselves. Surveillance is needed to investigate how mutations in viruses affect the transmissibility and lethality of the virus as well as responses against therapeutic medicines [1]. However, whole genome sequencing, which is currently utilized for variant identification, has a limitation in testing a large number of samples, especially in a pandemic situation. Herein, we present rapid multiplex RT-qPCR for SARS-CoV-2 variant discrimination using the TaqMan probe and primer-incorporated network (TaqPIN). TaqPIN is a hydrogel microparticle where target-specific reagents such as primers and probes are preloaded as encapsulated in nanoemulsions [2]. The main challenge is to fabricate TaqPIN because the photoinitiators (PIs) required for curing hydrogel destabilize nanoemulsions and damage the fluorescently labeled probes encapsulated within the nanoemulsion. We found that free radicals generated by PIs damage the probes encapsulated within the nanoemulsions via the infiltration of PIs into the nanoemulsions. We successfully fabricated TaqPIN by using water-dispersible nanoparticles of 2,4,6-trimethylbenzoyl-diphenylphosphine oxide (TPO) as PIs. We found that fluorescently labeled DNA was well retained in the hydrogel particles even when TaqPIN was subjected to strong agitation, and TaqPIN PCR with the same concentration of sample showed constant Ct values up to 2 months. Finally, we constituted a 9-plex TaqPIN array for the identification of five SARS-CoV-2 variants of concern, including alpha (B.1.1.7), beta (B.1.351), gamma (P.1), delta (B.1.617.2), and omicron (BA.1), and the original Wuhan strain within 40 min. From 76 clinical nasal swab samples, the TaqPIN array RT-qPCR successfully discriminated variants with 95.5% sensitivity and 100% specificity. We envision that the TaqPIN array RT-qPCR can be applied to simple diagnostics to help detect and characterize circulating pathogens.

8:00 PM SB04.03.15

Towards Multi-Responsive Pluronic F127-Based Copolymer Hydrogels for Engineering Living Materials Henrique Sepulveda Del Rio Hamacek¹, LeAnn Le², Petri-Jaan Lahtvee¹, Rahul Kumar¹ and Alshakim Nelson²; ¹Tallinn University of Technology, Estonia; ²University of Washington, United States

Engineered living materials (ELMs) are dynamic systems featuring capabilities such as biosynthesis, self-organization, and self-healing¹. Integrating polymeric matrices (abiotic) and cellular (biotic) components creates materials with novel functionalities and precise responsiveness². Here, we deployed additive manufacturing using extrusion-based 3D printing to develop hydrogels capable of retaining cells for longer periods due to increased toughness, while facilitating better nutrient transport to the cells through improved ionic conductivity.

Initially, we formulated hydrogels containing Pluronic F127-bisurethane methacrylate (F127-BUM), methacrylic acid (MAA), and dimethylaminoethyl acrylate (DMAEA) at different monomer concentrations. We characterized the rheological and mechanical properties of these hydrogels. Rheological results revealed that all hydrogel compositions decreased viscosity with increasing shear rate while maintaining their shear-thinning properties even after multiple cycles of applied shear. These results indicate the potential for creating high-resolution 3D-printed structures. Additionally, temperature ramp experiments demonstrated that the hydrogels exhibited the characteristic Pluronic F127 temperature-

dependent behavior³, with decreased gelation temperatures upon MAA and DMAEA addition to the precursor mixtures.

Subsequently, tensile mechanical tests were conducted to evaluate the toughness and elasticity of the newly developed hydrogels. The results showed that the hydrogel composition with equimolar concentrations of MAA and DMAEA exhibited a 50% increase in elongation at break compared to control hydrogels consisting solely of F127-BUM. This material could also be elongated up to 600% of its original size, while the modulus of elasticity decreased by 35% compared to the control. These effects were attributed to the disruption of electrostatic interactions between MAA and DMAEA, which carry opposite charges at neutral pH. The formulated hydrogels demonstrated the necessary mechanical properties for cell-loading applications.

Finally, we loaded bakers' yeast (10^7 cells/g of hydrogel) into the selected hydrogels and analyzed their viability, metabolite production, and morphology during cultivation at 50 rpm and 30 °C. The hydrogel with MAA and DMAEA enabled cell retention for longer than previously reported for F127-BUM hydrogels with the same initial cell concentration⁴. Additionally, the cells remained metabolically active throughout the cultivation experiments.

In conclusion, this work demonstrates the potential of the developed hydrogel platform, featuring enhanced mechanical properties and improved ionic conductivity, for the additive manufacturing of ELMs. This platform holds promise for applications in bioengineering and highlights the importance of advanced materials in creating functional ELMs with enhanced capabilities.

Molecular Dynamics Simulation of Free-Formed Nanocomposite Hydrogels Emily Sun¹, Shoumik Saha², Jose Nicasio², Dilip Gersappe² and Miriam Rafailovich²; ¹Westford Academy, United States; ²Stony Brook University, The State University of New York, United States

Hydrogels are crosslinked polymer networks that can absorb and retain large quantities of water within their structures. Typically made of hydrophilic polymers, their swelling ability gives these materials properties of both solids and liquids alike. Recent studies highlight that combining hydrogel materials with clay-based nanofillers and charged solvents results in a hydrogel with enhanced properties. However, little is known about the theoretical mechanism of the gel's network formation. Here, we explore a system of free-floating polymer chains, clay-based nanofillers, and solvent to determine the specific conditions for a stable network formation, and optimal rheology of the gel. The aim of this study is to produce the strongest hydrogel, which can then be used for soil-strengthening applications.

We performed coarse-grained molecular dynamics with the LAMMPS software. Our polymer chains were constructed using the Kremer-Grest model, which defines bond interaction via the finitely extensible

Updated as of October 28, 2024

nonlinear elastic (FENE) potential. Other pairwise interactions between monomers were modeled by using the simple 12-6 Lennard Jones potential. We implemented this model for different polymer concentrations of $N=300$, 600 , and 900 , with varying distributions for their attractive regions, or “stickers,” which were placed uniformly every 5th, 9th, and 14th monomers (5, 3, and 2 stickers). We turned on attractive interaction between stickers, which let polymer chains connect to undergo network formation. The polymers’ dynamics were calculated through diffusion coefficients, gathered from mean-squared-displacement (MSD) values. We calculated stress auto-correlation (SAC) to determine the point at which our system forms a gel. We further ran shearing tests and polymer chain orientation during the shearing process will determine the specific shear thinning properties of our system. Our results show that by proper choice of polymer architecture we can design networks that can be used for soil amendment purposes.

Utilizing Bioprinting for Hydrogel-Based Electric Double-Layer Capacitor Fabrication Bianca Seufert and Arash Takshi; University of South Florida, United States

While electric vehicles are slowly bringing in a new era of eco-friendly transportation, the mass production and use of Li batteries have raised serious concerns about their impacts on the environment. Hence, supercapacitors that are able to be charged and discharged at high rates with high power densities and a long cycling stability are potential alternatives to batteries. There are three different types of supercapacitors: electric double-layer capacitors (EDLC) supercapacitors, pseudo-supercapacitors, and hybrid-supercapacitor. For the scope of this paper, however, only EDLCs will be discussed. Using biocompatible materials, supercapacitors are a viable charge storage device for implantable electronic sensors. This paper addresses a new approach to supercapacitor fabrication using a bioprinting method. A series of experiments were conducted to derive a conductive bioink capable of being implemented as a viable material for energy storage devices. This bioink in conjunction with a gel electrolyte were utilized for the fabrication of supercapacitors in a planar structure. This study utilizes the testing methods of Cyclic voltammetry (CV) and electrochemical impedance spectroscopy (EIS) using the VersaStat 4 Potentiostat to measure the capacitor response. Devices with capacitances as high as $53.52 \mu\text{F}$ were fabricated and tested. The results of this study show the feasibility of using the bioprinting method for fabricating prototype storage devices.

Turgor Pressure Reinforces Mineral-Based Composites Ran Zhao and Esther Amstad; École Polytechnique Fédérale de Lausanne, Switzerland

Nature fabricates hard functional materials from soft organic scaffolds that are mineralized. To overcome the brittleness of inorganic components, biominerals are arranged in hierarchical structures and sometimes develop local compressive or tensile stresses. For example, the precipitation of hydroxyapatite minerals leads to contractile stresses in collagen fibrils, and eventually reinforces mechanical properties of bones ^[1]. The fibril contraction comes from the dehydration of the polymer matrix, even though it happens in a hydrated environment. Similarly in plant cells, osmotic pressure is used to stiffen leaves by exploiting a strong turgor pressure ^[2]. Osmotic pressure is well-known to change the mechanical properties of living biological materials. Nevertheless, this strategy has thus far not been leveraged in mineral-based composites. This shortcoming might in part be related to the inferior mechanical behavior of synthetic composites compared to natural counterparts due to the limited structural control over different length scales.

Here, we demonstrate a mineral-based composite whose strength and stiffness can be repeatably adjusted through osmotic pressure driven swelling and de-swelling of confined hydrogels. Specifically, we employ a synthetic porous matrix with a similar degree of structural control from the nanometer up to the centimeter length scale made from an emulsion-based, 3D printable ink ^[3]. Those pores in the matrix are back-filled with a hydrogel, which can generate internal compressive or tensile stresses triggered by osmotic pressure gradients. The matrix can selectively bind certain cations such as Ca^{2+} ions, which can serve as mineralization sites upon addition of CO_3^{2-} . The hydrogel contractions induced through the mineral precipitations and osmotic pressure gradients lead to a synergetic control over the mechanics of the composite. This work provides an exciting concept for enhancing mechanical properties of mineral-based composites through turgor pressure similar to biological systems, which can be used as soft actuators or intelligent devices for underwater applications.

Nanoengineered Ink for Designing 3D Printable Flexible Bioelectronics Akhilesh K. Gaharwar; Texas A&M University, United States

Flexible electronics require elastomeric and conductive biointerfaces with native tissue-like mechanical properties. The conventional approaches to engineer such a biointerface often utilize conductive nanomaterials in combination with polymeric hydrogels that are crosslinked using toxic photo-initiators. Moreover, these systems frequently demonstrate low signal accuracy, poor biocompatibility and face trade-offs between conductivity and mechanical stiffness under physiological conditions. To address these challenges, we introduce a class of shear-thinning hydrogels as biomaterial inks for 3D printing of flexible bioelectronics. These hydrogels are engineered through a facile vacancy-driven gelation of MoS_2 nanosheets and naturally derived polymer. Due to shear-thinning properties, these nanoengineered hydrogels can be printed into complex shapes that can respond to mechanical deformation. The chemically crosslinked nanoengineered hydrogels demonstrate twenty-fold rise in compressive moduli and can withstand up to 80% strain without permanent deformation, meeting human anatomical

flexibility. The nanoengineered network exhibits high conductivity, compressive modulus, pseudo-capacitance and biocompatibility. The 3D printed crosslinked structure demonstrate excellent strain sensitivity and can be used as wearable electronics to detect various motion dynamics. Overall, the results suggest that these nanoengineered hydrogels offer superior mechanical, electrical, and biological characteristics for various emerging biomedical applications including 3D printed flexible biosensors, actuators, optoelectronics, and therapeutic delivery devices.

9:00 AM *SB04.04.03

Conducting Polymer Hydrogels for Hydrogel Bioelectronics Hyunwoo Yuk; SanaHeal, Inc., United States

Electrical interfacing with biological tissues for interrogation and modulation of living systems – or bioelectronics – is one of the most important modes of communication between artificial machines and biological organisms. In conventional applications, bioelectronic interfacing has relied on conventional electrodes and devices made of metals and engineering solids like plastics and elastomers. However, the stark dissimilarity between biological tissues and conventional device materials has posed great challenges for long-term bioelectronic interfacing with living systems, especially for implantable devices. To address these challenges, electrically conductive hydrogels – polymer networks infiltrated with large amounts of water with electrical conductivity – have been substantially studied in the last decades owing to their unique advantages including tissue-like mechanical properties and high water contents, favorable electrical properties, and in vivo biocompatibility. However, conducting polymer hydrogels has faced several key challenges in their practical uses including poor electrical and mechanical properties in physiological environments, unreliable integration within devices and to the target biological tissue, and difficulties in small-scale fabrications into functional devices. In this talk, several advances in conducting polymer hydrogels to address these challenges will be discussed toward the vision of hydrogel bioelectronics.

9:30 AM SB04.04.04

Skin-printable, Self-adhesive and Bio-based Hydrogel for the Bioelectronic Interface Jia Xi Chen¹, Yi Xin Zhang¹, Terek Li¹, Zia Saadatnia¹, Milos Popovic^{2,1} and Hani Naguib^{1,1}; ¹University of Toronto, Canada; ²University Health Network, Canada

Inspired by the customizability of injectable hydrogels in the medical field as cell cultures and engineered tissues, a conductive and 3D-printable hydrogel based on bio-polymers is developed to interface between the skin and medical devices during rehabilitation treatments of surface functional electrical stimulation (sFES). The sFES treatment involves delivering electric currents through the skin to induce muscle contraction, with clinical evidence supporting the ability of sFES treatments to restore voluntary motor functions in previously paralyzed patients. However, physiological differences in muscle distribution and body curvatures among individuals require sFES treatments to be personalized. Therefore, to increase the accessibility of sFES rehabilitations by enabling remote sessions and shape-configurable electrodes universal to all patients, the authors developed a novel material capable of being adapted to any shape and size, with self-adhesive and electrically conductive properties to ensure conformity to body morphology and to guarantee sFES signal stability. As the electrodes are single-use, the hydrogel is made from naturally occurring, biocompatible, and eco-friendly polymers that are easy to fabricate and process. Carboxymethyl cellulose is adopted as the matrix for its water solubility and mechanical properties, along with poly(3,4-ethylene-dioxythiophene) polystyrene sulfonate (PEDOT:PSS) as the conductive additive and mussel-inspired polydopamine as the adhesive additive. A mild and biocompatible gelation method

exploiting hydrogen bonding is implemented by adding phytic acid, with *in situ* formation of the extruded hydrogel taking place minutes after being 3D-printed onto the skin. The gelation process is examined with FTIR spectroscopy, which confirms the molecular interactions between bio-polymer components, scanning electron microscopy, which ensures the macroscopic morphology of the formed hydrogel, and rheological measurements over time, which characterizes the printability of the precursor ink. The pre-gel solution exhibits tailorable viscosity, allowing for facile processability and shape-configurability. Adhesive and electrical properties of the hydrogel are studied in contact with porcine skin over time. Although the self-adhesion of the hydrogel is two folds lower than commercial tissue adhesives, the interfacial electrical impedance is improved by an order of magnitude compared to commercial hydrogel electrodes. The sFES performance of the printable and conductive hydrogel is further assessed with a developed handheld 3D printer, a lightweight instrument to extrude the hydrogel ink in uniformly deposited layers with shape fidelity of mm-thick resolutions. Compared to conventional sFES electrodes of both hydrogel and metal-electrolyte gel systems, the printable hydrogel electrodes can induce muscle movement during sFES with better precision and accuracy, improving the efficiency by 10% when stimulating eye closure to the orbicularis oculi muscle. The printable and conductive hydrogel created for wearable purposes may be adapted for other applications involving bi-directional communications of electric signals across the bioelectronic interface, such as surface electromyography and surface electrocardiography.

9:45 AM SB04.04.05

PEDOT:PSS Hydrogel Based Wearable Biosensor Utilizing Aerosol Jet Printed Organic Electrochemical Transistors (OECTs) for Lactate Detection Yuchen Shao¹, Luiz Marcelo², Lixin Zhang¹, Manisha Gupta¹ and Dipanjan Nandi¹; ¹University of Alberta, Canada; ²Monterrey Institute of Technology and Higher Education, Mexico

Poly (3,4-ethylenedioxythiophene) doped with polystyrene sulfonate (PEDOT:PSS) is a conductive polymer with excellent electrical conductivity, good processability and biocompatibility. Hydrogels have the advantage of soft, flexible and non-toxicity with cells and tissues. A combination of PEDOT: PSS and a hydrogel offers unique conductivity and mechanical properties, applying an alternative approach for biosensing applications.

In this work, we developed a PEDOT:PSS hydrogel based 3D printed organic electrochemical transistor (OECT) for lactate sensing, since OECTs offer high transconductance, low operation voltage and compatibility with aqueous environments. Optomec Aerosol Jet 5X 3D printer is used to fabricate the biosensors on the flexible Kapton substrate. Au was chosen as the metal contact, Pt as the gate with polyimide as the insulator layer. PEDOT:PSS hydrogel is drop casted on Au as the channel material. For PEDOT:PSS hydrogel, it was synthesized by mixing with dimethyl sulfoxide (DSMO) to improve the conductivity under vigorous magnetic stirring for 24 hours, then drop-casted 0.2uL solution on top of the channel for a printed OECT device and was placed into the oven under 60°C for another 24 hours to generate the partially formed gel. After that, 3 times cyclic annealing was applied for the device for 30 minutes at 130°C. Finally, the device was put under -20°C for 12 hours and took out for extra 12 hours, repeating 2 times. The unfunctionalized device exhibits a transconductance up to 110 mS and is compared to the printed PEDOT:PSS based device. Further, tetrathiafulvalene (TTF), chitosan, lactate oxidase (LoX), bovine serum albumin (BSA) and gelatin help realize the functionalization of the device. The functionalized lactate sensor can be preserved in PBS solution under 4°C for over one month. Spike tests on the PEDOT hydrogel-based lactate sensor was performed and achieved a sensitivity range between 100uM and 10mM. In addition, the combination of the printed PEDOT:PSS channel with drop-casted

Stimuli-Responsive Polymers as Precursors to Conductive Hydrogels Laure V. Kayser; University of Delaware, United States

Electronically-conductive hydrogels, composites of crosslinked and water-swollen polymers with a conducting material (polymer or inorganic nanoparticles) can address the mechanical and electronic mismatch between electronic devices and biological systems. While several methods have been reported to prepare these conductive hydrogels, several issues have to be addressed to enable their translation in bioelectronics. These issues include: (1) the increase in elastic modulus at high loading of conducting material, (2) the irreversibility of the gelation mechanism, which complicates the delivery and potential removal of the conductive hydrogel in vivo, and (3) the difficulty in controlling the micro- and macro-structure of the conductive hydrogels for applications in tissue engineering and wearable electronics. In this talk, I will share our progress towards addressing these issues through the use of synthetic chemistry, particularly using novel stimuli-responsive conducting polymers. In the first part, I will discuss the use of thermo-responsive conducting polymers that displays a reversible sol-gel transition close to body temperature, thereby enabling injectable conductive hydrogels. The second part will be focused on achieving spatiotemporal control by using photo-active polymers to simultaneously photo-catalyze the polymerization of a conducting polymer and photo-crosslink its supporting matrix. This approach has great potential for 3D printing conductive hydrogels with a controlled microstructure and high resolution using light.

Programmable Materials, Structures and Devices for Next Generation Intelligent Machine Jiyun Kim; Ulsan National Institute of Science and Technology, Korea (the Republic of)

In recent times, virtual intelligence has made significant strides, reaching and even surpassing the functional and cognitive abilities of humans, owing to advancements in computing power and novel operational methodologies. Meanwhile, physical objects or machines in the real world strive to imitate the forms and functions of specific living organisms, such as humans, cheetahs, and octopuses. However, they still lag behind in terms of intelligent and adaptive functions, necessitating the exploration of innovative mechanisms and approaches.

Therefore, our research group aims to develop an integrated robotic platform that possesses the ability to program its morphology, physical properties, interface, and function. This robotic paradigm requires

innovation at all levels of the system, including materials, components, architectures for their integration, manufacturing processes, data processing, and operation. In this talk, I will introduce research categories and recent research outcomes from our group. These include (1) the development of programmable robotic components using smart materials such as multifunctional 3D sensors, soft tensile valves, digital metamaterial, and soft end effectors, (2) the exploration of novel algorithmic architecture including tensegrity, lattice metamaterial, and folding-based structures, (3) the exploitation of manufacturing methods realizing the architectures and functions including intuitive pen-drawing and 3D/4D printing, and (4) the excavation of machine design and operation methodology using artificial intelligence for shape-shifting task, in-situ function programming, and robot/HMI device design and operation. Through these works, we aim to blur the boundaries between the virtual and tangible world and, more importantly, between humans and the environment, thereby sharing our vision for the future physical environment for humans.

11:30 AM SB04.05.03

Highly Transparent Conducting Ionic Hydrogels of Double Network Structure for Deformable Electronics Jinhwan Yoon; Pusan National University, Korea (the Republic of)

Highly deformable soft electrodes have garnered significant attention due to their potential to drive innovation in wearable electronics and soft robotics. To render the soft electrodes, stretchable, conductive, and transparent polymer networks have been studied extensively, but fulfilling these requirements remains challenging. In this work, we developed double-network ionic hydrogels of high transparency and stretchability due to the finely tuned network structure and transparent electrolyte. Based on the high performance of the ionic hydrogels, electroluminescent devices were achieved with an inorganic phosphor emission layer, which exhibits high luminance under extreme deformation. The remarkable transparency of the ionic hydrogels further enabled the fabrication of novel electroluminescent devices of tandem structures, allowing color variation by independent control of each emission layer.

Repeatably Autonomously Self-Healing Ultra-Stretchable PAAMPSA/PANI/PA Conductive Polymer Complex as Strain Sensor Colton Duprey¹, Yang Lu² and Evan K. Wujcik¹; ¹University of Maine, United States; ²Georgia Institute of Technology, United States

Wearable strain sensors should be comfortably adhered to the skin and capable of monitoring human motions with high accuracy/sensitivity while remaining robust with excellent durability/longevity. However, it is challenging to develop electronic materials that possess the properties of skin—compliant, elastic, stretchable, and self-healable while also having a high enough conductivity for adequate sensitivity. This work demonstrates a new regenerative polymer complex composed of poly(2-acrylamido-2-methyl-1-propanesulfonic acid), polyaniline, and phytic acid as a skin-like electronic material. The type-2 (zip) templated polymerization of aniline in the presence of poly(2-acrylamido-2-methyl-1-propanesulfonic acid) with phytic acid as a P-type dopant exhibits ultrahigh stretchability (1935%), repeatable autonomous self-healing ability (repeating healing efficiency >98%), quadratic response to strain ($R^2 > 0.9998$), and linear response to flexion bending ($R^2 > 0.9994$), mechanically outperforming current reported wearable strain sensors. Sensitive strain-responsive geometric and piezoresistive mechanisms of the material owing to the homogeneous and viscoelastic nature provide excellent linear responses to omnidirectional tensile strain and bending deformations. Furthermore, this material is scalable and simple to process in an environmentally friendly manner, paving the way for the next-

generation flexible electronics.

All-Aqueous Hierarchical Hydrogels for Microfluidics Anderson Shum^{1,2} and Yafeng Yu¹; ¹University of Hong Kong, Hong Kong; ²Advanced Biomedical Instrumentation Centre, Hong Kong

Hydrogels have demonstrated promising applications across fields, ranging from delivery of actives, to cell cultures, and to wound protection. Hydrogel designs have focused on the constituent molecules and molecular interactions via modifications of the molecular identities and structures. Hierarchical structures within the hydrogels can also be manipulated by structuring the precursor solution before hydrogel formation. The precursor solution can be directed via the use of microfluidic techniques, achieving underlying hydrogel architectures with different properties. Besides its use for designing and modifying hydrogels, microfluidic devices can also be made formed by hydrogels, rather than traditional elastomer-based materials. In this talk, I will share our works at the interface between hydrogels and microfluidics, and will discuss the potential functions and properties of the resultant hydrogels and microfluidic devices.

Acid-Crystallized PEDOT Nanoparticles: Scalable and Biocompatible Fillers for Highly Conductive Hydrogels Joshua Tropp and Jonathan Rivnay; Northwestern University, United States

Conductive hydrogels are widely used in bioelectronic applications due to their flexibility, biocompatibility, and conductivity. Conductive hydrogels have been leveraged to improve the biocompatibility of electrodes, act as transducing elements within biosensors, and as conductive scaffolds for cells to promote tissue regeneration. While the unique properties of conductive hydrogels make them a promising material for bioelectronics, achieving high conductivity while maintaining mechanical compliance remains a significant challenge. To meet these requirements, functional- π electron systems (conjugated polymers, carbon nanotubes, graphene, etc.) are typically dispersed within natural or synthetic biomaterials to afford conductive hydrogels. A significant challenge in the field remains the required high nanomaterial loadings to achieve significant conductivity; however, at such loadings the conductive hydrogels become prohibitively rigid for bioelectronic applications. Unlike 2D thin-film applications that leverage the long-range ordering of nanomaterials such as conjugated polymers to achieve significant charge percolation, the 3D, complex, and tortuous structure of hydrogels prevents such material alignment, creating a barrier toward highly conductive soft hydrogels. To overcome this limitation, PEDOT nanoparticles have been developed, which behave as three-dimensional seeds for charge percolation throughout the hydrogel. By carefully controlling nanoparticle surface chemistry and morphology via acid treatment, dispersible and highly conductive particles were afforded. Unlike other carbon nanomaterial fillers, the intrinsic dispersibility of the PEDOT nanoparticles enabled direct incorporation within hydrogels at high loadings ($> 100 \text{ mg mL}^{-1}$ of precursor), as well as deposition via spray coating and 3D printing without added surfactant or chemical modification. Upon sufficient particle

loading, charge percolation is achieved throughout the hydrogel, affording organic gels with high conductivity ($> 1 \text{ S cm}^{-1}$) without deleterious hydrogel stiffening. PEDOT nanoparticles were incorporated within various synthetic and natural biomaterials, demonstrating compatibility with common crosslinking modalities (photopolymerization, ionic, thermal, Schiff base). The scalability, conductivity, and biocompatibility of the acid-crystallized PEDOT nanoparticles make them attractive fillers for hydrogels/biomaterials for bioelectronic applications.

2:15 PM SB04.06.03

From Conducting Hydrogel to Semiconducting Hydrogel Dingyao Liu, Yan Wang and Shiming Zhang; The University of Hong Kong, Hong Kong

Thin-film semiconductor-based devices have revolutionized the field of microelectronics. In the realm of biomedical applications, conducting hydrogels have rapidly gained prominence due to their mechanical and biocompatible nature with biological systems. The realization of semiconducting hydrogel materials holds significant value within the field of bioelectronics for developing advanced biologics[1]. Advancing towards flexible and stretchable semiconducting hydrogels can enable direct applications at the interface of soft biological systems [1].

However, the development of semiconducting hydrogels presents challenges, primarily due to the thin-film nature of semiconductors, which are generally less than 1 micrometer in thickness. In contrast, hydrogels tend to have greater thicknesses and struggle to achieve good semiconductor properties.

The advent of organic electrochemical transistors (OECTs) has introduced a new paradigm that can be a powerful testbed to evaluate the performance of a semiconducting hydrogel. In this report, we present the development of the PEDOT:PSS semiconducting hydrogel and its application in the development of OECTs [2]. Furthermore, we provide our insight on how to define a semiconducting hydrogel when using OECT as a testbed. Finally, we delve into the development of stretchable semiconducting hydrogels and explore how they can revolutionize applications in the field of biomedical research.

2:30 PM *SB04.06.04

Conducting Polymers Biointerfaces for Bioelectronics Jadranka Travas-Sejdic; University of Auckland, New Zealand

Conducting polymers (CPs) have been widely used as electroactive biointerfaces in applications such as electrically stimulated tissue engineering and flexible organic bioelectronics. In this talk, several different approaches to advanced electroactive biointerfaces based on conducting polymers will be presented. The first approach addresses the issue of poor solubility and processability of CP by functionalization of CPs with various moieties, and, in particular, by grafting of CP backbones with polymeric sidechains. That enables modification of optoelectronic, physical and mechanical properties of the CPs and their use as biomimetic biointerfaces, e.g. responsive to stimuli, intrinsically stretchable and self-healing[1]. The second approach addresses the issue that electrodes used in tissue recording and stimulation are commonly 2D and made of rigid conducting materials, and as such cannot adequately probe the actual 3D cell environment within tissues and/or have a significant mechanical mismatch with biological tissue. Our approach to overcome that is based on a precise fabrication of individually addressable, high aspect ratio,

soft and flexible 3D CP-pillar microelectrode arrays by means of 'direct 3D writing'. Such 3D microelectrode arrays could be employed in a variety of applications, from biological sensing to recording and electrically stimulating cells and tissues[2], with the array design easily adjustable.

The third approach to electrochemically addressable biointerfaces is based on flexible, microporous, electrochemically switchable membranes that can selectively and efficiently capture, and then non-destructively release, cancer biomarkers, such as cancer cells-shaded extracellular vesicles (EVs)[3] and rare cancer cells[4] The platform allows for the EVs and cells to be captured from large volumes of complex biological samples and released into clean and small volumes of buffers - suitable for further analysis, for example, for medical diagnostics.

Conductive Hydrogels for Multimodal Bioelectronic Interfaces Ivan Minev^{1,2,3}; ¹Leibniz Institute for Polymer Science, Germany; ²Technische Universität Dresden, Germany; ³The University of Sheffield, United Kingdom

Hydrogels are attracting attention as materials for bioelectronic implants because they may solve some long-standing challenges encountered at the tissue-electrode interface. This will require appropriate viscoelasticity, hydration, bioactivity and dual electronic-ionic conductivity. Apart from improved integration with brain tissue, hydrogels may enable electrodes with superior charge injection capacity and capability for neuromodulation beyond the electrical domain (e.g. using biomolecules).

In this talk I will present our efforts to combine Glycosaminoglycans and the conductive polymer PEDOT into interpenetrating network hydrogels that are soft, conductive and bioactive. The material system is highly tunable offering control over electrical and mechanical properties. Furthermore the hybrid material has enabled us to sequester and release small proteins such as growth factors. The release profiles can be electrically tuned. The released proteins are bioactive and can influence cells in culture.

With this work we aim to advance the possibility to engineer synthetic bioelectronic materials that emulate some aspects of the extracellular matrix and may enable applications in next-generation tissue-mimetic bio interfaces.

4:00 PM SB04.06.06

Conducting Polymer Hydrogels for Soft and 3D Bioelectronic Interfaces Alexandra Rutz;

Washington University in St. Louis, United States

Hydrogels are insoluble polymer networks swollen with water (>90% water by mass) and are used widely in biomedical applications for their similarities to native extracellular matrix. For bioelectronics, there are many efforts to build devices based on these materials to achieve tissue-matching stiffness and other tissue-inspired properties in order to improve the biointerface. For making electrodes and other device components based on semiconducting materials, conjugated polymers can be gelled into electronically conducting hydrogels. Such methods include simple mix-and-cast techniques, similar to other methods used widely in traditional (non-conducting) hydrogel processing. We have investigated conducting hydrogels based on the conjugated polymer poly(3,4-ethylenedioxythiophene) polystyrene sulfonate (PEDOT:PSS) fabricated by mixing in a gelling agent, ionic liquid. We have studied how the hydrogel precursor formulation and other fabrication variables of this method affect gel properties, such as swelling, conductivity, and elastic modulus. Further, we have evaluated the potential of these PEDOT:PSS hydrogels for biointerfacing applications and have found that these gels when processed appropriately are stable in vitro and support mammalian cell culture. Finally, we are developing these conducting polymer hydrogels for compatibility with additive manufacturing to grant structural control of these soft bioelectronic interfaces. Such techniques provide manipulation of dimensions and microporosity, important for assembling these hydrogels into functional devices and optimizing tissue integration.

4:15 PM SB04.06.07

Ultra-Soft Semiconducting Hydrogels for Tissue-Like Organic Electrochemical Transistors Yahao Dai

and Sihong Wang; University of Chicago, United States

The rapid development of wearable/implantable electronics over the past decade opens the next era of human-integrated biosensors in pursuit of higher sensitivity and more seamless tissue-electronics interfaces. Transistor, especially organic electrochemical transistor (OECT)-based biosensor has attracted considerable attention as an advanced biosensing platform due to their high built-in amplification and water-compatible operation. To achieve the intimate biointerface and acquire the biological signal with the highest possible accuracy, the most ideal approach is to prepare the semiconducting materials with tissue-level softness and stretchability, and directly interface with the tissue surface. However, so far no semiconducting material is able to provide modulus even close to the tissue level due to the general paradox that semiconductors rely on stronger intermolecular interactions to facilitate charge transport. In this research, we proposed a novel material design strategy for developing a gel-like semiconductor that is able to simultaneously provide low modulus, high stretchability/elasticity, and high hole mobility. This is achieved by incorporating a secondary hydrogel matrix into a semiconducting polymer network for enhancing the water uptake to soften the composite, and utilizing solvent treatment to form strong percolation between polymer semiconductors to resist the negative effect of swelling. We further use ultra-soft semiconductors to fabricate gel-like OECTs with desired mechanical and electrical performance for human integration, and demonstrate its capability as the advanced platform for biosensing applications.

4:30 PM SB04.06.08

Developing Multifunctional Hydrogels with Tissue-Like Properties for Improved Cell-Material Interfaces Christina M. Tringides^{1,2}, Blandine F. Clément¹, Marjolaine Boulingre¹, Vilijus Dranseika³,

David J. Mooney² and Janos Vörös¹; ¹ETH Zurich, Switzerland; ²Harvard University, United States; ³UZH, Switzerland

Biomaterial scaffolds have emerged as a tool to build 3D cultures of cells which better resemble biological systems, while advancements in bioelectronics have enabled the modulation of cell proliferation, differentiation, and migration. Here, we first describe a porous conductive hydrogel with the same mechanical modulus and viscoelasticity as neural tissue. Electrical conductivity is achieved by incorporating low amounts (<0.3% weight) of carbon nanomaterials in an alginate hydrogel matrix, and then freeze-drying to self-organize into highly porous networks. The mechanical and electrical properties of the material can be carefully tuned and used to modulate the growth and differentiation of neural progenitor cells (NPCs). With increasing hydrogel viscoelasticity and conductivity, we observe the formation of denser neurite networks and a higher degree of myelination. Similarly, fibroblasts can be incorporated into the scaffolds and cell migration can be modulated through the application of exogenous electrical stimulation, for applications to wound healing. To investigate the functionality of neural systems, both *in vitro* and *in vivo* platforms can be realized. By placing a polydimethylsiloxane (PDMS) microstructure on an underlying multielectrode array (MEA), we can then explore different materials and techniques to integrate hydrogels into the PDMS microstructures and can facilitate the growth of neuronal networks in 3D. Additionally, implantable surface electrode arrays can be fabricated, with the ability to record from the brain and heart with enhanced tissue conformability and minimal damage to the biological organs. The described biomaterial platforms can be used to investigate neuronal development and disease progression.

4:45 PM SB04.06.09

Superstrong Electronic Hydrogel Actuators (ECO) Mahiar M. Hamed; KTH, Sweden

Intelligent systems combine sensing, actuation, and computation to achieve complex tasks and functions. Soft electrically controlled multifunctional materials, especially hydrogels, are the most promising materials for such systems as they are as adaptable as biological systems yet compatible with advanced systems through electronics.

We describe an electroactive hydrogel fabricated from cellulose nanofibrils from trees, and conductive nanomaterials, like CNTs or 2D MXenes. These nanoparticles self-assemble into an anisotropic composite networks with an open mesoporous structure that can hold lots of water and be highly permeable to substances in their surroundings. The anisotropy of the network allows high expansion in one direction while maintaining very high strength and high electric conductivity in the other. The electrochemical charge/discharge of the conductors in the hydrogels controls the internal salt concentration and consequently their osmotic swelling. This allows direct electrically controlled actuation where around 700 water molecules expand/contract the structure for each ion/electron pair inserted/de-inserted at only ± 1 volt, resulting in up to 300% electroosmotic expansion, with very high pressures reaching 1 MPa.

This mode of electronic actuation has not been shown before. We call these electroosmotic (ECO) actuators. Our ECO hydrogel actuators have emergent properties not present in any previously known soft material. ECOs allow formonolithic integration of sensors and many other functions into the same composite, rendering a new form of smart soft material not achievable with other materials systems.

8:00 PM SB04.07.01

Long-Term Durable and Ultrasensitive Multiple-Crosslinked Ionic Hydrogel Sensors with Multi-Functions for Wearable Electronics Byeong Su Kang¹, Jin-Young Yu¹, Jeong Hun Kim² and Seongmin Kang¹; ¹Chungnam National University, Korea (the Republic of); ²Electronics and Telecommunications Research Institute, Korea (the Republic of)

Hydrogels are considered promising for wearable devices because they are soft, flexible, stretchable, and biocompatible. However, existing hydrogels suffer from poor strength, weak and one-time adhesion, non-self-recovery, water evaporation, ice crystallization, and low sensitivity, and these problems have been only partly solved previously. We propose the one-pot synthesis of a multiple-crosslinked poly(2-(methacryloyloxy)ethyl)dimethyl-(3-sulfopropyl)ammonium hydroxide-co-acrylamide (P(SBMA-co-AAm) multifunctional hydrogel to overcome these limitations. The synthetic route provided elasticity, self-healing, and transparency, and the incorporation of glycerol and NaCl ions provided moisture stability (e.g., water retention) and antifreeze properties. Zwitterionic SBMA contributed to the increased gauge factor, resulting in high sensitivity and an ability to detect human movements at a strain of 800%–1600%, making the hydrogel sensor practical. The sensor retained its properties after even 300 cycles, indicating its durability and reliability for long-term applications.

8:00 PM SB04.07.02

Multi-Crosslinked Hydrogel-Based Needle Structure Capacitance Sensor with High Sensitivity and Stability Byeongsu Kang¹, Jeong Hun Kim² and Seongmin Kang¹; ¹Chungnam National University, Korea (the Republic of); ²Electronics and Telecommunications Research Institute, Korea (the Republic of)

The hydrogel-based sensor has better elasticity than the existing elastomer sensor, so the distance between the two electrodes can be reduced. Also, since the amount of change in contact area is also large, the amount of change in capacitance is excellent. Especially, by adopting a micro needle structure that can maximize the change in contact area, the change in capacitance is increased. However, the previous hydrogel-based sensor lacks recipe research to create a structure, and adding a structure reduces stability and repeatability, limiting its application as a sensor. In this paper, poly(acrylamide-co-N, N'-methylenebisacrylamide) multifunctional hydrogel can overcome the aforementioned limitations. Then, by making a hydrogel-based sensor with a micro needle structure, high sensitivity is sought by adjusting the amount of N, N'-methylenebisacrylamide. In addition, by adding sodium dodecylbenzenesulfonate lauryl acrylate, the stability of the structure that does not interfere with sensitivity is increased. This hydrogel-based sensor is a human-friendly material that can be applied not only to the biomedical measurement field, but also to fields where existing elastomer sensors are applied, such as robots,

hydraulic pressure measurement, and aviation.

8:00 PM SB04.07.03

Robust Integration of Highly Conductive Hydrogels with Stretchable Electronics for Skin-Interfaced Bioelectronics Hyun Su Lee and Dae-Hyeong Kim; Seoul National University, Korea (the Republic of)

Skin-interfaced bioelectronics mounted on human skin has the potential to revolutionize next-generation medical diagnostics and healthcare. To achieve this goal, designing a compliant and stretchable device is highly desirable for device reliability and long-term user comfort. In the material aspect, the limitations of conventional functional device components that originate from rigid and obtrusive interfaces must be overcome by materials with intrinsic softness and stretchability. Conductive hydrogels that possess tissue-level softness owing to their water-rich nature, can be an alternative option. Generally, for the fabrication of hydrogel-based, skin-interfaced bioelectronics, a hydrogel film is cut and placed onto an electrode. However, during device operation, large amount of water inside the hydrogel film tends to form a slippery surface rather than a robust interface between human skin and electronic device. Such poor integration capability could cause the lack of reproducible device performances, difficulty to scale up, and the loss of intimate physical/electrical contacts, which leads to critical problems in signal sensing and electrical actuation from/to human tissue. Here, we suggest direct polymerization and in-situ chemical-integration of hydrogel onto stretchable electronics as a methodology for enhancing the hydrogel-device interface of skin-interfaced bioelectronics. Highly conductive functionalized hydrogels are polymerized inside stretchable wells placed on a multichannel electrode array. The hydrogels are stably immobilized to the electronic devices during fabrication, and the robust interface contributes to the reliable measurement of bio-signals and effective electrical actuation on tissues. The demonstration shows that the direct polymerization and in-situ chemical-integration of hydrogel are key steps towards the realization of practical skin-interface bioelectronics based on functionalized hydrogels.

8:00 PM SB04.07.04

Self-Healing Stretchable Li-Ion Battery Based on a High-Voltage Hydrogel Electrolyte Peisheng He¹, Jong Ha Park¹, Chao Fang¹, Anju Toor² and Liwei Lin¹; ¹University of California, Berkeley, United States; ²Georgia Institute of Technology, United States

Safe and deformable batteries that can be conformally embedded onto irregular surfaces of electrical systems and human body are desirable for wearable electronic applications due to low user friction. Commercial state-of-the-art Li-ion batteries are packaged in rigid hermetic sealing materials that are not deformable. State-of-the-art deformable Li-ion batteries reported in research articles show fast degradation due to severe performance problems such as the penetration of moisture and the leakage of toxic and inflammable electrolytes. Here we report a non-toxic, aqueous hydrogel electrolyte instead of its organic counterpart that is demonstrated to: 1) enable highly safe operations due to its non-toxic and non-flammable nature; 2) alleviate the moisture penetration problem from outside environment; (3) have a high-voltage working window of ~2.8V; and (4) allow the construction of stretchable batteries by using elastic polymer packaging materials instead of rigid hermetic seals. In the prototype tests, fabricated batteries have shown good stretchability (50% strain) and flexibility (radius of curvature < 2mm) to enable conformal attachments to a wide range of geometric surfaces. The prototype battery also shows outstanding cyclic stability, retaining ~90% of the original capacity after 100 cycles for over 2 months in the ambient environment without using any rigid hermetic sealing package. Finally, a prototype battery with a self-healing elastomer package remains functional after being punctured by a needle 5 times at

different locations through the package. Furthermore, it can recover >90% of its capacity after being cut through by a razor blade and subsequently healed at 70 for 10 minutes. Such safe and highly stretchable batteries would be useful for several wearable electronic applications such as blood glucose monitoring, heart rate monitoring, temperature monitoring, wireless charging, smart clothing, etc.

8:00 PM SB04.07.05

Highly Sensitive Flexible Sensors using Autonomously Self-Healable and Temperature-Tolerant Eutectogel Jinyoung Lee and Jeong Sook Ha; Korea University, Korea (the Republic of)

With the increased demand for advanced wearable electronics, hydrogel-based devices have attracted enormous attention. Hydrogels have many advantages such as excellent flexibility, biocompatibility, ionic conductivity, and self-healing property, adequate for wearable devices. On the other hand, hydrogel-based devices exhibit limit in the performance due to the freezing and evaporation of water in the polymer network at low and high temperatures, respectively. To address such a thermal instability issue, there has been extensive effort on replacing the water within the hydrogel network with ionic liquids of low vapor pressure and high ionic conductivity. However, most ionic liquids are expensive and toxic to hamper the practical application to wearable devices. Therefore, research on deep eutectic solvents, mixtures of two or more components characterized by significant depressions in melting points compared to their neat constituent components, has been recently activated. Deep eutectic solvents show properties similar to those of ionic liquids as well as additional advantages of low-cost, non-toxicity, biocompatibility, and biodegradability. Furthermore, eutectogels having polymer networks composed of deep eutectic solvents have demonstrated the high potential application to wearable devices.

In this paper, we report on the fabrication of resistive-type strain and pressure sensors based on newly synthesized autonomous self-healing and temperature-tolerant eutectogel. Our synthesized eutectogel is prepared by UV polymerization of acrylamide with trehalose and phytic acid as crosslinkers, and choline chloride, glycerol and a small amount of water as solvents. In addition to the inherent low melting point of deep eutectic solvent, inclusion of bio-derived trehalose and phytic acid makes abundant hydrogen bonding, resulting in improved anti-freezing and anti-drying properties. Also, the dynamic hydrogen bond interactions between the polymer network and trehalose, phytic acid, and glycerol endowed the eutectogel with self-healing properties. The synthesized eutectogel exhibits high stretchability (>300%), temperature-tolerance, and good self-healing efficiency (>90%) after 24 hours at room temperature. By incorporating conducting polymer onto the eutectogel, highly sensitive resistive-type strain and pressure sensors are fabricated for detecting bio-signals after attachment onto a finger or wrist. The eutectogel-based wearable sensors demonstrate stable signal detection over a wide temperature range even after repetitive self-healing, thereby expanding their potential application to wearable electronics with longevity under extreme conditions.

8:00 PM SB04.07.06

Topology-Based Dual Lock-and-Key Structures for Hydrogel Self-Assembly in Macroscopic Supramolecular Assembly Eunseok Heo, Hye Been Koo and Jae-Byum Chang; Korea Advanced Institute of Science and Technology, Korea (the Republic of)

Macroscopic supramolecular assembly (MSA), which refers to the assembly of building blocks at a macroscopic scale, holds great potential for the fabrication of ordered bulk structures. Thanks to the high design flexibility of the building blocks and the precise controllability of the assembly process, MSA has found applications in a wide range of fields, including the fabrication of tissue scaffolds, soft actuators, and more. Additionally, among the candidates for building blocks, hydrogels are highly favored due to

their easily tunable properties and diverse type with different characteristics. In MSA, two challenges need to be addressed to achieve a high level of assembly: enhancing the precision of assembly and increasing the number of orthogonally matching pairs. To date, despite numerous attempts, none have effectively tackled both challenges simultaneously. In this study, we introduce topology-based design criteria for achieving precise and selective self-assembly of hydrogel building blocks. We suggest a unique design approach termed “dual lock-and-key structures.” In this design model, only topologically matching pairs can be assembled with exceptional precision. Through the implementation of dual lock-and-key structures, we establish principles for the selection of multiple orthogonally matching pairs. We demonstrate the selective assembly of both simple one-to-one matching and complex one-to-many assemblies. Moreover, by harnessing the easy property tunability of hydrogel, we synthesize DNA-mimicking single-stranded structures, which hybridize into double-stranded structures with sequence-specific arrangements. Finally, we present a hydrogel logic gate system, consisting of a YES gate, an OR gate, and an AND gate. Utilizing the high selectivity of our dual lock-and-key structures, the desired outputs are exclusively obtained when the appropriate building blocks are assembled, following the logic of each gate: YES, OR, and AND.

Conducting Polymer Granular Hydrogel Bioinks for 3D Printed *In Vitro* Bioelectronic Devices

Anna P. Goestenkers, Tianran Liu, Somtochukwu S. Okafor, Lianna Friedman, Riley Alvarez and Alexandra Rutz; Washington University in St. Louis, United States

Conjugated polymers have recently been used in their hydrogel form for the creation of soft bioelectronics with improved cell interfacing and the potential for enhanced measurement and stimulation of cellular activities. Cell-encapsulating hydrogels offer a truly 3D culture environment and when designed appropriately can be used as bioinks for 3D printing which grants spatially controlled deposition of cells and materials simultaneously. We developed a bioink based on the conducting polymer poly(3,4-ethylene-dioxythiophene):polystyrene sulfonate (PEDOT:PSS) by creating a granular hydrogel form. Emulsion methodology was developed to fabricate PEDOT:PSS hydrogel microparticles (microgels) with high circularity and monodispersity. Filtration techniques were used to size select microgels with diameters between 10 and 60 μm . When centrifuged to remove significant water, the conducting polymer microgels achieved dense packing characteristic of a granular material state. Increasing centrifugal force decreased the void fraction of the material which increased conductivity. Rheological investigations confirmed shear-thinning and self-healing properties, both ideal for 3D bioprinting for extrusion and ability to keep shape, respectively. Granular PEDOT:PSS hydrogels were in fact 3D printable via pneumatic extrusion and formed various 3D configurations. Evaluation of the material's printability in the granular state also revealed that increased centrifugal force facilitated better printability as evidenced by increased maximum filament length and filament diameter better matching the chosen nozzle diameter. Structural stability of the material within an aqueous environment for up to three months was achieved using a collagen hydrogel overlay. Human dermal fibroblasts encapsulated and cultured within the granular hydrogel showed high cell viability over fourteen days demonstrating cytocompatibility. This developed conducting granular hydrogel bioink exhibits balanced properties of printability, conductivity, and cellular responses for the additive manufacturing of future in vitro bioelectronics.

Extracellular Matrix-Compatible Additive Manufacturing of Bioactive, Conducting Polymer

Hydrogel Electrodes Tianran Liu, Somtochukwu S. Okafor, Anna P. Goestenkers, Sandra Montgomery, Riley Alvarez and Alexandra Rutz; Washington University in St. Louis, United States

Hydrogels of conducting polymers provide a soft and hydrated alternative to metal for interfacing electronic devices with biological systems. To fabricate devices based on conducting polymer hydrogels, the material is often patterned alongside bioinert and stiff substrates such as plastics and elastomers which lead to poor cell-material interactions. In order to further promote device integration with cells and tissue, one strategy is to utilize bioactive materials, such as mammalian extracellular matrix (ECM) components, as the substrate material to present a tissue-like microenvironment to cells. However, traditional semiconductor manufacturing is anticipated to impair the bioactivity of these natural materials. Here, we demonstrate methods for mild temperature additive manufacturing of highly conducting poly(3,4-ethylenedioxythiophene) polystyrene sulfonate (PEDOT:PSS) hydrogels with collagen substrates. Various types and concentrations of gelation agents were investigated to enable sufficient working time after addition to colloidal dispersions and to result in a water-stable hydrogel network once fully crosslinked. Among gelation agents tested, ionic liquid was found to be suitable for extrusion-based printing while an acidic surfactant enabled deposition by jetting due to low surface tension and appropriate viscosity. After room temperature gelation and treatment, hydrated PEDOT:PSS prints exhibited conductivity as high as 37.2 S/cm and were stable in cell culture conditions for at least 28 days. To complete the device, a top layer was fabricated by casting a collagen slurry onto the PEDOT:PSS prints which had a sacrificial material deposited on top to protect the intended electrodes from coverage. Once the collagen layer formed, the sacrificial material was removed with 36 °C water, leaving an unaltered PEDOT:PSS surface for direct biointerfacing. Since the fabrication methods were developed with mild temperatures and processing, the structure and bioactivity of the collagen are believed to be maintained, as evidenced by the support of fibroblast culture that reached confluency and sustained high viability for 28 days. This methodology offers a promising strategy for rapid prototyping soft, hydrated, and bioactive electronic devices that support cell attachment and proliferation.

A Zwitterionic Hydrogel-Based Heterogeneous Fenton Catalyst for Efficient Degradation of Persistent Organic Pollutants Ian S. Chen, Devashish Gokhale and Patrick Doyle; Massachusetts Institute of Technology, United States

Persistent organic pollutants (POPs) are industrial, pharmaceutical, or commercial byproducts that are highly resistant to degradation and decomposition in the environment, while causing significant health and environmental damage even in small concentrations. Significant existing research aims at destroying the POPs in an environmentally safe and cost-effective manner, but challenges remain in destroying POPs at environmental concentrations in scalable and sustainable processes. Many current approaches to degrading POPs require extreme reagents and conditions. One promising candidate, however, for the removal of POPs is the photo-Fenton reaction, where iron(II) ions catalyze the decomposition of hydrogen peroxide, in the presence of UV light, into highly reactive hydroxyl radicals that readily attack organic compounds, including POPs. Fenton oxidation is promising because iron(II) and hydrogen peroxide are low-cost, environmentally-safe materials, and because the process can target a broad range of POPs.

However, the photo-Fenton reaction requires the presence of water-soluble iron(II) ions that are difficult to reuse. As such, methods that immobilize the iron as a catalyst can be constantly reused, while also eliminating the need for further treatment steps to remove iron from water before it can be used. Unfortunately, existing solutions require challenging reaction conditions; due to the higher efficiency of the Fenton reaction at lower pHs, many catalysts require a low pH (usually around 3) to regenerate

iron(II) ions, which is unrealistic for large-scale wastewater treatment and can damage the catalyst itself. Furthermore, due to the non-selectivity of the Fenton reaction, catalysts using common polymers such as polyethylene or polyvinyl alcohol to encapsulate iron (II) or iron oxide (in the form of nanoparticles) often degrade easily due to the susceptibility of the polymer to the photo-Fenton reaction, also releasing nanoparticles into the environment. Other attempts at supported catalysts reduce the surface area and limit kinetics.
